Of international expositions, the first in the series, that of 1851 in London, was undertaken at the suggestion, and successfully carried out through the influence, of Prince Albert, who was at that time the president of the London Society of Arts. A building was erected in Hyde Park for the accommodation of the objects entered for exhibition, upon a design of an entirely novel and original character proposed by Joseph (afterward Sir Joseph) Paxton, a landscape gardener, at that time in charge of the gardens of the Duke of Devonshire at Chatsworth. The materials employed were almost exclusively iron and glass, whence the structure received the name of "the Crystal Palace," a name which has been applied to other similar constructions since. The plan was a long rectangle with a transept crossing the center, the whole covering an area of more than 20 acres of ground. In the contract for the erection of the building it was stipulated that at the close of the exhibition it should remain the property of the contractors, which stipulation reduced the cost to the commissioners by £100,000, or half a million of dollars. The total cost for building, maintenance, superintendence, recompenses to exhibitors, legal expenses, etc., was about £293,000. The total receipts from all sources were £506,000, showing that the exhibition, apart from the large and permanent indirect benefits accruing from it, was a direct financial success. This can not be said of any of those which have succeeded it.

The universal admiration attracted by the exposition of 1851 and its brilliant results stimulated a similar undertaking, two years later, in New York. The short intervening time allowed for preparation, and the distance of the place of exhibition from the countries most advanced in manufactures and other productive arts, suggested a large reduction in the scale of the display. The location selected was a public square, only 445 feet by 455 feet in dimensions, or about 4⅔ acres. Upon this a "crystal palace" was erected octagonal in ground plan, but having above two naves intersecting symmetrically at right angles, each 365 ft. 5 in. by 149 ft. 5 in. The intersection was crowned by a hemispherical dome, 100 feet in diameter, the height of the springing line being 70 feet, and the total height to the summit above the crown 123 feet. In order to increase the extent of floor surface for the purposes of the exhibition, spacious galleries were constructed in the arms of the building, the total surface thus secured amounting to 250,000 sq. feet, or 5¾ acres. The cost of the building was about $200,000, to defray which and to maintain the exhibition money was raised by an issue of stock, at first to $300,000, afterward increased to $500,000, in shares of $100 each. These shares soon rose in value, and they were at one time at a premium of 75 per cent. The enterprise nevertheless resulted in loss, the destruction of the building by fire a few years later having finally destroyed all prospect of redeeming its fortunes.

During the same year, 1853, a similar international exhibition was held in Dublin, in a building forming a series of parallel halls. The cost was £80,000; the receipts, £47,000.

The Paris International Exposition of 1855 was in effect a private enterprise, but it was conducted by a commission appointed by the Government, which also undertook to secure it against loss. The principal building on this occasion was erected of masonry in the Champs Elysées. The great hall devoted to the exposition was lighted from the roof. This building provided an extent of 1,770,000 sq. feet of floor surface to the industrial departments not employing machinery in motion. The machinery was established in an "annex" on the bank of the Seine, 4,000 feet long. The fine arts were provided for in another building; and the tapestries and carpets of the imperial establishments, as well as the crown jewels, in still another. This exposition cost 11,264,520 francs = $2,253,000, not including the cost of the main building, which was preserved as the property of the Government, under the name of the "Palais de l'Industrie," to be used for annual exhibitions of various kinds and for public ceremonials.

The second London Universal Exposition was held in 1862. For this, the location chosen was upon grounds which had been purchased at South Kensington by the commissioners of the exposition of 1851, with the surplus proceeds of that exposition and some aid from the Government. The principal building was nearly rectangular, and covered about 7 acres. The whole area covered by roofs was about 23 acres. The buildings were subsequently removed, the space occupied by them being required for Government purposes, and the principal one was transferred to the north of London, where, under the name of the Alexandra Palace, it was totally destroyed by fire in June, 1873.

The international exposition of 1867 at Paris was the most comprehensive in its plan, the most elaborate in its preparations, and the most colossal in its dimensions, of all which had been held up to that time. The Government announced its intention four years in advance. In June, 1865, an imperial decree created a commission to direct the work, under the presidency of Prince Napoleon, who shortly after resigned, and was replaced, in Feb., 1866, by the Prince Imperial. The place fixed upon for the principal exhibition was the Champ de Mars, the large paradeground in front of the École Militaire, containing about 111 acres. For the exhibition of farm and dairy operations, animals, and stock, the island of Billancourt in the Seine, 2½ miles from the Champ de Mars, was chosen, having an area of 74 acres. For the competitive trials of mowers and reapers and for other field operations, portions of the emperor's farms at Fouilleuse, near St.-Cloud, and of those at Vincennes, were given up as occasion required. The margin of the Seine in front of the Champ de Mars (from which it is separated by the Quai d'Orsay), offering an area of about 3 acres, was devoted to objects connected with navigation, to diving apparatus, and to machinery for raising water. Here also was found a convenient place for a chemical laboratory in which experimental lectures were delivered during the exposition. The principal exposition building was constructed mainly of iron, and was of enormous dimensions. The entire space inclosed within its exterior walls was 36 acres, but there was an open central court of about an acre in the center. This building occupied the center of the Champ de Mars. The surrounding area was called the park, and was allotted to the different countries represented in the exposition, for the construction of buildings to accommodate objects or to facilitate operations which could not be allowed in the main building, or to illustrate the characteristic domestic or school architecture of different peoples; or for more imposing structures representing the temples and palaces of prehistoric antiquity.

The principal building, or so-called palace, was constructed without any attempt at architectural effect, but with the design to make as conspicuous as possible the method of arrangement with reference to the plan of classification by correlated groups of objects, and by countries; and so to enable the visitor to study the exhibition easily and to enable him readily to find any particular object sought. It had the form of an ellipse with flattened sides, or more properly of a parallelogram with circular ends, the extreme length being 490 meters, or 1,607 feet, and the extreme breadth 380 meters, or 1,246 feet. The entire cost of the structure, including the necessary excavations and other earthworks, was about 11,785,000 francs = $2,357,000.

The total expense of the exposition on all accounts, from the beginning to the final liquidation, amounted to 22,983,-817·99 francs = $4,596,764. The total return produced by the exposition was only 14,114,662·09 francs = $2,822,900; but there was a "subvention" of 6,000,000 francs by the Government, and another of like amount from the city of Paris, making the total receipts 26,114,662·09 francs; giving an excess of 3,130,844·10 francs = $626,000 above expenditure. From calculations made by the imperial commissioners in their final report, it appears that the actual number of admissions to the exposition during its continuance, including repeated admissions of the same person, was 15,000,000, or upward, and that the average number of admissions daily was nearly 70,000. The number of exhibitors was 51,819.

The International Universal Exposition at Vienna, Austria, opened May 1 and closed Nov. 3, 1873. The Archduke Charles was protector. The location selected was the famous Prater, the park and favorite place of resort of the Viennese, lying about 1½ miles from the center of the city, and between it and the Danube. About 280 acres were inclosed by a high board fence. The principal buildings, all of one story and without galleries, were the Industry Palace, Machinery Hall, Art Buildings, and Agricultural Halls, ranged side by side in three zones. The rotunda of the Industry Palace, designed by Scott Russell, and made of wrought iron, was the chief architectural feature of the exhibition. It was a flat, truncated cone, with a pitch or slope of about 31°; a diameter to the edge of the base of 354 ft. 8 in.; the interior height to the base of the large lantern being 158 feet, and to the top of the crown 276 feet. The cost was $500,000. The display in all departments was very large and costly, exceeding that at Paris in 1867. The number of exhibitors was stated at 70,000. The exhibition was particularly rich in educational appliances and statistics of all countries, special attention to the subject having been requested in the official programmes. A succession of international congresses during the progress of the exhibition was a marked feature, and contributed to its interest and good results. The Medical Congress, the Congress on a Uniform numbering of Yarn, the Flax Congress, and the International Patent Congress were among the most important.

The entire number of visitors recorded at the turnstiles was 7,254,687. The gross revenues were about $2,000,000, and the expenditures about $9,850,000. The deficiency of some $7,850,000 was provided for by Government appropriations.

The Paris Universal Exposition of 1889 was much more extensive than any that had hitherto been held. It was designed primarily to commemorate the French Revolution, and therefore the only governments to give to it their official recognition were those of the U. S. and Switzerland. In response to the invitations of the French Government, however, executive commissions were formed in Great Britain and in most of the continental states to encourage private participation in the exposition. The results of these efforts were most gratifying. The exhibition occupied a much larger space than any of its predecessors. It completely covered the space of the Champ de Mars, and it was connected by the Pont de Jena with the gardens of the Trocadero. The exhibition buildings were constructed chiefly of iron and glass, and many of them had very picturesque designs. About 5,000,000 French people and 1,500,000 foreigners visited the exposition during the summer. There were 60,000 exhibitors, and of these 903 received grand prizes, 5,153 gold medals, 9,690 silver medals, 9,323 bronze medals, making a total of 33,139 awards. An even more successful exposition was held in 1900. There were 79,712 exhibitors, 6,674 from the U. S., 2,827 grand prizes were awarded, 8,166 gold medals, 12,244 silver medals, 11,615 bronze medals, and 7,938 honorable mentions. More than 50,000,000 persons attended the exhibition.

Expositions, Permanent: See the Appendix.

Ex post facto [Late Lat. *ex postfacto*, from or in reference to what is done afterward; *ex*, from, and *postfacto*, abl. of partic. *postfactus*, done afterward]: a legal term transferred from the civil to the common law. An *ex post facto* law is a law that operates by after-enactments. By the Constitution of the U. S. neither Congress nor the State Legislatures can pass *ex post facto* laws, and the meaning of the term thus used has been often defined and is fully settled by judicial decisions. It refers to criminal and penal statutes only, and not to those which simply affect private property. Chief Justice Marshall defined an *ex post facto* law to be one which rendered an act punishable in a manner in which it was not punishable when it was committed. The more specific definition usually laid down by the courts is: 1, any law which makes an innocent act, done before its passage, criminal; 2, any law which aggravates a crime, and makes it legally greater than when it was committed; 3, any law which changes the punishment, and inflicts a greater punishment than the law affixed to the crime when it was committed, or perhaps one different in kind; 4, any law that alters the legal rules of evidence applicable to an offense already committed, and to the injury of the offender.

Express [from Lat. *expri'mere*, to express, make definite and plain, past partic. *expres'sus*, clear, precise, definite, from which developed in the Rom. languages the meanings, special, special message, messenger]: (1) Fast passenger service. The minimum standard of express trains in Great Britain is about 40 miles an hour; in the U. S., 30 miles (except on the transcontinental and extreme Western lines); on the continent of Europe, about 25 miles. In the year 1888 Great Britain had 63,000 miles of trains daily running more than 40 miles an hour, the U. S. 14,000 miles, continental Europe almost none. Since that time these figures have been improved, especially in the U. S. and in Germany. The fastest trains in the U. S. are quite as good as the fastest British trains, but there are not nearly so many of them. An express on the New York Central road, running from New York to Buffalo, makes 440 miles in eight hours and forty minutes. The best systems of expresses are on the Baltimore and Ohio and Pennsylvania railways between New York and Washington. The best British expresses are between London and Edinburgh or Glasgow, their highest performances being nearly equal to those on the New York Central. On the continent of Europe the best trains are between Hamburg and Berlin.

(2) Arrangements for fast conveyance of parcels. In continental Europe this service is performed by the post-office; in the United Kingdom mainly by the railways themselves, though the parcels-post is also well developed; in North America by companies specially organized for the purpose. The parcels express business was started by W. F. Harnden between Boston and New York in 1839, this forming the beginning out of which the Adams Express Company ultimately grew. The Wells-Fargo Express was started in 1845, and the American Express some five years later. Besides these the most important companies are the United States and the Southern. Efforts have been made to induce the railway companies to do the work of collection and delivery, as is done in Great Britain, and thus supersede the necessity for express companies; but such experiments in Massachusetts and elsewhere have proved on the whole unsuccessful. See also FAST FREIGHT LINE. A. T. HADLEY.

Exterritoriality: that legal fiction which permits to certain persons or classes of persons who may be in a foreign land exemption from its jurisdiction. The laws of their own country therefore still govern them as if they had never left it. The classes of persons to whom these privileges may be granted are five:

(1) *Sovereigns.*—By the courtesy of nations these, with their suites, are not held subject to local jurisdiction, but their entrance may be refused or this privilege withdrawn. And they are still subject to the limitations imposed upon them by their own laws. If they own real property in a foreign country, that is not exempt from taxation.

(2) *Public Armed Vessels.*—A merchant ship on the high seas is governed by the laws of its own country; in a foreign port by the laws of that state. But a man-of-war in a foreign port applies the jurisdiction of its own country to its own crew on board. On shore, however, they are amenable to the local law. A ship of war can not exercise any war right, as of capture, within the waters of a friendly state. Its privileges are to be strictly construed, and are allowed for the sake of its representative character and for the proper control of its crew.

(3) *Armies in Transit.*—When such transit is permitted,

the army will be governed by its own officers, and its own military law will be in force. Otherwise it could have no cohesion, and control over it would be gone. But it is to be remarked that such transit is most unusual, and if granted in time of war, or in preparation for war, would inevitably amount to a breach of neutrality.

(4) *Diplomatic Agents and Consuls in Certain Countries.*—For an explanation of their exterritorial privileges, see DIPLOMATIC AGENTS and CONSUL.

(5) *Foreigners Resident in Certain Oriental States.*—Where the laws, the usages, the judicial system, and the state of civilization in a country are so different from the European standard, and so barbarous as to fail in guaranteeing the protection to person and property of resident foreigners, the latter may be allowed, in accordance with treaty, to remain under the jurisdiction of their own laws, though frequently subject to conditions as to behavior or residence. The U. S. have treaties securing to their citizens such privileges with Borneo, China, Korea, Japan, Madagascar, Persia, Turkey, Samoa, Siam, Tonga, and Zanzibar, and to a less degree with certain of the Barbary states.

T. S. WOOLSEY.

Extract [from Lat. *extrac'tus*, drawn out, past partic. of *extra'here*; *ex*, out + *tra'here*, draw]: in pharmacy, any solid substance (called simply an extract) or liquid substance (fluid extract) made by evaporating solutions containing medicinal principles, chiefly of vegetable origin. These solutions are made (1) by expressing the juices of fresh plants, or of dried ones after maceration, by means of hydraulic or other presses; (2) by means of liquid solvents, as water, alcohol, or ether, from which result "aqueous," "alcoholic," and "ethereal" extracts. These various methods are employed, some extracts being better prepared by one and some by another process. Sometimes the menstruum is allowed slowly to percolate and repercolate through the powdered drug, the solvent being at last removed by evaporation or distillation. Evaporation is frequently carried on *in vacuo* with great advantage, for a high degree of heat is injurious to many vegetable principles.

Extract of Meat (Lat. *extractum carnis*): a preparation of beef, and sometimes of mutton, or of both combined, in which the muscular fiber, fat, and gelatin are removed, and the highly nitrogenous elements preserved and condensed into a semi-solid mass of about the consistence of ordinary butter. Commercial extract of beef is prepared on a large scale in the Argentine Republic, in Texas, and in other countries. Most of what is sold in Europe and the U. S. comes from Buenos Ayres, where its manufacture was first established under the supervision of the chemist Liebig. One establishment at Fray Bentos slaughters 400 oxen daily. In general the finely cut beef is allowed to stand for a few hours in cold water; the liquid is then boiled for a time, and afterward evaporated in a vacuum-pan. In some places the mincemeat is steamed, and the resulting liquids evaporated on rapidly revolving steel plates. In other establishments superheated steam is employed under pressure; the material is then submitted to powerful hydraulic compression, and the expressed liquid partially dried *in vacuo*.

Extract of meat is of variable quality and composition, and at the best but imperfectly represents the beef it was made from; some forms of it are stimulants merely. Nevertheless, it is useful in preparing soups, and especially in nourishing those who are sick of low fevers, pyæmia, and other like diseases.

Extradition [from Lat. *ex*, out + *tradi'tio*, act of delivering over, surrender; *trans*, across + *dare*, give]: the surrender by one state or nation to another of fugitives from justice. The subject will be considered under two general divisions: 1, the surrender of fugitives from justice from one State of the U. S. to another; 2, the like surrender as between one nation and another.

1. The U. S. Constitution provides that "a person charged in any State with treason, felony, or other crime who shall flee from justice and be found in another State, shall, on demand of the executive authority of the State from which he fled, be delivered up to be removed to the State having jurisdiction of the crime." A like clause is found in the Articles of Confederation. The propriety and necessity of such a provision in the case of States bound so closely together as are those of the U. S., and yet exercising independent criminal jurisdiction, will not be questioned. It tends to promote harmony between the States and to repress crime, while it aids in the discharge of a high moral obligation. An act of Congress of Feb. 12, 1793, ch. 7, § 1, carries the constitutional provision into practical effect by declaring that the demand shall be accompanied by a copy of an indictment found against the alleged fugitive, or by an affidavit made before a magistrate of a State, etc., charging the fugitive with having committed a crime. These documents are to be certified as authentic by the Governor or chief magistrate of the State whence the demand comes. It is thereupon made the duty of the Governor on whom the demand is made to issue his warrant and to cause the fugitive to be arrested and delivered over to the agent of the demanding State. The essential ingredients of the case are that there must be a charge that an act has been committed which is a crime under the laws of the State where it took place, and that the person so charged has fled from justice. The Governor of the State where the fugitive is found is bound to comply with the demand when properly made and authenticated. Still, should he fail to do his duty, there are no legal means whereby he can be compelled to perform it. (*Kentucky* vs. *Governor Dennison of Ohio*, 24 Howard's Reports, 66.) If the fugitive is supposed to be arrested on insufficient papers, the regular course to test their validity in his behalf is to apply for a writ of *habeas corpus*. If they turn out to be defective, he will be discharged. When the proceedings are sustained, their effect is to return the fugitive to the State whence he came, where he will be entitled to his trial under the ordinary course of judicial proceedings.

2. Extradition as between separate nations is a topic belonging to international law. It is a limitation of the right of asylum. It was at one time supposed that it was the duty of a state under the law of nations to surrender up a fugitive from justice upon demand after the civil magistrate had ascertained the existence of reasonable grounds for subjecting the accused to a criminal trial. Those who maintained this doctrine found much difficulty in drawing the line between the graver crimes to which it was claimed that this rule was applicable and those of a minor character to which it could scarcely be considered that it would extend. (1 Kent's *Commentaries*, 37.) The better opinion now is that whatever obligation may exist in such a case is an imperfect one, and can not be insisted upon by the demanding nation unless there be a treaty stipulation. Nevertheless, in certain cases, extradition without treaty has been allowed by and to the U. S. In 1863 Secretary of State Seward surrendered Arguelles to Spain "under the law of nations and the Constitution of the U. S." on account of his high criminality. And the notorious Tweed was given up by Spain in 1876, an exact return for the former courtesy. Many similar demands upon the U. S. have been refused, and both law and usage are against the practice. The U. S. have treaties upon the subject of extradition with a large number of foreign nations. The following is believed to be a complete list of such treaties in force in 1893:

Great Britain	1842, 1890	Würtemberg	1868
France	1843, 1845, 1858, 1893	San Salvador	1870
Hawaiian islands	1849	Nicaragua	1870
Swiss Confederation	1850	Orange Free State	1871
Prussian and other states of the Germanic Confed.	1852	Ecuador	1872
Bavaria	1853	Ottoman Empire	1874
Austria	1856	Spain	1877, 1882
Baden	1857	Belgium	1882
Sweden and Norway	1860, 1893	Luxemburg	1883
Mexico	1861	Japan	1886
Haiti	1864	The Netherlands	1887
Dominican Republic	1867	Colombia	1888
Italy	1868, 1869, 1884	Russia	1893

The treaties are not precisely identical, though of the same general scope and character. They all include the more heinous crimes, such as murder and piracy, while some of them embrace robbery, burglary, arson, rape, embezzlement, and the fabrication and circulation of counterfeit coin or paper. The words here employed would refer to the offenses named as understood in the general jurisprudence of the two nations, and accordingly would not extend to a new statutory crime established by one of the United States, and called by a name used in the treaty, such as forgery. This conclusion was reached in Great Britain in the case of Winsor, 6 Best & Smith's Reports, 522. On the other hand, it has been considered that the word "piracy," as used in the treaty with Great Britain, does not refer to that offense as recognized in the law of nations, as the offender can be tried in the state where he is. Its reference is to piracy under the municipal law of the state making the demand. (*In re Tivnan*, 5 Best & Smith, 645.) The treaties require that the offense should be committed within the "jurisdiction" or within the "territories and jurisdiction" of the demanding nation. An interesting question has arisen in the U. S. as to whether these words would include the case where a nation by statute law made it a crime for one of its own subjects to commit an act like murder beyond its own territory, so that a surrender could be demanded by that nation, though the act were committed within the territory of a nation with which the U. S. had no extradition treaty. This was the case of Vogt, and, though the Attorney-General of the U. S. advised against the surrender, the point can scarcely be deemed to be finally settled. In order to carry an extradition treaty into practical effect, domestic legislation is necessary. Under the laws of Congress and the practice of the courts the following points must be observed: (1) There must be a demand from the supreme political authority of the state seeking the return of the fugitive; (2) There should be an authorization or a mandate by the President of the U. S., directed to a judge or U. S. commissioner, to examine into the case; (3) Complaint under oath should be made to the judge or commissioner by a proper person, such as a consul-general of the foreign country, showing the commission of the act on which the demand for the surrender is based; (4) There should be a warrant by the commissioner, etc., for the apprehension of the party charged; (5) The charge should be sustained before the commissioner by suitable evidence, such, for example, as would justify his commitment had the act taken place here; (6) On the certificate of the judge or commissioner that there is a probable ground to believe that the offense has been committed, and such certificate being satisfactory to the President of the U. S., the surrender is made to the agent of the demanding state. If the proceedings are defective, the prisoner may be discharged on a writ of *habeas corpus*. An extradition act was passed in Great Britain in 1870 to which all extradition treaties were to conform. The leading provision of this was that there should be no surrender without proper assurance that the accused shall be tried for no other than the crime specified in the demand. The attempt to apply this condition to the extradition of 1842 with the U. S. in Winslow's case, 1876, in other words to a prior contract, led to a temporary suspension of the agreement. The 1890 treaty accepts the conditions of the extradition act, and extends the list of extraditable crimes somewhat in the direction of fraud and embezzlement. The statutes relating to extradition in the U. S. will be found in 9 U. S. Stat. at Large, 302 (Aug. 12, 1848); 12 *ib.*, 84 (June 22, 1860); 15 *ib.*, 337 (Mar. 3, 1869). Consult also *Matter of Farez*, 7 Blatchford Reports, 345, 491; Brightly and Abbott, *Digests*, title *Extradition*; Wheaton, *International Law*, notes of Lawrence and Dana; Clarke, *On Extradition*, etc.: English statutes, 33 and 34 Vict., ch. 52 (1870); 36 and 37 Vict., ch. 60 (1873). See also the article ASYLUM (International Law). Revised by T. S. WOOLSEY.

Extraterritoriality: See EXTERRITORIALITY.

Extreme Unction [from Lat. *extre'ma unc'tio*, last anointing; *unctio*, deriv. of *un'guere*, *unctum*, anoint]: the fifth of the seven sacraments of the Roman Catholic Church, consisting of liturgical prayers recited by the priest and of the application, by the priest, of consecrated oil of olives (*oleum infirmorum*) to the eyes, ears, nostrils, lips, hands, and feet of a dying person or of one whose illness is alarming. It is administered, when possible, after confession and the Eucharist, and is believed to remove the last stains of sin, strengthen the patient spiritually, and, if required for his salvation, restore him to bodily health. The Greek and Coptic Churches recognize unction (which is by no means always administered *in extremis*) as a sacrament, and the Jacobites and Armenians have a similar practice. Certain ritualists among the Anglicans and Lutherans advocate a return to this ceremony. St. James v. 14, 15, thus describes the nature and effects of this sacrament: "Is any man sick among you let him call in the priests of the church, and let them pray over him, anointing him with oil in the name of the Lord. And the prayer of faith will save the sick man, and the Lord will raise him up and if he be in sins they shall be forgiven him." Roman Catholics hold extreme unction to be of divine institution, as no one but Christ could make it the means of forgiving sin. Revised by J. J. KEANE.

Exudation [from Lat. *ex*, out + *suda're*, to sweat]: the passage of a liquid outward through the walls (or membranes) of the vessel containing it. The term is also applied to certain substances which *exude* or come out of trees, as gum-resin, manna, etc. In pathology, exudation is a material product of inflammation; a gaseous, liquid, or solid substance foreign to the tissues, and resulting from disease. These morbid products, when solid, sometimes become organized and capable of growth.

Exu'ma, Great and **Little**: two of the Bahama islands. The former is about 30 miles long and 3 miles wide, and has one of the best harbors in the Bahamas. Salt is exported from them. Great Exuma is crossed by the Tropic of Cancer. The northwest point is in lat. 23° 42′ N., lon. 76° W.

Exuviæ, eks-yu'vi-ē [Lat., spoils, what is stripped off; deriv. of *exu'ere*, to strip off; cf. *induviæ*, clothes, to *indu'ere*, put on]: in natural history, the slough or cast-off skins of reptiles, crustaceans, insects (see ENTOMOLOGY), etc.; the molted feathers of birds; the hair of quadrupeds, which is shed at a particular season of the year. The term was anciently used to designate the personal spoils taken from an enemy in battle, hence it sometimes meant all booty taken in war.

Eyck, īk, JOHN, or JAN, van: painter; b. at Bruges in 1370. He worked together with his brother HUBERT, who was the elder in years but not in artistic merit; b. 1366 at Maestricht, d. in 1426. John van Eyck revived the art of painting in oil in attempting to obviate the tendency of paints to crack when exposed to the sun. This secret, jealously guarded by the brothers, was discovered and revealed to others by Antonello of Messina, who was painting at Bruges. The most important work of the two brothers is the *Adoration of the Spotless Lamb*, a picture with many subordinate or accessory pictures forming a great triptych. The chief picture, which is a large composition of many figures, is in the Church of St. Bavon at Ghent. The wings contained eleven separate pictures; all but two of these, which are in Brussels, are in the Museum of Berlin. John died at Bruges, according to one authority, July 9, 1440.

Eye [O. Eng. *ēage*: O. H. G. *ouga* > Mod. Germ. *Auge*: O. Sax. *ōga*: Icel. *auga*: Goth. *augō*, connected with Lat. *o'culus*, Gr. ὄσσε (**okie*), Sanskr. *akshi*]: the organ of vision. Eyes may be variously developed, and are by no means homogeneous throughout the animal series, but in the vertebrates, when developed, they are two in number, and essentially correspond in all. Among the more notable deviations are the apparently double eyes of ANABLEPS (*q. v.*), and the development of the two on one side of the head in flat fishes. Supposititious eyelike organs are in addition developed on the trunk in certain fishes.

The human eye is placed in a bony cavity called the orbit, and is further protected by the fatty cushion, within which it rests, as well as by the brows, eyelids, and eyelashes. Other appendages are the tear-gland and the sac and duct connected with it, the numerous muscles which direct its range, and the nerves and blood-vessels which supply it.

The human eye is a globe, with the segment of a smaller globe planted upon its anterior aspect. Its antero-posterior diameter is about an inch, its transverse one about eleven-twelfths of an inch. The larger sphere has about five-sixths of the whole surface. The eye is invested by three coats—first, the sclerotica, a white, tough, fibrous substance, the "white of the eye," visible through the delicate conjunctiva which covers its anterior portion and is reflected over the inside of the lids. The muscles are attached to it, and through a sieve-like "cribriform lamina" it transmits the filaments of the optic nerve with the vessels supplying the retina. The anterior sixth of the eye's surface is occupied by the transparent cornea. This is composed of four layers: (1) an outer epithelial layer continuous with the conjunctiva; (2) a central layer, the cornea proper; (3) an elastic layer; and (4) a posterior layer of cells which lines the anterior chamber. The cornea is a non-vascular body, and is nourished by imbibition from the surrounding capillaries, which terminate in loops at its border. It is freely supplied with sensitive nerves, and the cornea proper contains spaces (corneal spaces), each one occupied by a small body, called a corneal corpuscle.

The second coat of the eye is composed of the choroid tunic, the iris, and the ciliary processes and muscle. The choroid is a vascular, thin, chocolate-colored membrane, lining the sclerotica, and separated from it by the delicate membrana fusca. The choroid itself has three layers—an *outer*, consisting chiefly of blood-vessels (vasa vorticosa) and pigment-cells; a *middle* layer, of fine capillary vessels (Ruysch's layer); and on the inner surface of the last tunic a faintly fibrous membrane—the *lamina vitrea*—which separates it from the pigment layer of the retina. The ciliary processes

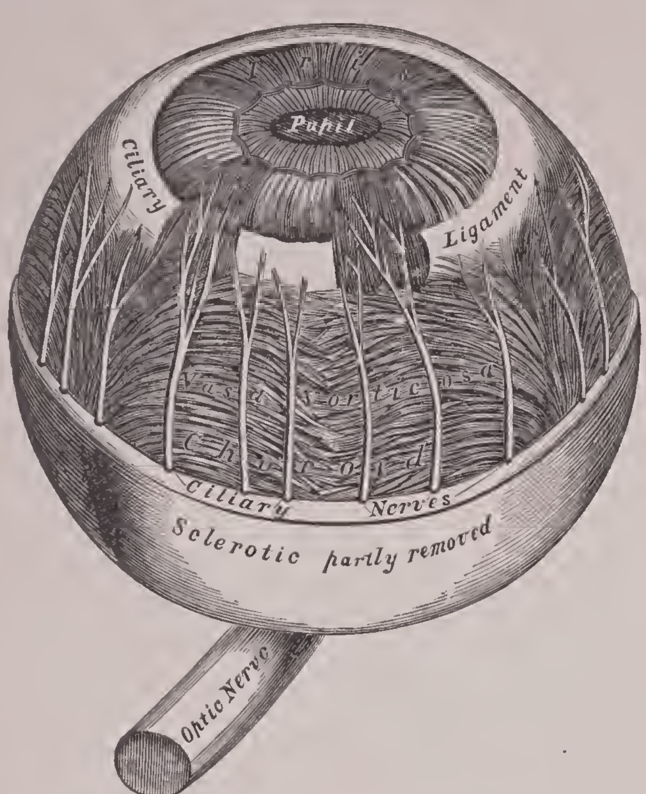

FIG. 1.—Choroid and iris.

are folds or plaits running forward from the choroid to the suspensory ligament of the crystalline lens. They number about seventy. The iris (rainbow) takes its name from its various colors in different persons. It is a colored curtain perforated by a circular aperture, the *pupil*, suspended in the aqueous humor. It is placed vertically in advance of the choroid and ciliary body, with which it is continuous. It is also connected with the adjacent border of the sclerotic and cornea by the ciliary muscle and a ligament called the *pectinate* ligament. It contains both circular and radiating involuntary muscle-fibers and a stroma of fibers and cells and pigment-cells. The circular sinus is a canal (Schlemm's) which runs around the eye outside the ciliary body. The ciliary muscle is a circular band of involuntary muscle-fiber which passes back from the junction of the cornea and sclerotic to the choroid. It is through the action of this muscle on the crystalline lens that the eye is accommodated or adapted to distinct vision at different distances.

The retina is a delicate nervous membrane which receives the images of external objects. Behind, it is continuous with the optic nerve; in front it extends nearly as far forward as the ciliary ligament, where it is termed the *ora serrata*. In the center of its posterior part, at a point corresponding to the axis of the eye, there is a yellowish spot called the *macula lutea*, having it in a central depression, the *fovea centralis*. At this point the sense of vision is most perfect. The retina is very complex and is composed of ten layers, named from within outward as follows: The *internal limiting membrane, the nerve-fiber layer, the nerve-cell layer, the inner and outer granular and nuclear layers, the external limiting membrane, the layer of the rods and cones,* and *the pigmentary layer*. The internal limiting layer is in contact with the hyaloid membrane of the vitreous humor. The nerve-fiber layer is continuous with the optic nerve. The layer of the rods and cones is often called Jacob's membrane, or the bacillary layer. The rods are solid, of nearly uniform size, and arranged perpendicularly to the surface. The cones are flask-shaped, their broad ends resting upon the external limiting membrane. In the region of accurate sight in Jacob's membrane, there are no rods, but only cones. The retina is supplied with blood by the central artery of the retina, which pierces the optic nerve and enters the globe of the eye through the center of the nerve, or *porus opticus*. The retinal vein accompanies the artery.

The contents of the eye are the aqueous humor, the crystalline lens, and the vitreous humor. The aqueous humor consists of about 4 or 5 grains of water, with a very small proportion of common salt and other matters in solution. It occupies the space between the cornea in front and the crystalline lens behind. This space is divided into the anterior and the posterior chambers, which the iris separates from each other. Behind the aqueous humor comes the crystalline lens, suspended in the capsule, an elastic, transparent membrane which is retained in its place by the suspensory ligament. Between this ligament and the hyaloid membrane is the space called the canal of Petit. The lens itself—a double convex body, one-third of an inch in transverse, and one-fourth of an inch in antero-posterior, diameter—consists, as is seen when it has been boiled or hardened in alcohol, of layers of transparent matter arranged in segments. The vitreous humor occupies four-fifths of the cavity of the eyeball. Like all the contents proper of the eye,

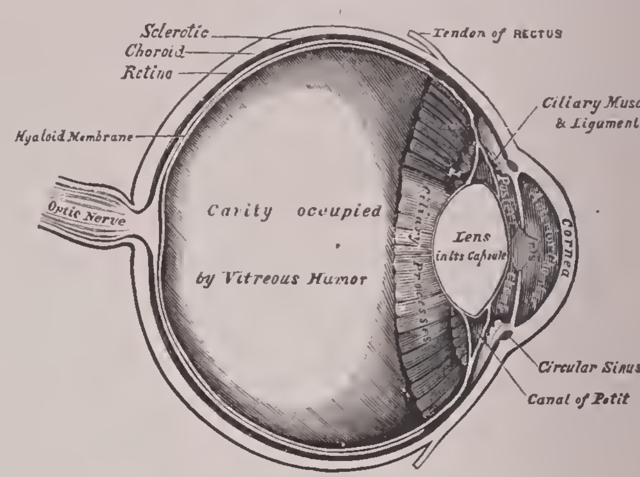

FIG. 2.—Vertical section of the eye.

it is transparent. It consists of a thin, jelly-like, albuminous fluid. When the aqueous humor has been evacuated by accident or operative interference, it is speedily restored like other serous fluids; but if the vitreous humor is entirely lost, it is never renewed. See LIGHT, VISION, and HISTOLOGY (*Organs of Special Senses*). Revised by G. E. DE SCHWEINITZ.

Eye, Diseases of: See GRANULAR LIDS, BLINDNESS, CATARACT, MYOPIA, SQUINTING, OPHTHALMIA, and VISION, DEFECTS OF.

Eye-bolt: on ships, a metal bolt screwed into the timbers or set up with washer and nut, with an eye in the outer end in which a block may be hooked.

Eyebright: See EUPHRASY.

Eyepiece: the lens or combination of lenses used in microscopes and telescopes to examine the aërial image formed at the focus of the object-glass. The ordinary eyepiece is a combination, and may be either positive or negative. The former consists of two plano-convex lenses, with their convex sides toward each other, and is used for micrometers. The negative consists of similar lenses with the convex sides turned away from the eye. Besides these, there are in use for observations of the sun a diagonal eyepiece, in which a very small percentage of the sun's light and heat is reflected from the first surface of a prism, the rest being transmitted; and Dawes's solar eyepiece, in which the light is reduced by observing only a very minute part of the solar surface.

Eyestones (in Lat. *oculi cancrorum*): the name given to two semicircular calcareous concretions which are found in the common European crawfish, in August, shortly before the molting season, in the space between the inner and outer coats of the stomach. They consist of carbonate and phosphate of lime and animal gelatin, and were formerly used in a powdered state in medicine as an antacid. They are sometimes used to remove small particles of dirt from the eyes, a method which is entirely to be condemned. They are collected in brooks in Dauphiny, near Astrakhan, and in other places in Europe, and have also been found in the Mohawk river, near Rome, N. Y.

Eylau, or **Eilau**, often called **Prussian Eylau**: a small town of Prussia; on the Pasmar; 22 miles S. of Königsberg (see map of German Empire, ref. 1–J). A great battle was fought here Feb. 8, 1807, between Napoleon, who had about 80,000 men, and the allied armies of Russia and Prussia, commanded by Gen. Bennigsen, who had fewer men, but more guns. The battle was opened early in the morning, immediately after daybreak, by a furious attack made by the French left on the Prussian right and center. But the attack proved utterly unsuccessful, and the attacking corps was all but completely destroyed. The murderous struggle was repeatedly renewed, and victory seemed to incline now to the one side and now to the other. When night closed, however, the whole allied line was pressing onward and driving the French before it. Nevertheless, the victory is generally claimed by the French, chiefly on the ground that the allied forces, which were unable to recruit their strength, were ordered to retreat from the field on the night of the battle, and to seek shelter behind the fortifications of Königsberg. After the day of Eylau, however, Napoleon spoke with much more respect of the Russians than he had done hitherto. The allies lost about 20,000, and retreated from the field, but the French loss was probably the greater. Pop. (1890) 3,446.

Eymeric, *ā*-m*ā*-reek', NICHOLAS: inquisitor; b. at Gerona, a town of Catalonia, Spain, about 1320; became a Dominican friar in 1334; was appointed by Innocent VI. to be inquisitor-general of Aragon, 1357, and became chaplain and judge of heresies to Gregory XI. at Avignon, 1371. D. at Gerona, Jan. 4, 1399. As an inquisitor his zeal was so great that he was for some years suspended from his office. He especially pursued the followers of Raymond Lully. His principal work was *Directorium Inquisitorum* (1376; published in Barcelona, 1503, in Rome, 1578; best edition 1587).

Eyre, ãr, EDWARD JOHN: explorer; b. in England in Aug., 1815. He emigrated to Australia about 1833, and began in 1840 the exploration of the unknown region between South Australia and Western Australia. In this sterile region he performed a journey of nearly 1,000 miles almost alone. He published in 1845 *Discoveries in Central Australia*. In 1862 he was appointed governor of Jamaica, where he suppressed an insurrection in Oct., 1865. He was censured and removed from his office for the execution of Gordon by court martial. John Stuart Mill and others took measures to try him for murder, but failed, Eyre being justified or excused by the British public. In 1872 the costs of his defense were refunded by the Government.

Ey'telwein, JOHANN ALBERT: civil engineer and physicist; b. at Frankfort-on-the-Main, Prussia, Dec. 31, 1764; entered the artillery, where he acquired the foundation of his future eminence. He afterward held important civil offices, and was employed on a great variety of public works. He wrote *Praktische Anweisung zur Konstruktion der Faschinenwerke an Flüssen und Strömen* (1800; 2d ed. 1818); *Praktische Anweisung zur Wasserbaukunst* (1802–08; 2d ed. 1807–21); *Handbuch der Perspektive* (1810); *Grundlehren der höhern Analysis* (1824); *Handbuch der Hydrostatik* (1826). D. in Berlin, Aug. 18, 1848.

Eyzaguirre, ā-zaă-gwee'rēe, AGUSTIN: Chilian statesman; b. at Santiago, 1766. He was one of the leaders of the movement for independence in 1810; was deputy from Santiago to the first Chilian congress, and in 1813 was a member of the governmental junta during the absence of Carrera. From 1814 to 1817 he was imprisoned by the Spaniards on the island of Juan Fernandez. During the administration of O'Higgins he took little active part in politics, being engaged in an enterprise for opening trade between Chili and India. On the overthrow of O'Higgins (Jan., 1823) Eyzaguirre was chosen a member of the executive junta. He was soon after elected vice-president, and by virtue of his office became acting president on Sept. 10, 1826. He was deposed by a military revolt four months after. D. at Santiago, July 19, 1837. H. H. SMITH.

Eze'kiel (i. e. God will strengthen): one of the greater prophets of the Hebrew Scriptures, the author of a canonical book which bears his name. He was the son of a priest, and was one of those who were carried away in one of the deportations by Nebuchadnezzar, perhaps 597 B. C. He was sent to dwell on the river Che'bar or Chaboras, a branch of the Euphrates. From that place he exercised his prophetical calling, warning and instructing the exiles, pronouncing rebukes against Jerusalem so long as it stood, and denouncing woes upon Judah's heathen neighbors for their attitude toward her in her distress. The dates given in the book cover twenty-two years, from the fifth to the twenty-seventh year of the Captivity. The book is commonly—and quite plausibly—treated in two divisions, of twenty-four chapters each; but, strictly speaking, it consists of two parts, the former (chaps. i.–xxxix.) containing prophecies delivered before and after the destruction of Jerusalem in 586 B. C.; the latter (chaps. xl.–xlviii.) containing a vision of an ideal restored Israel. In this he describes the new temple, the reformed ritual, and a redivision of the country into twelve parts, which is set forth in mathematical and geometrical descriptions. These descriptions do not apply to anything which ever existed, either before or after, and this has been a ground of much unfounded anxiety lest here should be an unfulfilled prophecy. It is evident, however, that the prophet had a vision of a restored, perfect, and ideal theocracy, and this is set forth in mathematical and geometrical arrangements which are ideally perfect, and take no note of physical circumstances. In his general tone Ezekiel is independent of Jewish dogmas. He gives fresh and true interpretations and applications of the Mosaic law, which contradict the traditional interpretations. His view of the Gentiles is also free from the severity of the traditional dogma of Israel's election. For these and other reasons there were disputes among the Jewish scribes as to the position of the book of Ezekiel in the canon. A good commentary is that by A. B. Davidson (London, 1892).

Revised by WILLIS J. BEECHER.

Ezekiel, MOSES JACOB: See the Appendix.

Ezion-geber, ee'zi-on-gee'ber, or **Ezion-gaber**: an ancient port on the Elanitic arm of the Red Sea. From this point Solomon sent a fleet to Ophir, and King Jehoshaphat also built ships here for the same destination. It probably stood near Elath, and is thought by many to have been at the northwestern extremity of the Gulf of Akabah.

Ezpeleta y Veire de Galdeano, ez-pā-lā'taă-ēe-vā-ee'rā-dā-gaăl-dā-aa'nō, JOSÉ, de: Spanish soldier and administrator; b. in Pamplona, 1740. He served in Cuba for some years, attaining the rank of brigadier; was sub-inspector-general in New Spain (Mexico), and from 1781 governor of Pensacola; from 1785 to 1789 captain-general of Cuba; and from 1789 to 1795 Viceroy of New Granada. In all these positions he was an energetic and enlightened ruler. Subsequently he served against the French in the Peninsula, attaining the rank of lieutenant-general. He was taken prisoner in 1808. D. in Madrid, Nov. 23, 1823.

Ez'ra (in Heb., help; Gr. Ἔσδρας): the name of several persons mentioned in the Bible, the most important of whom was the famous priest and scribe who went with a body of Hebrew exiles from Babylon to Jerusalem about the year 458 B. C. After that year no details are given, but he was in Jerusalem with Nehemiah in 445 B. C. (Neh. viii. 1); and again, perhaps after Nehemiah's return to Jerusalem from Babylon, subsequent to 433 B. C. (Neh. xii. 36). His reputed sepulcher is shown at a place on the Tigris, near its junction with the Euphrates. His great work was that of "Scribe of the law of the God of heaven." To him the preservation and transmission of the Old Testament are largely due. See BIBLE. Revised by WILLIS J. BEECHER.

Ezra, The Book of: called in the Thirty-nine Articles of the Anglican Church *The First Book of Esdras*, following the Vulgate. It narrates the history of the Jewish nation on their return to Jerusalem from the Babylonian captivity, and during the subsequent period of their re-establishment in the land of their fathers. It is a continuation of the books of Chronicles, and is mostly a compilation, probably by Ezra, written partly in Hebrew and partly in Aramaic, the Aramaic portion beginning at iv. 8 and extending to vi. 18. See the introduction to Ezra by A. H. Sayce (London, 1885) and by H. E. Ryle (1893).

Revised by WILLIS J. BEECHER.

F

F: the sixth letter of the English alphabet; a labio-dental voiceless spirant. As is shown by old Latin writers, it differed in power from the Greek φ, and in ancient times was doubtless a voiceless spirant, like the Greek digamma, Ϝ, from which it took its form, if not its power. The English *f* corresponds etymologically most commonly to Greek π, Latin *p*: cf. Eng. *father*, Gr. πατήρ, Lat. *pater*; Eng. *foal*, Gr. πῶλος, Lat. *pullus*. It may also represent an Indo-Europ. *q* (> Gr. κ, π, τ, Lat. *qu*, *c*); cf. Eng. *five*; Gr. πέντε; Lat. *quinque*; Eng. *wolf*, Gr. λύκος.

F in chemistry is the symbol of fluorine. F in music is the fourth degree in the ascending scale of C, major or minor, being the subdominant in that scale. The bass or F clef is placed on the fourth line of the staff, hence as a note on that line is called F, the other notes, above and below, take their names accordingly. The letter F, or *f*, is also used for *forte*, loud; and FF, or *ff*, for *fortissimo*, very loud.

Fa'am: an orchidaceous plant growing in the Mauritius, in Réunion, and in India—the *Angræcum fragrans*, highly prized for its fragrance, and long used in the same way as Chinese tea is used. Many residents in the East greatly prefer it to tea. It is aromatic, stimulant, and of very agreeable taste. It is used to some extent in France, and has reputation as an antispasmodic and an expectorant.

Fa'ba [Lat., bean]: an old genus of leguminous plants now referred to *Vicia*. It included the common bean of Europe under the name *F. vulgaris*, now known as *Vicia faba*.

Faber, Cäcilia Böhl, von: See Caballero.

Fa'ber, Frederick William, D. D.: theologian and poet; a nephew of George Stanley Faber; b. at Calverley, Yorkshire, England, June 28, 1814; graduated at Oxford in 1836; became fellow of University College in 1837; vicar of Elton in 1843; went over to the Roman Catholic Church in 1845; founded the Oratory of the brotherhood of St. Philip Neri in London in 1849; and in 1854 removed with it to Brompton, London, where he died Sept. 26, 1863. He wrote a considerable number of books, both controversial and devotional, in support of the Church of his adoption, but will be longest remembered as the author of some exquisitely beautiful hymns, equally admired by all communions. The first edition of his hymns, few in number, appeared in London in 1848, and the 5th ed., containing 150 hymns, in 1862. See his *Life and Letters*, ed. by J. E. Bowden (London, 1869; 2d ed. 1888).

Faber, George Stanley, D. D.: English theologian; b. at Calverley, near Bradford, Yorkshire, Oct. 25, 1773; graduated at University College, Oxford, in 1793, and was prebendary of the cathedral of Salisbury in 1831, and master of Sherburn Hospital, near Durham, 1832; d. there Jan. 27, 1854. Author of *Horæ Mosaicæ, or a View of the Mosaical Records with Respect to their Coincidence with Profane Antiquity and their Connection with Christianity* (Bampton Lectures, 2 vols., Oxford, 1801; 2d ed. 1818); *Prophecies that have been Fulfilled* (1807; 5th ed. 3 vols., 1814–18); *Difficulties of Infidelity* (London, 1824); *Difficulties of Romanism* (1826; 3d ed. 1853); *Origin of Expiatory Sacrifice* (1827); *The Vallenses and Albigenses* (1838), etc. See memoir by F. A. Faber, in G. S. Faber's *Many Mansions* (1854).

Faber, Jacob Jacobus Stapulensis, or Jacques le Fèvre d'Estaples: the greatest of the "Reformers before the Reformation" in France; b. at Estaples, near Amiens, about the year 1450, and died at the court of Margaret of Navarra, 1536 or 1537. His translation of the New Testament appeared in 1523, and of the Old Testament in 1528. He published also several commentaries. See *Life* by C. H. Graf (Strassburg, 1842).

Faber, John: a Dutch mezzotint engraver and one of the earliest workers in mezzotint, who died at Bristol, England, in May, 1721; the father of another John Faber, an excellent mezzotint engraver, b. in 1684, who produced portraits of the Kit Cat Club and the Hampton Court beauties. D. in 1756, probably in London.

Faber, Tanaquil: See Le Fevre.

Fabi'ola: a Roman matron of the Fabian gens, who founded the first Christian hospital in Rome. After being divorced from her worthless husband she married another; but after his death she came to consider her course sinful, and after public penance devoted her wealth and her time to the care of the sick. She died in Rome, 399 A. D. The procession at her funeral was compared by Jerome to the triumphs of Scipio and Pompey. See Eng. trans. *Jerome* (New York, 1893), Ep. lxxvii. (pp. 157–163), which is really a eulogistic memoir.

Fa'bius Max'imus Verruco'sus, Quintus, surnamed Cunctator (delayer): Roman consul; attained the consulate for the first time 233 B. C.; became dictator in 217. Contending against Hannibal the Carthaginian, he adhered so closely to the policy of defensive warfare that his opponent could gain no advantage, and his successes of this sort, long continued, secured for him his surname. His is one of the most illustrious names in Roman history.

Fa'bius Pic'tor, Quintus: the earliest Roman historian; a member of the patrician family of the Fabii. He lived at the time of the Second Punic war (which began B. C. 218), though the dates of his birth and death are unknown. The last distinct notice of him is that of his being sent as an ambassador to Delphi after the battle of Cannæ, B. C. 216. He wrote a history or annals of Rome (the name is not given) from the early settlement of the city to his own times, and his work is often quoted by Livy, Dionysius, and Polybius, and once by Diodorus. He has been charged with great carelessness and perversion of the truth, especially in the earlier portions of his work. But both Livy and Dionysius draw freely from him, and frequently commend his fidelity; and Polybius, who is his severest censor, uses his materials in his own account of the Second Punic war (in which Fabius was an actor), though charging him with carelessness and partiality for the Romans. His work was written in Greek, but it is supposed there existed also a Latin translation of it. Among modern writers Fabius has found a defender in the historian Niebuhr in his lectures on the history of Rome. The fragments of Fabius Pictor are collected, and the events of his life given, by Krause, *Hist. Rom. Fragmenta* (Berlin, 1833); by Müller, *Hist. Græc. Fragm.* (vol. iii., pp. 80–92); and H. Peter, *Hist. Rom. Fragmenta* (Leipzig, 1883), pp. 6–31. See also Gerlach, *Geschichtschreiber der Römer* (Stuttgart, 1855).

Revised by M. Warren.

Fabius River: a river of Missouri; rises by several forks, and flows into the Mississippi nearly opposite Quincy, Ill. The course of the main stream is short. The North Fabius, the longest fork, rises in Iowa.

Fables [viâ Fr. from Lat. *fa'bula*, deriv. of *fari*, speak]: originally, stories of any kind; thus Dryden's *Fables* (1700) consist merely of tales from Homer, Ovid, Boccaccio, and Chaucer; later it came to mean Beast-fables (*q. v.*), and sometimes short moral tales similar in style to beast-fables.

Fabliaux, fă̆'bli-ō', or, better, **Fableaux** [Fr. plur. of *fabliau*, *fableau*, which is a singular formed from *fabliaus*, *fableaus*, the latter being the forms of the obj. plur. of Old Fr. *fablel*, dimin. of *fable*. See Fable]: certain short stories in verse composed by French *trouvères* in the twelfth, thirteenth, and fourteenth centuries. The *fableaux* purport to be stories from real life, and are to be carefully distinguished from legends, romances, and didactic poems. Their sole aim was to amuse, and they are consequently usually comic and often gross. Many of them, however, are masterpieces of narrative. The great collection of *fableaux* is that of A. de Montaiglon and G. Raynaud, *Recueil général et complet des Fabliaux des XIIIᵉ et XIVᵉ Siècles* (6 vols., Paris, 1872–90). See also French Literature.

G. L. Kittredge.

Fabre, Edward Charles: Roman Catholic archbishop; b. at Montreal, Canada, Feb. 28, 1827; educated at the College of St. Hyacinthe and seminary of Issy, France; ordained priest in 1850; consecrated Bishop of Montreal in 1876, and archbishop in 1886. D. there Dec. 30, 1896. He founded an institution for the deaf and dumb at Montreal, and has been distinguished as a pulpit orator.—His brother, Louis K. Hector, was born at Montreal, Aug. 9, 1834; educated at the Colleges of St. Hyacinthe and St. Sulpice; admitted to the bar in 1856. He edited *L'Ordre* and *Le Canadien* newspapers; in 1869 founded *L'Événement*, Quebec, and was its editor and proprietor. Among his published works are *Esquisse biographique sur Chevalier de Lorimer* (Montreal, 1856); *Canadian Literature* (1866); and *Confederation, Independence, Annexation* (Quebec, 1871).

Neil Macdonald.

Fabre, faab'r, François Xavier Pascal: painter; b. at Montpellier, France, Apr., 1766; wrought at Rome and Florence. His best works are *The Judgment of Paris*, *The Preaching of John the Baptist*, and a portrait of Alfieri. He left to the city of Montpellier his collection of works of art, and the local museum, which is large and important, is named in honor of him Musée Fabre. D. at Montpellier, Mar. 12, 1837.

Fabre, Louis Hector, C. M. G.: journalist; b. in Montreal, Canada, Aug. 28, 1838; educated there and at Paris. He has been manager of *L'Événement*, Quebec; editor of *Le Canadien* and *L'Ordre*; commissioner-general for Canada in France; and a member of the Dominion Senate. He is an officer of the Legion of Honor, France; and in 1886 was constituted a Companion of the Order of St. Michael and St. George. Neil Macdonald.

Fabre, faab'r, Marie Joseph Victorin: poet and orator; b. at Jaujac, France, July 19, 1785; wrote a *Eulogy on Corneille*, prose (1808), which was crowned by the French Institute. Among his works are *Death of Henry IV.*, poem (1808); *Ode on Tasso*; *Eulogy on Montaigne* (1812); and *Literary History of France in the Eighteenth Century* (1810). D. May 29, 1831.

Fabriano, Gentile da: See Gentile.

Fabriano, faa-bree-aa'nō: town of Italy; province of the Marches; 38 miles S. W. of Ancona (see map of Italy, ref. 4–E); especially known for its paper-mills, established in the sixteenth century. It contains a cathedral and a museum. Pop. 7,800.

Fabrice, faa'brees', Georg Friedrich Alfred, von: Saxon soldier and statesman; b. at Quesnoy-sur-Deule, France, May 23, 1818; entered the Saxon service in 1834; became a member of the staff in 1850; was chief of the staff to the troops in Schleswig-Holstein in 1863 and 1864, and to the Crown Prince of Saxony in 1866, during the Bohemian campaign, in which position he distinguished himself greatly, though the latter campaign could boast of no victory; became Secretary of War Oct. 1, 1866, assuming the great task of reorganizing the Saxon army after the Prussian pattern; commander-in-chief of the army of occupation in France in 1871. In 1871 he was again made Minister of War for Saxony, and in 1876 Prime Minister and Minister of Foreign Affairs; created count, 1884. D. Mar. 25, 1891.

Revised by C. H. Thurber.

Fabric'ius, Johann: theologian; b. at Altorf, in Saxony, Feb. 11, 1644; Professor of Theology at Altorf in 1677 and at Helmstedt in 1697. King Charles of Spain, afterward Emperor of Germany under the name of Charles VI., proposed marriage to the Princess Elizabeth Christine of the house of Brunswick, and wished her to embrace the Roman Catholic faith. Fabricius published a *Gutachten*, showing that it was proper, and even her duty, to renounce her Protestant faith to become Queen of Spain and Empress of Germany. The Elector of Hanover, afterward George I. of England, disliked this *Gutachten*, and in 1709 Fabricius was removed from his chair at the university. D. at Helmstedt, Jan. 29, 1729. Revised by Henry E. Jacobs.

Fabricius, Johann Albert: classical scholar; b. in Leipzig, Nov. 11, 1668. He is chiefly known by his *Bibliotheca græca seu notitia scriptorum veterum græcorum* (1705–28; 4th ed. in 12 vols., and index by G. Chr. Harles, 1790–1809); *Bibliotheca Latina* (1697; 3d ed. in 3 vols. by Joh. Aug. Ernesti, 1773); *Bibliotheca latina mediæ et infimæ ætatis* (5 vols., 1734); *Bibliotheca antiquaria* (1713). Of these monumental store-houses of erudition the first mentioned is still an indispensable source of information. D. in Hamburg, as Professor of Rhetoric and Moral Philosophy, Apr. 30, 1736. See H. S. Reimarus, *De vita et scriptis Fabricii* (Hamburg, 1737). To theologians he is known by his collections of the apocryphal and pseudepigraphical literature (2 vols., Hamburg, 1703–13) and his *Lux evangelii* (1731).

Alfred Gudeman.

Fabricius, Johann Christian: entomologist; b. at Tondern, in the duchy of Schleswig, Jan. 7, 1745; studied natural history at Copenhagen, Leyden, Edinburgh, Freiberg in Saxony, at Upsal under Linnæus (of whom he became an enthusiastic disciple), and was appointed Professor of Natural Science in 1775 at the University of Kiel. Entomology was his favorite study, and his *Systema Entomologica* (4 vols., Copenhagen, 1775), *Philosophia Entomologica* (1778), and *Supplementum Entomologiæ* (1797) are his principal works. An utterance of Linnæus led him to establish the structure of the mouth as the principle of division in the entomological system, and he worked out this idea with great energy and enthusiasm. He undertook every year extensive pedestrian trips in different parts of Europe, studying the world of insects in nature and in the museums; and his writings are rich in observations. D. at Kiel, Mar. 3, 1808.

Fabrizio, faa-breet'see-ō, Geronimo: anatomist and surgeon; b. at Acquapendente, Italy, in 1537; was professor at Padua; wrote treatises on anatomy and surgery, and had for a pupil Dr. Harvey, whose discovery of the circulation of the blood was suggested by some observations of his teacher upon the valves of the veins. D. in May, 1619.

Fabro'ni, or **Fabbroni**, Angelo: biographer and Latin scholar; b. at Marradi, Italy, Sept. 25, 1732; published *Lives of Italians Eminent for Learning who Flourished in the Seventeenth and Eighteenth Centuries* (20 vols., 1778–1805); was prior of the church of San Lorenzo, Florence, 1767; is sometimes called the "Plutarch of modern Italy." D. at Pisa, Sept. 22, 1803.

Fabroni, or **Fabbroni**, Giovanni Valentino Mathias: scientist; b. at Florence, Feb. 13, 1752; studied natural science in his native city and in France and England; was appointed director of the physical cabinet of the Grand Duke of Tuscany, and went in 1798 to Paris as a member of the committee assembled in that city for the establishment of unity between the French and Tuscan weights and measures. While Tuscany was under French rule, Fabroni occupied a very conspicuous position both socially and politically, and performed with success many difficult tasks, both scientific and diplomatic. He constructed the bridge across the Dora Baltea, and the road across Mont Genèvre leading from the Sardinian province of Susa into the French department of the Hautes-Alpes, at an elevation of 6,500 feet. After the restoration of the house of Lorraine in Tuscany, in 1815, Fabroni retired to the chair of Natural Science at the University of Pisa. D. at Pisa, Dec. 17, 1822. His writings are on political economy, natural science, agriculture, education, etc.

Façade, fa-saad' [Fr., from Ital. *facciata*, deriv. of *faccia* < Lat. *fa'cia*, *fa'cies*, face]: one of the sides of a building viewed from without, especially the principal front. When applied to the other faces of a building it is used with some qualifying term, as *lateral façade*, *court façade*, etc.

Facatativá, faa-kaa-taa-tee-vaa': a town of Colombia; in the northwestern part of the department of Cundinamarca; about 20 miles N. W. of Bogotá, with which it is connected by railway (see map of South America, ref. 2–B). It is 8,500 feet above the sea. The river Facatativá here passes underground for some distance. Near the town there are various interesting antiquities, including some curious sculptured rocks. The place is an active commercial center, the trade from Bogotá to the Magdalena passing through it. Facatativá was a stronghold of the Zipas, or chiefs of the Chibcha Indians; Triquesupa, the last of the Zipas, was killed here in 1538. Pop. about 8,000. Herbert H. Smith.

Faccio, faat'chō, Franco: composer and conductor; b. at Verona, Italy, Mar. 8, 1841 (or 1840); started in life as a hotel waiter; studied music in the Milan Conservatory; made his first appearance as an opera composer Nov. 10, 1863, at La Scala, Milan, with his *I Profughi Fiamminghi*, following with *Amleto* in Geneva in 1865 to a libretto by Boito. He was appointed Professor of Harmony in 1868, and subsequently of Fugue and Counterpoint in the Milan Conservatory, and in 1872 succeeded Terziani as conductor of La Scala. D. July 21, 1891. D. E. Hervey.

Facciolati, fäat-chō-laa'tē, or **Facciolato**, GIACOMO: philologist; b. at Torreglia, near Padua, Italy, Jan. 4. 1682; was Professor of Logic in the University of Padua, 1722; published an edition of the *Lexicon Septem Linguarum* of Ambrogio Calepino, an Augustine friar of Calepio (2 vols., Padua, 1731), of the Greek lexicon of Schrevelius (Padua, 1715–19), and of the *Lexicon Ciceronianum* of Nizolius (Padua, 1734). He began a Latin lexicon, finished by Forcellini. D. at Padua, Aug. 27, 1769. See FORCELLINI.

Face [Fr., from Lat. *fa'cies*]: the front part of the human head, extending from the line of the hair on the forehead to the chin, and including the forehead, eyes, nose, cheeks, mouth, and chin, as distinguished from the posterior part of the head constituting the brain-case, or cranium. The face is composed of a solid bony foundation or skeleton, upon which lie numerous muscles, blood-vessels, nerves, and other structures, interspersed with a varying amount of fat, all of which are covered by the integument. The bones of the face, as grouped by anatomists, are fourteen in number, of which twelve (constituting the nasal, superior maxillary or upper jaw, lachrymal, malar or cheek, palate, and inferior turbinate bones) are in pairs, while two (the vomer and inferior maxillary or lower jaw bones) are single bones. Of the fourteen different bones entering into the structures technically regarded as included within the face, but seven (the nasal, superior maxillary and malar bones, and the inferior maxillary bone) take part in forming the facial surface; in addition to these, the frontal bone, although classed with the cranial group, contributes the important part of the osseous basis of the face supporting the forehead. Of all these bones but one, the inferior maxillary or lower jaw, is movable, this being attached by ligamentous structures in articulation with the temporal bones, at each side of the cranium. The four large openings which appear in the skeleton of the face (the orbits, nasal orifice, and interdental cleft) are partially or wholly closed by the soft parts occupying or surrounding them, which are respectively the eyes and their appendages, the nasal cartilages, and the lips.

The general character of the face, as expressive of the higher or lower grades of intelligence, is very largely influenced by the relative prominence of certain of its bony parts. Thus the large ample forehead, with well-developed bosses, usually accepted as indicating intellectuality, is directly dependent upon the development and expansion of the frontal bone; deep-set or sunken eyes are principally caused by the projection of the superciliary arches supporting the eyebrows, although depression of the root of the nose, and the narrowness of the aperture between the eyelids contribute to this appearance; the effect of undue prominence of the malar or cheek bones is familiar in the characteristic facial type of the races of Eastern Asia, and also, to an exaggerated degree, in the Eskimos; protrusion of the upper and lower jaws is also an important factor in modifying the general character of the face.

In order to facilitate comparison, certain lines have been agreed upon, whose measurements and mutual relations shall express definite types of face, in the same way that cranial measurements supply data for the comparison of skulls. Camper long ago suggested the use of certain planes in the study of the bony parts. For the purposes of craniometric investigations his methods have been supplanted by the more accurate and elaborate measurements carried out by Broca, Turner, and many other anatomists; but Camper's lines afford a useful and readily applied means of obtaining suggestive data in the comparison of faces. Many accurate measurements which may be made on the skull evidently can not be taken on the living subject; two useful lines, however, can be readily established: (*a*) the *horizontal line of Camper*, passing across the external canal of the ear and the base of the nostril; and (*b*) the *facial line of Camper*, extending obliquely from the most prominent central point of the forehead (glabella) to the anterior surface of the incisor teeth, intersecting the horizontal line at a point coinciding, in whites, with the nasal spine. The angle included between these lines is the *facial angle* of Camper, which in the intellectual races exceeds 80°, while in those of low intelligence it is much lower; in Negro, 60°–65°; gorilla, 31°.

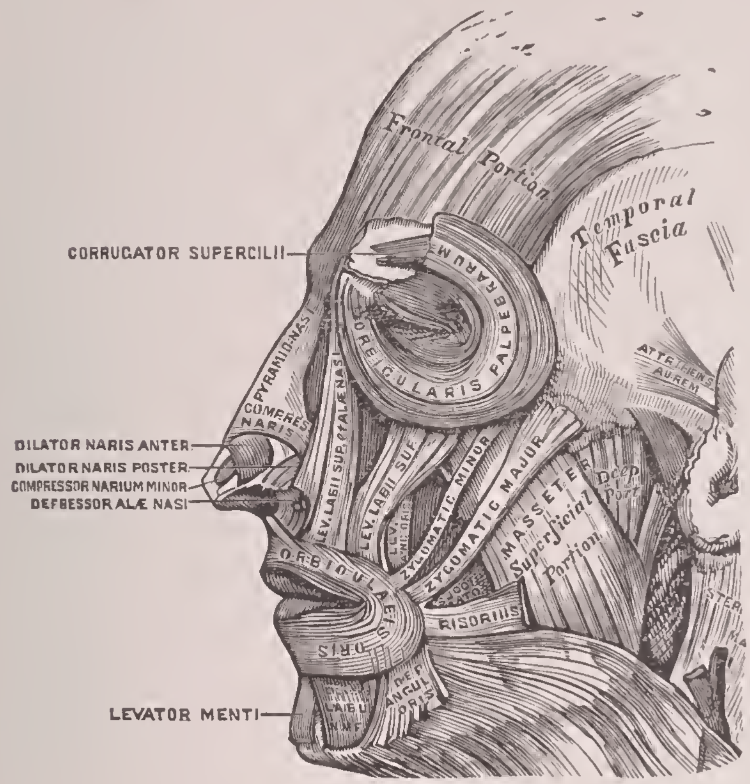
With regard to the general form, when observed in profile, faces may be divided into two groups: the one, *prognathous*, in which the facial line is very oblique, the lips large and everted, and the jaws very projecting; this is the Negro type, and is usually associated with a low degree of intelligence. The other, *orthognathous*, in which the facial line approaches the vertical, the lips are thin and small, and the jaws and line of the chin unprojecting; this is the European type, and is regarded as indicative of high intellect. Countenances may also be arranged in two other classes, according to the prominence of the central or lateral parts of the face. In the European type the middle of the face projects, while its narrow sides recede; in the Mongolian type, on the contrary, the central parts are flat, while the sides are wide and protruding, with prominent cheek-bones. Likewise, faces differ as to their *vertical* length, producing the long-faced and short-faced types, of which the Eskimos and Negritos respectively are examples.

The relation between the greatest width of the face, as measured on the skull just behind the cheek-bones—the *bizygomatic diameter*—and its length, as taken from a median point a little above the orbits (corresponding to the middle of the transverse line connecting the narrowest parts of the forehead) to the sockets of the upper middle incisor teeth—the *supraciliary-alveolar length*—has been accurately expressed by Broca's *facial index*, obtained by the formula, $\frac{\text{Supraciliary-alveolar length} \times 100}{\text{bizygomatic diameter}}$ = facial index. Broca found that 65·9 represents the average facial index for the European skull.

The character of the nose is also an important element in determining the race peculiarities of countenance. Among the points of comparison are the depth of the hollow at the root; the arching of the nose, as seen in the aquiline type so characteristic of certain races; the flattening of the nose, whether due to the participation of its entire skeleton or only of its cartilages; the form of nostril; the direction of the plane of the entire base. The peculiarities of the position and length of the eyelids largely account for the apparent obliquity of the eyes in the Mongols and other races.

In addition to the fixed anatomical causes producing variation of countenance when in repose, among which most potent are the conformation of the forehead, shape of the eyelids, prominence of the eyeballs, the nostrils, the lips, and the chin, the *movements* of the facial surface continually wrought by the constant play of the muscles induce the changes collectively known as "expression," which play so important a *rôle* in reflecting and revealing psychical processes. The muscles of the face constitute the immediate agents in producing such facial changes, whether the contractions result entirely from the exercise of the will or whether they occur unconsciously in association with certain mental conditions. The facial muscles are divided into two groups: those concerned in moving the jaw, hence called *muscles of mastication*, and those of *expression*. The latter differ from the majority of other muscles of the body in passing from their bony attachments to be fixed to soft parts, principally the skin, and in being loose in structure and poorly defined, mingled with fat and areolar tissue. They not only vary in development in different persons, but also on the two sides of the face of the same individual.

The muscles of expression may be conveniently grouped into (1) those which surround the eye; (2) those which move the nostrils; (3) those which encircle or are attached about the mouth. With the first or *orbital group* may be conveniently included the important muscle of the forehead (the frontal portion of the occipito-frontal) which is closely related to the other members of this group. The *frontal muscle* raises or arches the eyebrow and the skin over the root of the nose and throws the integument of the forehead into transverse wrinkles; the expression of surprise follows its moderate action, while fright or horror is depicted by its more violent contraction. The circular muscle of the eyelid, the *orbicularis palpebrarum*, completely encircles the cleft of the lids and surrounds the margins of the orbit, being the principal agent in closing the eyelids; two portions of the muscle are recognized: the *palpebral* portion, contained within the eyelids, whose action is involuntary and gently closes the lids, as in sleep or winking, and the *orbicular* part, surrounding the orbit, by which the eyelids are voluntarily forcibly closed and contracted. The orbicular muscle also acts powerfully in the expression of certain emotions, in laughing and crying, gathering up the skin into folds about the eye, which is thus more or less closed. The frowning muscle, the *corrugator supercilii*, is a little muscular slip extending obliquely upward and outward from the inner end of the ridge of the eyebrow; by its contraction it draws the eyebrow downward and inward, producing vertical wrinkles on the forehead expressive of perplexity, displeasure, or suffering. The *nasal* group includes a number of small muscular bands which pass in various directions, and by their actions subject the movable parts of the nose to compression, dilatation, depression, and elevation; many



Muscles of the face.

of these muscular slips are also connected with surrounding structures, so that their contraction affects other adjacent parts of the face. The small muscle passing from the inner margin of the orbit to the upper lip and wing of the nose, *the elevator of the upper lip and nose*, is the principal agent in expressing disgust and indignation; while the *dilators of the nose* enlarge the nasal apertures and are active in intense emotions, as in anger or pain. The *oral group* comprises numerous muscles, whose foci of attachment are the angles of the mouth, where they are joined to the muscular ring which surrounds the labial opening and supplies the fibers which close the mouth with greater or less force, and antagonize the muscles retracting its borders. Toward the angle of the mouth converge, from above, the *elevator of the angle of the mouth* and the *larger zygomatic* muscles, while the *elevator of the upper lip* and *smaller zygomatic* muscles are attached to the lip nearer the median line; converging from below, the *depressors of the angle of the mouth* and *of the lower lip* oppose the corresponding muscles of the upper lip; in addition, the *elevator of the lower lip* draws this structure upward and forward, at the same time slightly elevating the chin. The muscles of the oral group are very important and active agents in producing the expressions indicative of the opposed emotions of joy and sorrow; the depressor of the angle of the mouth is especially potent as a factor in producing a sorrowful countenance. It is, however, by the concerted contraction of some and relaxation of others of these muscles, often together with those of the orbital group, that the more complicated emotions find expression; thus the arching of the lips and the depression of the oral angle, indicating contempt, pride, etc., result from the combined action of the orbicular muscle and depressor of the angle. In smiling and laughing the muscles contracting the mouth are overcome by those retracting the lips, which are further drawn up, joined with the more or less pronounced participation of the orbital group, resulting, as in excessive laughter, in narrowing the fissure of the eyelids. In grief, the muscles of the lips are combined with those of the eyebrow, the extremity of the latter being drawn upward, while the retraction of the lips and depression of the angle of the mouth result from the associated contractions of the oral group. These are but instances of the endless variety of expression which the human face is capable of depicting through the immediate agency of the facial muscles, by whose co-ordinated contraction and relaxation all shades of emotion are so effectively portrayed.

The numerous *blood-vessels* supplying the face are principally branches of the facial artery, the main channel through which the blood is conveyed. This vessel is derived from the principal trunk at the side of the head, the external carotid, enters the face by winding over the lower border of the jaw, not far from its middle, and crosses the face obliquely to the side of the nose, along which it passes as far as the inner corner of the eye; in its course it gives off branches which supply the cheeks, chin, lips, and nose. Additional blood is brought to the face by the transverse facial and infraorbital arteries. The venous blood is returned chiefly by the corresponding facial vein.

The *nerves* distributed to the face are, as in other parts of the body, of two kinds—those of motion, for the control of the numerous muscles, and those of sensation, devoted to maintaining common sensibility. The former are principally derived from *the facial nerve*, although the muscles of mastication are supplied by the motor division of the trifacial; the nerves of sensation are chiefly branches of the great trifacial, whose principal cutaneous branches reach the surface just at the upper margin of the orbit—*supraorbital*; below the eye, where nose and cheek meet—*infraorbital*; at the side of the chin—*mental*; and in front of the ear at the side of the head—*temporal*; from these foci numerous twigs ramify in all directions, uniting with filaments from adjacent centers. A narrow zone along the lower margin of the jaw, however, forms an exception to the general facial surface, deriving its sensory nerves from the cutaneous branches of superficial cervical and great auricular nerves of the neck. G. A. PIERSOL.

Facet [from Fr. *facette*, dimin. of *face*, face]: one of the plane surfaces cut upon precious stones to increase their luster. The planes which bound a crystal, the flat surfaces of the cornea of an insect's eye, and in fact any minute plane surface may take this name.

Facetiæ, fā-see'shi-ē̆e [Lat., deriv. of *face'tus*, well-made, elegant, witty, deriv. of *fa'cere*, to make]: a collection of humorous sayings, witty stories, *bons mots*, repartees, in prose and verse. From the ancients nothing has come down except the *Jests of Hierocles*, the sayings and doings of one "Scholasticus," the typical blunderer of earlier times, the prototype of the modern perpetrator of "bulls." The earliest specimen in modern times is the *Liber Facetiarum* of Poggio Bracciolini (1st ed. Rome, 1470). The term as used in modern bibliography is limited to books or plates of an obscene character.

Facial Angle: See FACE.

Facial Nerves: The nerves of the face. The motor nerve of the face (the facial nerve proper) is also called the seventh or portio dura of the seventh according as to whether the cranial nerves are regarded as being twelve or nine in number. Its nucleus is in the floor of the fourth ventricle. Its superficial origin is from the lateral tract of the medulla oblongata in the depression between the olivary and restiform bodies immediately behind the pons. It passes forward and outward upon the cerebellar crus and enters the internal auditory meatus, at the bottom of which it enters the aqueductus Fallopii, along which it passes through the petrous portion of the temporal bone and emerges at the stylomastoid foramen. It passes forward through the parotid gland, and behind the ramus of the lower jaw divides into two primary branches—the temporo-facial and the cervico-facial. The divisions of the nerve in the parotid gland somewhat resemble a bird's claw, and hence this portion of it is called *pes anserinus*. All the muscles of expression in the face, as well as the buccinator, platysma, stapedius, lingualis, retrahens aurem, stylohyoid, and the posterior belly of the digastric are supplied by it.

The trifacial (*trigeminus*) or fifth is the sensory nerve of the face. It contains also motor fibers, and is possibly, to a certain extent, a nerve of special sensation. It arises superficially from the side of the pons Varolii. It has two roots—an anterior or motor and a larger posterior or sensory one—upon which is a ganglion (the Gasserian) precisely as in the spinal nerves. There are three main branches—the ophthalmic, the superior maxillary, and the inferior maxillary. The first is purely sensory. It supplies the eyeball, the lachrymal gland, the mucous lining of the eye and nasal fossa, and the skin and muscles of the eyebrow, forehead, and nose. The second is also sensory, and supplies the side of the nose, the lower eyelid, and upper lip. The third branch is made up of two parts, a larger sensory division which supplies the teeth and gums of the lower jaw, the skin of the temple and external ear, the lower part of the face, and lower lip. It also sends a large branch to the tongue which probably serves as a nerve of taste. The motor branch supplies the muscles of mastication—the masseter, temporal, and pterygoids.

WILLIAM PEPPER and C. W. BURR.

Facial Neuralgia: trigeminal neuralgia; tic douloureux; prosopalgia. (For causation, see NEURALGIA.) The fifth nerve is more often the seat of neuralgia than any other. While the nerve may be affected throughout its entire distribution, more frequently one or two of the three main divisions are involved, or it may be one only of the smaller branches. It practically never occurs on both sides at once. When the ophthalmic division is affected the pain is felt above the brow. So commonly is this due to malaria that it is often called "brow ague." The eyeball may be the seat of pain, sometimes accompanied by dimness of sight, contraction of the field of vision, and flashes of light. When the superior maxillary division is affected, the pain extends from the orbit to the mouth, over the cheek, and to the side of the nose. If the inferior maxillary be involved, the pain is felt in the side of the head, the temple, ear, lower jaw, and tongue. Sometimes there is a boring pain limited to a point in the temple, and occasionally the tongue alone is affected (glossalgia). The pain is intense, at times making life almost unbearable, and so increased by movement of the jaw as to render eating almost impossible. It may radiate from one division of the nerve to the next or even to other nerves. If the onset be sudden and severe, reflex muscular spasm may occur (tic convulsif). Palsy is rare, but there is often flushing, local sweating, increased nasal and buccal secretion, and lachrymation. In chronic cases there may be thickening of the periosteum and hardening of the skin, loss of hair or local grayness, and herpes about the eye or lip. Pressure at the points of exit of the nerves from bony canals causes pain. Treatment depends upon causation.

WILLIAM PEPPER and C. W. BURR.

Facial Paralysis: paralysis of the muscles of the face. There are two forms—(1) central, in which the disease is situated between the nucleus of origin of the nerve and the cortex of the brain; (2) peripheral, called Bell's palsy, in which the lesion is in the nucleus or the nerve itself. In the first the upper face muscles are but little or not at all affected, and those around the mouth suffer most. Voluntary movements are much more impaired than those due to emotion. Lastly the affected muscles respond normally to electrical stimulus, or if there be any diminution it is the same for both the faradic and galvanic current. In the second form there is complete palsy of one side of the face. The onset is rapid, but not sudden. The commonest cause is inflammation of the nerve due to cold, e. g. sitting while overheated by an open, draughty window. Ear disease, especially in children, is also a frequent cause on account of the close proximity of the nerve to the auditory apparatus in its course through the petrous portion of the temporal bone. Tumors or meningitis at the base of the brain may cause palsy by pressure upon the nerve, and fracture of the base of the skull may tear or bruise it. Wounds or operations about the angle of the jaw may cut it. A blow, as in boxing the ears, may cause palsy. In instrumental delivery the nerve has been injured by pressure of the blade of the forceps. Syphilis is an occasional cause. The face in this disease is characteristic. The wrinkles are smoothed out of the forehead, the angle of the mouth droops, the cheek flaps in and out with respiration, the folds at the side of the nose disappear, the patient can not whistle or blow out a candle, and on attempting to drink the liquid runs out of the side of the mouth. Food collects between the teeth and the cheek. The tongue is protruded to one side. The eye can not be closed, and on attempting to do so it is rolled upward so that only the white is visible. All muscular effort draws the face strongly to the healthy side. In certain cases taste is lost in the anterior part of the tongue on the palsied side. Hearing may be impaired. Reaction of degeneration comes on later. Wasting may follow, but, on account of the small size of the muscles involved, is never very marked. Sensation is unaffected. The immobility of the eyelid may permit foreign bodies to settle in the eye, but the increased quantity of tears usually floats them off, and nothing more serious than a slight conjunctivitis is apt to follow. After some time contractions may set in, and, owing to the pull of the contracted muscles, the folds and wrinkles may appear again, and at first sight it may seem that the normal is the palsied side. The first indication in treatment is to remove the cause. Hot fomentations to the ear and blisters are good at the beginning. Potassium iodide and mercury have their proper place. In chronic cases electrical treatment is often very beneficial.

WILLIAM PEPPER and C. W. BURR.

Fa'cies [Lat., the face]: a term which has come to be applied to the expression, especially as indicating various forms of disease, rather than to the face itself. The old-time physician, having fewer accurate methods of investigation at hand, relied largely on the expression to discriminate between different diseases, but it still remains of considerable value as a diagnostic means to the physician. Hippocrates first described the peculiar facies of approaching death, called by his name, *Facies Hippocratica*. The sunken eyes and temples, the sharp nose, contracted ears, distended forehead and dark-hued or leaden skin are certainly characteristic of approaching death, but acute collapse may be attended by these features and yet lead to no such end. Besides this, there are recognized in many diseases features more or less indicative of the disease, and the experienced physician frequently finds little difficulty in diagnosticating cases at first sight. The peculiar dull, lethargic, expressionless face of typhoid fever, the flushed, active appearance of that of pneumonia, are rarely to be mistaken. So, too, the hard lines about the mouth and nose in severe gastric and intestinal disturbances, the pinched features, with livid eyes and muddy complexion, of a victim of cholera, and the sallow, emaciated countenance of one afflicted with cancer, are sufficiently marked to allow of a diagnosis being made by this alone.

WILLIAM PEPPER.

Factor [from Fr. *facteur* < Lat. *fac'tor*, maker, doer, deriv. of *fa'cere*, make, do]: in mathematics, one of the several measures or divisors of a number or quantity. The name is given to each of those quantities which, when all are multiplied together, will produce the *product*.

Factor: a general agent employed in the purchase or sale of merchandise, with power to retain possession of the property in regard to which his authority is exercised, and to control, to a large extent, its management and disposal by proceedings in his own name. By the possession of these peculiar powers a factor is distinguished from a broker, who only conducts negotiations and bargains concerning property of his principal, without having it in his charge, and who properly acts in a representative character by the use of his principal's name. The term "factor," though the one usually employed in law, is not so common in popular usage as "commission merchant" or "consignee." Compensation by the principal is generally a certain percentage on the amount of purchases or sales, called factorage or commission. A *domestic factor* is one who resides in the same country with his principal; a *foreign factor*, one who resides in a different country. A foreign factor, in his relations with third persons, is regarded, to a large extent, as if he were himself principal, and he is therefore under a greater responsibility than one merely domestic. In the application of this distinction the States in the U. S. are not, according to the general course of decisions, regarded as foreign to one another. The fundamental duty of a factor is to exercise reasonable care in the performance of the duties with which he is intrusted, and to exhibit such skill and prudence as is required by the nature of the business and a proper consideration for the welfare of his employer. Otherwise, he has no valid claim for his commissions, and for injurious negligence and default may even be subjected to an action by his principal. In the management of the property committed to him he has commonly extensive discretionary power. He may buy and sell, sue and be sued, collect money, give receipts, etc., in the same manner as if he were himself owner of the goods, unless specially restricted by the principal. If any special instructions are given to guide his action, he is bound, as between him and his principal, to follow them strictly, except in some few cases where the necessary protection of his own interests requires that such directions be violated. An instance of the latter kind occurs where the factor has made advances for his principal, and finds it necessary to sell the goods upon the credit of which the advances were made, in order to reimburse himself, upon failure or refusal of the principal to make repayment after proper notice and demand. In such a case the generally established rule in the U. S. is that the factor has a right to sell to the extent of his advances, even in opposition to the wishes of his principal. The rule in Great Britain, however, is different. Even where the factor violates special instructions, he may, in certain cases, confer a title upon a purchaser acting in good faith. In the absence of instructions, factors should conform to the usages of the business in which they are engaged, and will be justified in the adoption of any practice which such usages warrant, provided there is no wanton disregard of their employers' interests. They have a lien upon the property intrusted to them for their commissions, advances, and other proper charges, so long as they retain possession. Sometimes, in consideration of an increased commission, a factor guarantees the payment of the price of goods by the purchaser to his principal. He is then said to act under a *del credere* or guarantee commission, and is subject to most of the obligations of a surety. A factor acquires no right to his commissions until all the services for which he was engaged have been rendered. (See AGENT and BROKER.) Statutes have been passed in Great Britain and some of the U. S. regulating the rights and duties of factors in certain respects.

Revised by T. W. DWIGHT.

Factor of Safety: a number which expresses the ratio of the breaking strength of a bar or structure to the actual stress upon it. For buildings and structures subject to quiet loads the factor of safety is taken at about 15 for brick and stone, 8 for timber, 6 for cast iron, and 4 and 5 for wrought iron and steel. For bridges, and for machinery subject to shocks, much higher values are used. Factors of safety are subject to variation not only on account of the different qualities and grades of materials, but also on account of the varying judgment of designers. The factor of safety has been called a factor of ignorance, and this is the case if it be blindly assumed without knowledge of the elastic and resisting properties of materials. The tendency among engineers is to avoid the use of the term, and to establish the proper working stresses for materials from the knowledge of such properties. See STRENGTH OF MATERIALS.

MANSFIELD MERRIMAN.

Factories and **Factory System** [*factory* is from Fr. *factorie*, from deriv. of Lat. *factor*, maker, manufacturer. See FACTOR]: buildings appropriated to the manufacture of goods, and the system of production therein employed. A factory has been created and "the factory system" has been evolved when goods are produced through consecutive processes carried on as a harmonious whole, by laborers congregated in works especially adapted for this purpose, and provided with productive machines actuated by some central motive power. Dr. Ure, in his *Philosophy of Manufactures*, has stated that "the factory involves, in its strictest sense, the idea of a vast automaton, composed of various mechanical and intellectual organs acting in uninterrupted concert for the production of a common object, all of them being subordinated to a self-regulated, moving force." A factory, then, to give an enlarged definition, is an establishment where several workmen are collected for the purpose of obtaining greater and cheaper conveniences of labor than they could procure individually in their homes, for producing results by their combined efforts which they could not accomplish separately, and for preventing the loss occasioned by carrying articles from place to place during the several processes necessary to complete their manufacture.

The factory system of manufacture has displaced the domestic or hand system of labor. It is applied to almost every branch of mechanical production, and its application is being constantly extended. It will probably become essential in what is known as the "extractive" industries. In many localities mining is more of a manufacture than anything else, being carried on by means of mechanical processes involving a central power. The birth of the factory system is easily assigned to the decade 1760–70, for it was during this period that the *régime* of machinery began. The spinning-frame, the spinning-jenny, and subsequently the mule spinning-machine were inventions on which the introduction of the factory system depended; but the system would not have grown at once to any very great proportions from the sole influence of these inventions. The extension of the canal system of transportation, the various improvements in the steam-engine, the suppression of the slave-trade diverting a great volume of capital which sought remunerative investment, the war between Great Britain and her colonies in America, the political economy of Dr. Adam Smith—all these were influences or forces which, combined, resulted in supplanting the domestic or hand-labor system of Great Britain by the factory system of labor. In the U. S. the domestic system of labor prevailed when the war of Independence closed, for the influence of inventive genius had not yet affected labor. On the opening of the ports of the new nation the market was fully supplied by British products. This caused a new fever of patriotism, which resulted in efforts to transplant the inventions which were becoming powerful in revolutionizing labor in Great Britain. The series of inventions relating to textiles was completed when the power-loom was invented; but Great Britain sought to prevent its use, as well as the use of other inventions, in the United States, through enactments prohibiting the exportation of machinery. The associations formed in the colonies for the purpose of inducing the people to purchase domestic productions only were a great assistance to the pioneers in manufactures, but this influence was increased or supplemented by the action of the Continental Congress through the resolutions relating to non-importation, under the influence of which the colonists could look only to their own resources for the supply of many commodities. The foundation of manufactures in North America was thus permanently laid. Many household industries were established and became profitable, and the desire of the whole people to shake off industrially, as they had politically, the yoke of the mother-country stimulated the first Congress to pay immediate attention to the promotion of manufactures, its second act, passed July 4, 1789, being an act for laying a duty on goods, wares, and merchandise imported into the U. S. While the factory system was established in the U. S. about fifteen years later than in Great Britain, the extension has been far more rapid, and many more industries have come under its operations than in the mother-country. The States of Massachusetts and Rhode Island claim together the honor of introducing power spinning-machines, and their early use in the U. S. Massachusetts is undoubtedly entitled to her claim to the first experiments in machinery in which the principles of Arkwright's inventions were embodied, and of erecting the first cotton-factory in America, and Rhode Island's claim of having erected the first factory for the use of perfected machinery comprehending the English inventions is undoubtedly valid, for Samuel Slater built a cotton factory in that State in 1790. Mr. Slater has been called the "father of American manufactures." Certainly from the date of the erection of his factory the progress in the production of goods under the factory system has been continuous. But Francis C. Lowell was the first in the world, so far as history teaches, to perfect a factory in which all the manipulations and processes necessary to carry raw material to finished goods were carried out consecutively under one directing mind. This was at Waltham, Mass., in 1813.

To give a detailed account of the history of the different industries coming under the factory system of labor would involve an article too extended for this place. An examination of the system itself and its effects in various directions is more appropriate and valuable.

The rapid extension of the factory system, absorbing as it does small enterprises and crushing out the ideal system of manufacture, has not been accomplished without great social changes, affecting the morals as well as the politics and the legislation of the countries in which it has been established. No one disputes the economic advantages of the modern system; few admit that it is a moral force in the actual progress of civilization; yet the system is, and has been, an active element in the upbuilding of the character of the peoples involved in the changes wrought by it; and it will remain until disintegration is the rule in society.

The domestic system, which claims the eighteenth century almost entirely, has not yet disappeared. The factory system is in every respect vastly superior to it as an element of civilization, although this is contrary to popular impression and largely against popular sentiment. Abuses have existed, great and abominable enough, but not equal to those which have existed in the imaginations of many. The common notion that the factory system exerts an influence for evil is largely due to the fact that it congregates evils or evil-disposed persons, and thus gives the appearance of creating that which already existed. People have not yet outgrown the impression created by the reports of Sadler before a parliamentary committee in 1832.

A factory is a scientific structure, its parts harmonious, the calculations requisite for their harmony involving the highest mathematical skill, and in the factory the operative is always the master of the machine, and never the machine the master of the operative. Under this system, the work is carried on in an establishment peculiarly adapted to it, and the operative's home is separated from the workshop. Under the domestic system, the home of the worker was the workshop also, and the wheels or looms disputed with the inmates for the room and the conveniences for housework. Small, close, crowded, with bad air and bad surroundings, the hut of the domestic worker was occupied day and night by a class which has not found and can not find its like under the factory system; for, as a rule, the operative of to-day occupies a home, even in the factory tenement or boarding-house, superior in every sense to the home of the domestic worker.

Under the domestic system of industry grew up that great pauper class in Great Britain which was a disgrace to civilization. It was fed by the agricultural districts more than by those devoted to manufactures. It continued to grow until one-fourth of the annual budget was for the support of paupers. The evil became fixed upon the social life as one of its permanent phases. Legislation, philanthropy, charity, were utterly powerless in checking it, and it was not checked until the inventions in cotton-manufactures came, since which time it has been on the decline. The factory absorbed many who had depended upon public support: on the other hand, it drew from the peasantry, by the allurements of better wages and without any guarantees as to permanence or care as to moral responsibility; yet on the whole the state was benefited more than any class was injured.

The domestic laborer's home was far from having the character poetry has given it. Huddled together in what poetry calls a cottage and history a hut, the weaver's family lived and worked, without comfort, conveniences, good food, good air, and without much intelligence. Drunkenness and theft of materials made many a house the scene of crime and want and disorder. Superstition ruled and envy swayed the workers. Ignorance under the old system added to the squalor of the homes of the workers under it, even making the hut an actual den, shared in too many instances by the swine of the family. The home of the agricultural laborer was not much better; in fact, in Great Britain and France he has to a great degree continued in his ignorance and in his degraded condition.

From the documents published by the poor-law commissioners of England, it appears that but for the renovating influence of her manufactures Great Britain would have been overrun with the most ignorant and depraved men to be met with where civilization has made much progress. It has been in the factory districts alone that the demoralizing agency of pauperism has been most effectually resisted, and a noble spirit of industry, enterprise, and intelligence called forth. Agriculturists gave children and youths no more than half the wages paid them in factories, while they filled the workhouses with the unemployed. Under the operation of the miserable poor-laws which the domestic system fathered the peasantry were penned up in close parishes, where they increased beyond the demand for their labor, and where the children were allowed to grow up in laziness and ignorance, which unfitted them for ever becoming industrious men and women. But in the chief manufacturing districts, while the condition of the factory children became the subject of legislation for their protection, their condition was one to be envied when compared with that of the children in mining and agricultural districts.

The spasmodic nature of the work under the domestic system caused much disturbance, for hand-working is always more or less discontinuous from the caprice of the operative, while much time must be lost in gathering and returning materials. For these and other obvious reasons a hand-weaver could very seldom turn off in a week much more than one-half what his loom could produce if kept continuously in action during the working hours of the day, at the rate at which the weaver in his working paroxysms impelled it. The regular order maintained in the factory cures this evil of the old system, and enables the operative to know with reasonable certainty the wages he is to receive at the next pay-day. His life and habits become more orderly, and when he has left the closeness of his home-shop for the usually clean and well-lighted factory, he experiences an agreeable and healthful change. It is commonly supposed that cotton-factories are crowded with operatives. From the nature of things the spinning and weaving rooms can not be crowded. The spinning-mules, in their advancing and retreating locomotion, must have five or six times the space for working that the actual bulk of the mechanism requires, so that in the spinning-rooms there can be no crowding of persons. During the agitation for factory legislation in the early part of the nineteenth century, it was remarked before a committee of the House of Commons "that no part of a cotton-mill is one-tenth part as crowded, or the air in it one-tenth part as impure, as the House of Commons with a moderate attendance of members." This is true to-day; the poorest factory in the U. S. is as good a place to breathe in as Representatives' Hall, in the national Capitol, during sessions, or as the ordinary schoolroom. In this respect the new system of labor far surpasses the old.

It is true that many disadvantages appear to accompany the factory system, and these, upon superficial study, are denominated evils; but a careful study shows that these apparent evils or disadvantages do not of necessity belong to the system, nor can they be attributed to it. Such study does show that existing factory evils, so called, may be congregated by it, but are not called into existence by it. For the categorical consideration of such alleged evils they may be classified as follows:

A.—Does the factory system necessitate the employment of women and children to an injurious extent, and is its tendency to destroy family ties and domestic habits, and ultimately the home?

B.—Are factory employments injurious to health?

C.—Is the factory system productive of intemperance, unthrift, and poverty?

D.—Does it foster prostitution and swell the criminal lists?

E.—Does it tend to intellectual degeneracy?

These questions indicate the apparent disadvantages which many honestly believe belong naturally to and are inseparable from the system, and which will be associated with the system as long as it exists. For the sake of directness these will be examined in order.

A.—In one sense it is true that the factory system is inimical to the home through the employment of women and children to an injurious extent; in another sense it is not true. The question as to differences in the capacity of individuals, and why this one is born to good conditions and that one to bad, can not be discussed, but the facts must be taken as they are. The majority of human beings are born to the lot of toiling with their hands for their daily bread. This decree necessitates employment, and until all classes can be employed at fairly remunerative rates poverty, even to pauperism, must be a large factor in society. This was the case at the birth of the factory system. In fact, the great evils which became apparent during the early days of the system were simply, as has been said, the results of bringing together the labor which had become pauperized under the domestic system and in agricultural districts. The factory brought these evils to light, and the employment of women and children became an offense in the eyes of the public, not because it was severer than under the old system, but because under the new the evils of such employment could be seen.

It is true that the success of the system, so far as textiles are concerned, has depended in a large degree upon such employment, and it is also true that such employment has enabled women and children to step from the ranks of degrading dependence and pauperism to the ranks of comparative comfort and the dignity which comes from self-support. In the early days of the factory the children were by their employment really placed in a much better position than they occupied before. The employment of married women is perhaps the very worst feature of factory employment, but the facts relating to it are meager. In Great Britain the proportion of married women to the whole number of women employed in textile works is unknown, but for those factories concerning which the writer has been enabled to make inquiries 10 per cent. is the average. In Germany it was found that from 20 to 50 per cent. of the textile-factory women were married. Dr. Engel gives the percentage in various industries as 24. Proprietors in both countries discourage the employment of married women. The statistics of Massachusetts show that the married female operatives constitute less than 8 per cent. of the whole number of women employed in all textile factories. Taking all textile factories into consideration, the percentage probably would not exceed 10. It is evident, then, that in Great Britain and the U. S. infant mortality is not, on the whole, affected to any great degree by the employment of married women; but it is affected seriously so far as the children of those employed are concerned. It must not be presumed that the employment of married women is the sole cause of the very high percentage of deaths under five years in factory towns compared with deaths in towns of diversified industries and agricultural towns. Crowded houses, bad sanitation, and the general effect of compact towns upon young children, especially during inclement seasons, are potent influenees in producing high rates of mortality. The statistics of factory towns in the United Kingdom do not exhibit a larger proportion of deaths of infants than occur in other large towns where few or no factories are in operation, yet the proportion is very much larger than in agricultural towns.

In Germany, according to information furnished by Dr. Ernst Engel, in a factory city in the district of Zwickau, out of 459 children born in one year, 169, or 36 per cent., died under one year of age. Of those who died it was learned that 98 had not been nursed at all, and only 32 for the full time. In another factory city in the same district, in the same year, out of 428 children born, 185, or 43 per cent., died the first year, of whom 98 were never nursed at all and only 23 for the full time, and of the remainder only two for more than twenty weeks. In a third city, 48 per cent. in 1873 and 41 per cent. in 1874 of all the children who died had not reached the age of one year, and the great majority were the children of factory operatives. In a fourth factory city, of 731 persons who died in 1874 the children numbered 510, of whom 406 were under one year of age. The attending physicians in the cities ascribed the infant mortality partly to the bad condition of houses, but mainly, without hesitation, to the fact that mothers gave their attention to the work in the factory; that natural nursing was either given up entirely or continued for only a short time; and that the children, instead of receiving a mother's care, were left to the guardianship of older children.

In the district of Liegnitz, in Prussia, the rate of mortality has decreased among small children since hand-loom weaving gave way to factory employment. At Aix, in all cases where the mothers resumed work in the factory soon after confinement, an unusual mortality occurred among the infants.

In the greater part of the districts of Bavaria the health of the factory operatives seems good. If here and there a greater mortality among infants and poor health among the older children are met with, it should not be ascribed to any special branch of industry, nor necessarily to factory work, but to the unfavorable conditions under which children belonging to the working classes, whether in the factory or out of it, are brought up.

In Swabia, the city of Augsburg alone furnishes unfavorable reports. Out of 418 children under one year belonging to the factory population, 273, or 65 per cent., died in a year; out of 1,692 infants of the remaining population, 732, or 43 per cent., died.

In Würtemberg much complaint has been made of an excessive mortality among infants, but the cause is thought to be not that the mothers are employed in the factories, but in that lack of maternal care which is notorious among the working classes of this district. According to the statistics from these districts, the mortality is often greatest in those plaees in which few women are employed in the factories, while places in which such employment is general make a favorable showing as to infant mortality. The mortality among infants in Baden and Hesse does not seem disproportionately large among the factory population.

The writer is confident, from all the testimony he has been able to gather, that there are many more children of mothers working in factories during pregnancy who die in infancy than of other classes; and that while many children die when only a few months or a year old, in eonsequence of the factory work of the mother during pregnancy, many born healthy, or apparently so, die from want of proper maternal care. He is further satisfied that the conditions of the homes of these women are as deleterious to their health, and to infants born to them, as the work of the faetory, and that to exclude such women from the factory would be an act of great injustice to those eoncerned. And yet he is satisfied that the employment of married women is the worst apparent evil of the factory system. Attempts to relieve communities of the unhappy results of such employment appear to be few in number.

Does the employment of women and children tend to destroy the home? To the extent that women who are mothers and have the care of a household, and who become careless of maternal ties through hard work and maternal duties combined, it does; the faetory mother who has buried several children learns sooner or later to speak of her losses in a careless and unfeeling manner. Domestic felicity does not and can not reaeh a very high place when a mother must arise before the rest of the family to prepare hastily the breakfast for all, then hasten to the mill and make her time good till the noon hour, when the dinner must be prepared as hastily as was the breakfast; while at night, after a day of constant labor, she must see that supper is served and then take up the thousand and one duties of the household, which keep her busy till the hour has long passed when she should be asleep. No ten-hour law has been able to reach the factory woman with a family. However, it is gratifying to be able to believe that the number of married women employed in factories is decreasing. Notwithstanding the evil results of their employment, their condition is a vast improvement upon that which surrounded the workers under the domestic system.

The home in the U. S. suffered more from the institution of the faetory system than it did in Great Britain, for there the faetory found a population ready to become faetory workers, while in the U. S. it was neeessary to provide for a new population, and this opened the way for the tenement-house and the factory boarding-house, two features of factory life which are quite unknown in Europe, and which are gradually disappearing in the U. S., while the individual home is inereasing in its influence. With this growth of the influence of the individual home there has been a gradual decrease in the employment of married women. If at times the employment of women has taken the mother from the care of her infant, it has enabled more who had no home to become self-supporting, for the employment of women generally is now no evil, thanks to improved machinery and generally wise legislation.

Young children are now almost universally excluded from the faetory and workshop. Where their age permits, they are much better off inside than outside the faetory, and their employment enables them to contribute to home support rather than to draw from the income of the family.

B.—That some factory employments are injurious to health is true, but it is not true that factory employment, as sueh, in comparison with any other meehanical employment, is unhealthful. A reeent writer, describing a watch-factory, states what is true of all factories:

"The first requisites of a wateh-factory are neatness and abundance of light. It is now recognized that no man can do his best work unless he is physically comfortable. Excess of heat or eold, poor light, and, more than all, bad air, are positive hindrances to good work. Of two men equally skilled, one in a close, damp, or hot room with a bad light, and the other in a dry, sweet, and healthful room with the best light, the man who has the most comfortable quarters will do the most and best work in a day."

It is now seen that everything that contributes to the physical and mental comfort of workmen pays a good return on the eost, and eertainly makes better citizens of the operatives. Intelligent employers of labor adopt all plans which can be devised for securing the health of the operatives. Factory legislation compels the ignorant employer to adopt them. If some means could be devised to make all the homes of the operatives as neat, elean, and wholesome as the factory, we should hear no more of the tendency of the factory to physieal degeneracy.

C.—If it could be shown that the faetory leads to intemperate habits, it would follow conclusively that it is productive of unthrift and poverty, the conditions sure to result from intemperance. It is true that a great deal of drunkenness exists in factory towns and among factory operatives; it is not true that the faetory is the creator of this. On the other hand, the investigations of Louis Reybaud, a member of the Institute of France, conducted in the name of the Academy of Moral and Politieal Science, relative to the condition of workingmen in various branehes of industry, prove conelusively that the factory operatives are far more temperate than those engaged under the domestic system. The industries of Franee afford the very best opportunities for comparative study in this respeet. In the U. S. drunkenness has never been much of an obstaele in the way of the sueeess of the factory. Factory towns support a large number of common laborers, and the intemperance of this class is usually attributed to the factory.

Unthrift and poverty do not belong to the factory system of industry to any such extent as they belonged to the system which it supplanted; indeed, the poverty existing at the birth of the factory system was one of the most potent influences which enabled it to grow. This is the historical view, not the sentimental one. There was a time when the drunkenness of factory operatives constituted a serious obstacle to the successful operation of factories in Great Britain and on the continent of Europe. Sunday was a day of debauch, and many, spinners especially, did not get into condition for work before Tuesday or Wednesday. It is the unanimous testimony of manufacturers in the leading factory towns of Great Britain that drunkenness is not now a serious obstacle to the running of their works, and in many places on the Continent the same testimony is given.

The U. S. affords the very best proof possible of the thriftiness of factory people, in this, that within a generation and a half the nationality of the cotton-factory operatives has changed from native-born and English to English and Irish, largely the latter, and now to French Canadian; with each change has come a class seeking an improvement of condition, and as the improvement has come the old have stepped up from the mills to higher occupations, shopkeeping, farming, etc., and the new have stepped in; and as their children become better educated than their parents, still others will crowd them out of the factories and receive the advantages which have advanced their predecessors in the way of progress.

D.—The charge that the factory fosters prostitution and swells the criminal lists is absolutely unfounded. This impression first grew from the condition of Manchester, England, where a large cellarage population, which has entirely disappeared, was attributed to the factory. It has been shown by the returns from the penitentiary of Manchester that the ranks of prostitution were not filled from the factory, 8 out of 50 coming from the factory, and 29 out of 50 from domestic service. An extensive examination of the criminal records of a large number of British factory towns discloses the fact that neither the ranks of prostitution nor the criminal lists are increased to such extent from the factory population of those towns as from other classes. This is equally true in the U. S. It should be borne in mind that regular employment is conducive to regular living, and that regular employment does not, as a rule, harmonize with a life of prostitution, intemperance, and crime. The virtue of the factory women of the U. S. and of Europe will compare favorably with that of any other class.

E.—In considering whether the factory system tends to an intellectual degeneracy of the operatives, as many urge, the writer can not use statistical data, but is obliged to rely to some extent upon the opinions of those whose positions entitle their statements to the fullest confidence. The impression that the factory system tends to intellectual degeneracy is entirely unfounded. Through the simplification of mechanical processes ignorant labor is congregated in factory centers, but it is not created or induced by the factory. The fact that the ignorant masses are enabled by the factory to engage in what it once took skilled labor to perform has given the widespread impression that factory labor has degraded the skilled, when in truth it has lifted the unskilled, and this is the inevitable result of the factory everywhere. It is a curious fact that after the factory system was established in Great Britain, and the poor, ignorant labor of the southern agricultural districts was lifted up to respectable and self-supporting employment and to comparative self-respect, the factory was held to be responsible for the ignorance which it found; and so the laws of Great Britain, and in later years of the U. S. too, have insisted upon the education of children as a prerequisite to factory employment. This may explain the superior intelligence of the children of factory towns in the United Kingdom as compared with those of agricultural localities. The half-timers of Great Britain and the factory children of the U. S. are laying a foundation, if proprietors will only recognize the power of moral forces in the conduct of industrial enterprises, which will ere long change the social complexion of factory towns. If the advantages afforded in factory towns will stimulate rural districts to emulate the work of providing for the proper amusement and instruction of children and young people, perhaps the constant depletion of such places may be checked and the inhabitants of crowded towns be attracted to the soil. The mental friction of the factory is not without its healthful influences. Instead of dwarfing the minds and the skill of the skillful, as is often alleged, the factory enlarges the minds and increases the power of the unskillful. Louis Reybaud, whose investigations have already been referred to, testifies that the abasement of intelligence, which is said to follow in proportion as tasks are subdivided, is a conjecture rather than a truth shown by experience, and is presumed, not proven. To prove abasement from factory employment it would be necessary to show, for example, that the hand-weaver, who throws the shuttle and gives motion to the loom, is of a class superior to the machine-weaver, who superintends such double movement. Employment of the muscles in several operations instead of one has nothing in it to elevate the faculties, and this is about all the opponents of the factory claim. "In their view," says Reybaud again, "the most imperfect machines, those which require the most effort, are the ones which sharpen the intellectual faculties to the greatest degree. We can easily see where this argument would carry us, if pushed to the end." There is no abasement; on the contrary, it is from the influences resulting from the factory system that one can discern the elevation of an increased proportion of working people from the position of unskilled to that of skilled laborers, and the opening of an adequate field of remunerative employment to women, two of the most important improvements in the condition of the working masses which could be desired; and these results are stimulated by the factory system.

The domestic system could not deal with machinery. While machinery in one sense means the factory system, it is really the type and representative of the civilization of this period so far as mechanics are concerned, because it embodies the concentrated, clearly wrought-out thought of the age. There is something educational in the very presence of machinery. A large proportion of the machines made use of under the factory system of industry were invented by workmen who have been desirous of finding out easier and readier means of performing their accustomed task. These things stimulate industry, which in turn stimulates frugality.

One of the positive results of the factory system has been to enable men to secure a livelihood in fewer hours than of old; this means intellectual advancement, for as the time required to earn a living grows shorter, civilization progresses. The most ignorant factory operative of to-day is more than the peer of the skilled workman of a few generations ago in all that goes to make up condition—environment. The fact that the lowest grade of operatives can now be employed in factories does not signify more ignorance, but a raising of the lowest to higher employments. This process will be repeated again and again, unless society is compelled to take up what is called a simpler system. This process is constantly narrowing the limits of the class which occupies the lowest step in the progress of society. This mission alone stamps the system as an active element in the moral elevation of the race. The factory system does not tend to intellectual degeneracy.

The main objections which are usually brought against the factory system have now been considered and it has been compared with the system it supplanted. Its evils come mostly under the heads enumerated, but they are evils which attend the development of the system; they are not its results. Before the system can be condemned as a system it must be shown that it is worse than that which it displaced. This can not be done. It is needless to apologize for the weaknesses of the present system, for they come mostly from ignorance, not from the system itself. Under enlightened men it becomes everywhere a great moral power, and a positive, active, and potential element in the processes of civilization. But, admitting every possible domestic evil which accompanies low social conditions—the neglect of young children, and consequent high rates of infant mortality, the physical degeneracy which follows mechanical employments when engaged in by married women—none of these can be attributed to the factory system as the creator of such evils. It can not be held responsible for their creation. They belong to the ignorance of the substratum of society, which the factory system is constantly lifting to another and higher plane, thereby lessening, instead of increasing, the misery of the world.

The misery caused by the change in systems has been softened, but in subtle ways. Transition stages are always harsh upon the generation that experiences them; the great point is that they should be productive of good results in the end. The mind recoils at the contemplation of the conditions which the vast increase of population would have imposed without the factory system.

The economic advantages of the factory system must be looked for in the increase of wages and production, and the decrease in the prices of goods produced. If the purchasing power of wages, so far at least as the products of the factory and the leading necessaries of life are concerned, has not been enhanced, the new system of industry has not yet wrought the good it is capable of working. Authoritative statistics from original and worthy sources, as well as from trustworthy writers and investigators, answer the question.

The true period from which to treat wages under the factory system in Great Britain is from 1830 to 1835. In the U. S. the period from 1815 to 1820 would be the true one, because there the condition of things related of the hand-loom weavers of Great Britain never existed. From 1833 the wages of factory operatives in Great Britain may be determined with sufficient accuracy to entitle the data to confidence. As already stated, at this period hand-loom weavers were in a deplorable condition; this was true of large towns and of villages; their wages were a miserable pittance, and they worked in confined and unhealthful dwellings. On the other hand, there was no large class of workmen in the kingdom receiving better wages than the operatives in cotton-factories.

The hours of labor in Great Britain have been reduced from twelve and one-half and thirteen per day to nine and one-half. An examination of British tables will convince one that for most divisions of labor in cotton-factories wages have very nearly doubled since the middle of the nineteenth century. The hours of labor have been reduced in the U. S., but not uniformly in all the States; where they were formerly thirteen or fourteen hours per day, they are now ten or eleven. It is true that where ten hours prevail both wages and production per person equal, if they do not exceed, the rates and quantities in States where longer hours constitute a day's work. Not only has the factory system reduced the hours of labor, but it has also increased the wages. For instance, in 1828 the average weekly wages of girls were $2.62; in 1880 they were $4.84. The consideration of most of the specific divisions of labor which can be compared will demonstrate the truth of this conclusion. In many cases wages have more than doubled, but from the data no general average can be deduced.

As to cost of production, a single illustration will suffice: the ratio of cost per pound, for labor, of common cotton cloth for the years 1828 and 1880 was as 6·77 to 3·31.

A study of industrial and social statistics relating to conditions in Great Britain and the U. S., as well as France, Germany, and Belgium, thoroughly corroborate all that has been said relative to the factory system. It can not be condemned until it is proven that it is worse than the system which preceded it.

Factory Mutuals: See FIRE-INSURANCE.

Faculæ: See SUN.

Faculty [M. Eng. *facult*e: Germ. *Facultät*, from O. Fr. *faculte* > Fr. *faculté* < Lat. *facul'tas*, skill, deriv. of *fa'cul* = *fa'cilis*, easy, skillful, liter., makable, deriv. of *fa'cere*, make]: the collective designation of the instructing body of an institution of learning. It is a term of mediæval origin, and at first designated all the graduates, or those who had received power or authority (*facultas*) to impart instruction. There were said to be four faculties—those of philosophy, medicine, law, and divinity. Even now the whole body of graduates is occasionally so called, especially in the phrases "medical faculty" and "legal faculty," but more frequently the term is restricted to the body of officers of instruction and discipline in a college or university. See COLLEGE and UNIVERSITY.

Faculties of the Mind: See PSYCHOLOGY.

Fæ'ces [plu. of Lat. *fæx*, the lees of wine or the dross of metals]: the substances ejected by animals from the alimentary canal, consisting in general of (1) the surplus of the food, over and above what is needed for nutrition for the time being; (2) those elements of the food which are not available for nutrition; and (3) certain excrementitious and effete matters which the liver, the intestine, etc., have removed from the blood (stercorin, cholesterin, etc.). To these, in the Monotremata and all the vertebrates inferior to mammals (as well as in many invertebrates), the renal excretions are added. Fæcal matters are highly important as fertilizers, and this is especially true of guano and the excrement of birds generally, since it contains the urinary excretions combined, as has been seen, with those of the intestine, the whole in a very condensed form.

Fæc'ula, or **Fecula**; See STARCH.

Faed, fād, JOHN: artist; b. at Burley Mill, Kirkcudbrightshire, Scotland, in 1820. His father was an engineer and millwright, but the lad showed a taste for painting that made the homely surroundings tributary to it, and at the age of twelve finished a picture so well that his future career was determined. In 1841 he went to Edinburgh for study, and there, in 1850, exhibited pictures which attracted attention from their naturalness and met a ready sale. He painted *Shakspeare and his Friends*, *The Cotter's Saturday Night*, *The Soldier's Return*, *Tam o' Shanter*, *Haddon Hall of Old*, *John Anderson, my Jo*, *Parting of Gabriel and Evangeline*, and other pieces of kindred character, clothing historical fact with sentiment. In 1864 he removed to London, where he lived until 1884, when he returned to Kirkcudbrightshire.

Faed, THOMAS: genre-painter; b. at Burley Mill, Scotland, 1826. Pupil of his brother, John Faed; Royal Academician, 1864. His work is very weak in technique, but is popular in Great Britain. *Shakespeare and his Contemporaries* is in the Corcoran Gallery, Washington. D. Aug. 17, 1900. W. A. C.

Faenza, fa̤a-en'za̤a: city of Italy; province of Emilia; 19 miles S. W. of Ravenna (see map of Italy, ref. 4–D). It has manufactures of linen, silk, paper, and glazed earthenware, which indeed received its name (*faïence*) from this city. The city has a cathedral and many palaces and remarkable old buildings. Salt is manufactured in the neighborhood. Pop. 36,100.

Faeroe, fā'rō, **Islands** (Dan. *Färöerne*): a group of islands, of which only seventeen are inhabited, belonging to Denmark, and situated in the North Atlantic nearly midway between the Shetlands and Iceland, between lat. 61° 20′ and 62° 20′ N., and between lon. 6° and 8° W. Their entire area is 514 sq. miles. The principal island is Stromö, capital Thorshavn. All these island are basaltic formations, rising conically to a height of 3,000 feet, with steep and lofty coasts, abruptly broken by deep inlets, which often afford the safest and most convenient anchorage, but which sometimes cause whirlpools or form currents, thereby making navigation very dangerous. The trap-rock is covered with a thin layer of vegetable soil, which yields a fine pasturage. There are no trees on account of the furious gales which always prevail here; peat and Miocene coal, of which there is a seam of good quality on Suderöe, are used as fuel. Of the common cereals and vegetables, only barley, turnips, and potatoes can be raised, on account of the high northern latitude; yet the oceanic influences modify the climate so greatly that snow rarely lies long on the ground, and cattle and sheep graze the greater part of the year in the open air. The waters abound with fish, and the feathers and eggs of the myriads of fowls which swarm around these coasts are sources of considerable wealth. The inhabitants are of Norwegian origin. In the ninth century the islands were discovered by the Norwegians and peopled by Norwegian settlements, but during the long connection between Denmark and Norway the islands passed into possession of the Danes. Pop. (1890) 12,954.

Fagging [deriv. of *fag*, a drudge, probably connected with O. Eng. *fœge*, doomed, timid: Germ. *feige*, cowardly]: a custom which is part of the public-school system of England. This custom differs in detail in the several schools, but rests in all on the same principle. This principle is that the discipline of the school should be left, as far as possible, to the boys themselves, the responsibility for order being thrown on the highest form, known as the sixth form, called also prefects (as at Winchester) or præposters (as at Rugby). Those who are thus responsible for discipline have also the right of "fagging" the boys in the lower forms, those in the forms immediately under the sixth being exempted. Dr. Arnold defines fagging as "the power given by the supreme authorities of the school to the sixth form, to be exercised by them over the lower boys, for the sake of securing a regular government among the boys themselves, and avoiding the evils of anarchy; in other words, of the lawless tyranny of brute force." (*Quarterly Journal of Education*, vol. ix.) The origin of this custom of fagging can not be ascertained with any certainty, but so far as there are any authentic records, it would seem always to have existed in the old schools. Thus it is clear, from Christopher Johnson's poem *De Collegiis* and the *Consuetudinarium Vetus Scholæ Etoniensis*, that it was in active operation at Winchester and Eton in the sixteenth century. It is probable, however, that the custom arose as soon as the schools received any large number of boys as boarders. It is indeed obvious that where large numbers of boys of ages ranging from ten and eleven up to nineteen are thrown together away from their own homes, they must be placed either under the constant surveillance of masters or under some distinct and recognized form of self-government. The latter alternative has always prevailed in the English public schools, and is in fact the only one which is in accord with the national character. There is abundant proof, moreover, that the custom of fagging as a part of the system does not stand merely on tradition, but is accepted as beneficial in the fact that it has been deliberately introduced in the schools which have been founded in the nineteenth century. The number of the great public schools had remained stationary for 300 years, since Queen Elizabeth's reign, during which Harrow, Rugby, and other schools not so well known were founded. A remarkable revival followed the accession to the throne of Queen Victoria, and a number of public schools have been founded, of which the best known are Marlborough, Haileybury, Wellington College, and Cheltenham. Fagging has been introduced in all but Cheltenham. At Cheltenham, where the school is in a large town, and is chiefly composed of day-scholars, or boys living at their own homes, though there is no legal system of "fagging" recognized by the school authorities, the practice exists, but without the usual safeguards against abuse. In all the schools the power of fagging carries with it certain duties. Besides that of keeping order generally, the sixth-form boy is the recognized adviser and protector of those fags with whom he comes in immediate contact. In any case of bullying or bad conduct the appeal of the aggrieved boy is to the sixth-form boy of his room or passage, or to the head of his house, and not to his tutor or house or form master. And the sixth-form boy is bound to accept the responsibility of acting himself, and would completely lose caste were he to refer any but flagrant cases of ill-conduct to the master.

Until well into the nineteenth century "fagging" included a number of menial functions, such as cleaning boots and candlesticks, and the power of the sixth form was practically unlimited as to hours. A boy might be fagged, for instance, during a whole afternoon at cricket, day after day. All this is changed. At Eton and one or two other schools there is no cricket-fagging, and in those where it exists it is very light. Thus at Haileybury the whole of the fags are taken in regular order for one hour, so that each fag's turn comes only once in three weeks, and even then he is let off if he makes a good catch or otherwise distinguishes himself. A similar custom prevails at Marlborough, where, however, besides the sixth form, the eleven have the power of fagging at cricket—a solitary example (it is believed) where this power is not dependent on proficiency in study as evidenced by position in the school. Football-fagging is also very light at all the schools except Rugby, only some half-dozen fags being told off to keep the ball in bounds. At Rugby every fag is obliged to play "little side," lasting two hours at most, unless he holds a medical certificate of inability to play. He is also obliged to run (in the paper chases) unless holding such a certificate. Apart from games, general fagging is practically confined to running errands, a sixth-form boy having power to call any fag, at any time, for this purpose. House-fagging, in like manner, consists of little beyond small services of this kind—carrying up the trays on which their master's breakfast and tea things are set, and perhaps toasting a round of bread or a rasher of bacon. "Study-fagging" still exists at Rugby, where each sixth-form boy has two fags specially attached to him, who sweep out his study and put it in order in alternate weeks. At the school-house also "night-fagging" is still in force. Every fag has his choice between study-fagging and night-fagging. The rota of night-fags is kept by the head fag, who tells off four for each week in the term. Their duties are to be ready in the passages between 8.30 and 9.30 to answer the call of any of the sixth form.

At Eton the fifth form have the power of fagging, but (as above stated) it is usually confined exclusively to the sixth form. The numbers of the sixth are not strictly limited, but seldom exceed thirty-five or forty. Harrow has the largest sixth form of any school, divided into the "upper," "lower," and "modern side," and numbering eighty, all of whom have the power of fagging, but only the fifteen highest, or "monitors," have the power of enforcing discipline with the cane, if necessary. At Harrow only the fifth-form boys are exempt from fagging.

The most distinguished masters of public schools, from Dr. Arnold downward, have been singularly unanimous in their approval of the modified system of fagging which now exists. The public opinion both of old public-school men and of the boys themselves is also strongly in favor of it as the best means of maintaining the due subordination of ranks, of keeping down "cheek," and preventing bullying. There is every likelihood, therefore, that it will continue in its present form. See also Arnold's *Life* by Stanley (1st ed. vol. i., p. 105), and *Report of Public School Commissioners* (1864), and *Appendix of Evidence of Bishop of Exeter, Drs. Butler, Balston, and others*; and specially section of *Report on Monitorial System*, p. 42, *et seq.* THOMAS HUGHES.

Fagius, faa'gĕe-oos, PAUL BÜCHEIN: German Protestant theologian; b. at Rheizabern, in the Palatinate, 1504; pastor at Isny in 1537, and Professor of Hebrew at Strassburg in 1544. Was in England in 1549, and was appointed to the chair of Theology at Cambridge University, but died Nov. 12, 1549. His body was exhumed and burned by order of Queen Mary, Feb. 6, 1557.

Fagotto, faă-got'tō: the Italian name for the bassoon, evidently from its resemblance to a faggot or bundle of sticks. In German the word is *Fagott*.

Fagrskinna, faăg'r-skin'-naă [Icel., Fair-skin]: a famous parchment manuscript containing a compendious account of the Norwegian kings from Hálfdan Svarti to Sverri; compiled about the beginning of the thirteenth century in Norway from Icelandic sources. The manuscript was called Fagrskinna by Torfæus on account of its handsome binding. It belonged to the Copenhagen University Library, and was destroyed in the fire of 1728. At the same time another parchment of the same compendium perished, with the exception of a small fragment. Paper copies of both manuscripts have been preserved, however, and from these the work was edited by Munch and Unger: *Fagrskinna. Kortfattet Norsk Konge-Saga fra Slutningen af det XII. eller Begyndelse af det XIII. Aarhundrede* (Christiania, 1847). See also G. Vigfusson, *Sturlunga Saga, Prolegomena*, pp. 87–88 (Oxford, 1878). G. L. K.

Fagus: See BEECH.

Fahlcrantz, faal'kraănts, CHRISTIAN ERIK: poet and theologian; b. in Dalarna, Sweden, Aug. 30, 1790; Professor of Dogmatic Theology at Upsala 1835; Bishop of Vesterås 1849. His most important literary works are *Noachs Ark* (Stockholm, 1825–26), rated as the best long humorous poem in Swedish, and an epic on the Scandinavian apostle Ansgarius (*Ansgarius. Bilder ur Nordapostelns Lif i fjorton Sånger*, Upsala, 1835–46). He also published various essays, sermons, and occasional and controversial writings. His *Rom förr och nu* (Vesterås, 1858–61) caused much discussion. D. at Vesterås, Aug. 6, 1866. His collected works (*C. E. Fahlcrantz Samlade Skrifter*) were published at Örebro in seven vols. (1863–65). G. L. K.

Fahlun: See FALUN.

Fahrenheit, faă'ren-hīt, GABRIEL DANIEL, F. R. S.: physicist; b. at Dantzic, Prussia, May 14, 1686; became a constructor of scientific instruments; resided in France, England, and afterward in Holland, and was everywhere recognized as one of the leading physicists of his time. In 1720 he first introduced the use of mercury in thermometers. He invented the Fahrenheit scale (see THERMOMETER); also an improved areometer and other valued instruments. He was the author of several learned papers, chiefly regarding heat and specific gravities. D. at Amsterdam, Sept. 16, 1736.

Faidherbe, fā'dārb', LOUIS LÉON CÉSAR: general; b. at Lille, France, June 3, 1818, and began his career in the colonies, principally in Algeria, where he served with distinction. He made himself favorably known while governor of Senegal by several valuable scientific papers which were published in the *Annuaire du Sénégal* (1859, 1860, and 1861) and in the *Bulletin de la Société de Géographie.* He also wrote *Chapitre de Géographie sur le Nord-Ouest de l'Afrique* (St. Louis, 1864), and *Collection complète des inscriptions Numidiques* (Paris, 1870). He published from

1860 the *Bulletin du Sénégal* (St. Louis), and rendered the French government in Africa service by his exact knowledge of the country and its population, and by his talent of organization. On Dec. 3, 1870, he received the supreme command of the armée du Nord, organized in and around Lille, and fought the indecisive battles of the Halluc (Dec. 23, 1870) and Bapaume (Jan. 3, 1871), and was defeated at St.-Quentin (Jan. 19, 1871). Acknowledged as a very able commander and organizer in war, Faidherbe after the war joined the party of Gambetta, and was elected from Lille. But when the government of Thiers triumphed, and the influence of Gambetta decreased, Faidherbe retired from public life. Author of *Campagne de l'armée du Nord* (Paris, 1871). D. Sept. 28, 1889. Revised by C. H. THURBER.

Faïence, făă'i-ăăñs [Fr., from Ital. *Faenza*, the original place of its manufacture]: glazed pottery, especially that which is painted in colors.

Faillon, făă'yōñ', MICHEL ÉTIENNE: missionary priest; b. at Tarascon, France, in 1799; became a Sulpician in Paris, and in 1854 went to Canada as a visitor to the Sulpician houses of that country. He published numerous valuable biographies of distinguished French Canadian religionists, and undertook an extended history of the French in Canada, of which 3 vols. (1865–66) were completed. D. in Paris, Oct. 25, 1870.

Failly, făă'yee', CHARLES ACHILLE, de: general; b. at Rozoy-sur-Serre, Aisne, France, Jan. 21, 1810. After 1828 served partly in France, partly in Algeria; commanded a brigade in the Crimean war; in the war against Austria, in 1859, commanded a division of the Fourth Army-corps, and on the day of the battle of Solferino received the grand cross of the Legion of Honor. In 1867 he commanded the expedition whose task was to protect the pope against the attacks of Garibaldi, and his name attained a sad celebrity from the battle of Mentana, in which Garibaldi's irregular host were slaughtered. In 1870 he commanded the Fifth Army-corps, and was deprived of his command on the day before the battle of Sedan for failing to go to the support of MacMahon at Wörth; wrote in his vindication *Opérations et marches du cinquième corps* (1871). D. Nov. 15, 1892.

Fainéants, fā'nā'ăăñ' [Fr. plur. of *fainéant*, idle, do nothing; *fait*, does + *néant*, nothing]: a name applied to several Frankish sovereigns, chiefly of the Merovingian dynasty. The title is indicative of their idle and worthless reigns, which, indeed, were merely nominal. Thierry III. of Austrasia and Burgundy, Clovis III., Childebert III., Dagobert III., Chilperic II., Thierry IV., and Childeric III., all Merovingian Kings of France, were *rois fainéants*, as was also Louis V., the last of the Carlovingians. The same appellation is often applied to worthless monarchs of later times and other countries.

Fainting, or **Syncope** [*fainting* is a deriv. of Mid. Eng. *feint*, from O. Fr. *feint*, perf. partic. of *feindre*, feign < Lat. *fin'gere*, shape, contrive, feign]: a more or less complete and sudden loss of sensation and of the power of motion, unaccompanied by convulsions, but usually attended by feebleness of the circulation and respiration. Fainting is attended by anæmia of the brain, its proximate cause; more remotely it may be caused by loss of blood, by profound emotional disturbance, or by heart-disease. Closely akin to it, but more permanent and dangerous, are the collapse which occurs in cholera (caused by loss of the fluid constituents of the blood) and the shock which follows severe injuries. Fainting is to be treated by placing the patient on his back in a horizontal position, or with the head and chest slightly depressed below the level of the rest of the body; by admission of fresh air to the patient; and, in prolonged cases, by applying diffusive stimulants to the nostrils and restoring to artificial respiration. Fainting is seldom mortal, unless in case of severe disease.

Faioum: See FAYUM.

Fair [Mid. Eng. *feire*, from O. Fr. *feire* > Fr. *foire* < Lat. *fe'riæ*, holidays. *Feast*, from Lat. *festus*, festal, is akin. The meaning has changed from holidays to fair, because mediæval fairs were held on saints' days]: originally a stated temporary market containing many kinds of goods and wares. When population was sparse, and the means of traveling and transportation were extremely limited, it was found most convenient to expose merchandise for sale at the largest gatherings of the people. Hence European fairs were early identified with religious festivals, and were often designated by the name of the saint in whose honor each festival was held. However, as the difficulties and dangers of intercommunication diminished, and the number of cities and villages increased, factories, shops, and warehouses became more accessible, and the inhabitants generally found it more convenient, as well as more profitable, to buy goods as they needed them, from time to time, than to purchase a year's supply in advance. Thus fairs for the sale of goods constantly decreased in number and importance with the growth and improvement of each country, until not more than two or three of any note were held in all Europe. The most famous of these—and, it is said, the largest in the world—is held annually at Nijni-Novgorod in Russia, situated at the confluence of the rivers Volga and Oka, about 265 miles E. of Moscow. It begins on July 15 and continues into September. The sales at this fair are reported to have reached in one year the enormous sum of 150,000,000 roubles (about $112,000,000). The average annual value of goods sold is not far from $100,000,000. Among other large annual fairs held in Europe are those of Leipzig, Germany, and Beaucaire, France. In Arabia, Hindustan, and other Eastern countries such fairs are still held, and will continue to be held until the general introduction of railways and other modern improvements. See COMMERCE and MARKET.

In the U. S. temporary markets containing the effects of itinerant merchants are entirely unknown, although the term *fair* is often applied to such collections of fancy articles as are generally sold by ladies for the benefit of religious and charitable associations. This term has, however, a far higher meaning, and now more frequently designates a collection of superior products which are exposed, not for sale, but mainly for public inspection, and for careful examination by experts as to their respective qualities. They may be divided roughly into agricultural fairs, local expositions, and international expositions or world's fairs. See EXPOSITION.

Attempts were made at an early day in the U. S. to encourage art and invention by offering prizes for superior specimens of a few kinds of goods, but no permanent system for improvement was established until the year 1810. Elkanah Watson, a merchant of Albany, N. Y., whose original plans regarding inland navigation, uniform currency, and general education entitle him to a prominent place among American philanthropists, was the real author of the present system of fairs and cattle-shows sustained and directed by agricultural societies. He retired from active business, removed to his farm near Pittsfield, Mass., where he conceived the idea of interesting the farmers of Berkshire County in holding an exhibition of improved breeds of cattle and superior products of the soil, for the purpose of proving what might be accomplished by proper culture; and to compensate and reward exhibitors for the care and labor bestowed on their specimens, prizes were to be awarded for the best. The first fair was a success, and for the purpose of enlarging the next he appealed to the citizens of Boston for pecuniary aid, but failed to get a single favorable response. Ex-President John Adams, in his reply, made it quite apparent that the leading men of that day did not appreciate the importance of this new step for encouraging the useful arts. This was pithily expressed in a single sentence: "You will get no aid from Boston; commerce, literature, theology, medicine, the university, and universal politics are against you." Watson was not thwarted by this rebuff; he redoubled his exertions at home, and for several years annual fairs were held. In 1815 he returned to Albany, and immediately proceeded to organize an agricultural society and to establish fairs and cattle-shows in the neighboring counties. In 1819 the Legislature of the State of New York passed an act appropriating $10,000 annually, for six years, for the promotion of agriculture and family manufactures, which was to be divided among the agricultural societies of the several counties in proportion to their population, provided a like sum was raised in each by voluntary subscription. In 1832 a State agricultural society was incorporated, and in 1841 a law was passed similar to that of 1819, appropriating the sum of $8,000. Under the present system each county agricultural society is required to report annually to the State society, which embraces the essential parts of the whole in its report to the Legislature. This plan of organizing State and county agricultural societies, with power to hold fairs, has since been adopted in nearly all the States of the Union.

Among local expositions or fairs of importance may be mentioned those of the American Institute of the city of New York, the Franklin Institute of Philadelphia, the industrial exhibitions of Chicago, Cincinnati, St. Louis, New Orleans, and San Francisco; besides numerous other cities of North America and Europe. These exhibitions embrace not only agricultural products, but superior specimens of the fine, ornamental, and useful arts, including working models of recent inventions, machinery in motion, improved chemical and mechanical processes, with the material resulting therefrom, and practical illustrations of the best methods of generating and utilizing force. Revised by A. T. HADLEY.

Fairbairn, ANDREW MARTIN, D. D: clergyman and author; b. near Edinburgh, Nov. 4, 1838; graduated at Edinburgh University 1860; studied theology at Evangelical Union Hall, Glasgow, 1856–61. He was in Germany, as a pupil of Dorner (1866 and 1867). In 1861 he became pastor of an Independent church in Bathgate, Scotland. He was principal of Airedale College in Bradford, England, from 1877 until 1886, when he became the first principal of Mansfield College, Oxford. Both these institutions are Congregational schools of theology. He was Muir lecturer in the University of Edinburgh 1878–83. Besides important contributions to the *Contemporary Review*, he has published *Studies in the Philosophy of Religion and of History* (1876); *Studies in the Life of Christ* (1880); *The City of God* (1882); *Religion in History and in Life of To-day* (1884). He also edited the *Hibbert Lectures* for 1888, by Dr. Hatch (1890); and is author of *The Place of Christ in Theology* (New York, 1893). In 1892 he delivered the lectures on the Lyman Beecher foundation at the Yale Divinity School. GEORGE P. FISHER.

Fairbairn, PATRICK, D. D.: theologian; b. at Greenlaw, Berwickshire, Scotland, Jan. 28, 1805; graduated at the University of Edinburgh 1826; was settled in 1830 in one of the Orkney islands, at Bridgeton, a suburb of Glasgow, in 1837, and at Salton, near his birthplace, in 1840. He joined the Free Church at the Disruption, 1843, and formed a new congregation at Salton. In 1853 he became Professor of Theology at the Free Church College in Aberdeen; was in 1856 made principal and Professor of Systematic Theology and New Testament Exegesis in the Free Church Theological College at Glasgow. His principal works are *The Typology of Scripture* (Edinburgh, 2 vols., 1845–47; 5th ed. 1870); *Commentary on Ezekiel* (1851; 2d ed. 1855); *Prophecy, its Nature, Functions, and Interpretation* (1856); *Hermeneutical Manual* (1858); *Revelation of Law in Scripture* (1868); and a commentary on *The Pastoral Epistles of Paul* (1873); *Pastoral Theology* (posthumous, 1875). He visited the U. S. in 1871. D. at Glasgow, Aug. 6, 1874. Revised by S. M. JACKSON.

Fairbairn, ROBERT BRINCKERHOFF, D. D., LL. D.: clergyman of the Protestant Episcopal Church; b. in New York city, May 27, 1818; educated at the Mechanics' School in Chambers Street, New York, at Trinity College, Hartford (B. A. 1840), and also at the General Theological Seminary, New York. Immediately after his ordination as deacon July 2, 1843, he became the rector of Christ Church, Troy, N. Y. From 1853 to 1862 he was the principal of the Catskill Academy, as well as rector of Calvary Church, Cairo, N. Y. In 1862 he was appointed the Professor of Mathematics and Natural Philosophy in St. Stephen's College, Annandale, N. Y., of which he became warden in 1863, and also Professor of Moral Philosophy. Later he was until 1891 president of the college, which, through the liberality of the Rev. C. F. Hoffman, D. D., of New York city, has been largely endowed and supplied with noble buildings. He wrote *On the Doctrine of Morality in its Relation to the Grace of Redemption* (1887), etc. D. in Brooklyn, N. Y., Jan. 27, 1899.

Fairbairn, Sir WILLIAM, Bart., F. R. S., LL. D.: civil engineer; b. at Kelso, Scotland, Feb. 19, 1789; began business at Manchester in 1817, and introduced several important mechanical improvements, among which were the substitution of iron for wood in the shafting of cotton-mills and the use of lighter shafting where metal was already in use. His attention was next directed to the use of iron for ships, and he was the first in England to construct an iron ship. More than 100 iron ships were constructed by his firm, varying in size from the smallest to the war-vessel of 2,600 tons. By invitation of the British Association (1834–35), in connection with Mr. Hodgkinson, he investigated the causes of certain supposed defects in iron produced by hot-blast furnaces, and submitted a valuable report upon the subject. His experiments to test the strength of iron and the resistance of tubes or cylinders led to valuable practical results. Mr. Fairbairn co-operated with Robert Stephenson in designing and constructing the great tubular bridge across the Menai Strait. Sir William was one of the founders of the British Association for the Advancement of Science, and the author of many valuable professional books and papers, among which may be mentioned *Mills and Mill-work*; *Iron, its History and Manufacture*; *Application of Iron to Building Purposes*; *Iron Ship-building*; *Useful Information for Engineers*, 1st, 2d, and 3d series; *An Experimental Inquiry into the Strength, Elasticity, Ductility, and Other Properties of Steel* (1869), which was several times reprinted. President of the British Association, corresponding member of the National Institute of France, member of many other learned societies, and chevalier of the Legion of Honor. Created a baronet in 1869. D. Aug. 18, 1874.

Fairbury: town and railway junction; Livingston co., Ill. (for location of county, see map of Illinois, ref. 4–F); 10 miles S. E. of Pontiac. It has grain-elevators, mills, shops, factories, etc., and is situated in a thickly settled and fertile region, abounding in coal, limestone, fire-clay, sandstone, and a micaceous quartz which affords a fine fireproof building material. Clays of nearly all colors abound. Pop. (1880) 2,140; (1890) 2,324; (1900) 2,187.

Fairbury: city and railway center (founded in 1869); capital of Jefferson co., Neb. (for location of county, see map of Nebraska, ref. 11–G); on Little Blue River; 55 miles S. S. W. of Lincoln. It has fine churches, good schools, abundant water-power, a flouring-mill, a foundry, and one of the largest nurseries in the U. S.; also electric lights, water-works, and a telephone system. Pop. (1880) 1,251; (1890) 2,630; (1900) 3,140. EDITOR OF "GAZETTE."

Fairchild, CHARLES STEBBINS, A. B., L. B., LL. D.: lawyer; b. at Cazenovia, N. Y., Apr. 30, 1842; graduated at Harvard College 1863, at the Harvard Law School 1865, and was admitted to the bar. He was deputy attorney-general of New York 1874–75, attorney-general of New York 1876–77, assistant Secretary of the Treasury 1885–87, and Secretary of the Treasury 1887–89. He received the degree of LL. D. from Columbian University.

Fairchild, JAMES HARRIS, D. D.: Congregationalist; former president of Oberlin College; b. at Stockbridge, Mass., Nov. 25, 1817; graduated at Oberlin College, 1838; a professor there, in different chairs, since 1839; elected president in 1866, which office he resigned, 1889. He has published *Moral Philosophy* (1869); *Oberlin, the Colony and the College*, etc. (1883); *The Elements of Theology, Natural and Revealed* (1892); and has edited the *Memoirs of Finney* (1886) and Finney's *Systematic Theology* (1878). Revised by GEORGE P. FISHER.

Fairchild, LUCIUS, LL. D.: U. S. military officer; b. at Kent, Portage co., O., Dec. 27, 1831. In 1846 he removed with his father to Wisconsin, and at the age of eighteen to California, but returned to Wisconsin in 1855, and in 1860 was admitted to the bar. On the outbreak of the civil war in 1861 he became captain of the First Wisconsin Regiment; subsequently was commissioned a captain in the Sixteenth Regiment of the regular army, also major, lieutenant-colonel, and colonel of volunteers; became a brigadier-general of volunteers, Oct. 19, 1863; resigned Nov. 2, 1863. He was Secretary of State of Wisconsin 1864–65; and Governor 1866–72; U. S. consul at Liverpool, England, 1872–78; consul-general at Paris, 1878–80; and U. S. minister to Spain 1880–81; in 1886 elected commander-in-chief of the Grand Army of the Republic; also served as regent of the State University and of the State Normal schools, and as president of the Cherokee commission. D. at Madison, Wis., May 23, 1896.

Fairfax, DONALD MCNEIL: rear-admiral U. S. navy: b. in Virginia, Aug. 10, 1823; entered the navy as a midshipman Aug. 12, 1837. In 1861, when executive officer of San Jacinto, he personally supervised the arrest of Messrs. Mason and Slidell on board the English mail-steamer Trent. Commanded steamer Cayuga in 1862 on the Mississippi river; in command of monitor Nantucket participated in the first attack upon Fort Sumter, Apr. 7, 1863. In command of monitor Montauk took part in all the fights with the forts and defenses of Charleston harbor which occurred during July and Aug., 1863. He became rear-admiral July 11, 1880; retired Sept. 30, 1880, at his own request, after forty years' consecutive service. D. at Hagerstown, Md., Jan. 10, 1894.

Fairfax, EDWARD: poet; son of Sir Thomas Fairfax; b. at Denton, Yorkshire, England, about 1580; translated Torquato Tasso's *Jerusalem Delivered* into English, verse for verse, and this work is still of standard excellence. *A History of Edward the Black Prince*, in verse, and a *Discourse of Witchcraft*, etc., are also his works. The American edition of his great translation (1855) gives the text of Charles Knight's edition from the old folio edition of 1600. D. at Fenston, near Otley, in Jan., 1635.

Fairfax, John Contee, M. D.: eleventh Lord Fairfax; a resident of Bladensburg, Prince George co., Md.; b. Sept. 13, 1830; a younger son of Hon. Albert Fairfax; succeeded to the title in 1869 on the death of his brother, Charles Snowden Fairfax, the tenth Lord Fairfax. Dr. Fairfax in early life practiced medicine at Woodburne, Md., and in 1857 married a daughter of Col. Edward Kirby, U. S. army. D. Northhampton, Md., Sept. 28, 1900. His cousin, Mr. Raymond Fairfax, is the heir-presumptive to the title. The Fairfaxes are of the Scottish peerage, and never had a seat in the British House of Lords. The first of the title was Ferdinando, a nephew of the poet, Edward Fairfax; made a peer in 1627, d. in 1648. He was the author of some extant writings.

Fairfax, Thomas, Lord: general; b. at Denton, Yorkshire, England, Jan. 17, 1611; was son of Ferdinando, Lord Fairfax, and Mary, daughter of Edmund Sheffield, Lord Mulgrave; served in Holland as a volunteer under Horace, Lord Vere, whose daughter he afterward married; at the outbreak of civil war in 1642 received from Parliament a commission as general of cavalry, his father being commander-in-chief of the northern forces; defeated the royalists under Col. Bellasis, Apr., 1644, and July 2 of that year was especially distinguished by bravery and activity at the king's defeat at Marston Moor, where he commanded the right wing; in Jan., 1645, became commander-in-chief of the parliamentary or "new model" army, with Oliver Cromwell as lieutenant-general; gained the battle of Naseby, June 14, 1645, and on June 18 took Leicester; on July 22 took Bridgewater, on Sept. 10 Bristol; in June, 1646, captured Oxford, and Charles I fled to Scotland. Fairfax was then commissioned by Parliament to carry £200,000 to the Scotch army, who agreed to deliver the king to him for that sum. He met the king near Nottingham Feb. 11, 1647. Soon after this he yielded to the genius of Cromwell, and when, in Mar., 1648, he succeeded to his father's titles, continued to fight for him. Appointed one of the high court of justice in 1649, he attended but a single session of the court. In the spring of 1649 he was made commander of all the forces in England and Ireland, but refused to fight the Scots, and resigned his commission in June, 1650. In Sept., 1654, he was a member of Cromwell's first Parliament, and in Dec., 1659, took part with Monk in the defeat of Lambert; Jan. 1, 1660, was a member of the council of state, and in May chairman of the committee delegated by the House of Commons to prevent the return of Charles II. Fairfax, who was a warm friend to learning, wrote *Short Memorials of Thomas, Lord Fairfax*, besides theological, poetical, and other compositions. D. of a fever at Nun Appleton, on his estates, Nov. 12, 1671.

Fairfax, Thomas, Lord: b. in England, 1691; settled in the county of Frederick in Virginia, where he had large estates. He made the acquaintance of George Washington in 1748, and the friendship between them was unbroken by the American Revolution, although Fairfax was ever a frank and avowed loyalist. Such were his qualities, indeed, that his property was always equally respected by the Americans and the English. D. at Greenway Court, Frederick co., Va., Dec. 12, 1781, and his immense domain of 5,282,000 acres was then confiscated.

Fairfield: town and port of entry; Fairfield co., Conn. (for location of county, see map of Connecticut, ref. 12–E); situated near Long Island Sound, and on railway; 52 miles N. E. of New York. It was formerly one of the capitals of the county; in 1637 it was the scene of the last conflict with the Pequot Indians, and in 1779 it was burned by the British troops under Tryon. Fairfield has some manufactures and considerable traffic, and is a place of summer resort, one of the most beautiful in the State. Fairfield township includes also the villages of Southport and Greenfield Hill, both beautiful places. Southport is the chief business center. Lat. 41° 8′ 30″ N., lon. 73° 12′ 44″ W. Pop. of township (1880) 3,748; (1890) 3,868; (1900) 4,489.

Fairfield: town and railway junction; capital of Wayne co., Ill. (for location of county, see map of Illinois, ref. 9–F); 108 miles E. by S. of St. Louis, Mo. It is the seat of Hayward Collegiate Institute, and has an extensive woolen factory, and large flouring and saw mills. Pop. (1880) 1,391; (1890) 1,881; (1900) 2,338.

Fairfield: city; capital of Jefferson co., Ia. (for location, see map of Iowa, ref. 7–J); situated on a fertile, high-rolling, and well-wooded prairie; on the Burlington Route, and the Chi., R. I. and Pacific R. R.; 50 miles W. of Burlington. It is the seat of Parsons College (Presbyterian), and has a business college, two schools, a large library, a canning factory, and manufactures of wagons, furniture, farming implements, and tile. Pop. (1880) 3,086; (1890) 3,391; (1900) 4,689.
Editor of "Journal."

Fairfield: town; Somerset co., Me. (for location of county, see map of Maine, ref. 6–C); on railway and on the W. bank of the Kennebec river; 21 miles N. of Augusta; has excellent water-power. The township contains an extensive canning-factory, furniture-factories, woodshops, saw-mills, tannery, machine-shop, and foundry; also a large framing-mill where buildings are manufactured entire. Pop. of township (1880) 3,044; (1890) 3,510; (1900) 3,878.
Editor of "Journal."

Fair Haven: post-village; New Haven co., Conn.; on the Quinnipiack river; constitutes a ward of the city of New Haven (*q. v.*). It has some important manufactures, but its chief industry is oyster-culture, and the manufacture of lime from the oyster-shells.

Fair Haven: town; Bristol co., Mass. (for location, see map of Massachusetts, ref. 5–I); on branch of Old Colony Div. of N. Y., N. H. and Hartford R. R., and on the east side of Acushnet river; opposite New Bedford; 60 miles S. of Boston. It has four churches, excellent schools, a large and well-endowed public library, a fine town-hall, and manufactures of tacks, nails, castings, etc., besides some fishing interests. The harbor is good and will admit vessels drawing 18 feet. The village is connected with New Bedford by two bridges. On Sept. 7, 1788, it was attacked by the British, who were repulsed by the militia under Maj. Israel Fearing. Pop. of township (1880) 2,875; (1890) 2,919; (1900) 3,567.
Editor of "Star."

Fairhaven: town (founded Oct. 27, 1779): Rutland co., Vt. (for location of county, see map of Vermont, ref. 7–B); on railway; 16 miles E. of Rutland and 9 miles N. E. of Whitehall, N. Y. It has seven churches, an incorporated school, great water-power, and extensive manufactures of milled and roofing slate, the materials for which are quarried here. Pop. of township (1880) 2,211; (1890) 2,791; (1900) 2,999.
Editor of "Era."

Fairhaven: city (founded May 10, 1889); Whatcom co., Wash. (for location of county, see map of Washington, ref. 1–D); situated on Bellingham Bay, in the Puget Sound basin; 7 miles from the Gulf of Georgia and 16 miles from the Strait of Juan de Fuca, which leads into the Pacific. It is 17 miles S. of British Columbia and 80 miles N. of Seattle; comprises 6 sq. miles, adjoining New Whatcom, and has 3 miles of water-front available for ocean-going vessels. The city is well provided with churches and schools. The principal resources are lumber, coal, and iron; there are also fertile suburban farms and orchards. The railway facilities comprise the Canadian Pacific and the Great Northern. Pop. (1890) 4,076; (1900) 4,228.
Editor of "Herald."

Fair Havens (translation of Gr. Καλοὶ Λιμένες): a harbor on the south side of the island of Crete, mentioned by Luke (Acts xxvii. 8), and by no other ancient writer. St. Paul sailed out of this harbor shortly after the middle of October, and was shipwrecked about Nov. 1, 60 A.D. It appears to have been the port of Lasæa, the ruins of which were discovered in 1856 by the yachting-party of Hugh Tennent, Esq. See James Smith, *Voyage and Shipwreck of St. Paul* (1848; 3d ed. 1866).

Fair Head, or **Benmore Head**: a lofty promontory of the coast of county Antrim, Ulster, Ireland, opposite Rathlin Isle. It consists of Carboniferous strata overlaid by greenstone columns, and rises 636 feet perpendicularly above the sea. Lat. 55° 13′ N., lon. 6° 8′ W.

Fair'holt, Frederick William: English artist and writer; b. in London, 1814; published *Costume in England, a History of Dress to the Close of the Eighteenth Century* (1846); *The Home of Shakespeare Illustrated and Described* (1847); *Remarkable and Scientific Characters* (1849); *Dictionary of Terms in Art* (1854); etc. D. Apr. 3, 1866.

Fair Isle: a solitary isle, 4 by 2½ miles in extent, between Orkney and Shetland. It rises 408 feet above the sea, and is accessible for ships only at one point, on the S. E. In 1588 the Duke of Medina Sidonia, admiral of the Spanish Armada, was wrecked here, and most of his crew were murdered. Lat. 59° 33′ N., lon. 1° 38′ W.

Fairlamb, James Remington: See the Appendix.

Fair Oaks, or **Seven Pines**, Battle of: a battle fought May 31 and June 1, 1862, at Fair Oaks, Va., a station on the Richmond and York River Railroad, where it is crossed by the Nine Mile road, about 6 miles from Richmond. The junction of the Nine Mile and Williamsburg roads, about a mile S. E. of Fair Oaks, is called Seven Pines (hence the alternative name of the battle). McClellan, moving from Yorktown viâ White House, had reached the Chickahominy, and on May 27 Keyes and Heintzelman's corps were on the south (right) bank of this stream, their front extending from Fair Oaks to Seven Pines, while Sumner's, Franklin's, and Porter's corps were on the north (left) bank, the line extending up to Mechanicsville.

McDowell at Fredericksburg was reported to be marching southward to join McClellan. Gen. Johnston, commanding the Confederate army, disposed his troops to attack the Union right wing near Mechanicsville, on May 29, before McDowell's arrival. Before the attack was made he was informed that McDowell had turned back toward Washington, whereupon he changed his plans and attacked the Union left wing, consisting of the two corps south of the Chickahominy, with a view to destroying this wing before it could be re-enforced from the right, which was separated from it by the river, much swollen by recent rains. To overwhelm the Union left wing, he designed to reinforce his right wing under Gen. D. H. Hill with the divisions of Gens. G. W. Smith and Longstreet, which had been massed on his left for the attack previously contemplated. Owing to some misunderstanding of orders, Longstreet's division was marched and countermarched in rear of the Confederate army in such a way that less than half its brigades came into action that day; and by occupying the roads it delayed the movements of other troops. This, in connection with some errors in transmitting orders, prevented the attacks being made simultaneously along the Union left wing. About 1 p. m. D. H. Hill on the Confederate right began the attack, drove in the pickets, and by successive advances forced back the Union line about 2 miles to a position between Seven Pines and Savage's Station, where at about 6 p. m. a line was formed which was held, and during the night was strengthened by intrenchments. Meanwhile McClellan ordered Sumner's corps to cross the Chickahominy and re-enforce Keyes. Sumner starting at once, and marching toward Keyes's right, met and repulsed the attack just made by Gen. G. W. Smith's troops upon Couch, who was on the extreme right of Keyes's command and separated by some distance from the troops on his left. Fighting for the day closed at about 6.30 p. m. in this part of the field, and the Union lines were made continuous and strengthened during the night.

On the morning of the next day (June 1), after some preliminary skirmishing commencing at about 5 a. m., the Confederates at about 6.30 a. m. made a determined attack upon the Union left center situated upon the railroad, about half a mile east of Fair Oaks. After about an hour and a half of fighting this was repulsed. Subsequently a second was made, which continued about an hour, when the Union troops charged upon the Confederates, and, driving them back, advanced and reoccupied the line from Fair Oaks to Seven Pines. No further pursuit was attempted, and the fighting ceased at about 1 p. m. The aggregate strength of the three corps of the Union army engaged was 51,543, that of the four Confederate divisions about 39,000. The numbers in the front or fighting lines were about 20,000 on each side.

The total Union losses in killed, wounded, and missing were 5,031. The Confederate losses 6,134. See *The Battle of Seven Pines*, Gen. G. W. Smith: articles by Gen. Johnston and Gen. Smith in *Battles and Leaders of the Civil War*; *The Peninsula*, by Gen. Webb; and the *Official Records*. James Mercur.

Fairport: village; Monroe co., N. Y. (for location of county, see map of New York, ref. 4–D); on the New York Central and West Shore railways, and on the Erie Canal; 11 miles E. of Rochester. It has 7 churches, 2 union school-buildings, a flouring-mill, a furnace, a large shoe-factory, marble-works, 3 planing-mills, 2 fruit-canning establishments, and manufactures of barrels, staves, agricultural implements, carriages, confectionery, saleratus, cream of tartar, baking-powder, etc. Pop. (1880) 1,920; (1890) 2,552; (1900) 2,489. Editor of "Monroe County Mail."

Fairy-lore: a name sometimes given (on the analogy of folk-lore) to the body of popular beliefs, often oddly inconsistent, about various supernatural beings known as *fairies.* The term *fairies* is used very loosely, being often applied not only to such diminutive, sylph-like creatures, tricky but not malevolent, as Shakspeare has drawn in *A Midsummer Night's Dream*, but to the dwarfs, elves, and kobolds of German popular tales, many of whom are earthy and malicious, the fées of Celtic (and French) romance, who are beings of human stature and more than mortal power and beauty, and the genies or *djinns* of Arabian story. Indeed, almost any kind of supernatural being not accounted for in the creeds of Christendom, and not exalted enough to be regarded as a heathen god, has been included under this general term—apparitions of the dead excepted. It follows that there can be no satisfactory statement of the origin of fairy-lore. Some of it is due to ancestor-worship, some to misinterpreted natural phenomena, some to the survival in a degraded condition of divinities dethroned by Christianity. Much of it may be the detritus of myth; more is assuredly the raw material of myth. It is always influenced by climate, natural scenery, and manner of life; and sometimes, even in Christian countries, it stands in a curious relation to the popular, as opposed to the educated, religion. (See also Folk-lore and Mythology.) The term *fairy-tales* is often used in English as an equivalent for the German *Märchen*, and is thus not infrequently applied to stories in which fairies play no part.

Bibliography.—Works on the folk-lore of a country usually contain something about its fairy-beliefs, and the folk-lore journals contribute much that is of interest. The following books and articles may also be consulted: Allies, *On the Ignis Fatuus*, etc. (London, 1846); J. T. Bunce, *Fairy Tales, their Origin and Meaning* (London, 1878); F. J. Child, *English and Scottish Popular Ballads* (Boston, 1882 ff.); R. H. Cromek, *Character of the Lowland Scotch Fairies*, in his *Remains of Nithsdale and Galloway Song* (1810); Jacob Grimm, *Deutsche Mythologie* (4th ed. Berlin, 1875–78); Wilhelm Grimm, *Einleitung über die Elfen*, in his *Kleine Schriften* (1881, i. 405–490); J. O. Halliwell, *Illustrations of the Fairy Mythology of A Midsummer Night's Dream* (London, 1845); E. S. Hartland, *The Science of Fairy Tales* (London, 1891); W. Hertz, *Die bretonischen Feen*, in his *Spielmannsbuch* (Stuttgart, 1886); T. Keightley, *The Fairy Mythology* (London, 1833; new edition 1850); W. Mannhardt, *Wald- und Feldkulte* (Berlin, 1877); L. F. A. Maury, *Les Fées du Moyen Âge* (Paris, 1843); J. Ritson, *Fairy Tales* (London, 1831); H. Schreiber, *Die Feen in Europa* (Freiburg im Br., 1842); Sir Walter Scott, *On the Fairies of Popular Superstition*, in his *Minstrelsy of the Scottish Border*; the same, *Letters on Demonology and Witchcraft.* Compare also the references in an article on *Sir Orfeo*, in *The American Journal of Philology*, vol. vii., No. 2. The relations of fairy-lore to Germanic mythology are well set forth by E. Mogk in his article *Mythologie*, in Paul's *Grundriss der germanischen Philologie.* G. L. Kittredge.

Fairy-rings: imperfectly circular or annular patches in grass-land in which the vegetation is either richer or more scanty than that around it. They are common in the British islands and other parts of Europe, where, according to folk-lore, they are caused by the dancing of fairies. They began to attract the attention of scientists in the latter part of the eighteenth century. At first they were considered to be the effect of lightning. After much investigation, however, and not a little debate, it was shown that they are caused by the growth of *Agaricus* and other fungi, which spread from the center outward, and at first check, but afterward by their decay accelerate, the growth of the grass. They are also found in Western U. S.

Faith [M. Eng. *feith*, *fayth*, *fay* from O. Fr. *feid*, *feit*, *fei* > Fr. *foi* : Span. *fe* : Ital. *fede* < Lat. *fides*, deriv. of *fi'dere*, to trust : Gr. πείθειν, πιθεῖν, to persuade : Teuton. *bid-*, to ask < Indo-Eur. *bheidh*, *bhoidh*, *bhidh*]: belief, conviction, assurance, or trust, resting on any sort of evidence whose force is affected subjectively—that is, by the mental condition of the recipient. An assurance resting on purely objective grounds relies upon the common state of all minds, not on the special condition of any, and involves knowledge. Man *believes* there is a God, but there are temptations to unbelief which have led men to atheism. He *knows* that twice two are four, and it is not possible to tempt him to doubt it. One and the same thing may be an object of faith at one stage of evidence, and of knowledge at another. There may be a subjective difficulty which is invincible to the sort and degree of evidence which is ordinarily sufficient for faith, yet is overcome by the evidence which produces knowledge. The mind may pass therefore from unbelief to belief, from belief to knowledge, or from unbelief to knowledge. It may pass from unbelief to belief without addition to evidence, solely by change in itself. but it can not pass from either to knowledge, except by additions to evidence. The faith of one man may rest on the presumed knowledge of another, and thus be confounded with knowledge itself. The great body of scientific fact is actually the object of knowledge to a few, and is supposed to be a part of the knowledge of the many only because the many have faith in the statements of the few, though they can neither verify them, nor even understand the processes by which they are reached. "We *believe*," says Lewes (*Problems*, i. 21), "that the sensation of violet is produced by the striking of the ethereal waves against the retina more than seven hundred billions of times in a second. . . . These statements are accepted *on trust* by us who know that there are thinkers for whom they are irresistible conclusions." Knowledge involves intellectual *coercion*—faith involves *freedom*. One is not *responsible* for the fact that under the conditions of knowledge he *knows*, or in defect of them does not know; he is responsible if under the conditions of a well-grounded faith he disbelieves. In the history of philosophy the names of Hobbes, Huet, Leibnitz (*Faith and Reason*), d'Alembert, Kant, and Daub are connected with special views of faith.

In theology the relations of faith to knowledge and the question of precedence have long been agitated. Augustine and his school held that faith precedes understanding; Jacobi confessed that to him the dualism of the two was hopeless; Hegel proposed to relieve the antagonism by absorbing faith into knowledge; Schleiermacher says they are the two foci of one ellipse. In the Bible, faith is by pre-eminence trust, a conjoint movement of the intellectual powers, the affections, and the will. Its object is the supersensuous, God, and God in Christ. It involves knowledge or mental vision, voluntary reception, personal adhesion, and obedience. The Scholastics distinguish between believing that God is, believing God, and believing *in* God. Faith *informis* is merely intellectual; faith *formata* involves love, and is a virtue. Faith was regarded as a general intellectual assent to revealed truth as interpreted by the Church. In contradistinction to this, the Reformers laid stress on faith as a personal assurance of the forgiveness of sins for Christ's sake. This faith involves knowledge, assent, and trust. It justifies not by the merit, or on the ground of the works which follow it, but as the medium, the hand which lays hold of and appropriates Christ and his merit. See JUSTIFICATION. Revised by S. M. JACKSON.

Faith, Articles of: See FAITH, CONFESSIONS OF.

Faith, Confessions of: official statements of doctrine—"symbols" in the theological sense. As distinguished from creeds, confessions of faith are fuller presentations. We speak of the Apostles' Creed, the Westminster Confession. In the extent of reception they are (1) œcumenical, catholic, or general, as accepted by the whole Church catholic; (2) particular, as accepted by particular parts of the Church. The term has also been applied to the carefully prepared statement of the faith of individuals. Articles of faith are the separate parts of confessions. A confession is an organic body or *corpus* of faith, its parts are members or *articuli*, such as the articles concerning God, sin, Christ, the Church. See the articles on the particular systems, as ARMINIANISM, etc., on the confessions, as the AUGSBURG CONFESSION, etc., and on the various churches.

Faith, Rule of (in Lat. *Fidei Regula*): that to which faith appeals as its source and guide. *Why* do I believe this or that? and *what* am I bound to believe? are questions answered by the rule of faith, while the confession of faith, as such, simply states what I do believe. The confession is drawn from the rule. In the Roman Catholic Church the rule of faith is the body of revealed truth embraced in Holy Scripture and tradition (in libris scriptis et sine scripto traditionibus—*Council of Trent*, Sess. IV.), in the sense in which the Church holds that truth. In the Protestant churches the canonical Scriptures are regarded as the sole rule of faith.—RULE OF FAITH, ANALOGY OF FAITH, have been applied also from very ancient times to the body of most necessary and saving doctrines, so explicitly and clearly set forth in the Scriptures as to form a general guide in interpreting the more obscure parts. The APOSTLES' CREED (*q. v.*) was frequently so styled by the Fathers. The *Regula Fidei* is valid on the assumption that there is absolute unity in all parts of the doctrinal teaching of the Bible.

Faithfull, EMILY: philanthropist; b. at Headley rectory, Surrey, England, in 1835; educated at Kensington; at an early age became interested in the condition of women, and devoted her time to extending their sphere of labor, establishing in 1860, in spite of great opposition, a printing establishment in which women were employed. Queen Victoria gave this project her approval, a printing business was formed styled "The Victoria Press," and Miss Faithfull was appointed publisher in ordinary to the Queen. In 1863 the *Victoria Magazine* was begun, and for eighteen years was devoted to the claims of women to remunerative employment. Miss Faithfull published in 1868 a novel entitled *Change upon Change*. Soon after she appeared as a lecturer on her favorite topic, and in 1872 and 1882 visited the U. S., where her lectures were favorably received. See her *Three Visits to America* (1884). D. in London, June 3, 1895.

Faithorne, WILLIAM: engraver; b. in London, England, about 1616; was imprisoned as a loyalist, and then banished from England under Cromwell. He went to France and studied engraving. From 1650 to 1680 he was a printseller in London, and died there in May, 1691. He engraved a large number of portraits, chiefly from his own studies, and of great historical and considerable artistic value; also for Taylor's *Life of Christ, Christ at Prayer in the Garden of Olives, The Marriage at Cana in Galilee*, etc., and wrote a treatise on the art of engraving.

Faizabad, fī-zaa-baad', or **Fyzabad**: a commissionership, district, and town of Oudh, British India, now within the jurisdiction of the Northwest Provinces. The commissionership is S. of Nepal, between the parallels 26° and 29° N. and the meridians 81° and 84° E. Area, 7,671 sq. miles. Pop. 3,500,000. The district is on its western side, S. and W. of the Gogra and E. of the Gumti rivers. The area is 1,649 sq. miles, and the population a little over 1,000,000. It is an historical district, celebrated for its calamities and antiquities. It is traversed by a railway, has an important trade, raises principally rice and wheat, and is now prosperous. The city is the chief town and capital of the district, and is on the right bank of the Gogra, in lat. 26° 47′ N. (see map of N. India, ref. 6–F). A suburb of the city is Ajodhya, a very ancient town, formerly great, and still celebrated in Sanskrit literature. Faizabad was for a time the capital of Oudh, but in 1775 the capital was removed to Lucknow, and it rapidly decayed. It is reviving under British rule. Pop. (1869) 37,804; (1891) 79,500.

Fajardo: See the Appendix.

Fakir, fay'ker or faa-keer' [from Arab. *faqīr*, poor man]: one of a class of religious mendicants in India, found there in large numbers and with evidence of their existence very early in Hindu history. Some of them are ascetics, who practice surprising mortifications and bodily tortures, such as swinging on hooks thrust through their flesh, lying on a bed of spikes, walking on sandals through which spikes are driven, hanging suspended during life before a slow fire, fulfilling a vow to continue in one position during life, holding the limbs in a fixed position till they become immovable, carrying a cumbrous load or drawing a heavy chain, crawling on their hands and knees for years, rolling on the earth from one end of the land to the other, etc. By these means they acquire a reputation for sanctity which gives them a great hold upon the superstitions and the fears of their countrymen, though there is little religious sense displayed in all these performances, which are adopted, for the most part, as a mode of obtaining notoriety or a livelihood. The Hindus have apparently little respect for these men, but they dread their curses, and the powerful rajah will rise up on his elephant and salute one of these "saints" as he passes by.

Falaise, faa'lāz' [O. Fr. *faloize* and *falize*, from O. H. Germ. *felisa*, rock, cliff > Mod. Germ. *Fels, Felsen*]: town of France; department of Calvados; 22 miles S. S. E. of Caen (see map of France, ref. 3–D). It is picturesquely situated on a lofty platform bordering on a rocky precipice (*falaise*), which position made it a very strong fortress in olden times, before the invention of gunpowder. Its old castle, now mostly in ruins, was the seat of the Dukes of Normandy and the birthplace of William the Conqueror. There are manufactures of cottons, hosiery, and bobbinet, and dye and tan works. Pop. (1896) 8,163.

Falashas [the name signifies wanderers or exiles]: a strange people in Abyssinia inhabiting the mountainous regions of Samen and the plains along Lake Tzana, and numbering about 100,000. They are the remnant of natives who were converts to Judaism. The name *Falashah* signifies exile or wanderer, and they have been much oppressed by the neighboring Christians. However uncertain their origin, they have become thoroughly Abyssinian, and are distinguished from their fellows only by their religion. Like the native Christians, they are well formed, and resemble the nomads of Arabia. They are of medium height, with face oval, nose finely sharpened, mouth well proportioned, lips properly formed and by no means exuberant, sparkling eyes and well-set teeth, and hair somewhat curled or straight. (See Figuier, *Les Races Humaines*, Paris, 1872, p. 406.) Until the beginning of the nineteenth century they constituted an independent tribe, and were governed by their own prince; it is said that in the tenth and twelfth centuries they even ruled over the Abyssinians. They were subjected by the Amharas about 1800, and are now under the rule of the princes of Tigré. The Falashas speak both the Amharic and a dialect of the Agaon tongue, and are very industrious, devoting themselves to the various trades, particularly architecture; also largely to agriculture. Unlike other Semitic races they are averse to commerce, regarding traffic an obstacle to fidelity and rigor in religious observances. The Falashas, although they possess the whole of the Old Testament or Jewish canon (in the Geez language, a sister-tongue of the Hebrew, Arabic, and Aramean dialects and the mother of the Amharic), together with the apocryphal books accepted by the Abyssinian Church, deviate in many instances from Jewish usages. Thus the fringed "praying-scarf" (*taleth*) and the "phylacteries" are not used in their devotions; and while they retain the usage of offering sacrifices, it is rather as commemorative ceremonies than as real sacrifices. The most common is the offering for the repose of the dead; but no sacrifice is permitted on the Sabbath or on the day of atonement. Like other Jews, the Falashahs hope for a return to Jerusalem. Their priests, who live round the inclosures of the temples (which are situated near the edge of the villages, and have more the appearance of the ancient sanctuary than the modern synagogue), observe the laws of purity with rigor, prepare their own food, and keep aloof from the world. They are principally engaged in the education of youth, making the Bible and tradition the basis of their instruction. Polygamy, though tolerated, is nevertheless discouraged. Slave-holding is suffered, but slave-dealing is strictly forbidden. Slaves are kindly treated, instructed in the laws of Moses, and on conversion are manumitted. Attempts on the part of the London Missionary Society and the Scottish Church Mission to convert the Falashas to Christianity induced the Jewish Alliance Universelle in 1867 to send among them M. Halévy, of Paris, to secure their education and to counteract the Christianizing influence of the missionaries. See, besides works on Abyssinia, Hotten, *Abyssinia and its People* (London, 1868); J. M. Flad, *The Falashas of Abyssinia* (Eng trans. 1869); J. Halévy, *Travels in Abyssinia* (Eng. trans. 1878).

James H. Worman.

Falcid'ian Law: a law under the civil or Roman law system, proposed by a tribune, Falcidius, about 40 B. C., by which it was enacted that testators should not have power to dispose of more than three-fourths of their property by will, and that the remaining one-fourth should descend to the heir. This fourth was termed the "Falcidian portion." No such restriction exists at common law, a testator having an unqualified power to distribute his property entirely among strangers, and leave his family unprovided for if he desires. In the U. S. Louisiana, which has adopted the civil law, has a provision similar to the Falcidian law. In some of the other States restrictive enactments have been made in regard to bequests to charitable corporations or associations. For instance, in New York a testator having a husband, wife, child, or parent living can leave to such institutions only one-half of his property after the payment of his debts. *Laws* 1860, ch. 360.

Falck'enstein, Eduard Vogel, von: Prussian general of infantry; b. in Silesia, Jan. 5, 1797. He was the son of a Prussian major, but the father died early, and the mother, unable to educate the boy herself, asked assistance from her relative the Prince-Bishop of Breslau. The prince-bishop promised to help, but on the condition that the boy should be a clergyman. But at the rising of the Prussian people against Napoleon, in 1813, the boy left the ecclesiastical career and entered as a volunteer into the West Prussian Grenadier battalion of Col. von Klück. He distinguished himself in the battle of the Katzbach, and at Montmirail, when all the officers had fallen, he led the battalion with imperturbable calmness, though a youth of hardly seventeen years. After the war he studied topography with great zeal, and founded a school for glass-painting in Berlin under the auspices of Friedrich Wilhelm IV. On Mar. 18, 1848, in the riots in Berlin, he was wounded, but took part in the same year in the campaign in Holstein, and became commander of the foot-guards in 1849, and in 1851 colonel and chief of the staff of Wrangel. He held the same position in 1864 during the second war with Denmark, but after the war he was made commander-in-chief of the Seventh Army-corps. In the war of 1866 he commanded against Hanover, Hesse, Nassau, Baden, Würtemberg, and Bavaria, and displayed considerable strategic talent. After the war he received a dotation, was elected to the North German Diet by the city of Königsberg, and spoke energetically for a triennial military service and a strong military budget. During the war of 1870 he held the chief command of the maritime provinces, and organized the whole defense of the Baltic and of the North Sea. D. in Silesia, Apr. 6, 1885.

Falcon [M. Eng. *faucon*, from O. Fr. *faucon* < Lat. *falco*, name derived from *falx, falcis*, sickle, because of the falcon's curving talons]: a name applied to various species of hawks, but more especially to those of the genus *Falco*, which includes the most active and fearless of the birds of prey. Among the numerous and widely distributed species are the gerfalcons (*Falco candicans* and others), the peregrine falcon, or duck hawk (*Falco peregrinus*), the merlin (*Falco*

Gerfalcon (*F. candicans*).

æsalon), and the hobby (*Falco subbuteo*). The gerfalcons are the most northern of the diurnal birds of prey, inhabiting Greenland, Iceland, and the northern parts of Europe, Asia, and America. The Greenland species (*Falco candicans*) is, when adult, white, with fine black markings on the back and wings; young birds have more black in their plumage. The peregrine falcon is bluish ash above, whitish or dull buff below, with numerous dark spots and bars; it is about 18 inches long and the long, pointed wings have a spread of about 3½ feet. This species, which is found in nearly all parts of the globe, was from its dash and courage particularly dear to the heart of the falconer, and, says Dr. Sharpe, to write its history would be to write the history of falconry. In ornithology the term falcon is usually restricted to the members of the sub-family *Falconinæ*, which may readily be distinguished from the other birds of prey by their notched bills. *Noble falcons* and *ignoble falcons* are terms of FALCONRY (*q. v.*). See FALCONIDÆ and FALCONRY.

F. A. LUCAS.

Falcon, făal-kōn′ (formerly called CORO): the northwesternmost state of Venezuela: bounded N. by the Caribbean Sea, E. by Lara, S. by Los Andes, and W. by Colombia. Area, 36,212 sq. miles. The western and larger portion, forming the section of Zulia, was formerly a state; it was united to Falcon in 1881, but, like other sections, is liable to be erected into a state again with a change of Venezuelan government. As at present constituted, Falcon is divided physically into two nearly equal parts by the great Gulf and Lake of MARACAIBO (*q. v.*). The Gulf of Maracaibo is formed by two peninsulas, that of Guajira on the W., and Paraguaná on the E., the latter connected with the mainland by a very narrow neck. These peninsulas and the shores of the Caribbean Sea are low, sandy, or stony, and form the most sterile region on the Venezuelan coast; owing to the lack of water in the dry season, artificial cisterns are everywhere used. Around Lake Maracaibo the country is low and partly swampy. Inland there are mountains of no great height, with considerable forests, and the valleys are very fertile. The climate everywhere is warm, but generally healthy. Pop. (1891) estimated at 224,566. The most important products are tobacco, coffee, cacao, and goatskins. Principal towns, Coro and Maracaibo. The capital, Capitarida, on the Gulf of Maracaibo, has about 2,000 inhabitants.

HERBERT H. SMITH.

Falcon, JUAN CRISÓSTOMO: Venezuelan general and statesman; b. on the peninsula of Paraguaná, province of Coro (now Falcon), 1820. He early entered the army; fought with the *progressistas* in 1846, and against Gen. Paez in 1848. In 1849 he defeated and captured Carmona at La Bacoa. In 1858 he headed the federalist revolution in his native province of Coro; driven out in 1860, he returned in 1862, and was finally successful, entering Caracas July 29, 1863. He was elected president of Venezuela, with Guzman Blanco as vice-president, and in 1864 he sanctioned a new constitution. The *Azul* revolution of 1867 resulted in his overthrow, after three days' battle in the streets of Caracas (July 24–26). He retired to Europe; a counter-revolution, headed by Guzman Blanco, put his party again in power, and he was recalled, but on his way back died at Martinique, Apr. 29, 1880. HERBERT H. SMITH.

Falconer, HUGH, M. A., M. D., F. R. S.: botanist and palæontologist; b. at Forres, Scotland, Sept. 29, 1808; graduated M. A. at Aberdeen 1826; M. D. at Edinburgh 1829; went to India as a surgeon 1830; began palæontological explorations in the Siwalik Hills 1831; became superintendent of the botanical garden at Seharanpoor 1832; received the Wollaston medal 1837; became F. R. S. 1845; superintendent of the botanical garden at Calcutta 1847; published *Selections from the Bostân of Saadi* (1838); *Fauna Antiqua Sivalensis* (1846, with T. P. Cautley); *Palæontological Memoirs* (1868). D. in London, July 31, 1865.

Falconer, JOHN M.: See the Appendix.

Falconer, WILLIAM: poet; b. in Edinburgh, Feb. 11, 1732; son of a barber; became a sailor, and is best known by his poem, *The Shipwreck* (1762; new ed. 1804, 1872). He published also a universal *Marine Dictionary* (1769; new ed. 1815), and various minor poems. Lost at sea in 1769 off the coast of Mozambique, while purser of the frigate Aurora.

Falconet [dim. of FALCON, *q. v.*]: in falconry, a male falcon, smaller and weaker than the female.

Falcon′idæ [mod. deriv. of Lat. *fal′co, falco′nis*, falcon]: a family of *Raptores*, containing all the *Accipitres*, or diurnal birds of prey, except the secretary bird and the vultures of the New World. The members of the family are characterized by the presence of a bony septum between the nostrils, legs of moderate length, strongly hooked bill, sharp, curved claws, and, save the vultures, a well-feathered head. The family is divided into the following sub-families: *Vulturinæ*, the Old World vultures; *Aquilinæ*, the eagles; *Pandioninæ*, the fish-hawks; *Circinæ*, the harriers; *Milvinæ*, the kites; *Polyborinæ*, the carrion hawks; *Accipitrinæ*, the hawks; and *Falconinæ*, the true falcons. The fish-hawks are by some authorities placed in a family by themselves. F. A. LUCAS.

Falconry: the art of capturing, rearing, and training falcons for the chase of other birds, and even of small quadrupeds. The name *falconry* was also applied to the aviary or inclosure where the falcons were kept. The practice of hunting with falcons was introduced into Europe from the East. Ctesias alludes to the existence of such a custom in India in his time; Marco Polo also, in his *Milione*, speaking of the Tatars, says that their great khan "took with him full ten thousand falconers and good five hundred ger-falcons, with falcons *peregryne* and falcons *sacre* in great abundance; also he had a great number of goshawks for fowling along the waters," etc. Hawking seems to have passed over from the Tatars to the czars of Muscovy, who took great pleasure in this amusement. (See *Prince Serebrianni*, by Alexis Tolstoi, London, 1874). In Europe this pastime is anterior to the Middle Ages, as, among the later Romans, Martial, Apuleius, and Julius Firmicus make special mention of it. On the descent of the Lombards into Italy, hawking became much more general, and from this it may be inferred that the ancient Germans were acquainted with it. Charlemagne took great delight in it, and he is said to have kept as many falconers as huntsmen. Pope Gregory IX. appears to have kept falcons. Henry the *Fowler* received his surname from his passion for this sport. The Emperor Frederic II. not only enjoyed hunting with falcons, but he was a master of the art, and even wrote a treatise upon it, annotated by his son Manfred, with the title *De arte venandi cum avibus.* Another treatise on the same subject is attributed to Edward the Confessor of England. Brunetto Latini, in his *Tesoro* (chs. ix., x., xi., xii.), speaks of falconry; Dante reminds him of it in the *Divina Commedia.*

In the language of falconry the term *noble falcon* designates those birds of whatever species which may be trained for use in hawking; the rest are *ignoble.* Others designate the high-flying falcons which stoop upon the prey as *noble*, while those which fly low, chasing the prey, are *ignoble.* The most important of the long-winged, high-flying falcons are the gerfalcon, the merlin, the lanner, the peregrine, and the white falcon. Of the ignoble birds may be mentioned the hobby, the goshawk (or falcon gentle), the sparrow-hawk, and certain small species of *Hypotriorchis* and *Ierax*, much used in Asia in hawking. Of these, the more important are noticed in this work under their alphabetical heads. Anciently, the term *falcon* designated only female birds, while the male, always smaller and weaker, was called a *falconet*, or tercel, whatever the species.

The treatise on this subject most interesting to English readers is that ascribed to Dame Julyana Berners, forming the first part of the *Boke of St. Albans*, first printed in 1486. Among the many continental writings upon falconry should be mentioned *La Venerie et Fauconnerie de Jacques du Pouilloux* (Paris, 1535), and the Italian work of Federigo Giorgi, who published in Venice in 1578 a volume entitled *Del Modo di conoscere i buoni falconi, astori e sparvieri, di esercitarli e farli perfetti, di governarli e di medicarli*, describing the various qualities of the falcon and the methods of keeping and caring for it. According to the *Glossary* of Du Cange, the privilege of keeping falcons was, in the Middle Ages, confined to the nobility. This, however, does not seem to have been the case in all countries, for in the *Boke of St. Albans* it is stated that certain falcons belonged by right to certain ranks; for instance: "an Egle, a Bawtere, a Meloune, . . . thyse thre by theyr nature belonge unto an Emperor. A Gerfawkon, a Tercell of a Gerfawkon, are dewe to a kyng. There is a Fawkon gentyll; and a Tercell gentyll; and thyse be for a prynce. There is a Fawkon of the rocke; and that is for a duke. There is a Fawkon peregryne; and that is for an erle." Then follow various other classes, till we come to "the Merlyon; and that hawke is for a lady"; and finally, "there is a Goshawk; and that is for a yoman. There is a Tercell; and that is for a poore man," etc. From this it is evident that in England, at least, the amusement of hawking was not wholly confined to the nobility. The office of grand falconer at the Byzantine court, in that of England, and in the ducal court of Savoy, was one of the highest dignity. Both the art of falconry and the practice of it, hawking, had their special vocabularies or "kindly speche," the thorough knowledge and accurate use of which were thought highly important as a test of good-breeding and as a means of distinguishing "a gentylman fro a yoman, and from a yoman a vylayne."

A great number of these terms and much other quaint matter on this subject will be found in the *Boke of St. Albans* and the other treatises above quoted. In the fifth chapter of Cibrario's *Della Economia Politica del Medio Evo* is a full description of this sport: "The time of the chase was either early in the morning or toward evening. The sportsmen rode out, with their falcons resting upon their strongly gloved wrists. When a bird was discovered suited to the nature and the habits of the falcon, the little hood which covered its eyes was drawn off, and the falcon rose in rapid circles high above its destined prey; if the quarry was a small bird, she then suddenly swooped (or *stooped*, as the phrase was) directly upon her victim; but if the latter was a large and powerful bird, formidable in beak and wing, the falcon was cautious and cunning in her advances, turned and wheeled with great dexterity, seizing only the favorable moment to strike. Having secured the prize, she swept in large circles over the head of the falconer, and finally presented him the booty; the falconer put it in the game-bag, and then set before his falcon the food prepared for her. Falcons which soared high and pursued birds of lofty flight were called *altani*; others took a lower but more extended range; some were for the inland country, others for aquatic birds. These last were assisted by dogs. When, for example, a flock of herons was discovered, the falconer approached them secretly, and suddenly beat a drum before the herons could get sight of the falcon, otherwise they would not dare to rise. Frightened by the drum, they took to flight; then the sportsman let loose his falcon, and while she prepared to seize the herons in the air, the barking of the dogs prevented the poor birds from hiding again in the water. Eagles and falcons of the largest species may be trained for this chase, and they will even take foxes and hares." With Eastern sovereigns hawking is still in great favor, but it has almost entirely disappeared from Europe. The rare occasions in which the falcon is now employed are rather scenic representations of the old custom than attempts to revive it. The history of this pastime is especially interesting, as being almost the only outdoor amusement in which women of rank, in the Middle Ages, took an active part, and it has furnished the writer of fiction with many a romantic situation, the poet and the painter with many a happy illustration. See Freeman and Salvin, *Falconry, its Claims, History, and Practice* (London, 1859); Harting, *Hints on the Management of Hawks* (1884). ANGELO DE GUBERNATIS.

Faleme, fā-lā'mā: a river of Senegambia, Western Africa. It is one of the most important tributaries of the Senegal, which it joins in lat. 14° 40' N., lon. 11° 48' W.

Fale'rii: powerful city of ancient Etruria; situated N. of Mt. Soracte and W. of the Tiber. It is believed to have been one of the twelve cities of the Etruscan confederation. It was often at war with Rome, but in 241 B. C. was conquered and destroyed by that power. A new Roman Falerii was founded near by, the ruins of which, 5 miles distant from Nepi, are of great interest. The old Falerii probably stood at Civita Castellana.

Faler'nian Wine [from Lat. *Falernus*, pertaining to the Falernus Ager, or Falernian District in Campania]: the most celebrated of the wines of the ancient Romans. According to Pliny, it was of three varieties—a light, a sweet, and a dry. It was very strong and generous, so that it would take fire from a lighted taper. When new it was very harsh and unpleasant. The excellent Massic wines came from the same region, and the two sorts were often confounded. Indeed, the better qualities were called indiscriminately by either name. These regions still produce good wine. From all accounts, the Falernian must have resembled the modern sherry wine.

Falguière, fāal'gee'ār', JEAN ALEXANDRE JOSEPH: sculptor and figure-painter; b. at Toulouse, France, Sept. 7, 1831. Pupil of Jouffroy; Grand Prix de Rome (sculpture) 1859. His work in both branches of the fine arts is strong, and possesses qualities of the highest order. In sculpture, *Diana*, *Christian Martyr* (1868), and *Victor in the Cock-fight* (1870), the last two in the Luxembourg Gallery, Paris, are among his best works. In painting, *The Wrestlers* (1874), *Susanna*, *Slaughter of a Bull* (1881), and *Fan and Poignard* (1882; Luxembourg Gallery) are celebrated. Member of the Institute; medal of honor (sculpture) 1868; officer Legion of Honor 1878. Studio in Paris. W. A. C.

Faliero, fāa-lēe-ā'rō, or **Falieri**, fāa-lēe-ā'rēe, MARINO: doge of Venice; b. of an eminent family in 1274; served the republic in war and on important embassies, and in 1354, when seventy-nine years old, was chosen to the dogate, soon after which the Venetian fleet was lost in a great battle with the Genoese. Not long after, at a carnival feast, his wife was grossly insulted by a young nobleman, and in revenge Faliero determined to destroy the whole body of nobles, who were detested by the people, and become sole ruler. His conspiracy was detected and suppressed, and the doge, after a full confession, was beheaded Apr. 17, 1355. His story has been a favorite one with the poets, dramatists, and musical composers—Byron, Delavigne, Hoffman, Donizetti, and others.

Falk, faalk, PAUL LUDWIG ADALBERT: statesman; b. in Matschkau, Prussia, Aug. 10, 1827; educated at the Gymnasium and University of Breslau; studied law and became a member of the Prussian House of Deputies 1858–61. He was Minister of Worship and Education 1872–79, and in 1882 was nominated to the presidency of the supreme court in Hamm. During his administration of the Department of Worship and Education he passed several rigorous measures directed against the hierarchy and clergy. (See FALK LAWS.) Bismarck at first sustained this legislation, but subsequently made some advances to the ultramontane party in order to gain their support, and Falk was forced to resign. D. July 7, 1900. C. H. THURBER.

Falkirk, faw'kirk: city of Stirlingshire, Scotland; 25 miles W. N. W. of Edinburgh; on the Edinburgh and Glasgow and Scottish Central Railway, near the old Roman wall of Antoninus and the well-known Carron Iron-works (see map of Scotland, ref. 11–H). It contains, among other institutions, a science and art school, a free library, and a cottage hospital. Its three annual "trysts" at one time were the largest cattle-fairs in Scotland, sales being made to the amount of nearly £1,000,000. These have been largely superseded by weekly auctions. In 1298 Sir William Wallace was defeated here by Edward I., and in 1746 the Highlanders, under Prince Charles Edward, defeated the royal troops. Pop. (1891) 16,615; with suburbs, 25,000; (1901) 29,271.

Falkland, fawk'land: royal burgh of Fife, Scotland; 22 miles N. of Edinburgh (see map of Scotland, ref. 10–H). It is situated at the base of the Lomond Hills, which rise so abruptly behind it as to intercept the rays of the sun from it for several weeks during winter. The remains of Falkland Palace are very interesting, both in architectural respects and on account of their connection with the history of James IV. and James V. Pop. 3,000.

Falkland, LUCIUS CARY, Viscount: son of Sir Henry Cary, a man of literary tastes; b. probably at Burford, Oxfordshire, in 1610; educated at St. John's College, Cambridge. In 1633, upon the death of his father, Lucius succeeded as viscount, and was made by King Charles gentleman of the royal bedchamber. In 1640 he was chosen member of the Short Parliament, and was re-elected to the Long Parliament. Opposed to what seemed to him the excesses and illegalities of the popular party, he entered the lists in defense of the king, and in 1642 became Secretary of State. When civil war broke out he joined the king, fought admirably at the battle of Edgehill, and was killed at the battle of Newbury, Sept. 20, 1643. He wrote various treatises, of which is best known the *Discourses of the Infallibility of the Church of Rome* (best ed. London, 1660, 4to). A volume of poems by Falkland, edited by A. B. Groshart, was published in 1871.

Falkland Islands (MALVINAS or MALUINAS of the Spanish): an archipelago in the South Atlantic Ocean; 300 miles E. of the Straits of Magellan; between 51° and 52° 45' S. lat., and occupying about seven and a half degrees of longitude. Entire area, about 6,500 sq. miles, of which 3,000 is in the island of East Falkland and 2,300 in West Falkland; besides these there are over 100 small islands and numerous islets and rocks. Nearly all are high, and in the interior of the two larger islands there are several peaks rising above 2,000 feet. The coasts are much broken, with numerous deep fiords and some excellent harbors. The climate is severe, owing rather to the frequent storms than to cold. The indigenous fauna and flora are both very poor. There are no trees. Hardly any of the land is fit for cultivation, but it affords excellent pasturage. Sheep-farming is the principal and almost the only industry. The Falklands, with SOUTH GEORGIA (*q. v.*), form a crown colony of Great Britain. The colonists, nearly all of Scotch birth or descent, are industrious and prosperous, and crime is almost unknown. Exports, wool, frozen mutton, sheepskins, and tallow. The trade is mainly with England and Uruguay. Stanley is a free port, except for liquors, wine, tobacco, and a few other articles of luxury. Weights and measures and currency as in England. It is supposed that the islands were first discovered by Davis, in 1592. In 1690 Capt. Strong gave the name Falkland (in honor of Lord Falkland) to the straits, and eventually it passed to the islands. The Spanish name, Malvinas, arose from the great numbers of St. Malo fishermen who formerly frequented the archipelago. The French under De Bougainville formed the first settlement in 1763, but in 1765 Byron seized the islands for England. France transferred her rights to the Spanish, who drove the English out, and the islands remained nominally under the jurisdiction of the viceroys of Buenos Ayres, and later of the Argentine Confederation, but without being settled. The English again took possession in 1833, and the present colony was formed in 1851, but Argentina has never given up her claim to the archipelago. Pop. of the islands (1891) 1,789. Chief town and capital, Stanley or Port Stanley, in East Falkland, with 694 inhabitants.

HERBERT H. SMITH.

Falk Laws, or **May Laws**, **The**: certain measures introduced into the Prussian Diet by the Minister of Worship and Education, Dr. PAUL LUDWIG ADALBERT FALK (*q. v.*). The first of those laws was passed in May, 1872, and transferred the superintendence of the primary schools from the Church to the state by ordering that the inspector of schools should be a layman, and a ministerial order of June of the same year almost completely excluded the Roman Catholic Church from exercising any influence on the schools by forbidding the members of the religious orders to teach in them. By a law of Nov., 1872, a supreme ecclesiastical court was established, which enabled the Government to deal in an effective manner with refractory bishops, and another law, of May, 1873, considerably restrained the power of the bishops over the inferior clergy, and the power of the clergy in general over the laity. At the same time, civil marriage was made obligatory, the religious orders living within the boundaries of the Prussian kingdom were forbidden to receive new members, the control of church property was transferred from the clergy to boards of trustees composed of laymen, and a law of May, 1875, required the whole clergy, inclusive of bishops, to sign a declaration of obedience to the laws of the state before entering upon office. The rigor of these laws was relaxed in 1879 and again in 1887.

Falköping, faal'chö-ping: town in Sweden, Westergöthland; 38 miles S. W. of Mariestad (see map of Norway and Sweden, ref. 11–E); known by the battle of 1389, in which the Danish Queen Margrethe conquered the army of the Swedish King Albrecht, and took him prisoner. This victory led to the famous Union of Kalmar, 1397, by which Sweden, Norway, and Denmark were united under one crown.

Falkner, fawk'ner, THOMAS: Jesuit missionary; b. in Manchester, England, Oct. 6, 1707. He studied medicine and became surgeon on a slave-ship, in which he sailed to Africa and thence to Buenos Ayres; there he fell sick and was kindly cared for by the Jesuit fathers of the colony. In May, 1732, he entered their order, and for thirty-eight years he was employed as a missionary, at first in Paraguay and Tucuman, and after 1740 among the wild tribes of Patagonia. After the Jesuits were expelled from South America (1767) he resided in England, where he was chaplain to several distinguished Catholic families. He wrote two works on South America, and a Latin treatise on surgery, all of which probably are lost, but a compilation from his papers was published in 1774 as *A Description of Patagonia and the Adjoining Parts of South America*. Of this there are German, French, and Spanish translations. D. at Plowden Hall, Shropshire, Jan. 30, 1784. HERBERT H. SMITH.

Fallacy [Mid. Eng. *fallace*, from Fr. *fallace*, deception < Lat. *falla'cia*, deriv. of *fal'lax*, deceitful, deriv. of *fal'lere*, deceive]: in logic, a wrong notion resulting from an incorrect performance of the process of reasoning. Not every wrong notion is a fallacy. If the process of reasoning is performed correctly, and the wrong notion rises either from a biased and prejudiced assumption of distorted premises or from a weak and groping confidence in insufficient premises, it is in the first case an error—in the latter, a mistake.

As the whole process of reasoning can be reduced to the making of inferences, and as the fundamental character of all inferences is the syllogism, the fallacy may be defined as the result of some fault in the formation of the syllogism. And furthermore, as all faults which can be committed in the formation of a syllogism rise either from the two propositions being repetitions of each other, and consequently incapable of producing any legitimate third proposition, or from their being wholly incongruous, lacking the true middle term, which alone could draw the premises together into a conclusion, all fallacies fall into two classes corresponding to these two divisions of faulty syllogisms, and may be characterized either as a reasoning in a circle or as a jumping to the conclusion.

The first kind of logical fallacy, the reasoning in a circle —which in the terminology of the old logical systems was called a *petitio principii*—consists in proving one position by assuming another which is identical with it. Of all kinds of logical fallacies this is the most desperate. When a person is caught by such a fallacy, debate must stop; when an age is caught, civilization must stop. It acts on the mind like a magical ring. A person or an age may move around in it, with steadily increasing passions, and there is no escape from it unless through a revolutionary concussion of the whole mind. It is of most frequent occurrence in theological matters, and in those questions of politics which it seems impossible to solve satisfactorily by the mere application of the principle of expediency, without any intermediate agency of moral principles.

The other kind of logical fallacy is much less dangerous, though much more frequent, and comprises a great number of distinct forms, which the old logic describes as the fallacy of the *æquivocatio*, *accidens*, *argumentum ad hominem*, *post hoc ergo propter hoc*, *undistributed middle*, etc. The general characteristic of all these different forms is the application of a middle term composed not of truly constituent, but of merely accidental, qualifications of the two ideas which it is meant to combine. Thus, in a comedy of Holberg, Erasmus Montanus proves that his mother is a stone in this way:

A stone can not fly; you can not fly. *Ergo*, You are a stone.

A more thoroughgoing definition of the terms will, in most cases, be able to destroy this kind of logical fallacy, which, however, has become dangerously frequent in cases in which statistics are applied to the solution of historical or moral questions. Thus Buckle, in his *History of Civilization in England*, reasons as follows: "Necessary laws exclude free will. Statistics show the existence of necessary laws in history. *Ergo*, free will is excluded from history." Any definition of history which in any way can pretend to cover the field which in reality belongs to the idea will break this syllogism to pieces, and show the fallacy of the conclusion.

It must be noticed, however, that even when a fallacy of this kind shows a fault in the construction of the syllogism, thus making the incorrectness of the performance of the process of reasoning perfectly apparent, it generally originates in a willful or unwarranted assumption of premises; and in his book on logic Mill treats fallacies of this kind as errors and mistakes, though he retains the name of fallacy.

Revised by W. T. HARRIS.

Fall Dandelion: See HAWKBIT.

Fallet, NICOLAS: author; b. at Langres, in the department of Haute-Marne, France, in 1753. He was the son of a hatter, and was destined for the bar; but, irresistibly drawn toward literature, he removed to Paris, where he became a contributor to the *Gazette de France*, the *Journal de Paris*, and the *Dictionnaire universel*. Chief among his works are the tragedies *Barnevelt* (1775) and *Tibère* (1783); the comic opera *Matthieu*, represented at Fontainebleau in 1783, and afterward in Paris; *Les fausses Nouvelles*, a comedy; and the two collections of poems, *Mes Prémices* (1773), and *Mes Bagatelles* (1776). D. in Paris, Dec. 22, 1801.

Falling Bodies: The motion of a falling body, assuming it to meet with no resistance from the air, affords the simplest example of uniformly accelerated motion; that is, of a motion the velocity of which increases by equal amounts in equal times. It is found that in the case supposed all bodies fall according to the same law, the velocity constantly increasing at a rate, in north temperate latitudes, of 32·2 feet in a second.

It may be shown mathematically that the general law of uniformly accelerated motion leads to the conclusion that if the distance which the body falls during the first second, or the first unit of time be represented by unity, the distances fallen during the following seconds or other units of time will be 3, 5, 7, etc. If the total distance be computed it will be found that in two seconds a body falls four times as far as in one; in three seconds, nine times as far, etc., the distance increasing as the square of the time of fall.

From this follows another law of the fall, namely, that at the end of any period of time the body is falling with a velocity which, in an equal period of time, would carry it through double the space actually fallen. This is illustrated by the following table, which shows the spaces fallen during the number of seconds, or fractional parts of seconds specified in it, the distances through which the acquired velocity, continued uniform, would carry the body in a time equal to the time of fall, and the acquired velocity (per second) itself:

t = time of fall, seconds or fractions.	s = space fallen, feet and decimals.	d = distance in time t, with vel. = v.	v = vel. acquired by fall, in feet.

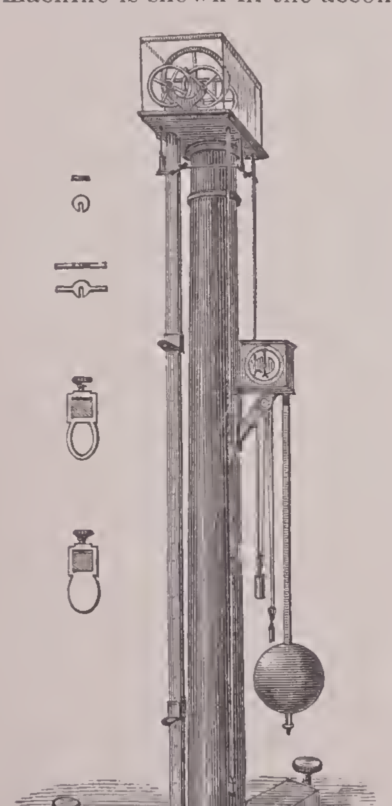
The law of falling bodies is illustrated by a machine invented by George Atwood (*q. v.*). The appearance of the machine is shown in the accompanying figure. An upright column about 8 feet high sustains a small platform on which the essential part of the machine rests. This consists of a light wheel delicately supported upon large friction-wheels and carrying two equal weights suspended at the extremities of a slender and very flexible silken cord, which runs in a groove upon its circumference. While these two weights continue to be equal the system remains at rest, but if an additional weight, however small, be placed upon either, this one will descend, and in descending will generate a velocity in a given time as many times less than that produced in the same time by gravity in bodies falling freely, as the added weight is less than the entire mass moved. It is common, in experimenting with this machine, to employ weights having a definite proportion to this mass. Thus if the whole mass is sixty-four times as heavy as the added weight which furnishes the motive-power, the velocity generated in one second will be the sixty-fourth part of 32 feet (disregarding for the moment the fraction)—that is to say, 6 inches. And as the space fallen through in the first second from rest is only half as great as that which expresses the acquired velocity, the weights of the machine will move only 3 inches in this first second. In preparing for experiment, one of the weights is loaded and raised nearly to the platform at the top of the column, where it is detained by a movable arm brought beneath it, and is held at rest at the zero of a divided scale, shown in the figure, on which the distances of descent are to be noted. A clock, supported by a bracket on the side of the column, is connected with the movable arm above mentioned by a mechanism which causes the arm to drop just as the second-hand marks zero. Sliding on the scale is a small movable brass stage, which may be placed at any point at which it is desired to arrest the fall. And there is also a ring sliding on the same scale, on which the load of the descending weight may rest, leaving the weight afterward to descend unloaded. The forms of the weights used as loads may be seen represented on the left in the figure, where also are given direct views of the stage and ring. The loading weights designed to be arrested by the ring are constructed with arms. The others are simple disks notched to the center, that they may not interfere with the suspending hook and cord. The clock marks the seconds with a loud tick. The moment at which the load is taken off by the ring, or at which the moving weight strikes the stage, is indicated by the sound of the contact. The law of motion is illustrated by noting the points on the scale at which coincidence takes place between these sounds and the beats of the clock. Thus if, as above supposed, the load is one sixty-fourth of the whole moving mass, and the stage is fixed 3 inches below zero, the stroke of the weight on the stage will coincide exactly with the first beat of the clock heard after the movement begins; but in order that coincidence may occur at the second beat, the stage must be placed at four times as great a distance down, or at 12 inches. For coincidence at the third beat the distance must be nine times as great, or 27 inches. In like manner four seconds require sixteen times as great a distance; and five seconds twenty-five times, or 75 inches, which is equal to 6 ft. 3 in. This illustrates the law of uniform acceleration theoretically established above—viz., that the space is as to the square of the time. If, however, the moving weight be unloaded at the distance *three*, by placing the ring at that point, then its subsequent motion will not be accelerated, but uniform, and its velocity will be $2 \times 3'' = 6''$; so that it will take it twelve additional seconds (or thirteen in all) to reach the stage at the seventy-fifth inch—a point which, under the previously supposed conditions, it reaches in five. See Acceleration and Force. S. Newcomb.



Atwood's machine.

Falling Stars: See Meteors.

Fallmerayer, fāal-me-rī'er, Jakob Philip: traveler, political agitator, and historical investigator; b. at Tschötsch, in Tyrol, Dec. 10, 1790. His contributions to the history of Greece during the Middle Ages are of great value and include *Geschichte der Kaiserthums Trapezunt* (Munich, 1827); *Geschichte des Halbinsel Morea in Mittelalter* (Stuttgart, 1830–36). He was the first who asserted that the modern Greeks are properly a branch of the Slavonic family of races, and that in spite of their language they have but little of the blood of the ancient Greeks in their veins. D. at Munich, Apr. 26, 1861.

Fall of Man: in theology, the lapse of the first man, and through him the lapse of the race, from the state of integrity into that of corruption. The myths and legends of paganism have many parallels with the scriptural account of the Fall. The tree of knowledge is generally regarded as simply affording the means of testing man, not as having in its fruit any special objective character. The serpent is simply organic and instrumental, the mask of the real tempter, the devil. The sin of the Fall is apostasy from moral fellowship with God, caused by abuse of the freedom of the will, and followed by the loss of the divine image and by liability to temporal and eternal death on the part of Adam and his posterity. Various explanations have been urged as substitutes for the historical sense of the narrative, both in ancient and modern times. The Ophites regarded the serpent as incarnate Wisdom. Many modern German thinkers consider the Fall as a necessary part of man's development in reason and character, "the happiest event in human history." Hase calls it "the image of that which occurs in every man." Nitzsch says, "it is true history, but not actual." See Krauth, *Conservative Reformation*, 376–455, and Hodge, *Systematic Theology*, ii. 123–129.

Fallopian Tubes [named from Fallopius, *q. v.*], or, more properly, **Oviducts**: in the higher animals, two canals in the free margin of the broad ligaments of the uterus, one on either side, extending from the ovary to the uterus. In woman the tubes are each about 4 inches long, with a very narrow passage along the inner half of the length, but much larger outward. The inner end opens into the cavity of the uterus, and the trumpet-shaped outward end opens into the abdominal cavity. The outward end is fimbriated with fringe-like processes, and has been called *morsus diaboli.* The oviducts are identical with what are called Müller's ducts in the fœtus. Birds have but one developed oviduct. In most marsupials each tube serves as a separate uterus. In the higher animals the uterus and vagina are regarded as formed by the union of the oviducts. The function of the Fallopian tubes is to convey the ovum from the ovary to the uterus.

Fallo′pius, or **Fallopio**, Gabriele: anatomist; b. at Modena, Italy, in 1523, or, according to Tomassini, in 1490. With Vesalius and Eustachius (the latter his rival) Fallopius has the honor of being the chief restorer of anatomical science; he taught at Ferrara and Pisa, and in 1551 became Professor of Anatomy and Surgery at Padua and director of the botanic gardens. His name is given to the Fallopian tubes, which he did not first discover (as he was long reputed to have done), though he first suggested their real function. A complete edition of his works was published in 1600. D. at Padua, Oct. 9, 1562.

Falloux, făal′loo′, Frédéric Alfred Pierre, Vicomte de: author and politician; b. at Angers, France, May 7, 1811; became distinguished as a political leader of the Catholic party, but retired from public life in 1851; became one of the editors of the *Correspondant* in 1855; and was known by his *Histoire de Louis XVI.* (1840), a legitimist work; *Histoire de Pie V.* (1844); *Madame Swetchine, sa vie et ses œuvres* (1859); *Madame Swetchine, Journal de sa conversion* (1863); another volume of Madame Swetchine's letters 1866; and some devotional works; also by two volumes of political speeches and writings (1882). D. at Angers, Jan. 6, 1886.

Fallow [probably same word as *fallow*, in *fallow deer*], or **Naked Fallow**: land which is allowed to rest after cropping for one or more seasons with no tillage, except perhaps one or more plowings. The custom is a very ancient one, and is chiefly useful on heavy soils, where it acts probably by way of liberating plant-food from hitherto unavailable compounds. It has, among the best farmers, given way to what is called the green fallow, of which the clover-fallow is one of the best kinds. Some green crop, as clover or buckwheat, is grown and allowed to rot on the surface, or is plowed under. This crop serves to choke the weeds and to fertilize the land, and while growing saves the soil from blowing away and from baking.

Fallowchat: See Wheatear.

Fallow Deer [*fallow* is from O. Eng. *fealu*, pale yellow : Icel. *fölr*, pale : O. H. Germ. *falo*, pale, withered, yellow > Mod. Germ. *Fahl*. Cf. Lat. *palle're*, be pale : Lith. *pálvas*, yellow : Sanskr. *palita-s*, gray]: a species of deer (*Dama vulgaris*); the most common deer of Europe, found also in Northern Africa. Though very common in England, it is supposed to have been introduced there only by the Roman colonists. In a wild state it exists in Southern Europe, but, as remains found in the later Tertiary show, its range originally extended farther N. In summer it is beautifully mottled. The male is called a buck, the female a doe, the young a fawn. The doe is without horns. The venison of the fallow deer is regarded as the most savory known. It is smaller than the stag, and has more spreading and palmated horns. It goes in herds, and each herd has its master, an old buck, which all the others obey.

Fallows, Samuel, D. D.: clergyman; b. at Pendleton, near Manchester, England, Dec. 13, 1835; removed with his parents to Wisconsin 1845; graduated as valedictorian at the University of Wisconsin 1859; became a minister of the Methodist Episcopal Church; entered the army as chaplain 1861; afterward engaged in active military service; reached the rank of colonel and brevet brigadier-general; was seven years a regent of the University of Wisconsin; was State superintendent of public instruction 1870–72; became president of the Illinois Wesleyan University at Bloomington 1874; rector of St. Paul's Reformed Episcopal church, Chicago, May, 1875; editor-in-chief of the *Appeal*, the organ of the Reformed Episcopal Church, Jan., 1876; and was chosen a bishop of the Reformed Episcopal Church July 15, 1876, at the fourth general council of that organization, held at Ottawa, Canada. He has published a *Supplemental Dictionary* (1884) and *Past Noon* (1886).

Fall River: city, port of entry, and important railway and manufacturing center; Bristol co., Mass. (for location of county, see map of Massachusetts, ref. 5–I); in lat. 40° 42′ 3″ N., lon. 71° 9′ 37½″ W.; on the Rhode Island border, on the eastern side of Mt. Hope Bay, the northeastern arm of Narragansett Bay, and along Taunton river, some 20 miles from the sea. It is about 11 miles in length, comprising 41 sq. miles; is 48½ miles S. of Boston, Mass., 20 from Providence, R. I., 15 from Taunton, Mass., 13 from New Bedford, Mass., and 18 from Newport, R. I., being central to them all and connected with each by railway. It has a safe and commodious harbor at the head of deep-water navigation.

Quequechan river furnishes abundant water-power, as it here falls 127 feet in less than half a mile. The volume of water is so uniform that mills are built directly across the stream without danger from freshets. The industries comprise immense granite quarries, 2 large calico print-works, a large bleachery, a spool and bobbin factory, etc., but the city is chiefly noted as the most important cotton-manufacturing center in the U. S. In 1900 there were 83 mills, keeping in motion 3,029,586 spindles and about 74,000 looms.

Public Institutions, etc.—The city contains 65 churches (51 Protestant and 14 Roman Catholic), a children's home, a public library with over 60,000 volumes, and excellent schools, comprising, besides those of lower grade, 14 grammar schools. There are 3 kindergarten schools and a normal-training school. The B. M. C. Durfee High School occupies an entire square and cost $750,000, and was a memorial gift to the city from Mary B. Young in honor of her son. The city also has a textile school with buildings valued at $150,000. There are 7 national banks with a capital of $2,150,000. There are 3 large orphanages and 2 large hospitals, sustained largely by private contributions. The city has electric street railways, an excellent system of sewers, several public parks, and a system of water-works, completed at a cost of $1,500,000, bringing the water from Watuppa Lake, a beautiful sheet of water 10 miles long on the eastern side of the city. Fall River was first settled in 1659, became a town in 1803, and was incorporated a city in 1854. Pop. (1880) 48,961; (1890) 74,398; (1900) 104,863. J. J. Manning.

Falls City: city; capital of Richardson co., Neb. (for location of county, see map of Nebraska, ref. 11–H); on two railways; 9 miles W. of the Missouri river; in the Great Nemaha valley. It has excellent flouring-mills, broom-factory, pork-packing house, foundry, canning-factory, windmill-factory, steam elevators, a fine system of water-works, etc. Pop. (1880) 1,583; (1890) 2,102; (1900) 3,022. Editor of "Journal."

Falls of Montmorency: See Montmorency, Falls of.

Falmouth, făl′mŭth: seaport of Cornwall, England; on a branch of the estuary of the Fal, which here forms one of the best harbors in England; 5 by 1 to 2 miles in extent, 12 to 18 fathoms deep, and capable of sheltering 500 vessels at once (see map of England, ref. 15–C). It is a rendezvous for fleets and mail-packets. The entrance is defended by Pendennis and St. Mawes castles. Tin, copper, fuel, and pilchards are exported. Pop. (1891) 4,273.

Falmouth: town; capital of Pendleton co., Ky. (for location of county, see map of Kentucky, ref. 2–I); on the Louisville and Nashville Railroad; 40 miles S. by E. of Cincinnati, O., and on Licking river at the mouth of the South Licking. It has 7 churches, a large free school and academy, a woolen-mill, sawmill, 2 flouring mills, distillery, creamery, and canning-factory. Agriculture is the chief industry, and the place is a trading-point for the White Burley tobacco district. Pop. (1880) 967; (1890) 1,146; (1900) 1,134. Editor of "Guide."

Falmouth: township; Barnstable co., Mass. (for location, see map of Massachusetts, ref. 5–K); on Cape Cod Div. of N. Y., N. H. and H. R. R., at the extreme west end of Cape Cod; on the shores of Buzzard's Bay and Vineyard Sound. It has a spacious harbor at Wood's Holl, which is safe, never freezes, and is of sufficient depth for the largest ships or steamers. It is noted as a watering-place, and Falmouth Heights has a wide reputation as a seaside resort. Pop. (1880) 2,422; (1890) 2,567; (1900) 3,500.

Editor of "Cape Cod Independent."

False Bay: an inlet on the east side of the mountainous district of South Africa, which terminates in the Cape of Good Hope. As it is sheltered from the northwest monsoon, to which the harbor of Cape Town is exposed, it receives periodically all trading-vessels from Cape Town for temporary protection, and it is the permanent station of the naval force of Cape Colony.

False Decretals: See DECRETALS, FALSE.

False Imprisonment: an unlawful deprivation of personal liberty. To constitute this offense it is not necessary that there should be an actual incarceration of the person, or that any actual force should be employed in procuring the wrongful restraint. An unwarrantable detention in a private apartment, or even in a public highway, is sufficient, and there need be no other exercise of power than a mere command or direction to submit to arrest, provided it is accompanied with such a display of authority, or such threats of compulsion, or exhibition of means to procure compliance, as naturally lead the person accosted to believe that he is submitting to legal authority, or that he will be forced to yield if he attempts resistance. It is enough that one's voluntary control and direction of his own movements is wrongfully interfered with. False imprisonment usually occurs from the unjustifiable exercise of pretended legal authority, as by arresting without process when process is known to be necessary, or when there is a mistaken assumption that a case is one in which no process is required to sanction an arrest. For instance, a constable or other peace-officer has power to arrest without warrant if he have reasonable ground of suspicion that a felony has been committed and that the person whom he seeks to detain is the offender. In like manner a private individual needs no legal process to justify him in taking into custody the supposed perpetrator of a felony whose guilt is reasonably presumable. A private person's privilege in this respect, however, is more restricted than that of a constable, for mere suspicion that the offense has been committed is not enough, but it must be shown to have actually occurred, even though the party suspected be in fact innocent. Furthermore, any person, whether he be an officer or not, in whose presence a breach of the peace is committed, may detain the wrongdoer and deliver him to the proper legal authorities for punishment. But whenever the right of arrest without warrant is exercised, a just occasion must be shown to exist by the entire correspondence of the circumstances of the case with those requirements which alone afford a sufficient cause for detention without process, or the person making the arrest will be guilty of false imprisonment. In all other grades of offense legal process is necessary to justify an arrest, and without it any restraint or detention of a person is unlawful. So an arrest is invalid and wrongful, even if made under color of process, if the process be void from some irregularity or defect, or if the arrest be made on an unlawful occasion, as on Sunday or a legal holiday upon civil process merely. All who are engaged in a wrongful interference with a person's liberty, either as principals or instigators, or those who are indirectly its cause, as by suing out illegal process, knowing it to be unjustifiable, are guilty of an unlawful arrest, and equally punishable.

The remedies for false imprisonment are adapted to secure either a restoration of the person confined to liberty, as by writ of HABEAS CORPUS (*q. v.*), or the punishment of the party who is chargeable with the wrongful confinement, as by a civil action for damages or a criminal indictment. The jealous care and watchfulness with which the right of personal liberty is protected at common law, and the numerous safeguards which have been provided to secure its unhampered exercise, are abundantly indicated by this variety of remedies, and by the strict rules which confine the power of arrest without process within narrow limits, only permitting its exercise when offenses of a particularly criminal character are to be punished, and when any requirement of delay for the purpose of obtaining a warrant would be attended with danger to the welfare of the community. The high degree of civil liberty which English-speaking peoples have developed and maintained so sedulously is an outgrowth of that sense of personal independence and individuality of which the law of false imprisonment furnishes so ample and noteworthy an exemplification. See the article IMPRISONMENT.

False Pretenses: See CHEAT.

Falster, faal'ster: Danish island in the Baltic; separated from Seeland, Möen, and Laaland by very narrow straits. It is very low, entirely flat, and somewhat unhealthful, but it is very fruitful and well cultivated. It has an area of 183 sq. miles, and a population of 35,000. The principal town is Nykjöbing, on the Guldborgsund.

Falster, CHRISTIAN: Danish poet and classical scholar; b. Jan. 1, 1690. He spent his life as rector of the school at Ribe, refusing two calls to the university. As a poet he is chiefly distinguished for his satires, which were published anonymously at various times between 1720 and 1740. His philological activity was mainly in the line of Latin. He made collections for an extensive work on Aulus Gellius, which was never published. His best-known contribution to scholarship, a collection of papers under the title of *Amœnitates Philologicæ*, was published at Amsterdam in 3 vols. (1729–32). D. Oct. 24, 1752. G. L. K.

Falun, faa'loon, or **Fahlun**: town of Sweden; at Lake Runn; 120 miles N. W. of Stockholm (see map of Norway and Sweden, ref. 10–F). It is famous for its copper mines, which gave Gustavus Adolphus occasion to call it "the treasury of Sweden," as at that time the mines yielded 3,000 tons annually. The amount yielded yearly has decreased to 400 tons, however. Pop. (1891) 8,010.

Famagos'ta, or **Famagusta**: city on the eastern coast of Cyprus (see map of Turkey, ref. 7–G). From the twelfth to the eighteenth century, while Cyprus was under the Venetian rule, Famagosta was one of the principal commercial cities of the Levant, but now its defenses, warehouses, palaces, and churches are in ruins, and its harbor is choked up by sand. Corn and pomegranates are exported. Pop. (1891) 3,367.

Familiars [liter., those belonging to the family, i. e. to the official family of the inquisitor. From Lat. *familia'ris*, deriv. of *fami'lia*, family]: See INQUISITION.

Familiar Spirits [*familiar* is viâ Fr. from Lat. *famili-a'ris*, familiar, domestic, deriv. of *fami'lia*, family, household]: demons supposed to be in attendance upon fortune-tellers, necromancers, and the like. The original Hebrew word (אוב; plu. אובות) which is rendered in the English version *familiar spirit* or *spirits* occurs in the Bible at least fifteen times (Lev. xix. 31; xx. 6, 27; Deut. xviii. 11; 1 Sam. xxviii. 3, 7, 8, 9; 2 Kings xxi. 6; xxiii. 24; 1 Chron. x. 13; 2 Chron. xxxiii. 6; Isa. viii. 19; xix. 3; xxix. 4). The primary meaning of אובות, *oboth*, is *leathern bottles*, suggesting the idea of *inflation* by the familiar spirits, with some reference, perhaps, to the tricks of ventriloquism. The Hebrew word has also two secondary senses. In some of the passages referred to above it denotes the persons who "have" or employ familiar spirits; in others, it denotes the spirits themselves. For example, persons are meant in Lev. xix. 31, and spirits in Deut. xviii. 11. Nothing is said in the Bible to justify the inference that such spirits were actually in attendance upon fortune-tellers and necromancers. The witch of Endor (1 Sam. xxviii.) was generally *supposed* to have a familiar spirit. But the coming of Samuel in answer to her incantations appears to have been more than the witch herself was expecting.

Familists, or **Family of Love**: an English mystic sect; founded in Holland by Henry Nicholas, a native of Westphalia, and originally an Anabaptist, and finally transferred to England near the middle of the sixteenth century. They taught that religion consists wholly in love, independently of any form of truth held and believed. Through love man could become absolutely absorbed in and identified with God in a subjective sense; that God regards not the outward actions, but only the heart; that to the pure all things are pure, even things forbidden. Nicholas, as the apostle of this "service of love," claimed, it is said, superiority over Christ, on the ground that Moses only preached *hope*, Christ *faith*, but he preached *love*. Much misrepresentation of their confession of faith (given in Strype's *Annals*, ii. 57) brought out an *Apology* in 1575, in which they sought to identify themselves with evangelical Christianity. In 1580 Queen Elizabeth instituted an investigation into their practices, and in consequence they were dispersed and their books publicly burned. They continued to flourish, however, for another century, and in 1604 petitioned King James for permission to publicly clear themselves of the charges preferred against them. This request was denied them, because they were known to have been guilty of grossly immoral practices. (Baxter, *Autobiography*, p. 77.) See a curious book by J. R. (John Rogers) entitled *The Displaying of an Horrible Sect naming themselves the Family of Love* (London, 1579), and

Knewstub, *Confutation of Monstrous and Horrible Heresies taught by H. N., etc.* (London, 1579); Mosheim, *Ecclesiastical History*, ch. xvi., § iii., p. xii., § 25: Collier, *Ecclesiastical History of England*, vi. 609; vii. 311; Hardwick, *History of the Reformation*, ch. v.; Carrière, *Philos. Weltanschauung d. Reformationzeit* (Stuttgart, 1847); R. Barclay, *The Inner Life of the Religious Societies of the Commonwealth* (2d ed. London, 1877).

Family [Fr. *famille* < Lat. *familia*, household]: etymologically the servants or slaves of a household; extended to designate the group of persons, including wife, children, and servants, who in Roman law were under the *patria potestas*. The word acquired biological, ethnological, and legal meanings that are often confused. The traditional belief, definitely formulated by Aristotle in the *Politics*, that the patriarchal family was the primitive social group, which grew, by the multiplication of descendants, into the tribe and the state, has been challenged by modern ethnographers. Bachofen, Morgan, McLennan, Post, etc., find many evidences, including a descent of names and property in the female line, that mankind lived originally in unorganized hordes or bands, within which definite family relationships were slowly evolved. The patriarchal theory has been defended by Sir Henry Sumner Maine, and Starcke and Westermarck hold that a definite paternal family has always existed in human communities. In Europe and the U. S. the stability of the family is threatened by the increase of divorce. See SOCIOLOGY. FRANKLIN H. GIDDINGS.

Family: in zoölogy, a group of animals intermediate between the genus and order; it is based on structural features of a more general character than the genus, while the limits are determined by the range and extent of the differential characters which exist between the typical form and the next allied: a family may therefore be monotypic (i. e. limited to a single known species), or exceedingly polymorphic (i. e. embracing thousands of species). Examples of family groups are found among mammals in the cat-like animals (*Felidæ*), the dog-like animals (*Canidæ*), and the bear-like animals (*Ursidæ*), in the order of *Carnivora*; in the horses and asses (*Equidæ*), the rhinoceroses (*Rhinocerotidæ*), the tapirs (*Tapiridæ*), and the hollow-horned ruminants—i. e. cattle, sheep, goats, and antelopes (*Bovidæ*)—in the order of *Ungulates*, and in man (*Hominidæ*) in the order of *Primates*. Inasmuch as a distinctive similarity of form is associated with the structural characters which distinguish most of these and many other families, especially of mammals, the group has been defined, by Prof. Agassiz, as the embodiment of form determined by structure. This definition, however, entirely fails in many, and even perhaps most, cases; for example, in the *Unionidæ* some forms are higher than long, while others are extremely elongated; and in the *Primates* there is a greater difference in form between some monkeys of one family than there is between others of different families. Families are therefore distinguished on account of certain differences in structure which may or may not be correlated with corresponding modifications of form. No exact criterion can be given, discrimination being a matter of judgment.

The term *family* was originally introduced by French naturalists as the vernacular equivalent of the Latin *ordo*, and in this sense it is still used by botanists—e. g. by Dr. Asa Gray, who combined certain forms in groups, for which he employed the word *order* as the scientific term, and *family* as the popular; thus, *Order 1. Ranunculaceæ* (*crow-foot family*). By Lamarck and Latreille, however, the two terms were restricted in meaning, the word *order* being retained in the sense in which it was employed by Linnæus, while the word *family* was re-established for a section of the order. Later (in 1811), William Kirby (*Trans. Linn. Soc.*, London, xi., p. 88) proposed that all families should have the patronymic termination *-idæ*; and this was gradually adopted, and now it is almost universally employed by zoölogists. Although, strictly speaking, the use of this termination may not always be in exact accordance with grammatical purity, its great convenience as a uniform indicator of the taxonomic value of the group outweighs the objections, and has insured its currency.

THEODORE GILL.

Family of Love: See FAMILISTS.

Famine [M. Eng. *famine*, from O. Fr. *famine* > Fr. *famine* < Low Lat. **fami'na*, deriv. of *fa'mes*, hunger]: an extreme dearth of food, resulting in death by starvation and disease to large numbers of people. The U. S. has never known a famine, in the proper sense of the word. Droughts, long-protracted terms of cold weather, plant-diseases, grasshoppers, mice, etc., have now and then caused dearths, but even these have generally been confined within narrow limits. In Europe also famines belong to the past, in consequence of the change which has taken place in the cultivation of the soil and the diet of the great mass of the population since the latter part of the eighteenth century. Since the general introduction of the potato a failure of the cereal crop does not mean immediate want of breadstuffs. By means of the steamship, the railway, the telegraph, etc., the movement of both bread and meat can be regulated at will. A famine in Western and Central Europe is impossible.

In Asia the situation is quite different. There nature has only partially provided for a speedy communication with the interior by means of navigable rivers. Canals and roads are rare. The aversion to railways and the great difficulties in building them have been successfully overcome only in India and Japan. In the interior and in the northern parts immense regions of deserts or steppes occur, in which good crops can be raised only along the rivers and by means of irrigation. In the southern parts, where the vegetation is generally luxuriant, good crops depend upon rain in the right season; and there the climate and religious prejudices have engendered many peculiar customs; millions of people eat no meat, others eat only one kind of cereals—for instance, rice, etc. Add to this the enormous density of the population in many districts—a thousand to a square mile in Howrah, near Calcutta, and about half that number in the Chinese province of Kiang-su—and it will be easily understood that a failure of the crops must cause great distress. As every means of making up for the dearth of one region by the abundance of another is wanting, famines, with all their horrors, are of frequent occurrence. India, Persia, the northern provinces of China, and Turkish Armenia have suffered from them, and Japan has escaped only by prohibiting all exportation of rice.

In 1873 the rice crop of the district of Behar, in Northwestern Bengal, yielded only a quarter of the average harvest, and as 15,000,000 people were dependent on this crop for sustenance, the Government was obliged to make purchases of rice, chiefly in Farther India, and provide means of conveying it to the distressed districts, including the building of a railway 45 miles long. For a long time 3,900,000 persons received daily support—650,000 in the form of alms, 1,800,000 in the form of pay for work, and the rest in the form of loans. This relief was continued from Oct., 1873, till Dec., 1874; the expenses of the Government amounted to £6,500,000, while private subscriptions yielded £280,000 more, large donations having been sent from all parts of the British empire. Thus, through the prompt action of the Government, a great famine, in which the people of themselves would have been helpless, was averted, with a record of only twenty-five deaths from actual hunger.

While the Indian authorities were discussing the most effective means of preventing a repetition of this calamity, a new famine, caused by insufficient rainfall, began to threaten the Deccan, in Southern India. The crops yielded only one-sixteenth the average harvest, and the threatened district had a population of about 8,000,000. The Government left the supply of food to private speculation, and confined itself to giving alms and providing work. In Jan., 1877, support in the form of pay for labor in public work was given to 1,500,000 persons, and the public debt of the country was increased on account of the famine by £5,000,000.

The famine in Persia from 1870 to 1873 extended over the whole country. More than 1,500,000 people died. To add to the general distress, the Turcomans of the desert took advantage of the calamity, invaded the country several times, and carried away more than 20,000 Persians to the slave-markets of Khiva and Bokhara.

The interior provinces of Asia Minor—for instance, Angora and Konieh or Iconium, situated immediately to the S. of Angora—suffered severely from 1873 to 1875. On account of the drought, 2,500,000 oxen and horses and 528,000 goats died in Angora; the number of persons who starved to death varied in the different provinces from 6,000 to 20,000.

The European country which has suffered from famine in modern times is Russia. There was a severe general famine in 1833; one in the central provinces in 1840; in the western provinces in 1844–46; in the south in 1867–68; in the Volga region in 1872; in the central provinces in 1880; and throughout the center and east in 1891–92. The famines of 1833 and 1891–92 have been the worst. The latter was due to the failure of the rye crop on account of drought, to the general poverty, and to the insufficient means of transportation to the most afflicted districts. It was general in thirteen provinces and partial in five others, the population affected by it being estimated at 27,000,000. It was signalized by more efforts at relief than the earlier, and the contributions from the U. S. to this end were large and generous. But the difficulty lies too deep for superficial measures of relief. It is found in the inferior economic organization of Russia. The deficiency in the harvest of 1891 was only 20 per cent.—about the same as the deficiency in the U. S. wheat crop of 1885. Yet there was no famine in the U. S.; partly because of the free communication between different parts of the country, partly because of forethought, which had accumulated supplies from past years. A comparison of these two cases shows better than anything else the reason why famine disappears with advancing civilization.

Deaths in times of famine occur quite as often from famine types of disease as from starvation. Thus relapsing fever is so characteristic of famines as to be called famine fever. Typhus and cholera follow on the weakness that results from insufficient food, and where drought is the main cause, the concentration of bad elements in the water engenders other destructive diseases.

The following table shows the most noted famines mentioned in history:

B. C.
1708–01. Egypt.
436. Rome.
A. D.
42. Egypt.
262. Rome.
272. Britain.
306. Scotland.
310. England.
370. Phrygia.
450. Italy.
739. Britain.
823. The same.
954–58. The same.
1005. England.
1016. Europe, generally.
1051. Mexico.
1052–60. Ghor, India.
1064–72. Egypt.
1069. England, north.
1087. England.
1193–95. England and France.
1251. England.
1314. Silesia, Poland, and Lithuania.
1315. England.
1335. England.
1344. Deccan, India.
1347. Italy.
1353. England and France.
1438. England.
1491. Ireland.
1565. British isles, generally.
1586–89. Ireland.
1600. Russia.
A. D.
1631. India, Asia generally.
1693. France.
1711. Carniola, Austria-Hungary, several years.
1748. British isles, generally.
1769–71. Bengal.
1775. Cape de Verde.
1781–83. Carnatic and Madras.
1772–84. Northwest Provinces, India.
1789. France.
1790–91. India.
1795. England.
1801. British isles, generally.
1813. Drontheim, Norway.
1814, 1816, 1822, 1831, and 1846. Ireland.
1837–38. India, northwest.
1860–61. The same.
1865–66. Bengal and Orissa.
1868–69. Rajputana, India, northwest.
1870–73. Persia.
1873–74. Bengal.
1873–75. Angora and Konieh, Asia Minor.
1877. Bombay, etc., India.
1877–79. Northern China.
1879. Kashmir.
1880. Asia Minor.
1888–89. Northern China.
1891–92. Russia.
1896–97. India.
1900. India.

Fanar′iots: See Phanariots.

Fancinlli, Francesco: See the Appendix.

Fancy [M. Eng. *fantasy*, from O. Fr. *fantasie*, *fantaisie* < Lat. *phanta′sia* = Gr. φαντασία, appearance, imagination]: a term used sometimes as synonymous with Imagination (*q. v.*); but better practice appears to conform more or less closely to that of Dugald Stewart, who says: "The office of this power is to collect materials for the imagination; and therefore the latter power presupposes the former, while the former does not presuppose the latter."

Fandan′go: a national dance of Spain and Spanish America, usually in 3–4 or 6–8 time. It is thought by some to have been introduced by African slaves into the colonies, and thence carried to Spain. It is very popular, and is danced generally to the guitar and the castanets.

Faneuil, făn′el or fŭn′el, **Hall**: a building in Dock Square, Boston, Mass.; built in 1742 by Peter Faneuil, a merchant of the city (b. at New Rochelle, N. Y., 1700; d. in Boston, Mar. 3, 1743), and given to the town. It was burned in 1761, its walls of brick remaining. It was rebuilt in 1763, at the expense of the town. It is called the "Cradle of Liberty," from the fact that the "Sons of Liberty" held many meetings there during the early years of the final struggle of the colonies with the mother country. The British troops, during the occupation of the city, used it as a theater. In 1805 it was made 40 feet wider and one story higher. The hall, which is used for public meetings, is about 80 feet square, and contains several good paintings, including *Webster replying to Hayne.*

Fanino, fa̤ă-nee′nō, or **Fannio**, Faventino: one of the earliest martyrs during the Reformatory period in Italy; a native of Faenza, then in the papal dominions. He was won over to the Protestant cause by the reading of the Scriptures (probably Bruccioli's version, 1532) and of Protestant apologies, and became so enthusiastic for the new religion that he gave himself to proselyting efforts, which came to the ear of the ecclesiastics, and he was imprisoned. Being the head of a family, he was persuaded to recant for the sake of his wife and children. Upon his release, however, he became dejected in mind, and found peace only in the resolve to openly battle for liberty of conscience; and he set out on a tour through the Romagna, preaching everywhere the Reformed religion. He was arrested in 1548 at Bagna Cavallo, and conducted in chains to Ferrara. During his imprisonment he was visited by many distinguished Italians, among them the Princess Lavinia della Rovero and Olympia Morata, who were edified by his instruction and prayers, and took a deep interest in his fate. But his repeated and emphatic refusals to recant caused his condemnation to the stake by Pope Julius III. Fanino was strangled at dawn and his body burned at noon in Sept., 1550. See for interesting details Young, *Life of Paleario*, ii, 111; McCrie, *History of the Reformation in Italy*, pp. 259–261.

Fanning, Col. David: Tory leader in American Revolution; b. in Wake co., N. C., about 1756; became the leader of a band of Tories or loyalists, chiefly of Chatham and Randolph Counties, who during the later years of the war of the Revolution performed in Central North Carolina many daring exploits, tarnished by wholesale cruelty and the desolation of settlements. In 1781 he took the town of Pittsborough, and soon after Hillsborough, then the State capital, carrying off Gov. Burke and his whole suite. He was one of the three persons excluded by act of the North Carolina Legislature from the amnesty proclaimed after the peace; escaped into Florida, traded with the Indians, made his way to New Brunswick, and thence to Digby, Nova Scotia, where he died in 1825. He wrote a curious *Autobiography* (limited eds. Richmond, Va., 1861, New York, 1865).

Fanning, Edmund, LL. D.: b. on Long Island, 1737; graduated at Yale College 1757; settled in Hillsborough, N. C., and became colonel of militia, clerk of the superior court, and a member of the Legislature; by his exactions as recorder of deeds for Orange County provoked the hatred of the people, and in 1771 went to New York with Gov. Tryon, who was his father-in-law. He took part against the people in their struggle for independence of Great Britain, and in 1777 raised and commanded the king's American regiment of foot. In 1779 his property was confiscated. After the war he was appointed councilor and lieutenant-governor of Nova Scotia, and governor of Prince Edward island (1786–1805). He was successively major-general, lieutenant-general, and general in the British army, and received the degree of D. C. L. from Oxford in 1774, and that of LL. D. from both Yale and Dartmouth in 1803. D. in London, Feb. 28, 1818.

Fanning, John Thomas: civil engineer; b. in Norwich, Conn., Dec. 31, 1837. He was educated in the schools of Norwich, and afterward studied architecture and civil engineering. During the civil war he served with the Third Regiment of Connecticut volunteers. From 1862 to 1871 he was acting city engineer of Norwich. From 1872 to 1886 he held a similar position at Manchester, N. H. In 1886 he removed to Minneapolis, Minn., where he has since resided. He has been a consulting engineer of many water-powers, of the drainage commission of the valley of the Red River of the North, and of railway enterprises. He is the author of a *Treatise on Water Supply Engineering* (1877; 10th ed. 1892). He is an ex-president of the American Water-works Association.

Fanning Islands: See the Appendix.

Fanning-machine, or **Fanning-mill**: an agricultural implement for winnowing grain, operated by machinery or by the hand. The principal feature is a rotary fan. As the grain passes through the sieve in which it is agitated, the strong current of wind produced by the fan cleanses it thoroughly from chaff. Anciently, the wind was the agent chiefly employed for separating chaff and dirt from grain; and the *mys-*

tica vannus Iacchi, like the winnowing fan of the Bible, seems to have been at first a mere shovel for throwing up the grain and exposing it to the action of the wind. A machine for winnowing grain was invented in Scotland in 1737 by Andrew Rodger, a farmer of Roxburghshire, but though it in every respect far excelled the old method of winnowing by throwing the grain across the threshing-floor, its introduction met with great opposition, because the raising of wind by human art was believed to be an impious act. There have been many improved forms invented, especially in the U. S.

Fan'nius Stra'bo, Gaius: son-in-law of Lælius; introduced by Cicero as one of the speakers in his works *De Amicitia* and *De Republica*; served in the Third Punic war under Scipio Africanus (B. C. 149–146); was distinguished as an orator, and was one of the earliest Roman historians who wrote in Latin. His *History* treated of contemporary events, and the eighth book is referred to, though the extent is not known. An epitome of it by M. Brutus is mentioned by Cicero. The few fragments remaining are collected in H. Peter, *Hist. Rom. Fragm.*, pp. 87–89. (See Gerlach, *Geschichtschreiber der Römer*, pp. 70–71, and Hirschfeld, *Die Annales des C. Fannius, Wiener Studien*, vi. 127.) This Fannius is now identified with C. Fannius Strabo, who was consul B. C. 122, and from whose speech on the allies and Latins, directed against Gracchus (praised as good and noble by Cicero), certain fragments are preserved. These are given by Meyer, *Orat. Rom. Fragm.*, pp. 199–200.

Revised by M. Warren.

Fano, faa'nō: seaport of Central Italy; province of the Marches; on the shore of the Adriatic, lat. 43° 51′ N., lon. 13° 1′ E.; 30 miles N. W. of Ancona (see map of Italy, ref. 4–E.) It is a well-built and beautifully situated town, containing a cathedral with paintings by Domenichino and Guido, and the remains of a triumphal arch of white marble erected in honor of Augustus. There is a large trade in corn, oil, and silk goods. Pop. 22,000.

Fans [Ang.-Sax. *fánn*, from Lat. *vannus*, which is akin to *wind*]: implements used to agitate the air for coolness, and apparently in use from the remotest times with all people living in hot or warm climates. China, however, is generally called the fatherland of the fan, and there and in Japan it is as indispensable to a gentleman as his boots. It is used in different ways, even as a newspaper, since on important occasions news, libels, and political caricatures are transmitted on it. The common palm-leaf fan is generally supposed to be the oldest form of this implement, as it is still by far the best for simple utility. It is manufactured in immense quantities in China, especially at Canton and Nankin, where also fans of great elegance are produced from bamboo, palm leaf, silk, sandal-wood, tortoise-shell, and ivory. A very singular style of Chinese fan consists of a round paper disk mounted in a split handle on a pivot like a wheel. When not in use it is turned around and folded up, so as to make a straight stick. In Persia, Egypt, Greece, and Rome fans were known at a very early period, and in each country they attained great elegance. The Egyptians carried a peculiar fan made of a bird's wing extended, such as are beautifully manufactured by the Chippeway Indians. From a passage in Euripides it appears that Greek fans were round and made of feathers, and when the peacock was introduced into Greece (about 500 B. C.) the people began to use its plumes for fans. In Herculaneum there is a fresco representing a youth holding a peacock fan. The Roman fan for ladies was often made of thin tablets of perfumed wood; and as branches of myrtle, acacia, and palm were the first fans or materials for them, these shapes were preserved in imitations for centuries. A fan with a wooden handle, and a *feuille* provided with a picture of a love-affair or a view of a city, with a corresponding inscription, was much in use in Italy during the Middle Ages. In a work of costumes which appeared at Venice in 1664, containing plates of several hundred dresses, especially those worn in Lombardy from the eleventh century, women often hold fans, some of them of very eccentric shapes. The *tuft*-fan of peacock's feathers was set on an ivory handle adorned with gems, and one like this, but with a horse's tail, appears on the sculptures of Persepolis. In the list of articles in Queen Elizabeth's wardrobe twenty-seven fans are enumerated, one of which cost £40, and about 1660 the manufacture was quite extensive in England, as appears from a petition of the fan-makers, who complained that, 550,000 fans having lately been brought over, "great numbers of poor people, continually employed in the work, must perish unless a stop be put to the importation." In 1660 a protective duty of 40*s*. per dozen was imposed on fans, and the importation of all painted fans was prohibited. The folding fan was introduced in France by Catharine de Medicis, and under Louis XIV. the manufacture became a great industry. Those who exercised it formed a corporation, established in 1673, and four years of apprenticeship were required, though the masters who made this regulation wisely set it aside in favor of their own sons or of any man who should marry their daughters or widows. One of the most original patterns of French fans was the so-called Pompadour, consisting of brins without *feuilles*, and forming, when opened, a beautiful oval. During the Revolution fans went out of fashion, but in the nineteenth century the manufacture revived and has become very prosperous. Large quantities of costly fans are produced in Paris, made of what is called chicken skin (a very thin yet tough preparation of kid skin), satin, gauze, tulle, crape, or parchment, and provided with beautiful pictures by well-known artists, priced at from £50 to £130. Large numbers of these fans are exported to Spain, where the fan is as essential an article as in China or Japan. The native Spanish product, however, is rather coarse and ungainly, and, although Spain has laid a heavy duty on French fans, the Spanish workmen are yet not able to compete with the French. A fine exhibition of fans was held at the South Kensington Museum, London, in 1870. The Empress of France, who had been instrumental in developing this branch of industry, as of all kinds of luxury in dress, sent to it all her finest fans, thirty-four in number. See works by Blondel (Paris, 1875); Uzanne (Paris, 1881; Eng. trans. London, 1883); and Lady Charlotte Schreiber (2 vols., London, 1889–91).

Charles G. Leland.
Revised by F. H. Groome.

Fans, otherwise called **Fanwe, Panwe**, and **Osheba**: a cannibal race found upon the Gaboon river and to the northeast over an extensive area in equatorial Africa. They are coffee-colored, have rather thin lips, and are slight of frame. They are cannibals for ceremonial purposes, use poisoned arrows and the crossbow, and are fast becoming the dominant people of that region, where they first appeared about 1842.

Fanshawe, or **Fanshaw**, Sir Richard, D. C. L.: diplomatist and translator; b. at Ware, Hertfordshire, England, 1608; studied at Cambridge; and was minister resident at the court of Spain under King Charles I. of England. He was a royalist, and at the battle of Worcester, 1651, was taken prisoner and kept captive for years. He was privy councilor of Ireland 1661; the same year ambassador to Portugal, and negotiator of the marriage between Charles II. and the Princess Catharine. In 1664 was ambassador to Spain. D. in Madrid, June 16, 1666. His translations were Guarino's *Pastor Fido*, *The Lusiad* of Camoens, etc.

Fantail: See Pigeon.

Fanta'sia [Ital., fancy < Lat. *phanta'sia* = Gr. φαντασία. See Fancy]: in music, a species of composition nearly identical with the cappriccio, in which writers express their thoughts with the highest freedom compatible with an observance of the fundamental laws of harmony. Originally, the fantasia was probably nothing more than simple improvisation—a transient, unstudied, and unwritten effusion of the performer's fancy. But as extempore playing naturally leads to the recording of the ideas, themes, and general course of thought pursued in any successful effort, the transition was easy to the writing, at leisure, of compositions resembling improvisations in peculiarities of movement, form, modulation, expression, and harmony. In many of these compositions writers give free play to the impulses of a luxurious fancy, regardless of method and design, but still preserving a certain continuity of outline amid much that is wild, rugged, and abrupt. The term "fantasia," however, is now often given to compositions which are nearly regular in form and harmony.

Revised by Dudley Buck.

Fan'ti, or **Fantee**: a tribe, and the country it inhabits in Western Africa; on the Gold Coast. The country consists of a small strip of land extending along the Atlantic from Accra on the E. to Cape Coast Castle on the W., and separated N. from the country of the Ashantees by a belt of impenetrable forests crossed only by a few narrow and intricate paths. But this strip of land is very fertile, densely peopled, and rich in gold-dust. The inhabitants belong to the same family and speak nearly the same language as the Ashantees, though they are inferior to them both in skill and vigor. They succeeded, however, in defending their independence. They started an individual civilization. They built large cities, such as Yankumasi, Abrah, Annamabu, etc., and they began trading and manufacturing. But early in the nineteenth century they came in contact with the British, who built a fort and established a commercial station at Cape Coast Castle. Their labor became subservient to English enterprise and speculation. Their political organization became weakened and almost dissolved under English influence and authority. Their civilization faded away, and they became a prey for the Ashantees, who in their turn were conquered by the British. See ASHANTEE.

Fantin-Latour, fäaṅ'tăṅ'läa'toor', HENRI: portrait and genre painter; b. at Grenoble, France, Jan. 14, 1836. Pupil of Lecocq de Boisbaudran; medal, Salon, 1870; second-class medal, Salon, 1875; Legion of Honor 1879. A talented, conscientious painter whose work has not attracted wide attention until recent years; his portraits are notable for their air of truth and quiet, reserved style. *Homage to Delacroix* (1864) is one of his celebrated portrait groups. Studio in Paris. W. A. C.

Fantoccini, făn-to-chee'nē: See MARIONETTES.

Fan-tracery: the tracery-like system of ribs forming panels in English FAN-VAULTING (*q. v.*).

Fan-vaulting: a species of vaulting peculiar to the English Gothic of the fifteenth century; so named from the fan-like radiation of groups of ribs from the caps of the vaulting-shafts. Each group forms a kind of inverted semicone with curved sides; the bases of these semi-cones, meeting at points along the ridge of the vault, inclose between them horizontal lozenge-shaped panels. Cusps and foils adorn the panels left between the ribs. Among the finest examples are the chapels of King's College, Cambridge; St. George at Windsor; and Henry VII. at Westminster Abbey. See illustration under ARCHITECTURE (Fig. 42).

Revised by A. D. F. HAMLIN.

Farad [from MICHAEL FARADAY (*q. v.*) the electrician, in recognition of his classical researches in static electricity. For the method of naming, see OHM, AMPÈRE, VOLT, etc.]: the practical unit of electrostatic capacity. It is the capacity of a condenser such that the introduction of a charge of one coulomb of electricity will produce a difference of potential of one volt between the coatings. A *farad* is one-thousand-millionth of the absolute unit of capacity (c. g. s. system). A *micro-farad*, a lesser unit, the size of which renders it of much more general application than the farad, is one-millionth of the latter. The capacity of the ordinary condenser is a micro-farad or a simple multiple of it.

E. L. NICHOLS.

Far'aday, MICHAEL, D. C. L., F. R. S.: scientist; b. at Stoke Newington, near London, Sept. 22, 1791. His father was a blacksmith, and his own education he describes as being "of the most ordinary description, consisting of little more than the rudiments of reading, writing, and arithmetic." In 1804 he became an errand-boy to a bookbinder, and in 1805 he was taken as an apprentice. He read many of the books he bound, especially Mrs. Marcet's *Conversations on Chemistry* and the articles on electricity in the *Encyclopædia Britannica*. He also made electrical experiments, and went occasionally to evening lectures on natural philosophy, and in order to draw the apparatus employed he took lessons in perspective. After his apprenticeship he worked for a time as a journeyman bookbinder, and as amanuensis for Sir Humphry Davy, who had become interested in him.

On Mar. 18, 1813, Davy reported to the managers of the Royal Institution his engagement of Faraday at weekly wages. Faraday subsequently traveled with Davy on the Continent, returning to the institution in 1815. Not long after he became connected with the City Philosophical Society, where he sometimes lectured.

Three years after his appointment in the Royal Institution he made his first published contribution to science: it was an analysis of some caustic lime from Tuscany. Both skill and insight are revealed by a short paper on sounding flames published in 1818. Other smaller contributions followed. In 1820 a chemical paper opened the long series with which Faraday subsequently enriched the *Philosophical Transactions*.

Oersted's discovery in 1820 directed all minds to the interaction of magnetism and electricity. In 1821 Faraday wrote *A History of the Progress of Electro-Magnetism*, and, thus prepared, he succeeded on Christmas morning, 1821, in making a magnetic needle rotate round a wire carrying an electric current. To Faraday's intense annoyance it was whispered that he had plagiarized the experiment from Wollaston, but he completely cleared himself of this charge. In 1823, aided by suggestions from Davy, he liquefied chlorine and other gases. In 1824 Faraday was elected a fellow of the Royal Society. In 1825 and 1826 he published chemical papers in the *Philosophical Transactions*. In one of these he announced the discovery of benzol, which afterward became the basis of aniline dyes. From 1825 to 1829, in conjunction with Herschel, he tried to improve the manufacture of glass for optical purposes. Practically considered, this investigation was a failure, but the "heavy glass" they produced led afterward to two of Faraday's greatest discoveries. In 1827 he succeeded to Davy's chair of Chemistry in the Royal Institution.

Disciplined and strengthened by his previous work, Faraday, in 1831, made his great discovery of magneto-electric induction, opening thereby a vast and novel electrical domain. Enigmas which had previously challenged and defeated the efforts of the greatest men ceased to be enigmas. The magnetism of rotation, for example, discovered by Arago and experimented on by Babbage and Herschel, was shown to be due to a special manifestation of Faraday's induced currents. In the paper here referred to he for the first time calls the "magnetic curves" formed when iron filings are strewn around a magnet "lines of magnetic force." All his subsequent researches upon magnetism were made with reference to those lines. They enabled him to play like a magician with the magnetic force, guiding him securely through mazes of phenomena which would have been perfectly bewildering without their aid. The spark of the *extra current* had been noticed by Prof. Joseph Henry, and independently by Mr. William Jenkin. Faraday at once brought this observation under the yoke of his discovery, proving that the augmented spark was the product of a secondary current evoked by the reaction of the primary upon its own wire.

The desire to refer diverse natural energies to unity of principle is the strongest of the scientific mind, and in 1833 Faraday proved experimentally the "identity of electricities." He then passed on to electric decomposition, both by the machine and the pile, and was led to conclude, though he was almost afraid to publish the conclusion, that the amount of electricity involved in the decomposition of a single grain of water equals that produced by 800,000 discharges of his large Leyden battery. In May, 1833, he published a paper on a *New Law of Electric Conduction*, in which he forcibly showed the influence of the "state of aggregation" on the transmission of the current. This led him to a profound consideration of the subject of electrolysis. Again, in June, 1833, he published a paper on this subject, and in the same year another entitled *On the Power of Metals and other Solids to Induce the Combination of Gaseous Bodies*.

Far more important, however, was the establishment of the doctrine of "definite electro-chemical decomposition." He included in the same circuit water and fused chloride of tin, and found that for every atom of hydrogen and oxygen liberated in the one cell there is an atom of tin liberated in the other. With the indications of his voltameter he compared the decompositions of other substances, both singly and in series, and after submitting his conclusions to numberless tests he finally established the truth, "that under every variety of circumstance the decompositions of the voltaic current are as definite in their character as those chemical combinations which gave birth to the atomic theory."

With regard to the origin of power in the voltaic pile scientific opinion had been divided. Volta found the source of power in the contact of heterogeneous metals, and he proved beyond a doubt that electricity arises from such contact. Faraday's experience had showed him that chemical action was the invariable accompaniment of the current; it had led him to conclude that the one was proportional to the other, and therefore forced upon him the conviction that the "contact theory," as maintained by Volta, was a delusion. The origin of power in the pile he referred to its chemical actions. He thus became the strongest pillar of the "chemical theory," which had been previously enunciated by Fabroni and Wollaston. His researches in frictional electricity occupied him from 1836 to 1838. He entered with keen insight into the subject of conduction and induction, regarding both from a wholly original point of view. One of his principal results was the establishment of the specific inductive capacity of insulators—a subject of supreme importance in connection with submarine cables. As a striking illustration of Faraday's insight, it may be mentioned that as early as 1838 he had virtually foreseen and predicted the retardation produced by the inductive action between the wires of submarine cables and the surrounding sea-water.

Toward the close of 1840 Faraday broke down, and for two years was prohibited from working. He went to Switzerland in 1841, and slowly improved after his return. He knew that polarized light was a most subtle investigator of molecular condition, and he had tried it frequently in investigating the state of electrified bodies. He placed a piece of his heavy glass between the poles of an electro-magnet. Including both magnet and glass between two Nicol prisms, he sent a beam of light through the system. When the prisms were parallel the light was transmitted—when they were crossed the light was cut off. On exciting the magnet in the case of the crossed prisms, the light was instantly transmitted, and one of the prisms had to be turned through an angle depending on the strength of the magnet and the length of glass traversed to again quench the light. The experiment proved that by the act of magnetization "the plane of polarization" is caused to rotate. Faraday proved the direction of the rotation to be determined by the polarity of the magnet, being reversed when the polarity is reversed. He also proved that the voltaic current exercised a similar power. He pointed out the difference between this effect and the rotation of the plane of polarization by quartz and certain other bodies, and entitled his discovery "the magnetization of light."

This was the first reward of Faraday's long and apparently futile inquiry on the manufacture of optical glass. His second reward was the discovery, in 1846, of diamagnetism, the name given to a force of repulsion exerted by a magnet on the great majority of known bodies. He called it diamagnetism because an elongated diamagnetic body acted upon a magnet sets *across* the lines of magnetic force, while a paramagnetic body, like iron, sets parallel to the lines of force. He pushed his inquiries in diamagnetism into the heart of the subject. Faraday's antecedent culture and his notions regarding molecular force are strikingly illustrated by this inquiry and the subsequent one on magnocrystallic action. To these discoveries succeeded his investigations on the magnetism of gases, his elaborate papers on atmospheric magnetism (1851), his speculations on the nature of matter and force, and his researches on "lines of magnetic force, their definite character, and their distribution within a magnet and through space"—inquiries marked by profound insight and illustrated with refined experimental skill. In 1835 Faraday was pensioned. He was throughout life a devout Christian, and was a member of the small body of Christians called Sandemanians. D. at Hampton Court, Aug. 25, 1867. See *Life* by Tyndall (4th ed. 1884) and *Life* by J. H. Gladstone (1892). JOHN TYNDALL.

Faradization: in medicine, the application to the animal frame of induced currents of electricity. The name faradic electricity is applied (1) to the alternating current from any small "magneto-generator" in which currents are induced by the movement of coils of wire in a magnetic field; (2) to the secondary currents of a small induction coil. The primary circuit coil is usually fed from a few cells of primary or storage battery, and variations in the character and strength of the induced currents are obtained either by changing the speed of the interrupter by the use of various secondary coils, different windings, or by adjustment of the iron core of the coil. The term faradic battery is applied to both of the above types of apparatus.

The best methods for making use of faradism in therapeutics were discovered by Dr. Duchenne, a physician of Paris. It is used for two purposes: (*a*) to produce muscular contractions (passive exercise); (*b*) to excite the nerves of sensation. The first object may be attained in two ways—first, by placing both electrodes (ends of insulated conductors armed with sponge, of various shapes) upon the moistened skin covering the muscles to be contracted; or, second, by placing one electrode as above and the other over the nerve-trunk which sends branches to that muscle. To excite the nerves of sensation, a portion of skin should be made dry by means of starch-powder, a wire-brush electrode held upon or drawn lightly over this dry skin, while the other sponge electrode is held (wet) on the integument not far away. The current can be made to reach the internal organs (bladder, uterus, etc.) by means of peculiarly shaped electrodes. The popular use of faradism by holding both electrodes in the hands is worthless.

Revised by E. L. NICHOLS.

Farallo'ne Islands: a group of six small, lofty, and rocky islands of San Francisco co., Cal.; lying in the Pacific Ocean; 30 miles W. by S. of the Golden Gate, or entrance to San Francisco Bay. They are owned by a company, which here collects, for the San Francisco market, the eggs of the gull and the murre, a sea-bird of the auk family. The southeasternmost and largest island (lat. 37° 41′ 49″ N., lon. 122° 59′ 5″ W.) has a lighthouse, with a flashing white light of the first order, 360 feet above the sea. The islands breed great numbers of rabbits, and their coasts abound in sea-lions.

Farce [Fr. *farce*, orig. meaning stuffing, deriv. of *farcir* < Lat. *farcire*, to stuff]: a peculiar kind of comedy in which the characters are without psychological truth and the plot without moral impression. When in a comedy the *dramatis personæ* are not characters representing complete mental organisms, but figures representing only one single feature of the human mind, and when the situations of which the plot consists are formed without any intention of imitating life, but so as to show off this single mental feature in its most extravagant appearance, a high degree of comical effect can be attained; and there is in the principle itself on which the farce rests no reason why its comical effect should not be accompanied with perfect elegance and gracefulness. The farce originated in the Southern European countries from rustic festivities, in which masks and every other description of disguise were used. There are traces of it in the so-called Fabulæ Atellanæ, far back in the days of the old Roman republic, and it is met with now and then during the Dark Ages, until in the sixteenth century it enters the stage, where it led a brilliant life under the name of *commedia dell' arte*, as a kind of improvised drama. Molière introduced it among the arts. Many of his plays are simply farces. But after his time it was utterly neglected, and degenerated into comedy for the mob, and it showed no signs of revival until the middle of the nineteenth century. The present French farce is often indecent, but its mirthfulness can not be denied. It needs only some purification to be brilliant art.

Farcy [corrup. of M. Eng. *farcin* < O. Fr. *farcin*, a disease of horses: Ital. *farcino*, from deriv. of Lat. *farci're*, cram]: the more chronic form of glanders; a disease attacking horses, asses, and mules, and from them transmissible to men. This disease is highly contagious, and thus far generally incurable. Farcy differs from glanders in having a slower course, and in involving the skin and lymph glands, whereas glanders affects particularly the respiratory tract. It is characterized by the formation of tumors involving the glands of the lymphatic system alone (button farcy), the glands and the adjacent areolar tissue (bud farcy), or the lymphatic vessels (farcy pipe), and is followed by fever. Where farcy runs a somewhat rapid course it is generally fatal; while if its course proves very slow a recovery may be looked for, at least in man. Glanders, however, which is the same disease, primarily attacking the nasal mucous membrane instead of the lymphatics, is almost always fatal. The treatment of acute cases is palliative chiefly; that of very chronic ones is expectant, the strength being maintained by nutritious food. In horses the disease is most common in those which are overworked, exposed to the weather, and kept in ill-ventilated stables. Farcied horses should be killed at once, without any attempt at treatment. See GLANDERS. Revised by WILLIAM PEPPER.

Fardel-bound [M. Eng. *fardel*, from O. Fr. *fardel* > Fr. *fardeau*, bundle, burden < Mediæv. Lat. *fardellus*, pest, from Arab. *far'd*]: a disease of sheep and neat cattle, known in its milder form as "loss of cud." The animal refuses to chew the cud, is stupid, feverish, has a dry nose, and sometimes grunts as if in pain. The disease is an irritation or inflammation of the third stomach (*omasum*, manyplies, or fardel), the folds of which are dry and often inflamed. Sometimes this organ is impacted with food. The treatment is gentle purgation, as with Epsom salts, followed by liquid food, such as mashes sweetened with molasses and flavored with a little ginger. As a preventive, avoid the use of coarse and overripe hay. The animal will generally recover within three weeks.

Farel, fāā'rel', Guillaume: the boldest of the French Reformers and father of Swiss Protestantism; b. in a little hamlet near Gap, in Dauphiny, in 1489. His parents, Roman Catholics of noble descent, subjected him to rigid religious training, and intended him for the army. But the boy gave himself to study, and when all opposition seemed fruitless he was suffered (about 1500) to set out for Paris, there to study philosophy, Greek, and Hebrew at the university. The shining light of the Paris school was at that time the brilliant Jacques Lefèvre d'Estaples (Faber Stapulensis), around whom were gathered disciples from every country. Young Farel became one of the most devoted of these. This illustrious connection was, moreover, the means of withdrawing Farel from obscurity and securing him a large circle of acquaintance and a chair in the College of Cardinal le Moine. Farel had accepted the views of his instructor, and was therefore in danger from persecution. In 1521 Lefèvre retreated to Meaux, but Farel remained in the capital, and for a time boldly continued to maintain his cause with professors, priests, students, and citizens, wherever he could do so, in the university and in the city. The doctors of the Sorbonne, however, proved the stronger party, and Farel soon found it expedient to join Lefèvre at Meaux. Here also persecution found them out, and "the heretics of Meaux" were obliged to quit the town. Farel dared to return to Paris, but, finding himself in great danger, retired to Dauphiny. His three brothers became converts, and many adherents were gathering when the authorities, civil and ecclesiastical, combined against him, and he was obliged to quit the vicinity of Gap. He now visited other parts near the foot of the Alps and labored successfully. His life becoming endangered, he crossed over, early in 1524, into Switzerland, where he was warmly welcomed by the Reformers. He tarried for a while at Basel, making his home with the learned Œcolampadius, who was charmed "with the learning, piety, and courage of the young Frenchman." Basel was at this time much exercised by the religious innovations prevalent there, but officially no action had been taken in favor of the Reformed doctrines. Farel published thirteen theses covering the chief points of dispute, and defended them publicly without answer from the Romanists. In consequence the Reformed doctrines became quite popular, and their success might have been established had not Farel fallen into angry dispute with Erasmus, whom he charged with cowardice and named a Balaam, and who in return called him a disturber of the peace and advised the council to expel him. He left Basel in May, 1524, and repaired to Schaffhausen, Zurich, and Constance. On his return to Basel he was ordered to leave the place. He retired to Strassburg, and there enjoyed the companionship of Capito and Bucer until secretly recalled to Basel to be set apart by Œcolampadius for the ministry at Montbéliard. Farel had from the first been rather turbulent. After he was installed as a priest his intemperance in language and conduct soon made him an object of much hatred. He was driven from his parish in the year 1525. After a brief visit to Œcolampadius, Farel joined Capito and Bucer at Strassburg, where he had another meeting with his beloved teacher, the saintly and now aged Lefèvre. In 1527 he went to Aigle, where he taught school, at first under an assumed name (*Ursinus*), but no sooner had he secured a sufficient hold on the people to warrant his safety than he boldly made known his real mission, and when Berne became Protestant (1528) extended his labors throughout its territory. He communicated his zeal to the Switzers, and by 1531 secured the reformation not only of the western cantons, but also "caused the balance to incline in favor of the new doctrines throughout the confederation." Sent to the Waldenses, then in synod in the valley of Angrogna, he returned in 1532 by way of Geneva, which was at this time agitated by great religious strife. Though a stranger, he dared to preach while in the city. In consequence he was driven from the place, and only escaped with his life by the bursting of a gun that was aimed at him. He returned again in the next year and was again expelled. Still undaunted, he returned a third time, and was successful. The new doctrines were now largely heard and accepted. Farel was full of toil, and his triumph came Aug. 27, 1535, when the city council, by special edict, proclaimed Geneva as an adherent to the Reformation. In 1536 his cause was strengthened by a visit from Calvin, who was persuaded by Farel to take up his residence at Geneva. Farel and Calvin henceforth labored unitedly for the good of the Genevese; Calvin, by common consent, assuming the leadership in ecclesiastical organization. These men found an able assistant in Viret. In consequence of their bitter attack on the sensuality which many of the Genevese had fallen subject to under Savoyard rule, and the strict enforcement of ecclesiastical discipline, the Reformers became unpopular, and (Apr., 1538) were expelled from the city. They went together to Berne, Zurich, and Basel, where they separated, Farel going to Neuchâtel, whose Reformed society was then in deplorable disorder. Farel soon restored harmony (1542). He went to Metz to organize a society, but was persecuted, and finally obliged to retire to the neighboring town of Montigny, and afterward to Gorze, where he enjoyed the protection of Count Fürstemberg. Attacks upon his life caused his removal to Strassburg, and ultimately his return to Neuchâtel, where he married, when sixty-nine years old, a young wife, very much to Calvin's disgust. In 1560 he visited his native Dauphiny, and at Gap by his bitterness excited the rabble, who put him in prison, from which he was rescued by his friends. He now returned to Neuchâtel, and died there Sept. 13, 1565. See Kirchhofer, *Life of Farel* (in German, 2 vols., Zurich, 1831–33; in English, London, 1837); Blackburn, *Farel and the Story of the Swiss Reformation* (Philadelphia, 1865).

Revised by C. K. Adams.

Farewell, Cape: See Cape Farewell.

Fargo: city and railway center; capital of Cass co., N. Dak. (for location of county, see map of North Dakota, ref. 3–G); situated on the Gt. Northern, Ch., M. and St. P., and Northern Pacific railways, and on the west bank of the Red River of the North; at the head of navigation, opposite Moorehead, Minn. It has a Young Men's Christian Association building, two high schools, a Roman Catholic academy, a Congregational college, a U. S. land-office, the Holly system of water-works, sewers, gas, and electric lights, and a telephone system. It is one of the most important markets for wheat and farm machinery in the Northwest. The city suffered severely from fire June 7, 1893; the loss was estimated at $3,000,000. Pop. (1880) 2,693; (1890) 5,664; (1900) 9,589.

Editor of "Argus."

Farias, Valentin Gomez: See Gomez Farias.

Faria y Sousa, fāā-ree'āā-ee-sō'zāā, Manuel, de: historian and poet; b. at Pombeiro or Souto, Portugal, Mar. 18, 1590; studied at Braga; entered the service of the Bishop of Oporto; was envoy to Rome 1630–34; and spent the rest of his life in Madrid, where he died June 3, 1649. His historical works are his *Epitome de las historias portuguesas* (Madrid, 1628); his *Europa portuguesa* (3 vols.), *Asia portuguesa* (3 vols.), and *Africa portuguesa*, published at Lisbon, 1678–80, and containing valuable information in regard to the political and intellectual history of Portugal; and his commentary on the life and works of Camoens (4 vols., Madrid, 1639), a work which can lay no claim to trustworthiness. He is also the author of a number of moral dialogues, characterized, as are indeed all his works, by a very pedantic and tedious display of learning. These dialogues were published at Madrid in 1624, under the title *Noches claras, Primera parte.* As a poet he was a pupil of Gongora's *estilo culto*, and his four volumes of poems (published in Madrid, 1644–46) have little literary merit.

H. R. Lang.

Faribault, făr-i-bō': city and railway center; capital of Rice co., Minn. (for location of county, see map of Minnesota, ref. 10–F); situated at the confluence of Straight and Cannon rivers; 53 miles S. of St. Paul. It has State schools for the deaf, for the blind, and for the imbecile; Seabury Divinity College, Shattuck school for boys, and St. Mary's school for girls, all Protestant Episcopal; Bethlehem academy for girls (Catholic); public library and reading-rooms, 2 parks, 4 flouring-mills, a woolen-mill, 2 furniture-factories, rattan-works, a manufactory of windmills, 2 carriage-factories, water-works, gas-works, and electric lights. Pop. (1880) 5,415; (1890) 6,520; (1900) 7,868.

The so-called "Faribault plan" of public education, adopted here in 1891 but abandoned in 1893, caused considerable controversy among Roman Catholic writers. It was a compromise between the common-school system of the U. S. and the parochial system of the Roman Catholic Church, and involved the surrender of the parochial school property to the city board of education, the expense of conducting the schools to be borne by the city, the employment by the board of sisters of the Church as teachers, subject to the usual examinations, and the exclusion of religious teaching and emblems; although religious instruction was to be permissible after school hours if any wished it. EDITOR OF "REPUBLICAN."

Fari'na [Lat., flour > Fr. *farine*]: a powdered preparation of cereal grains, pulse (peas, beans, etc.), or in a still wider sense it includes the starchy preparations prepared as food from various roots and stalks, such as arrowroot, sago, tapioca. From the fact that such substances abound in starch, starchy food is often called farinaceous.

The pollen of flowers, after it has been gathered by bees, is also called farina. This is made into bee-bread, to serve as food for the larvæ, and probably enters into the paste which covers the larva-cells of honeycomb.

Farinelli, fă̄ā-rē̆e-nel'li, CARLO: Italian soprano singer (proper name CARLO BROSCHI); b. at Naples, Jan. 24, 1705; studied under Porpora; performed with applause in London 1734–35; and in 1737 went to Madrid to sing to and soothe King Philip V., and, succeeding, became his favorite, as also the favorite of Ferdinand VI., Philip's successor. He spent the last years of his life in great splendor. but lonesome and melancholy. D. at Bologna, July 15, 1782. He was a eunuch, and not only the best singer of the eighteenth century but a complete marvel with respect to voice, and possessed of fine musical education. He displayed brilliant talents for court-intrigue at Madrid, but possessed many amiable and even generous traits.

Farini, fă̄ā-ree'nē̆e, CARLO LUIGI: Italian statesman, historian, and orator; b. at Russi, in the Roman States, Oct. 22, 1812; studied medicine and wrote medical treatises. Proscribed for political offenses in 1843, he returned after the amnesty proclaimed by Pope Pius IX. in 1846, and was chosen a member of Parliament for Faenza; then exiled again 1848–49, but was Minister of the Interior in Piedmont in 1850. He took part in negotiations with Napoleon III., and was named dictator of Modena 1859. In 1860 he was commissioner extraordinary to the court of Naples. In the last cabinet of Cavour he was Minister of Commerce, and was president of the cabinet Dec., 1862, holding the position until Mar. 24, 1863, when he retired on account of ill-health. D. Aug. 1, 1866. *Storia della Stato Romano dall' anno 1815 al anno 1850* (1850), of which the first part was translated into English by Mr. Gladstone; *Letters to Mr. Gladstone* (1856); and *Letters to Lord John Russell* (1859), are among his works. His remains were originally buried at Turin, but were in 1878 removed to his native town, and monuments have been erected to his memory there and at Ravenna.

Farjeon, BENJAMIN LEOPOLD: English novelist; b. in 1833. He spent some years in Australia and New Zealand, engaged in journalism. Among his numerous novels, which deal mainly with low life and have been compared to Dickens's, are *Grif* (1870); *London's Heart* (1873); *Bread and Cheese and Kisses* (1874): *Toilers of Babylon* (1888); *The Betrayal of John Fordham* (1897), and *Pride of Race* (1900). H. A. B.

Farlow, WILLIAM GILSON, M. D.: botanist; b. Dec. 17, 1844, in Boston, Mass.; graduated at Harvard, A. B. 1866, M. D. 1870; appointed assistant Professor of Botany at Harvard University 1874–79, and in 1879 Professor of Cryptogamic Botany. He is a member of the National Academy of Sciences, the American Academy, and several European societies. His principal work has been upon the lower plants, and his publications upon this subject have given him the position of leading American cryptogamic botanist. His principal publications are *Marine Algæ of New England*; *The Black Knot*; *The Gymnosporangia of the United States*; *Enumeration of the Peronosporeæ of the United States*; *Host Index of Fungi*, etc.

Farmer, HUGH: English Dissenting clergyman of great learning and ability; b. on the Isle Gate farm, near Shrewsbury, Jan. 20, 1714; studied under Dr. Doddridge at Northampton, and from about 1737 was pastor of a congregation at Walthamstow, London, where he died Feb. 5, 1787. Published *Inquiry into the Nature and Origin of our Lord's Temptation in the Wilderness* (London, 1761; 5th ed. 1822), designed to show that the temptation was not objective and real; *A Dissertation on the Miracles* (1771; 3d ed. 1810); *Essay on the Demoniacs of the New Testament* (1775; 3d ed., really the 4th ed., 1818)—famous books in their days, real contributions to the growth of thought, their interest now mainly historical; *Prevalence of the Worship of Human Spirits in Ancient Heathen Nations* (1783).

Farmer, RICHARD: Shakspearean scholar; b. at Leicester, England, in 1735. He was educated in the free grammar school of his native town and at Emmanuel College, Cambridge; became a classical tutor in the latter institution in 1760, and a master in 1775, and was appointed librarian at the university in 1778. He held various benefices at Lichfield, Canterbury, and St. Paul's, but he twice declined the offer of a bishopric, unwilling to give up the free-and-easy life he was used to. The only monument of his learning and industry he has left is his *Essay on the Learning of Shakspeare*, published in 1766, and afterward often reprinted. D. at Cambridge, Sept. 8, 1797. See John Nichols, *Literary Anecdotes*.

Farmer City: city and railway junction; De Witt co., Ill. (for location of county, see map of Illinois, ref. 6–E); on the Peoria Division of the Cl., Cin., Ch., and St. L. Railway, and on the Springfield Division of the Illinois Central; 25 miles S. E. of Bloomington. It has churches of four denominations and an excellent high school, and is a trading-center of a rich agricultural district, especially known for its fine and fast horses. Pop. (1880) 1,289; (1890) 1,367; (1900) 1,664. PUBLISHERS OF "JOURNAL."

Farmers' Alliance, or **National Farmers' Alliance and Industrial Union**: a political organization of the U. S., the outcome of a movement which led, shortly after the civil war, to the formation of the Patrons of Husbandry, more commonly known as the Grange. The object of this organization was the mutual protection of farmers against the encroachments of capital. The first Alliance proper was formed in Texas to oppose the wholesale purchase of public lands by private individuals. The Alliance remained a Southern organization for about ten years. The Farmers' Union of Louisiana united with it in 1887 under the name of Farmers' Alliance and Co-operative Union of America. The order quickly established branches in Missouri, Kentucky, Tennessee, North and South Carolina, Georgia, Alabama, Florida, and Mississippi. The Agricultural Wheel, a similar society, located in the States of Arkansas, Missouri, Kentucky, and Tennessee, was later in the same year amalgamated with the Alliance in a new organization which took the name of Farmers' and Laborers' Union of America. The same spirit which led to this movement in the South had been embodied in Illinois in the National Farmers' Alliance which was started in 1877 and quickly spread to Wisconsin, Minnesota, Iowa, Missouri, Kansas, and Dakota. A minor organization, the Farmers' Mutual Benefit Association, started in 1887 in the southern part of Illinois. In 1889 these different bodies were all practically united into a union for political purposes at a meeting held in St. Louis. The object of the organization was to procure legislation in the interests of farmers and laborers, and the present name, that of Farmers' Alliance and Industrial Union, was then taken. The professed reason for the formation of an Alliance party in politics was that the already existing parties totally failed to undertake the adjustment of the problems covered by the Alliance demands. The Alliance entered the political field in Kansas at once, and it is here that the organization has achieved its greatest victories. At the meeting held in Topeka in June, 1890, which was attended also by the Knights of Labor, the new People's Party was formed, though it was left to the individual member's choice in the case of both organizations whether he should co-operate in the political movements or not. At this convention a platform was adopted and a State ticket nominated. The election resulted in the triumph of the new party, which elected an attorney-general, 5 out of 7 Congressmen, 93 out of 125 members of the State House of Representatives, and one U. S. Senator. On May 19, 1891, delegates from the Farmers' Alliance, Knights of Labor, and several other similar organizations met in a national union conference in Cincinnati, adopted a platform, and formed a new national political party called the People's Party of the United States of America. The organizations represented did not, however, heartily indorse the new party. In Nov., 1891, delegates from the Farmers' Alliance, Farmers' Mutual Benefit Association, and People's Party met in Indianapolis, and an earnest effort was made to bring about an amalgamation of the three organizations, but opposition to this purpose was developed, and action toward that end was postponed to the meeting of the National Industrial Conference at St. Louis, Feb. 22, 1892. The Farmers' Alliance was represented in this conference by 246 delegates out of a total of 656, and it was decided at this meeting to appoint a committee to act with the People's Party national committee on the nomination of a national ticket, and to hold a national convention for that purpose. A platform was also adopted. For the political aspects and principles of the organization, see PEOPLE'S PARTY. C. H. THURBER.

Farmers' Clubs: associations of agriculturists, generally those of some one community or neighborhood, who meet at stated times for the discussion of questions affecting the interests of agriculture, and more especially for considering the methods of practical farming—the relative values and uses of different fertilizers, the adaptation of special crops to particular soils, the choice of breeds of live-stock and of varieties of cultivated plants, and the like. Solon Robinson and Horace Greeley were among the early and influential advocates of farmers' clubs. They were associated with the Farmers' Club of the American Institute in New York, the discussions of which were for many years printed weekly in the *New York Tribune*, and widely read. Some farmers' clubs have libraries and invested funds, and sustain regular courses of lectures in the winter season, and in general ladies are admitted. The constitution and by-laws are, or should be, simple in plan, and the meetings are social rather than formal. In many places, besides the regular discussion, there is the reading of one or more original papers, usually agricultural, and music adds variety to the exercises. To some extent the old farmers' clubs have been converted into or replaced by the granges of the Patrons of Husbandry and the farmers' institutes. See GRANGE and FARMERS' INSTITUTES.

Farmers-general: an association of persons in France, under the old monarchy, to whom the privilege of levying certain taxes, as imposts on salt or tobacco, or town-dues in particular districts, was farmed or let out for a given sum paid down. This system of raising the public revenue was employed by the Roman state. (See PUBLICANS.) It was introduced into France in the thirteenth century, when Philip the Fair gave to Lombard Jews and brokers the privilege of collecting the *gabelle*, or tax on salt, to provide means for carrying on war against the English. It continued to be employed under various modifications down to 1789. In 1720 the farmers of the taxes formed a regular association, called the *ferme générale*, with exclusive management of the *gabelle*, the tax on tobacco, the *octrois* of Paris, and other excise duties. These men accumulated enormous wealth, and by bribing ministers of state, courtiers, and functionaries of all classes had influence enough to keep up the ruinous system. Turgot and Necker, in the reign of Louis XVI., attempted to change the arrangement, but the nobility, clinging to their privilege of exemption from taxation, effectually resisted their efforts. By the revolutionary constitution of 1791 the system was swept away, and many of the farmers-general were afterward executed. Revised by A. T. HADLEY.

Farmers' Institutes: the series of meetings held in many of the U. S. under the auspices, directly or indirectly, of the Government of the particular State, usually during the winter, in which the various agricultural operations and the various matters pertaining to the farmer's life are discussed. The central organization usually is vested in some State agricultural society or the agricultural college, and itinerant lecturers are sent to the various meetings to co-operate with the local speakers. Each meeting lasts from one to four days, during which time all the leading agricultural problems of local interest are touched upon. About thirty States appropriate funds, either directly or through the official State agricultural organization, for the maintenance of institutes. The amounts vary considerably, being led by New York with $15,000 per annum and Wisconsin with $12,000. About $100,000 are now spent annually in the U. S. and Canada for this purpose. The State institutes are stimulating the organization of many local and county institutes and farmers' clubs, so that the institute movement, considered as a whole, reaches nearly every farming community, at least in the North.

Although the institute movement has acquired the greater part of its momentum since 1880, it really originated about the middle of the nineteenth century. The proceedings of the New York State Agricultural Society for 1842–43 record what is perhaps the first real concerted effort to establish itinerant agricultural lectures and instruction. A similar movement was made by the Massachusetts State Board of Agriculture in 1859. In 1861 the State Board of Agriculture of Michigan, which controls the State Agricultural College, was authorized to "institute winter courses of lectures for others than students of the institution, under necessary rules and regulations." This appears to be the first attempt to connect a farmers' lecture-course with an educational institution. Ten years elapsed, however, before such lecture-courses were actually provided. For a fuller history and statement of funds expended, see Bailey, *Annals of Horticulture for 1891*. L. H. BAILEY.

Farming: See AGRICULTURE.

Farmington: town; Hartford co., Conn. (for location of county, see map of Connecticut, ref. 9–G); on Farmington river and on the Northampton Division of the N. Y., N. H. and H. Railroad; 31 miles N. of New Haven. It has an excellent school for girls, established in 1844, a savings-bank, and important manufactures. The town was settled in 1640. Pop. of township (1880) 3,017; (1890) 3,179; (1900) 3,331.

Farmington: town; Van Buren co., Ia. (for location, see map of Iowa, ref. 7–J); on the Des Moines river, and on the Ch., B. and K. C., and the Ch., R. I. and Pac. railways; 30 miles N. W. of Keokuk. It has a woolen-factory, a grist-mill, manufactures of cigars, brooms, and trusses, a wagon and carriage factory, electric lights, and water-works. Pop. (1880) 781; (1890) 1,002; (1900) 1,332.
EDITOR OF "HERALD."

Farmington: village; capital of Franklin co., Me. (for location of county, see map of Maine, ref. 7–B); on the Maine Central Railroad; 80 miles N. E. of Portland. It has a State normal school, a family school for boys, an excellent high school, and graded public schools, numerous machine-shops, saw and grist mills, manufactories of novelties in wood, spool-factory, several corn-canning factories, an electric-light plant, etc. Its schools make it one of the best educational centers in the State. Principal business, mercantile, farming, and dairying. Pop. of township (1880) 3,353; (1890) 3,207; (1900) 3,288; of village (1890) 1,243; (1900) 1,251.
EDITOR OF "CHRONICLE."

Farmington: city; capital of St. François co., Mo. (for location of county, see map of Missouri, ref. 5–J); $2\frac{1}{2}$ miles from the St. L. and Iron Mountain Railroad; on the turnpike leading from Iron Mountain to Ste. Genevieve; 87 miles S. of St. Louis. It has the Elmwood Female Seminary (Presbyterian), Carleton College, Baptist College, and a very large public school. In the vicinity are many important lead-mines, also Iron Mountain. Pop. (1880) 608; (1890) 1,394; (1900) 1,778. EDITOR OF "TIMES."

Farmington: town (incorporated in 1798); Strafford co., N. H. (for location of county, see map of New Hampshire, ref. 8–G); on a branch of the Boston and Maine Railroad, 28 miles W. N. W. of Dover and 86 miles N. of Boston, Mass.; 10 miles S. E. of Alton Bay. It has three churches, a high school, and manufactures of boots, shoes, and lumber. Pop. of township (1880) 3,044; (1890) 3,064; (1900) 2,265.

Farm Laws: See the Appendix.

Farmville: town; capital of Prince Edward co., Va. (for location of county, see map of Virginia, ref. 7–G); on railway and on the Appomattox river; 70 miles S. W. of Richmond, and 7 miles N. of Hampden-Sidney College and the Union Theological Seminary. It has a State school for women, and several large tobacco-factories and warehouses. Principal business, tobacco-trade. Pop. (1880) 2,058; (1890) 2,404; (1900) 2,471.

Farnaby, or **Farnabie**, THOMAS: grammarian and teacher; b. in London, 1575. He was educated at Oxford; became a Roman Catholic, and went to Spain, where he entered a Jesuit college. He soon left it, and after some experience in the army finally settled at Martock, in Somersetshire, where he opened a school, This undertaking proved so successful that after the lapse of a few years he was able to remove the institution to London, where his success was still greater. His school contained more than 300 pupils, most of whom were sons of noblemen, boarding in his house, and more churchmen and statesmen issued from it than from any other in the kingdom. He finally removed the institution to his estate, Oxford, in Sussex. He published annotated editions of a great number of ancient authors and a *Systema Grammaticum* (London, 1641). D. at Oxford in 1647.

Farnam, HENRY WALCOTT: Professor of Political Economy; b. at New Haven, Conn., Nov. 6, 1853; educated at Yale (A. B. 1874 and M. A. 1875); studied three years in

Germany, taking degree at Strassburg 1878; University Professor of Political Economy at Yale 1880; Professor of Political Economy Sheffield Scientific School 1881; editor of *Yale Review* 1892; author of *Die Innere Französische Gewerbepolitik von Colbert bis Turgot* (Leipzig, 1878), etc.
C. H. THURBER.

Farne, or **Fern, Islands**: a group of seventeen islets and rocks, some of which are visible only at low tide; situated 2 to 5 miles off the east coast of England, opposite Bamborough, Northumberland. On two of the islands lighthouses have been built, as navigation is extremely dangerous in these waters. On another of the isles is a tower raised in honor of St. Cuthbert, who lived there during the last two years of his life. Latitude of Farne lights, 55° 37′ N., lon. 1° 39′ E.

Farnese, faar′nēez (Ital. pron. fa͡ar-nā′sā): the name of a noble Italian family, many of whose members have played conspicuous *rôles* in the history of Europe. For the greater part the family owed its prominent position and immense wealth to the circumstance that one of its members, Alexander Farnese, became pope (Paul III., 1534–49) and in the most shameless manner misused the influence and revenue of his position for the advancement of his family. He made his son Pierluigi (1493–1547) Duke of Parma and Piacenza, and he provided in an equally lavish manner for his four grandsons, two of whom, Alexander and Ranuccio, were made cardinals when they were fourteen years of age, while a third, Ottavio Farnese (1520–86), was married in his twelfth year to Margaret of Austria, better known under the name of Margaret of Parma, a natural daughter of Charles V., and succeeded his father as Duke of Parma; and the fourth, Orazio, was made Duke of Castro and married to Diana, a natural daughter of Henry II. of France.

The most celebrated member of the family was ALEXANDER FARNESE (1546–92), Prince of Parma and governor of the Low Countries. He was a son of Ottavio Farnese and Margaret of Parma, was educated at Alcala and Madrid, fought with great distinction in the battles of Lepanto and Gembloux, and succeeded his uncle, Don Juan of Austria, as governor of the Low Countries. He was one of the greatest generals of his age. The conquest of Antwerp, the raising of the siege of Paris, etc., were brilliant feats of courage and skill, and the failure of the invasion of England was due to no fault of his. But he was also one of the greatest diplomatists of the age; he conquered as many cities by his tongue as by his sword. He created a party in the Low Countries in favor of the union with Spain; and when the Armada was about to sail, neither Elizabeth nor Raleigh had the least suspicion of what the movement really meant. But he was ill rewarded by Philip II., who recalled him in the midst of his career. He was on the way to Spain when he died.

In 1731 the male line of the house became extinct by the death of Antonio Farnese. But Antonio's daughter, Elizabeth Farnese, married to Philip V. of Spain, succeeded in securing all the Farnese fiefs for her sons, Philip, Duke of Castro, and Charles, King of Naples, and afterward King of Spain.

Farnese Bull: a marble group formerly in the Farnese palace at Rome, but removed with other art treasures in 1786 to the National Museum at Naples. It represents the punishment of Dirce, whom Amphion and Zethus are tying to the horns of a bull. Apollonius and Tauriscus are said by Pliny to be the joint authors of the work, which was discovered in the baths of Caracalla in 1546 and was restored by Bianchi under the guidance of Michelangelo. See APOLLONIUS OF TRALLES.

Farn′ham: a town of England; in the W. of Surrey; on the left bank of the Wey; 40 miles from London (see map of England, ref. 13–I). It contains the fine old castle of the bishops of Winchester, first built by Bishop de Blois, brother of King Stephen, but razed by Henry III., then rebuilt by Charles I., and, having been dismantled, restored to its present state in 1684. Farnham is principally noted for the superior hops which are cultivated in the surrounding country; it is abundantly supplied with water from neighboring springs. The parish church is spacious and of the later Gothic style. It was once a chapel of ease to Waverley Abbey, now in ruins, which was founded in 1128. Aldershot Camp is situated 3 miles N. E. of Farnham. Pop. 5,000.

Farnham, Quebec, Canada: See WEST FARNHAM.

Farnham, ROSWELL: lawyer and soldier; b. in Boston, Mass., July 23, 1827; removed in 1840 to Bradford, Vt.; graduated with honors at the University of Vermont in 1849; taught school for several years; admitted to Orange County bar in 1857; State attorney 1859–61; lieutenant of First Vermont Regiment 1861; provost-marshal of Newport News, Va., 1861; captain of Bradford Guards 1862; lieutenant-colonel Twelfth Vermont Regiment during its service in the field; member of Vermont Senate from Orange County 1868–69; delegate to Republican national convention at Cincinnati in 1876, and also one of the presidential electors the same year; trustee of the University of Vermont; Governor of Vermont 1880–82.

Farn′worth: township of Lancashire, England; 12 miles E. S. E. of Liverpool (see map of England, ref. 7–F); manufactures sail-cloth, watches, files, and all kinds of iron tools. Pop. (1891) 23,758.

Faro [deriv. of *Pharaoh*, because of a conventional representation of the Egyptian Pharaoh formerly contained on one of the cards. Cf. Fr. *pharaon*]: a game at cards, used only in playing for money. It is played in different ways in different countries, but in all the player contends against a bank, represented by a professional faro-banker; and the chances, though apparently only slightly in favor of the bank, are in reality quite strongly so. In the U. S. the game is illegal in many cities and in some of the States.

Faro, faa′rō: the capital of the province of Algarve, Portugal; situated at the mouth of the Fermosa, where three small islands form a somewhat confined but otherwise convenient and safe harbor (see map of Spain, ref. 19–B). Faro exports considerable quantities of oranges, figs, anchovies, and cork, and is a bishop's see. Pop. 8,100.

Faro: a province of Portugal. See ALGARVE.

Faröe Islands: same as FAEROE ISLANDS (*q. v.*).

Farquhar, faar′*k*har, GEORGE: dramatist; b. at Londonderry, Ireland, 1678; educated at the University of Dublin; acted for a short time at a theater in Dublin, then retired from the stage and settled in London. *Love and a Bottle* (1698); *Twin Rivals* (1703); and *The Beau's Stratagem* (1707), comedies, were among his productions. D. in London in 1707.

Farr, WILLIAM, M. D., F. R. S., D. C. L.: statistician; b. at Kenley, Shropshire, Nov. 30, 1807; educated at Dorington and Shrewsbury and at the Universities of Paris and London. Practicing medicine in London, he edited the *Medical Annual* and the *British Annals of Medicine.* In 1839 he became connected with the registrar-general's office in London, and subsequently became superintendent of the statistical department, retiring in 1880. He wrote much for medical journals, the Vital Statistics in *McCulloch's Statistics of the British Empire*, official reports on the public health, and on the *Causes of Death in England* (1837–70), reported in detail the cholera epidemic of 1849, framed a new *Statistical Nosology*, etc. D. in London, Apr. 14, 1883.

Farragut, DAVID GLASGOW: the most distinguished admiral of the United States of America; b. at Campbell's Station, near Knoxville, Tenn., July 5, 1801; son of George Farragut, a native of Minorca, who emigrated to North America in 1776, and was a soldier in the Revolutionary war, and subsequently muster-master of the militia of East Tennessee; also magistrate of Pascagoula, Miss. He died in New Orleans in 1808, and Commodore David Porter, of the U. S. navy, who had formed a friendship with the family, adopted David Farragut, and procured him an appointment in the navy, which he entered as a midshipman Dec. 17, 1810. He served under Commodore Porter on board the Essex, and at the age of twelve was made prize-master of a captured vessel. In 1815–17 he served on the Independence and the Macedonian in the Mediterranean; spent nearly a year, 1817–18, in study at Tunis under the U. S. consul, Charles Folsom; in 1819 became acting lieutenant on board the Shark; in 1820 returned to the U. S., and in 1822–23 took part in several conflicts between the U. S. naval forces under Commodore Porter and the pirates of the West Indies. In 1825 he was commissioned lieutenant and ordered to the frigate Brandywine; and after serving in various vessels reached the rank of commander in 1841. During the Mexican war he blockaded the harbor of Tuxpan with the sloop of war Saratoga. From 1848 to 1850 he was on duty at the Norfolk navy-yard; in 1850 was ordered to Washington to aid in compiling a book of ordnance regulations for the navy. From 1854 till

1858 he was engaged in establishing the navy-yard at Mare Island, in San Francisco Bay. In 1858 he was given command of the sloop of war Brooklyn. He passed the winter of 1860–61 at Norfolk, Va. In Dec., 1861, he was placed in command of the steam sloop of war Hartford in an expedition commanded by David H. Porter, sent to capture New Orleans. The force included the West Gulf blockading squadron and Porter's mortar flotilla, and was the largest expedition that ever sailed under the U. S. flag. The fleet sailed from Hampton Roads, Feb. 2, 1862; on Apr. 24, under Farragut's directions, it passed Forts Jackson and St. Philip at the mouth of the Mississippi, destroyed a Confederate fleet of fifteen vessels, the loss on the Union side being thirty-seven men and the gunboat Varuna, which was sunk, silenced the Chalmette batteries 3 miles below New Orleans, and on the 25th accomplished the surrender of the city. On June 28 Farragut's fleet, after an engagement of about two hours, passed the batteries at Vicksburg, and again passed the batteries on his return on July 15. The following day he was commissioned rear-admiral. In Mar., 1863, he ran the fire of the forts at Port Hudson and opened communication with Flag-Officer Porter, who commanded the upper Mississippi. On May 24, in conjunction with the army, he commenced active operations against Port Hudson, and when it fell, on July 9, he turned over to Admiral Porter the entire control of the Western waters above New Orleans. After a short respite from his labors, he, in Jan., 1864, made a reconnoissance of Forts Morgan and Gaines, the defenses of Mobile, and expressed the opinion that with a single ironclad and 5,000 men he could take that city.

On Aug. 5, 1864, with four ironclads and fourteen wooden vessels, Farragut passed the forts at the entrance of Mobile Bay, after a desperate engagement, in which the Tecumseh, one of the vessels of his fleet, was sunk by striking a torpedo, and 335 men in all were lost. During the fight Farragut gave his directions from a place high up in the main rigging of the Hartford. In a few days the forts surrendered, and the passage of blockade-runners was stopped, although the city itself was not taken, because of shoal water and obstructions in the channel. In November Farragut returned to the North, and in New York was presented with a purse of $50,000 for the purchase of a home in that city. On Dec. 22 a bill creating the grade of vice-admiral was created, and on Dec. 23 Farragut was nominated for the office by President Lincoln. On July 25, 1866, Congress created the grade of admiral and the rank was given to Farragut. In 1867, in the flagship Franklin, he commanded the European squadron, and was received with highest honors in the cities he visited. In 1870 he passed the summer at Portsmouth, N. H., and died there on Aug. 14. He was buried in Woodlawn Cemetery, New York. Among the memorials erected in his honor are statues in Madison Square Park, New York, and in Marine Park, South Boston, Mass. See Com. Foxhall Parker, *The Battle of Mobile Bay* (Boston, 1878); the *Life* by Loyall Farragut (New York, 1879); Capt. A. T. Mahan, *Admiral Farragut* (New York, 1892).

Farrakhabad′: city of the Agra division, Northwestern Provinces, British India; the capital of the district of the same name; on the Ganges, on the road between Calcutta and Delhi; 3 miles W. of the military station of Fathigarh, with which it is sometimes confounded on maps (see map of N. India, ref. 6–F). It is one of the commercial centers of Upper Hindustan. Lord Lake defeated the troops of Holkar here in 1805. Pop. 65,000.

Farrar, Frederic William, D. D., F. R. S.: English divine and author; son of a clergyman; b. in the Fort, Bombay, India, Aug. 7, 1831; graduated at Cambridge in 1854; became assistant master at Harrow in 1855, and master of Marlborough College in 1871; rector of St. Margaret's, London, and canon of Westminster 1876; archdeacon 1883; chaplain of the House of Commons 1890, and dean of Canterbury 1895. He is also chaplain in ordinary to the Queen. He has published the following works of fiction: *Eric* (10th ed. 1858); *Julian Home* (4th ed. 1859); *St. Winifred's* (4th ed. 1863): *Darkness and Dawn* (1891; 3d ed. 1892). His philological works are *The Origin of Language* (1860); *Chapters on Language* (1865); *Greek Grammar Rules* (6th ed. 1865); *Greek Syntax* (3d ed. 1867); and *Families of Speech* (1870). His more important theological works are *Seekers after God* (1869); *The Witness of History to Christ* (1871); *The Silence and Voices of God* (1873); *The Life of Christ* (in 2 vols., 1874); *The Life and Works of St. Paul* (2 vols., 1879); *The Early Days of Christianity* (2 vols., 1882); *The Messages of the Books: Discourses and Notes on the New Testament* (1884); *The History of Interpretation* (Bampton Lectures, 1886); *Lives of the Fathers* (2 vols., 1889). He also contributed to Smith's *Dictionary of the Bible*, and is master of a singularly fresh and brilliant style. He delivered a eulogy on Gen. Grant in Westminster Abbey, Aug. 4, 1885, and in the same year lectured in the U. S.

Revised by S. M. Jackson.

Farrar, John: b. at Alnwick, Northumberland, July 29, 1802; educated near Leeds; became a Wesleyan minister in Aug., 1822; was governor of Abney House Wesleyan Theological Institution, Stoke Newington, London, in 1839; and subsequently of Headingley College, Leeds (1868); was secretary and president of the Wesleyan Conference, the latter in 1854 and in 1870. D. at Headingley, Leeds, Nov. 19, 1884. Wrote *Proper Names of the Bible* (1839); *A Biblical and Theological Dictionary* (London, 1851); *Ecclesiastical Dictionary* (1853).

Farren, William: actor; b. in London, England, in 1825. His father was a well-known comedian of the London stage, contemporary with Macready, and was descended from a family of actors. Previous to entering the dramatic profession he appeared in London with some success as a singer at concerts. At the outset of his stage career he performed at the Strand and Olympic theaters under the name of Forrester and as William Farren, Jr. In Jan., 1851, he became a member of the company of the Olympic theater, and on Jan. 13 he played the part of Frederick Plum in the first performance of Morton's comedy *All that Glitters is Not Gold*. In 1853 he joined Buckstone's company at the Haymarket theater, where he appeared as Captain Absolute, Mar. 28, in *The Rivals*. At the Vaudeville theater, in July, 1872, he played Sir Peter Teazle in a revival of *The School for Scandal*. In 1875, at the same house, he was the Sir Geoffrey Champneys in the comedy of *Our Boys*, which character he continued to play without intermission until July, 1878. At the Shaftesbury theater in 1888 he appeared as Adam in *As You Like It*. In 1890 he played in *David Garrick*, and took the part of Sir Peter Teazle in a revival of *The School for Scandal* in 1891. B. B. Vallentine.

Farrer, Henry: landscape-painter; b. in London, Mar. 23, 1843; "self-taught"; removed to the U. S. in 1861; member American Water-color Society. He exhibits chiefly paintings in water-color. His work is carefully wrought out, but is somewhat dry in general aspect. Studio in New York. W. A. C.

Farriery [deriv. of *farrier*, horseshoer < M. Eng. *ferrour*, *ferrer*, from O. Fr. *ferreor*, *ferrier* < Low Lat. *ferra′tor*, *ferra′rius*, shoer, derivs. of *ferra′re*, to shoe, deriv. of *fer′rum*, iron, horseshoe]: originally the trade of applying iron to the horse's foot. However, as all horse-surgery was of the coarsest and often of the most brutal kind, performed by the common smith with the tools and implements at hand, it is natural that veterinary surgery as it grew into a profession should have been called *farriery*. Now, however, the treatment of the diseases of domestic animals is no longer of necessity left to the guesswork of the blacksmith, nor surgical operations to the tongs and searing-iron.

The foot of the horse is wonderfully guarded against injury from without, and equally protected against painful jars and disease which one might suppose would arise from the tremendous blows which the feet sustain when traveling upon hard roads. The hoof is a tough, elastic, hornlike substance, completely boxing in the delicate tissues, cushions, and bones of the foot. In the living animal and in its first state it is in one piece, but after maceration it may be separated into the crust or wall, the sole, and the frog. The front part of the crust of each hoof is called the toe, the hindmost parts the heels, and the intermediate parts the quarters. The corresponding parts of the shoe have the same names. The *crust* grows from the coronet, at the top of the hoof next the hair, and from the sensitive laminæ which surround the pedal or coffin bone upon its upper sides. It is about half an inch in thickness at the edge, and in many horses so hard and tough that they hardly need shoeing at all except in icy weather or when used upon paved roads. The *sole* is a slightly arched dome with a large segment removed, in the place of which the frog is found. The horn of the sole differs essentially from that of either the crust or the frog, it being more granular and shelly, wearing off naturally with comparatively little abrasion. At the rearward portions of the sole, divided as they are by the frog, two elevated ridges, of a character of horn more resembling the crust, occur. These are called the *bars*, and are really the ends of the crust reflected inward at the heels. The *frog* is a wedge-shaped body in form like a sharp-pointed V, the point being turned forward. It is of an exceedingly spongy and elastic kind of horn, and is placed as a cushion between the navicular bone and joint and the ground, to relieve concussion and to distribute jars so as to break their force. With every step of the natural foot, unshod as well as when at rest, the frog communicates a pressure directly upon the navicular joint and the tendons which underlie it. In ordinary shoeing the frog never touches the ground, being cut away and left reduced in size, while at the same time the foot is lifted up from the earth by thick-heeled or calked shoes. That a foot so treated becomes diseased is not to be wondered at. The wonder is that acute diseases of the foot are not much more prevalent. The flexibility and elasticity of the hoof, concerning which so much is written, rests chiefly, indeed almost altogether, in the frog, slightly in the sole, and practically very little or not at all in the crust or walls of the foot. Much has been written about the expansion and elasticity of the quarters and heels. It may be disregarded. There is indeed elasticity in the crust, but it is only brought into play perceptibly under extraordinary circumstances.

When an unshod natural hoof is placed upon hard ground, the parts which bear upon it are the edge of the crust all around and the frog. Upon uneven ground the sole is frequently called upon to sustain its share of the weight, and when the horse steps upon frozen clods or stones the sole often bears the whole. In traveling upon ordinary country roads the hoof wears very evenly; upon gravelly roads the toe usually wears fastest, and will first become tender. If the toe and quarters be protected from wear by a narrow shoe, for ordinary service no other shoeing will be necessary. If such a shoe, which is the "half-moon shoe" of Coleman, drawn out thin at the quarters, be seated nearly level with the sole by cutting out the crust of the hoof upon the toe and quarters, it is evident that the horse will have his natural foot, with simply an iron front edge to take the wear. This is the lightest and best shoe a horse can wear when his work is not too severe nor upon too rough ground. Were the same principle to be carried out in a shoe similarly seated (level with the sole), much wider in the web, and extended to the heels so as to protect the foot thoroughly, the foot would still have its natural bearings, and be guarded against even extraordinary wear and tear. The frog would bear upon the ground, and so would the sole, nearly as much as if the hoof were not shod.

The presence of a shoe prevents the natural wear of the hoof; hence sooner or later, according to the rapidity of growth of the horn, it must be reset and the horn pared back as nearly as possible to the condition it would have been in if it had not been shod and had worn off evenly and naturally. The earliest shoes worn by horses were probably plates of iron, having a similar shape to modern horseshoes, but covering a much larger portion of the hoof. This necessitated a paring away of both crust and sole when the shoes were reset. The sole is very easily cut by the smith, and so is the frog, while the crust is hard and tough. It is easily rasped off, however, after the sole is cut away, and the smith has plain sailing.

When a horse is brought to a common blacksmith to be shod, the "clinches" at the ends of the nails are first cut off; then the shoe is wrenched off with the tongs, a portion of the crust coming off frequently with it. This is done by an apprentice, who then proceeds to pare out the sole all around, cutting close to the frog. The cutting down of the crust is done by the smith himself, if he is a very careful man, or by an experienced journeyman, but quite as often trusted to an apprentice, who forms roughly, at his discretion, the seat for the shoe. Then the shoe is shaped, heated red hot or nearly so, and a seating burned level by the application of the hot shoe—an operation liable to do serious harm. When the shoe is formed to fit the foot it usually happens that if flat at first the heels are made nearly twice as thick as the toe, if indeed they be not turned down into calks, making the shoe at the heels half an inch to an inch or more in thickness; and thus it is applied. The result is that no part of the hoof touches the ground. The frog, upon which so much depends, is gradually reduced in size, both by the paring of the smith and (especially) by lack of use: it shrivels often to one-third its proper size. The paring out of the sole is usually accompanied by the cutting away of the bars entirely, which the smith says he does "to open the heels." The foot, thus weakened and placed in a most unnatural position, becomes the seat of disease. When the bars are cut away, or the soles pared too thin near the heels, and the frog has no bearing upon the ground, ulcers occur near the heels, which are called *corns*.

The frog should, by its constant pressure at every step, give healthy action to the navicular bone and joint; this wanting, inflammation or fever of these parts, *navicular disease*, results. To this, horses with strong, solid-looking hoofs are especially liable. Flat-footed horses are liable to another trouble from the same cause—namely, *founder*. As already said, the weight of the horse is sustained naturally upon the crust of the hoof and upon the frog. Where the frog can bear none the crust must sustain all. The crust grows in part from the sensitive laminæ enveloping the pedal-bone, and is attached to them by laminæ of horn interlocking—or, rather, interleaved—with them; and it is upon these sensitive laminæ that all the weight is thus placed. They can bear a great deal naturally, but inflammation (*laminitis*) is almost sure to come when there is a provoking cause, and the horse is foundered. *Seedy toe* is a form of laminitis, where the crust separates from the laminæ at the toe. *Pumice foot* is a name given to another form of laminitis, wherein the sole becomes convex instead of concave, and the horn is spongy within and externally brittle, the whole foot being in a highly feverish condition. *Contraction of the heel* comes from the same general cause—namely, want of frog-pressure. *Thrush* is a disease of the frog, made apparent by a very offensive discharge from the cleft, and results primarily from lack of use of the frog, and, except the frog be wounded, probably altogether from this cause. *Quittor* is an ulcer or abscess of the foot, resulting from bruise, nail-prick, thrush, or any other cause which may finally, if neglected, affect the coffin or pedal-bone. It can not be treated by the farrier, but presents a problem which only a surgeon can properly solve. Taken in time, a cure is possible. *Sand-crack*, *quarter-crack*, etc.—The fibers of the horn in the wall of the hoof run from the coronet to the ground direct. In hoofs subject to inflammation the secretion of horn is often of a weak character, and the fibers separate, forming a crack, or, in case of an injury to the coronet, a soft, spongy streak in the horn, causing lameness. The cause of the former is bad shoes and bad shoeing—of the latter, usually, "calking," the horse treading on his own coronet. The cure for both is causing healthy horn to be secreted by rest and counter-irritants, and shoeing so as to give bearing to the frog and sole. *Nail-prick* in shoeing shows itself either at once, in which case little harm usually results, or after the horse has been used a day or so, in which case suppuration may take place. The horse will tell which nail is at fault when the hoof is tapped by the hammer around the clinches. The offending nail must be taken out, the shoe being removed, the hole probed, and if any fetid odor be perceptible and the hoof be hot, the hole must be enlarged, and, in case of any discharge, cut out until blood flows, and the opening syringed out with chlorinated soda, chloride of zinc, or some other active prophylactic. The shoe may be replaced if necessary, provided the animal is not seriously lame, the nails being lightly driven. The foot must be kept cool and rest given. Nails picked up on the road will seldom enter the sole to do injury if it be not pared down, and thus softened and weakened: but they may be found between the frog and the bars, in which situation they seldom do much injury unless neglected. The wound should be cleaned out and syringed with some corrosive as above mentioned. *Overreaching* is when a horse throws his hind foot into the heels or against the sole of the fore foot as it is partially raised to take the step in trotting. It occasions bruises on the heels or in the sole near the toe. The former are treated by external applications—tincture of arnica, etc.; the latter like a prick or any bruise of the sole. A horse well shod will seldom overreach, but long hoofs or big toe-calks on the fore feet will cause the foot to be placed upon the ground an inch or two short of where it should rest, and this is sufficient cause for the trouble. *Interfering, or "cutting."*—A horse allowed to tread fairly on the ground seldom or never cuts himself if the shoe does not extend outside the crust.

In the Goodenough system the shoe is applied by cutting out a seating for it, leaving the sole and frog as much exposed as possible, and never applying the knife to either. It is light, has five calks or bearings, a lower surface, similar to the edge of the natural foot, is beveled on both surfaces, the nail-holes are countersunk, and the shoes are applied *cold*.

M. C. WELD.

Fars, or **Farsistan** [Pers.; from Arab. *Fārs*, Persia, from Pers. *Pārs* + Pers. *stan*, place]: a province of Persia; stretching along the eastern shore of the Gulf of Persia; between lat. 26° and 32° N. and lon. 50° and 58° E.; having an area of about 55,000 miles. The province is bounded by the Persian Gulf and the provinces of Khuzistan, Isfahan, Yezd, and Kerman. Along the gulf the land is low, sandy, or argillaceous, scorched by the sun—a desert; but the coast-line presents several convenient and secure harbors. Farther back it rises through broad terraces, separated from each other by high and wild mountain-ranges, into a flat, sandy table-land, where the large salt lake Bakhtegan occurs. The terraces are fertile and beautiful, well watered by the Bundemeer (Araxes), which flows into Bakhtegan, and by the Nabou and the Tab (Arosis), which fall into the Persian Gulf. They produce tobacco, wine, rice, dates, opium, linen, cotton, silk, and kermes. They are the home of the rose, from which is manufactured the celebrated perfume, attar. They have iron and lead mines and marble and alabaster quarries. The principal towns are Shiraz, Jehrum, Darab, and Bushire. In this province occur the ruins of Persepolis, Pasargadæ, and Shapur, and the celebrated sculptured rocks called by the Persians *Naksh-i-Rustam*. Pop. (estimated) 1,700,000.

Farther India, or **Chin-India**: See INDO-CHINA.

Farthing [M. Eng. *ferthing* < O. Eng. *fēorðung*, deriv. of *fēorða*, fourth]: a British coin; the fourth part of a penny. It was coined by the Saxons, and again by King John (1210), but the quarter of a penny, cut twice across, also passed for a farthing. In Edward VI.'s time the coinage of silver farthings ceased. An act 9 Henry V. mentions a *gold* farthing. Copper farthings were first struck in 1665; tin farthings appeared in 1684 and 1692; half farthings were coined in 1843 and 1852. A farthing is worth about half a cent.

Farthingale, or (obs. form) **Fardingale**: See CRINOLINE.

Fasano, fāā-saa'nō: town in Southern Italy; province of Apulia; on the road from Bari to Brindisi (see map of Italy, ref. 7–H). It is celebrated for its olive plantations, and carries on a considerable trade in produce. But in the summer the flies become such a plague as to drive away most of the inhabitants to the neighboring La Selva, on the hills. Pop. 18,500.

Fas'ces [= Lat. *fas'ces*, plur. of *fas'cis*, bundle]: a bundle of rods of birch or elm, sometimes having an ax (*securis*) tied up within it. Such fasces were borne by the lictors before the superior magistrates of ancient Rome. The ancient kings, the consuls, the prætors, the dictators, etc., had the fasces carried before them; while the quæstors had this distinction in the provinces only. Generals who had been saluted as imperatores had fasces crowned with laurel, a custom anciently observed with some of the other magistrates. The number of the fasces and lictors varied with the rank of the dignitary, and was different in different ages.

Fas'cia [from Lat. *fas'cia*, bandage; cf. FASCES]: in the anatomy of man and most of the vertebrate animals, a laminated tissue of fibrous or aponeurotic character found in nearly all parts of the body. There are two kinds, the superficial and the deep fasciæ. The superficial fascia lies under the skin, is of varying thickness, and is disposed into several layers of fibro-areolar substance, containing particles and layers of fat. Between its layers blood-vessels and nerves run. Its fat serves to keep the body warm. The deep fasciæ are composed of unyielding fibrous substance. They sheathe the several muscles and the entire limbs (aponeuroses of investment), or serve instead of bones for the insertion of certain muscles (aponeuroses of insertion).

Fascination by Serpents: a power of so charming weak animals by the eyes and movements of body that they are easily secured as prey. This is not a blind, overpowering force, but one which the doomed animal seems partly to appreciate, and yet is unwilling to resist entirely. Squirrels, mice, and the weaker birds are the animals which are most often captivated by this power. They are described as running in front of the fascinator by short vibrations of distance or passing round in a circle, gradually shortening the intervals until they are seized by the serpent. Often the animal during the process utters piercing cries, as if aware of its danger, and yet unable to resist. Sometimes a diversion of the animal's attention by a sudden noise, or the interposition of some material obstruction to the vision, breaks the charm and sets the captive free.

Unfortunately, thoroughly full and accurate accounts, by good observers, who have witnessed the fascination of a bird by a serpent from beginning to end, are practically lacking, but there would seem to be several more or less plausible explanations of the phenomenon. Many animals are extremely curious, and are attracted by any unfamiliar object or unusual sound. A familiar example of this is the manner in which wild ducks are attracted by the antics of a dog, which has been trained to gambol in front of a "blind" and thus draw ducks within gunshot. Squids are caught with bits of looking-glass, the electric light is used with great success to attract fishes, and many others bite readily at artificial baits which resemble nothing in nature. The antipathy of birds, and especially small ones, for owls is well known, and monkeys appear to have much the same feeling toward a snake, being at once terrified and attracted by the reptile. It may happen that the snake's original intention was to secure the young of the bird or mouse that ultimately becomes his prey, and that in the effort to frighten or coax the enemy away from the vicinity of the nest or burrow one of the parents becomes a victim instead. Or the birds or squirrels may at first be attracted toward the serpent by curiosity, or by the same impulse which leads birds to mob an owl, and as they flit back and forth, and circle around the snake, screaming with terror and anger, becoming more and more excited all the time, an incautious move brings one within striking distance.

There is still another possible explanation: It is well known that the common hen may be readily hypnotized, and music seems to have much the same effect on some small mammals, rendering them incapable of movement. The first approach of bird or mammal toward the snake may be caused by curiosity, but once sufficiently near, the snake may, even without himself being aware of it, exert a hypnotizing influence, and seeing his prey within reach naturally avails himself of the opportunity. F. A. LUCAS.

Fascines [Fr., from Lat. *fas'cina*, a bundle]: bundles of brushwood tied together. These are formed into mattresses for construction of levees and jetties, for breakwaters, and in marshy places for the foundation of piers of bridges.

Fâsher, El: See the Appendix.

Fashion [M. Eng. *fasoun*, *facioun*, shape, manner, from O. Fr. *faceon*, *façon*, thing made, making < Lat. *fac'tio*, *factio'nem*, a making, deriv. of *fa'cere*, make. Cf. FACTOR]: the peculiar shape, make, or style of anything. The etymology of the word points to special characteristics caused by the composition or construction of anything, and this is the original force of the term; thus *The Fashion of Furniture* was the well-chosen title of an essay on fitting and appropriate design in modern domestic interiors. Nearly akin to this is the most usual meaning, namely, the rapidly changing character of dress, or of table furniture, or of house-decoration, or of writing-paper, visiting-cards, or any appendage of easier and more elegant life. A bonnet which was *in fashion*, that is, in the accepted character or style of the day, in 1860, looked very odd in 1890: *the fashion*, then, is that special character or style to which the bonnet was made to conform. *The reign of fashion* is the arbitrary imposing of this character or style upon every woman, no matter what her complexion or stature, under penalty of seeming ridiculous; and, in like manner, its imposition upon every man, every carriage, the interior of every room of any elegance. *In fashion* or *in the fashion* means in accordance with the accepted character or style, when said of any object; or, when applied to a person it means clothed, gloved, and having jewelry, etc., in accordance with the accepted character or style of each object of apparel.

The extent to which changes of fashion are carried is very curious. Thus in jewelry, coral either is or is not a beautiful and effective material for necklaces, earrings, etc. If it is not so, why was it in use so freely before 1875? If it is so, why was it wholly neglected and despised for the fifteen years thereafter? Or if pink coral is becoming to one person and not to another, why is it worn by all when in fashion, and abandoned by all when the fashion changes? Earrings in the form of long pendants may be thought highly becoming to one woman, and large, light hoop-earrings becoming to another, and a third will do well to have no earrings at all; but fashion decides that all women shall wear pendants from 1860 to 1870, that all shall wear small knobs or buttons hugging the lobe of the ear close from

1870 to 1890, and that after 1890 no earrings at all shall be worn by any woman calling herself elegant. In 1820 women wore their gowns so close and straight that even young girls were unable to step across a moderately wide gutter in the street. In 1850 the circumference of a lady's gown, at the hem, was perhaps eight yards. In 1890 the skirt was as straight and slim in appearance as in 1820, but had nearly as much stuff in it as in 1850.

For many years before 1852 no Englishman of social position dared wear a mustache, or any part of the beard except whiskers, unless he were a cavalry officer or an artist. The following year there was a "beard movement," if we may believe *Punch*; at all events from 1853 on it has been tolerably free for Englishmen to wear more or less hair on the face. Here is an instance of freedom from the rule of fashion: any man may wear his full beard, or any part of it, or none, as his appearance or his desire to avoid trouble may bid him, but at any moment this freedom may cease to exist. The hair of men's heads has never been emancipated; for about 1852 or 1853 there was a sudden order issued to cut the hair short, and that order has remained in force ever since.

These are only illustrations of the tyranny of the rule of fashion in matters which would naturally be thought free from it. It may be harmless in these instances. It is in dress and other ornamental arts that this rule of fashion does serious harm. No great care and no sincere feeling will be put into designs which are prepared for the brief use of a season or two. If the silks of elaborate *damassé* patterns which "come into fashion" in the autumn are not only to be of wholly different patterns next year and the old ones unfit to be seen, but also to be wholly abandoned in favor of plain striped fabrics the third year, then the patterns of the costly silks will not be well drawn, not rich, not graceful. That is a well-known truth: it results from the indifference of the designer for a thing which he knows will not endure, from the careless treatment by the merchant of the one-year investment, and from the absence of any awakened respect for the decorative art involved on the part of the buyers and wearers of such fabrics. The patterns and the ornaments of two years ago, or even of one year ago, very often, are absolutely out of the market this year. The large dealers would not dream of offering them, or of keeping them for those who might ask.

It is a sort of sin against commercial laws to have any old-fashioned goods on hand. Once, when some wall-papers, the accumulation of several years of an architect's work for his clients, were sent to an emporium for sale, there was serious complaint, as of dishonesty, "that Mr. X. should offer that paper as if it were a new paper, when Mr. Y. had had it on his parlor walls for three years." Of course no fine designing in wall-papers is possible if only the year's goods are salable during the year, and each dealer hurries the old ones out of sight and out of existence to make room for the new styles. See DECORATIVE ART, and for consideration of fashions in dress see COSTUME.

RUSSELL STURGIS.

Fasho'da: a large town in the Egyptian Sudan. See the Appendix.

Fassett, CORNELIA ADÈLE: See the Appendix.

Fast: a period of voluntary abstention from food, particularly as a religious discipline. All ancient nations known to history had their fasts—the Egyptians, the Phœnicians, the Assyrians, the Indians, and after these the Greeks and Romans.

Extraordinary religious acts were preceded by fasts. The mysteries demanded this discipline, especially from those about to be admitted to them. In consequence of certain prodigies the Sibylline books directed "a fast in honor of Ceres to be instituted and to be kept every fifth year." (*Livy*, lib. 36, c. 37.) A stated fast imposed by Jupiter is spoken of by Horace (*Satires*, ii. 3). Fastings were sometimes practiced before undertaking military enterprises, or whenever there was special cause to seek the favor of the gods or to avert their anger. A notable instance is given in the book of Jonah. When Nineveh was threatened with destruction, to avert the calamity a fast was proclaimed, and the order given, "Let neither man nor beast, herd nor flock, taste anything; let them not feed nor drink water." Among heathen philosophers and religious people fasting was reckoned a duty—markedly so by the Pythagoreans, who lived a life of constant asceticism, abstaining always from flesh and fish, and at times from food altogether. The nations of the East and the Indians of North America are alike exceedingly severe in this respect. The Mohammedans keep as an annual fast their ninth month, Ramadan; during every day of this month, from sunrise to sunset, they eat nothing, drink nothing, and give up the solace of their pipe and every other usual indulgence. Their months being lunar, each in the course of thirty-three years occurs in every season. When the Ramadan happens in summer, the long hot days are exceedingly trying to those who must labor. The Jews from their earliest existence have observed stated and special fasts, national and private. Under the law, as first given, there was but one day imposed on the nation—the great day of the Atonement. In the course of time four other days were added in commemoration of sorrowful events in Jewish history. These days, especially the first, have been always, and are now, observed with great rigor: no food, no water, is allowed to pass the lips, not even for the rinsing which, on first rising, must always make clean the mouth before the pronouncing of God's name; even the swallowing of the saliva is carefully avoided. The fast lasts from sunset, when the Jewish day begins, until the shining of the stars the night after. Besides the public fasts, there were and are many observed by individuals in consequence of vows, or because of personal cause for affliction, or by way of discipline. The Pharisees fasted statedly twice in the week—Monday and Thursday. These fasts are not all of equal severity.

Under the New Testament there is no fast-day appointed by the Lord or by his apostles, nor does the practice rest upon direct command from them. It is even clear that Jesus imposed no special abstinence on his disciples, but it is also clear that he assumed that this exercise would not be neglected by any who desire the rewards given by God. He gave directions for fasting, for the shunning of hypocritical show, saying, "When ye fast be not of a sad countenance," etc., and by his example he taught the duty. It may be said that he thus taught and acted as a Jew. But when it was objected that his disciples did not fast as did those of other Jewish teachers, he gave as a reason why they did not that so long as he was with them the signs of sorrow were not expedient; and he added that the time would come when they should fast, referring to a time after the fulfilling of the law. If the apostles gave no rule on the subject, there is no room to doubt as to their practice. One reference is sufficient. In Acts xiii. it is said that as certain prophets and teachers at Antioch "ministered to the Lord, and fasted, the Holy Ghost said, Separate Barnabas and Saul for the work whereunto I have called them. And when they had fasted and prayed, and laid their hands on them, they sent them away."

It is not so stated in the New Testament, but it is probable that from its first recurrence the day of the crucifixion was observed as a day of humiliation, as it has been through the many centuries since. It is certain that rules were soon laid down touching this and other seasons of bodily mortification. Wednesday and Friday in every week were kept as such, and early writers who speak of these days of abstinence refer the observance to apostolic usage. The duty of bodily mortification at times of repentance or humiliation or of special spiritual exercises (for fasting does not of necessity imply sorrow) is recognized, it is believed, in this day by all classes of Christians without exception. There are some bodies of believers who have rejected the seasons so long observed, but yet these, on what they deem proper occasions, appoint days to be kept by all their members. Even the Puritans of New England had their yearly fast-day.

In the West, the churches of the Roman obedience, together with the Church of England, impose as stated fasts, first, Lent, the *spring* fast, beginning with Ash Wednesday in the seventh week before Easter, and counting forty days, Sundays being excluded. This long fast is of very early observance, but the time of its commencement and the period of its duration were not always the same, it being an expansion of the observance of the time of the passion of our Lord. As now kept, Lent was fixed by St. Gregory the Great in the sixth century. Second, the Ember Days, which are Wednesday, Friday, and Saturday preceding the four quarterly seasons of ordination. It has been already shown that in apostolic days fasting preceded ordination. The name is variously accounted for: probably it is a corruption of the Latin name for the seasons—*quattuor tempora*, or *tempora*. Third, the Rogation Days, the three preceding Ascension Day. This fast is not older than the close of the fifth century; it was first instituted in Vienne in France, to accompany a season of special rogations (petitions) that God would withdraw certain temporal chastisements. It was probably fixed because of its being a meet introduction to a great festival. Fourth, every Friday, this day being the weekly commemoration of the crucifixion, even as the first day, the Lord's Day, is a joyful remembrance of his resurrection. Fifth, the vigils on the eves of certain great festivals. At one time these vigils were literally kept as watches, the whole night, or a part, being spent in devotions in the churches. They are not so kept now. Advent, the four weeks before Christmas, bears some analogy to Lent, but its Wednesdays and Fridays are alone kept as fasts. The Protestant Episcopal Church in the U. S. follows the Anglican rule, excepting that vigils are not imposed, though in the new Standard (1892) recognition of the "eves" or "vigils" is found. In the English and American prayer-books the "Table of Fasts" comprises Ash Wednesday and Good Friday, while the "other days of fasting on which the Church requires such a measure of abstinence as is more especially suited to extraordinary acts and exercises of devotion" are:

I. The forty days of Lent.

II. The Ember Days at the four seasons, being the Wednesday, Friday, and Saturday after the first Sunday in Lent, after the Feast of Pentecost (Whitsunday), after Holy Cross Day (Sept. 14), and after St. Lucy's Day (Dec. 13).

III. In the Roman Catholic Church Fridays, outside of the above-mentioned fasting-seasons, are simply days of abstinence. The observance of the Rogation fast has varied greatly, and has generally ceased.

The rule of the Orthodox, the Armenian, and other churches of the East is nearly like that of the Western, having the same origin, that of the usage before the schism, but in some details they differ—e. g., in the Holy Orthodox Church on Aug. 1 begins the fast of the Mother of God, which lasts until the feast of her repose—fourteen days. It is to be observed, however, that in the East the strict idea of a fast is preserved to a greater extent than in the West. From earliest times a distinction in food was recognized, and allowance made for those who through bodily weakness could not wholly abstain. To whatever due, it is a fact that in the West the rules of fasting have always been more lenient than in the East. Very few of the days spoken of as fast-days are strictly such; they are days of abstinence, when less food and of a coarser character is taken. In the Holy Orthodox Church 266 days in the year are kept as fasts with scrupulous fidelity.

A practice so universal as that of fasting must be based on some necessity of man. Nevertheless, the objection is sometimes heard that it tends to spiritual pride and formalism. This must be granted, but abuse is no argument against due use. A Christian, who knows that his Lord joined together prayer and fasting, can hardly advance the objection. It is also objected that health is frequently injured by religious fasting. It may be so. But on the other hand, it can admit of no doubt that in an age and country particularly luxurious a stated abstinence from food, a weekly putting aside of self-indulgence, and supporting the body on plainer, less attractive food, would go far toward freeing men from many of the evils that wait on appetite. See FASTING. Revised by WILLIAM STEVENS PERRY.

Fast Freight Line: an organization for prompt delivery of through freight. It has two forms, the incorporated or non-co-operative one, which is very much like an express company, making contracts on its own account with the shippers and being responsible for the goods received. It differs from an express company chiefly in handling business in larger bulk, and not occupying itself with the collection and delivery of parcels. The more common form of freight line, known as the co-operative line, is not a company at all, but an arrangement between connecting roads for reporting car mileage to one another and tracing the responsibility for loss or damage of goods. Most freight lines are of this kind. They have the advantage, as compared with the incorporated line, of allowing no opportunity for inside rings to make unfair profits; they have the disadvantage of giving the shipper less security for responsible treatment, inasmuch as he is dealing with a number of different railroads instead of a single incorporated company.

A. T. HADLEY.

Fasti [Lat. (sc. *di'es*), court-days, liter., lawful days, plur. of *fas'tus*, lawful, deriv. of *fas*, divine right, law, deriv. of *fa'ri*, speak]: the court-days or festival-days of the ancient Romans. In accordance with the derivation, *dies fasti* were days on which it was allowed to speak, hence days on which judgment could be pronounced, on which courts could be held—court-days. A *dies nefastus* therefore denoted the opposite, and *dies nefasti* were esteemed unlucky days. To the *dies fasti* belonged the *dies comitiales*; to the *dies nefasti*, the *dies religiosi*, which were considered days of evil omen. The institution of these days is ascribed to Numa Pompilius, and belongs therefore to the earliest days of Rome. Their order or succession was long known only to the priests, who thus acquired great political power, until Cn. Flavius made it public about 304 B. C. From this time onward the lists of the *dies fasti et nefasti* received more particular attention, and contained, gradually enlarged and perfected, an accurate description of the whole year, according to its months, with exact specification of the *dies fasti*, *dies comitiales*—festivals and holidays, days appointed for the celebration of public games, etc. Thus they assumed the form of the later calendars or almanacs. As they were still, notwithstanding the care taken in their preparation, unavoidably inaccurate and imperfect, we are told of Cæsar "fastos correxit," etc. As the fasti or calendaria of ancient Rome were engraved on stone and set up in public places, remnants or fragments of such records, more or less complete, have been preserved and put together, in order to produce as perfect a representation as possible of one of these ancient Roman calendars or almanacs. If the ordinary fasti or calendaria are valuable as affording a correct knowledge of the Roman year, much more important are those which Livy calls "fasti consulares," and which, because they were set up on the Capitoline, are also called Capitolini. The Fasti Capitolini contain lists of the annual consuls, of the censors, dictators, magistri equitum, and also of generals who celebrated triumphs (*fasti triumphales*) and a record of the services for which a triumph had been granted. Of such Fasti Capitolini important fragments, discovered in 1547 at Rome, are extant. For further particulars, see Pauly's *Real-Encyklopädie*, etc.

Fasti is also the title of a well-known but unfinished poem by Ovid, the subject of which is the Roman festivals —the festival-calendar. It may be regarded as "a poetical year-book or companion to the almanac, having been composed to illustrate the Fasti published by Julius Cæsar," who corrected and entirely reformed the calendar.

Fasting: properly, the total abstinence from food; commonly, however, a restricted diet in which only certain articles of food are excluded because of religious or other motives.

The effects of fasting upon the organism are determined by the kind of foodstuffs that are withheld and the degree of abstention, the state of the body and mind, the species of animal, the length of time the fast continues, the sufficiency of the supply of water, and certain attendant conditions. A study of dietetics teaches that the human organism absolutely demands for its healthy maintenance certain kinds of foodstuffs, whereas others which enter largely into everyday diet and are of great nutritive value are merely of incidental importance. Albuminous substances are a necessity because it is only by their means that the demands for nitrogen are supplied, and were these entirely withheld starvation would as inevitably ensue, even though an abundance of other food be taken, as when there is total abstinence. On the other hand, starchy and saccharine matters might be rejected without causing physical want, because they are capable of being replaced as nutritive elements by fat and partly by the albuminous materials. Similarly may the fats be replaced. Abstention from single articles of food does not affect the nutritive condition of the body provided that their dietetic values are replaced by other foodstuffs. In certain morbid states of the system, as in the various forms of dyspepsia, mal-assimilation, diabetes, etc., the exclusion of certain articles of food often proves of great benefit.

When there is total abstinence for short periods of a day or two no important effects are observed save intense hunger, gastric distress, headache, weakness, and a feverish condition; but when practiced for prolonged periods other phenomena of a marked character are noted. In order that these may be understood it is necessary to bear in mind that the vital processes depend for their activity upon energy which is continually being supplied by means of chemical processes, whereby the complex compounds which are ingested as food undergo decomposition into simpler substances. When food is insufficient to supply the demand the organism consumes its own tissues (autophagy), which results in a loss of body-weight and an enfeeblement of all the vital processes.

The earliest symptoms usually observed in enforced fasting, apart from those mentioned in the preceding paragraph, are irritability, lassitude, a slight increase in the frequency of the pulse and respiration (especially upon any exertion), a decrease of the temperature of the body, constipation, and a diminution in quantity and increased acidity of the urine. There then appears a tendency to delirium, particularly noticed and of a serious character in cases of individuals who are deprived of food because of shipwreck or similar accident; but in voluntary fasting it is seldom of much moment and soon passes off. The body loses weight from day to day with considerable regularity; the stools become scant and tarry; nausea, flatulence, and colic are apt to be more or less annoying; the blood and tissues lose more and more of their water, and consequently the blood becomes thicker and the tissues less moist; the white blood corpuscles gradually and after a time ultimately disappear; the red corpuscles of the blood do not seem to be affected in their relative numbers, although apparently increased owing to the loss of water from the blood; but in prolonged fasts large numbers of them are small and imperfect. Albumin and all matters in the blood that are available for nutritive material for the tissues are diminished. The skin loses its elasticity and becomes pale, harsh, dry, and shriveled; the body exhales a peculiar fetid odor. Wasting of the body and enfeeblement of all the vital processes continue until the loss of weight in the adult reaches about 40 per cent. of the original, in the young about 20 per cent., when death occurs from exhaustion.

In the report of Mr. Robins of the forty days' fast of the professional faster Succi, there is probably the most satisfactory account of any on the subject. Succi is a native of Italy, 5 ft. 5½ in. tall, aged 27, slightly built, and of sallow complexion. He claims to have accomplished thirty-two fasts previous to the forty days' fast alluded to, in which he abstained from food for periods varying from twenty to thirty days. Before beginning the forty days' fast he ate a fair luncheon, and from this time to the end of the ordeal was kept under rigid vigilance to prevent deception. Robins states that from the first day to the last Succi did not develop a single alarming symptom nor experience any great amount of discomfort. Even during the first few days, when the pangs of hunger might have been expected to assert themselves most acutely, he made no complaint, but in reply to questions said he felt very comfortable. The change in his condition from that of a well-formed though slight man to one of extreme emaciation, though very great, was almost uniform from day to day. There was not at any time any irregularity in the heart's action, although his pulse was a little more frequent. He smoked usually one or two pipes a day and occasionally a cigar or cigarette. During each day he took a small quantity of an "elixir," on an average of less than 60 drops per diem, in doses varying from 5 to 20 drops in water. He took this as a sedative to the stomach, and to relieve slight colic and flatulence, from which he suffered at times. It resembled chlorodyne in composition and effects, and did not contain coca or anything of a nutritive character. During his fast he drank filtered water, Kaiser-brunnen alkaline table-water, and Hunyadi-janos (purgative) water. The total quantities were: water, 535½ oz.; Kaiser-brunnen, 354 oz.; and Hunyadi, 33 oz. Total, 922½ oz., or about 57½ pints—less than a third of what the average individual would consume under ordinary circumstances. During the first ten days Succi lost 16 lb. 5 oz.; during the first twenty days, 22 lb. 15 oz.; during the first thirty days, 28 lb. 12 oz.; and during the forty days, 34 lb. 3 oz.—the total loss of weight being 26·55 per cent.

The amount of urea eliminated was diminished during the first week to 3·04 grains per pound of body-weight per diem (the normal being 3·5 grains); during the second week to 2·12 grains; during the third week to 1·66 grains; during the fourth week to 1·5 grains. During the fifth week it rose to 1·79 grains, and during the last four days the average was 2·10 grains. The increase in the amount of urea during the fifth week indicates the beginning of what may appropriately be considered the second stage of autophagy. During the first stage the energy of the body is derived almost solely from the consumption of nutritive substances which are stored in the blood and various structures; and subsequently from the consumption of fat. As soon as the fat has largely disappeared the muscular and other albuminous tissues are fed upon to a relatively greater extent, with the consequent increase in the amount of urea. With the second stage the danger line is reached, and each day adds increasingly and disproportionately to the peril, because of the gradual destruction of the more important of the vital structures.

During the progress of autophagy the various tissues do not suffer alike, some being preyed upon earlier and consumed to a greater degree than others. The first portions used are nutritive substances which are stored in the different structures, such as sugars, glycogen, loose particles of fat, albumin, etc. As soon as these are gone the solid parts suffer, first, chiefly adipose tissue, and after its practical disappearance the muscular substance especially. Consequently, during the first stage the loss of weight is mainly due to the disappearance of fat, whereas during the second stage the loss is chiefly due to the using up of the nitrogenous structures. During the entire period of fasting there is a steady loss of weight owing to a loss of water.

In cases of death from starvation the blood is increased in specific gravity, and contains less water, albumin, corpuscles, and substances available as nutritive materials; fat has almost entirely if not entirely disappeared; the liver is dark and much reduced in size; the muscles are greatly wasted and, together with the other tissues, greatly lacking in water. All of the structures are wasted.

The ability to withstand the total abstinence of food varies in different individuals, and is materially affected by many attendant circumstances; consequently, the effects vary in different cases. As a rule, death occurs within a period of three to three and a half weeks, but there are many cases on record in which death ensued much sooner, and, on the other hand, in which it was not noted until forty to sixty days. Claims have been made, but never properly substantiated, that total abstinence has extended over many months or even years, but sixty days is the longest period that at present can be accepted as having been demonstrated. Age exercises a material influence; the middle-aged withstand fasting better than the young or old; infants die in a few days, and young children in a week or ten days.

The lower animals, as a rule, are less severely affected by fasting than man. A pig has been known to fast for 160 days, and snakes and certain other cold-blooded animals for periods of a year or over. Cats, horses, and mules live for over three weeks, and dogs and wolves for two months. Rabbits live for two or three weeks, and birds, Guinea pigs, and rats for about a week. During hibernation animals exist for months without food or drink, but in this condition the mind is in abeyance and the general state of vitality is exceedingly low, almost on the border of death, and, as a consequence, there is relatively little consumption of the tissues.

Life is prolonged by a sufficient supply of water, and by mental and physical quiet; and in man and warm-blooded animals by high ambient temperature and abundant clothing to prevent the loss of bodily heat, and thus diminish the consumption of the tissues. Fasting as observed in the insane, hysterical, and fanatics is usually exceptionally well borne because of the peculiar mental states. In instances of enforced fasting, as in the case of the shipwrecked, entombed miners, etc., the terrible mental strain adds greatly to ill effects due to the want of food, and commonly in these unfortunates the mind is soon unbalanced. When water is also withheld death occurs about one-third sooner. When drinking water is not to be had great relief has been experienced and life prolonged by placing wet cloths to the body or by immersing the feet, etc., thus allowing absorption of water through the skin.

Auselmier has shown in the results of experiments on dogs that if a certain amount of blood is drawn from them when they are subjected to inanition and given to them as a food the daily loss of temperature is less, life is prolonged, and emaciation more complete, so that the loss of weight may reach 60 per cent. of the initial weight. In fat subjects the emaciation reached 60 per cent., in medium 50 per cent., and in the young 40 per cent. Animals live one-half longer than when this was not practiced. The value of this method, which is spoken of as "artificial autophagy," has been illustrated in cases of starving men.

In the restoration of diet after prolonged fasting the administration of food should be begun by giving small quantities of beef tea, milk, diluted spirits, rice broth, or similar very light diet; after twenty-four hours, corn starch, rice, mellow apples, orange juice, etc.; then gradually increasing the number of articles from day to day as indications suggest. In instances in which absolute freedom of diet has been permitted, the most serious results have followed. See FOOD. EDWARD T. REICHERT.

Fasting, faas'ting, CLAUS: Norwegian poet and critic; b. in Bergen, Oct. 29, 1746. He studied divinity, and took his theological examination at Copenhagen in 1766; but his tastes were for music and literature. From 1770 to 1777 he resided in Copenhagen, where he became a distinguished member of the Norske Selskab. His tragedy *Hermione* (1770) shows the influence of Voltaire. He was more important as a critic and the editor of critical journals (1773, 1775-76) than as a poet or a dramatist. From 1777 till his death (Dec. 24, 1791) he lived in Bergen. His drama *Aktierne* appeared in 1788. A selection from his works was edited by L. Sagen: *Udvalg af Claus Fastings Skrifter med Bidrag til hans Biografi* (Bergen, 1837). G. L. KITTREDGE.

Fastnet Rock Light: See the Appendix.

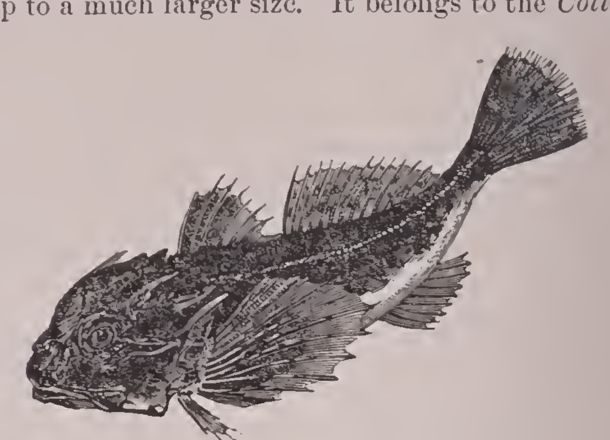
Fat: See HISTOLOGY and FATS.

Fata Morgana, faa'taa-mōr-gaa'naa [Ital., the Fairy Morgana, the phenomenon being regarded as the work of a fairy (*fata*) named *Morga'na*. *Fata* < Low Lat. *fata*, a goddess of fate, a fairy > O. Fr. *fee, fae* (> Fr. *fée*), whence Eng. *fay*, fairy]: a remarkable and singularly beautiful effect of mirage, occasionally observable in the Sea of Reggio, Straits of Messina, between Sicily and Calabria. It presents a series of magnificent architectural structures and landscape views, embracing columns, arches, towers, castles, palaces, trees, avenues, and wooded plains, with crowds of moving men and animals, all constantly varying and assuming new aspects, and in certain conditions of the atmosphere becoming resplendent with prismatic colors. There can be no doubt that these images are derived from objects on the shore, their singular forms and transformations being the result of extraordinary refractions in the atmosphere (for the explanation of which see MIRAGE).

Fate [M. Eng. *fate* < O. Fr. *fat* < Lat. *fa'tum*, thing spoken, decree, fate, neut. perf. partic. of *fa'ri*, speak: Gr. φάναι, speak]: inevitable destiny. The belief in such a destiny has various forms. The old Chaldaic or astrological fatalism looked upon the visible heavens as the book of this destiny, and found all things necessarily prefigured in the positions of the stars. The old Stoical fatalism considered the rise and the decay of the world as controlled by an absolute necessity, but while this necessity, with them, was a fate (εἱμαρμένη), which determines, it was also a providence (πρόνοια) which governs all things. The fatalism of the Greek dramatists made all events fixed under the control of Dike and Nemesis, Justice and Retribution. Mohammedan fatalism regards all things, great and small, as so inexorably predetermined from the foundation of the world that no accident is possible, and any attempted defense against danger is futile. Pantheistic fatalism considers the infinite substance which it calls God to be developed in space and time by a procedure so changeless that things extended or things thought are equally necessary; and which not only destroys all freedom of the will, but obliterates all distinction between good and evil. The modern philosophical conception of fate is that of a blind causality undirected and undetermined by any conditions.

Fates, The (transl. of Lat. *Par'cæ*, Gr. Μοῖραι, the goddesses of fate, liter., the distributers, or dividers): in the Greek mythology, three goddesses who ruled the fates of men and all thing. They are generally named Clotho, who spins the thread of life; Lachesis, who marks off the allotted span; and Atropos—the inflexible—who cuts the thread. Their genealogy and the whole mythus are quite variously given in different authors. The Homeric poems speak usually only of one Moira, and the personification is not complete; no particular appearance of the goddess, no attributes, and no parentage are mentioned. Nor is the Homeric Moira an inflexible fate to which the gods themselves must bow; on the contrary, Zeus, as the father of gods and men, weighs out their fate to them. With Hesiod the personification of the Fates is completed, but they are still represented as depending on their father Zeus, and subject to his commands. And it was not until the time of Æschylus that they appeared as the divinities of fate in the strict sense of the word, independent of the Olympic gods, the messengers of the eternal necessity to which even the gods must bow. They are generally associated with the Erinnyes, who inflict the punishment for evil deeds, and they are sometimes called their sisters.

Father Lasher, or **Lucky Proach**: a marine fish (*Acanthocottus bubalis*) of the European coasts, from 6 inches long up to a much larger size. It belongs to the *Cottidæ* or



The father lasher.

sculpin family, its head is covered with spines, and it has a repulsive aspect. It can live a long time out of water, and, though regarded with aversion it affords a palatable article of food.

Fathers, Apologetic: See APOLOGETICS.

Fathers (of the Church): the distinguished earlier laborers in the Christian Church. (See APOSTOLIC FATHERS.) The Roman Catholic Church distinguishes between Church Fathers, Church teachers, and Church writers. The Church teachers are men of acknowledged orthodoxy, authorities for the doctrines of the Church, while the Church writers are of less, or even doubtful, authority. The greatest of the Church teachers are also Church Fathers. Such were Athanasius, Basil the Great, Gregory of Nazianzen, and Chrysostom in the Oriental Church—Jerome, Ambrose, Augustine, and Gregory the Great in the Church of the West. Thomas Aquinas and Bonaventure may be named as Church teachers who were not Fathers, and Tertullian in his second era and Origen as Church writers who were not Fathers according to the Roman definition, which includes orthodoxy. The line of Church Fathers is generally regarded by Protestant theologians as terminating with the eighth century (John of Damascus in the Greek, Gregory I. in the Latin Church); the Roman Catholic writers extend it to the thirteenth, or even to the Council of Trent. The scientific treatment of the matter contained in the writings of the Fathers is embraced in Patristics, while their lives and the topics which are related to the externals of their works come under the head of Patrology. This distinction, however, is not always observed. The Fathers are of great value in the history of biblical interpretation, the history of dogmas, creeds, rituals, the constitution of the Church, and indeed in every part of historical theology; nor is there any part of theology in which they may not be made highly useful. In the greatest internal struggles of the Church the importance of the Fathers as witnesses or as authorities has been recognized on both sides, as in the Reformation, and in the nineteenth century in the controversies of the Anglican Church. (The principles to be observed in interpreting the Fathers are stated in Krauth's *Conservative Reformation*, 726, *seq.*) Next to the Apostolic Fathers in value are the Apologists, or Apologetic Fathers (see APOLOGETICS); the Alexandrians, Clement and Origen; the Nicene and Post-Nicene Fathers: Eusebius, Athanasius, Gregory of Nyssen, Chrysostom, Augustine, and Jerome. (All the earlier writers on patrology, beginning with Jerome, were edited together by Fabricius, 1718.) The greatest laborers in the issue of editions of the Fathers have been the BENEDICTINES (*q. v.*; see also BENEDICTINE EDITIONS OF THE FATHERS). Next to them have been the Anglican divines. The most recent interest in patristics in Great Britain has been shown in the issue of translations of the Fathers. In the Roman Catholic Church, among the names illustrious in patrology are Bellarmin, Oudin, Du Pin, Le Nourry, Tillemont, Möhler, Hefele, Alzog, Nirschl; in the Protestant churches of the Continent, Scultetus, Walch, Danz, Neander, Otto, Harnack, Zahn; in Great Britain, Cave, Cureton, Routh, Pusey, and Lightfoot. Among the editions of the collected writings of the Fathers, the most complete are De la Bigne's (17 vols., 1654); the Lyons *Maxima Bibliotheca* (27 vols., 1677); Cailleau and Guillon (148 vols., 1829, *sqq.*); Migne (1844–66; new ed. 1878, *sqq.*). The last is, *in bulk*, the greatest of the collections, and embraces the Greek Fathers in 167 volumes and the Latin Fathers in 222 volumes. It is continued by Abbé Horoy, and is to be brought down from 1216 (Innocent III.) to the Council of Trent. The very numerous editions of particular Fathers are mentioned under their names. Books of selections, Rösler, Augusti, Orelli, Philo, Oehler. English editions of the principal Fathers: *The Oxford Library of the Fathers* (48 vols., 1837–85); *The Ante-Nicene Library*, by Roberts and Donaldson (24 vols., Edinburgh, 1866–72; 8 vols., New York, 1886); *Nicene and Post-Nicene Library*, first series ed. by Schaff (14 vols., New York, 1886, *sqq.*), containing the works of Augustine in 8 volumes and the works of Chrysostom in 6 vols.; second series by Schaff and Wace (14 vols., New York and Oxford, 1890, *sqq.*). Best edition of the Apostolic Fathers in Greek and English by Lightfoot (London, 1891). Patristic manuals in German by Alzog (4th ed. 1888) and Nirschl (3 vols., 1885). The standard English work on patristic biography and literature is Smith and Wace's *Dictionary of Christian Biography* (1882–88). Revised by PHILIP SCHAFF.

Fathipur′: the capital of the district of the same name, Allahabad division, Northwest Provinces, in British India (see map of N. India, ref. 6–F). The town is of both commercial and military importance. Pop. 20,000.

Fathom [M. Eng. *faðme* < O. Eng. *fæðm*, the outstretched arms, fathom: O. H. Germ. *fadam* > Mod. Germ. *faden*, thread < Indo-Eur. *pat-*, spread out, extend; cf. Lat. *pate're*, be open, extend]: originally the length which a man can measure by extending both his arms. It now denotes a measure equal to 2 yards, or 6 lineal feet, and is chiefly employed in nautical measurements. It is the unit of measure in soundings, and is employed in the measurement of cables, etc. The early colonists of the present U. S. reckoned the Indian wampum chains, then current as money, in fathoms.

Fatigue: See MUSCLE-SENSE.

Fatigue of Materials: the injury done to materials by stresses which exceed the ELASTIC LIMIT (*q. v.*). For instance, if the ultimate strength of a bar of wrought iron is 55,000 and its elastic limit is 25,000 lb. per sq. inch, a single application of a load will not cause rupture until the 55,000 lb. per sq. inch is reached. But if stresses be often applied which exceed the 25,000 lb. per sq. inch, the molecular structure is altered, the iron becomes brittle, and finally rupture will occur under a stress of perhaps 30,000 or 40,000 lb. per sq. inch. It is hence a fundamental rule that the materials in permanent structures should not be strained beyond the elastic limit, and the factor of safety should be selected with this in view. The experiments of Wöhler, conducted for the German Government about 1870, have proved of great value in establishing some of the laws governing the fatigue of materials. He showed that in the case of repeated stresses, the greater the range of these stresses the less is the unit-stress which is finally required to produce rupture, and also that a range of stress from tension into compression, or *vice versa*, produces rupture with a less number of repetitions than for one kind of stress alone. Engineers make allowance for the fatigue of materials due to repeated stresses by means of formulas deduced by Weyrauch, Launhardt, and others. See Weyrauch's *Iron and Steel Constructions* (1875) and Merriman's *Mechanics of Materials* (1892). See also STRENGTH OF MATERIALS.

MANSFIELD MERRIMAN.

Fats: in the common sense, those unctuous parts of animal and vegetable bodies secreted in the cellular tissues and separable therefrom by fusion at a moderate temperature. The animal fats do not differ chemically from those of vegetable origin. Both are definite compounds of certain fatty acids, chiefly oleic, stearic, and palmitic acids, with a basic substance called GLYCERIN (*q. v.*), which belongs to the class of alcohols. The fats are, as a rule, nearly insoluble in water, but dissolve readily in ether, which is their proper solvent. They are also soluble in naphtha, benzine, and the oils from coal; in oil of turpentine and other essential oils; bisulphide of carbon, chloroform, fusel oil, etc. They are scarcely at all soluble in cold ordinary alcohol. In absolute alcohol they dissolve much more readily than in weaker alcohol, and especially with the aid of heat. See FOOD.

The fats stain paper permanently and are not volatile by heat, a high degree of heat being required to make them boil. They distill over at a high heat, but not without complete, or nearly complete, decomposition, and the evolution of a substance of a pungent, disagreeable odor, irritating the eyes, and known as *acrolein*. Those fats which are fluid at ordinary temperatures are called oils. All the fats burn with a bright flame and with little smoke.

The chemistry of fats was first cleared up by CHEVREUL (*q. v.*), who showed that they belong to the class of compounds known as ethereal salts, or compound ethers. (See ETHER.) Most fats are mixtures of three compounds, olein, stearin, and palmitin, the hard fats being chiefly stearin and palmitin, and the soft fats olein. The hard fats are beef fat, mutton fat, human fat, wax, spermaceti, etc.; the soft fats, hog's lard, butter, etc., which are greasy at ordinary temperatures; while the liquid fats, or oils, are fluid at ordinary temperatures. When a fat is boiled with a caustic alkali, or treated with lead oxide, or superheated steam, it is decomposed, yielding glycerin as one of the products, and a mixture of acids or salts of acid. When the decomposition is effected by an alkali, the products are glycerin and a soap. (See SOAP.) Hence this process is called saponification. Lead oxide forms glycerin and "lead plaster." Steam forms glycerin and the acid or acids which were combined with the glycerin in the fats.

The researches of Berthelot have demonstrated the accuracy of Chevreul's views by the synthesis of fats from the union of fatty acids with glycerin, and the separation of one, two, and three molecules of water. See GLYCERIN, OILS, and SOAP.

The memoirs of Chevreul on the fatty bodies are among the most remarkable examples of a chemical research which has remained almost without important addition or change from the labors of subsequent investigators.

Revised by IRA REMSEN.

Fatty Degeneration: in pathology, a condition in which the minute structural elements of the tissues of living organisms are gradually replaced by fat globules. In man this diseased condition has been observed in nearly all the tissues.

In the great closed glands of the fœtus, which disappear after birth, and in the corpus luteum of the ovary, fatty degeneration is a normal process. In the liver, it is merely an excess of the normal fatty element contained in the acini, which, however, encroaches upon the organized elements of those structures, and becomes a true fatty degeneration. It also attacks the muscles, and especially the heart; the bones (in some forms of *mollities*), the brain (yellow softening), the cornea (*arcus senilis*), and the kidney in many cases of so-called Bright's disease. The fatty degeneration of the heart unaccompanied by valvular disease is very difficult to detect, even by the trained diagnostician. When suspected, a quiet life and a nourishing but not too stimulating diet, with the judicious use of tonics and iron, are to be recommended. For the disease there is no cure known.

Revised by WILLIAM PEPPER.

Fatuity [from Lat. *fatu'itas* (> Fr. *fatuité*), deriv. of *fa'tuus*, insipid, senseless, foolish]: a state of mind characterized by absence or great deficiency of the will and the intellect, and by apathy with regard to those things which usually arouse the feelings and impulses. If congenital, it constitutes complete or partial idiocy. When it is associated with, or consequent upon, acute disease, it has no significance except as a symptom of that disease; while if it be long continued, obscure in its origin, and progressive in character, it is almost certain to result in dementia, one of the most hopeless forms of mental disorder.

Fau′ces Ter′ræ [Lat., jaws of the land]: projecting headlands or promontories, including arms of the sea, as, e. g. bays, creeks, lakes, basins, harbors, rivers, etc., where the tide ebbs and flows. In England the general rule is that such bodies of water, as far as the point to which the flow of the tide extends, and unless they are within the body of a county, are under the jurisdiction of the courts of admiralty. In these exceptional instances the common-law courts exercise exclusive jurisdiction, except in a few classes of questions to which admiralty powers have been extended by statute. A stream is said to be "within the body of a county" (*infra corpus comitatus*) when a person standing on one shore can see what is done upon the other. In the U. S. the admiralty jurisdiction is not confined to tide waters, and is not excluded from waters "within the body of a county," but extends over the Great Lakes and over all rivers, etc., capable of navigation for practical commercial purposes. The whole subject is fully developed in the decisions of the Supreme Court of the United States, which will be found in the volumes of reports.

GEORGE CHASE.

Fauche, fōsh, HIPPOLYTE: Sanskrit scholar; b. at Auxerre, France, in 1797. His translations of the *Râmâyana* (9 vols., 1854–58) and the *Mahâbhârata* (7 vols., unfinished, 1863–67) are among his most important works. He published an original tale and some poems. D. at Juilly, Seine-et-Marne, 1869.

Faucher, fō'shā', LÉON: state minister, political economist, and financial writer; b. in Limoges, France, Sept. 8, 1803; was in youth a designer of embroidery patterns, and then a teacher; wrote for the *Courrier Français* and the *Revue des Deux Mondes*. In 1846, in the French Chamber of Deputies, acted with the Left; Minister of the Interior from Dec., 1848, to May, 1849, and from Apr. to Oct., 1851; was liberal but not republican in politics. *Studies on England* (1845) and *Miscellanies of Political Economy and Finance* (2 vols., 1856) were his productions. D. at Marseilles, Dec. 15, 1854, having always declined office under the Emperor Louis Napoleon.

Faucher de Saint-Maurice, Le Chevalier NARCISSE HENRI EDOUARD, LL. D.: Canadian journalist; b. at Quebec, Apr. 18, 1844; educated there and at the College of Ste. Anne de la Pocatière. He went to Mexico in 1864; became a captain in the army of Maximilian, and subsequently aide-de-camp to Gen. Viscount d'Hurbal. He served through the war, and for his services was created a Knight of the Imperial Order of Guadeloupe; received the medal of the Mexican campaign from Napoleon III., and the military medal for valor and integrity given by the Emperor Maximilian. He returned to Canada in 1866; has since edited *Journal de Quebec* and *Le Canadien*, and is now (1893) president of the Press Association of Province of Quebec. He was created a chevalier of the Legion of Honor, France, in 1881, and is a member of various learned societies. For fourteen years he was clerk in the Legislative Council, Province of Quebec; a representative in its Legislature 1881–92, and is (1893) president of the Quebec Oriental Railway Company. Among his works are: *À la Brunante, De Quebec à Mexico* (2 vols.), *Choses et autres, De Tribord à Babord, Cours de Tactique, Deux ans au Mexico, Les Iles*, and *En Route*.

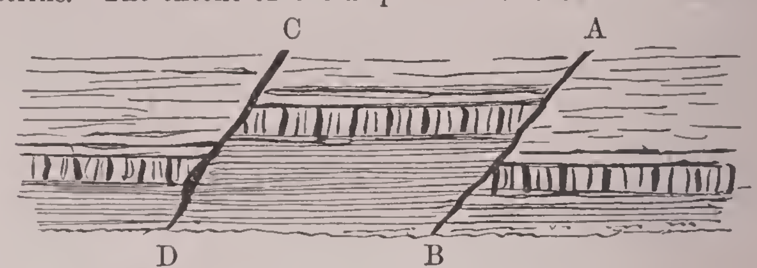
NEIL MACDONALD.

Fau'cit, HELEN (*Lady Martin*): actress; b. Oct. 11, 1819; made her *début* at Covent Garden, London, Jan. 5, 1836, in the character of Julia in *The Hunchback*, in which she achieved great success and at once took high rank as an actress, becoming a leading member of Macready's companies during the production of his Shakspearean revivals. She was the original representative of the heroines in Bulwer's *Lady of Lyons, Richelieu*, etc., and in many other plays of different authors. In 1851 she married Theodore Martin, but continued to appear on the stage at intervals. In 1880 her husband was knighted by Queen Victoria for his literary attainments. Lady Martin's last appearances were at Stratford-upon-Avon in Apr., 1879, when she played Beatrice at the opening of the Shakspeare Memorial theater, and at Manchester when she played Rosalind for the benefit of the widow of an actor. D. Oct. 31, 1898.

Faulkner, fawk'ner, CHARLES JAMES: lawyer; b. in Berkeley co., Va., in 1805; received a collegiate education, and was admitted to the bar in 1829. In 1832–33 he was elected to the House of Delegates, in 1841 to the Senate of Virginia, in 1848 again to the House of Delegates, and in 1850 was a member of a convention to revise the constitution of the State; representative in Congress from Virginia 1851–60, when appointed minister to France by President Buchanan. He returned to the U. S. in 1861, was imprisoned, on suspicion of disloyalty, in Fort Warren, Boston harbor, and exchanged in December of that year for Hon. Alfred Ely. In 1874 was elected to Congress from West Virginia. D. Nov. 1, 1884.

Faulkner's Island: a small elevated island lying off the harbor of Guilford, Conn., in Long Island Sound. It is within the limits of New York, and has a lighthouse with a flashing light and a fog-bell; lat. 41° 12' 41" N., lon. 72° 38' 54" W.

Fault [readapted from M. Eng. *faut, faute*, from O. Fr. *faute* > Fr. *faute* < Low Lat. **falta*, deriv. of *fal'lere*, deceive, lack]: in geology, a displacement of rocks along a plane of fracture. The inclination of a fault plane is called its *hade*, and is counted in degrees from the vertical. The direction of a horizontal line lying in a fault plane is called its *strike*. The direction of the hade is the direction toward which the plane descends, and is at right angles to the strike. The extent of the displacement is called the *throw*



Ideal section showing normal and reverse faults.

of the fault, and oblique throw is distinguished from vertical throw. A fault of which the hade is directed toward the body of rock that has been relatively depressed is said to "hade to the downthrow," and is called a *normal* fault; a fault hading to the upthrow is called a *reverse* fault. A reverse fault of which the hade is great is called a *thrust* fault, or *overthrust* fault. A system of parallel faults with throw on the same side are called *step* faults. Fault planes are never planes in the mathematical sense, but are variously curved, the hade and strike continually changing. The bodies of rock on the two sides are not always in contact, but there usually intervenes a sheet of crushed material known as *fault rock*. The walls of a fault usually exhibit polish and fine striæ (*slickensides*), the striæ showing the direction of movement.

As related to mining, faults are interruptions in the continuity of ore-beds; as related to earth structure, they are incidents of orogenic dislocations whereby great masses of rock have been lifted higher or dropped lower than contiguous masses. Overthrust faults involve the horizontal crowding together of rock masses, and are associated with other evidence of such compression. Normal faults are associated with movements causing the affected bodies of rock to occupy greater horizontal space. The dimensions of faults exhibit great range. The throw may be measured by inches, by feet, or even by tens of thousands of feet. The linear extent may be a few hundred yards, a few miles, or even some hundreds of miles. See GEOLOGY and MOUNTAINS.

G. K. GILBERT.

Fau'na [from Low Lat. *Fauna*, a rustic goddess, sister of *Faunus*, but by analogy with *flora* (thought of as plur. of Lat. *flos*, flower), the word is thought of as a plural of *faunus*, a faun, with generalized meaning]: the assemblage of animals inhabiting any given locality, either in the present or past ages of the globe. In palæontology, however, it is sometimes used with more latitude, and is given to an assemblage of animals characteristic of a given period. Inasmuch as there are no very abrupt demarkations for any given region, the idea of a *fauna* is based, to a greater or less extent, on the forms combined in a central, or, as it is called, metropolitan district. Various combinations of animals are more or less characteristic of certain countries or portions of the earth's surface, many forms being limited by climatal or physiographical or unknown conditions.

Various names have been applied to these combinations, or to the areas of which these combinations are characteristic, different authors using the same term in different senses. The larger areas have been variously designated *realm, region*, or rarely, as by Louis Agassiz, *fauna*. The more limited areas have been called *region, district*, or *fauna*, this latter being the name adopted by Dr. J. A. Allen, who has devoted particular attention to the study and systematic arrangement of life areas. Fauna, then, is used in two different senses—1, as expressing the sum total of animals inhabiting *any* area or locality; and 2, less often as the designation of one of the life areas of the world. The consideration of the faunas of the respective regions of the earth is the subject of a particular branch of science, ZOÖLOGICAL GEOGRAPHY; and under that head the principles and facts involved will be treated, while the principal features of the geographical distribution of the various groups of animals—the subject of geographical zoölogy—will be presented in the articles on such groups.

THEODORE GILL.

Fau'nus: a Roman woodland deity, corresponding to the Grecian Pan, many of whose attributes were assigned to him. He possessed the power of prophecy, and his oracles were in the groves. A festival, named Faunalia, was celebrated in his honor by the country people. As a frolicsome wood deity, represented with the horns of a goat and the feet of a satyr, he was multiplied by the poets, and the Fauni or Fauns corresponded to the Greek satyrs. Poetic tradition represented him as an early King of Latium, son of Picus, grandson of Saturn, and father of Latinus.

Fauque de Jonquières: See the Appendix.

Faure, fōr, FRANÇOIS FÉLIX: President of France: b. in Paris, Jan. 30, 1841; was a merchant at Havre. During the Franco-German war he was chief of battalion of the Garde Mobile. He was several times elected to the Chamber of Deputies, and was Under-Secretary of State in the ministry of Commerce and of the Colonies in the cabinets of Gambetta (Nov., 1881–Jan., 1882), Jules Ferry (Sept., 1883–Mar., 1885), and Tirard (Jan. 5 to Feb. 16, 1888), and afterward Minister of Marine. He became President Jan. 17, 1895. D. in Paris, Feb. 16, 1899.

Faure, JEAN BAPTISTE: See the Appendix.

Fauriel, fō'rē-el', CLAUDE CHARLES: philologist and historian; b. at St.-Étienne, France, Oct. 21, 1772; nephew of the Abbé Sieyès. In 1830 a chair of Foreign Literature was founded for him in Paris. Among his principal works are a *History of Southern Gaul* (1836); *History of Provençal Literature* (1846); and *Popular Songs of Modern Greece*, with a French version (1825). D. July 15, 1844.

Fausset, ANDREW ROBERT: See the Appendix.

Faust, fowst, JOHANN, Dr.: a German magician who flourished during the first thirty years of the sixteenth century; generally supposed to have been a native of Knittlingen, in Würtemberg; b. about 1480; d. about 1538. His history is obscured by extravagant fiction, and it is impossible to state with certainty the place of his birth or decease. Regarding his existence there is undoubted testimony, and it is known that he spent some time at Wittenberg, at one time enjoying the association of Melanchthon. (See Scheibel, *Kloster*, ii. p. 14.) Conrad Gesner and Luther (*Tischreden*, p. 216) also make mention of him. Dr. Faust seems to have been a learned man who had studied magic and astrology, and, traveling about the country performing various feats, came to be regarded as a dealer in the black art, and one maintaining an intimate relation with evil spirits. The belief in witchcraft was universal in Europe in the Middle Ages, and nowhere did it prevail so universally as in Germany. A bull of Pope Innocent IV. (1243–54) declares that it having come to his ears that in parts of Germany persons forgetting or denying the Christian faith have dealings with the devil, he commands all such individuals to be seized and punished forthwith with loss of property and life; and soon after appeared a work on sorcery and witchcraft—the *Malleus Maleficarum*, or *Witch's Hammer*—which enjoyed the approbation of the theological faculty of Cologne. "Germany indeed seemed to live and breathe in an atmosphere of sorcery. The ground which Faith had lost Superstition made her own." Even the Reformers believed in witchcraft and in the bodily presence of the Spirit of Evil upon the earth. According to tradition, Faust enjoyed in his youth a large fortune, gave himself to a life of extravagance and licentiousness, and soon squandered his vast possessions. He then devoted himself to the study of magic at Cracow, determined to regain his wealth and enjoyments, and after a mastery of the secret sciences made a compact with Satan, according to which the latter was to serve Faust for twenty-four years, when the Evil One should possess the soul of Faust. The contract signed by Faust with his own blood contained the following conditions: "1. He shall renounce God and all celestial hosts; 2, he shall be an enemy of all mankind; 3, he shall not obey priests; 4, he shall not go to church nor partake of the holy sacraments; 5, he shall hate and shun wedlock." Mephistopheles, a devil "who liked to live among men," was given Faust as an attendant, and the two together roamed over the land, Faust enjoying every form of sensual pleasure, and performing magical feats never before performed, until at last the time arrived when the fatal debt was due, and Satan appeared in the most hideous form imaginable between twelve and one o'clock at night, and finished Faust's earthly career, bearing away with him the soul of the unhappy being. Such is the monstrously mythical form in which Faust's life appears in the popular tradition. Its aim evidently is to describe that tendency to sacrifice the future, however precious—nay, salvation itself—to immediate gratification. Embodying all the dire superstition, the idle terrors, the thirst for the strange and wondrous, the story of Faust entertained the popular mind, while the clergy availed themselves of the moral it taught to recall men from sensuality and vice, and from the foolish attempts to fathom the mysteries of the supernatural.

The story of Faust was first published by the printer Spies, of Frankfort-on-the-Main, in 1587, under the title *Historia von D. Johann Fausten, den weitbeschreyten Zauberer und Schwarzkünstler*, and in 1588 another edition was called for. In the latter year appeared also a rhymed edition and a version in Low German and Danish. In 1590 two English translations came out—one entitled *A Ballad of the Life and Death of Dr. Faustus, the great Conjurer*, and the other, *The History of the Damnable Life and Deserved Death of Dr. John Faustus* (which was probably used by MARLOWE (*q. v.*) in 1591 in the preparation of his drama). In 1592 appeared a Dutch and in 1598 a French version. In 1599 G. R. Widmann published an "improved" edition, entitled *Wahrhaftige Historien von den grewlichen und abschewlichen Sünden und Lastern, auch von vielen wunderbarlichen und seltzamem abentheuren so D. Johannes Faustus hat getrieben* (Hamburg, 3 vols.); still further improved by Pfitzer in 1674 (Nuremberg). Widmann's edition, but without his or Pfitzer's notes, was published at Reutlingen in 1834. A large number of books on necromancy have inserted Faust's cabalistic formulas, charms, talismans, etc. All of these publications, and also all important monographs bearing upon this subject, are found in Scheibel, *Das Kloster, weltlich u. geistlich* (Stuttgart, 1847). German literature abounds in elegies, pantomimes, tragedies, and comedies on Faust. As far back as 1594 appeared a work by Tholeth Schotus, purporting to be from the Spanish and treating of Faust and his disciple Wagner. Its form intended it for the marionettes, and it was promptly taken up. (See *Puppenspiel*, edited by Charles Simroek (Leipzig, 1850); Magnin, *Histoire des Marionnettes* (Paris, 1854, 8vo); Hagen, *Ueber die ältesten Darstellungen der Faustsage* (1844); and Scheibel's work.) In a dramatic form, Faust was first treated in the German by Lessing in his masterly fragment entitled *Faust und die Sieben Geister*, but the grandest of all on this subject is Goethe's *Faust*, of which Bayard Taylor furnished a masterly English version (Boston, 1870, 2 vols. 4to). Goethe, however, introduced an element foreign to his model—that of the ardent, inextinguishable thirst for knowledge for its own sake alone. (Compare Kreyssig, *Vorlesungen über Goethe's Faust*, Berlin, 1866, 12mo, p. 3–36.) Goethe's *Faust* has furnished Gounod with the subject of his opera. See Düntzer, *Die Sage von D. Joh. Faust* (Stuttgart, 1846); Peter, *Literatur der Faustsage* (2d ed. Leipzig, 1851); and especially Kühne, *Das älteste Faustbuch* (Leipzig, 1868).

JAMES H. WORMAN.

Faust, originally written **Fust**, JOHANN: a native of Mentz, Germany, who shares with Gutenberg and Schöffer the honor of establishing the art of printing. He was (1450–55) Gutenberg's partner in the new business of printing books, but Faust probably did nothing but furnish capital. In 1455 Faust prosecuted Gutenberg for money advanced, took the business into his own hands, and associated with himself his son-in-law, Peter Schöffer, who originally was a calligrapher of great repute. They carried on the business successfully until 1462, when, at the sack of Mentz, the workmen were scattered and the art of printing was no longer a secret. Faust still went on with his business, and is thought to have died of the plague at Paris in 1466. There are in existence copies of quite a number of books printed by Faust and his partners, some of them beautifully executed.

Faustin I., Emperor of Haiti: See SOULOUQUE, FAUSTIN ÉLIE.

Faustina (THE YOUNGER) **Annia**: daughter of Antoninus Pius; was married by her father to Marcus Aurelius, her cousin, who had been adopted by Antoninus at the suggestion of Hadrian. She died A. D. 175, near Mt. Taurus, in Asia Minor, and though, like her mother, she had proved unworthy of the affection of her virtuous husband, yet at the request of Aurelius divine honors were decreed to her by the senate. As a further testimonial of his regard for her memory, Aurelius established, as Antoninus had done in the case of the elder Faustina, an asylum for orphan girls, to whom the name "Faustinian" (*Faustinianæ*) was given.

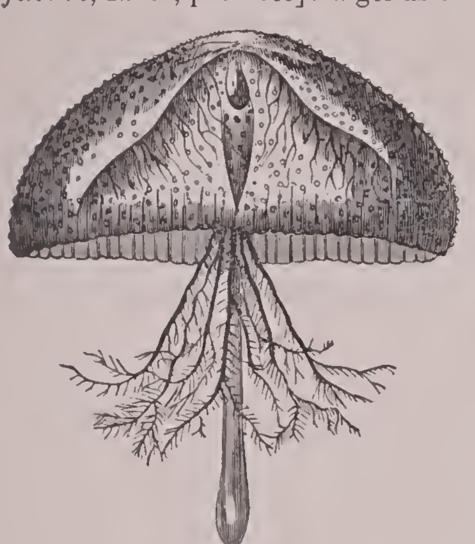
Fauvette [Fr. dimin of *fauve*, fawn-colored]: See Blackcap.

Favara, faa-vaa'raa: town of Sicily; 4 miles S. E. of Girgenti (see map of Italy, ref. 10–E); celebrated for its rich mines of sulphur and its marble quarries. Pop. 17,000.

Fav'ersham, or **Feversham**: municipal borough and river-port of Kent, England; 52 miles E. S. E. of London (see map of England, ref. 12–L). It has valuable oyster-fisheries. Pop. (1891) 10,478.

Favignana, faa-veen-yaa'naa: the chief of the Ægades, a group of islands in the Mediterranean, 6 miles off the west coast of Sicily. It is fruitful, has good pasturage, excellent wine, and a town of the same name with a population of 4,000. Lat. 37° 57′ N., lon. 12° 18′ W.

Favo'nia [from Lat. *Favo'nius*, the west wind, deriv. of *fave're*, favor, promote]: a genus of acalephs (jellyfishes) of the order *Discophora*, including some of the most characteristic organisms of that order. The *Favonia octonema* of the South Seas has a somewhat hemispherical body, with a long proboscis and eight branchiferous appendages.



Favonia octonema.

Favo'nius, Marcus: Roman politician, whose career was marked by strong personal opposition to Pompey and admiration for Cato. In 55 b. c. he was ædile, and probably was prætor in 49; went over to Pompey's party in 48, and after the battle of Pharsalia was reconciled to Cæsar, but after Cæsar's murder was a partisan of Brutus, and was outlawed and put to death 42 b. c.

Favori'nus: a philosopher and rhetorician in Rome under Trajan and Hadrian; b. at Arelate (now Arles) in the south of Gaul. He received his education in Rome, and became distinguished for his knowledge of Greek, in which language he had Dion Chrysostom as instructor. He stood high in the favor of Hadrian, and numbered among his friends Demetrius of Alexandria, Fronto, Plutarch, who dedicated to him one of his treatises, and Herodes Atticus, to whom he bequeathed his library and his house in Rome. Wrote numerous works on a great variety of subjects, all in Greek, and was famed also as an orator. His orations have all perished, but a few fragments of his historical writings have been preserved. See J. L. Marres, *Dissertatio de Favorini Arelatensis vita, studiis, scriptis, accedunt Fragmenta* (Utrecht, 1853). The fragments are collected also in Müller's *Hist. Græc. Fragm.* (vol. iii. pp. 577–585). Revised by B. L. Gildersleeve.

Favosi'tes [Mod. Lat., as if deriv. of *favo'sus*, honeycombed, deriv. of Lat. *favus*, honeycomb; so called because some of the species closely resemble a honeycomb]: a genus of extinct corals exceedingly common in the Devonian and Carboniferous rocks, of which a large number of species are described. The corallum of *Favosites* is compound, and usually forms hemispherical or conical masses, composed of a large number of prismatic columns divided horizontally by transverse septa or *tabulæ*, and usually having the vertical walls pierced by one or several rows of pores.

Favre, faav'r, Jules Claude Gabriel: politician and author; b. in Lyons, France, Mar. 21, 1809; became a prominent lawyer and liberal of Paris, and in 1848 held positions in the revolutionary ministry. He opposed Louis Napoleon during his presidency, and more especially after the *coup d'état* of 1851. In 1858 he ably defended Orsini, the would-be assassin, and in the Corps Législatif eloquently and irreconcilably opposed the policy of the emperor on all leading public questions; opposed the measures which ended in the Franco-German war, and after the fall of Sedan advocated the deposition of the imperial dynasty, and became Minister of Foreign Affairs and vice-president in the provisional government. As Minister of Foreign Affairs he took an important part in the negotiations for peace with Bismarck. He was for a time, during the siege of Paris, acting Minister of the Interior, but withdrew in 1871 from the Government during the presidency of Thiers, and devoted himself to law and literature. He was the author of *Rome et la République Française* (1871) and *Le Gouvernement du 4 Septembre* (1871–72). D. at Versailles, France, Jan. 19, 1880.

Fa'vus [from Lat. *favus*, honeycomb], or **Scald Head** [*scald* for *scalled*, deriv. of *scall*, scurf, scab < M. Eng. *scalle*, from Dan. *skal*, husk. *Scale* and *shale* (< O. Eng. *scealu*) are originally the same]: a disease formerly known as *tinea* and *porrigo*, generally seated on the hairy part of the scalp, but sometimes attacking the roots of the nails and other parts. It is a disease especially met with in the poorer classes, and is somewhat rare in the U. S. It frequently affects cats, rabbits, and mice, from which it may be communicated to man. This disease is known to be caused by a parasitic fungus, known as *Achorion schœnleinii*. Favus is a contagious disease, best prevented by cleanliness, and best cured by carefully removing the hair and applying parasiticide medicines, such as have the power of destroying low organisms. Sulphurous and carbolic acids and weak solutions of corrosive sublimate are the best applications. It is called *favus* because the diseased surface often assumes a honeycombed appearance. It leads to permanent baldness. Revised by William Pepper.

Fawcett, Edgar: novelist and poet; b. in New York city, May 26, 1847; graduated at Columbia College. Among his novels are *A Hopeless Case* (1881) and *The House at High Bridge* (1887). He wrote a successful play, *The False Friend* (1880), and has published a number of volumes of verse, including *Poems of Fantasy and Passion* (1878) and *The Buntling Ball* (1884), a clever anonymous satire which had much vogue. H. A. B.

Fawcett, Henry: political economist and statesman; b. at Salisbury, England, in 1833; educated at Cambridge, where he graduated as seventh wrangler in 1856. In 1858, while hunting near Salisbury, an accidental shot from his father's gun destroyed his eyesight, but this misfortune did not induce him to abandon his determination to enter Parliament, and after three unsuccessful attempts he finally secured a seat in 1865. He had in the meantime brought out his *Manual of Political Economy*, which has passed through many editions. Though this work represents the *laissez-faire* system of economic philosophy, and is based in general on the principles of Ricardo and J. S. Mill, its keen reasoning and clear and effective style have given it a wide popularity. Its publication was followed in the fall of 1863 by his election to the chair of Political Economy in Cambridge, a position which he held till his death. In politics Fawcett was a Liberal, but somewhat inconsiderate of party ties and opposed to several important features of Mr. Gladstone's policy. His career in Parliament was marked by his devotion to the interests of the native populations of India, by his efforts to preserve the commons and open spaces in the towns of Great Britain, and in general by his support of measures of practical reform. After his second election for Hackney in 1880 he was appointed by Mr. Gladstone's government to the Postmaster-Generalship, an office which he administered with zeal and ability, introducing useful reforms into the service and improving the condition of the employees of the department. D. Nov. 6, 1884. The best known of his other writings are *The Economic Position of the British Laborer* (1868); *Pauperism* (1871); *Free Trade and Protection* (1878). Revised by F. M. Colby.

Fawcett, Millicent Garrett: English writer; b. June 11, 1847; married Prof. Henry Fawcett 1867; soon became a prominent leader of the woman's suffrage movement; author of *Political Economy for Beginners*, *Tales in Political Economy*, etc.—Her daughter, Philippa Garrett Fawcett, was born in London, 1868; educated at Clapham High School, Bedford College, and University College, Cambridge, where she passed the higher local examinations with brilliant standing and received the Gilchrist scholarship; attained the unique distinction of being rated as "above the senior wrangler" in the competition in the mathematical group at Cambridge.

Fawkes, Guy, or Guido: English conspirator in the reign of James I.; a Roman Catholic; b. in Yorkshire. From 1593 till 1604 he served in the Spanish army in the Netherlands. In 1605, with Robert Catesby, Thomas Percy, and others, he endeavored to blow up the English House of Parliament, with king, Lords, and Commons, having hired a vault under the House of Lords and lodged in it thirty-six barrels of gunpowder, but was arrested on the night of Nov.

5 in the vault, and hanged at Westminster Jan. 31, 1606. See Jardine, *Narrative of the Gunpowder Plot* and the *Fawkeses of York*.

Fay, Amy: See the Appendix.

Fay, András: poet, dramatic author, and novelist; b. in Kohany, Hungary, May 30, 1786; studied law and became an advocate, but devoted himself chiefly to literary work. He represented the county of Pesth in the Hungarian Diet in 1835, and until Kossuth appeared in political affairs was the most prominent orator of the liberal opposition. He worked earnestly for the literary and artistic, as well as political, advancement of the people; was one of the founders of the Hungarian national theater, the director of important literary and industrial societies, and the founder of the first savings-bank in Pesth. D. in Pesth, July 26, 1864. His *Mesék* (*Fables*) have been translated into German and partly into English, by E. D. Butler, *Hungarian Poems and Fables* (London, 1877). Most of his poems are in the collections *Bokréta* (*Nosegay*), published in Pesth, 1807, and *Fris* (*Fresh*) *Bokréta*, 1818. Of his novels the most interesting are the humorous stories *House of the Beltekis* and *Dr. Javor*. His earlier works were published in eight volumes in Pesth (1843–44); his novels in three volumes (1883).

Fay, Theodore Sedgwick: See the Appendix.

Fayal′: one of the most important of the Azores, a group of islands in the Northern Atlantic belonging to Portugal. It has the best harbor in the islands and lies directly in the track of vessels crossing the Atlantic. Its name is derived from the extreme abundance of the *faya*, an indigenous shrub. It resembles the other members of the group, and has 69 sq. miles, with 24,000 inhabitants. It is very fertile, and besides its considerable transit trade with America it exports a great quantity of oranges and wine. The climate is very healthful. Its principal town, Horta, lies in lat. 38° 30′ N. and lon. 28° 41′ W.

Faye, fā, Hervé Auguste Étienne Albans: astronomer; b. at St.-Benoit, Indre, France, Oct. 5, 1814; studied astronomy with Arago; on Nov. 22, 1843, discovered the comet bearing his name; became Professor of Astronomy in the Polytechnic School at Paris 1873, and published a number of astronomical treatises. The comet which bears his name has a periodic time of seven and a half years, and is never visible to the naked eye.

Fayette: city; on railway; capital of Howard co., Mo. (for location of county, see map of Missouri, ref. 3–G); 12 miles from the Missouri river and 60 miles N. W. of Jefferson City. It is the seat of Central College and of the Howard-Payne College for Women. Pop. (1880) 1,247; (1890) 2,247; (1900) 2,717. Editor of "Howard County Advertiser."

Fayetteville: city and railway center; capital of Washington co., Ark. (for location of county, see map of Arkansas, ref. 2–A); in the Ozark Mountains, 1,500 feet above the sea and surrounded by grand scenery. It is called "the Athens of Arkansas," and is a popular summer resort. It is the seat of the Arkansas Industrial University, and has fine public schools, large wagon-factory, fruit-evaporating establishment, flouring-mills, foundry, etc. Pop. (1880) 1,788; (1890) 2,942; (1900) 4,061.

Editor of "Arkansas Sentinel."

Fayetteville: village; Onondaga co., N. Y. (for location of county, see map of New York, ref. 4–F); on railway; 10 miles E. of Syracuse. It has an excellent union school and academy, a public library, large flouring-mills, paper-mills, a machine-shop, two glove-factories, a furniture-factory, and a large corn-canning factory. The manufacture of hydraulic cement, quick-lime, and land-plaster is extensively carried on. Pop. (1880) 1,556; (1890) 1,410; (1900) 1,304.

Editor of "Recorder."

Fayetteville: town and railway junction; capital of Cumberland co., N. C. (for location of county, see map of North Carolina, ref. 4–G); on the Cape Fear river; 60 miles S. by W. of Raleigh and 90 miles N. W. of Wilmington. It has a flourishing graded school, a dozen or more private and primary schools, a State normal colored school, an excellent school for colored children, a fine military school, a carriage-factory, a wagon-manufactory, a large corn and wheat roller-mill, an ice-factory, 4 mills, 2 coppersmith establishments, an extensive manufactory of wooden-ware, a large vineyard, gas and electric lights, and water-works. There are also several cotton-factories near the village. It has a large trade in rosin, turpentine, and cotton, is a great horse and mule market, and has several steamboats running to Wilmington. Fayetteville is an old town and was for many years the State capital. It suffered largely from invasion and destruction to property at the close of the civil war; prior to this it was commercially and in other respects the most important city of the State. Pop. (1880) 3,485; (1890) 4,222; (1900) 4,670. Editor of "Observer."

Fayetteville: town (founded in 1808); capital of Lincoln co., Tenn. (for location of county, see map of Tennessee, ref. 7–F); on railway; 120 miles by rail S. by E. of Nashville. It has 10 churches (6 white and 4 colored), 2 flourishing schools, a large flouring-mill, 2 planing-mills, electric lights, etc. Pop. (1880) 2,104; (1890) 2,410; (1900) 2,708.

Editor of "Observer."

Fayrer, Sir Joseph, K. S. C. I., LL. D., M. D., F. R. S. E.: b. at Plymouth, Dec. 6, 1824; studied medicine in London, Edinburgh, and on the Continent; entered the Bengal medical service in 1850; served in the Burmese war of 1852 and during the mutiny of 1857, and was appointed Professor of Surgery in the medical college of Bengal in 1859, and in 1874 surgeon-general and president of the medical board of the India office. Among his published papers are *Clinical Surgery in India*; *Clinical and Pathological Observations in India*; *European Child-life in Bengal*; *Malarial Splenic Cachexia of Tropical Climates*; *Bronchocele in India*; *Physiological Action of the Poison of Naja Tripudians*; *Some of the Physical Conditions of the Country that Affect Life in India*; *The Claws of the Felidæ*; *Anatomy of the Rattlesnake*.

Fayum, Fayoum, or **Faioum** [from the Coptic *pi omi*, the cultivated land, or (according to some) from *pi eiom*, the sea]: a province of Egypt; on the west side of the Nile, between lat. 29° and 30° N. and lon. 30° and 31° E. Area, 493 sq. miles; pop. in 1897, 312,757. Its capital, Medinet-el-Fayum (pop. 31,262), is about 65 miles S. W. of Cairo and 30 miles N. W. of Benisuef. The Fayum is a basin formed by a depression in the Libyan range, its main plateau being on about the level of the Nile, but in its lowest point 116 feet below sea-level. Of its area, which was anciently somewhat greater than at present, more than 100 sq. miles are occupied by the natural lake Birket-el-Kerun. It is still the most fertile province of Egypt, abounding in figs, grapes, apricots, olives, and other fruits. But its ancient renown was much greater. It contained the Labyrinth and the artificial lake Mœris (*qq. v.*), both built by Amenemka III., the great king of the twelfth dynasty—according to Wilkinson, nearly 2000 B. C.; according to Mariette, nearly 3000 B. C. See Herodotus, ii. 148–150; Auguste Mariette Bey, *Aperçu de l'Histoire d'Égypte* (2d ed. 1870); and Zincke's *Egypt of the Pharaohs and of the Khedive* (1871).

Fazy, faa'zee', Jean James: Swiss party leader; b. in Geneva, May 12, 1796; descended from a family of French Protestants exiled by the Revocation of the Edict of Nantes. He was educated in France, studied law and political economy, and settled in Paris, where he took active part in the opposition of the liberal party to the restoration. Returning to Geneva, he joined the radical party, which in 1846 succeeded in changing the constitution. Fazy was the head of the government 1846–63. After the fall, however, of the French republic, in 1852, the position of the radical party in Geneva became less and less secure. It lost its hold on the sympathy of the masses; it suffered one defeat after the other; a heavy reaction at last set in and became almost threatening; and in 1865 Fazy retired into private life. D. in Geneva, Nov. 6, 1878.

Fear, Cape: See Cape Fear.

Feast, or **Festival** [*feast* is from M. Eng. *feeste*, *feste*, from O. Fr. *feste* > Fr. *fête* < Lat. *fes'ta*, plur. of *fes'tum*, a holiday, neut. of *fes'tus*, festal; *festival* is from M. Eng. *festival*, from O. Fr. *festival* < Mediæv. Lat. *festiva'lis*, deriv. of Lat. *festi'vus*, festive]: a periodically returning or occasional day set apart for rejoicing, and often distinguished by the observance of religious ceremonies. There has probably never been any community which has not had its festivals, and which has not owed much to them. Such aids were formerly more important, for higher civilization multiplies bonds of union. As their history shows, a marked influence on the segregated states of Greece was produced by their common festivals, the Olympic, Pythian, Isthmian, and Nemean games. To these all of Hellenic race were admitted, and none other, as competitors for the prizes given. The right to contend was highly esteemed. Each state habitually sent representatives, and so did colonies when scarcely any other tie was maintained with the mother country. It could not be that the associating thus as members of one family on equal footing did not keep alive to some extent a feeling of common interest. Whatever their dissensions among themselves, as against the rest of the world they were of one blood; they made a clear distinction between Greeks and barbarians, and their national games helped to mark this line of separation and to draw them to each other. Among the Romans there were many festivals, private and public; the latter were *stativæ*, fixed, or *conceptivæ*, movable, or *imperitivæ*, occasional; these were divided into days of sacrifice and days of banqueting, days of games and days of rest, or *feriæ*. Some of the feasts were celebrated with very great pomp.

It has been said that the observance of seasons is in obedience to an instinct with most persons. The believer in revelation recognizes also that it was commanded by God. The Son of Sirach asks (Eccles. xxxiii.), "Why doth one day excel another, whereas all the light of every day in the year is of the sun? By the knowledge of the Lord they were distinguished; and he altered the seasons and the feasts. Some of them hath he made high days and hallowed, and some of them hath he made ordinary days." In Leviticus xxiii. is given a list of the "feasts of the Lord"; α. The Sabbath; β. The Passover; γ. The Feast of Weeks; δ. The Feast of Trumpets; ε. The Atonement; ζ. The Feast of Tabernacles.

Under the New Testament there are no festivals of Divine appointment, save as the Church rules in God's name—none enforced as were those commanded to Moses. During the first few years of Christianity while the essentially Jewish character of the Church was in a measure continued, the Jewish yearly festivals were without doubt observed, especially the Passover and Pentecost, which associations with the Resurrection and the gift of the Holy Ghost had invested with an increased dignity. The Jewish Sabbath, the seventh day of the week, also continued to be observed, and with it the first day of each week became a lesser Easter day—"an Easter day in every week." Additions were gradually made to these feasts, until each prominent event in the life of our blessed Lord had its special day of observance. Some of these are, as near as may be, anniversaries; others are assumed to be such. Some are fixed, recurring always on the same day of the month; others, dependent upon Easter, are movable. All Christian bodies who keep stated festivals agree in their general observances while differing in respect to the minor feasts. The Church of England, when the Book of Common Prayer was set forth, provided special services (with two exceptions) only for the days of saints connected directly with the history of our Lord, while yet, from whatever reason, other names were retained on her calendar. The Episcopal Church in the U. S. has omitted all days for which there is no prescribed service.

As the term "holy day," a day of sacred rest, has been changed to "holiday," a mere season of leisure and enjoyment, so the word "feast" has naturally come to express in a lower sense feasting, banqueting. For, as sorrow is marked by a setting aside of luxuries, so joy that is shared with others generally finds expression in indulgence of appetite, in eating and drinking. The plea, "for good fellowship," which has led to so much intemperance, has its warrant in nature, if the habits of all ages result from the teaching of nature. The word *festum*, whence comes "feast," has been derived from ἑστιάω, to "receive on one's own hearth," to "feast"; however true this may be, festivals were always accompanied by sacrificial banquetings. The habits of the Jews on glad days holy to the Lord was to "eat the fat, drink the sweet, and send portions." And in the Christian Church, while spiritual joy is not connected with indulgence of the senses, feasts are contrasted with fasts. The most ascetic rule is modified by the occurrence of a feast-day. Revised by S. M. JACKSON.

Featherfoil [*feather* + *foil* < M. Eng. *foile*, from O. Fr. *foil*, *foille* > Fr. *feuille* < Lat. *fo'lium*, leaf], **Water-feather**, or **Water-violet**: the popular name of the *Hottonia inflata* of the U. S. and *Hottonia palustris* of Europe, curious primulaceous plants which grow submerged in water, and thrust up long scapes into the air to produce the blossoms, which in the European species are very beautiful. Other species are known. The generic name commemorates Peter Hotton, a Dutch botanist who died in 1709.

Feather-grass [so called from its long feathery awns]: any one of several long-awned grasses, particularly any species of the genus *Stipa*, several of which grow in the U. S. From the hygroscopic twisting and untwisting of these awns the name "weather-grass" is also used. This hygroscopic twist causes the awn to screw the seed down into soft earth, where it takes root. On the Great Plains of the Western U. S. some species, e. g. *S. spartea* and *S. comata*, are called porcupine grasses because the pungently pointed fruits work their way into clothing, and even through the skin. Sheep and dogs are often seriously injured by them.

CHARLES E. BESSEY.

Feather River: a river of California; formed by the union of its N., S., and Middle forks, which rise in Plumas County, in the Sierra Nevada. Its waters reach the Sacramento in Sutter County. It is a beautiful stream, whose lower waters are navigated by steamboats as far as Yuba City.

Feathers [M. Eng. *fether* < O. Eng. *feðer*, feather, pen: Icel. *fjöðr* : O. H. Germ. *fedara* < Mod. Germ. *Feder*, feather, pen < Teuton. *feþr-a* < Indo-Eur. *pet-*, fall, fly, cf. Sanskr. *pattra*, feather, Gr. πτερόν, feather, and Lat. *pen'na* (for **pet-na*), feather]: epidermal structures peculiar to birds. No bird is without feathers, and no other animal has them. A typical feather consists of a stiff central stem, or *scapus*, on either side of which is the soft web, or *vexillum*. The stem consists of the lower, horny, transparent barrel, quill, or *calamus*, and the shaft (*rhachis*). The shaft, which is usually longer than the quill, tapers from base to apex, is nearly four-sided, and is more or less curved toward the bird's body. Its inner face is marked with a fine longitudinal groove, while the outer surface is smooth and slightly convex. It is composed of a white elastic pith, covered by a horny material similar to that of the barrel. At the point where quill and shaft unite there frequently grows from the barrel an appendage termed the aftershaft, or *hyporhachis*. This is usually small and downy, but in the emu and cassowary it almost equals in size the feather from which it springs. The web is formed by the long slender *barbs* which grow from either side of the shaft, and in a like manner short *barbules* spring from the sides of the barbs, each barb being thus a feather in miniature. The upper and under edges of the barbules give off little hair-like projections, or *cilia*, and finally these may terminate in little hooks, *hamuli*. The object of these little hooks, which grow only on the under side of those barbules which point toward the tip of the feather, is to fasten the barbs together, and make the web a compact structure. This they do by catching on the upper edges of those barbules pointing toward the root of the feather. These upper edges bear no hooks, but are simply bent over.

Feathers may be divided into several classes, although no hard and fast line can be drawn among them, and between the firmest feather and the softest down all intermediate conditions may be found. The first and largest group is that of contour feathers, *pennæ* or *plumæ*. These have a well-developed shaft and webs, and attain their greatest development as tail or wing feathers. Some contour feathers have the barbs far apart and the barbules without hooks, and such are soft and wavy in their character, like the plumes of birds of paradise. Others again may lack the web, like some of the tail feathers of birds of paradise and of the lyre bird, and the bristles about the mouths of goat-suckers.

The downs, *plumulæ*, which are usually hidden beneath the contour feathers, have the *rhachis* weak or wanting, the barbs long, soft, and loose, owing to the absence of hooks. Lastly the filoplumes, *filoplumæ*, are slender, hair-like feathers, such as are seen here and there projecting from among the neck feathers of sparrows or thrushes. The down which clothes the young of birds is slightly different from that on the adults, as the barbules have no projections whatever, and the barrel has no aftershaft.

The first indications of feathers are minute projections which appear on the skin of the embryo about the fifth or sixth day, and from these the downy covering is developed. The feathers which follow are produced from the same pulp, the feathers being formed around the papilla, between it and the inclosing sac or sheath. Prof. Huxley in his *Introduction to the Classification of Animals* describes the process as follows: "The external surface of the dermal papilla, whence a feather is to be developed, is provided upon its dorsal surface with a median groove, which becomes shallower toward the apex of the papilla. From this median groove lateral furrows proceed at an open angle, and passing round upon the under surface of the papilla become shallower, until, in the middle line, opposite the dorsal median groove, they become obsolete. Minor grooves run at right angles to the median furrows. Hence the surface of the papilla has the character of a kind of mold, and if it were repeatedly dipped in such a substance as a solution of gelatin, and withdrawn to cool until its whole surface was covered with an even coat of that substance, it is clear that the gelatinous coat would be thickest at the basal or interior end of the median groove, at the median ends of the lateral furrows, and at those ends of the minor grooves which open into them, while it would be very thin at the apices of the median and lateral grooves, and between the ends of the minor grooves. If, therefore, the hollow cone of gelatin, removed from its mold, were stretched from within, or if its thinnest parts became weak by drying, it would tend to give way, along the inferior median line, opposite the rod-like cast of the median groove and between the ends of the casts of the lateral furrows, as well as between each of the minor grooves, and the hollow cone would expand into a flat feather-like structure with a median shaft and a 'vane' formed of 'barbs' and 'barbules.' In point of fact, in the development of a feather, such a cast of the dermal papilla is formed, though not in gelatin, but in the horny epidermic layer developed upon the mold, and, as this is thrust outward, it opens out in the manner just described. After a certain period of growth the papilla of the feather ceases to be grooved, and a continuous horny cylinder is formed, which constitutes the quill."

The growth of feathers is very rapid, and if by mischance a feather is lost or injured another is formed in its place. The only feathers which grow continuously are the greasy powder-down feathers such as are found on herons.

The first feathers of a bird are direct continuations of the down with which the nestling is clothed, this down being borne on the tips of the growing feathers and later on broken or worn off. The second, and all succeeding growths of feathers, although produced from the same papillæ as the first, have no connection with their predecessors, the old feathers being shed and new ones grown in their places.

This change of plumage, termed molting, takes place at least once annually, while some birds molt wholly, or partially, twice a year. Some birds, like the crow, acquire their adult plumage at the first molt; others, such as the albatross and male eider duck, require several years for the attainment of their full dress.

When, as is often the case, the sexes are different in color, the young birds of both sexes resemble the female, and it is also common for the fall dress of the male to be like that of his mate, the more brilliant and distinctive plumage being assumed for the nuptial suit of spring.

The colors of feathers are due to the presence of pigment in the feathers, to pigment combined with a peculiar arrangement of their outer surface, or to the structure of the outer surface alone. To the first class of colors belong black, red, and brown; the second are well shown by the green or blue feathers of parrots, while the gorgeous metallic hues of humming-birds are examples of the third. White is not due to pigment, but to the presence of innumerable air-cells in the substance of the feather.

The entire plumage of a bird forms its *ptilosis*, the manner in which the plumage is arranged its *pterylosis*, and this is treated of under PTERYLOGRAPHY (*q. v.*).

The chief use of feathers is probably for ornament, and, aside from ostrich plumes, the number of birds used for millinery purposes is enormous. The quarterly sales of a single London firm have amounted to 750,000 skins of bright-plumaged birds, while the dainty humming-birds are received in lots of from 10,000 to 40,000 at a time. The Aztec nobles robed themselves in feather garments, the Chinese wove feathers into cloth, and the mamo (*Drepanis pacifica*) was exterminated that its feathers might be woven into the cloaks of the Sandwich Island chieftains. The days of the ostrich have been lengthened by the fact that it has proved practicable and, what is more to the purpose, profitable to domesticate the bird, so that a large share of the ostrich feathers of commerce are supplied by the ostrich farms of the Cape of Good Hope, California, and other localities. The wing and tail feathers of the male are the most valuable, but all, even the smallest, are utilized.

The ostrich of South America serves a strictly utilitarian end in supplying the feathers for dusters, and the common turkey contributes largely to the same purpose.

The Australian emu furnishes feather trimming, and the silky breast of the grebe is converted into muffs and collars.

The Romans used feathers for stuffing beds and cushions. "The geese that come from Germany," says Pliny, "are most esteemed. They are white, of a small size, and are called *gantæ*. The price paid for their feathers is ten denarii per pound. Hence we have repeated charges brought against the commanders of our auxiliaries, who detach whole cohorts from their posts in pursuit of these birds." Pliny further complains: "We have reached such a pitch of effeminacy that nowadays not even men can lie down without the aid of goose feathers as pillows." (*Nat. Hist.*, x. 27.) Down was also used. Martial, in his 161st epigram, says, "When fatigued, you may recline on Amyclæan feathers, which the swan's inner down provides for you."

The date when feather beds were first used in England is unknown. An old chronicle states that the Duke of Gloucester, uncle to Richard II., was smothered with "a federbedde." (Strutt, *Manners and Customs of the English*, ii. 88.) By a statute of Henry VII. it was forbidden to make beds of mixed down and feathers: "The mixture of such being conceived contagious for man's body to lie on." (*Stat.* xi., ch. 59.) From this period "fether-beddes" are included in most inventories of household furniture.

Goose feathers are exported from Germany, Russia, and Poland, the annual consumption of the United Kingdom alone being something like 700 tons. In the fenny parts of Lincolnshire, called Holland, flocks of geese are kept for the sake of their feathers, which are plucked four or five times a year. New feathers are dried by the sun's heat or in ovens, and then beaten to clean them. Those that have been used are purified by a short exposure to steam, and are dried in the air. Eider down, so much prized for lining quilts, skirts, etc., is found most commonly on small rocky islands from 45° N. to the highest Arctic regions yet explored.

The oldest authentic mention of writing-quills is in a passage of Isidorus, who died in 636. (*Origines*, lib. vi. 13, p. 132, cited in Beckmann's *History of Inventions.*) A short poem on a writing-pen is found in the works of Aldhelmus, who died in 709. The Dutch invented the art of preparing quills so as to free them from a fatty humor which prevented the ink from flowing. They used hot ashes, and for a long time kept the process a secret, but it was discovered and improved. A bath of fine sand is kept at a temperature of 140°; into this the quill end of the feather is put and left a few instants. It is then rubbed with flannel, and becomes white and clear. The yellow tint of age is given by dipping the quills into diluted muriatic acid and then drying them. Each goose-wing produces five good quills, which are classified according to their order in the wing, the first being the best. A portion of the barb is stripped off for packing. A pen-cutter will make about 800 pens in a day. So late as 1855 Great Britain imported no less than 26,500,000 goose and swan quills. F. A. LUCAS.

Feather-star: the popular name in England for crinoids belonging to the genus *Comatula* or *Antedon*. In the young stages they are fixed, like other crinoids, on a stem, but when adult the disk and arms become detached and live a free life. Both mouth and vent are on that side of the disk opposite to the stalk, while from the disk radiate five feathery arms, whence the name. J. S. K.

Featherstonhaugh, GEORGE WILLIAM, F. R. S.: traveler and author; b. in 1780; published a translation of the *Republic* of Cicero in 1828; in 1834 made a *Geological Report of the Elevated Country between the Missouri and Red Rivers*; *Geological Reconnoissance in 1835 to Coteau de Prairie* (1836); *Excursion through the Slave States* (1844); *Geology of Green Bay and Wisconsin* (1836); *Observations on the Ashburton Treaty* (1842); and *Canoe Voyage to the Minnesota* (2 vols., 1847). He was commissioner for Great Britain to settle the northern boundary of the U. S. under the Ashburton treaty; afterward British consul for Calvados and Seine, France. D. at Havre, France, Sept. 28, 1866.

Febiger, JOHN CARSON: See the Appendix.

Febric'ula, or **Ephemeral Fever** [*febricula* is Lat. dimin. of *febris*, fever (see FEVER); *ephemeral* is viâ Mod. Lat. from Gr. ἐφήμερος, lasting for a day; ἐπί, upon + ἡμέρα, day]: a short feverish attack lasting from one day to a week, marked by a rapid pulse, a furred tongue, and often by a very considerable increase of heat and by headache. Persons suffering from febricula are said to be "threatened with a fever," and are too often improperly dosed. A warm bath, warm or cold water to drink, as best suits the patient, the use of enemata if called for, and other simple treatment is sufficient, for the disease will pass away of itself if allowed to do so. It is often followed by an eruption or a stage of profuse sweating. There would appear to be no constant factor in the causes of febricula, which may be associated with a severe cold, a profound emotional disturbance, or with some excess on the patient's part. It is especially common during epidemics of typhoid and typhus fevers.

Feb′rifuge [from Fr. *fébrifuge* : Ital. *febbrifugo* < Low Lat. **febri′fugus* ; *fe′bris*, fever + *fuga′re*, drive away, deriv. of *fu′ga*, flight]: a medicine capable of diminishing or banishing fever. The term was formerly used in the sense of a remedy which has the power of entirely removing fever. In the present state of knowledge it is clear that remedies hardly ever have this power, for on the one hand the infectious diseases known as "fevers" are for the most part self-limited diseases which subside when the infection has spent its force, and in which the temperature or fever may only be temporarily reduced, and on the other hand the fevers due to inflammations are permanently removable only by removing the cause. In the limited sense of temporarily reducing temperature there are a number of remedies which may be styled febrifuge. Aconite, sweet spirits of niter, and quinine are the drugs most frequently used in mild cases; and antipyrin, antifebrin, and phenacetin those which are useful in severer fevers; but the external use of cold water has to a large extent supplanted these remedies. In typhoid fever, particularly, cold bathing is of great value, and under its use the mortality in this disease has been lowered fully 10 per cent., that is, from a previous death-rate of 15 per cent. to 20 per cent. the mortality is now reduced to 5 per cent., and under the most favorable circumstances only 1 per cent. of patients succumb. There is often objection on the part of the patient's friends against a seemingly cruel treatment, for the patient often shivers and moans or grows somewhat blue, but the systematic employment of this mode of treatment in hospitals has been overwhelmingly convincing of its value. Sponge bathing, with water or diluted alcohol, or the cold pack (wrapping the patient in sheets wrung out in cold water), may be used instead of the full bath, but are much less powerful.

Revised by WILLIAM PEPPER.

Febro′nianism [deriv. of *Febronian*, pertaining to Justinus Febronius, the pseudonym of the founder of Febronianism]: the views taught in the writings of J. N. von Hontheim (1701–90), suffragan bishop of the Roman Catholic diocese of Treves. He taught that the primacy of the pope is of human origin, and opposed with great success the Ultramontane view. He had many followers, but in his old age was so annoyed by the persecutions visited upon himself and his family that he recanted twice, and finally abandoned his bishopric; but Febronianism long survived, and the Old Catholic movement of the nineteenth century is its development. See HONTHEIM, VON.

February [from Lat. *Februa′rius*, deriv. of *fe′brua* (plur.), the festival of purifications, deriv. of *februa′re*, purify, akin to *febris*, fever]: the second month of the Gregorian year, having twenty-eight days, except in leap-years, when it has twenty-nine.

Fécamp, fā′kaán′ (in Lat. *Fiscannum*): seaport of France, department of Seine-Inférieure (see map of France, ref. 2–E). Its port, though small, is one of the best on the English Channel, and is much frequented by colliers from Newcastle and Sunderland, and by timber-ships and fishing-vessels from the Baltic. Lat. of Fécamp light, 49° 46′ N., lon. 22′ E. It is a favorite resort for sea-bathing, and has ship-yards, tanneries, cotton-mills, sugar-refineries, and some manufacturing interests. Pop. (1896) 14,656.

Fechner, fech′ner, GUSTAV THEODOR: scientist; b. at Gross-Särchen, Germany, Apr. 19, 1801; after a brilliant course of study at Sorau and Dresden studied medicine at Leipzig, where he was Professor of Physics from 1834 till 1839; wrote much and ably upon chemistry, physics, anthropology, medical science, philosophy, and antiquities, and under the pen-name of Dr. Mises, poetry, criticism, and humorous literature. Among his more important works are *Ueber das höchste Gut* (1848); *Elemente der Psycophysik* (1860); *Zur Geschichte der Holbeinschen Madonna* (1866). D. Nov. 18, 1887.

Fechter, fech′ter, CHARLES ALBERT: actor; b. in London, Oct. 23, 1824. His father was a German, his mother a Frenchwoman, and he was educated in England and France. For some time he devoted himself to sculpture, but having an inclination for the stage, he made his *début* in 1840 at the Salle Molière in *Le Mari de la Veuve*; after passing some weeks at the Conservatory he joined a company and made the tour of Italy; on his return he resumed his occupation of sculptor. His first success on the French stage was as Duval in *La Dame aux Camélias*. In 1860 he appeared on the stage as Hamlet, and in 1861 as Othello; and in 1863 he leased the London Lyceum theater and produced *The Duke's Motto*, *Bel Demonio*, etc., assuming the principal characters himself. In 1870 and in 1872 he played successful engagements in the principal cities of the U. S., and managed the Globe theater in Boston for a season. He purchased a farm near Quakertown, Pa., and died there Aug. 5, 1879.

Feckenham, or **Feckenam**, JOHN, de: Catholic divine, whose real name was HOWMAN: b. in Feckenham Forest, Worcestershire, England, about 1516; educated at the Benedictine monastery at Evesham and at Gloucester College, Oxford, where he took the degree of B. D. in 1539. Chaplain to the Bishop of Worcester and afterward to Bonner, Bishop of London, both vigorous opponents of the reform movement, he showed such zeal for his religion that he was sent to the Tower 1549, but afterward released temporarily to take part in religious disputations. On Mary's accession he was received into favor, and in 1556 made Abbot of Westminster. During Lady Jane Grey's captivity he was sent to convert her to the Roman Catholic faith, but did not succeed. In his time of prosperity he showed a tolerant spirit toward the Protestants, opposing the adoption of cruel measures against them, and going so far as to intercede with the queen for the imprisoned Elizabeth, a service which the latter rewarded after her accession by the offer of the archbishopric of Canterbury, subject, however, to the condition of conforming to the newly established religion. Feckenham refused, and in Parliament, where he was the last of the mitered abbots to have a seat, he opposed every measure in the interest of the reformed Church. He was again thrown into the Tower 1560, and for the rest of his life was held in confinement, with the exception of a few brief intervals. D. at the Castle of Wisbeach, 1585. He has left, besides funeral orations and sermons, an account of his interviews with Lady Jane Grey in the *Conference Dialogue*.

Fec′ula: See STARCH.

Fecundation: See EMBRYOLOGY and GESTATION.

Federalist [deriv. of *federal*, from Fr. *fédéral* < Lat. **fœdera′lis*, deriv. of *fœ′dus*, *fœ′deris*, league]: a term in politics which in general is applied to an advocate and supporter of a close union of states under a common government as against those who would weaken or destroy such a union. More specifically the term has been applied to a remarkable series of papers written in the early history of the U. S. Government for the purpose of securing the adoption of the Federal Constitution, and to the political party which, immediately after the adoption of the Constitution, advocated a strong central government instead of a weak one.

I. With the exception of the concluding nine of the eighty-six numbers, the collection of essays termed the *Federalist* was originally published in *The Independent Journal*, a semi-weekly newspaper printed in the city of New York, between Oct. 27, 1787, and Apr. 2, 1788. Its authors were Alexander Hamilton, James Madison, and John Jay, who addressed themselves over the common signature of "Publius," in a series of letters, "To the People of the State of New York," with the avowed purpose of securing the accession of that State to the Constitution as proposed by the Federal convention of Sept. 17, 1787.

The immediate cause, or, so to say, provocation of the work, was the appearance, almost simultaneously with the recommendation of the convention, of two series of able articles so severely criticising the proposed Constitution that its adoption was more than endangered. Hamilton resolved to counteract these attacks through the same means, the public press—to answer the arguments advanced, and, in reply to a charge that the supporters of the Constitution designed to supplant the Union of the States by their fusion under a centralized (if not monarchical) government, to retort upon its opponents with an implied accusation of favoring the division of the States into separate confederacies. For this purpose he drew up a syllabus of essays, to be written by himself and associates, which should perspicuously exhibit the advantages of the Union, expose the insufficiency of the subsisting Confederation, with the necessity of a more energetic government, and advocate the plan under consideration by showing that it was the least objectionable of all feasible schemes, and that it conformed to republican principles and approved institutions.

It is beyond reasonable doubt that Jay, then Secretary for Foreign Affairs, discussed the foreign relations of the States in the second, third, fourth, and fifth numbers, and the lodgment with the Senate of the treaty-making power in the sixty-fourth. Concerning the respective shares of Hamilton and Madison in the authorship a dispute early arose between the admirers of those gentlemen. The curious reader may consult the introduction to Mr. Dawson's edition for a summary account of this not unembittered controversy, which was never of much moment save, perhaps, as to No. 49 and those immediately succeeding, relating to the independence of the several departments of the government. It is a noteworthy indication of the importance attached by Hamilton to the posthumous fame of his connection with the work that he was at pains to leave a significant memorandum concerning it in the office of a friend the day before his fatal duel with Aaron Burr.

In estimating its merits the *Federalist* is to be judged as a collection of fugitive pieces intended to vindicate a specific Constitution, rather than as an elaborate treatise on the science of government. For the end aimed at it was admirably adapted. The basis of the argument well-nigh throughout is utility, or, as has been somewhat harshly said, "interest and fear." From this point of view it would have been difficult to adduce more convincing reasons for the preservation of the Union; many of them, in the light of more recent events, savor of prescience. The method is mainly empirical, rarely speculative. The style is elevated, yet designedly popular. The whole is replete with more or less familiar illustrations, particularly from history. It may be true, as was the opinion of John Stuart Mill, that a more philosophical work upon modern democracy has been founded upon American institutions, but it was also said by a no less eminent foreigner, M. Guizot, that "in the application of the elementary principles of government it is the greatest work known."

If the Constitution is to be interpreted according to the intention of its framers and the understanding of those who ratified it, an acquaintance with the *Federalist* is nearly indispensable. It also affords a valuable view of many of the cardinal differences of the parties which, under various names, have contended in American politics.

The first collected edition appeared in 1788 in two 12mo volumes from the press of J. & A. M'Lean, the proprietors of *The Independent Journal*. It has since been issued, in the U. S. and abroad, in over twenty editions. The references in this article, however, are made to the numbers of the first and more familiar edition.

II. Whatever the proximate cause, the real basis of the *Federalist* party must be sought in divergent connections and interests of long and gradual growth. Upon the accomplishment of the Revolution and relaxation of the motives to the self-denial which alone had made it possible, the necessity of a more vigorous authority for the unimpassioned purposes of peace became manifest. What change would be most expedient was the question to be decided.

Experience of the shortcomings of the existing system had peculiarly impressed its defects upon the leading citizens who had had the most to do with administering it. A majority of these were imbued with British constitutional traditions and not unaffected by the exercise of peremptory powers during the war. They distrusted the capacity of the masses to manage their own concerns, and feared in the common people a disrespect for the rights of persons and of property. They believed it necessary to consolidate the country under a general national government powerful enough to dominate the whole. Though by no means harmonious as to the powers to be conferred, they were unanimously in favor of a "strong government." With these the commercial classes generally sided, as did also the greater number of those distinguished by wealth and social position.

On the other hand, the very self-sacrifice so long practiced had increased the attachment of the masses for independent local institutions, and quickened their jealousy of an overshadowing authority beyond the reach of "a swift responsibility." They had dearly learned the worth of the Union, but, imputing to the more aristocratic party a design to subvert their liberties, and believing a limited alliance of free States sufficient for their purposes, they desired to retain the federal league (under the Articles of Confederation), somewhat modified to suit unforeseen needs.

Out of this conflict came the Constitution, "extorted," in the words of John Quincy Adams, "from the grinding necessity of a reluctant nation." By one of those freaks of nomenclature not uncommon in religion and politics, those who favored the consolidation of the States into one nation received the name of "Federalists," while the misnomer of "Anti-Federalists" was bestowed upon their opponents, who least of all deserved it.

With the administration of Gen. Washington the Federalists came into ascendency. In common with the Anti-Federalists, having only accepted the compromise Constitution in default of something more to their liking, they, under the accomplished leadership of Hamilton, set about finding in that instrument a warrant for the government they desired through the doctrines of "implied and constructive" constitutional power, of the exercise of which the establishment of a national bank and the assumption of the State debts may serve as examples. This caused the defeat of the Federalists and the accession of their opponents (under the name of Republicans) in the election of Thomas Jefferson, who announced as the new policy "the support of the State governments in all their rights as the most competent administrations for our domestic concerns and the surest bulwark against anti-republican tendencies—the preservation of the general government in its whole constitutional vigor as the sheet-anchor of our peace at home and safety abroad." The power of the Federalists was irretrievably lost by their action in the famous HARTFORD CONVENTION (*q. v.*), which was called to protest against alleged neglect of New England during the last war with Great Britain, but which fastened upon them the imputation of condemning the war itself. The party, as such, expired six years later on the election of Mr. Monroe and the commencement of the "era of good feeling."

III. The term *Federalist* has also been used at other periods to designate other less prominent partisans, particularly in Spain and Spanish America.

Federalist Party: See FEDERALIST and REPUBLICAN PARTY.

Federal Theology: See COVENANT.

Federation [from Fr. *fédération* < Lat. **fœdera'tio*, deriv. of *fœdera're*, federate, deriv. of *fœdus*, league]: a union of states under a compact by which the general or common government is supreme in its own sphere. As distinguished from a confederation, with which it is often confounded, a federation is a composite sovereignty under a supreme government formed from attributes of sovereignty relinquished by the constituent states or component parts of the new body politic. It follows, as to domestic economy, that a federal government within its proper sphere can act directly upon the individual citizens of the several states, instead of mediately through the state governments; as to international relations, it follows, further, that the supreme central power alone can hold intercourse with foreign governments, which recognize only independent sovereignties. Contrariwise, the several states forming a confederation retain their autonomy and sovereignty, and can maintain all international relations not conflicting with the conditions of the union, while the individual subject is answerable only to his own state government. In short, a confederation differs little from an ordinary alliance except in the permanency and intimacy of the association. The distinction between the two forms of government is aptly suggested by the German names *Bundesstaat* (Union-State) and *Staatenbund* (Union of States), as also in the phraseology of English writers on constitutional law by the terms "composite state" and "system of confederated states."

The principal existing examples of this form of government are the American republics and the federation of the Swiss cantons. In all of these the superintendence of the foreign relations of the states is vested in general congresses, which also have more or less direct and controlling relations to the individual subjects. The U. S. of America furnish the most complete and thorough model of a federation (see CONSTITUTION OF THE UNITED STATES)—a model after which the other American federations have been more or less directly fashioned. The latter are the United States of Mexico (twenty-seven states, a federal district, and a territory), the United States of Colombia (Antioquia, Bolivar, Boyacá, Cauca, Cundinamarca, Magdalena, Panama, Santander, Tolima), and the United States of Rio de la Plata (fourteen provinces, commonly called the Argentine Republic).

The Swiss or Helvetian federation is composed of twenty-two political cantons, of which the supreme authority is vested in a federal diet composed of a national council (a deputy for every 20,000 inhabitants) and a state council (two delegates from each canton). Seven members are chosen by the two branches of the diet, on a joint ballot, to form the federal council, which exercises the executive authority under a president, who holds office but one year, and is ineligible for the next ensuing term. The diet is responsible for the internal and external security of the federation. It alone can declare war or conclude treaties of peace, commerce, or alliance with foreign powers. The several cantons can, however, conclude conventions respecting matters of revenue and police with subordinate departments of foreign governments, subject to the approval of the federal authority. Revised by C. K. ADAMS.

Federmann, fā'der-maăn, NICHOLAS: soldier; b. at Ulm, in Swabia, Germany, 1501. In 1529 he went to Venezuela as a captain in the employ of the Welsers of Augsburg; there he was made chief lieutenant of Alfinger, and conducted an extended exploration from Coro to the interior. After visiting Europe (1532) he returned in 1534 as lieutenant of George of Spire. The latter started for the interior, leaving orders for Federmann to follow with re-enforcements; instead of doing so, he engaged in pearl-fishing on the coast, and in 1535 started on an independent expedition with 200 men. He wandered for some years in the Orinoco valley, finally crossed the mountains westward, and early in 1539 reached the rich country of the Chibchas of New Granada. There he found GONZALO QUESADA (*q. v.*), who had already entered this region, coming from Santa Marta. It is said that Quesada paid Federmann 10,000 *pesos* of gold to relinquish the conquest. The two leaders descended the river Magdalena together, and went to Spain; thence Federmann passed to Augsburg, where he immediately fell into trouble with the Welsers, owing to his desertion of Quesada. He lost his office, and narrowly escaped confiscation of his property. He then started for Spain to seek employment, but died, either in a shipwreck or shortly after reaching Madrid (about 1543). He wrote an account of his first exploration, which was published in German at Haguenau 1557, and there is a French translation in the Ternaux-Cómpans collection, 1837. HERBERT H. SMITH.

Fee [M. Eng. *fee*, *feoh* < O. Eng. *feoh*, cattle, property, money: Mod. Germ. *Vieh*, cattle: Goth. *faihu*, cattle. property; cf. Lat. *pecus*, cattle, money: Sanskr. *paçu*, cattle]: in its original signification under the feudal-law system of tenure, the allotment of land which a vassal received from his superior lord on condition of the performance of various services in his lord's behalf—especially of military service in time of war. (See FEUDAL SYSTEM.) It was used in contradistinction to *allodium*, which applied to land which a man owned in his own right, without any obligation to render service to another. But in the gradual modification of the law appertaining to the tenure of landed property the word "fee," while still retained, has undergone a change of signification, being used to designate the estate which a land-owner possesses. And by "estate" in this connection is meant not the property itself—though such an application of the term is common in popular parlance—but the interest which one has in the land as regards the nature and duration of his title. A fee therefore signifies an estate of inheritance—i. e. an interest in land which, on the death of the owner without a will, passes immediately to his heirs. When used without any word of description it has the same general extent of meaning as the phrases "fee-simple" and "fee-simple absolute." These words of designation appended are employed to indicate more specifically that the estate is to be enjoyed without any qualifications or restrictions limiting or tending to limit the indefinite duration and absoluteness of the tenure, and that it is indefeasible, in contradistinction to the terms "qualified fee," "determinable fee," etc., to be hereafter explained. A fee or fee-simple is the highest estate known to the law. Its mode of creation by deed at common law still exhibits the application of arbitrary rules derived from the feudal system, which derive their justification only from the circumstance that they are the result of the historic growth of the system of tenure, a factitious importance being given to them which seems, to a great degree, unreasonable when they are considered without reference to their origin. Thus it is absolutely essential that the word "heir" or "heirs" be employed in a deed in connection with the name of the grantee, or the only interest created will be a life estate. The purely arbitrary nature of this requirement has caused its abrogation in a few of the U. S. by statute. In wills. moreover, and in estates created under the doctrines of uses (see USES and TRUSTS), it has never been obligatory, since in these cases the object of legal interpretation has been to arrive at the true intent of the devisor or grantor, and to effectuate his real purposes without such precise regard to the forms in which they are couched. When a fee is conveyed to a corporation aggregate the word "heirs" is unnecessary, even in a deed, since it is not properly applicable; if the conveyance be to a corporation sole, the word "successors" should be substituted. The most important right which the owner of a fee-simple possesses is that of free and unrestricted enjoyment of the property, and an unlimited power to dispose of it at his own pleasure. Even if any language be inserted in the conveyance through which he received his title restricting his power of alienation, it is void and may be disregarded. This is not true, however, as to restrictions upon the mode of occupation, for there may be prohibitions against erecting buildings of a certain character or the use of the land for certain specified purposes which can not be transgressed. An owner in fee may transfer his entire estate to another, or he may carve out of it any inferior estate, such as a life estate or an estate for years, retaining in himself a reversion or creating a remainder in a third person, or he may make any other transfer he may think desirable. His interest may be seized and sold for the payment of his debts, either in his own lifetime or after his death, in exclusion of the claims of his heirs.

Estates in fee inferior to a fee-simple are termed "base" or "qualified" or "determinable" fees—i. e. estates of inheritance which are granted with qualifications or restrictions which may cause their defeasance. These assume various forms. Thus there may be a *fee upon limitation*, as an estate given to A until B goes to Boston. In such a case, if B ever goes to Boston the estate is at once defeated; if he never goes, the fee becomes absolute. A fee may be granted upon *condition*, as an estate to A on condition that he builds a market upon the land within three years. If the grantee fails to comply with the stipulation, the grantor or his heirs may re-enter after the condition is broken and recover the estate. Limitations are created by words of time; conditions, by terms in the nature of a proviso. There are also what are styled estates upon *conditional limitation*, as an estate to A until B goes to Boston, when the estate is to pass to C, some third person. No entry is required in such a case by the grantor to defeat the estate, as in the case of a condition, but on the occurrence of the event specified the estate is at once, *ipso facto*, vested in C, the grantee in the alternative. There was, moreover, a fee conditional at common law, which was afterward modified by statute into a peculiar estate termed a *fee tail*. This was created when an estate was given to a man and the "heirs of his body." In this case the grantee had a fee, but could not make disposition of it so as to defeat the right of the heirs designated. This particular restriction at common law was, in course of time, in England avoided by a resort to ingenious legal fictions, as by fines and recoveries; and in the United States there has been very generally an entire abolition of this form of estate, or so fundamental a change in it that this mode of limitation is made equivalent to a conveyance in fee-simple. On this general topic consult Washburn on *Real Property*; Williams on the same subject; Cruise's *Digest*; Kent's *Commentaries*, etc. See also ENTAIL and FEOFFMENT.

GEORGE CHASE.

Feejee: same as FIJI (*q. v.*).

Feeling: in its narrower meaning the sensation produced by an object on the sensory nerve, as hearing denotes the sensation produced by an object on the auditory nerve, sight the sensation produced by an object on the visual nerve, and so on. In its wider sense it comprises all the impressions received through the senses, as they all arise from the same general sensibility, which is merely particularized in the special sensory organs; but it refers to them not as far as they are sensations in the organs of sense, but as far as they are modifications of consciousness. Thus feeling is nearly synonymous with emotion, and the two expressions are often used synonymously, though emotion is more properly applied to the separate states of the feeling.

and feeling to the general capacity for emotions. Emotion refers to the shifting, changing surface of the feeling—feeling, to the steadily recurring sentiments rooting in the depths of our organization.

In this, its wider sense, feeling is one of the three forms under which the mind becomes conscious of itself, thought and will being the two others. The mind is conscious of itself only as far as it feels or thinks or wills, and it is never conscious of itself as performing more than one of these operations at a time, the two others being either dormant or absorbed. But although intellect, volition, and feeling thus form three very different manifestations of the mind, the distinction between them is nevertheless only an abstraction; in actual life no line of separation can be drawn. Thus feeling involves thought, and thought feeling. An impression on the sensibility remains a sensation in the organ of sense until an idea is sent out to meet it, to introduce it into consciousness, and to transform it into a feeling. All feelings—anger, pity, sorrow, love, joy, etc.—are charged with ideas. They express themselves not only through laughter and tears, but in winged words, and when they are strong they make men eloquent. Feelings which are untouched by intellect are not feelings; but instincts, cravings, appetites, desires, and so on. On the other hand, ideas are nothing but feelings which have been fixed in the memory, and by comparison, analysis, abstraction, and other processes of thinking, wrought into thoughts. A man has so many original ideas as he has living feelings, and no more; the rest are unoriginal, often borrowed, sometimes stolen. Ideas correspond to feelings, not only with respect to their number, but also with respect to their quality—nay, even with respect to their most delicate coloring. A man who feels hatred can rise in morals to the idea of justice, but never to that of love. All the ideas of Seneca were tinged by a cold, vain pride; those of Voltaire, by a malicious, cowardly joy; those of Hegel, by a broad, benign sympathy; those of John Stuart Mill, by a machine-like exactness and delicate subtleness. To draw a broad and unwavering line of demarkation between thought and feeling, or, generally, between the three manifestations of the mind, and to assign to each of them its own encircled sphere, as the old psychology tried to do, is impossible, and leads to grave errors. To discover and describe the delicate transitions or transfusions of thought, feeling, and will, as modern psychology tries to do, is of paramount importance for the right understanding of the mind, and has proved less difficult than it seemed at first sight.

Fehmarn: See FEMERN.

Fehmic or **Vehmic Court** [*fehmic* is from Germ. *Vehmgericht*; *fehme*, *vehme* < M. H. Germ. *veime*, secret tribunal; orig. obscure]: a tribunal of somewhat mythical origin that flourished in Germany during the Middle Ages. It is claimed by some that Charlemagne first organized these courts, and by others that they came down from the ante-historic Germans; but whether either of these statements is correct or not, they first appear in history during the anarchical days which followed the expulsion of Henry the Lion from his estates by the Diet of Wurzburg in 1180. This court was composed of "initiated" members (*Wissende*), who were sworn to secrecy by a tremendous oath. The Archbishop of Cologne (as Lord of Westphalia) and the emperor were at least nominal members. The courts were presided over by a *Freigraf*, or free count. Their tribunals were either open—held by day in the open air—or secret, the latter being held for the trial of the more serious offenses. The Fehmic courts were at first administered in a fair and upright manner, and enforced a respect for law and order at a time when society was in confusion, but they finally came to have a most extensive and dreadful authority. Not only feudal barons were cited before this irresponsible tribunal, but at least in one instance the emperor himself. In the Pact of Westphalia (1371) they were recognized as lawful. In 1438 the Emperor Albert II. attempted to suppress them. In 1461 so dreadful was their influence that many nobles, prelates, and cities of Germany and Switzerland combined to resist their power. In 1495 Maximilian I. gave them a new code, which greatly reduced their authority. In 1568 their last open court was held near Celle in Hanover, but in Westphalia, their true home, these courts nominally existed until 1811, holding secret meetings, but were suppressed in the latter year by Jerome Bonaparte. Born of a stern necessity, the Fehmic courts came in time to be a serious evil, and are chiefly remembered for the excessive cruelty of their punishments.

Feia, fā-yaā' (Port., ugly): a lake of Southeastern Brazil; in the eastern part of the state of Rio de Janeiro, near the coast. It is about 20 miles long, has an area of 190 sq. miles, and is so shallow that the waves make the waters constantly turbid. The little river Macabú and other streams flow into it. The Lagoa Feia abounds in fish. It is the largest of numerous lakes forming a system along this part of the coast; they are properly lagoons, kept fresh by barrier sand-bars, are united by an intricate network of channels, and part of their water eventually flows N. to the Parahyba river. HERBERT H. SMITH.

Feigned Diseases: a term used to cover all the manifestations coming under the head of the technical terms "malingering" in English and "simulation" in French and German. As commonly understood, these terms apply to the pretense that one has a disease, an injury, or a defect, which is not present. Such pretending has been common from the earliest epochs of human history. The most ancient case on record is said to be mentioned in the book of Genesis, chap. xxxi., though it may be unjust to assume that the asserted condition in that case did not exist. Another case is that of David, who when fleeing from King Saul took refuge with Achish, King of Gath, and then made his escape from a rather hazardous situation by pretending to be mad or insane. Still another interesting case, from the historical standpoint, is that of Pope Sixtus V., who is said to have pretended to be in a decline when he was a candidate for the papal chair, and unable to speak above a whisper or without a violent spell of coughing, but, as soon as he was elected, threw away the staff upon which he had been wont to lean and intoned the *Te Deum* in a voice which astonished all who heard him.

The earliest medical writer to speak of malingering is said to be Hippocrates; but it requires some forcing of the statement he makes, in his book *On Airs, Waters, and Places*, in regard to the mildness and cowardice of the Asiatics, to find in them a charge of malingering or of mutilating themselves in order to escape military service. Galen (131–200 A. D.), however, devoted a book to this subject, entitled *Quomodo morbum simulantes sint deprehendendi* (How those who simulate disease are to be detected), and described a number of conditions feigned or imitated by malingerers, such as spitting of blood, inflammation of the knee, pain, and insanity. Among a host of later writers may be mentioned Ambroise Paré (1573), Sylvaticus (1594), Zachias (1628), Gavin (1843), Bartholow (1864), Keen (1864), and Boisseau (1870).

Systematic writers have adopted various classifications for the conditions included under the terms considered. The best of all is that of Gavin, of London, who divides them as follows:

I. Fictitious diseases. $\left\{ \begin{array}{l} a.\ \text{Asserted.} \\ b.\ \text{Imitated.} \end{array} \right.$

II. Exaggerated diseases.

III. Factitious (provoked) diseases.

Class I. includes cases in which there is merely a false claim that disease or injury is present, or, in addition, an attempt to imitate the symptoms of disease or injury. In Class II. the attempt at deception consists in exaggerating the symptoms of a disease or injury actually existing. In Class III. are cases in which disease or injury is self-inflicted. To these classes of Gavin might well be added a fourth, attributed diseases, covering cases in which the results of an old injury are charged to a recent accident—a form of imposture which is not very rare after railway accidents.

For the purposes of this article mere mention will suffice for all the forms of "simulation," except those of Class I., which includes all to which the term "feigned disease" could with strict propriety be applied. Of these there are enough in numbers and variety to occupy much space. Among the most common are feignings of insanity, epilepsy, paralysis, loss of consciousness, inability to eat, deafness, and defects of sight. It is not unlikely that many of the cases of peculiar nervous diseases studied so minutely by Charcot and his followers in Paris (grave epilepsy, hystero-epilepsy) were cases of voluntary or involuntary imitation or simulation.

Some examples of malingering require an extraordinary amount of determination, shrewdness, and persistency. A case of pretended tetanus is on record which compelled the malingerer to maintain himself for hours in the most trying and exhausting attitudes, and to submit to most heroic methods of treatment. The malingerer went from hospital to hospital in London, and was the subject of so many demonstrations and lectures to students that he gradually improved his acting, rectifying in one hospital the anomalies in his case which he had heard pointed out in the preceding one, and finally received the ministrations of a clergyman in view of his expected death before his imposture was discovered.

The motive for malingering is usually a desire to avoid unpleasant or dangerous situations, or to secure money or sympathy or notoriety, or to punish others through their feelings. Thus in all countries and all times persons liable to military or naval service have pretended to be unfit for such service, and those already engaged in it have sought to secure discharge or exemption from the performance of duty by like pretending. In European countries especially, and in times of more rigorous exactions, attempts to escape military duty have been so widespread and so ingenious that stringent laws have been adopted to punish not only those making such attempts, but also those who in any way aid or abet them. The pretense of insanity is an altogether too familiar resource of criminals, and especially of murderers. In hospitals patients often endeavor to enlist special sympathy or to secure unusual privileges by feigning curious disorders, peculiar feebleness, or pain. In a case in the Philadelphia Hospital, under the care of the writer, a young woman repeatedly submitted to painful and dangerous operations in support of her pretense of excruciating pain in order to get morphia. In schools, almshouses, reformatories, and prisons the same mode of imposture is practiced, while beggars on the streets and pampered women alike avail themselves of this method of securing their desires.

The detection of malingering or simulation is sometimes easy, but often it is very difficult. Ingenuity often plays a more important part in unmasking an impostor than does mere skill in medicine. A French surgeon once watched a pretended epileptic in a fit, and when it subsided put his hand on the patient's heart and said: "It is all over with him. Carry him to the dead-house." This brought the man out of that attack, and frightened him out of having any other.

An exercise of acumen was also shown in the case of a pretended deaf-mute, who was exposed by the Abbé Sicard, director of the Institute for Deaf-mutes in Paris, who observed that the mistakes the pretender made in writing were phonetic—that he wrote as he *heard*, and not as he *saw*. In cases of pretended defects of vision the instruments and methods of examination of modern oculists furnish a very strong defense against deception. For example, when one eye is said to be blind, the examiner places in front of the eyes of the pretender a pair of spectacles, one lens of which contains a prism with its base turned up or down, and then makes him look through an aperture at a hitherto concealed candle. He is then asked what he sees; and if he says he sees (as he does, if he is using both eyes) two candles, his fraud is discovered. Or the eye admitted to be sound is covered with a red glass, and he is asked to read lines written in green upon a black ground. If he can do this, he is known to be reading with the eye said to be defective; because at a certain distance green rays passing through a red glass appear black.

Countless other methods have been employed in dealing with malingerers. Some of them were such as would test the fortitude of the suspect. In earlier times these used to be in great favor, and were often carried to a barbarous extent. But modern civilization and the advance of medical science have led to the dismission as abhorrent, or the abandonment as unnecessary, of every method which is cruel or which may be injurious. It is regarded as proper, however, to apply a test which is painful, *provided* the procedure would be beneficial if the pretended disease were actually present. For example, a blister, or even the actual cautery (burning with the red-hot iron), might be used in a case of asserted stiff-knee.

Fortunately, with the general elevation of the human race and with the improved conditions of military and naval service, malingering is no longer as common as it once was. But there still remain sufficient occasions when cupidity or fear prompt to this form of imposture to make it necessary to recognize its existence and to guard against it. Modern times have also furnished a comparatively new form of this sort of fraud, of which corporations are the special victims—the nervous affections following railway accidents. The obscurity of the processes of many injuries of the nervous system makes it very difficult at times to determine whether a claimant is a real sufferer or a pretender, and medico-legal experts are often unable to decide surely whether or not a particular claimant is a real sufferer or an impostor. In all such cases it is important for those who are called upon for an opinion to weigh carefully the motives for deception which may be present, so to give them due and yet not undue weight. Justice requires that the expert in these cases shall not make the mistake of regarding himself as an inquisitor, and that he shall always be willing to admit uncertainty when he feels it. A wise conclusion in this matter is recorded by an eminent German expert, Dr. L. Bruns, in Schmidt's *Jahrbücher*, 1891, No. 4. He had had submitted to him the opinions of four physicians, two of whom expressed a positive opinion that a case was one of malingering; one said positively it was not; and one wrote: "Non liquet: I do not know whether the patient lies or tells the truth." "This," says Dr. Bruns, "was the only just opinion."

Such a prudent attitude may be assumed without danger of mortification by any medical man who is at all familiar with the facts on record in regard to malingering; and justice to all concerned makes it important that no one should hastily formulate as opinions mere suspicions, lest he find himself in the quandary of choosing between retracting what he has said or doing a wrong to the innocent.

CHARLES W. DULLES.

Feijó, fā-zhō', DIOGO ANTONIO: Brazilian statesman; b. in São Paulo, Aug., 1784. He took orders, and was a priest in Parahyba, Campinas, and Itú. In 1822 he was deputy of São Paulo to the Cortes at Lisbon, and was one of the five Brazilian deputies who left that body on the declaration of independence. He was deputy 1826–33, and a leader of the liberals; in 1827 he presented a bill for the abolition of celibacy in the clergy. From July 4, 1831, to July 26, 1832, he was minister of justice, preserving order under very difficult circumstances. In July, 1833, he entered the Senate, and next year he was elected regent of Brazil during the minority of Pedro II.; he retained his post from Oct. 12, 1835, until Sept. 18, 1837, in an almost constant struggle with the conservatives. In 1842 he took the leadership of the liberal revolt at Sorocaba, and for a short time was under arrest. The Padre Feijó was noted for his virtue and austere adherence to principle. D. at São Paulo, Nov. 10, 1843. HERBERT H. SMITH.

Feints: See FENCING.

Feith, RHIJNVIS: poet; b. at Zwolle, Overyssel, Holland, Feb. 7, 1753; studied law at Leyden, but returned to his native town 1772; was elected burgomaster 1780, and became a prominent member of important literary societies. His work was singularly successful, and won for him the highest honors from his countrymen. His life was one of remarkable prosperity, but his poems deal with emotions of melancholy and despair to a greater extent than those of any other Dutch poet. Though this provoked adverse criticism, and was characterized by many as sentimentalism, Feith was undoubtedly the most popular poet of his time. D. at Zwolle, Feb. 8, 1824. His earliest important work was *Julia*, a novel written in the style of Werther (1783). Then followed *Thirza* (1784), a tragedy; *Ferdinand and Constantia*, another novel, and the *Patriots* (1785), works which were publicly crowned at Leyden. *Het Graf* (*The Grave*), published in 1792, was a didactic poem of a gloomy and sentimental tone. From 1796 to 1814 appeared five volumes of *Odes and Miscellaneous Poems*, among which are many specimens of his best style, notably his spirited patriotic lyrics. *De Ouderdom* (*Old Age*), another didactic poem, appeared in 1802. In prose he has left *Brievenover verscheiden Onderwerpen* (*Letters on Different Subjects*, 1784–94).

Felaniche, fā-lăă-neech', or **Felanitx**: an old town of the Spanish island of Majorca (see map of Spain, ref. 16–L). It has considerable trade in wine, brandy, and fruit. On a neighboring mountain is the old castle, with its subterranean vaults constructed by the Moors. Pop. 11,000.

Felch, ALPHEUS, LL. D.: lawyer; b. in Limerick, York co., Me., Sept. 28, 1806; graduated at Bowdoin College 1827, and became a lawyer of Michigan, whither he emigrated while still very young; sat in the State Legislature 1836–37; bank commissioner 1838–39; auditor-general of Michigan; was a judge of the State Supreme Court 1842-45; Governor of Michigan 1846–47; U. S. Senator 1847–53; a commissioner of California land claims 1853–56 under the treaty of Guadelupe Hidalgo, and was elected a delegate to the Chicago convention of 1864, in which he took an active part. Retired from practice 1877. Professor of Law in Michigan University 1879–83. Received the degree of LL. D. from Bowdoin in 1877. At the time of his death in Ann Arbor, Mich., June 13, 1896, he was the oldest surviving member of Michigan Legislature from Monro County; the only surviving bank commissioner of the State; oldest surving auditor-general of the State; oldest surviving judge of the Supreme Court of Michigan; and the only surviving member of the California Land Company.

Feldkirch, felt'keerch: manufacturing town of Austria; in the Vorarlberg; 20 miles S. W. of Bregenz (see map of Austria-Hungary, ref. 6–A); the seat of a bishop, suffragan to the Bishop of Brixen, and Vicar-General of the Vorarlberg. It has an important Jesuit educational institution (Stella Matutina) and a Capuchin cloister, and is the seat of important courts, etc. Its manufactures are varied and important. Mar. 22 and 23, 1799, it was the scene of the victory of the Austrians under Jellachich over the French under Massena. Pop. (1890) 3,811.

Feldspar, or **Felspar** [corruption of Germ. *Feldspath*, under influence of Eng. *spar*]: a term applied to a family of minerals embracing many species, which crystallize in several systems. In chemical composition they all agree in being silicates of alumina, with silicates of other bases, either soda, potash, or lime. By some authors the term is restricted to one species, the common potash feldspar, or orthoclase. Popularly the term is also applied to albite, a soda feldspar, and to labradorite and oligoclase, soda-lime feldspars, etc. Feldspars enter largely into the composition of all granitic and of many metamorphic rocks, and form the chief element of porphyries and volcanic rocks. In their decomposition they are the source of clay. Moonstone and lapis-lazuli are members of this family valued in the arts, and feldspar is also used as a glaze for porcelain.

Félibres: See PROVENÇAL LITERATURE.

Felice, fā-lee'chā, FORTUNATO BARTOLOMMEO, de: author; b. at Rome, Aug. 24, 1723; studied at Rome and Naples; eloped with a nun to Switzerland; became a Protestant and a printer; editor and teacher at Yverdun; published Italian and other translations of the leading philosophical works of that period; wrote some original works upon natural, national, and civil law, and was the principal editor of an *Encyclopédie* (in 58 vols., 1770–80) based upon the great French *Encyclopédie*. D. at Yverdun, Feb. 7, 1789.

Felicis'simus: a deacon of Carthage; ordained by the enemies of the bishop Cyprian while he was absent in time of persecution, between Feb., 250 A. D., and Apr., 251 A. D. He was a man of wealth, of talents, of energy, and of influence. As soon as he returned to Carthage, Cyprian summoned a council which excommunicated Felicissimus and the presbyters who sympathized with him. Refusing to submit, the party chose one of their own number (Fortunatus) in place of Cyprian as bishop. Felicissimus was deputed to represent their cause at Rome and to sustain charges against Cyprian. This project failed, and the schism soon came to an end. See *Cyprianic Epistles*, 38 and 55, for the character of Felicissimus, drawn in the darkest colors.

Another Felicissimus was a friend of Cyprian, and first to suffer in the Decian persecution. It is uncertain whether he is the St. Felicissimus named in the martyrologies.

Felic'itas, SAINT: a martyr; put to death, with her seven sons, at Rome under Antoninus Pius (about 150 A. D.). All were arraigned together before the tribunal of Publius the prefect. To the question whether they would sacrifice to idols, they replied by a firm refusal, fearlessly confessing their Christian faith. The officer informed the emperor of their refusal, and by him they were left to the sentence of the judges, who ordered the sons to be put to death by diverse punishments, but the mother to be beheaded.

Fel'idæ [Mod. Lat. deriv. of Lat. *felis*, cat]: a family of carnivorous mammals (typical genus *Felis*) comprising the cats; distinguished by the reduction of the true molars to one on each side of either jaw, by the absence of an alisphenoid canal, thirteen dorsal vertebræ, and digitigrade feet provided, with the exception of the cheetah, with retractile claws. The skeleton shows special modifications for a predatory life. The wide zygomatic arches allow room for the powerful muscles which move the jaws; the canine teeth are for piercing and tearing; the digitigrade feet give an elastic, noiseless step; the hind limbs are adapted for leaping, while the powerful fore legs have great freedom of motion for striking, grasping, or tearing. The family is the most highly specialized of the *Carnivora*, and its members, almost without exception, live on the fresh flesh of animals which they have killed themselves. For various kinds of cats see CHEETAH, JAGUAR, LEOPARD, LION, LYNX, OCELOT, PANTHER, PUMA, and TIGER. F. A. LUCAS.

Felix I.: saint; succeeded Pope Dionysius Jan. 5, 269 A. D. In the persecutions under the Roman Emperor Aurelian he was condemned to die, but expired in prison Dec. 30, 274.—FELIX II., pope; chosen by the Arians or by the Emperor Constantius in 355, during Liberius's exile, upon whose return he was expelled. D. Nov. 22, 365, and was canonized by the Romish Church.—FELIX III., pope in 483 A. D., was a native of Rome and great-grandfather of Gregory the Great. His condemnation of Acsius, Patriarch of Constantinople, accused of heresy in 484, occasioned the first schism between the Eastern and the Western Churches. D. Feb. 24, 492.—FELIX IV., pope in July, 526, appointed by Theodoric, King of the Goths. D. Oct., 530.—FELIX V., pope or antipope. Duke Amadeus of Savoy abdicated his ducal crown in 1433, and retired to Ripaille on Lake Geneva to live as head of a monastic community. But he was elected pope by the Council of Basel Nov. 5, 1439, and consecrated July 24, 1440. Failing to get recognition from the great powers, he renounced the pontificate Apr. 9, 1449, became Cardinal of San Sabina and papal general-vicar for Savoy, Basel, Strassburg, and contiguous parts, and d. in Ripaille, Jan. 7, 1451.—FELIX, Bishop of Urgel, in Catalonia, in the eighth century; was a man of great acuteness and learning and formulated the "Adoptian heresy"—i. e. that Christ, as man, was merely the adopted son of God. He was banished about 800, and died at Lyons about 818.

Felix (in Gr. Φῆλιξ), ANTONIUS: a freedman of the Emperor Claudius, whence he was also, according to Suidas, called Claudius; a brother of the powerful freedman Pallas, through whose influence with the emperor and the Empress Agrippina Felix was appointed as procurator of Judæa in 52 A. D. Throughout the whole of his administration he had to contend against riots and seditions of every sort, stirred up by bandits, the so-called *sicarii*, religious zealots, and false prophets. His suppression of them was distinguished by a cruelty and rapacity which defeated its own end and was productive of more crime and disturbance than ever. It was this Felix to whom St. Paul was sent for trial after his arrest at Jerusalem, and before whom he so "reasoned of righteousness, temperance, and judgment to come" that "Felix trembled." Nevertheless he was detained by him for two years, and was finally released by Felix's successor, Festus. In A. D. 60 (or 61) he was succeeded by Festus, whereupon the leading Jews of Cæsarea went to Rome and brought accusation against him before the emperor (probably with special reference to the part he had played in the suppression of the riots between the Jewish and Syrian inhabitants of Cæsarea), but through the intercession of his powerful brother, the freedman Pallas, he escaped punishment. Cf. esp. Josephus, *Antiq. Jud.* (xx., 7 and 8) and *Bel. Jud.* (ii., 12 and 13). G. L. HENDRICKSON.

Felix, MARCUS MINUCIUS: commonly called MINUCIUS FELIX; an eloquent Roman lawyer and one of the earliest Christian writers, perhaps before Tertullian, although his period is variously set between 170 and 303 A. D. Wrote the dialogue *Octavius*, designed as a popular defense of Christianity, and remarkable for its choice diction. Possibly he came from Africa. See Wölfflin, *Archiv für Lat. Lexikographie*, vol. vii., pp. 468–484. M. WARREN.

Fellah, fel'lā, plur. **Fellahin**, -heen [Arab., plowman, peasant]: one of the laboring class in Egypt. The fellahin are mostly Mohammedans, but a few of them are Copts. Except the slaves, they are the lowest class of the population. Politically and socially they have considerably improved under the British *régime*. They form 61 per cent. of the Egyptian people. They are of mixed Coptic, Arabian, and Nubian stock. They are licentious, idle, and obstinate from the effects of many ages of grievous oppression. The name *fellahin* is also given to the laboring classes of other Mohammedan countries.

Fellat'as, or **Fu'las**: a Mohammedan people of the Western Sudan in Africa, remarkable for their enterprise, intelligence, and religious zeal. They are a foreign race distinct from the Negroes, have many tribes, several shades of color and varieties of form, probably from the fact that they have blended with subject races. They cultivate Mohammedan learning enthusiastically. Their history is quite obscure. Sokoto is their principal state, but they are the predominant people of several Sudanese lands, and are found as far E. as Darfur.

Fellenberg, fel'len-bărch, PHILIPP EMANUEL, von: educator and statesman; b. in Berne, Switzerland, June 27, 1771; was a descendant on the mother's side of Admiral Van Tromp. In youth he imbibed in some measure the philanthropic views of Pestalozzi, his father's friend. Fellenberg studied at Colmar and Tübingen, and a visit to Paris just after Robespierre's death convinced him that a better public education was necessary to the safety of society. He opposed the French in their occupation of Switzerland, for which cause he was banished, but after his return was employed in important diplomatic, political, and military offices. After failing to secure government aid in his plans, he founded in 1799 his famous educational and manual-labor establishment on his own estate at Hofwyl, near Schönbühl, in the canton of Berne, and to this school he consecrated all his large fortune. In 1804 Pestalozzi removed his Burgdorf school to the old monastery of München-Buchsee, adjoining Hofwyl. Here the teachers gave the chief direction to Fellenberg, as Pestalozzi said, "Not without my consent, but to my profound mortification." In 1805 Pestalozzi accepted a call to open a school at Yverdun. In 1807 Fellenberg established a scientific department, and in 1808 a normal school and an agricultural institution, where scientific agriculture was taught and practiced and farming implements manufactured. The Hofwyl institution flourished, and before Fellenberg's death there were in it ten distinct departments of instruction. Children of all ages, the rich and poor alike, were received. The wife and nine children of Fellenberg assisted him in his work. He died at Berne while grand bailiff, Nov. 21, 1844. A few years after his death his establishment was abandoned. Fellenberg was in temper and method almost the exact opposite of Pestalozzi, though he pursued the same ends. The ruling spirit of his school was common sense. Order was there as prominent as the lack of it was at Yverdun. See Payne's *Lectures on the History of Education.* Revised by C. H. THURBER.

Fellows, Sir CHARLES: b. at Nottingham, England, in 1799; made four expeditions into Asia Minor; collected the Lycian Marbles, now in the British Museum; was knighted in 1845. Author of *Journal of an Excursion into Asia Minor* (1839); a *Journal* (1841) of his second expedition; *Xanthian Marbles* (1843); *Account of an Ionic Trophy Monument* (1848); *Coins of Ancient Lycia* (1855), etc. The rich archæological remains of Lycia were quite unknown until described by him. D. at Nottingham, Nov. 8, 1860.

Fellow Servants: two or more persons who are subject to the same general control, and engaged in the same pursuit. The rule of law is that one who engages in the employment of another for the performance of specified duties and services, for a compensation, takes upon himself the ordinary risks and perils incident to the performance of such services, including the perils arising from the carelessness and negligence of those engaged in the same employment. So that while a master is ordinarily liable to a third person for the wrongful acts of his servant if the acts are done in the execution of the master's business within the scope of the servant's employment, yet the master is not liable if the person injured is a fellow servant with him who worked the injury in the manner above defined. The test for determining who are fellow servants does not consist in the grade or rank of the offending or injured servant, but in the character of the act done by the offending servant. If the act is one which the law implies a contract duty upon the employer's part to perform, then the offending employee is not a servant but an agent, and the master's liability is clear. A master who knowingly employs and retains an incompetent servant is liable for injuries done by such servant to a fellow servant, if it appears that the injured servant did not know and did not have the means of knowing of the incompetency of his fellow servant, and provided the injury is the result of the fellow servant's unskillfulness or incompetency. If a servant is generally known to be incompetent the master is chargeable with negligence in not knowing what that reputation is. If the master originally used due care in the selection of the servant, and subsequently obtains knowledge of his unfitness, but continues him in his employment, he makes himself thereby liable for injuries resulting to fellow servants from such unskillfulness. In Great Britain, and in some of the commonwealths of the U. S., statutes have been passed on this subject changing the common-law rule, and making the master in some cases liable for injury caused to employees by the negligence of a co-employee. See MASTER and SERVANT.

HENRY WADE ROGERS.

Fellowship: in the universities of Oxford, Cambridge, Durham, and Dublin, a position held by the fellows (*socii*) of a particular college. The fellows were originally poor students (chiefly of divinity) who received the income of the fellowship as a means of support, but when they obtained a sufficient benefice, or became owners of property beyond a certain amount, or by marriage signified their abandonment of the Church, they lost the fellowship. The same causes, with some modifications and exceptions, will vacate a fellowship at present. Now, however, the fellowships are rewards for eminent scholarship, yielding in some cases a very handsome income, besides other valuable perquisitites. Recent legislation has much simplified the ancient system of fellowships. The system of fellowships has extended rapidly among colleges and universities in the U. S. The conditions under which they are awarded vary in different institutions. They are, however, always given to college graduates of superior attainments, to enable them to pursue advanced studies. Generally they are tenable for a year only, though holders may be re-elected. The stipends are never large, $500 per annum being the usual amount. The fellows hold the most dignified position in the student body, and the ranks of the faculties are apt to be recruited from them. In a number of institutions in the U. S. the trustees are called fellows. Revised by C. H. THURBER.

Felltham, or **Feltham**, OWEN: author; b. in Suffolk, England, 1608; was for a time an inmate of the Earl of Thomond's household. Felltham wrote about 1628 his *Resolves, Divine, Moral, and Political*, a book of moral reflections which was very popular in the seventeenth century, and has been often reprinted. D. in 1677.

Fe'lo de se [Med. Lat., a felon concerning himself, murderer of himself; *felo* is the Lat. form of a Romance word; cf. Ital. *fellone*, Fr. *felon*, ultim. of Germ. origin]: one who commits suicide. See SUICIDE.

Felon: See WHITLOW.

Felony [O. Fr. *felonie*, deriv. of *felon*; cf. Ital. *fellone*, outlaw, a word of German origin]: as a term of the English common law, an offense the commission of which was attended with a forfeiture of the wrongdoer's lands, goods, or both; distinguished from a *misdemeanor*. The principle of classification in accordance with which all crimes were divided into the two classes of *felonies* and *misdemeanors* did not depend upon any definite inherent peculiarity by which the offenses in one category were separated from those in the other, but merely upon the difference in the modes of punishment adopted. Death was in a large number of instances superadded to forfeiture in the case of felonies, but was not a distinguishing characteristic of this grade of offense. The common belief that in order for a crime to be felonious it must be one for which capital punishment is inflicted, is entirely erroneous. In the law of Great Britain there have been some important changes made in the laws concerning forfeiture, but the term "felony" retains its previously established signification, and no offense comes under this designation to which forfeiture is not annexed as a penalty. Goods and chattels are forfeited upon conviction for any felony, but in the case of lands conviction alone is not sufficient, but sentence of attainder must be pronounced. (See ATTAINDER.) By attainder for felony the offender forfeits the profits of all freehold estates during life; if the offense be *murder*, he also forfeits, after his death, all lands held in fee simple to the crown for a year and a day. (See FORFEITURE.) In the U. S., where the nature and punishment of crimes are generally determined by statutory provisions, there is no universally recognized meaning given to the word "felony." Some States which have still retained it in use give to it a specific definition, employing it to designate crimes involving a certain kind of penalty, but making the penalty of a different character from that by which its meaning was originally determined. Thus in New York any offense punishable by death or by imprisonment in a State prison is a felony. In a few States the use of the term is entirely discarded, and if it be employed at all in legal proceedings it is without definiteness and precision of meaning. Forbearing to prosecute a felony for a consideration constitutes the crime of COMPOUNDING OF FELONY (*q. v.*). See the article CRIME.

GEORGE CHASE.

Fel'sing, JAKOB: engraver; b. at Darmstadt, Germany, in 1802; wrought in Italy ten years, and then, in 1832, obtained at Darmstadt the title of engraver to the court. *The Marriage of Saint Catherine*, after Correggio, *Holy Family*, after Overbeek, are among his best works. D. at Darmstadt, Mar. 29, 1875.

Felsite, or **Felstone**: a hard flinty rock which has about the same chemical composition as granite, but which to the unaided eye appears homogeneous. The microscope shows such rocks to be composed of the same mineral ingredients as granite, but in an extremely finely divided state. They are therefore called cryptocrystalline. Such rocks are identical with the base or groundmass of the porphyries, with which they are genetically closely related, although they are free from porphyritical crystals. They have originated through the devitrification of ancient glassy rocks, or were produced by the original crystallization of a molten magma. They are frequently banded, and may be of any color. The banding may be due to original flow structure in the viscous mass, or it may be the result of pressure and shearing on the solid mass. Possibly similar rocks may also be produced from acid volcanic ashes or other sedimentary material, and may then have a true stratification. Felsite is also known as *petrosilex* or *halleflinta*. GEORGE H. WILLIAMS.

Felspar: See FELDSPAR.

Felstone: See FELSITE.

Felt [O. Eng. *felt*: Germ. *Filz*. Cf. Lat. *pilus*, hair, and Gr. πῖλος, felt, fez]: a stuff composed of wool, fur, or hair, of which the fibers are so entangled and interlaced that they can not readily be separated. Felt is an article which has long been known. Homer and Hesiod distinctly mention it. It was a common material for caps, hosiery, floor-cloths, tents, and cloaks. It has long been known in the East, and the nomads of the desert largely occupy tents of felt. There is, however, a tradition that St. Clement discovered felt while on a pilgrimage. Having put a bat of carded wool into each shoe to save his feet from blistering, he found at his journey's end that moisture and friction had converted the wool into felt.

Waste wool is largely employed for felting. It is first deprived of its oil, then carded and placed in a machine, where it is kept wet with hot water and subjected to a process of beating, by which the fibers are made to move upon each other until the interlocking of their serrations and the curling of the fiber itself unite the whole into a compact sheet of felt. The *fulling* of cloth is but a partial felting of wool already woven. Felted wool is used for carpets (often beautifully printed), carpet-covers, coarse hats, carriage-linings, and even for cloaks and other garments. The cheapest woolen rags, etc., are worked into felt for covering steam-boilers. This is an excellent non-conductor, and greatly diminishes the waste of heat. Roofing felt is a coarse kind, usually coated and filled with coal-tar and sometimes with tar and powdered slate. Felt is also used for sheathing walls, and is useful as a non-conductor of heat. Felt for hats is made of the fur of nutria, raccoons, beavers, conies (rabbits), etc., and is generally mixed with some Saxony or other felting wool. The heap of fur is struck with a bowstring until it falls into an even layer, and it is felted by working it with the hands in a soapy liquid. Machinery is also sometimes used in this process.

Felt, JOSEPH BARLOW, LL. D.: antiquary; b. at Salem, Mass., Dec. 22, 1789; graduated at Dartmouth College 1813; was pastor of Congregational churches at Sharon and at Hamilton, Mass., from 1821 to 1824, and from 1824 to 1834, respectively. In 1846 he completed the classification and binding of the archives of the State of Massachusetts, for which he had been commissioned by Gov. Everett in Apr., 1836. He also procured from the English archives duplicates of records which had been lost. He was president of the New England Historical and Genealogical Society 1850–53, besides holding other offices in kindred institutions. *Annals of Salem* (1827); *Historical Account of Massachusetts Currency* (1839); *Ecclesiastical History of New England* (2 vols., 1855–62), etc., were among his publications. D. at Salem, Sept. 8, 1869.

Felton, CORNELIUS CONWAY, LL. D.: scholar and author; b. at West Newbury, Mass., Nov. 6, 1807; graduated at Harvard College 1827; in 1829 he was appointed Latin tutor at Harvard College; in 1830 Greek tutor at the same institution. In 1832 he became Eliot Professor of Greek there, and July 19, 1860, was inaugurated president of the college. Member of the American Academy of Arts and Sciences, and regent of the Smithsonian Institute. Among his numerous publications may be mentioned: *Homer, with English Notes and Flaxman's Illustrations* (1833); Aristophanes, *Clouds* (1841); *Birds* (1852); Isocrates, *Panegyricus* (1849); Æschylus, *Agamemnon* (1849); Menzel's *German Literature* (translation, 3 vols., 1840); *Ancient Literature and Art*, in conjunction with Sears and Edwards (1843); revision of Smith's *History of Greece* (1855); *Selections from Modern Greek Writers* (1856); translation of Guyot's *Earth and Man* (1849); *Life of Gen. Eaton*, in Sparks's *American Biography*. D. at Chester, Pa., Feb. 26, 1862.

Revised by ALFRED GUDEMAN.

Feluc'ca [Ital. *felucca* (whence Fr. *felouque*, Germ. *Felucke*), from Arab. *falūka*, deriv. of *fulk*, a ship]: a vessel used in the Mediterranean Sea, having a small tonnage, light draught, and great speed with a light wind. These vessels have from ten to eighteen sweeps, or large oars, carry lateen sails, and have frequently a rudder at each end so that they may be used as "double-enders" and may reverse their course without tacking or veering.

Feme Coverte: See MARRIED WOMEN.

Fem'ern, or **Feh'marn**: a very low, perfectly level, marshy, but fertile island in the Baltic, belonging to Prussia, and separated from Holstein by a narrow and shallow sound. It has two towns, Burg and Petersdorf. Pop. 9,800.

Fe'mur [Lat., thigh-bone]: in the vertebrate skeleton the proximal bone of the posterior extremity, interposed between the innominate bone and the tibia and fibula, the bones of the leg. It has (1) a globular *head*, rotating within the acetabulum or socket of the hip, and joined by a (2) *neck* to the main femur or (3) *shaft*; also (4, 5) a *greater* and a *lesser trochanter*, prominences for attaching the rotating muscles and giving them leverage; (6) a *linea aspera*, or "rough line" running lengthwise for the attachment of muscles; and (7, 8) *outer* and *inner condyles*, at the lower end, affording articulating surfaces for union with the bones of the leg. The femur in man is popularly called the thigh-bone. The term *femur* is also applied to a part of the leg of an insect. See ENTOMOLOGY.

Fences: See the Appendix.

Fencing [deriv. of *fence*, an abbrev. of *defence*]: properly, the art of using a weapon as a means of defense as well as attack. When men covered with armor and carrying large shields assailed one another with swords, halberds, axes, or other cutting and piercing weapons, there was but little attempt at *fencing*; the sword-play, etc., of the time had to do chiefly with ways of reaching the flesh in spite of its coverings and guards. But men undefended, or almost undefended, carrying only small bucklers and perhaps head-pieces, used a kind of fencing called sword-and-buckler play, in which the parrying or *fending* was done chiefly but not wholly by the buckler. The adaptation of this to the supposed needs of the noble or knightly class at the close of the fifteenth century, when armor was less commonly worn than before, took the form of rapier and dagger play. The rapier, a heavy, straight, double-edged, and pointed sword, over 4 feet long and weighing from 2½ to 3 lb. without its sheath, was used chiefly for the thrust; rarely, though sometimes, to cut with the edge. Parrying was chiefly done by means of the dagger held in the left hand. In default of the dagger, a cloak wrapped around the arm enabled the arm alone to put thrusts aside. In the sixteenth century many works were published with copious illustrations to explain the numerous systems of fence which different Italian, Spanish, and French "masters of arms" had devised. The dagger, though chiefly for warding, would sometimes give the thrust; so the rapier would sometimes parry, and some systems supposed the use of two swords of equal length, even as the Chinese sometimes carry two swords of the same pattern in one scabbard, for very similar fencing. There was also an elaborate system of fencing with the huge two-handed sword of the Swiss mountaineers, the Highlanders of Scotland (this being the original and proper *claymore*), and of many kinds of foot-soldier all over Europe. There was also a system of fencing with the halberd, not unlike that used by the Japanese, as their own illustrated handbooks show, and somewhat like modern practice with the bayonet. Bayonet-fencing has been slowly developing ever since the bayonet was finally arranged so as to remain fixed to the musket and not interfere with loading and firing.

During the reign of Louis XIV. the small sword proper replaced the heavier weapons of earlier times, the two-handed fence was abandoned, and the modern system was slowly developed. The small-sword, when once it came into use, was adopted as the fairest weapon for dueling; and though to the custom of wearing it may be charged the disposition to indulge in violence, many desperate encounters in which innocent persons sometimes suffered, and the loss of valuable lives, it must be said that the practice of DUELING (*q. v.*), which had previously been so conducted that every unfair advantage was taken and allowed, and with a revolting display of ferocious passions, was greatly humanized by the refinement introduced by the rules and art of fencing. Skill with the sword is practically of advantage to those upon whom falls the duty of the national defense, to enable them to use loyally the weapon they alone are required to wear. But as the sword is no longer generally worn, and is not, among English-speaking peoples, used in dueling, adroitness in its use may no longer be feared as likely to create a fondness for contention; and fencing may be and is now resorted to as an enjoyable and healthful recreation and as a certain means of physical development. As an exercise it is void of danger, gives no occasion for rudeness, calls for no over-exertion, yet brings into active and graceful play every muscle of the body, and demands the eager and unremitting attention of every faculty.

A distinguished French authority on the art of fencing declares that a swordsman, on crossing blades with an antagonist and before closing in combat, must take in at a glance the intellectual and physical powers of his adversary, so as to judge of the employment he will likely make of them, and decide by the first few movements of his weapon if he is a man of nerve or one that may be intimidated or confused; observe on the instant if his guard is faulty, and what advantage may be taken of it; discover by feints his natural parry, and by his attitude and aspect whether his *forte* is the attack or defense; if he will probably rush in, trusting all to strength and audacity; and if he is one of whose attack signal advantage may be taken if anticipated, or who will contend warily with the skill of one accustomed to fencing, and must therefore be attacked with caution. This, so true in mortal combat, must be borne in mind by fencers to secure the best advantages from the use of foils as an exercise.

The Foil.—The foil or small-sword consists of two parts, the hilt and blade; and the hilt of three pieces, the pommel, the gripe, and the guard. The part of the blade nearest the guard is the fort. The two-thirds nearest the point are the feeble. The side of the gripe on which the thumb rests should be broad, flat, and convex, the opposite side slightly concave.

To hold the foil or sword in the most advantageous manner, the thumb must be extended along the convex side of the handle, and at least half an inch from the guard. The forefinger is partially extended on the under side, the middle portion opposite the thumb. The remaining fingers embrace lightly the side of the handle. At the moment of making a blow or parry the handle is firmly grasped, but to hold it so constantly would soon fatigue and paralyze the hand.

The *guard* is the attitude a swordsman assumes, best calculated for attack and defense. It is the position men take naturally when they meet in combat. The right foot is twice its length in front of the left, the knees bent equally, the right being vertically over the instep. The body should be erect, and its weight resting a little more on the left than the right leg. The right foot should point directly to the front, and the knees be flared apart. The weapon is at the same time raised to the height of the waist and turned near the left side, bringing the point to the front; the right arm is extended till it is half bent, the elbow about 6 inches in front of the side and turned in toward the body, the hand at the height of and opposite the right nipple, the nails turned up, the thumb horizontal, the back to the right. The point of the blade should be at the height and in front of the eyes. The left hand is extended to the rear and a few inches higher than the head, the elbow is slightly bent, the hand open, palm to the front. The arm from the shoulder to the end of the fingers forms a curve. The reverse of this position is true for left-handed men. The guard here described is the "middle guard," because in it the weapon occupies a middle position in reference to those it assumes in the defense. When on guard it is essential to be *covered* on the side toward which the adversary's blade points.

If the hand is carried to the right till it is so nearly in front of the right shoulder that the adversary's point, if extended on that side, would not touch, one is covered and the guard of tierce is formed; if to the left till the hand is sufficiently in front of the left breast to divert the point on that side, the guard of quarte is formed. The moment blades are crossed one or the other of these guards is formed, and is called the *engagement.*

Men of small stature should form the guard with the hand nearly as high as the neck; those of medium size, with the hand as high as the breast; tall men, with the hand a little below the breast. Although the guard should be habitually taken according to stature, still it must be varied, for it is dangerous not to make the height of the guard correspond with that of one's adversary.

The *engagement* is the act of crossing weapons and bringing them into contact. When the right of the blades is in contact, the engagement is in tierce; if the left, the engagement is in quarte. When the hand is turned so as to bring the back up and obliquely to the left, and the points lowered and brought in contact on the right, and at the height of the groin, the engagement is in seconde.

These are the only three engagements, and from these all blows are made; the last is rarely offered, unless from a feeling of superiority and to provoke an attack.

The *opposition* is a slight movement of the sword to bear the point of the antagonist's weapon out of the line of the person while delivering a blow to prevent falling upon it, and to avoid receiving a blow in return when in the act of recovering the position of guard. It must be insisted upon from the first blow a beginner makes till it becomes a confirmed habit.

To *change the engagement*, make a very small quick movement of the point, passing it under and as near as possible to the blade of the antagonist to the opposite side; this movement must be abrupt, and executed with the fingers only, without lowering the hand. *Cover* at the instant the point of the opposing blade is felt.

Feeling the blade consists in supporting and keeping the weapon in contact with the adversary's, without pressing upon it. This requires a delicate sensibility of the hand most essential to acquire. It indicates, in connection with the eye, when the opponent's blade has commenced an attack, and enables the weapon to be so managed in the parries as to deflect a blow without violence.

Fingering the sword is to conduct the point of the sword by the action of the fingers alone, without the aid of the wrist. To do this, the grasp, particularly of the two middle fingers, must be alternately relaxed and tightened. It is only by cultivating this that disengagements can be abruptly and closely made, and the point moved with quickness, dexterity, and precision either in making a feint or avoiding the adversary's disengagement in order to deliver a blow.

The *blow* is the act of directing the point toward the antagonist. It may be delivered in two ways—by means of the *thrust*, or with the thrust combined with the extension of the body called the *development*.

To *thrust*, extend the arm to the front fully and vigorously, raising the hand to the height of the mouth, and lower the point slightly by bending the wrist, but without loosening the grasp. At the same time throw the weight of the body forward on the right leg by straightening quickly and stiffly the left, and bring down the left arm by the side, rigidly extended, the hand about 3 inches above the left leg, fingers extended and joined, the palm to the left.

The *elevation* is raising the sword-hand when delivering the blow. This movement of the hand increases the probabilities of making a successful blow, while it acts as an important protection from a return blow.

The *development* is executed by, in addition to the action prescribed for the *thrust*, advancing the right foot close to the ground about twice its length, the left foot remaining firm in its position; the body is slightly thrown forward in an easy attitude, the head erect; the right knee vertical over the instep.

To *recover the guard*, raise the toe of the right foot, and exert strongly the muscles of the right leg, throwing up rapidly the left arm to the rear at the same moment, and take the position of guard. The right hand should be brought instantly to its position, never falling *below* it.

The left arm is an important auxiliary in all these movements in maintaining the equilibrium, and in materially assisting in the development and recovery of the guard.

To *advance*, move the right foot quickly forward its own length, raising it but slightly from the ground, and follow it at once with the left, moving it the same distance, and resume the position of guard. In advancing to make a blow at an antagonist who is out of distance, it is necessary to bring up the left foot near the right, keeping the legs well bent.

To *retreat*, move the left foot its length to the rear, and follow it quickly with the right, moving it the same distance, and resume the position of guard. The hand and point must neither rise nor fall in these movements. The point must remain steadily presented in a menacing attitude at the adversary.

Points of Attack.—There are three general points where an antagonist may be attacked when on guard. As the breast is nearest and most vulnerable, it is to be aimed at whenever exposed. But the point can not, in a desperate encounter, be directed with absolute certainty, and can not but be damaging wherever it touches. The blow at the face and right side, on the right of the weapon, is the attack on the "right"; at the face and left side, on the left of the weapon, the attack on the "left"; and under the sword-arm, the attack "below." Two of these points are always exposed, as the weapon can guard but one at any one moment.

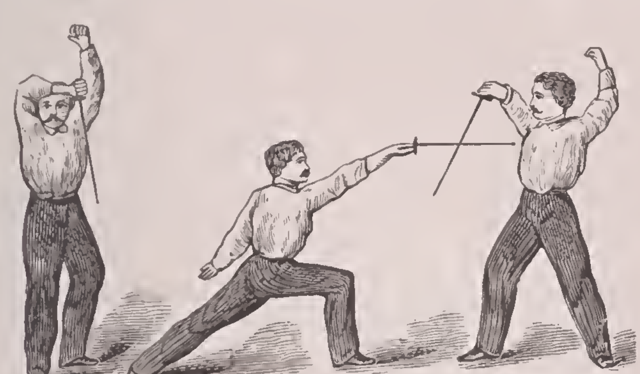
The *direct blow* is the result of the effort which carries the point to the front, in the most direct line, to the point of attack. It is the quickest of all the blows, and of course should be executed whenever the opportunity offers—that is, whenever the antagonist is *uncovered*. For instance, if engaged in tierce, to deliver a direct blow the point would be moved to the front on the same side (the right) as the engagement, should the antagonist momentarily uncover himself.

To *disengage* is to change the direction of the point and deliver a blow at the antagonist where he is not protected by his weapon; the movement of the point must precede the development. But these acts must be as nearly simultaneous as possible.

The *measure* is the distance the point attains when the person is fully developed.

The *appel* is striking the right foot on the ground, and generally twice in rapid succession, by raising it about an inch and striking it back with force. It is resorted to in making a feint to discompose the antagonist, or is done by the fencer to reassure himself in his position after a retreat, and deter his adversary from advancing too rapidly.

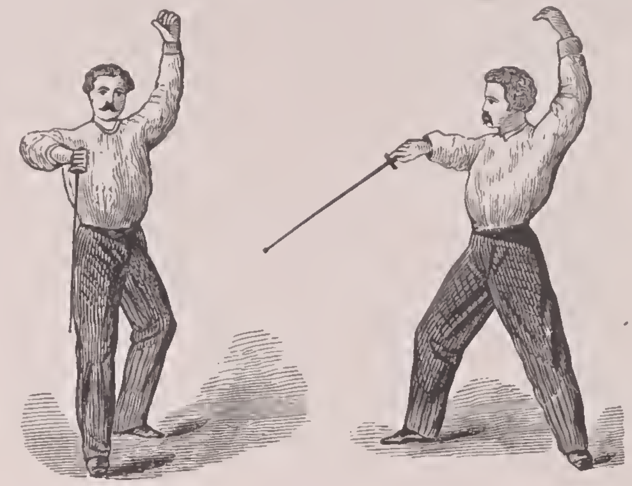
A *parry* is the action of turning aside the antagonist's blade from the point at which it is aimed. This is done with the fort of the blade. Ten parries have been decided upon as affording protection to the person from all blows that can be directed at it. They are designated by the (old) French ordinal numbers, and are thus known in all languages—viz., prime, seconde, tierce, quarte, quinte, six, sept, octave, counter-tierce, and counter-quarte. Tierce, quarte, quinte, and six are called simple parries, as the weapon is



Front view. Parry. Side view.

but slightly moved from the position of guard. Prime, seconde, sept, and octave are called half-counters, as the point describes a half circle in effecting the parry. The remaining two are called counters, as the point is made to describe a complete curve, returning to its original position. To parry correctly, the weapon must take a position which will protect the person, while at the same time the point is retained in front of the antagonist. The advantage of having a number of parries is to add to the security of the defense by embarrassing the antagonist in deciding which will be resorted to.

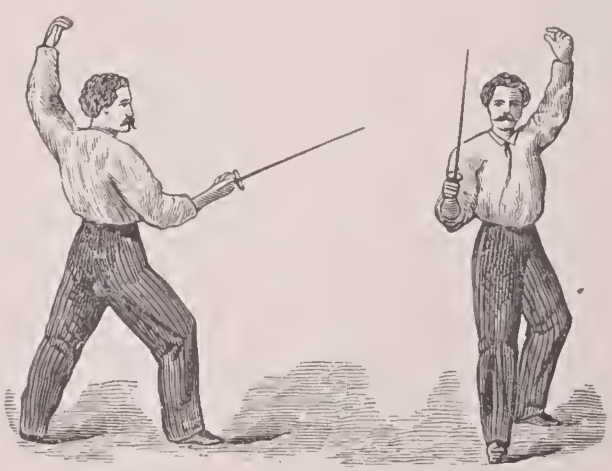
Prime is the position that would be involuntarily taken by one if attacked when in the act of drawing his blade from the scabbard. From the position of guard it is formed by turning the hand until the back is toward the left, keeping the point stationary to the front, then raising the hand



Front view. Prime. Side view.

diagonally to the left until the fore arm is in front of the forehead, describing with the point, in descending, a curve from right to left, arresting it on a line with the left side at the height of the waist. It is necessary to describe a curve with the point, so that the blade will cut the line of approach of the opposite weapon. Executed properly, it is most effective, as it may be used to turn aside every blow that can be made from the position of guard, which can not be said of any other parry. It is particularly advantageous to men of small stature.

Seconde naturally follows prime in case that parry is avoided. From guard it is formed by turning the hand in



Side view. Seconde. Front view.

pronation, both lowering it and moving it slightly to the right, describing with the point a curve, the convexity to the left, arresting the point on a line with the right side and at the height of the groin.

Tierce.—When seconde has been avoided by the antagonist's point, tierce would be resorted to involuntarily; it is

Front view. Tierce. Side view.

nearly the same as the guard of tierce. From the middle guard it is formed by moving the hand to the right till it is opposite the right side, keeping it in supination—that is, with the back down; the point moves as little as possible, the hand is drawn slightly back.

Quarte would naturally follow to parry a high disengagement from tierce. It is formed from the middle guard by

Front view. Quarte. Side view.

moving the hand to the left as far as the left side, inclining the nails slightly to the left. The point is maintained in its position as nearly as possible.

Quinte.—Quinte is naturally resorted to in order to parry a low disengagement from tierce. It is formed by lowering the hand diagonally, placing it in front of the left side at

Front view. Quinte. Side view.

the height of the groin, the nails to the left; the point is arrested as nearly as possible on a line with the right shoulder of the antagonist.

Six was formerly tierce parry, and constituted among early masters the guard of tierce; it is yet too frequently confounded with the true tierce. It is formed from middle

Front view. Six. Side view.

guard by turning the hand in pronation and moving it opposite the right side; the point is in front of the antagonist and at the height of the crown of the head.

Sept.—This parry is also called demi-circle. It is formed from middle guard by bending the wrist and lowering the point, describing with it a slight curve, the convexity to the right; the hand is raised slightly and moved to the left, opposite the left side, and the point is arrested in front of the groin of the antagonist. Sept is used to parry blows delivered at the waist, but is less effective than quinte.

Side view. Sept. Front view.

Octave.—This parry is formed from guard by bending the wrist, retaining the arm in its position, and lowering the point, describing with it a slight curve, the convexity to the left; the hand is moved in front of the right side, and the point is arrested opposite the groin of the antagonist.

Counter-parries are those in which the point moves under and around the antagonist's weapon, returning to the position from which it started. In executing a counter the arm should not move, the wrist alone acts. The point in its motion describes an ellipse. Every parry may have a corresponding counter; but two, however, are found to be of advantage—counter-tierce and counter-quarte. The counters have two advantages: they cut all the lines of attack, and throw off the weapon of the antagonist to the side on which he is prepared to take the opposition, and consequently may leave him uncovered and exposed to a direct return blow.

Counter-tierce.—Being engaged in tierce, when the antagonist disengages at the "left" lower the point with a quick bend of the wrist, passing it under the approaching weapon, and throw it off to the right.

Counter-quarte is executed after the same manner from the engagement of quarte; the blow is thrown off to the left. The point in both these parries must be arrested opposite the antagonist's face.

Double Counters.—The execution of the counters twice in quick succession is called a *double counter*. It is a parry that should be much practiced, as it gives great command of the weapon.

Disengagements.—The disengagement from tierce to quarte, or from quarte to tierce, is made by pressing on the gripe with the thumb and middle fingers, changing the point from one side to the other with an abrupt and rapid motion, at the same time that it is moved in a spiral direction to the front. The point should be directed at the right nipple. The curve which the point makes around the blade should be as small as possible. To disengage "below" from tierce or quarte, the point is lowered by bending the wrist, and moved to the front at the same time just under the blade of the antagonist. The disengagement from tierce at the "left" may be parried with quarte, a simple parry, prime, seconde, and octave, half counter, and with counter-tierce. The disengagement from quarte at the "right" may be parried with tierce and six, with prime and sept, and with counter-quarte. The disengagement "below" from tierce may be parried with quinte, prime and with seconde and octave; from quarte, with prime and sept.

Feints.—A feint is a quick movement of the point toward an exposed "point of attack," as if a blow was intended, the object being to disquiet the antagonist and induce him to move his blade, and thus expose himself. To execute a feint, the point must be moved smoothly and quickly to the front, nearly to the full extent of the arm, and as close as possible to the antagonist's weapon. The hand should be raised to the height of the mouth; neither the body nor the legs should move. The feint may be accompanied with an appel. In feinting "below," lower the point in a vertical line, and move it to the front just under the antagonist's guard, being careful to raise the hand well. To execute a feint at the "left," supposing the engagement to be in tierce, change the point and advance it nearly to the full length of the arm, describing with it the smallest possible circle around the antagonist's weapon. A feint is followed by a disengagement or by a direct blow. If the opponent moves his weapon to oppose the feint, disengage; if he does not move it, deliver a direct blow, being careful to take in either case the opposition.

Counter-disengagements.—To avoid the counter-tierce and counter-quarte parries, it is necessary to move the point entirely around the adverse blade, describing a very small circle near the shoulder of the foil. This, if followed by delivering a blow, is called a counter-disengagement.

The *riposte* is the blow that immediately follows a successful parry. It may be delivered with the thrust or development, direct or with a disengagement. If delivered direct, it should be with such rapidity as to touch the opponent before he recovers his guard. It may be made also by first menacing a direct thrust, and as soon as the opponent recovers his guard and covers the point of attack menaced, then disengaging.

To *menace* is to advance the point quickly by a partial extension of the arm on the side of the engagement, as if about to make a direct blow. In menacing after a parry the opposition must be maintained. If the adversary moves his blade toward the point menaced, disengage; if he does not, deliver a direct blow.

Ripostes are usually attempted after quarte, quinte, six, and tierce, counter-quarte, and counter-tierce parries. The riposte, after six, from the favorable position of the hand, can be delivered with more certainty and fatal effect and with more rapidity than any other. These ripostes are all executed by the thrust or development, raising the hand and lowering the point, directing it at the face and neck, or by first menacing and then disengaging at whichever point of attack may be uncovered.

Riposte after Prime Parry.—Keep the hand in the position of prime, and by a rapid extension of the arm, and making a strong effort with the thumb and wrist, direct the point "below."

To Riposte after Seconde Parry.—Lower the hand, keeping it in pronation; raise the point and deliver the blow at the flank, or menace "below" and turn the hand as in tierce, and deliver the blow at the "right."

To Riposte after Six.—Raise the hand as high as the head, turning the thumb directly down; lower the point over the guard of your antagonist, and deliver the blow at the "right," or disengage "below."

To Riposte after Sept Parry.—Lower the hand and deliver the blow at the flank; or menace, and as the antagonist covers himself and recovers his guard, disengage.

To Riposte after Octave Parry.—Lower the hand very slightly, raise the point, and deliver the blow at the flank. This is also called *flanconade.*

Disengagements by cutting over the point are made by raising the blade over the point of the antagonist's weapon and as close as possible to it. The cut, as a simple blow, is always preceded by a feint, or an attack upon the weapon, by exerting some force upon it, pressing or striking it aside. For instance, whether on guard in quarte or tierce, turn the hand, the thumb up, and with a sudden energetic pressure move the antagonist's point out of the line of the body; then leave his blade abruptly and extend the point to the front; as soon as the antagonist covers, raise the blade over his point and develop. The cut is most successfully made at the "right," first compelling the antagonist to parry quarte.

Ruse.—Force in fencing accomplishes little, quickness much, but ability and skill to deceive the antagonist everything.

On Commencing the Attack.—The disengagement, simple feint, and menace have been explained. The other modes of commencing an attack are as follows:

Gliding the weapon is executed by moving it smoothly along, and in slight contact with the adversary's, till the arm is nearly extended, then terminating the movement with the greatest celerity, executing a direct blow. The opportunity for making this blow can only occur when the opponent is not covered, and, as the point approaches him, does not take the opposition. If the opponent protects himself, taking the opposition, a disengagement may be made.

Pressing.—Without quitting the adversary's blade, move the weapon forward quickly, bearing upon his, commencing at the feeble, and develop, or if the opposition is taken, disengage. This blow is employed with advantage against one who extends the blade too much.

Beating.—Raise the point slightly and strike the opponent's weapon at an acute angle, the fort against his "feeble." It is employed against an extended guard to displace the point of an adversary upon whom a feint has no effect, in order to afford an opportunity for a disengagement.

False beating or *tapping* is to strike the adversary's weapon with the "feeble" on the side of the engagement a slight quick tap, by the action of the wrist alone, for the purpose of disquieting him, and causing him to grasp nervously his weapon and make some movement of which advantage may be taken. It is often done several times in rapid succession. The same effect may be produced by rapidly changing the guard.

Removing the Point.—When an adversary has a hard hand and bears upon the weapon, remove the point suddenly, but only a short distance. Finding the support to his blade removed, he will involuntarily seek it, and will almost certainly afford an opportunity for making a direct blow or disengagement; or he may attack, of which, being anticipated, advantage may be taken.

Crossing is employed against an antagonist who, without replying to a feint, extends his blade, presenting it at the breast. It is executed by holding the hand high and turning the blade over that of the adversary, and forming the parry of seconde or sept (demi-circle), thus securing command of his weapon and an opportunity of attacking "below." Crossing, if done with force and skill, will disarm. To disarm, however, in fencing as an exercise, is a discourtesy.

Binding is employed the instant after a successful parry, when the feeble of the adversary's blade is controlled. For instance, if the antagonist disengages from quarte "below," and the blow is parried with sept, then an opportunity occurs to bind his weapon by turning the blade under his, and with a quick motion of the wrist raise it and throw it off to the right. If done at the nick of time, as the antagonist is recovering his guard, an opportunity is given to deliver a blow at the "right," where he will be uncovered, his weapon still retaining its opposition in quarte with which he delivered his blow. Binding after the parry, if octave, may be effected after the same manner. The weapon in this case is thrown off to the left, and a blow may be delivered at the "left." In either case, if the antagonist is quick enough after his weapon has been bound to close the line of the direct blow, a disengagement should follow.

Flanconade.—The blow delivered at the flank of the antagonist when he menaces at the "left" is called flanconade, and is executed as follows: If engaged in quarte, the antagonist menaces or extends his point too far to the front and low, or if he feints at the "left" from the engagement of tierce, execute the parry of octave and deliver a blow at the flank, raising well the hand. This blow is parried with octave or seconde.

Time thrusts are made at an antagonist who, in delivering his blow, is uncovered or who makes a too wide disengagement. Such blows may be best parried by attacking in return, by a quick extension of the arm, taking a strong opposition.

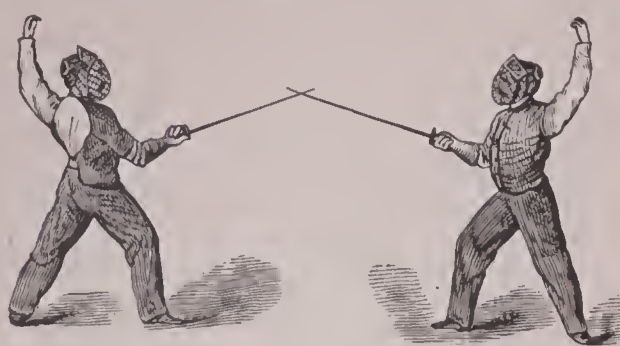
Time blows are those delivered at an antagonist who advances within distance uncovered, or who makes his feints too slow or wide. As the success of such blows depends upon the readiness with which advantage is taken of the momentary indiscretion of an antagonist, they are regarded as the most brilliant in fencing.

Encircling is effected by raising the hand after parrying six, mastering with the fort the feeble of the adversary's blade, then (as the latter rises and tries to guard against the riposte) turning or sliding the blade around it without quitting it, and riposting "below" or by a cut over the point at the "left."

Combinations.—A feint followed by a disengagement is called "feint *one, two.*" For instance, if engaged in tierce, feint one, two would be made by showing the point at the "left," and when the opponent covers the "left," disengaging at the "right." If, instead of this disengagement, a feint be made at the "right," and when the opponent covers the blow be delivered "below" or at the "left," the combination would be feint *one, two, three.* Two feints and a disengagement or counter-disengagement, or cut over the point, or a feint and a double counter-disengagement, is as much of a combination as can be attempted in an assault.

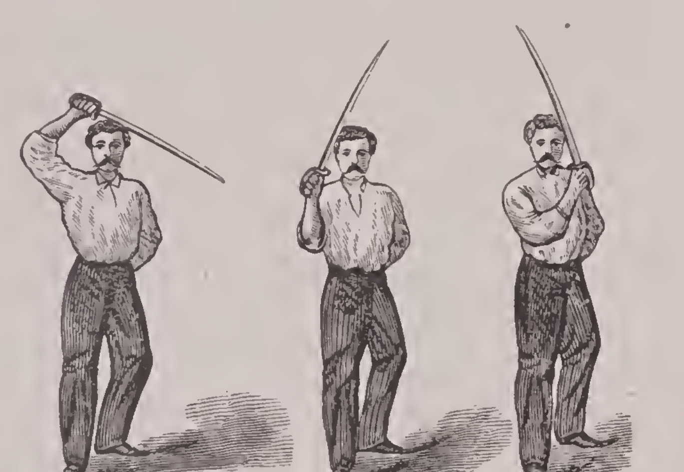
Wall practice, or tierce and quarte, is an exercise for the purpose of acquiring a fine development and great precision in making the simple disengagement at the "right" and "left."

The *salute* is a preparatory exercise in the fencing-hall in which fencers indulge as a compliment to spectators and



The assault.

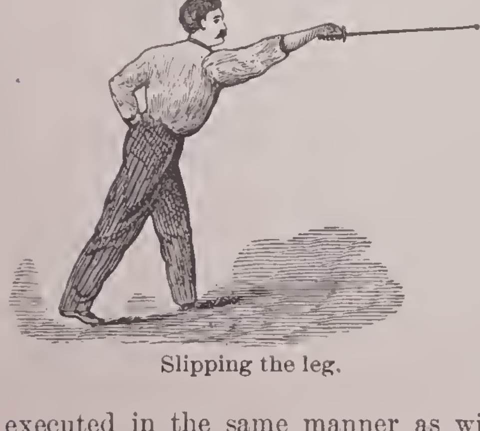
to each other, and to assure themselves before engaging in an assault. The masks are laid aside. The fencers, on first taking the position of guard, rise, salute with their weapons each other and the spectators on the right and left. On resuming guard in tierce, one disengages first at the "left," then at the "right," the blows being delivered with a loose hand, so that the weapon, on being parried, will be turned and the point thrown to the rear, the parrier at the same time lowering his point out of line. After a few repetitions of these disengagements the first fencer will discontinue, and will so indicate by an appel, both rising. The guard of tierce is then again resumed, and the other fencer will make the same disengagements. On appelling and both rising, the salute with the weapon will terminate the exercise, when masks will be resumed and the assault commenced.



Prime against cut. Tierce against cut. Quarte against cut.

The Saber.—The attack and defense with the foil are the bases for those of the saber.

The guards with the saber are essentially the same as with the foil—in tierce, quarte, and seconde; the left hand, however, is placed on the hip, to avoid cutting the arm. The edges of the sabers are in contact. The ordinary guard is tierce. The points of attack are the same—at the "right," "left," and "below." Blows, both points and cuts, are delivered with the thrust and development, direct or by disengagement. The attack is begun by feints or by attacks upon the weapon. In delivering the point at the "right" from the engagement of tierce, the saber is turned, the edge up, the back of the hand to the left. The parries are prime, seconde, tierce, quarte, and demi-circle, and against points are executed in the same manner as with the foil. Against cuts at the head, the hand, in parrying prime, tierce, and quarte, is raised, so that the saber affords the required protection. Cuts are made with the point of the saber and by a motion of the wrist alone, raising the saber as little as possible. With a keen edge slight force will inflict a fatal cut. From the ordinary engagement of tierce the first cut would



Slipping the leg.

be made at the face or right of the head, and parried with tierce. Or the cut may be at the left of the head by raising the hand, turning the edge of the saber to the left as it is launched beyond the antagonist, making the cut in drawing the hand back. The parry against this cut is prime. The cut "below" at the right flank would be parried by seconde. From the engagement of quarte the first cut would be at the face or left of the head, and parried by quarte, or at the right of the head, by raising the hand, turning the edge to the right as it is launched beyond the antagonist, making the cut in drawing the hand back.

Riposte with point after tierce parry.

The cut "below" at the left flank would be parried by demi-circle. The cut at the leg is best avoided by withdrawing the leg, at the same time extending the point.

Cut after prime parry.

The most effective parries are prime and seconde. The most effective ripostes are with the point after tierce parry, with the cut after prime. J. C. Kelton.

Fen Country: See the Appendix.

Fendall, Josias: Governor of Maryland from 1656 to 1660; appointed by Parliament in 1658, his previous appointment, in 1656, having been made by the proprietors; superseded in 1660 for intrigue, and subsequently banished; in 1681 a fine of 40,000 lb. of tobacco was imposed upon him.

Fénelon, fā'ne-lōn', François de Salignac de la Mothe: archbishop and author; b. at the château de Fénelon, Périgord, France, Aug. 6, 1651; went to the University of Cahors in 1663, and thence to the College of Plessis. He preached his first sermon in 1666, went thence to the Seminary of Sulpice, and received holy orders about 1675. In 1678 was superior of the order of Nouvelles Catholiques, for the instruction of new converts. In 1686, after the Revocation of the Edict of Nantes, he was sent by Louis XIV. to Poitou to convert Protestants. He was preceptor to the Duke of Burgundy in 1689, tutor to the Duke of Anjou in 1690, and to the Duke of Berri in 1693. In the same year he became a member of the French Academy. Was appointed Archbishop of Cambray Feb., 1695, and during that year, as afterward, became the friend and defender of Madame Guyon. Bossuet denounced him as a heretic in 1697, and in 1699, Fénelon, having in vain appealed to the pope, signed his renunciation of Mme. Guyon's doctrines, and died at Cambray, Jan. 7, 1715. Among Fénelon's earliest works was *Traité du Ministère des Pasteurs*, an argument against Protestantism. While tutor to the Duke of Burgundy he wrote *Dialogues of the Dead*, etc. His *Explication des Maximes des Saints*, regarded as an indirect apology for Guyonism, appeared in 1697, *Les Aventures de Télémaque* in 1699. Other works of Fénelon's were *Dialogues on the Eloquence of the Pulpit*, *Demonstration of the Existence of God*, *On the Temporal Power of the Mediæval Popes*, a *Treatise on the Education of Girls*, etc. The following works may be consulted: Ramsay, *Vie de Fénelon* (Paris, 1725); Cardinal de Bausset, *Histoire de Fénelon* (4 vols., 1808); Gosselin, *Histoire littéraire de Fénelon* (1843); Charles Butler, *Life of Fénelon* (London, 1810); Alphonse de Lamartine, *Fénelon* (Paris, 1854); Henri Lemaire, *Vie de Fénelon* (1826); J. F. de Laharpe, *Éloge de F. de Salignac de la Mothe Fénelon* (1771); Maury, *Éloge de Fénelon* (1771); Roy, *Histoire de Fénelon* (1842); Werfer, *Leben des F. Fénelon*, etc. (1852); E. Gandar, *Fénelon et son Temps* (1864); H. L. Lear, *Fénelon, Archbishop of Cambrai* (London, 1876; 3d ed. 1884). Revised by J. J. KEANE.

Fen′elon Falls: village; Victoria co., Ontario, Canada; between Cameron and Sturgeon lakes; 16 miles N. of Lindsay, with which it is connected by steamboat (see map of Ontario, ref. 3–E). It has large lumber-mills, and a waterfall 20 feet high and 300 feet wide. Pop. about 1,200.

Fenestel′la: a genus of fossil bryozoans, of which many species have been obtained from the Palæozoic rocks. They usually have the form of a calcareous network, of which the meshes are often quadrangular, resembling little windows, whence the name. The threads of the network are poriferous. The corallum of *Fenestella* frequently grows in the form of a broad, ribbon-like frond, spirally wound round and radiating from a central axis. J. S. NEWBERRY.

Fenestella: a Latin historian who flourished under Augustus, and continued to live into the reign of Tiberius, since, according to the statement of Jerome, he died in the seventieth year of his age, A. D. 19. Nothing further is known positively of his life. He wrote a work entitled *Annales*, of which the twenty-second book is cited by Nonius, and which supplied to Plutarch materials for some of the statements in his *Lives* of distinguished Romans. It probably extended from the period of the kings down to and including the later history of the republic, which portion seems to have been more fully treated than the earlier. See J. Pöth, *De Fenestella hist. script. et carm.* (Bonn, 1849). The fragments are collected in H. Peter's *Hist. Rom. Fragmenta* (Leipzig, 1883), pp. 272–278.

Fêng-shui: same as FŬNG-SHUI (*q. v.*).

Fe′nian: a name first applied in the early history of Scotland and Ireland to a tribe of warriors noted for their prowess. Finn MacCumhail was their most famous chief. According to Irish annals he died about 285 A. D. So great was his renown that these Gaelic warriors were henceforth called Feinne, Fiana, or Fenians. Their deeds form the theme of many poems and legendary tales in Celtic literature, and are also commemorated by various names in Scotch and Irish topography. In early Irish histories they are represented as an established militia, whose duty it was "to defend the country against foreign or domestic enemies, to support the right and succession of their kings, and to be ready, upon the shortest notice, for any surprise or emergency of state." With the rise of monasticism the ancient order disappeared, but Finn and his Fenians, and especially his two sons, Fergus and Oisin (the Scottish Ossian), long remained to the Gaelic imagination what Arthur and his knights were to the Cymric.

In 1859 the name was applied to an organization of Irishmen that was formed in the U. S. and Great Britain to secure the independence of Ireland. The organization was constituted on republican principles, having its social, district, and State circles, and its congress, in which was vested the supreme legislative authority and the choice of the chief executive officer. The first Fenian congress met in Chicago in 1863; the order, however, did not attract much attention until its second congress, in Cincinnati in 1865. It then became very popular among the Irish, 80,000, it was said, belonging to it in the U. S. In 1866 several attempts were made by the Fenians in the U. S. to invade the British provinces, but all, except two, were frustrated by the U. S. authorities. The two companies of Fenians who succeeded in crossing the Canadian frontier were speedily driven back, and most of those who returned were taken prisoners by the authorities and sent on parole to their homes. During the following year there was a number of Fenian riots in Great Britain, but all were soon quelled, and some of the rioters hanged. From that period the Fenian excitement rapidly subsided. Divisions occurred in the organization, the masses lost confidence in their leaders, and many of the wrongs of Ireland which they sought to redress were abolished by legislation.

Fénin, fā′năn′, PIERRE: a nobleman from Artois; served at the court of Charles VI., and became prefect of Arras, where he died June 5, 1433. He was for a long time considered the author of the so-called *Chronique de Fénin*, but Mlle. Dupont, the last and most competent editor of that book, ascribes it to his son. The book, as it now exists, seems to be a compilation lacking both the beginning and the end. The existing fragment consists of two parts, differing considerably both in style and method of composition, the first part comprising the period from 1407 to 1422—that is, the close of the reign of Charles VI.—and the second the first five years of the reign of Charles VII.

Fennec [from Arab. *fanek*]: a small fox (*Vulpes* or *Fennecus zerda*), distinguished by the size of its ears, inhabiting Northern Africa. The body is about a foot long, the bushy tail a little less; the ears are 3 inches in length. The general color is yellowish, except the tip of the tail, which is black. The fennec lives in burrows, and is partly nocturnal in its habits. The name fennec is sometimes erroneously applied to a small South African fox, *Megalotis lalandii*.

F. A. LUCAS.

Fennel [from O. Fr. *fenoil* > Mod. Fr. *fenouil* < Lat. *feni′culum*, deriv. of Lat. *fe′num*, hay]: the popular name of a genus (*Fœniculum*) of Old World umbelliferous herbs, closely allied, and by many assigned, to *Anethum*, the dill genus. The *Fœniculum vulgare* (common fennel), *Fœniculum dulce* (sweet fennel), and *Fœniculum officinale* of Europe (the first cultivated in the U. S. also) are raised extensively for their seeds, a very pleasant, warm, aromatic much employed in pharmacy. These seeds abound in volatile oil of fennel. The leaves and blanched shoots are used as salad and potherbs in Europe. The *Fœniculum capense* of South Africa has an edible root. The *Fœniculum panmorium* of India is much cultivated for its aromatic seeds. Among the popular superstitions there is a belief that he who sows fennel-seed sows sorrow. Fennel-leaves were once emblematic of grief. The giant fennel, in whose stalk Prometheus concealed the fire which he stole from heaven, was the *Ferula ferulago* of the Mediterranean coasts, whose pith is still used as a port-fire and as tinder. This coarse plant is also umbelliferous. "Small fennel" is the *Nigella sativa* of Europe and Asia, the "love-in-a-mist" of gardens, a small ranunculaceous herb with quaint flowers and aromatic seeds, sometimes used in cookery and medicine.

Fenton: village; Genesee co., Mich. (for location of county, see map of Michigan, ref. 7–J); on the D., G. H. and M. Railroad; 50 miles N. W. of Detroit. It has a union school, a large normal school, two gold-cure institutes, an extensive flouring-mill, a cooperage, an iron-foundry, an extensive window and door-screen factory, manufactures of drills, pumps for water-works, whip-sockets, novelties, etc., electric lights, and a fine system of water-works. Pop. (1880) 2,152; (1890) 2,182; (1900) 2,408.

EDITOR OF "INDEPENDENT."

Fenton, ELIJAH: poet; b. in Staffordshire, England, in 1683; had M. A. from Cambridge University in 1704. He assisted Pope in the translation of the *Odyssey*. His *Mariamne* (1723), tragedy, was successful. He wrote also *Life of Milton* (1727) and other works. D. in Berkshire, July, 1730.

Fenton, REUBEN EATON: statesman; b. at Carroll, Chautauqua co., N. Y., July 4, 1819; educated at Pleasant Hill and Fredonia academies; studied law, and settled at Jamestown, N. Y.; after practicing a few years became a merchant. He was supervisor of Carroll in 1843, Representative in the U. S. Congress from the Thirty-third District of New York from Dec., 1857, to Mar., 1865, Governor of New York from 1865 to 1869, and U. S. Senator from New York 1869–75; chairman of the U. S. commission at the international monetary conference in Paris in 1878. D. at Jamestown, N. Y., Aug. 25, 1885.

Fen Town: See LONDON.

Fen′ugreek [cf. Fr. *fenu-grec* < Lat. *fenum græcum*, Greek hay]: a name given to the *Trigonella fœnum-græcum* and other species of the genus, leguminous annual herbs of Asia and Europe, resembling clover. The above species is cultivated in France and Germany for its seeds, which are ground into an oily, mucilaginous meal, much used in farriery as a vehicle for drugs. They were once valued in medicine, but are now only employed in poultices, etc. Another species, growing spontaneously in India, is much used as fodder for cattle.

Fenwick, Sir JOHN: English Roman Catholic conspirator in the reign of William III.; b. near the middle of the seventeenth century; was committed to the Tower for his part in the assassination plot June 11, 1696, and a bill of attainder against him being passed on Jan. 11, 1697, he was executed on Jan. 28 in the same year. This was the last execution in consequence of attainder in Great Britain.

Fenwick, JOHN: Quaker and founder of a colony in New Jersey; b. in England in 1618. His grant of land in West Jersey was obtained in 1673, and he settled at Salem in 1675. In 1678 Gov. Andros, disputing his claim to the governorship, confined him in prison two years. Fenwick transferred his claim to William Penn, and died in poverty in 1683.

Fenwick, JOHN R.: soldier; b. at Charleston, S. C., 1780; educated in England, and entered the service of the U. S. as lieutenant of marines Nov., 1799; promoted to be captain in that corps 1809. In Dec., 1811, he accepted the commission in the army of lieutenant-colonel of artillery; as such served with distinction in the war with Great Britain 1812–15, particularly at the assault on Queenstown Heights, Oct. 13, 1812, where he was three times wounded and made prisoner. Breveted colonel Mar. 18, 1813, for gallant conduct on the Niagara frontier, was on same date appointed adjutant-general of the army, with the rank of colonel, and disbanded as such June 1, 1815, but retained in the army as lieutenant-colonel of light artillery; commissioned colonel Fourth Artillery May 8, 1822; brevet brigadier-general Mar. 18, 1823. D. at Marseilles, France, Mar. 19, 1842.

Feodosia: See KAFFA.

Feoffment [from O. Fr. *feoffement*, deriv. of *fieffer*, to invest with a fee, deriv. of *feu*, from O. H. Germ. *fehu*, property, cattle: O. Eng. *feoh* > Eng. *fee*; cf. Lat. *pecu*]: a mode of conveyance of landed property, formerly in use in the English law, by which land or other corporeal hereditaments were transferred by one person called a *feoffor* to another called a *feoffee*. Feoffment meant originally, under the feudal system, the giving of a feud or fee (see FEE), but in the modification of the system of land tenure which afterward ensued it was employed to denote the grant of an estate in fee-simple, and was then extended to any transfer of freehold estates in hereditaments purely corporeal. An actual delivery of the land was made by a peculiar ceremony known as *livery of seizin*—i. e. a delivery of the possession of the land by taking the feoffee upon or near it and directly investing him with the ownership and occupation. When the parties entered upon the land the livery was said to be *in deed*, and in the presence of witnesses the feoffor handed to the feoffee a clod or turf or a twig or bough as a symbol of actual investiture, at the same time uttering certain words of transfer. When the delivery was made in sight only of the land, the livery was said to be *in law*; and in order to make the transfer effectual the feoffee had to make an actual entry during the feoffor's life. The words of donation which accompanied the livery were at first oral, but at an early period they were reduced to writing in the form of a deed of transfer, though no written instrument was imperatively required until the enactment of the STATUTE OF FRAUDS (*q. v.*). Conveyance by feoffment was for a long period in English history the only ordinary method of transfer of land in possession. It has been entirely superseded by more convenient methods. It was only to be tolerated at a time when the means of communication between different sections of country were imperfect, and transfers of property were generally made between residents in the same immediate neighborhood. As a part of the common law it was in use in the U. S. until abolished. It was frequently resorted to as a means of "disseising" a claimant of land, and thus setting in motion the statute of limitations. In this way, after the lapse of a certain number of years (say twenty-one), a party would gain a title by force of his uninterrupted possession and claim of ownership. For an instance of this, see *McGregor* vs. *Comstock*, 17 New York Reports, 162. The mode of conveyance now in use is by deed. See DEED. GEORGE CHASE.

Fe'ræ Natu'ræ [Lat., of a wild nature]: a legal term applied to such animals as are naturally of a wild disposition, as bears, foxes, deer, pigeons, wild geese, etc. The separation of such animals as a class from those which are domestic is of importance in law, on account of the difference in the right of property which an owner is held to have in the two instances. Property in domestic animals is absolute, or indefeasible, while in animals *feræ naturæ* it is only qualified—i. e. the right of property continues to exist only as long as the animals are reclaimed from their savage or wild condition, and ceases when they return to it. When animals are of such a kind that if once restored to their freedom they would never return of themselves to their owner, his ownership of them can continue only so long as he keeps them confined. Wild beasts in a menagerie would be of this character. But if animals naturally wild have become so tamed that if suffered to escape or roam at large they have a habit or disposition of returning (*animum revertendi*), a qualified property in them continues so long as this habit is found to have a controlling influence. But if they stray and remain absent it is lawful for any stranger to take them as his own property. Pigeons, bees, deer are familiar examples of this kind of wild animals. A property in bees is obtained by hiving them. But if they swarm and fly away, the owner retains his property as long as he keeps them in sight while pursuing them, so that he may distinguish them as from his own hive. A qualified property may also exist in certain cases by reason of the inability of the animals to depart from a person's property, as in the case of the young of wild birds who have built their nest in trees. While a qualified property continues, the owner's right is as much under legal protection as is his interest in property of any kind, and any interference with it is punished in the same manner. The owner of such animals will in some instances be liable for their acts. A distinction is to be taken between animals that are and are not naturally inclined to do mischief. In cases of the first class the owner is not in general responsible for injuries done by his animals unless he is shown to have special knowledge of some vicious propensity. This knowledge is technically called *scienter*, and must be alleged in an action and proved. This proof would not be necessary if the animals were trespassing on the land of another. The owner in that case is liable for acts done in the course of the trespass. When the animal belongs to the second class, and is naturally inclined to do mischief, no proof of knowledge is requisite, as the owner is presumed to have knowledge of its vicious propensities.

In regard to the right in wild animals killed upon any person's property, certain peculiar rules have been established. If such animals, while upon or flying over a person's land, are killed either by himself or by a trespasser, they become the land-owner's property. If he starts animals upon his own grounds, follows them into another's, and there kills them, the property remains in himself. If a trespasser chases game from one man's land into another's, and there kills it, he has a claim superior to that of the owner of either of the contiguous estates. This last rule has, however, been questioned. A number of statutes in regard to the preservation of game and the protection of wild animals of various kinds have been passed both in Great Britain and in the U. S.

GEORGE CHASE.

Fer de Lance, fār'de-läañs' [Fr., liter., lance-iron, lance-head]: a venomous serpent (*Craspedocephalus lanceolatus*) of the West Indies. It is so named in allusion to the peculiar markings on its head. This much-dreaded serpent is extremely prolific, and is from 5 to 8 feet long. It gives no warning of its attack. The bite is very often fatal, and when its present effects are warded off by stimulants it usually ruins the health of the sufferer, who is for years afflicted with boils and ulcers, and often with paralysis and other distressing symptoms. It is dreaded by all animals, and the horse can not by the spur or the whip be forced to pass within striking distance of this formidable reptile.

Fer de lance.

Ferdinand the Just: King of Aragon; was co-regent of Castile and Leon near the close of Dec., 1406; became king in June, 1412, and in 1413 defeated and imprisoned the Count of Urgel. D. 1416.

Ferdinand I.: Emperor of Austria; eldest son of Francis I., Emperor of Germany; b. Apr. 19, 1793; married Maria Anna Carolina Pia, daughter of Victor Emmanuel I., King of Sardinia, in 1831. He took the throne Mar. 2, 1835, but was under the direction of Prince Metternich, his Prime

Minister. On Dec. 2, 1848, he abdicated in favor of Francis Joseph, after having repeatedly fled from Vienna during the revolutionary agitations of that year. D. at Prague, June 29, 1875.

Ferdinand I.: King of Bohemia and Hungary and Emperor of the Romans; b. at Alcalá, Spain, Mar. 10, 1503; married Anne Jagellon May 5, 1521, and was made King of Bohemia Feb. 24, 1527, of Hungary, Oct. 28, 1527, and of the Romans in Jan., 1531. He took the title of emperor when his brother, Charles V., abdicated, near the end of Sept., 1556, and was recognized as emperor by the electors at Frankfort in 1558, but was forbidden to take the title by Pope Paul IV. In 1562 he sent ambassadors to the Council of Trent. D. at Vienna, July 25, 1564.

Ferdinand II.: King of Bohemia and Hungary and Emperor of the Romans; b. July 9, 1578; crowned King of Bohemia July 29, 1617. He failed to protect his Protestant subjects against the persecutions of the Roman Catholics, and the Bohemian states deposed him Aug. 19, 1619, and offered the crown to Frederick, elector-palatine. This brought on the THIRTY YEARS' WAR (*q. v.*). Ferdinand had been crowned King of Hungary at Presburg July 1, 1618, and was elected Roman emperor Aug. 28, 1619. Frederick, having accepted the Bohemian crown, was defeated by Ferdinand's army, under Maximilian of Bavaria, at Prague, Nov. 8, 1620, and in 1623 the Bavarian duke received the Palatinate. In 1625 the imperial generals Wallenstein and Tilly defeated the armies of another Protestant league against Ferdinand, with the King of Denmark at its head. In Dec., 1625, and Nov., 1627, respectively, Ferdinand resigned the crowns of Hungary and Bohemia to his son, Ferdinand III. In 1630–32 Gustavus Adolphus of Sweden, with France and Venice in a new league against the emperor, invaded Germany, and gained important successes over Ferdinand, although at the battle of Lützen in Nov., 1632, the Swedish monarch was slain. The battle of Leipzig was fought in Sept., 1631, that of the Lech in Apr., 1632. Chancellor Oxenstiern directing the league after the death of Gustavus Adolphus, Ferdinand was more fortunate, made peace with some of the allies, and procured the election of his son Ferdinand as King of the Romans. D. at Vienna, Feb. 15, 1637.

Ferdinand III.: King of Bohemia and Hungary and Emperor of the Romans; b. in July, 1608, and became King of Hungary and Bohemia 1625 and 1627, respectively. In 1631 he married Mary Anne of Spain, who died in 1646. He gained the battle of Nördlingen in the contest of his father (Ferdinand II.) against the Swedes and their allies Sept. 6, 1634, and was made King of the Romans in 1636, and became emperor in 1637. The Thirty Years' war continuing, the battles of Thionville, of Fribourg, and of Sommershausen were fought in June, 1639, in 1644, and in 1648. In this latter year Ferdinand married Maria Leopoldina, who died in 1649. In 1648 he also signed the peace of Westphalia, guaranteeing religious liberty to his Protestant subjects. In 1651 he married Eleanor of Mantua. D. at Vienna, Apr. 2, 1657.

Ferdinand I. (THE GREAT): King of Castile and Leon; married Doña Sancha of Leon, and was named King of Castile in 1033, succeeding to the throne in 1035, and being crowned King of Leon June 22, 1038. He invaded Portugal, and acquired Coimbra in 1044 and 1045. In 1046–49 he warred against the Moors. In Sept., 1054, he defeated Garcia III., King of Navarre, near Burgos; in 1063 conquered Mohammed ben Abad, dividing his kingdom between his three sons in 1064. Forced the Kings of Saragossa and Toledo to become his tributaries in 1065, and died at Leon, Dec. 27 of that year.

Ferdinand III. (THE SAINT): King of Castile and Leon; b. 1199; son of Alfonso IX., King of Leon, and Berengaria, Queen of Castile, succeeding in Castile, on his mother's abdication, in 1217, and in Leon in 1230. In his Moorish wars he conquered the kingdom of Baeza, took Cordova and Seville, and made the Kings of Granada and Murcia his tributaries. D. May 31, 1252, and was canonized by Pope Clement X. in 1671.

Ferdinand V. (THE CATHOLIC): King of Castile and Aragon; b. at Sos, Spain, Mar. 10, 1452; married Isabella of Castile Oct. 18, 1469. At this time Spain was divided into the kingdoms of Castile, Aragon, Navarre, and Granada, the last held by the Moors. On the death of Isabella's brother, Henry IV., Ferdinand was proclaimed king, with her as queen, at Segovia, Dec. 13, 1474. Isabella's title being disputed by the Princess Joanna, Henry IV.'s acknowledged daughter, Ferdinand defeated Alfonso, King of Portugal, who supported her claims, at Toro in 1476. In 1479 Isabella secured undisputed possession of the kingdom by a peace with France, signed Nov. 9, 1478. In Jan., 1479, Ferdinand succeeded his father, John II., in Aragon; and immediately afterward in both kingdoms, but especially in Castile, the two sovereigns commenced salutary reforms in the administration of justice, restraining the excesses of the nobility, and checking their power as feudal lords. In 1480 Ferdinand established the Inquisition at Seville, and subsequently permitted its establishment in Aragon. He began his wars with the Moors for the possession of Granada in 1482, the Moors having in 1481 captured the fortress of Zahara in Andalusia, and on Jan. 6, 1492, with Isabella his queen, he entered Granada in triumph. The same year he issued an edict for the expulsion of all Jews from his dominions. This year also Isabella furnished to Christopher Columbus two vessels in his fleet of three, with which he discovered San Salvador. Columbus returned in Mar., 1493, and during that year Ferdinand and Isabella obtained a bull from Pope Alexander VII. confirming their title to all the territories which they should discover in the western hemisphere. In 1493 Ferdinand reacquired Roussillon and Cerdagne from Charles VIII. of France, and in 1495 opposed Charles in Italy, the Spanish troops being commanded by Gonsalvo de Cordova. In 1497 he promoted the expedition of Amerigo Vespucci. By 1500 the Spanish conquest of Naples was complete; by 1501 every Moor had been expelled from the kingdom or was compelled to be baptized. Isabella died in 1504, and in 1505 Ferdinand married Germanie de Foix, niece of Louis XII. of France. On the death of Philip, his son-in-law, he became regent of Castile in Sept., 1506. By the treaty of Cambray (Dec., 1508) he received several Venetian cities, which were incorporated with the kingdom of Naples. In Oct., 1511, he joined the Holy League against France, and Jean d'Albret, King of Navarre, having leagued himself with the French monarch, Ferdinand invaded his dominions, drove him from the throne, and in 1512 subjugated that kingdom, thus finally uniting Aragon, Castile, Granada, and Navarre under one sway. Ferdinand died Jan. 23, 1516.

Ferdinand I.: King of Naples; b. in 1423; married Isabella de Clermont in 1445; was legitimized by Pope Eugene IV., and crowned king in 1458. In a short time his subjects invited John of Anjou to take the throne, and having done so, John sustained himself for a time, but Ferdinand defeated him at Troia in Aug., 1462, and became master of the kingdom in 1463. Isabella having died in 1475, he married Joanna of Aragon in the following year. In 1486 the barons of Naples revolted. Ferdinand having made peace with them on Aug. 11, treacherously arrested and massacred them at the palace on Aug. 13. For this he was excommunicated by Pope Innocent VIII. in 1489; he made peace with the pope in May, 1492. D. Jan. 25, 1494.

Ferdinand IV.: King of Naples, and **I.** of the Two Sicilies; was b. at Naples, Jan. 12, 1751, and succeeded to the throne when his father, Don Carlos, became King of Spain Oct. 5, 1759. In 1767 he expelled the Jesuits; in 1768 married Maria Carolina of Austria. In 1777 he dismissed his Prime Minister, Tanucci; in 1793 joined the coalition against France, but in 1796 purchased peace from the Directory. In Nov., 1798, a secret alliance having been formed with Russia, Austria, and England against France, the Neapolitan army marched to Rome, but was defeated by the French, who took possession of Naples, and established the Parthenopean Republic 1799. The king and queen fled to Sicily, but during the same year were restored to power by the successes of the allies, and then took a bloody revenge on the republican citizens of Naples. Mar. 18, 1801, by the treaty of Florence, Ferdinand made peace with France, but in 1805 joined a third coalition against her. In the end of that year he was deprived of Naples by Napoleon I., and retired to Sicily under English protection. In Jan., 1812, he resigned his authority in favor of his son Francis, but on Napoleon's fall he was restored, entering the capital Aug. 14, 1815. In Dec., 1816, he took the title of King of the Two Sicilies (Naples and Sicily), but in the latter part of his reign (1820–21) was threatened with a fresh revolt of his subjects. He annulled their constitution, and entered Naples, supported by the Austrian army, May 15, 1821. D. Jan. 4, 1825.

Ferdinand I.: King of Portugal; b. at Coimbra in 1345; succeeded to the throne in 1367. In 1369 he claimed Castile, but was opposed by Henry II. of that kingdom, and after an indecisive war made peace in 1371. The war being renewed, a like issue ensued in 1373. He again warred with Castile, assisted by Edmund, Duke of Cambridge, in 1381. D. Oct. 20, 1383.

Ferdinand VII.: King of Spain; b. at St. Ildefonso, Oct. 14, 1784, and was proclaimed Prince of Asturias and heir to the crown in 1790; in 1802 he married Maria Antoinetta Theresa of Naples, who d. May 21, 1806. On the abdication of his father (Mar. 19, 1808) he succeeded to the kingdom, but was compelled by Napoleon to give up his claims May 6, 1808, and sent with his brother and uncle to the château of Valençay. On being liberated he returned to Spain Mar., 1814, and in May annulled the Spanish constitution and dissolved the Cortes; Sept. 29, 1816, he married Isabella Maria, Infanta of Portugal, who d. Dec. 26, 1818; Oct. 2, 1819, married Maria Josephine of Saxony. The French having invaded Spain under the Duke of Angoulême in Apr., 1823, Ferdinand was held a prisoner by the revolutionists, but the success of the French caused his restoration, which he celebrated by an amnesty and false promises of good government. He married the daughter of Maximilian of Saxony in 1824, and she died in 1829. The same year he married Maria Christina of Naples. Mar. 29, 1830, he reestablished the Pragmatic Sanction of 1789. D. Sept. 29, 1833.

Ferdinand II.: of the Two Sicilies; known as KING BOMBA; b. Jan. 12, 1810; succeeded his father, Francis I., in 1830; by false promises and liberal measures at first excited great hopes among the friends of liberty, which his subsequent course cruelly disappointed. The history of his reign is a catalogue of conspiracies, rebellions, executions. His reckless bombardment of Messina Sept. 2–7, 1848, won him his shameful title. D. at Naples, May 22, 1859.

Ferdinand, PRINCE of BULGARIA: b. Feb. 26, 1861; youngest son of Prince Augustus of Saxe-Coburg and Princess Clémentin, daughter of King Louis Philippe; served as lieutenant in the Austrian army until 1886; accepted the throne of Bulgaria in 1887, but was not recognized by the great powers until Mar., 1896.

Ferghana: See the Appendix.

Fergus: town; Wellington co., Ontario; on the Grand river; 10 miles N. of Guelph, and on Ellora Branch of the Canadian Pacific and the Wellington, Gray and Bruce Branch of the Grand Trunk R. Rs. (see map of Ontario, ref. 4–C). It contains mills, distilleries, manufactories, and an iron-foundry. Pop. 1,600.

Fergus Falls: city and railway center (founded in 1870); capital of Otter Tail co., Minn. (for location, see map of Minnesota, ref. 6–B); on the Red River of the North, and on the Great Northern and N. Pac. R. Rs.; 187 miles N. W. of St. Paul. It is situated in a rich agricultural country in the center of the famous "Park" or Lake region, and has 14 churches, 4 school buildings, a State high school, the Norwegian Lutheran College, fine water-power, and manufactures of flour, paper, etc. Pop. (1880) 1,635; (1890) 3,772; (1900) 6,072.
EDITOR OF "JOURNAL."

Ferguson, ADAM, LL. D.: an historian and philosopher who occupies a place of his own in the history of Scotch philosophy by his application to morals of the principles of perfection. He was born at Logierait, Perthshire, Scotland, June 20, 1723; studied at St. Andrews; read divinity in Edinburgh; was ordained in 1745; became Gaelic chaplain in the Forty-second Regiment; succeeded David Hume as keeper of the Advocates' Library in Edinburgh; was Professor of Natural Philosophy at Edinburgh 1759–64; Professor of Moral Philosophy 1764–85; was one of the commissioners sent in 1778 to the U. S. to effect a peace. Author of a *History of Civil Society* (1767); *History of the Progress and Termination of the Roman Republic* (1783); *Institutes of Moral Philosophy* (1769); *Moral and Political Science* (1792). D. at St. Andrews, Feb. 22, 1816. See *Life* by Small (1864).

Ferguson, JAMES, F. R. S.: astronomer and mechanician; b. near Rothiemay, Banffshire, Scotland, Apr. 25, 1710. His mechanical genius was developed at a very early age by investigation into the wheel and axle and the construction of a wooden clock and watch which were good timekeepers. He spent several years in Edinburgh, and in 1743 went to London, supporting himself in both places by drawing portraits. In 1747 he published a *Dissertation on the Phenomena of the Harvest Moon*, and in 1748 commenced lecturing upon astronomy and mechanics. Elected a fellow of the Royal Society in 1763, he was chosen a member of the American Philosophical Society in 1770. *Astronomy Explained* (1756) and *Lectures on Subjects in Mechanics, Hydrostatics, Pneumatics, and Optics* (1760), were among his *Works*, which were edited in 5 vols. 8vo by Sir David Brewster. The *Encyclopædia Britannica* is authority for the assertion that "in his whole life he had not received above half a year's instruction at school." D. in London, Nov. 16, 1776. See the *Life* by Henderson (1867; 2d ed. 1870).

Ferguson, JAMES: astronomer; b. in Perthshire, Scotland, Aug. 31, 1797; removed to New York Sept., 1800, and was assistant civil engineer on the Erie Canal 1817–19; assistant surveyor on the boundary commission under the treaty of Ghent 1819–22; astronomical surveyor on the same commission 1822–27; civil engineer for the State of Pennsylvania 1827–32; first assistant of the U. S. Coast Survey 1833–47; and assistant astronomer of the U. S. Naval Observatory 1847–67. He discovered during this latter service the following asteroids: Euphrosyne in Sept., 1854; Virginia in 1857; Echo in 1860, for which he was awarded the astronomical prize medal by the Academy of Sciences of France in 1854, and again, by the same institution, in 1860. Prof. Ferguson was a valued contributor to Dr. Gould's *Astronomical Journal* and to the *Astronomische Nachrichten*; also to the Episcopal *Church Review*, to the Albany *Argus*, the *Merchants' Magazine* of New York, and to other standard papers. D. Sept. 26, 1867.

Fergusson, JAMES, LL. D., D. C. L., F. R. S.: writer on architecture; b. at Ayr, Scotland, in 1808; became an indigo-planter in Bengal; journeyed in the East, and published *Illustrations of the Rock-cut Temples of India* (1845); *Picturesque Illustrations of Ancient Architecture in Hindostan* (1847); *Essay on a Proposed New System of Fortification by Earthworks* (1849); *The Palaces of Nineveh and Persepolis Restored* (1851); *History of the Modern Styles of Architecture* (1862); *Temples of the Jews and the Other Buildings in the Haram Area at Jerusalem* (1878). His *History of Architecture* (2 vols., 1865–76); *History of Modern Architecture* (i. e. since the beginning of the Renaissance), 2 vols.; and *History of Indian and Eastern Architecture* form together the most important work of the kind in English. On Apr. 17, 1871, he received the royal gold medal at a meeting of the Royal Institute of British Architects. D. Jan. 9, 1886.

Fergusson, ROBERT: poet; b. at Edinburgh, Scotland, Sept. 5, 1750; educated at St. Andrews University; took up medicine as a profession, but soon wearied of it and entered the office of the commissary clerk at Edinburgh. Much of his spare time was spent in writing verses in dialect, which were printed in a local magazine and were greatly admired. His health became impaired by dissipation, insanity resulted, and he died from the effects of a fall Oct. 16, 1774. His poems were collected in 1773, and several editions have been printed, the latest being that of Groshart (1851). Robert Burns had a profound admiration for Fergusson's talent, and imitated him to some extent, especially in the subjects of his poems. In 1789 he erected a memorial stone over Fergusson's grave.

Fergusson, Sir WILLIAM, Bart., F. R. S., F. R. S. E.: surgeon; b. at Prestonpans, East Lothian, Scotland, Mar. 20, 1808; studied under Dr. Knox and Dr. Turner in the Royal College of Surgeons at Edinburgh at the age of eighteen; and became a licentiate of that institution in 1828, a fellow of the corporation in 1829, and began to lecture on the principles and practice of surgery in 1831. In 1836 he was assistant surgeon to the Royal Infirmary, and in 1839 a fellow of the Royal Society of Edinburgh. He settled in London in 1840, having been appointed Professor of Surgery in King's College and surgeon to King's College Hospital; became Professor of Clinical Surgery in King's College, having also been elected president of the Royal College of Surgeons of England July 4, 1870, and having been for some time Professor of Surgery and Human Anatomy in that institution. These are but a few of the active and honorary positions to which he was called. His *Progress of Anatomy and Surgery in the Nineteenth Century* (1867) was the substance of two courses of his lectures. His *System of Practical Surgery* has passed through several editions; he was the inventor of numerous surgical instruments, and in 1866 was made a baronet. D. in London, England, Feb. 10, 1877. See H. Smith, *Sir W. Fergusson, a Biographical Sketch* (London, 1877).

Fe′riæ [Lat., holidays, plur. of *fe′ria*, for older **fe′sia*. See FAIR and FEAST]: in ancient Rome, those holidays whereon business could not lawfully be done and when slaves might rest from their labors. These public festivals were of many kinds and were very numerous. Marcus Antoninus fixed them at 135 in the year, though before his time they had been much more frequent. The way in which they were kept varied extremely, but in general their celebration resembled that of the Christian Sabbath, there being a religious element in their observation.

A feria in the Ordo of the Roman Catholic Church is a week-day having no feast. The feriæ of Ash Wednesday, Holy Week, Whitsun Eve, and the Octaves of Easter and Whitsuntide have the offices of Sundays of the first class. The feriæ of Advent, of Lent, the Ember Days, and the Monday of Rogation Week are called greater feriæ.

Revised by J. J. KEANE.

Ferish′tah, or **Firishta**, MOHAMMED KASIM HINDU SHAH: Persian historian; b. at Astrâbâd, 1550 or 1570; wrote the *Tarîkh-i-Firishta*, a history of the Mohammedan power in India, commencing about the close of the tenth century. In the introduction he gives an account of Indian history prior to the invasion of the Mussulmans. His history was translated by A. Dow (2 vols., 1768) and by Gen. Briggs (4 vols. 8vo, London, 1832). D. about 1612.

Ferland, făr′laañ′, JEAN BAPTISTE ANTOINE, l'Abbé: author; b. at Montreal, Canada, Dec. 25, 1805; admitted to orders in the Roman Catholic Church in 1823. He was priest and professor in Canada for several years, then superior of the College of Nicollet in 1847, afterward professor at Laval University June 10, 1855. *Observations on the History of Canada* was published in 1851; then *Notes on the Registers of Notre Dame de Quebec, A Voyage to Labrador, Courses of History of Canada from 1534 to 1633, Journal of a Voyage to the Coast of Gaspé*, and *Life of Bishop Plessis*, the last in 1863. D. at Quebec, Jan. 8, 1864.

Fermanagh, fer-măn′a: inland county of the province of Ulster, Ireland; area, 714 sq. miles. Its surface varies from the richest vales to the wildest uplands. Its rocks are mountain limestone, with many huge cavities and underground watercourses, millstone grit, and old red sandstone, with some coal, iron, and marble. In the low grounds the soil is a deep and rich loam, which grows thin and cold in the uplands. Fermanagh returns two members to Parliament. Pop. (1891) 74,037. Capital, Enniskillen.

Fermat, făr′maa′, PIERRE, de: mathematician; b. at Beaumont de Lomagne, near Montauban, France, in 1601. French savants claim for him a great part of the honor of the discovery of the differential calculus. He made important discoveries in the theory of numbers, and invented a theory of finding maxima and minima. Laplace thought Fermat ought to share with Pascal in the fame of the invention of the calculus of probabilities. His *Works* (*varia opera*) were published by his son in 1670–79. He was a councilor of the Parliament of Toulouse, and cultivated mathematics as a recreation, and is known as the first to propose two celebrated theorems called by his name. D. at Toulouse, Jan. 12, 1665.

Fermentation [Fr. *fermentation*, deriv. of *fermenter*, ferment < Lat. *fermenta′re*, deriv. of *fermen′tum*, yeast]: an obscure and seemingly spontaneous change or decomposition which takes place in most vegetable and animal substances when exposed at ordinary temperatures to air and moisture. When the process is accompanied by the liberation of fœtid gases, as in the decomposition of urine, blood, or flesh, it is termed *putrefaction*. When it occurs with free access of air, and without excess of water, it is termed *decay* or *eremacausis*, as when a fallen tree moulders into brown pulverulent humus. The term *fermentation* is limited in common language to the process as conducted for the production of inoffensive and useful products, as when grape-juice and malt-wort are fermented into wine and beer. While these processes differ widely in their products, they are all similar in their general character. The substances most liable to undergo putrefaction are compounds rich in nitrogen, such as albumen, fibrin, casein, gluten, gelatin, etc. These bodies require only the presence of water, and access of ordinary unfiltered air for a short time, to bring them into a state of putrefactive fermentation, which is very offensive, owing to the liberation of sulphuretted hydrogen, ammonia, and a variety of volatile bodies, whose exact nature has not been definitely determined. These bodies which thus appear to ferment spontaneously are composed of carbon, hydrogen, nitrogen, oxygen, and sulphur. Many non-nitrogenous substances, consisting of carbon, hydrogen, and oxygen only, which are incapable of fermenting or putrefying spontaneously, readily undergo this change when brought in contact with albuminous or gelatinous compounds, either in a fresh state or in a condition of incipient putrefaction. These latter bodies, which are capable of exciting fermentation, are called *ferments*, and bodies which are made to ferment by them are said to be *fermentable*. One of the most active of all ferments is yeast, a plant which develops in liquids undergoing vinous or alcoholic fermentation. Bodies composed wholly of carbon and hydrogen do not appear to be capable of undergoing fermentation under any circumstances. Bodies may be brought into different states of fermentation by the same ferment, according to the particular stage of decomposition which it may have attained. Thus in the raising of bread by the aid of leaven, vinous fermentation may occur, with the production of alcohol and carbon-dioxide gas (CO_2), which makes the bread light and porous, or lactous fermentation may occur, with the formation of lactic acid, which makes the bread sour and heavy. It is probable, however, that the ultimate cause in the two cases, though apparently the same, is really different. Temperature influences both the development and the character of fermentation. It can not occur at a temperature much below 40° F., nor much above 140°.

Fermentation is generally indicated by a sensible internal motion, the development of heat, and the liberation of bubbles of gas, and when it occurs in a clear liquid always results in turbidity and the formation of a scum and a sediment. During the process complex organic bodies are resolved into simpler organic bodies, as when milk-sugar is changed to lactic acid; or into simpler organic bodies and inorganic compounds, as when glucose is changed to alcohol and carbon-dioxide; or the decomposition may result in the liberation of elementary bodies, as hydrogen and nitrogen. The elements of water are often assimilated during fermentation, and enter into the composition of the new bodies. The process is always complex, and while it often results in the formation of some well-characterized predominating product, as alcohol, acetic acid, lactic acid, butyric acid, etc., there is always produced a variety of bodies in smaller quantities the exact nature of which has not been fully determined, although many of these secondary bodies have been identified. Fermenting substances generally have a tendency to abstract oxygen from the air and other bodies. When fermentation occurs with free access of air it is accompanied by oxidation (*eremacausis*) on the surface. Putrefying bodies reduce ferrous sulphate to sulphide of iron by withdrawing oxygen, and sewage is able likewise to reduce nitrates to free ammonia.

Fermentation has long been resorted to in raising bread with leaven or yeast, in preparing alcoholic beverages, and in preparing certain vegetables, as sour beans and *Sauerkraut*. It is the process, too, by which all vegetable and animal substances ultimately undergo destruction, and finally return to the inorganic world in the form of carbon dioxide (CO_2), water (H_2O), ammonia (NH_3), nitrogen (N), etc., to become again the food of plants, and under the influence of the solar rays again to generate complex organic bodies. It is the process by which milk and vegetables sour, meats putrefy, and fats become rancid, and by which timber and textile fabrics decay. It is, moreover, intimately associated with the development of contagious diseases, and its study leads to the discovery of methods for preserving food and timber and for preventing the occurrence and spread of many diseases.

There is an endless variety of processes to which the term fermentation may be applied with more or less propriety; the following are a few of the most important: (1) Vinous, alcoholic, or panary fermentation; (2) acetous; (3) lactous; (4) butyrous; (5) mucous or viscous; (6) putrefaetive; (7) saccharous; (8) glucosic; (9) pectous; (10) gallous; (11) amygdalous; (12) sinapous; (13) urinous; and (14) peptous.

I. *Vinous or alcoholic fermentation* is the process by which grape-juice is converted into wine and the wort of malt into beer. A solution of pure sugar in water may remain unaltered for a long time, but finally mould appears upon it, and it becomes sour and dark-colored. If, however, a suitable ferment is added to it, such as yeast, putrid blood, or partially decomposed flour-paste, albumen, casein, fibrin, or any similar body, it rapidly passes into a state of active fermentation, by which the sugar is converted into alcohol, carbon dioxide, etc. What has really happened here is that the so-called ferment contains not only the true ferment, but also certain nitrogenous and mineral substances, which, added to the sugar, facilitate decomposition. The sweet juices of plants contain, in addition to sugar, small quantities of albumen, gluten, and legumen, and when they are exposed to unfiltered air and maintained at a temperature of about 80° F., they appear to undergo fermentation spontaneously, the process continuing from forty-eight hours to several weeks, according to the temperature, the amount of sugar present, and the nature and quantity of the nitrogenous bodies which act as ferments. The most striking phenomena of this fermentation are—(1) the liquid becomes turbid; (2) bubbles of gas rise to the surface; (3) the temperature rises; (4) the sugar disappears; (5) alcohol makes its appearance; (6) by and by the liquid becomes clear and quiet again, and a light scum and a light-colored deposit are formed. This deposit consists of yeast, which is capable of exciting vinous fermentation in other solutions of sugar. The conditions essential to vinous fermentation are—(1) an aqueous solution of sugar, which may be either glucose, cane-sugar, or milk-sugar. The two latter are, however, invariably changed to glucose before they undergo vinous fermentation (see *Saccharous Fermentation*, page 329).

$$\underset{\text{Cane-sugar.}}{C_{12}H_{22}O_{11}} + \underset{\text{Water.}}{H_2O} = \underset{\text{Glucose.}}{2C_6H_{12}O_6}.$$

(2) The presence of yeast or of some similar nitrogenous ferment; (3) access of air, at least at the outset; (4) a certain temperature, the limits of which are 41° and 86° F. The lower the temperature the slower the process, while at the temperature of 86° the vinous fermentation is liable to pass into butyrous fermentation by the greater activity of the butyrous ferment. The chief products of the fermentation are alcohol and carbon dioxide, which might be produced from the glucose by the following decomposition:

$$\underset{\text{Glucose.}}{C_6H_{12}O_6} = \underset{\text{Alcohol.}}{2C_2H_6O} + \underset{\text{Carbon dioxide.}}{2CO_2}.$$

Were these the only products, 100 parts of glucose would yield 51·11 of alcohol and 48·89 of carbon dioxide; but as a fact only about 95 per cent. of the sugar is accounted for by these products. Most of the missing 5 per cent. is converted into succinic acid (discovered by C. Schmidt in 1847) and glycerin (discovered by Pasteur), so that the real equation of decomposition must be far more complex. In addition to these bodies, there is a host of others in minute quantities, derived partly from the glucose, partly from the ferment, and partly from the other bodies always present in vegetable solutions. The following scheme gives approximately the products from 100 parts of glucose:

Alcohol	48·5 per cent.
Carbon dioxide	46·5 "
Glycerin	3·6 "
Succinic acid	0·7 "
Acetic acid; Cellulose; Fatty substances; Hydrogen; Nitrogen; Hydrocarbon (methane ?); Propylic alcohol*; Butylic alcohol*; Amylic alcohol*; Acetate, butyrate, valerianate, and œnanthate of ethyl, amyl, etc.*	0·7 "
Total	100·0 per cent.

The last-mentioned bodies, indicated by a *, constitute, when separated by distillation, what is called the *fusel oil*.

The infusion of malt and sugar solutions to which gluten, casein, albumen, or substances of like nature are added, does not generally undergo a purely vinous fermentation; lactous, butyrous, acetous, and putrefactive fermentation also occur, and offensive products result. This can be prevented by the addition at the outset of a proper quantity of yeast, which at once determines the vinous fermentation; and if a temperature below 86° F. is maintained, and the air is properly excluded, the products of this kind of fermentation alone ordinarily result. Sometimes, however, the other (non-alcoholic) fermentations prevail to such an extent as to do damage, and thus arise the so-called "diseases" of wine and beer. (See beyond.) In the making of wine and the brewing of beer the complete destruction of the sugar is not desirable, and rarely, if ever, occurs, but in the manufacture of spirits the change to alcohol is made as complete as possible. (See WINE and BEER.) When vinous fermentation is resorted to in making bread, the object is not to produce alcohol, but carbon dioxide, which shall make the bread light. Many substitutes for fermentation are in use by which the carbon dioxide is produced without the alcohol. See BREAD.

Theories of Fermentation.—The discovery of fermentation and the preparation of wine date back beyond historic times. According to the Egyptians, Osiris, and according to the Greeks, Bacchus, taught the art to men. The Israelites attribute the discovery to Noah. The alchemists often employed the terms *fermentation* and *putrefaction*, but in a sense quite different from that in which the words are now used; the gradual solution of an inorganic body was called putrefaction, while fermentation was used as equivalent to our word *digestion*—i. e. the digestion of a mineral with an acid. The term *ferment* was applied to every active chemical agent. Valentine supposed the alcohol to pre-exist in the wort, and to be simply set free during fermentation. Libavius believed fermentation and putrefaction to be similar processes, differing merely in their products. Van Helmont (1648) attributed to fermentation the formation of gases during digestion, also the formation of the blood and of the sap. He considered fermentation to be the cause of the formation of living organisms, and of their reproduction and development. Mayow (1669) noticed the importance of air to fermentation. Sylvius de le Boë (1659) claimed that fermentation differed entirely from the action of acids upon alkalies (carbonates). He says the latter results in combination, while fermentation results in decomposition. Lemery (1775) recognized a similar distinction. Becher (1669) considered fermentation as similar to combustion (separation of phlogiston from calx) and as resulting in a splitting up of the fermenting body. Willis (1659) and Stahl (1697) considered fermentation and putrefaction similar processes, and attributed them to the action of a ferment—a body possessed of internal motion, which motion it communicated to the fermentable bodies.

The modern theories of fermentation have been developed as knowledge of the conditions and products of the process has become more accurate. The production of alcohol attracted attention very many centuries ago. Van Helmont (1648) noticed the gas liberated during vinous fermentation, and called it "gas vinosum," to distinguish it from "gas carbonum," produced by coal. He recognized the fact that during fermentation something disappears or evaporates (sugar), which could otherwise be changed to coal (charcoal). He says *fermentum volatilisat quod alias in carbonem mutatur*. McBride (1764) showed that fermentation and putrefaction yielded the gas called "fixed air" by Black, and Cavendish (1776) showed that sugar yielded 57 per cent. (correctly 48·89) of the same gas which is obtained from marble. After the discovery of oxygen, hydrogen, and nitrogen, of the composition of water and of the atmosphere, and the elementary composition of vegetable and animal bodies, and the recognition of the true character of combustion, Lavoisier (1789), in his *Traité élémentaire de Chimie*, exhibited the quantitative relations of cane-sugar to its products on fermentation. He assumed that sugar, an oxide, was split into two products, the gas and the alcohol, which, if they could reunite, would regenerate the sugar. Berthollet (1803) believed that the alcohol had no isolated existence in the wine, but that, excluding the argol and the acids, the wine was a homogeneous body, in which alcohol was produced by heat. Brande (1811) and Gay-Lussac (1813) proved the pre-existence of alcohol in wine. The further investigation of the nitrogenous ferments, and finally the study of the yeast-plant, have given us the following definite theories of fermentation: (1) *acid theory*; (2) *contact theory*; (3) *influence theory*; (4) *chemical theory*; (5) *galvanic theory*; (6) *germ theory*.

1. *The Acid Theory.*—Pliny considered the action of leaven in raising bread to be due to an acid. Fabroni, in his prize essay on fermentation, published at Florence in 1787, claims that fermentation depends on the action of a vegetable acid on sugar. He afterward advanced the theory that the ferment is a vegeto-animal body, like gluten, and that the products result both from the sugar and from the ferment—the carbon of the ferment and oxygen of the sugar forming the carbonic acid, while the deoxidized sugar forms alcohol with the hydrogen and nitrogen of the ferment. The acid theory was long since disproved by the fact that fermentation occurs in the presence of calcic as well as of alkaline carbonates, and of metallic oxides.

2. *Contact Theory.*—Berzelius supposed that fermentation is due to the contact or *catalytic* action of the ferment, in

the same way that platinum sponge was supposed to effect the union of alcohol and the oxygen of the air, and sulphuric acid was formerly supposed to change alcohol to ethylic ether. As these reactions have already received more rational explanations, the idea of catalysis has been generally abandoned.

3. *Influence, Contagious, Mechanical, or Physical Theory.*—This theory originated with Stahl, and was re-established by Liebig in 1839, and was held by Pelouze, Frémy, Gerhardt, etc. It attributes fermentation to the mechanical action of certain nitrogenous matters (ferments), which are themselves in a state of decomposition, which is imparted to the sugar as soon as it comes in contact with the decomposing ferments under favorable circumstances. The more changeable body, by its own inherent instability, initiates molecular movements in a more permanent compound. The action is compared to several inorganic reactions, as the solution in nitric acid of platinum when alloyed with silver, platinum alone being insoluble; the decomposition of hypochlorous acid, chloride of nitrogen, peroxide of hydrogen; action of pyroracemic acid on argentic carbonate; the kindling of combustible bodies; crystallization from supersaturated solutions by rubbing the side of the vessel with a rod or introducing angular particles. The yeast-plant is supposed by the advocates of this theory to be only an incidental product of some varieties of fermentation, and to be active in inducing fermentation only in that it contains decomposing albuminous substances. The access of air is by them supposed to be necessary only to initiate by oxidation the activity of the ferment.

4. *The chemical theory* supposes a purely chemical action of the ferment or yeast on the sugar. It was founded by Trommsdorff and Meissner, but has at present few if any adherents.

5. *The galvanic theory* assumes that the decomposition is called forth by the dualism of the exciting body in a conducting fluid. Its adherents are Schweigger, Colin, and Kölle.

6. *The Germ, Vital, or Physiological Theory.*—This theory, which is the one which is generally accepted, attributes the decomposition of the fermentable body to the vital action of minute living organisms, the vegetable cells of the yeast-fungus. These plants are introduced in relatively small numbers from without either accidentally, as in the fermentation of wine and apple-juice, or intentionally, as in the process of brewing or bread-raising. They immediately begin to grow and to multiply at the expense of the nitrogenous substances present in the grape-juice, beer-wort, or other fermenting material, and involve the consumption and consequent destruction of the sugar, and the production of a variety of products of which in vinous fermentation, alcohol, carbon dioxide, glycerin, and succinic acid are, as already stated, the most abundant. "It is now fully established that (1) the growth and reproduction of the yeast-fungus takes place only in fermentable liquids; (2) that the saccharine liquid will only ferment when the yeast-plant [or some similar ferment] is present in a state of active development."—*Dalton.* This view is now so well established that any process which is proved to proceed without the development of living organisms must be excluded from the class of decompositions known as fermentation.

The Yeast-plant.—In 1680 Anthony Leeuwenhoeck, with his newly invented microscope, discovered the fact that yeast consisted of "little globules collected into groups of three or four together." Fabroni (1787), as already stated, considered the yeast to be a "vegeto-animal" body, like gluten. Fourcroy entertained the same idea. In 1803 Thénard stated that yeast contains a nitrogenous "animal" substance common to all ferments. Mulder (1844) endeavored to show that a peculiar nitrogenous body, which he called *protein*, was essentially characteristic of living matter, and was nearly allied in chemical composition to albumen, casein, fibrin, and gluten. Payen in 1846 recorded the opinion that all vegetable cells contain materials similar in composition to animal organisms; and in the same year von Mohl, a German botanist, invented for the active compound in living vegetable cells the term "protoplasm." The true relation of the yeast-cells to fermentation was recognized by Thénard in 1803. He then first enunciated the "germ theory," by assuming that the yeast assimilates a little of the sugar, while the rest breaks up into alcohol and carbon dioxide. The same idea was maintained by Erxlebens in 1818, and in 1825 Desmazières examined the yeast-cells of beer and of wine, and called them animals. These investigations attracted comparatively little attention, even after Cagniard de la Tour in 1837 rediscovered the yeast-plant, made some most important observations upon it, and "declared that by some effect of their vegetation the equilibrium of the sugar was destroyed." He measured the yeast-cells and found them to be about $\frac{1}{2500}$th of an inch in diameter; and he also noticed that by a process of budding they multiplied during fermentation, and increased six or seven fold. Schwann made similar observations in the same year; Kützing investigated the subject; and Turpin, in 1838, made an elaborate botanical study of beer-yeast, which he considered to belong to the genus *Torula*—a name still often applied to yeast. All of these writers considered yeast organisms to be alone capable of initiating fermentation. Mitscherlich adopted this view, and referred fermentation to vegetable organisms, and putrefaction to minute animals. Helmholtz, in 1843, made a remarkable confirmatory experiment: he placed a quantity of yeast on one side of a film of bladder, and a solution of sugar on the other, and although the liquids circulated freely through the membrane, the yeast could not pass, and fermentation took place only on the side of the yeast. Nevertheless, owing to the powerful influence of Liebig and to the contempt and ridicule with which he met all the evidence offered by these and other observers, the "influence" theory of Liebig was generally accepted, until through the most elaborate and conclusive investigations of Pasteur it was overthrown, and the germ theory or vitalistic theory was finally established. Pasteur says: "Albuminous bodies are never the ferments, but the aliment of the ferments"; "the true ferments are living organisms."

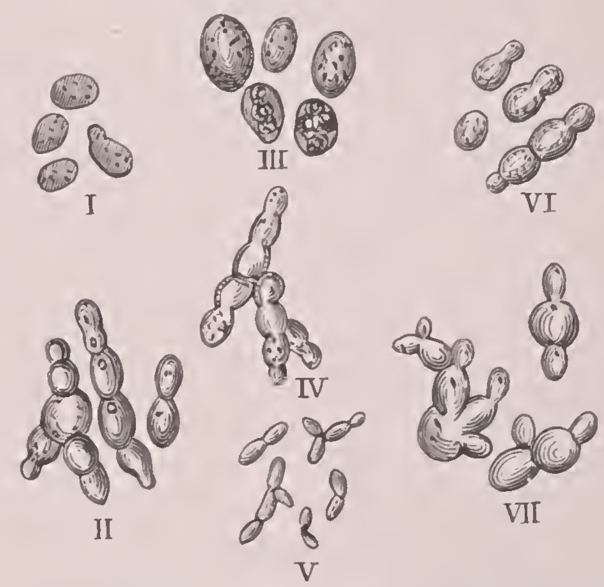


FIG. 1.—Beer-yeast, Reess: *Saccharomyces cerevisiæ.* I. Top yeast; III. Top yeast, developing ascospores; II., IV. Top yeast, fully developed; VI. Bottom yeast; VII. Bottom yeast, cultivated at 61° to 65° F. *Saccharomyces exiguus*; V. The yeast of the after-fermentation.

The study of this subject has expanded far beyond its original limits, and has involved the questions of spontaneous generation and the germ theory of disease, which are now engrossing the attention of the most acute observers on both sides of the Atlantic. This arose from the necessity of accounting for the presence of the living yeast-cells in fermenting and putrefying liquids, which decompose spontaneously without the addition of yeast. Appert, who studied early in the nineteenth century the preservation of vegetable and animal food, found that by boiling such perishable articles, and sealing them up so as to exclude the air, they could be preserved indefinitely. This was explained by many by supposing that the oxygen of the air, which is necessary to initiate decomposition, was excluded. It was long supposed that a large number of animals were produced spontaneously. Aristotle supposed that shellfish, sponges, maggots, worms, moths, eels, etc., were produced without parents, and the idea that putrefaction is peculiarly favorable to the production of life was entertained by him, repeated by Pliny four centuries later, by Fabricius in 1600, Harvey in 1650, and is now held by the advocates of spontaneous generation. In the year 1668, Francis Redi, an Italian, showed that maggots in meat were the progeny of flies. His experiments were important, as they demonstrated the fact that insects were produced from eggs. As investigations continued, the idea of spontaneous generation was narrowed down to include only the microscopic organisms, the Infusoria. Needham, in 1748, wrote that he had seen them produced from decaying organic matter. He boiled solutions containing animal matter, corked them hot to exclude air, and found after a few days that they were full of living organisms, whose origin he attributed to "vegetative force" residing in the solutions. Spallanzani, in 1776, repeated these experiments in glass flasks, with more care, and satisfied himself that the germs of life entered the solutions from the air. Schultze, in 1836, successfully repeated the experiments, renewing the air, but subjecting it on its way to the flasks to the action of sulphuric acid or caustic potassa, to destroy the vitality of any germs it might contain. Schwann, in the following year, varied these experiments by passing the air into the flasks through tubes heated to 600° F. They showed that the Infusoria were not produced spontaneously, but from spores or germs floating in the air. Schroeder and Dusch in 1854, and Schroeder alone in 1859, went still further, and found that if the air admitted to the flasks was merely filtered through cotton plugs, it failed to induce decomposition and develop animal or vegetable organisms. Pasteur employed guncotton for the filter, dissolved it, and detected germs on the cotton plugs by the microscope, and found that when the plugs were placed in suitable solutions they at once gave rise to numerous animals and fungi. Dr. Lemaire, in 1864, collected germs by condensing the moisture of the air in glass tubes cooled by ice, and Tyndall showed that the floating particles made visible in the air by a beam of light may contain the germs of putrefaction. It was thus established that the germs of the yeast-fungus and of Infusoria float in the air, fall into organic solutions, and give rise to fermentation and putrefaction, and, as many think, to infectious diseases. There are still, however, some advocates for the theory of spontaneous generation, who base their belief on the experiments of Wyman, Bastian, Cantoni, and others, who claim to have seen living organisms develop in sealed flasks which had been exposed, after sealing, to temperatures varying from 140° to 300° F. The facts upon which the theory of spontaneous generation is based are, however, now more easily explained as errors of experiment, e. g. in the cases first cited, by imperfect sterilization by heat.

FIG. 2.—Wine-yeast, Reess: VIII., IX., X. *Saccharomyces ellipsoideus*; XI. *S. apiculatus*; XII. *S. Pastorianus*; XIII. *S. conglomeratus*; XIV. *S. reessii*; XV. *Mucor racemosus*, bullet-yeast.

The yeast-fungus consists of little cells composed of cellulose, containing a protoplasmic fluid, in which may be seen granules or germinal cells; it multiplies by budding (gemmation). The name *Torula* or *Torvula cerevisiæ* was first applied to it; it was subsequently called *Mycoderma vini*, *Cryptococcus*, *Hormiscium*, etc. Dr. Max Reess, who was one of the first to make an elaborate study of the subject (*Botanische Untersuchungen über die Alkoholgährungspilze*, Leipzig, 1870), found that there is a variety of yeast-fungi, and adopted for the genus the name *Saccharomyces*, proposed by Meyen, which has been generally adopted. Beer-yeast is *S. cerevisiæ*, which develops in two different ways, according to the temperature. At about 72° F., as in the brewing of ale, the fermentation is rapid, and the yeast is carried to the surface of the liquid by the bubbles of carbon dioxide; this is *top yeast*. When the fermentation proceeds at a temperature between 40° and 50° F., in brewing lager beer, it proceeds much slower, and the yeast appears as a sediment—*bottom yeast*. (See BEER.) These two varieties have a tendency to reproduce the kind of fermentation by which they were developed; and if the bottom yeast is placed in wort at a temperature of 72° F., it does not develop into top yeast, although its mode of growth is considerably modified. The after-fermentation of beer is caused by the development of another species, *S. exiguus*, the smallest of all yeast-fungi.

According to Reess and others, there is a greater number of species noticed in the fermentation of wine; *S. ellipsoideus* is the most common, and often the only form seen. Next in order of frequency occurs *S. apiculatus*. Engel insists that this form belongs to a different genus, and calls it *Carpozyma apiculatus*. During the after-fermentation of wines, especially of sweet wines and of other wines than the grape, *S. pastorianus* appears. *S. conglomeratus* is often noticed at the beginning of the fermentation. *S. reessii* occurs in some red wines. One or two familiar mould-fungi, *Mucor mucedo*, and especially *M. racemosus*, have the property, in the total exclusion of the air, of developing their mycelium in sugar solutions in more or less globular forms, producing true alcoholic fermentation. This was formerly considered as a confirmation of the suggestion made by certain observers, that the yeast-fungus is developed from the spores of common mould-fungi, like *Penicillium glaucum*, etc. Fitz noticed that when the quantity of alcohol reached 3½ per cent., the development of the *Mucor* ceased.

The whole subject has taken on a highly practical aspect since the labors of Pasteur established the germ theory of fermentation. Pasteur showed that beer and wine are subject to certain diseases due to the influence of germs other than yeast (bacteria). He therefore urged that yeast be cultivated in a "pure" condition—i. e. free from bacteria—and placed the art of brewing on a scientific basis. More recently Hansen, in an elaborate series of papers, has carried these ideas into practice, so that in brewing "pure cultures" of yeast are now very widely employed.

The chemical composition of yeast has not been very fully determined. It consists chiefly, as do all plants, of cellulose, albuminoids, fat, and metallic salts. It contains no chlorophyll. An elementary analysis gives about the following percentages: carbon, 48·9; hydrogen, 6·8; nitrogen, 10·8; oxygen, 29·9; sulphur, 0·6; ash, 3. Some analyses make the ash in dry yeast as high as 7 or 8 per cent. The ash consists chiefly of potassic phosphate, with small quantities of sodic, calcic, magnesic, and ferric phosphates.

II. *Acetous Fermentation.*—While it is true that alcohol and other organic bodies may be readily oxidized to acetic acid without the aid of fungi, as when platinum-black, containing condensed oxygen, chromic acid, nitric acid, hypochlorous acid, etc., is employed, it is nevertheless true that in the ordinary process of vinegar-making there is a true fermentation, caused by a peculiar fungus, the *Mycoderma aceti*, which acts as a carrier of oxygen. Pure diluted alcohol does not undergo oxidation to acetic acid when exposed to the air. Like all other fungoid plants, the *M. aceti* requires food in the form of nitrogenous bodies and mineral salts, which are always present in wine, beer, and other fermented vegetable juices. The formation of vinegar is always preceded in such cases by the development of the plant, either from small additions from a previous fermentation or from germs from the air. The plant acts as a carrier of oxygen from the air to the alcohol, and the oxidation occurs in two successive stages; alcohol becomes aldehyde by the loss of hydrogen (withdrawal by oxygen), and then passes into acetic acid by a gain of oxygen.

$$\underset{\text{Alcohol.}}{C_2H_6O} + O = \underset{\text{Aldehyde.}}{C_2H_4O} + H_2O.$$

$$\underset{\text{Aldehyde.}}{C_2H_4O} + O = \underset{\text{Acetic acid.}}{C_2H_4O_2}.$$

In the quick vinegar process considerable losses occurred at first from the evaporation of the very volatile aldehyde, which escaped conversion into acetic acid from a deficient supply of air. The conditions most favorable to the formation of acetic acid by fermentation are—(1) a sufficient dilution; the fluid should not contain more than 10 per cent. of alcohol, nor should it be much below 4 or 5 per cent.; (2) the presence of nitrogenous and saline bodies; (3) the presence of the *M. aceti* added from a previous operation; (4) a suitable temperature, not above 36° C. (96·8° F.), nor below 10°C. (50° F.); below 7° C. (44·6° F.) the formation of vinegar no longer takes place. Above 40° C.

(104° F.) it takes place very rapidly, but there is a considerable loss of alcohol and acid by evaporation; (5) a plentiful supply of air, with an extended surface of liquid for its ready contact. The progress of the fermentation is indicated by the development of the fungus, a rise of temperature, an increase of the specific gravity, the disappearance of alcohol, and the sour taste of the acetic acid. The plant acts best when it simply spreads over the surface. If it becomes diffused through the liquid, its action proceeds too far, and the acetic acid is in turn oxidized and destroyed. This second fermentation or putrefaction, which may be caused by other species of bacteria, is most liable to occur in vinegar made from malt or stale beer, and is attributed to the presence of large quantities of nitrogenous bodies. Vinegar-makers believed that this putrefaction could be prevented by an addition of sulphuric acid, and in England they were allowed by law to add $\frac{1}{1000}$ by weight. Although it is now known that this practice is unnecessary, it is still continued. In practice, acetic acid is made chiefly from wood by distillation, but large quantities of vinegar are still made by acetous fermentation. The materials employed are wine, malt, sour beer, cider, sugar, molasses, and spirits. Dr. Stenhouse has shown that when seaweeds are subjected to fermentation at 96° F. in the presence of lime, acetate of lime is found in large quantities, from which acetic acid can be readily extracted. See VINEGAR.

III. *Lactous fermentation* occurs in milk which has been allowed to stand, the milk-sugar changing to lactic acid.

$$\underset{\text{Milk-sugar.}}{C_{12}H_{22}O_{11}} + H_2O = \underset{\text{Lactic acid.}}{4C_3H_6O_3}.$$

The milk is at the same time coagulated by the lactic acid formed, which neutralizes the alkali by which the casein is held in solution. By the addition of carbonate of lime, oxide of zinc, etc., the lactous fermentation is not prevented, but the lactic acid being neutralized as soon as it is formed, the coagulation of the milk is prevented. Glucose and cane-sugar are also capable of undergoing lactous fermentation.

$$\underset{\text{Glucose.}}{C_6H_{12}O_6} = \underset{\text{Lactic acid.}}{2C_3H_6O_3}.$$

$$\underset{\text{Cane-sugar.}}{C_{12}H_{22}O_{11}} + H_2O = \underset{\text{Lactic acid.}}{4C_3H_6O_3}.$$

Albuminous substances, which at an advanced stage of putrefaction act as alcoholic ferments, often induce lactous fermentation at a certain period of decomposition. The azotized matters of malt, when suffered to putrefy in water for a few days, induce lactous fermentation, while in a more advanced state of putrefaction they cause vinous fermentation. The gluten of wheat flour, which is the active agent in leaven, behaves in the same manner. When wheat flour is made into a paste with water, and left for four or five days in a warm place, it becomes a lactous ferment; if left a few days longer, it acts as an alcoholic ferment. This accounts for the uncertainty which attends the use of leaven for raising bread: when it acts as a vinous ferment the bread is light, porous, and spongy: when it causes lactous fermentation, the bread is heavy and sour. (See BREAD.) Cheese, glue, urine, and many other substances containing more or less nitrogenous matter induce lactous fermentation under certain conditions. The same property is possessed by many animal membranes in a certain state of decomposition. The most active of these is the inner coat of the stomach of the sucking calf, called rennet. This is the agent employed to coagulate milk in the manufacture of cheese. The stomach, bladder, etc., of the dog possess the same property. Lactous fermentation occurs between 58° and 104° F.; a temperature of from 75° to 90° F. is probably the most favorable. Lactous fermentation is often accompanied by vinous fermentation, the product exhibiting the products of both, with an evolution of carbonic acid (CO_2). Butyrous fermentation often occurs at the same time, with an evolution of hydrogen and carbonic acid and the formation of butyric acid. Mannite, a product of mucous fermentation, is said to occur among the products of lactous fermentation, but it is not clear whether this is also a product of this fermentation or is an evidence of mucous fermentation.

According to Pasteur (*Ann. Chem. Phys.* [3], li. 298; lii. 404), lactous fermentation is caused by the common mould-fungus (*Penicillium glaucum*) which develops in solutions containing milk-sugar, cane-sugar, or glucose, and the necessary nitrogenous matters and mineral salts, just as the vinous fermentation is caused by the yeast-fungus. Pasteur collected this plant as a gray sediment formed during lactous fermentation, and introduced it into a cooled filtered decoction of beer-yeast, with from 15 to 20 pints of water, together with chalk, and sugar equal to from $\frac{1}{20}$th to $\frac{1}{15}$th of the liquid. On keeping this mixture at from 86° to 95° F. for some days, a brisk effervescence of carbonic acid and hydrogen took place, the chalk dissolved in the lactic acid formed, while the liquid became turbid and deposited a sediment. This sediment, a purer form of the fungus, produced lactous fermentation within an hour in a solution of sugar containing chalk. When air is excluded from solutions which otherwise undergo lactous fermentation, or is supplied through heated tubes, fermentation does not occur, because the germs of the *P. glaucum* do not gain admission. The lactous ferment resembles in mass ordinary beer-yeast. It is gray, somewhat glutinous, and appears under the microscope to consist of minute spherules $\frac{1}{15000}$th to $\frac{1}{10000}$th inch in diameter—some isolated, others in groups. It increases at first by the formation of new round cells, but afterward by the formation of elongated and branched groups, which ultimately cover the surface like a white mould. A small quantity of lactous ferment is capable of decomposing a large quantity of sugar, provided the liquid is kept neutral by chalk, which forms calcium lactate; otherwise its action on the sugar is retarded by the presence of the free acid. If no other ferment is present, the lactous fermentation goes on regularly, and often more quickly than vinous fermentation. According to Blondeau (*J. Pharm.* [3], xii. 257), the liquid becomes viscous previous to lactous fermentation, in consequence of the development of the *P. glaucum*, whose ramifications fill the liquid.

The name *Oïdium lactis* has been given to a peculiar mould-like fungus often found in sour milk. De Bary, in his *Ueber Schimmel und Hefe*, insists that the *O. lactis* is a distinct plant, not to be confounded with *P. glaucum*. Reess (*Botanische Untersuchungen über die Alkoholgährungspilze*, p. 2) and Mayer (*Lehrbuch der Gährungschemie*, p. 162) insist that the true lactous ferment is a minute bacterium, which the latter figures, and that the mould-fungus, called *P. glaucum* and *O. lactis*, is merely an incidental growth. Béchamp claimed to have shown that the germs of the real ferment were contained in the chalk used in lactous fermentation. He called the fungi *Microzyma cretæ*. His conclusions are disproved by the fact that oxide of zinc, chemically prepared, may be substituted for the chalk without modifying the character of the fermentation; and also by the experiment of O. Loew, of heating the chalk red hot previous to introducing it into the liquid. (*American Chemist*, i. 244.) The most recent and probable view of these somewhat contradictory phenomena is that various micro-organisms may under favorable conditions convert lactose into lactic acid. It is known, for example, that the common intestinal bacillus of man (*B. coli communis*) can do this, although a form closely resembling it—the bacillus of typhoid fever—is unable to do so.

Lactous fermentation is conducted in the following manner for the production of lactic acid: To 2 gal. milk are added 6 lb. raw sugar, 8 oz. putrid cheese, and 4 lb. chalk. The mixture is placed in a loosely covered jar, and maintained at a temperature of about 86° F., with occasional stirring. After two or three weeks the process is complete, and a semi-solid mass of calcium lactate is the result, from which lactic acid is readily prepared. By substituting oxide of zinc for the chalk, zinc lactate is obtained. A certain quantity of mannite is formed at the same time. The spontaneously developed fermentation of saccharine juices is sometimes lactous, sometimes vinous, more frequently both together. Lactous fermentation is the process by which articles of food are so often spoiled when they are said to become sour; it is also the process by which the German *Sauerkraut* and *Sauerbohnen* are prepared.

IV. *Butyrous fermentation* sets in when lactous fermentation is allowed to proceed beyond the point indicated by the formation of calcium lactate. The calcium lactate redissolves, carbonic acid and hydrogen are evolved, and calcium butyrate is found in the solution.

$$\underset{\text{Lactic acid.}}{2C_3H_6O_3} = \underset{\text{Butyric acid.}}{C_4H_8O_2} + 2CO_2 + 2H_2$$

A temperature of 100° F. or more seems to favor this fermentation. By adding to calcium lactate a certain quantity of cheese, and maintaining an elevated temperature, butyrous fermentation is induced, and the lactate is converted into calcium butyrate, with some valerianate and acetate. (Williamson, *Chem. News*, xxii. 236). Blondeau refers butyrous fermentation to *Penicillium glaucum*, but Pasteur (*Compt. rend.*, lii. 344; liv. 416) refers it to minute bacteria or vibrios. They appear as small cylindrical stems, rounded at the ends, usually straight, and occurring singly or in chains of two, three, or more, $\frac{1}{12000}$th of an inch in thickness, a single stem varying from $\frac{1}{12000}$th to $\frac{1}{1200}$th of an inch in length. They increase by division, and may be sown and cultivated in a suitable medium like beer-yeast. Sugar or lactates, with ammonia salts and phosphates, constitute the necessary food of the plant. (*Bull. Soc. Chim.*, 1862, p. 52.) As soon as the lactate is all converted, the vibrios die. Here also it is probable that various micro-organisms are able under favorable conditions to produce butyric acid, and that its production is not the specific privilege of any one form. *American Chemist*, ii. 371.

V. *Mucous* or *viscous fermentation* occurs in solutions of cane-sugar under the influence of nitrogenous bodies, and in contact with the air, under circumstances not fully investigated. Carbonic acid gas and hydrogen are evolved, and the sugar-cane is converted into mannite, a peculiar gum, and a mucilaginous substance. The ferment is composed of spherules about $\frac{1}{20000}$th of an inch in diameter. When these are added to 100 parts of cane-sugar in water, with some albumen, 51·09 parts of mannite and 45·5 parts of gum are obtained, which corresponds to

$$\underset{\text{Cane-sugar.}}{25C_{12}H_{22}O_{11}} + 13H_2O = \underset{\text{Mannite.}}{24C_6H_{14}O_6} + \underset{\text{Gum.}}{12C_{12}H_{20}O_{10}} + 12CO_2.$$

Although often accompanied by vinous and lactous fermentation, mucous fermentation may occur without the formation of either alcohol or acid. It occurs at temperatures ranging from 68° to 104° F. The juice of the sugar-cane, sugar-beet, mangold wurzel, carrot, dandelion, etc., is liable to undergo this form of fermentation spontaneously when exposed to the air. Effervescing lemonade, made from sugar, citric acid, oil of lemon, and carbonic acid, loses its fluidity on long keeping from this kind of fermentation. The most recent view of the several fermentations just described is that, given the proper raw material, acetic, lactic, or butyric acids, or mannite, will be formed by the bacteria present, although some kinds are certainly more adapted to a particular work than others are.

When yeast is washed with cold water, then boiled with water, and $\frac{1}{20}$th part of sugar added to the filtrate, the liquid undergoes fermentation for a week or two, evolving hydrogen, carbonic acid, and carbonic oxide, and becoming turbid and tenacious like a decoction of linseed. Water boiled with gluten produces a similar change in solutions of cane-sugar. When the fermentation is completed, the liquid is still sweet, but is so thick that it runs out in threads when the vessel is inverted. The gum produced resembles gum arabic, but is less soluble in water, makes a thicker mucilage, but yields scarcely any mucic acid when treated with nitric acid. Pasteur, *Bull. Soc. Chim.*, 1861, p. 30; Hochstetter, *J. pr. Ch.*, xxix. 30; Plague, *J. Pharm.*, xxvi. 248; Kircher, *Ann. Pharm.*, xxxi. 337; Desfosses, *J. Pharm.*, xv. 602; Vauquelin, *Ann. Chim. Phys.*, xx. 93.

VI. *Putrefaction*, or putrefactive fermentation, is the process by which azotized animal and vegetable substances undergo decomposition spontaneously, with the production of offensive gases. The essential conditions are the presence of moisture, a temperature between 32° and 140° F., and exposure to the air during or previous to the process. The process is very complicated, resulting in the formation of carbonic acid, sulphuretted hydrogen, phosphuretted hydrogen, marsh gas, ammonia, nitrogen, hydrogen, acetic, lactic, butyric, and valerianic acids, and many offensive bodies which have not yet been identified. Resins, if present, are but little changed, and fats often resist all decomposition save saponification, remaining as free fatty acids for years. (See ADIPOCERE.) The process varies considerably with the quantity of water present and the extent to which air has access. Two theories were formerly advanced to account for putrefaction. Liebig claimed that "when the life-power or vital force has ceased to control the organic combinations, the nitrogen in the albuminous bodies, by its affinity for hydrogen, decomposes water, with the formation of ammonia." "The molecule set in motion by this affinity imparts its motion to other molecules with which it is in contact." A few investigators still hold that the true putrefactive ferment is an albuminoid substance not endowed with vitality. (Panum, in *Virchow's Archiv für path. Anat.*, 1874.) The theory generally accepted, however, is that of Schwann, Pasteur, and Cohn, which describes putrefaction as a chemical process induced by bacteria. The bacteria bear the same relation to putrefaction that the yeast-plants bear to alcoholic fermentation, the *Bacterium termo* (Fig. 3, 2) being one of the most common species. If a clear solution of any nitrogenous animal or vegetable matter, such as an infusion of hay, be exposed to the air at ordinary temperatures, it will soon become turbid, and exhibit the usual signs of decomposition, evolving offensive gases. The microscope shows the turbidity to be caused by innumerable bacteria, which move in every direction and multiply by division. After a time putrefaction ceases, the liquid becomes clear, and a sediment of bacteria is found to have separated. The smallest portion of this sediment will excite putrefaction in another albuminous liquid, just as yeast causes fermentation. Any process by which the access of bacteria germs to the albuminous solutions can be prevented is found to protect them from putrefaction. Dr. Burdon-Sanderson has shown (*13th Rep. Med. Officer of the Privy Council*) that contamination by germs of bacteria usually occurs from contact with water and moist surfaces, not directly from the air, while the germs of the mould-fungi enter directly from the atmosphere. This is now known to be subject to many exceptions, although it is a fact that the bacteria settle more rapidly than mould-germs, probably because they have greater specific gravity. Substances protected from bacteria germs mould, but do not putrefy. A piece of muscle cut out of a recently killed animal with a knife which had just been heated was hung under a bell-jar, and after thirty-one days, although overgrown with mould-fungi, *Penicillium*, etc., it showed no signs of bacteria or putrefaction. In the ordinary process of decay the putrefaction occasioned by bacteria is accompanied by the action of the mould-fungi, the organisms themselves being subsequently destroyed by similar agencies, other bacteria, and fungi, till nothing remains save brown humus (see HUMUS) and the mineral salts, the carbon, hydrogen, nitrogen, sulphur, and oxygen passing into the atmosphere or washed into the soil as carbonic acid, ammonia, water, etc.

Bacteria, *Vibriones*, *Microzymas*, *Microzoaires*, *Mycoderma*, etc., were first recognized by Kircher about 1650 and next by Leeuwenhoeck in 1684. O. F. Müller in the eighteenth century recognized and described the most important forms, and Ehrenberg in 1830 established for them the family of *Vibrionidæ*, which Dujardin in 1841 placed as the first and lowest form of Infusoria. They were first supposed to be animals—at least those which are endowed with motion—but all are now regarded as plants. Ferdinand Cohn established their vegetable character and structural relations. (*Nova Acta Ac. Car. Leop. nat. cur.*, xxiv. 1, 1853), and subsequently added much to the knowledge of their classification and general physiology. (*Beiträge zur Biologie der Pflanzen*, Heft. ii. p. 127. 1872.) The bacteria consist of cells composed of cellulose or a body similar to it, containing protoplasmic matter, but no chlorophyll. They are spherical, oblong, cylindrical, curved or twisted, isolated or connected in chains. They are extremely minute, taxing the powers of the best immersion lenses. The *Bacterium termo* is $\frac{1}{500}$th mm., or $\frac{1}{12000}$th inch, in length, and $\frac{1}{1000}$th mm., or $\frac{1}{24000}$th inch, in diameter; according to Cohn 41,000,000,000 weigh one grain. They multiply by division or scission, neither buds nor spores having been detected. Cohn, believing that they divide once every hour, finds that one bacterium will by doubling every hour produce in 24 hours $16\frac{1}{2}$ millions bacteria; in 2 days, 281 billions; in 3 days, 47 trillions; and in a week a number expressed by 51 figures. Spores (so called) consisting of spherical masses of protoplasm are formed in the interior of some bacteria, and when set free sink to the bottom of the liquids. Most bacteria are killed

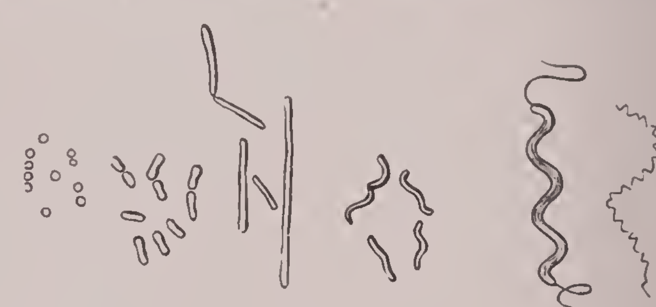

FIG. 3.—Bacteria.

by an exposure to 140° F. for several hours, to 212° for 10 or 15 minutes, to 215° for 4 or 5 minutes. Near the freezing-point the movements stop, but are resumed again on warming to 40° or 45° F. Billroth finds that the spores described by him retain their vitality after freezing, boiling, and drying. He has some which were kept eight years without losing their power of producing bacteria. To kill them he employs a temperature of 302° F. In general boiling destroys and cold suspends the activity of bacteria; but to destroy all bacteria (including spores) by mere boiling has been found practically impossible. Bacteria live upon albuminous ammonia or urea and carbonaceous matters, organic acids, sugar, etc., and require mineral salts. They are supposed to absorb oxygen and exhale carbonic acid.

Cohn subdivided the bacteria into six genera, distributed among four families:

I. Family, *Sphærobacteria* (spherical bacteria).
 1. Genus, *Micrococcus* (Fig. 3, 1).
II. Family, *Microbacteria* (short rods).
 2. Genus, *Bacterium proper* (Fig. 3, 2).
III. Family, *Desmobacteria* (thread-like).
 3. Genus, *Bacillus* (Fig. 3, 3).
 4. Genus, *Vibrio* (Fig. 3, 4).
IV. Family, *Spirobacteria* (corkscrew-like).
 5. Genus, *Spirillum* (short, stiff screws, Fig. 3, 5).
 6. Genus, *Spirochæte* (flexible spirals, Fig. 3, 6).

For a description of the species, see *Beit. z. Biol. d. Pflanzen*, ii. p. 146. See also BACTERIOLOGY.

Modern investigations have shown that bacteria may exist in the interior of living animals, that they often exist in the body during various diseases, and that healthy animals may be inoculated with them as with a virus. The germ theory of fermentation established by the labors of Schwann, Schroeder, and Dusch, and above all others by Pasteur, led inevitably to the germ theory of infectious disease (see GERM THEORY), now almost universally accepted. This theory assumes that such diseases as smallpox, diphtheria, malignant pustule, septicæmia, cholera, typhus and typhoid fever, etc., are caused by bacteria, and that they are true processes of fermentation. The discovery that the potato-rot is caused by a fungoid plant, the muscadine of silkworms by a mould-fungus, and the pébrine of the same animal by a minute plant, and the study of the trichinæ and of several skin-diseases caused by mould-fungi have furnished a very solid foundation for this theory; but the closest analogy is to be found in the more active and rapid fermentative diseases, such as those of wine and beer, which were clearly understood by Pasteur as early as 1865.

VII. *Saccharous fermentation* is the process by which starch is changed to dextrin and glucose. This change is effected by the diastase of germinating barley and other seeds, saliva, blood-serum, pancreatic juice, etc. The starch first changes to dextrin and glucose, the former in turn changing to glucose.

$$\underset{\text{Starch.}}{2C_6H_{10}O_5} + \underset{\text{Water.}}{H_2O} = \underset{\text{Dextrin.}}{C_6H_{10}O_5} + \underset{\text{Glucose.}}{C_6H_{12}O_6}.$$

$$\underset{\text{Dextrin.}}{C_6H_{10}O_5} + \underset{\text{Water.}}{H_2O} = \underset{\text{Glucose.}}{C_6H_{12}O_6}.$$

This is one of the most important processes of nature; by it the store of starch laid up in seeds, tubers, bulbs, and in the bark of some trees, is made available for assimilation and conversion into vegetable tissue. Observations have shown it to be unconnected in any way with living organisms corresponding to yeast. See DIASTASE, GLUCOSE, DEXTRIN, BEER, GERMINATION, etc.

VIII. *Glucosic fermentation* takes place when cane-sugar is subjected to vinous fermentation.

$$\underset{\text{Cane-sugar.}}{C_{12}H_{22}O_{11}} + H_2O = \underset{\text{Lævoglucose.}}{C_6H_{12}O_6} + \underset{\text{Dextroglucose.}}{C_6H_{12}O_6}.$$

Although acids produce a similar change, it is produced by yeast, or a watery solution from yeast, in the presence of carbonate of soda. Berthollet attributes it to a nitrogenous ferment analogous to diastase or pancreatin. Béchamp (*Comp. rend.*, lviii. 601, 723; lix. 496) finds a soluble ferment in the mould of sugar solutions, which he calls *zymase*, which converts cane-sugar into glucose. See SUGAR.

IX. *Pectous Fermentation.*—Many unripe fruits and fleshy roots contain an insoluble substance called *pectose* which is converted by a ferment called *pectase* into the soluble gelatinous bodies pectin, parapectin, pectic acid, and metapectic acid. See PECTIN.

X. *Gallous Fermentation* (*Tannous Fermentation*).—When powdered nut-galls are exposed to moisture, the tannic acid they contain is changed to gallic acid with the formation of sugar; hence tannic acid has been classed with the glucosides. See GLUCOSIDES.

$$\underset{\text{Tannic acid.}}{C_{27}H_{22}O_{17}} + 4H_2O = \underset{\text{Gallic acid.}}{3C_7H_6O_5} + \underset{\text{Glucose.}}{C_6H_{12}O_6}.$$

(Stas, *Ann. Ch. Pharm.*, xxx. 205; Strecker, *ibid.*, xc. 328.) This change is said by Van Tieghem (*Compt. rend.*, lxv. 1091) to be due to the growth of the two common mould-fungi *Penicillium glaucum* and *Aspergillus niger*, but it is probably effected by various organisms. See TANNIC ACID.

XI. *Amygdalous fermentation* results from the action of the emulsin of bitter almonds upon the amygdalin, by which benzoic aldehyde, hydrocyanic acid, and glucose are produced. See ALMONDS, OIL OF.

XII. *Sinapous fermentation*, the formation of the volatile oil of mustard by the action of myrosin on myronic acid. See MUSTARD, OIL OF.

XIII. *Urinous fermentation* occurs when urine becomes putrid. The urea is changed to carbonate of ammonia by the action of bacteria.

$$\underset{\text{Urea.}}{CH_4N_2O} + 2H_2O = \underset{\text{Carbonate of ammonia.}}{(NH_4)_2CO_3}.$$

In the presence of yeast the change takes place very rapidly. (C. Schmidt, *Ann. Ch. Pharm.*, lxi. 168.) This action was very early referred to bacteria. (Pasteur, *Ann. Chim. Phys.*, 1862, 1864; Van Tieghem, *Compt. rend.*, lviii. 210, 1864.)

XIV. *Peptous fermentation* is a name given to the action of pepsin of the gastric juice on the albuminoids of the food. The exact nature of the process is not known. See PEPSIN.

XV. *Nitrification.*—It has long been known that nitrates, especially potassium and sodium nitrates, occur in the soil. Their formation in the soil has been shown to be due to the action of a living organism. The process of nitrification is therefore a kind of fermentation, if to this term be given its broadest definition. Nitrification will, however, be treated of in the article NITRIC ACID (*q. v.*).

XVI. *Soluble Ferments*, or *Enzymes.*—In addition to the changes produced by organisms, there are others of a somewhat similar character caused by unorganized bodies known as soluble ferments or enzymes. Prominent among these bodies is DIASTASE (*q. v.*). As has been pointed out, this substance has the power to convert starch into dextrin and glucose. The soluble ferments are widely distributed in nature, both in the vegetable and animal kingdoms. They fall into several groups, according to the character of the changes which they effect. These groups are: 1. *Diastatic.*—There seem to be several soluble ferments capable of causing diastatic action, or the conversion of starch into dextrin and glucose. Such substances are contained in sprouted barley, in the saliva, in the pancreatic juice, and in the secretion of the liver. 2. *Inverting Ferments.*—By the term *inversion* is meant the breaking down of certain complex sugars into simpler ones. Thus cane-sugar is broken down under the influence of a number of substances into lævulose and dextrose, and milk-sugar under similar influences yields dextrose and galactose. The ferments that cause these changes are called *inverting ferments.* They are found in the alimentary canal in animals, and, probably, in higher plants. 3. *Peptonizing Ferments.*—These "convert coagulable albuminoids into soluble and diffusible albuminoids, or *peptones.*" Among these are *pepsin*, found in the gastric juice; trypsin, found in the pancreatic juice, etc. 4. *Ferments causing the Coagulation of Casein.*—The principal ferment of this class is that contained in rennet, which is largely employed in the preparation of cheese. 5. *Ferments causing the Decomposition of Glucosides.*—An emulsion of sweet almonds contains a soluble ferment known as *emulsin*, which has the power to decompose the glucoside, amygdalin, into benzoic aldehyde, or oil of bitter almonds, glucose, and hydrocyanic acid. So also there is a similar substance, *myrosin*, which is found in the seeds of black mustard, together with potassium myronate. The ferment acting upon the latter causes the formation of glucose, allyl mustard oil, and acid potassium sulphate. 6. *Ferments causing the Conversion of Urea into Ammonium Carbonate.*—While the conversion of urea into ammonium carbonate is usually effected by means of organized ferments, it has been shown that this change can also be effected by means of an unorganized or soluble ferment.

Some of the soluble ferments are produced by the organized ferments. Thus yeast produces a substance, *invertase*, which has the power of converting cane-sugar into dextrose and lævulose.

XVII. *Prevention of Fermentation and Putrefaction.*—As moisture and the development of bacterial germs are necessary to induce these processes, they may be prevented by (1) drying thoroughly; (2) cooling to prevent the development of the germs; (3) sealing hermetically in jars or tin cans, and subjecting to a temperature sufficient to destroy the vitality of all the germs present; (4) employing antiseptic substances, such as alcohol, common salt, saltpeter, sugar, sirup, tannic acid, creosote, smoke, phenol, salicylic acid, salts of iron, zinc, lead, mercury, and copper, borax, sulphurous acid, sulphites, etc. See PRESERVATION OF FOOD, PRESERVATION OF TIMBER, and EMBALMING.

Fermented Liquors: See BEER and WINE.

Fermoy': town; county of Cork, Ireland; 19 miles N. E. of Cork, on the right bank of the Blackwater, over which a bridge on thirteen arches was built in 1689 (see map of Ireland, ref. 13–E); is the site of St. Colman's College (Roman Catholic). The town dates from the twelfth century, when it was the seat of a magnificent abbey. Pop. 6,500.

Fern [O. Eng. *fearn*: Germ. *Farn* (in *Farnkraut*, fern); cf. Sanskr. *parna*, feather, leaf]: any plant belonging to the class *Filicinæ*. See FERNWORTS and FOSSIL PLANTS.

Fern, FANNY: See PARTON.

Fernald, JAMES CHAMPLIN: See the Appendix.

Fernandez Cordova, FRANCISCO: See CORDOVA, FRANCISCO HERNANDEZ.

Fernandez de Castro Andrade y Portugal, PEDRO ANTONIO: See CASTRO ANDRADE Y PORTUGAL.

Fernandez de Castro, dā-kaas'trō, MANUEL: geologist; b. in Madrid, Spain, Dec. 25, 1825. He graduated at the Madrid School of Mines in 1844, was sub-director of a mine at Almaden, and afterward traveled in various countries, studying railroad systems. In 1857 his work, *La electricidad y los caminos de hierro*, was published by the Government. In it he proposed a new system of railroad signals which was generally adopted. From 1859 to 1869 he was engaged in Government mining and geological work in Cuba and Santo Domingo. He made an extended report on the latter island, of which only portions were published. In 1869 he accepted a professorate at the Madrid School of Mines, and in 1873 took charge of the commission appointed to form a geological map of Spain. Under his direction a large number of geological reports and maps connected with this work have been published. In 1879 he was elected to the Spanish senate to represent Santa Clara, Cuba. Besides the works mentioned, he has published a treatise on hurricanes (1872) and many geological papers. HERBERT H. SMITH.

Fernandez de Cordova, DIEGO: Marquis of Guadalcazar; Spanish administrator of the seventeenth century. He was probably a native of Cordova, and was descended from Gonzalo de Cordoba, called "the great captain." From Oct. 18, 1612, to Mar. 14, 1621, he was Viceroy of New Spain or Mexico: beyond some trouble with corsairs on the coast, and with revolted Indians, his term was quiet. Transferred to Peru, he was viceroy there July, 1622, to Jan., 1629. The incursions of the corsairs, especially of the Dutch, had now extended to the Peruvian coasts; Jacob l'Heremite blockaded Callao for four months, and attempted to take Lima, and one of the treasure-ships was captured by Heyn; much of the coast was ravaged; the miners of the Potosi district engaged in a bloody faction war, which was brought to an end with difficulty. Returning to Spain, 1629, the marquis resided in his estate of Guadalcazar, near Cordova, and probably died there. HERBERT H. SMITH.

Fernandez de Enciso, MARTIN: See ENCISO.

Fernandez de la Cueva, FRANCISCO: Duke of Albuquerque; Spanish administrator; b. about 1610. From Aug., 1653, to May, 1661, he was Viceroy of New Spain or Mexico. His term was marked rather by lavish display and expenditure than by any real benefit to the country. The great cathedral of Mexico city was finished and dedicated during this period. On Mar. 12, 1660, the duke narrowly escaped death at the hands of an insane soldier who attacked him in his private chapel. After his return to Spain he was made Viceroy of Sicily. The date of his death is not recorded. H. H. S.

Fernandez de la Cueva Henriquez, FRANCISCO: Duke of Albuquerque; grandson of FRANCISCO; was Viceroy of New Spain Nov. 27, 1702, to Jan. 15, 1711. Like his grandfather he was greatly given to display, and his immense wealth enabled him to surpass all his predecessors in magnificence; few courts of Europe equaled that of Mexico in the pomp and show of this period. By his order various new towns were founded in the north, among others that of Albuquerque, New Mexico, so named in his honor. H. H. S.

Fernandez de Palencia, -pāā-len'thē-āā, DIEGO: soldier and author; b. in Palencia, Spain, about 1520. He went to Peru in 1545 or earlier, and served in the civil war against the rebel Giron 1553–54. The Viceroy Mendoza made him historiographer in 1556, and he began the work which was extended and finished after his return to Spain. It was finally published in Seville (1571) as *Primera y segunda parte de la historia del Peru*, including the events of the rebellions of Gonzalo Pizarro and Giron. It is one of the principal authorities for this period. D. in Seville, 1581. H. H. S.

Fernandez Madrid, JOSÉ: physician, poet, and statesman; b. at Cartagena, New Granada, Feb. 9, 1789. He studied at Bogotá, and received the degree of doctor both in law and medicine. In 1810 he joined the party of independence, was twice elected to congress from Cartagena, and on Mar. 14, 1816, accepted the difficult post of president of New Granada, succeeding Torres, who had resigned. Obliged to fly from the Spaniards, he resigned his office, and soon after was captured and sent to Havana, Cuba. There he remained for nine years, and distinguished himself as a physician and scientific author. In 1825 he returned to New Granada, and Bolivar made him minister to England. Among his published works are his poems, which have passed through several editions; two tragedies, *Atala* and *Guatimozin*; an important treatise on yellow fever; and others on medical, agricultural, and scientific subjects. D. near London, June 28, 1830. HERBERT H. SMITH.

Fernandina, fẽr-năn-dee'na: city; port of entry and capital of Nassau co., Fla. (for location of county, see map of Florida, ref. 1–J); on the west side of Amelia island, between Nassau and Prince William sounds, and separated from the mainland by a channel called Amelia river, which affords a deep, safe, and spacious anchorage. The harbor entrance is marked by a lighthouse. Vessels drawing 20 feet can enter at high tide. Fernandina ships large quantities of phosphate and lumber; it has a manufactory of superior plastering fiber from raw palmetto, extensive works for creosoting lumber and piling, sawmills, etc., and is the Atlantic terminus of the Florida Central and Peninsular Railway system, with steamships to New York, etc. Pop. (1880) 2,562; (1890) 2,803; (1900) 3,245.

EDITOR OF "FLORIDA MIRROR."

Fernando de Noronha, fer-naan'dō-dē-nō-rōn'yaa: island of Brazil; in the South Atlantic; about 260 miles E. N. E. of Cape São Roque. It is of volcanic origin, 4½ miles long from N. E. to S. W., and 1½ miles wide; the surface is much broken, the highest peak being that called the Pyramide, at the southern end. The vegetation is mainly a low forest or scrub. The climate is dry, and little of the land is available for culture; small quantities of maize, cotton, manioc, and cocoanuts are produced, and cattle, goats, and sheep are kept. A few miles N. E. of the main island there are six islets, the largest of which (Rata) is cultivated. A substance resembling guano has been found on the rocks. Fernando de Noronha was discovered in 1503 by the Portuguese navigator of that name, who called it São João. For many years it has been the site of a Brazilian penal settlement. Pop., including prisoners, over 2,000. Remedios, on the northeast coast, is the only village.

HERBERT H. SMITH.

Fernando Po: a volcanic island belonging to Spain; in the Bight of Biafra, about 20 miles from the Cameroon coast, in lat. 3° 12′ N. and lon. 3° 48′ E. It is rectangular, 44 miles by 20, with a ridge of mountains extending through it and culminating in Ste. Isabelle, 10,700 feet high. It is covered by a luxuriant forest; has a fertile soil and salubrious climate. The island was discovered in 1471 by Fernao da Pao, a Portuguese navigator, was occupied by Spain in 1778, but abandoned in 1782. It was again occupied, this time by the British, in 1827, but abandoned in 1834. The Spaniards resumed possession in 1844, and now use it as a penal settlement. The capital is Clarence Cove, a port on the northern coast. Exports, india-rubber and palm oil. The population numbers about 15,000, nine-tenths of whom are natives called Bobies, or Amigos, who are stupid, repulsive in appearance, and hostile to immigrants.

M. W. HARRINGTON.

Ferney, făr'nā': town of France; department of Ain; 4½ miles N. W. of Geneva (see map of France, ref. 6–H). It is famous as the residence of Voltaire during the last twenty years of his life (1758–78); it was a miserable hamlet when Voltaire arrived; it was a prosperous town when he left. The château in which he lived has undergone many alterations since his death, yet it retains many relics of him, and is annually visited by many thousand tourists. Pop. 1,200.

Fern Islands: See FARNE ISLANDS.

Fernow, BERNHARD EDWARD: forester; b. Jan. 7, 1851, in Inowraclaw, in the province of Posen, Prussia; studied forestry and law at the Forest Academy of Münden and University of Königsberg; entered the Government service in the forestry department; served in the Franco-Prussian war; settled in the U. S. 1876; after engaging in business without success in Brooklyn, entered on the management of timber lands in Pennsylvania 1884; in 1886 called to the head of the forestry division of the U. S. Department of Agriculture, having several years previous become secretary of the American Forestry Association and champion of the forest reform movement. Author of numerous reports, bulletins, and addresses.

C. H. T.

Fernworts: the great division of the vegetable kingdom, known otherwise as the Pteridophytes, and including the ferns proper, the horsetails, the lycopods, etc. They are related on the one hand to the mosses (Bryophytes), and on the other to the flowering plants (Anthophytes), with which they agree in the alternation of generations, the production of archegonia, and the development in one generation of a plant-body possessing a leafy stem. They are separated from the mosses by having a small and short-lived thalloid oöphore, and a large, long-lived leafy-stemmed sporophore, and from the flowering plants by the independent growth of the oöphore, and the formation of spores which separate from the sporophore. These resemblances and differences may be shown as follows:

BRYOPHYTES.	PTERIDOPHYTES.	ANTHOPHYTES.
Oöphore, a large thalloid or leafy long-lived, independent growth.	Oöphore, a small thalloid, short-lived, independent growth.	Oöphore, a small thalloid, short-lived, dependent growth.
Sporophore, small, leafless, short-lived, forming separating spores.	Sporophore, large, leafy-stemmed, long-lived, forming separating spores.	Sporophore, large leafy-stemmed, long-lived, forming spores which do not separate.

In all the ferns the germination of the spore results in the production of a small, flattish, cellular growth, usually a few millimeters or less in diameter; this is known as the prothallium (i. e. the first growth), the oöphore (i. e. the egg-cell bearer), and the sexual generation (Fig. 1, A). The second and third names refer to the fact that this growth produces the sexual organs, which consist of (1) more or less club-shaped structures (antherids, Fig. 1, B), whose inner cells develop motile spirals of protoplasm (antherozoids, Fig. 1, B, *a*), and (2) more or less flask-shaped structures (archegones, Fig. 1, C), each containing a germ-cell or egg-cell,

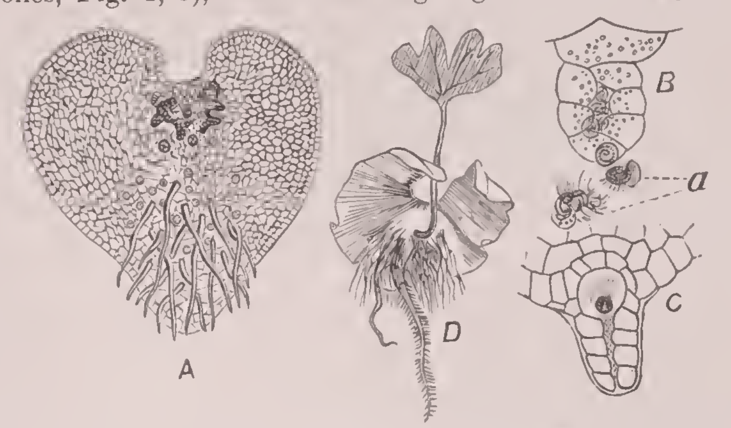

FIG. 1.—A, the prothallium (oöphore) of a fern, lower view, showing antherids mingled with the hairs, and archegones nearer the notch; B, antherid, with antherozoids (*a*) escaping; C, young archegone; D, prothallium after fertilization, with a young fern (sporophore).

called also an oösphere. When the germ-cell is mature an antherozoid fertilizes it by passing down the neck of the archegone (now open), the two masses of protoplasm fusing into one. The new cell so produced quickly undergoes division in several directions, and soon gives rise to a small shoot (with stem and leaf) and a root—the plant of the second generation (Fig. 1, D).

Throughout all the fernworts there is not much difference in the development of the sexual generation, and what has been said above of ferns is essentially true of their near allies, the horsetails and lycopods. The asexual generation, however, which develops from the fertilized egg-cell shows marked structural differences, and it is upon these that the

FIG. 2.—Asexual plants (sporophores): A, *Notholœna*; B, *Scolopendrium*.

classification of the fernworts is based. In all cases there is a high development of the internal tissues of root, stem, and leaf, while in their external conformation the leaves usually attain a high degree of complexity. Upon (or in) some of the leaves certain cells divide and give rise (asexually) to thick-walled cells which separate from the parent plant as spores (Fig. 3, B). In the details of the spore-formation, again, there are many differences, and these are used in the separation of orders, families, and genera.

The living fernworts now known number about 4,000 species, and possibly, when all parts of the world are thoroughly explored, this may approach close to 5,000. If to the living fernworts there could be added the vast number of extinct species, which extend a measureless distance back in geologic time, doubtless the number would be swelled to many times that given above. As it is, although fossil fragments are very abundant, the definitely known species do not number above 1,000. The living species are widely distributed, being most abundant in the hot, moist regions, and least

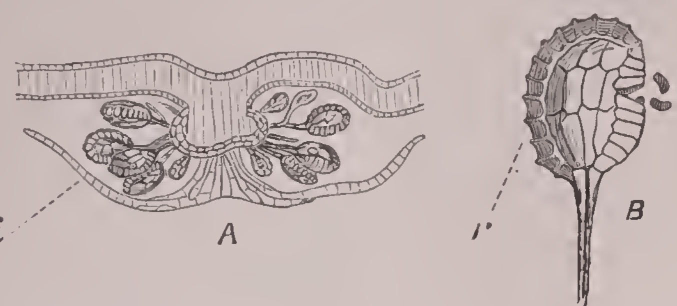

Fig. 3.—A, cross-section of a leaf through a sorus, showing the sporangia, and the indusium (*i*); B, a sporangium splitting open, *r*, its ring of thick-walled cells.

abundant in dry climates. In North America there are about 250 species and well-marked varieties, three-fourths of which are ferns proper.

The fernworts are usually separated into three classes, although investigations by Campbell render it probable that this number must be increased. The sequence of the orders is likewise in doubt, as shown by Campbell's studies. The following synopsis is therefore provisional:

Class I. Filicinæ.—The ferns. Stems solid, leaves usually large, with broadly expanded blade, and elongated petioles.

Order 1. *Ophioglossaceæ*, spores developed from cells in the tissue of the leaf; leaves erect in the bud (not circinate).

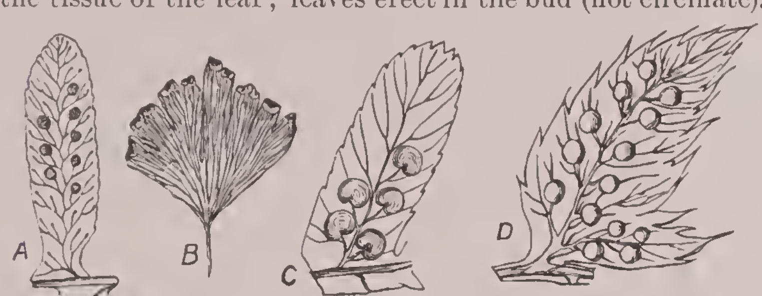

Fig. 4.—Parts of spore-bearing leaves, showing sori: A, *Polypodium*; B, *Adiantum*; C and D, *Aspidium*.

Family 1. *Ophioglosseæ*, the adder-tongues, with the characters of the order. There are several species of *Botrychium* and *Ophioglossum* in the U. S.

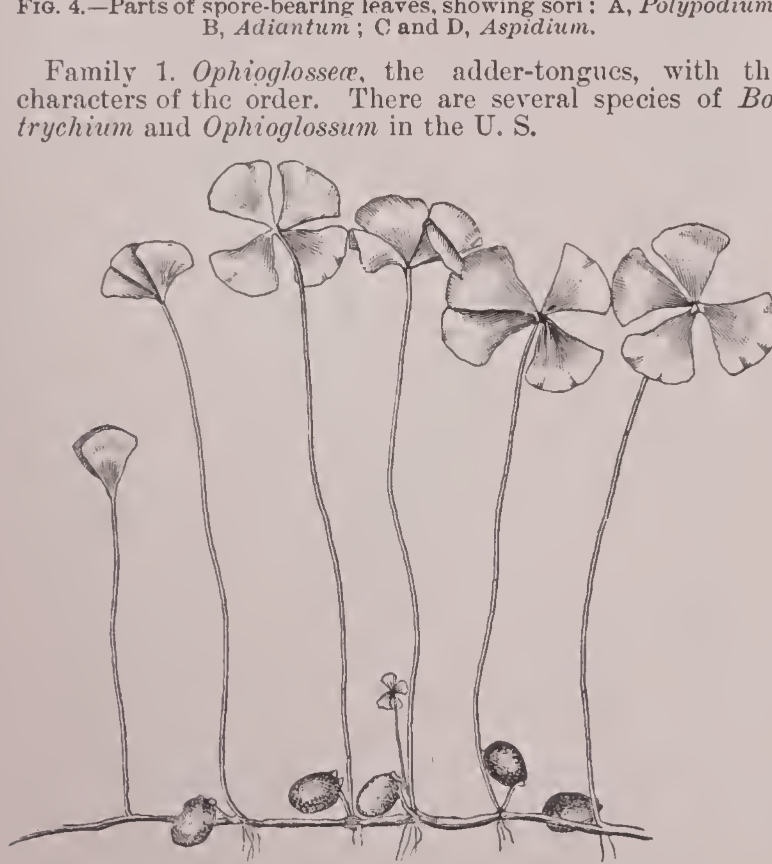

Fig. 5.—*Marsilia vestita*, of America, slightly reduced.

Order 2. *Marattiaceæ*, the ringless ferns; spores developed in external cell-masses (*sporangia*) which originate as massive outgrowths by the division of internal cells beneath the lower surface of the leaves: leaves circinate in the bud.

Family 2. *Angiopterideæ*, with a single surviving genus, *Angiopteris*, containing one variable tree-like species of Southeast Asia, Australia, and Madagascar.

Family 3. *Marattieæ*, with two genera, *Marattia* and *Kaulfussia*, of the tropics of both hemispheres, some of the species tree-like.

Family 4. *Danæaceæ*, with but a single genus—*Danæa*—of about a dozen species of smaller ferns of tropical America.

Order 3. *Filices*, the true ferns; spores developed from cells in specially modified hairs (*sporangia*), usually on the under surface of the leaf and collected in clusters (*sori*); leaves circinate in the bud.

Family 5. *Osmundaceæ*, with globose sporangia which have only a trace of a horizontal belt of thick-walled cells, and split open vertically. Three of the six species of *Osmunda* occur in North America; *Todea* with four species (one tree-like) is almost confined to the south temperate zone.

Fig. 6.—*Pilularia globulifera*, of Europe.

Family 6. *Gleicheniaceæ*, with globose sporangia which have a horizontal belt (ring) of thick-walled cells, splitting vertically. *Platyzoma* of Australia and *Gleichenia* of the hot regions of both hemispheres are represented by about thirty species of small or slender ferns.

Family 7. *Schizæaceæ*, with ovate or sub-globose sporangia, which have a terminal belt of thick-walled cells, splitting vertically. *Lygodium*, the climbing ferns of many species, represented by *L. palmatum* in Eastern U. S.; *Schizæa* mostly of the tropics (one of U. S.); *Anemia* of tropical America (two species in Southern U. S.); and *Mohria* of Africa are the principal genera.

Family 8. *Hymenophyllaceæ*, with compressed sporangia which have a horizontal or oblique belt of thick-walled cells, splitting vertically. The leaves are mostly composed of but a single layer of cells, and the sori are marginal, the sporangia developing on a prolongation of a vein. *Hymenophyllum* and *Trichomanes* (two species in Southern U. S.), the principal genera, include 150 or more species of delicate ferns, mostly of warm climates.

Family 9. *Cyatheaceæ* (tree-ferns), with compressed sporangia which have a vertical or sub-oblique belt of thick-walled cells, splitting transversely. Sori often covered or surrounded by an involucre (*indusium*). Mostly large tropical ferns with erect stems. *Alsophila*, *Hemitelia*, *Cyathea*, and *Matonia* are the principal genera, some species of which reach 40 to 50 or more feet in height.

Family 10. *Polypodiaceæ*, with compressed, stalked sporangia, which have a vertical incomplete belt of thick-walled cells, splitting transversely. Sori often covered or surrounded by an involucre (*indusium*). This is by far the largest family of living ferns, and includes nearly all the common species of the U. S. The principal genera are *Acrostichum*, *Adiantum* (Fig. 4, B), *Asplenium*, *Aspidium* (Fig. 4, C, D), *Blechnum*, *Cheilanthes*, *Camptosorus*, *Cystopteris*, *Dicksonia*, *Gymnogramme*, *Notholæna* (Fig. 2, A), *Onoclea*, *Polypodium* (Fig. 4, A), *Pteris*, *Pellæa*, *Phegopteris*, *Scolopendrium* (Fig. 2, B), *Woodwardia*, and *Woodsia*.

Fig. 7. — Fruiting branches of *Equisetum arvense*, with a detached spore-bearing leaf enlarged at *a*.

Order 4. *Hydropterideæ*, the water-ferns; spores of two kinds, developed from cells in specially modified hairs (sporangia), these inclosed in "sporocarps" which are much modified leaves. The smaller spores (microspores) in germination develop minute prothallia, bearing antherids only, while the larger spores (macrospores) develop prothallia bearing archegones only. The sexual plants (oöphores) are therefore diœcious.

FIG. 8.—Terminal portion of *Lycopodium annotinum*, spore-bearing leaves above.

Family 11. *Salviniaceæ*, small floating plants of two genera, *Salvinia* (twelve species, one in U. S.) and *Azolla* (five almost microscopic species, two in U. S.).

Family 12. *Marsiliaceæ*, creeping semi-aquatic or aquatic plants, rooting in the mud, and bearing filiform or four-parted leaves. The two genera, *Marsilia* (Fig. 5) and *Pilularia* (Fig. 6), include respectively forty, and six species widely distributed. Four or five species of *Marsilia* and one of *Pilularia* occur in North America.

CLASS II. EQUISETINÆ.—The horsetails. Stems hollow, jointed, the joints solid; leaves rudimentary and whorled.

Order 5. *Equisetaceæ*, with sporangia on the under surface of the whorls of peltate leaves at the summit of the stem.

Family 13. *Equisetaceæ*, including twenty widely distributed species, all of the genus *Equisetum*; thirteen species occur in North America.

CLASS III. LYCOPODINÆ.—The lycopods. Stems solid, dichotomously branched, leaves small and narrow, scattered. Probably an unnatural group.

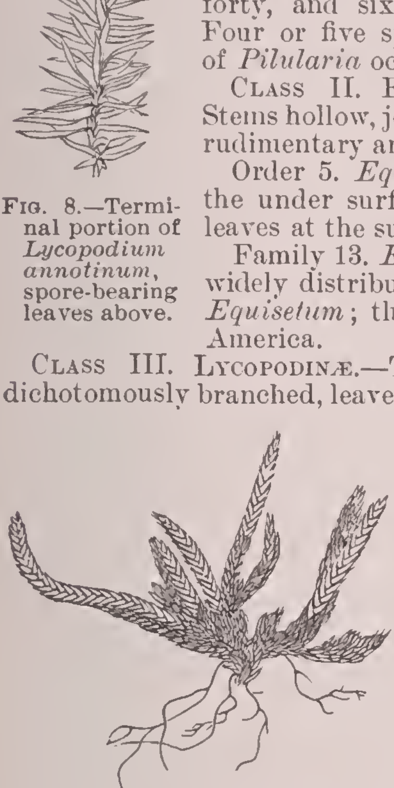

FIG. 9.—*Selaginella rupestris*, fruiting specimen, natural size.

Order 6. *Lycopodiaceæ*, the club-mosses. Sporangia single in the axils of the small upper leaves, spores all alike.

Family 14. *Lycopodiaceæ*, small evergreen perennial plants. There are four genera, *Lycopodium* (with ninety-four species, twelve in U. S.), *Psilotum* (two species, one in U. S.), *Phylloglossum*, and *Tmesipteris*.

Order 7. *Selaginellaceæ*. The little club-mosses. Sporangia single in the axils of the small upper leaves; spores of two kinds, viz., macrospores and microspores.

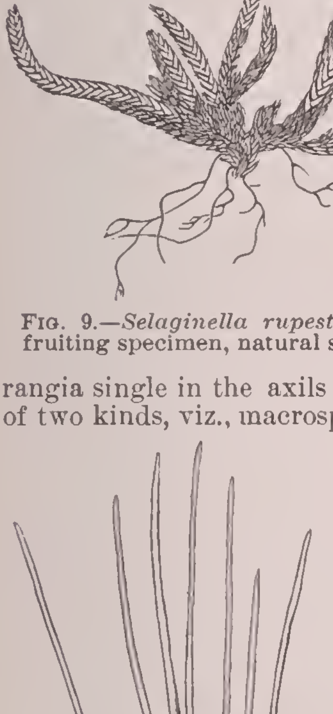

FIG. 10.—*Isoetes melanopoda*, of the Mississippi valley, slightly reduced.

Family 15. *Selaginelleæ*, contains the single genus *Selaginella* (334 species, mostly tropical, eight in U. S.), of small evergreen perennial plants.

Order 8. *Isoetaceæ*, the quillworts. Very short-stemmed plants; sporangia in the axils of the narrow, rush-like leaves; spores of two kinds, viz., macrospores and microspores.

Family 16. *Isoetaceæ*, aquatic or semi-aquatic plants of a single genus, *Isoetes*, containing forty-nine species, seventeen of which occur in North America.

Of the economic uses of fernworts little need be said. Pulu, used for stuffing pillows and cushions, is obtained from the woolly-hairy covering of the young leaves of a Sandwich island species of *Dicksonia*. The stems of a few species contain enough starchy matter to make them useful for food in some parts of the world, e. g. *Pteris aquilina* in Australia, and *Cyathea medullaris* on the Pacific islands. A few species are of doubtful value as astringent medicines. One species of horsetail (*Equisetum hyemale*) is the "scouring-rush," much used in Europe for polishing cutlery. *Lycopodium* furnishes the "lycopodium powder" of the shops. Many fernworts are in use for ornamental purposes, many ferns especially being grown in greenhouses and conservatories.

LITERATURE.—The reader is referred to the following works: K. Goebel, *Outlines of Classification and Special Morphology of Plants* (1887); Chr. Luerssen, *Handbuch der Systematischen Botanik* (vol. i., 1879); A. De Bary, *Comparative Anatomy of the Vegetative Organs of the Phanerogams and Ferns* (1884); W. J. Hooker and J. G. Baker, *Synopsis Filicum, or a Synopsis of all Known Ferns* (2d ed. 1883); J. G. Baker, *Handbook of the Fern Allies* (1887); D. C. Eaton, *The Ferns of North America* (2 vols., 1879–80); L. M. Underwood, *Our Native Ferns and their Allies* (1888). Also various papers by D. H. Campbell: *The Development of the Ostrich Fern* (*Mem. Bos. Soc. Nat. Hist.* 1887); *The Development of Pilularia globulifera* (*An. Bot.* 1888); *Development of the Prothallium and Embryo of Osmunda* (*An. Bot.* 1892); *The Affinities of the Filicinæ* (*Bot. Gaz.* 1890); *On the Relationships of the Archegoniata* (*Bot. Gaz.* 1891).

CHARLES E. BESSEY.

Fero′nia: an Italian goddess concerning whose cultus and myth little is known. She has been variously regarded as goddess of the earth, of the inferior world, of commerce, and of liberty. She appears to have been especially honored among the Sabines; and the chief seat of her worship was the town of Feronia, at the foot of Mt. Soracte.

Ferozepore: See FIROZPUR.

Ferrand, JOSEPH: See the Appendix.

Ferrand, MARIE LOUIS, Baron and Count of: soldier; b. at Besançon, France, Oct. 12, 1753. He served as a volunteer in the North American war for independence, and after 1790 distinguished himself in the French army of the West. In 1802 he commanded under Leclerc in the Santo Domingo expedition. After Leclerc's death (Nov. 1, 1802) and the capitulation of Rochambeau, Gen. Ferrand retreated to Santo Domingo city, where he withstood a siege by Dessalines (Mar., 1804), and was finally left in possession of the eastern or Spanish part of the island; here he resisted the advance of the revolutionists for several years, and was named captain-general by Bonaparte. The war between France and Spain led to the invasion of Santo Domingo by a Spanish force under the governor of Porto Rico; Ferrand was defeated at Palo Fincado, and shot himself on the battle-field Nov. 7, 1808. HERBERT H. SMITH.

Ferrar, NICHOLAS: religious enthusiast; b. in London, England, 1592; studied at Clare Hall, Cambridge, and took the degree of B. A. 1610; early manifested intense religious feeling, and pursued his studies with such diligence as to impair his health and necessitate a period of rest and foreign travel 1613–18. On his return to England he entered his father's business, that of a merchant in high standing in London and closely connected with the interests of the Virginia Company. Ferrar was prominent in the affairs of that company and active in opposing the attempts of the council to override the charter. He was elected to Parliament in 1624, but soon gave up public life to found the religious community at Little Gidding, in Huntingdonshire, with which his name is identified. With his wife and relatives, numbering some thirty persons, he passed a life of strict religious discipline, acting as chaplain for the little community. The observance of all the rules and exercises of the Church, including the attendance at worship twice daily, and nightly watches and prayers, brought upon the community the unfavorable comments of the Puritans, who characterized it as a "Protestant nunnery." All members of the society were required to learn a trade, and that of bookbinding was practiced. Ferrar died Dec. 4, 1637. He left some religious writings, among which are a harmony of the Gospels and translations of the *Divine Considerations* of Valdez and Lessio *On Temperance*. The establishment of Little Gidding suffered in the civil war. It was visited by Charles I. in 1642, but in 1647 the house and church fell into the hands of the Parliamentarians and the community was broken up. See Mayor, *Nicholas Ferrar, Two Lives* (Cambridge, 1855). F. M. COLBY.

Ferrara, fer-raa′raă: province of Italy; bounded N. by the main branch of the Po, E. by the Adriatic, S. and W. by the provinces of Ravenna, Bologna, and Modena. Area, 1,144 sq. miles. The ground is low, in many parts below the level of the Po, marshy, and unhealthful, but the soil is rich, and produces grain, flax, and hemp; there are also extensive pastures. In the Middle Ages Ferrara formed a dukedom belonging to the house of Este. In 1598 Clement VIII. united it to the Papal States. In 1860 it became a part of the kingdom of Italy. Pop. (1890) 250,430.

Ferrara: a fortified city of Northern Italy; capital of the province of the same name; 29 miles by rail N. E. of Bologna (see map of Italy, ref. 3–D). While this province belonged to the house of Este, Ferrara was the ducal residence and a city of great splendor and importance. It was a commercial center in Northern Italy; it developed a school of art of its own; Tasso, Ariosto, and Guarino lived here. Under the papal rule it went into decay, and it has now a somewhat deserted and melancholy appearance. The cathedral, the ducal palace, etc., with their collections of pictures, are of great interest. The university, founded in 1264, has an excellent library of 100,000 volumes. Ferrara is an archbishop's see. Pop. 28,814; commune, 86,000.

Ferrara, Council of: an ecclesiastical council whose sixteen sessions were in continuation of the Council of Basel, and which began on Jan. 8, 1438. In March of that year it was visited by the Byzantine emperor, John Palæologus, with 700 followers, including the Patriarch of Constantinople, the emperor hoping, by obtaining a union of the Eastern and Latin Churches, to gain the aid of the West against the Turks. On Apr. 9, 1438, the council was opened as a union council of the two Churches, and discussed principally their points of difference. In Jan., 1439, the council was transferred to Florence. See FLORENCE, COUNCIL OF.
Revised by S. M. JACKSON.

Ferrari, -raa'rēē, GAUDENZIO: painter; b. at Valduggia, in Piedmont, in 1484. His artistic training began under Girolamo Giovannone, and afterward at Milan he studied with Scotto, and as some assert with Bernardino Luini. He then went to Rome, attracted by the fame of Raphael, who received him as a colleague, and with whom he worked till he was recalled to his own country to execute important commissions in 1514. Lomazzo considers Ferrari as one of the seven principal painters the world ever had. His chief work is the *Crucifixion*, in a chapel of the sanctuary of Varallo. At Milan he painted the *Passion of Our Lord*, in the church of the Grazie, and *St. Paul in Meditation*. These two pictures were taken to Paris in 1797. Milan, Vercelli, Saronno, and other cities of Lombardy contain many of his works. He had a flourishing school of painters, who imitated him. D. in 1550. W. J. STILLMAN.

Ferrari, GIUSEPPE: philosopher and historian; b. in Milan in 1811; studied law at Pavia, but devoted himself subsequently to literature; published in 1835 a complete edition of the works of Vico; went in 1837 to Paris, where in 1839 he published *Vico et l'Italie*; was appointed Professor of Philosophy in 1840 at Rochefort, and afterward at Strassburg, but was removed on account of his communistic ideas; published in 1847 *Essai sur le Principe et les Limites de la Philosophie de l'Histoire*; was reinstated in his chair in Strassburg in 1848, but again removed, and returned in 1859 to Italy, where he was successively made professor in Turin, Milan, and Florence. Of his numerous works, the most remarkable are *Filosofia della Rivoluzione* (1851); *Histoire des Révolutions d'Italie* (4 vols., 1856–58); *Corso di Lezioni sugli Scrittori Politici Italiani* (1862–63). D. July 1, 1876.

Ferrari, PAOLO: dramatist; b. in Modena, Italy, 1822. His first comedy, *Bartolommeo il Calzalajo*, was produced in 1847. In 1852 he wrote his masterpiece, *Goldoni e le sue sedici commedie*, which was followed by *Parini e la Satira* (1857). Both these works are among the best of modern Italian comedies. A collection of his *Opere drammatiche* was published in Milan in 1877–80. He was made Professor of History at Modena in 1860, and later in the academy at Milan. D. in Milan, Mar. 10, 1889.

Ferraris, GALILEO: See the Appendix.

Ferreira, ANTONIO: poet; b. at Lisbon, Portugal, 1528; studied law at Coimbra, but took more interest in literature, and especially the works of the classic poets, whom he strove to imitate in the Portuguese tongue. With his model, Sá de Miranda, he was the founder of the patriotic classical school of Portuguese poetry. He is the author of many sonnets, odes, epigrams, and a tragedy of Inez de Castro; but the best of his works are probably his epistles. D. of the plague in 1569. Nothing of his was printed in his lifetime, but his son Miguel published a collection of his poems under the title *Poemas lusitanos* in 1598.

Ferrer, RAFAEL: Spanish Jesuit missionary; b. in Valencia, 1570. He was sent to Peru, was one of the founders of the Jesuit convent at Quito 1593, and subsequently labored among the Yumbos Indians. In 1601 he penetrated to the territory of the savage Cofanis, in the forest E. of the Andes, and established them in mission villages. From 1605 to 1607 he was employed, by order of the Viceroy of Peru, in exploring the Napo. Returning to his Cofani missions, he was murdered at San José by an Indian whom he had forced to renounce polygamy (1611). H. H. S.

Ferret [from O. Fr. *furet* < Mediæv. Lat. *furetus*, dimin. of *furo*, ferret; deriv. of Lat. *fur*, thief, because of its craftiness]: a carnivorous mammal (*Putorius furo*) of the weasel family, so closely allied to the European polecat (*Putorius fœtidus*) that many regard it as merely a delicate albino variety of the latter. It breeds freely with the polecat, has red eyes, a white or yellowish fur, and is so tender that the winters of England are too severe for it unless it is well housed. It is half-domesticated in Europe, but is probably of African origin. It is much employed in hunting rabbits and rats, but often has to be muzzled, as otherwise it will suck its victim's blood and leave the body in the burrow. It is fierce and treacherous, sometimes severely biting the hand of its master.

Ferric Oxide: See IRON.

Ferricy'anides [Mod. Lat. *ferri-*, a compounding form of *ferrum*, iron + Eng. *cyanide*. See CYANIDE]: a class of chemical compounds formed by the action of oxidizing agents upon ferrocyanides, from which an atom of the metal is extracted. For example, the potassium ferrocyanide (yellow prussiate of potash, $4KCy.FeCy_2$) is changed by the action of chlorine into potassium ferricyanide (red prussiate of potash, $6KCy.Fe_2Cy_6$). The most important of these salts are the potassio-ferrous ferricyanide (soluble Prussian blue) and Turnbull's blue (ferrous ferricyanide). Potassium ferricyanide is a delicate test for ferrous salts, and is invaluable in the laboratory. The ferricyanides may be regarded as compounds of ferric cyanide (Fe_2Cy_6) with some other cyanide.

Ferrier, fer'ri-er, DAVID, M. D., LL. D., F. R. S., F. R. C. P.: neurologist; b. at Aberdeen, Scotland, in 1843; educated at the University of Aberdeen, graduating as master of arts in 1863, with double first-class honors in classics and philosophy. In the same year he gained the Ferguson scholarship in classics and philosophy, open for competition to graduates of the four Scotch universities. In 1854 he entered the University of Heidelberg, where he prosecuted psychological studies and began the study of anatomy, physiology, and chemistry; in 1865 he began his medical studies proper at the University of Edinburgh, where he gained most of the university medals in his various classes, and where he graduated M. B. in 1868, with first-class honors. He continued at the university as assistant to Dr. Laycock, Professor of the Practice of Physic, until 1869, when he became assistant to a practitioner at Bury St. Edmunds, where he remained for a year, meanwhile prosecuting his researches on the comparative anatomy and histology of the brain. In 1868 he received his M. D. degree, and was awarded the gold medal for his thesis, *Comparative Anatomy of the Corpora Quadrigemina*. In the same year Dr. Ferrier removed to London, and in 1871 was appointed Demonstrator of Physiology in King's College. In 1872 he was appointed Professor of Forensic Medicine in the same institution, succeeding Dr. Grey, whom he aided in the preparation of the fourth and fifth editions of his *Principles of Forensic Medicine*. This position he retained until 1889. He was appointed junior physician to the West London Hospital in 1872, assistant physician to King's College Hospital in 1874, and full physician in 1880. He was assistant physician to the Hospital for Epilepsy and Paralysis, Regent's Park, from 1877 till 1880, when he was appointed physician to the National Hospital for the Paralyzed and Epileptic. Besides numerous papers on questions touching cerebro-spinal disease, Dr. Ferrier has published *The Functions of the Brain* (1876 and 1884) and *The Localization of Cerebral Disease* (Gulstonian Lectures, 1878). He was one of the founders and remains an editor of *Brain: a Journal of Neurology*.

Ferrier, JAMES FREDERICK: moral philosopher; b. in Edinburgh, Scotland, June 16, 1808; son-in-law and nephew of Prof. John Wilson; graduated at Magdalen College, Oxford, in 1831; became Professor of History at Edinburgh University in 1842, and of Moral Philosophy and Political

Economy at St. Andrews in 1845. *Institutes of Metaphysic, the Theory of Knowing and Being*, was his chief work, though he edited the *Works* of his father-in-law in 12 vols. Ferrier died at St. Andrews, June 11, 1864. His *Lectures on Greek Philosophy*, with a *Life* prefixed, were published in 1866.

Ferrier, fā'ri-ā', Joseph Marie Augustin Gabriel: figure and portrait painter; b. at Nîmes, France, Sept. 29, 1847. Pupil of Lecocq de Boisbaudran; Grand Prix de Rome 1872; first-class medals, Paris Expositions, 1878 and 1889; Legion of Honor 1884. A strong draughtsman whose work is solid and vigorous. *David, Conqueror of Goliath*, Nîmes Museum; *St. Agnes, Martyr*, Rouen Museum, are among his works. Studio in Paris. W. A. C.

Ferris, Isaac, D. D., LL. D.: clergyman; b. in New York, Oct. 9, 1798; graduated at Columbia College in 1816, having served for a time during his college course in a military company during the war of 1812; taught in the Albany Academy for one year; studied theology under Dr. J. M. Mason two years, and in the Rutgers Seminary at New Brunswick, N. J., one year; was licensed to preach in 1820; held Reformed Dutch pastorates at New Brunswick, N. J., 1821–24; at Albany, N. Y., 1824–36; in the Market Street church, New York, 1836–53; chancellor of the University of New York city 1852–70. He found the university in a depressed state, and largely by his own personal efforts brought it to a condition of prosperity. He was Professor of Moral Science and Christian Evidences 1853–70, and acting Professor of Constitutional and International Law 1855–69. Previous to his chancellorship he was for a time principal of the Rutgers Institute for young women. D. at Roselle, N. J., June 16, 1873.

Fer'ro: the smallest and least fertile of the Canary islands; situated in lat. 27° 45' N. and lon. 18° 7' W.; area, 106 sq. miles. As it is the most westerly isle of the archipelago, it was by ancient geographers considered the most westerly point of the world, and they drew through it the first meridian, which is still used as the prime meridian on maps designed to show all of Europe in the eastern hemisphere. Pop. (1887) 5,892.

Ferrocy'anides [Mod. Lat. *ferro-*, a compounding form of *ferrum*, iron + *cyanide*]: a class of chemical compounds formed by uniting ferrous cyanide with some other cyanide. Thus ferrous cyanide ($FeCy_2$), added to four equivalents of potassium cyanide (KCy), gives $K_4Fe''Cy_6 = 4KCy.Fe''Cy_2 =$ the ferrocyanide of potassium (yellow prussiate of potash), an extremely valuable chemical reagent; useful also in pharmacy, and especially in dyeing and calico-printing. Refuse animal matters, iron-filings, and commercial potash are melted together, and the mass is poured into hot water, filtered, evaporated, and repeatedly crystallized, yielding a very pure salt; but several other processes have been invented. Ferric ferrocyanide is commercial Prussian blue.

Fer'rol: a strongly fortified seaport of Spain; province of Corunna; 11 miles N. E. of Corunna (see map of Spain, ref. 11–B). Its harbor, surrounded by splendid dockyards, is formed by an inlet of the Bay of Betanzos, so narrow as to admit only one ship of the line at a time, and defended by the castles of San Felipe and Palma. Ferrol is one of the chief naval arsenals of Spain, and has sardine-fisheries and manufactures of naval stores, cotton, and leather. Pop. (1887) 25,701.

Ferrotype: See Photography.

Ferry (Fr. pron. fā'ree'), Jules François Camille: advocate, journalist, and statesman; b. at St.-Dié, France, Apr. 5, 1832; was admitted to the Paris bar in 1851 and became connected with the *Gazette des Tribunaux*. In 1865 he contributed to the *Temps*, obtaining notoriety in 1868 by his attacks on Baron Hausmann's administration of Paris. In 1869 he was returned to the Corps Législatif from Paris, and in Sept., 1870, became a member of the government of the national defense; Minister of Public Instruction and Fine Arts 1879–80 and 1882; president of the council 1880–81; Prime Minister and Minister of Public Instruction 1883–85. In 1880 he caused a great excitement in France by a paragraph of his education bill, which forbade members of the unauthorized orders (Jesuits) to teach in the schools. The paragraph was rejected by the senate, but the minister succeeded by enforcing some old laws long fallen into oblivion. However, this led to the downfall of the ministry. He formed another cabinet, and remained Prime Minister until 1881, but was forced to resign on the Tunis question. In 1883 he again became Prime Minister; the result of his colonial policy led to the war in Tonquin, the unsatisfactory issue of which culminated in the overthrow of M. Ferry in 1884. He retired one of the most unpopular men in France. In 1887 he was an unsuccessful candidate for the presidency, and just after the election he was shot by Aubertin. He retired from public life for a time, but was re-elected to the chamber in Dec., 1890, and was soon after made senator. Feb. 25, 1893, he was elected president of the French senate. He was the most distinguished of the few great men in France who were not involved in the least in the Panama scandal, and he was regarded as almost certain to succeed to the presidency of the republic on the retirement of M. Carnot. He died Mar. 17, 1893, from the effects of the wound received in 1887. He was one of the most brilliant of French journalists, and one of the strongest leaders in French political life. His rise to power again after the disaster that befell his fortunes in 1884 has few parallels. Revised by C. H. Thurber.

Ferry, fer'ri, Orris Sanford: U. S. Senator; b. in Bethel, Conn., Aug. 15, 1823; graduated at Yale College in 1844, and was admitted to the bar in 1846; in 1847 was lieutenant-colonel of the first division of Connecticut militia; in 1849 judge of probate for the district of Norwalk, Conn.; State Senator in 1855 and 1856; in 1856–59 State attorney for the county of Fairfield; in 1859 was chosen Representative to Congress from Connecticut. Served as colonel and brigadier-general in the U. S. volunteers in the war of 1860–65, and was then chosen U. S. Senator from Connecticut for 1867–73. In 1872 he was re-elected to the same office for a second term. D. at Norwalk, Conn., Nov. 21, 1875.

Ferry (Fr. pron. fā'ree'), Paul: a French Protestant divine, noted for his irenic proclivities. He was born at Metz, Feb. 24, 1591; his mother was sister to Attorney-General Jolly. Paul was destined for the ministry, and educated at the Huguenot seminary in Montauban, where, while yet a student, he issued a volume of poems of considerable merit. In 1612 he took holy orders, and returned to his native place to become pastor of a congregation which he served until his death July 28, 1669. Ferry was distinguished for his eloquence, and ranked second only to Calmet in all Lorraine. He was not only the pride of Protestants, but was beloved also by Roman Catholics, and gave himself so largely to efforts not only for a union of all Protestants, but of all Christians, that he was surnamed The Pacificator. He corresponded for this purpose with the great Scotch irenic, John Dury, and with the noted French ecclesiastic Bossuet. (See *Œuvres de Bossuet*, Versailles ed., vol. xxv.) The correspondence with Bossuet was provoked by Ferry's *Catéchisme Général de la Réformation* (Sedan, 1654), which, holding that the corruption of the Church had called for the Reformation, was replied to by Bossuet, and thus opened the way for an exchange of opinions on many topics, until the irenical subject became uppermost. Ferry is charged with having received a pension of 500 crowns from the Government, under Richelieu, for agitating the reunion of Roman Catholics and Protestants in France. His receipt for the amount is said to exist in the National Library at Paris. Ferry wrote much, but published little. His most important works are *Scholastici Orthodoxi Specimen* (Geneva, 1616); *Le dernier désespoir de la tradition contre l'écriture* (Sedan, 1618; defended against attacks in 1624); *Vindiciæ pro Scholastico orthodoxo adversus Leon. Perinium Jesuit.* (Leyden, 1630). See Haag, *La France Protestante.*

Ferry, fer'ri, Thomas White: U. S. Senator; b. at Mackinaw, Mich., June 1, 1827; entered early upon a business life; removed to Grand Haven; sent to the State Legislature in 1850, to the State Senate in 1856; long an active member of the State Republican committee; a vice-president of the Chicago convention of 1860; member of Congress 1864–71; U. S. Senator 1871–83; chosen president *pro tem.* of the Senate; became acting Vice-President of the U. S. on the death of Henry Wilson, Nov. 22, 1875; was reelected to the Senate Jan. 17, 1877, and was several times elected president *pro tem.* of the Senate. After his term expired in 1883 he spent several years in foreign travel. D. at Grand Haven, Mich., Oct. 14, 1896.

Ferryland: port of entry of Newfoundland and the capital of Ferryland district; 44 miles S. of St. John's. It was settled by Lord Baltimore in 1623, and called Avalon; was deserted in consequence of disturbances by the French. Ruins of the old batteries remain. It has a good harbor and a lighthouse. Pop. 680.

Fertilization of Plants: the process by which the contents of two sexual cells are blended to form the starting-point in a new development. In flowering as well as flowerless plants the mechanism of reproduction is so complicated that some knowledge of vegetable physiology is necessary to its comprehension. See FLOWER and PHYSIOLOGY, VEGETABLE.

Fertilizers [from Lat. *ferti'lis*, fertile, deriv. of *ferre*, bear]: substances which enrich the soil and promote the growth of plants. Agriculturists distinguish usually between home-made and artificial mineral or commercial fertilizers. The former consist mainly of the various refuse matters, animal and vegetable, incidental to the particular farm operations carried on. The latter include a large number of articles which are obtained elsewhere than from the farm. The use of animal secretions of every description, and of all kinds of vegetable refuse matter in the form of barnyard manure and farm composts, has been known in agriculture from time immemorial, while the application of the commercial fertilizers can scarcely be dated further back than to the close of the eighteenth or the beginning of the nineteenth century. Lime, salt, saltpeter, oyster-shells, gypsum, and ground bones are among the first more prominently mentioned commercial fertilizing substances. The consumption, however, of these and similar articles remained quite limited until Prof. Justus von Liebig made his famous exposition of the relations which exist between the constituents of the soil and the growth of plants.

The extensive use of commercial or artificial fertilizers is one of the most important features in the present management of farms. Their merits are so generally recognized that a rational and thorough system of agriculture is thought impracticable without their assistance, particularly when it is proposed to apply them for the purpose of rendering the stable manure a complete fertilizer for the various crops under cultivation. The successful introduction of these fertilizers furnishes one of the most striking illustrations of the influence and the value which exact modes of inquiry with well-defined questions have over mere experimenting without a previous correct appreciation of the agencies and the principles involved in the operation.

Agriculture, although one of the oldest industries, was, comparatively speaking, long deficient in rational explanations of many of its modes of operation. Stable manure, ashes of plants, and various other means, as fallow and rotation of crops, irrigation, and drainage, etc., had been employed for ages in the interest of a successful fertilization of cultivated lands, yet no satisfactory explanation regarding their respective action was offered until quite recently —a fact which readily accounts for their repeated failures in former ages. The state of the natural and the physical sciences previous to the beginning of the nineteenth century rendered in many instances a correct exposition of the processes involved impossible. To enter with any reasonable prospect of success upon the discussion of so intricate questions as the relation of animal secretions to plant-life required not only a familiarity with the composition of the air, the water, and the soil, and the various reactions of these agencies upon each other and on plant-life under the influence of light and heat, but also a thorough knowledge of the various constituents of plants and animals, their respective organizations, and the functions of their assimilative, respiratory, and excretory organs. Without any knowledge of the nature of the previously mentioned important physiological processes peculiar to animal and vegetable life, not even an approximately correct appreciation could be entertained regarding the mutual dependency of plants and animals in the economy of farming. Modern agriculture rests its claim of real progress, as compared with previous centuries, less on the introduction of new means for the maintenance of an increased production of cultivated lands than on a more efficient because more rational use of the best features of well-known modes of cultivation. It ascribes the present advanced position, and its claims of being a scientific art, to the accumulated results of the scientific researches of many of the most illustrious scientists of the eighteenth century in every branch of the natural and physical sciences, and recognizes in Lavoisier, Sir Humphry Davy, and Liebig the foremost and most influential minds during its various stages of progress. One of the most important services which the experimental sciences have rendered to practical agriculture consists in the elucidation of the fact that it is essential to a successful cultivation of the various crops to restore without delay to the soil those of its constituents which the crops have abstracted.

Not long before the middle of the nineteenth century the mineral constituents of plants were looked upon as being merely of incidental occurrence, and without any essential bearing upon their development: these views have been entirely changed in consequence of careful analytical investigations. In comparing the ash-constituents of different plants it was noticed soon that certain mineral elements were present in a more or less conspicuous proportion in every plant. The general occurrence of these substances led ultimately to the quite natural assumption that their presence might be necessary for the performance of some physiological process of vegetable life. These important relations were in their general outlines for the first time pointed out in the year 1840 by Justus von Liebig in his work on *Organic Chemistry in its Application to Agriculture and Physiology*. Subsequent additional actual experiments, instituted under well-defined circumstances for testing his views, not only confirmed their correctness in their main features, but furnished much additional information in regard to the requirements for a successful cultivation of plants. It has been learned, also, that of all the substances which enter into the composition of plants, only potassium, calcium, magnesium, iron, sulphuric acid, phosphoric acid, and carbonic acid, besides some nitrogen containing compounds, as ammonia or nitric acid, and water, are indispensable for their growth; while the functions of a few other elements quite frequently noticed in plants, as sodium, silicium, chlorine, etc., remain still less explained. As soil and air were thus proved to be equally important contributors of the essential articles of plant-food—the former furnishing the mineral constituents of plants, the latter mainly their organic portion—it became evident that the atmospheric resource of plant-food could only serve its purpose in the same degree as the soil-constituents present would be able to support them in the production of vegetable matter. To store the farm-lands with the largest possible amount of available essential mineral constituents of plants in particular has thus become the most important point of consideration in practical agriculture. The intelligent farmer recognizes this principle in the selection of his modes of operation. An early experience has taught him that the soil he cultivates differs more or less, as a general rule, in its physical condition and its chemical composition. Chemists have proved to him that any improvement in the former direction tends to render the natural and original resources of the soil treated sooner and in a larger degree available, and thus hastens on its final sterility in consequence of the production of larger crops. Superior mechanical treatment of the soil before seeding—rotation of crops, fallow, irrigation, and drainage—is for this reason resorted to mainly for the purpose of turning the natural resources of the soil to better account, either in consequence of a more uniform distribution of its plant-food or at the expense of time; while a continued unimpaired production is secured by returning in the form of some suitable fertilizer the soil-constituents which the removed crops have abstracted. The selection of a fertilizer is for economical reasons always made with reference to the nature and the amount of available plant-food in the soil under cultivation, and to the special requirements of the crops to be raised. Most home-made fertilizers are of a compound nature, while the commercial or artificial fertilizers supply usually but one, two, or three articles; they are for this reason frequently called "special fertilizers." Stable manure, although the most complex of home-made fertilizers, can not be considered a complete one as long as farmers sell a part of their produce. The commercial fertilizers furnish excellent means to correct the composition of the stable manure obtained under any system of agricultural industry, and to make it a complete fertilizer for the crops under cultivation. Although the stable manure represents still by far the largest bulk of the fertilizers used in general mixed farm-management, the demand for commercial fertilizers is already so great that their manufacture ranks among the most extensive branches of chemical industry. Their importance can not be overestimated in regard to the maintenance of the fertility of farm-lands as long as farmers still allow a fair portion of their home fertilizing material to waste, and as long as the sewage question of the centers of social life remains practically unsolved. Bones, mineral phosphates (see APATITE), and superphosphates—the latter frequently mixed with nitrogenous animal matter, as fish, blood, meat, etc., or ammonia compounds and nitrates—have been for years the main portion of commercial fertilizers. Phosphoric acid, lime, sulphuric acid, and nitrogen were thus for years duly represented in the market, while potassa and magnesia were less attended to. The sources of potassa for fertilizing purposes consisted formerly largely of niter and wood-ash; the former proved too expensive, and the latter insufficient in quantity, to encourage a more general application for agricultural use. The discovery of large mineral deposits at Stassfurt and elsewhere, containing both potassa and magnesia in soluble form, gave a peculiar interest to extensive and systematic agricultural experiments, by which their great value has been abundantly demonstrated. Many of the artificial fertilizers have acquired also an additional value on account of their special character, and thus their special action on the quality of various important crops for industrial purposes, as tobacco, sugar-beets, etc. The study of the peculiar influence of each article of plant-food in reference to the production of vegetable substances, such as starch, sugar, oil, etc., has engaged the particular attention of agricultural chemists.

The fact that important pecuniary advantages in the production of farm and garden crops may be secured by a judicious use of commercial fertilizers is universally recognized. As the success depends for obvious reasons in a controlling degree on favorable physical conditions and a definite chemical composition of the fertilizing materials to be used, a system of state inspection has been introduced to secure the desired information. Germany has taken the lead in that direction from an early date. In many parts of the U. S. the same course has been adopted. The laws adopted in different States for the regulation of the trade in commercial fertilizers as a rule agree in the following point: every package of material offered for sale for manurial purposes must be accompanied by a plainly fixed statement stating the amount of nitrogen, potash, and phosphoric acid it contains. CHARLES A. GOESSMANN.

Fes'cennine Verse [transl. of Lat. *carmen Fescenni'num*, pl. *versus Fescenni'ni*; *Fescenninus*, deriv. of *Fescennia*, name of an Etruscan city]: in ancient Italy, a rude and generally extemporaneous kind of poetry, often roughly satirical and licentious, sung at first in rustic communities at harvest-homes and weddings, and afterward introduced into Rome, where it was long popular. This verse was originally in form a dialogue.

Fesch, JOSEPH: cardinal: half-brother of the mother of the first Napoleon; b. at Ajaccio, Jan. 3, 1763; was a commissioner attached to the French army of Italy 1795–99; Archbishop of Lyons Apr., 1802; ambassador to Rome and cardinal 1803; grand almoner and senator 1805; president of the Council of Paris 1811; then retired in disgrace to Lyons for opposing Napoleon 1811; on Napoleon's second fall in 1814 retired permanently to Rome, and there d. May 13, 1839. His correspondence with Napoleon was published by Albert Du Casse in his *Histoire des négociations diplomatiques* (3 vols., Paris, 1855), vol. i.; his *Life* by J. B. Lyonnet (2 vols., Lyons, 1841).

Fescue [corruption of *festue* < M. Eng. *festu*, a straw, from O. Fr. *festu* > Fr. *fétu* < Lat. *festu'ca*, stalk, straw]: any one of numerous species of grass of the genus *Festuca*, which abound in most temperate regions of the globe. The sheep's fescue and the tall fescue (*Festuca ovina* and *elatior*) are excellent pasture and forage grasses. Peru has the *Festuca quadridentata*, which is reputed poisonous to stock. The European fescues are more numerous and important than the American.

Fessenden, THOMAS GREEN: poet and agricultural writer; b. at Walpole, N. H., Apr. 22, 1771; graduated at Dartmouth College 1796. He studied law, but the success of a poem, *Jonathan's Courtship*, led him to literature. In 1803 he wrote in London *A Terrible Tractoration*, a satirical poem; in 1804 settled in Boston, publishing there, in 1806, *Democracy Unveiled*, a political poem, etc. Afterward he edited the *Weekly Inspector* at New York city two years. In 1812 practiced law at Bellows Falls, Vt., removing to Brattleboro, Vt., in 1815, where he published *The Reporter*. From 1816 to 1822 he edited *The Intelligencer* at Bellows Falls, Vt. From that time until his death, at Boston, Nov. 11, 1837, he published *The New England Farmer* at Boston, Mass., and edited *The Horticultural Register*. Among his works are *Original Poems*; *The Ladies' Monitor* (1818); *American Clerk's Companion* (1815); and *Laws of Patents for New Inventions*.

Fessenden, WILLIAM PITT, LL. D.: statesman; b. at Boscawen, N. H., Oct. 16, 1806; graduated at Bowdoin College 1823; admitted to the bar 1827; began the practice of his profession at Bridgeton, Me., removing two years later to Portland, Me., where he continued to reside, and with whose interest and progress he was ever identified. Chosen as a Whig to the State Legislature in 1832, though the youngest member of that body, he attained distinction as a legislator and debater; refusing further political preferment, he devoted himself (1832–39) to his profession, rising to the highest rank as counselor and advocate. He was, however, returned to the Legislature in 1840, and in 1841–43 represented his district in the Congress of the U. S., where he made a brilliant record as an eloquent and forcible debater; was returned to the State Legislature in 1845 and 1846, and again in 1853, when he was elected to the U. S. Senate as a Whig, though the Legislature was Democratic. He took his seat Feb., 1854, and was placed upon the finance committee, and the following month made one of the most eloquent and effective speeches delivered against the Nebraska bill, establishing him at once as a leading member of the Senate. Re-elected in 1859, he was made chairman of the finance committee, and throughout the civil war rendered valuable service as such, by aiding the Secretary of the Treasury to maintain the national credit, as well as by his eloquence and counsel in the Senate chamber. In 1864, on the retirement of Mr. Chase from the Secretaryship of the Treasury, he accepted that portfolio, and discharged the duties of the office during a most critical period of the nation's finances until Mar., 1865, when, owing to his delicate health and the overwhelming duties of the office, he resigned and resumed his seat in the Senate, to which he had been re-elected. On the conclusion of the impeachment trial of President Johnson, he cast his vote for acquittal, in accordance with his opinions, which he set forth fully in an able and logical speech. For this act he was severely censured by his party, which was strong for conviction, but no taint of suspicion could be attached to the integrity of his vote, and he regained its confidence upon the subsidence of momentary excitement, and retained his place in the Senate as a leading debater and member of the party. He was for a number of years an invalid, and suffered from a chronic complaint that finally hastened his death, which occurred at Portland, Me., Sept. 8, 1869. Revised by C. K. ADAMS.

Fess'ler, IGNAZ AURELIUS: author; b. at Czurendorf, Hungary, May 18, 1756; was at first a Capuchin (1773), but in 1791 became a Protestant; was 1785–87 Professor of Oriental Languages at Lemberg, and in 1809 received the same chair at St. Petersburg, and afterward was a prominent Lutheran official in Russia. Besides novels, Masonic treatises, etc., he wrote *Marc-Aurel* (a romance, 1790–92); *Matthias Corvinus* (1793); *Aristides und Themistokles* (1792); *Attila* (1794); a history of Hungary (1812–25); and an autobiography (1826; 2d ed. Leipzig, 1851). D. at St. Petersburg, Dec. 15, 1839.

Festival: See FEAST.

Fes'tus (in Gr. Φῆστος), PORCIUS: procurator of Judæa; succeeded Antonius Felix A. D. 60, while Nero was emperor. On his arrival in his province he found the apostle Paul a prisoner, examined his case, refused to gratify the vindictive feelings of the Jews against him, and would have set him at liberty, but as the apostle had appealed to Cæsar (i. e. Nero), he sent him to Rome to lay his case before the emperor. The disturbances caused by the robbers, assassins, and magicians which had prevailed in the time of Felix still continued under the government of Festus, and he was obliged to use vigorous measures to subdue them. Died about two years after his appointment, and was succeeded by Albinus. Revised by G. L. HENDRICKSON.

Festus, SEXTUS POMPEIUS: a Latin grammarian and lexicographer; of uncertain date, but after Martial (A. D. 100), from whom he quotes, and before Charisius and Macrobius (400 A. D.), who quote from him. No particulars of his life have come down apart from his connection with the great work of VERRIUS FLACCUS (*q. v.*), *De Significatu Verborum*. Festus prepared an abridgment of this work, which he arranged under the letters of the alphabet into twenty books, following the order and authority of Flaccus, introducing additional matter from his other writings, but rejecting certain points, which he intended to treat of in his *Priscorum Verborum cum exemplis*. This abridgment, entitled *De Significatione Verborum*, caused no doubt the loss of the original work of Flaccus, but it would have been, even in its reduced form, an exceedingly valuable treasure-house of the forms of Latin words and of Roman antiquities and mythology. In the eighth century, however, Paulus Diaconus (*q. v.*) made a meager abridgment of Festus's work, adapted to the wants of his own time, and thus no doubt caused the discontinuance, and finally the disappearance, of the latter. One manuscript only of the eleventh century, now preserved at Naples, survived, but in a very imperfect condition, as it began with the middle of the letter *M*, and part of the remainder was defaced by fire. The labors of many scholars have been bestowed on the restoration of this important work, from some slight fragments of the original treatise of Flaccus, from the surviving MS. of Festus, and the compend of Paulus. The results are presented in their best and most complete form by K. O. Müller (Leipzig, 1839), who has printed the several works in separate columns. Part I., giving the text of a new edition by E. Thewrewk de Ponor, appeared in Budapest, 1889. Revised by M. Warren.

Fetials, or **Fecials** [in Lat. *fetia'les*. Etymology unknown]: a body of ancient Roman priests who had charge of certain international affairs, acting as heralds in the announcement of war to a foreign state, and presiding over the solemnities attending the return of peace. They were probably twenty in number, were anciently citizens of high birth, were chosen for life, and were called *patres patrati*. Their duties were performed with much ceremony. Their rites and regulations constituted a code known as the *Jus fetiale*.

Fetich: See Fetish.

Fet'id Gums: in pharmacy and medicine, certain gum-resins which are the concrete natural juices of umbelliferous plants. They have a strong, unpleasant, alliaceous odor, whence the name. They are antispasmodics and expectorants. Assafœtida, ammoniac, galbanum, and sagapenum are the best known.

Fétis, fā'tees', François Joseph: writer on music and biographer; b. at Mons, Belgium, Mar. 25, 1784; studied at the Conservatory of Paris in 1800; organist and Professor of Singing at Douai in 1813; director of the conservatory at Brussels in 1833; member of the Academy of Belgium in 1845; musical executor of Meyerbeer, producing his *Africaine* in 1864; officer of the Legion of Honor in 1864; grand officer of the Order of Leopold 1869. He published treatises on music, *Biographie universelle des musiciens* (Universal Biography of Musicians, 8 vols., 1834–44; 2d ed. 1868–70) and *Histoire générale de la musique* (General History of Music, 8 vols.). Founded and edited the *Revue Musicale*. D. in Brussels, Mar. 27, 1871.

Fetish, fee'tish [viâ Fr. from Portug. *feitiço*, artificial, applied by the Portug. in Africa to native objects of worship < Lat. *facticius*, deriv. of *facere*]: an object worshiped by the degraded tribes of Senegal and Congo. A fetish is not an idol, and is not properly a symbol, but is looked upon as the actual and visible dwelling-place of a preternatural power. It may be thus some fixed object of nature, as some lofty mountain, a grove, or a tree; it may be an animal, as a snake, a snail, a crocodile, and often a sheep or a goat; or it may be any object on which the whim or the fancy has fixed, as the beak of a bird, the fin of a fish, the hoof of a quadruped, a stone, a block, a feather, a stick, a nail, or almost anything else that can be named. One thing will do about as well as another for a fetish, provided the worshiper can believe that his god resides therein; and this he is easily led to do in reference to anything which pleases or is useful to him. A fetish is often worn about the person or hung up in the hut as a talisman, and is employed in the most disgusting rites of superstition and witchcraft. Fetishism shows the religious instinct degraded into its lowest forms. See Animism.

Fetlock [M. Eng. *fetlok*, *fitlok*, from Scand., but etymology uncertain. The second element is equal to Eng. *lock* (of hair): Icel. *lokkr*, and the first probably equal to Eng. *foot* (cf. Icel. *fet*, a step)]: the point on a horse's leg behind the pastern-joint. The fetlock is covered by a tuft of long hair.

Feud: a legal term used to designate land held of a superior, on condition of rendering him service. The term is opposed to *allodium*, the absolute or ultimate property, which continued to reside in the superior.

Feudalism: See Ethnology and Feudal System.

Feudal System, The [*feudal* is from Mediæv. Lat. *feuda'lis* (cf. Fr. *féodal*), deriv. of *feudum*, from O. H. Germ., *fihu*, *fehu*: Goth. *faihu*, cattle money. See Feoffment and Fee]: a form of society, prevalent in Europe during the Middle Ages. In the Roman empire, as in all compact states where the central power has its due degree of strength, the individual was placed directly under the supreme magistrate, and all authority of subordinate officers was exercised in his name. This dependence of the freeman in the direct way on the head of the state continued in the Germanic kingdoms, after they superseded the Roman power, for a length of time. In the tenth century, however, a new set of institutions began to work, rooting out and breaking up the institutions of the state proper. To them is given the name of *feudalism*, *feudality*, or *the feudal system*. They developed themselves, without absolutely destroying all earlier institutions, in France, England, Germany, Spain, Italy, and in the neighboring lands of Hungary, Poland, and Denmark. They appeared also in other parts of Europe, and out of Europe in the Christian kingdom of Jerusalem. If traced back, they must be brought into connection with the Germanic element which diffused itself by invasion over a large part of Europe, while yet there was, properly speaking, no feudalism among the invaders. It is a mistaken notion that the invading armies consisted of bands under chieftains to whom the conquering kings gave lands for their services, and who in turn gave lands to their *comitatus* or retainers. Feudalism was a German growth, but had no such antique and tangible shape. It grew up, by little and little, out of institutions which were ripened in the Carolingian period, no one of which is enough of itself to explain feudalism, and which in combination could not have brought it about but for concurrent historical causes.

Feudalism controlled society and government for several centuries and began to grow weak at the same time that the countries of Europe began to be nationalized; that is, at about the end of the fourteenth century. It was, however, not the sole, but only the controlling, power of society. The Church, the suzerains, the towns, were at heart its foes, although they put on some of its forms.

The word *feudum* in Mediæval Latin, from which *feudal* is derived, did not come into use until about the ninth century, when it began to take the place of *beneficium*, which denoted a property given for use on certain conditions, the ownership of which did not go over with the usufruct. *Feudum* and *allodium* included the two tenures by which property was held in independent right—in fee-simple, as we say—and by which it was held on condition of performing a service to the former owner.

But what was the feudal system? It may be defined as that political form in which there was a chain of persons holding land of one another on condition of performing certain services, beginning with the serfs and lowest freemen, and ascending through *milites*, or knights, to the arrière-vassals and immediate vassals of the suzerain. Every member in the chain, from the milites upward, was bound to his immediate superior, held land from him, took the oath of allegiance to him, and became his man. The suzerain, then, had, when the system was pure, no direct connection with any but the great vassals, and they, with others, it might be, under them, were lords in their districts. The legal fiction was that the land was originally in the hands of the suzerain (that is, all the land which was not allodial, of which there was much in Germany, but in France very little); that allegiance and certain services fixed by custom were due to him; and that for neglect to perform these services the lands and all rights going with them could be forfeited. With the lands, down to the holders of knights' fees, jurisdiction was connected, as well as legislation within certain limits, military command over the fief-holders of the barony, and, to a considerable extent, the right of coining money, together with that of giving charters. In short, nearly all sovereign powers passed over from the old sovereign—who now must be called a *suzerain*, to show his altered position—to his vassals; so that society was disintegrated, as much as it would be if every county in one of the U. S. had the right of holding courts of itself and of passing laws. This it is that formed the most marked peculiarity of the system, and obstructed for centuries all uniform development, all national existence, all unity. In this disunited condition there grew up endless diversities of customs; there was for a long time no general law; every feudal connection stood on its own foot, and was subject to compact between the suzerain and the vassal, a lord and an inferior. For instance, if a baron died and left no son, females could not inherit, but in the first part of the twelfth century they began to gain this right in Eastern France, England, Castile, Aragon, and the kingdom of Jerusalem. By this change it was brought about that females could inherit the throne, this being viewed in the light of a fief. And thus the law of succession in some monarchies took more or less definitely a new shape. This is one of many instances which will justify the statement that in European feudalism public or political relations were confounded with private relations—political rights were blended with private rights.

The origin of the system has been traced by some writers to the Roman custom in the empire, from the time of Alexander Severus, of protecting the borders toward Germany by military colonies, in which the soldiers received land and were bound, they and their descendants, to military service. This, which was by no means confined to the Roman empire, but is seen in other parts of the world, was perhaps suggested by a Germanic usage. As Waitz says (*Deutsch. Verfassungsgesch.*, i. 376), "the way in which, among various Germanic tribes, Scandinavian as well as Teutonic, military service was united with possession of land, gives a probability to the opinion that even in the earliest times a certain connection between them subsisted." But this is the least characteristic element of the feudal system. It does not account for subinfeudation, or for the political powers which the fief-holder had, which was the striking characteristic of feudalism.

Neither can the *comitatus*, or relation of the *comites* or companions to the *princeps* or chief, as existing among the Germans of the time of Tacitus, account for feudal institutions. That was a relation of any chieftain to his companions, and not of a German king only to his followers. And that relation conveyed no political authority.

The true account of the matter seems to be this. Under the first race of Merovingian kings the kingdom was modeled much after the plan of the Roman empire. The county was assigned to a man (a *comes* or "count") who was both civil and military ruler, who commanded the forces of the county, administered justice, had no hereditary right to jurisdiction, but who might have grants of land for his lifetime, or on some other condition, from the king.

During the reigns of the later Merovingians, and after the East Frank or Carolingian dynasty got possession of the throne, there were growing up several institutions in some respects new, in some respects analogous to older Germanic ones. These were vassalage and commendation, the beneficiary system, and immunity or exemption. To give a complete exposition of these elements of new social and political forms, and indeed to exhibit full-grown feudalism in its details, would require far more space than can be here afforded. A brief outline is all that can be given.

1. *Beneficia and the Beneficiary System.*—This was a relation of *property*, and long before the feudal system proper grew up *beneficium* denoted a gift of property, especially of landed property, in usufruct only, with reversibility to the donor or his heirs. The early meaning still appears in the word "benefice," in its sense of an ecclesiastical property, the use of which is given to a clergyman as officiating in a certain parish. The donor or grantor of the *beneficium* might be a king, any lay person, any ecclesiastical corporation; while the grantee might be any man, even the king himself, or a female, or a corporation, as before. *Beneficia* given for a short term of years or revocable at pleasure were called *precaria*—that is, obtained by the prayers or requests of the beneficiary; and the short, uncertain tenure of such holdings illustrates the modern word "precarious." But the distinction between *beneficia* and *precaria* is by no means a perfectly exact one. Such precaria were given, for instance, where a donor of land to a monastery in full ownership received it back in usufruct, with perhaps some of the older Church property besides.

Beneficia are distinguished in the course of time from leased lands transferred for use to dependent persons, such as serfs. Thus a monastery might have serfs on its lands or free tenants. The lands so cultivated by them were not regarded as *beneficia*, but a man who received from such a foundation tracts of land to be cultivated by his own people, or lands with laborers on them, would be called a "beneficiary."

The terms and conditions on which such benefices were held were very various. Some were for short terms, some were renewable every five years, while others were expressly excepted from this condition. *Beneficia* of the king usually terminated with the life of the grantor or of the grantee, but sometimes they passed on to the grantee's heirs. Under the grandsons of Charlemagne they came to have more and more of an hereditary character, and in the kingdom of the West Franks (or France) a sort of acknowledgment of the hereditary principle was made in 877 A. D. by Charles the Bald at the convention or diet of Quiercy-sur-Oise (*conventus Carisiæus*). Yet diplomas of Charles the Bald show that this rule of inheritance was not absolutely fixed by the celebrated capitulary referred to. And this provision had no necessary authority in other parts of the kingdom of Charlemagne. On the renewal of grants of benefices sometimes money was demanded, reminding one of the subsequent fine or relief, but this was not thought to be becoming. The obligation for holding a benefice might be something like a rent, real or nominal, or no requital of any outward sort might be called for. But a certain kind of tie grew out of the giving and receiving of benefices—something expressed by the Latin word *obsequium* in the formulas of gifts—that is, a readiness to comply with the wishes of the benefactor; if he were the king, a personal feeling of gratitude apart from the sense of duty as a subject. This is expressed in a form of which the following is a translation: "Let him know that he ought to show such (*obsequium*) dutiful compliance toward his senior on the ground of that gift, as other men, on the ground of similar beneficence, are wont to show toward their seniors." Here is seen the reception of benefices becoming connected with

2. *Vassality* or *commendation*, which was a merely *personal tie*. The latter of these words has the more extensive meaning, and several relations were described by it besides that which was called "vassality." The essence of these relations lay in formally putting one's self under the protection of another. The king was regarded as the protector of certain helpless classes, such as widows and orphans. They were *in his peace*, as also were the whole people and the Church. So, too, pilgrims and travelers were for the time under his care—under the tutelage or the defense of the king—although *commendation* is not the term specially used in such cases. Again, young men brought to the court to be trained for some service or court office are said to be commended, although no formal taking of them into his protection or guardianship (*mundium*) may have found place. Nor was the king alone in giving his protection. The *major domus*, or mayor of the palace, sometimes gave his protection with or instead of the king, and Pepin made his son Charles (Charlemagne) joint protector with himself. The property of a diocese might be in the tutelage of a count—that of a convent under a count's or bishop's protection. Free men put themselves under the guardianship of a convent. Thus originally there were manifold relations, differing, yet having resemblances to one another, which were described by the same words.

A person who made commendation of himself was called *vassus* or *vassallus*, a word probably of Celtic origin, and at first denoting a servant, then in time confined to the relation above spoken of. (See Waitz, *Deutsch. Verfassungsgesch.*, iv. 205, for examples of the use of the words as applied to inferior proprietors.) Another equivalent term was *gasindus*, of Germanic origin (cf. Modern German *gesinde*), and another still was *homo*, of Latin origin, whence *homage* comes. The person who received another into his protection was especially called *senior* (whence *seignior*), and also *dominus*. In later documents the seignior's relation or standing is called *senioratus* (as if seigniorship). The entrance into the relation of a vassal was denoted by the form of folding the hands together and laying them in the hands of the *senior* or protector. This was accompanied by an oath containing a promise of fidelity. The oath and the form in general were used as well when a count or other important person took an inferior under his protection as when the king received a vassal into his service. The oath and obligation were contemporaneous with the general oath of allegiance on the part of the subjects as required by Charlemagne and other Carolings. And yet the oath to the king's or emperor's subject certainly tended at length to weaken the tie between the head of the state and those members of it who were bound to others than the sovereign or suzerain.

The vassal sometimes remained with his senior, especially if the king was the senior, and served in his court; sometimes he lived remote from the king on lands which had been given to him for his use. If an inmate of his senior's dwelling, he was bound to services, such as military duty, going on messages, presence at his courts (*placita*), following in his train. In a capitulary of A. D. 811 it is said of such vassals of the king that if they have benefices, and vassals on them, they shall not keep these subordinate vassals with them, but "shall allow them to go with the count to whose district they belong." From this it appears that already vassals had vassals; that some vassals had no benefices; and apparently, also, that the old-received jurisdiction and military power of the count in his county (*pagus*) was beginning to be weakened, for it was necessary to give orders that such vassals should follow the count to his county and upon military expeditions.

At first the tie between a person other than the sovereign and his man was probably weaker than that between the magnates and the king. In the disorders after Charlemagne's death, and in the time of his grandsons, the great people seduced each other's vassals away, so that this had to be expressly prohibited. The vassal also could not leave his senior or lord except for reasons which involved a crime on the senior's part, unless, indeed, the latter freely dismissed him. Such crimes as mentioned in a capitulary of Aix-la-Chapelle (A. D. 816) are attempts on the senior's part to enslave the vassal, seduction of his wife by the senior, plots against his life, running upon him with a drawn sword, neglecting to protect him if this were in the senior's power. With this may be compared the feudal crime of felony, which is generally committed by the vassal against his lord, but may also be committed by the lord himself against his vassal.

It came to pass in the course of time that vassals held benefices and beneficiaries became vassals—that is, that no person could stand in the one relation without its involving the other. Waitz says (*Deutsch. Verfassungsgesch.*, iv. 216) that "no one could get a benefice without binding himself by commendation more closely to the grantor of the land—more closely than would take place by the fact of having another's land put for use into his hands." Roth, in his *Beneficialwesen*, says more safely that this union of the two relations was usage only for some time, and not universal custom. When the custom was becoming universal a class of landholders was growing up who held estates by a tie of personal obligation to a superior; and this class, owing to the vasts tracts of land which the Frank kings could dispose of, embraced a large part of the leading persons, especially in the West Frank kingdom.

3. *Immunity* (*emunity*) or *exemption*, a *political* privilege, was the third constituent element of the feudal system. The first form under which this element appears is immunity from taxes or burdens on the land. When the king gave benefices he transferred that which before belonged to the *fisc*, and which was exempt from taxes. It was a great thing for a person to obtain this exemption. The first exemptions that are known are all granted to convents or to other ecclesiastical foundations, the property of which was entirely derived at first from gifts of lands. Originally, this grant of immunity could only proceed from the king, yet documents issued to such corporations by nobles who were vassals of kings confer it, in the expectation, perhaps, that a confirmation of the step would be obtained from the supreme authority. There seems also to have been a special anxiety on the part of convents that a public officer should not enter within their premises and disturb their sacred quiet. However little or much this cause may have effected, the immunity naturally took the shape under Pepin and the next sovereigns that no public officer should enter the court or lands of the foundation, either to levy peace-money (*freda*), or to demand quarters and lodging, or to take securities, or to hold the people of the foundation to justice, or to set up judicial proceedings there. These dispensations from what was due to the state were not granted all at once, but one at a time; and, on the other hand, there were cases where the public officer might enter the religious precincts. These privileges were eagerly coveted, and in regard to nothing in the mediæval times do so many forged documents exist as in regard to these grants of immunities. They were protected by fines very considerable in amount. But as free men commended themselves to the Church corporations to get rid of public service in war, an edict of 825 gives the counts the right to distrain on them, "notwithstanding the immunity." In some cases this privilege was given for hedged or inclosed lands only, not for plow, pasture, or wood lands, at least so far that breaches of it should not have the same penalty outside of the court and buildings as within.

This privilege evidently could amount, if bestowed on all holders of benefices (or fiefs, as we now may call them), to an overthrow of direct public power, and was evidently worth the efforts of the secular proprietors to secure for themselves. When and by what steps they obtained it does not so clearly appear as in the case of convents and other Church foundations. But such a privilege could not be confined to ecclesiastics, and in the unquiet times under the grandsons of Charlemagne and afterward, public power became weak, while at an equal pace the power of the landholding grantees became great. The smaller free proprietors could not stand alone in those times, but found it necessary, in order to protect themselves, to join some society where they could find protection, and so gave up their lands to a count or other great person, to receive them back as his men owing allegiance and securing support. The counts would naturally be large landholders within the county, and if their functions, at their death, passed out of the family, the son would naturally want to have the same authority in his estates which his father had in the county or district. These are some of the reasons which brought it about that multitudes of men, ecclesiastical and civil, in process of time got exemptions from public authority—that is, as far as justice, police, military headship were concerned—broke up society into fragments, and denationalized a great part of Europe.

These three causes, then, working together, produced the feudal system. Public property, by the distribution of lands in the way of beneficiary gifts, which were finally held by hereditary right, created great proprietors. Vassalage connected these proprietors by a personal tie with one another, and at length *only* with one another, the high vassals alone having immediate relations to the sovereign. Finally, immunity distributed in process of time the principal powers of the state to the vassals of the suzerain or to their vassals also. In this course of things different parts of Europe moved forward independently. In France, where there was very little allodial property, the maxim of feudalism was "Nulle terre sans seigneur." In Germany there were many small free proprietors who stood their ground, as in Ditmarsch, and many large proprietors whose allods alone, without their fiefs, were very wide territories. When Henry the Lion was deprived of both his Saxon and Bavarian dukedoms, in 1180, for his want of fidelity to Frederick Barbarossa, he had still in his hands the extensive Brunswick territories, which when divided up made several important German principalities.

In another particular, which was of no inconsiderable moment, the countries differed. In France all the feudal holdings became hereditary at an early day. It was otherwise in Germany and in Italy. In Germany there had been no acknowledgment of the right of the great vassals to transmit their imperial fiefs to their children until the Emperor Henry II. silently acknowledged it in every known instance but one (1002–24). But still, the princes retained the right to dispose of the fiefs on the death of arrière-vassals as they pleased, until Conrad II. (1024–39) gave it to be understood—without any positive law, as it would appear—that the same usage must prevail toward them also, and thus raised up a class of friends to the imperial power among the smaller nobility. In Italy things were even worse for the arrière-vassals—the *valvassors* as they were called—until the same emperor by his constitution, given out before Milan, granted to the valvassors the right of inheritance in their fiefs, of trials by their peers, of appeal to the emperor or his deputies the counts palatine, and of security against the conversion of fiefs into leasehold or copyhold properties—a measure by which he made friends of the smaller nobles, and took away arbitrary power from the larger.

Feudalism grew up and spread in the different parts of Europe amid so many different influences, favorable or counteracting, that its minor diversities in the several countries were countless. Thus in France the north was especially the home of customary law (*coutumes*), while the south retained influences from the Roman times. In England a Duke of Normandy, a vassal of the French Capets for his French possessions, is supreme ruler under no superior, brings the land and land tenures into the forms of feudalism, but endeavors to mitigate the disintegrating tendencies of that system and to uphold the royal power by modifications more or less drawn from the Saxon institutions. In Germany an elected emperor, an intimate connection with the papacy, a necessity during a long time for a vigorous head to protect the land from Eastern neighbors, with various other causes, gave a peculiar turn to many of the institutions. Here the old Teutonic ideas stood their ground, while foreign law and institutions crept in from Italy. So also in the internal affairs of each part of Europe, opposing elements were at work and there was a most vigorous, unquiet life; the kings, at war with their principal feudatories, leaned for support on the towns or the lawyers; the Church was feudalized, but in contest with the unruly nobles, and falling back upon the ecclesiastical unity represented by the pope. Further, new institutions like the towns were arising, capital other than land was becoming important, unions of the citizens of various communities against the nobles were coming into existence.

The theory of feudalism, not true in matter of fact, has been already stated to be that all the land belonged originally to the king, and was given over on certain conditions to his principal vassals, and by them to theirs. Long after the fiefs became hereditary their original lapse into the hands of the superior was indicated by the fine or payment called *relief* which the heir paid on entering into possession of his father's or next relative's possession. As the tenure was personal, the holder of a fief could not sell it without his lord's consent, who had on such occasions the right of prior purchase, called *rachat*. The necessity of defending the kingdom or fief led for a time to the exclusion of females from succession, and, especially in France, to the indivisibility of a fief where a deceased person had left more than one son; but to these rules there were extensive exceptions. Where more than one fief pertained to a family, a subordinate one might be given to a younger son. In Germany subdivision among the male children of the fief-holder was the general rule. It was natural that if an unmarried daughter succeeded to the fief, the superior's consent should be necessary before she could marry the man of her choice. Again, when an heir was a minor there was a propriety that the superior should be his or her guardian—a very gainful thing for the higher vassal or for the suzerain.

As for the termination of the feudal relation, it could cease by extinction of the line; by the vassal's felony toward his lord, which comprehended a number of the grossest and most dishonorable actions in violation of his feudal oath; by the felonious conduct of the superior against his vassal (which has already been spoken of); or by the vassal's voluntary relinquishment of his fief where this was permissible. When a vassal's crime subjected him to loss of his fiefs, a judgment of a court of peers was necessary; the superior could not generally, by his own act, without such consent, declare him to have forfeited his estate. The most remarkable cases of such trial were that by which John of England, on sentence of his French peers, was stripped of the lands he held in France by homage as a vassal of Philip Augustus (A. D. 1203), and that by which Henry the Lion in 1180 lost the dukedom of Saxony, as has been already mentioned.

As feudalism grew up, not only laymen but ecclesiastics and corporations were invested with fiefs, and in fact the great bishops and abbots ranked in some countries among the most important feudatories. The kings were quite willing to have such vassals, for the lay barons gave them trouble by active resistance more frequently, and there was an opportunity, on the death of a feudal ecclesiastic, of influencing the appointment of a successor, as well as of deriving advantages from the introduction of a new ecclesiastical person into the feudal relation. But as the ecclesiastics holding fiefs had two characters—that of feudatories and that of churchmen under the Pope—it was natural that just at this point there should be a conflict of secular and religious authority. The most important struggles of the Middle Ages grew out of the two characters of the ecclesiastical princes, the sovereigns being unwilling to give up their feudal rights over Church lands held as fiefs, and the popes claiming the independent relation of the great ecclesiastics toward the sovereign, as well as the inalienability and sacredness of lands once consecrated to religious purposes. As the bishops and abbots could not sit in capital trials according to the canons, and could not without irregularity take part in traffic, they needed lay vicars, who often managed to enrich themselves and grow into power at the expense of the foundations.

The complexity in the feudal system was increased by the fact that not only land, but everything that could be held as property, could take the form of fiefs. So also certain offices at the suzerain's court, as those of the high chamberlain, butler, seneschal, constable, pertained to certain families; and the counts palatine, who were originally assistants of their suzerain in the administration of justice, transmitted their title and the lands connected with their office to their sons.

The principal obligations of the fief-holders or vassals were the following:

1. Service in war (*service d'hoste*). The customary obligation in France, when the superior was involved in war or followed his own superior in war, was a military service of forty days with his men or with a fixed number, after the expiration of which the vassal could go home, although the war was not at an end. If certain specific reasons prevented his appearing at all, a fine (in Old French an *écuage*) could be demanded from him. Such a limited time of service, of course, broke up many expeditions. Hence in France—which is selected as especially the feudal country—toward the end of the eleventh century fiefs were granted on the condition that the vassal should serve until the end of the war. The vassal under these obligations was especially a liegeman (*homo ligius—ligius* being derived from the Latin *ligo*, to bind, most probably), while the vassal bound to definite service was his lord's man simply, and his relation was called ordinary homage (*hommage ordinaire*). Still another kind of service, called *hommagium planum*, bound the vassal neither to service at his lord's court nor to service in war, but simply to fidelity and neutrality. Others, still, were bound to defend only a castle of their superior, and were maintained at his expense.

2. Another general obligation was that called *justitia*, or that the vassal must appear, when summoned, at his lord's courts, either to act the part of a judge, together with his fellow vassals or peers (*pares curiæ*), or to submit to trial before them as judges. The rule was trial by peers, and the power of administering justice was vested in all the gradations of the feudal persons down to the knights (*milites*), who themselves, if there were free persons on their estates, were their natural judges. The great lords did their office by deputies for the most part, and in process of time their vassals came into the habit of having their representatives also. Besides other proof, wager of battle or trial by combat was a common method of deciding cases in these courts, being a kind of feudal ordeal.

3. *Aids or Auxilia.*—These were money payments, determined according to feudal usage. They were due in France and in England when the lord was to be redeemed from captivity, when his son (or eldest son) was made a knight, and when his daughter (or eldest daughter) was married. (Cf. *Magna Charta*, § 14.) At one time aids were demanded and given when the lord went on a crusade.

Besides these, the specific duty of fealty implied general respect and obedience, honesty in not altering the condition of the fiefs, and similar duties.

The feudal system not only broke up countries into almost independent parts, encouraged private feuds, and made the leaders of society a law unto themselves in great measure, but it rested on a system of serfage, which appears as well among the Germans before the emigrations as in the later Roman empire. Under it there could be no unity except that of the Church. Its evils were immense, but amid the evils, by the help of Christian ideas, there grew up the sentiments of honor and of fidelity, the spirit of courage and of personal independence, the sense of obligation to protect the weak, a new respect for woman unknown to the classical nations. Among its good principles of a political kind, those of trial by peers and of taxation only by consent of the tax-paying inferior were the most important.

At length the feudal system began to fall; new political ideas and forms, new powers in society, began to take its place; nations arose out of separate fiefs, and suzerains again became kings. What broke up feudalism? The most prominent immediate causes were the substitution of a better law in the place of feudal law, the growth of the cities, and new methods of warfare. These causes added strength to the central power, created an opulent class outside of the feudal nobility, gave birth to new political institutions, helped somewhat the lower classes, and brought in new knowledge, a new civilization. In the first place, as the feudal law was found inapplicable to the new circumstances which the growth of cities and of industry had introduced, the Roman law was called in the twelfth century out of the obscurity where it had long lain in the north of Italy; and the University of Bologna owed its origin or its first prosperity to this study. Hither multitudes resorted for the purpose of learning the new science. From this starting-point it was propagated through Europe. The courts of the suzerains made use of it, and with the more effect owing to the fact that the appeals to their courts, which had in France at least been long disused, were revived. In this way a code which was favorable to the growth of a central power began to prevail over one unsuited to the times, and the kings began anew to be regarded as centers of justice. In the next place, the growth of towns all over Europe in and after the crusades was a source of changes in the political system. The towns acquired privileges by especial charters granted by their feudal lords, whose resources might in this way be increased. As they grew they became a new power, which, like the suzerain's, was naturally opposed to the feudal power. The kings aided them because both were enemies of the feudal nobility, and they in turn helped the kings. Their self-government, capital, and common interests made the towns, though isolated, aware of their strength; they were able to send deputies to the estates-general, parliaments, or cortes through which nations expressed their national feeling; they could give assistance to the kings in struggles against the feudal element by their men and money. Louis IX., who died in 1270, the best sovereign in the Middle Ages, in his testament exhorted his son to be mindful of the interests of the "good towns," as if there were a natural alliance between them and the sovereign.

Again, the new modes of warfare had advantages over the feudal military system, which was heavy in its movements and unreliable. Its great strength lay in its mail-clad horsemen. The use of cross-bowmen, gunpowder, guns, and cannon, and of a population in the towns or of freemen in the country who could serve as hired soldiers, changed the face of war. The battle of Crécy, gained by Edward III. of England in 1346, was due to two causes—that a yeomanry had grown up in England earlier than in France, and that these intrepid freemen were skilled at the cross-bow. The battle of Agincourt (1415) was won by bill and bow, the French chivalry literally sticking fast in the mud, to be shot down by the English archers. The victories of Granson and Murten or Morat (1476) were won by free Switzerland over the troops of the most feudal of princes, Charles the Bold. What is remarkable here is that the superiority as it respects arms lay on the Duke of Burgundy's side, so that guns alone were not the cause of the fall of the feudal military system. But there is no doubt that the use of weapons capable of producing an effect at a distance gave to foot-troops, and to those who were cheaply equipped, a greater advantage over the heavy moving horsemen and the undisciplined infantry of feudalism, and thus helped the sovereigns and others who soonest availed themselves of the new instruments of war.

Underlying and acting with the other causes of the downfall of feudalism were the more general ones which indicated the progress of society. Intelligence was spreading in the middle class, but not so much in the higher. There were men in many towns who had traveled into the East and seen the institutions of the nations in remote parts; there were professional men who were cultivated in law or in medicine at the universities; there were great merchants whose views were enlarged by the intercourse which they kept up with the world; the arts were beginning to refine the dwellers in the towns; church architecture was already in its glory. It was impossible that capital, intelligence, the means of closer intercourse, should not have an effect in modifying political forms which had given power to soldiers and land-owners less intelligent and with less available capital. The feudal lords themselves in many places entered the town and became burghers, thus confessing that the center of social life was altered.

The feudal period, one of the most remarkable in the history of the world, passed away, leaving a multitude of influences which will never die out of civilization. It must not be despised—it ought to be justly dealt with—blamed and admired on good grounds. But it is becoming in the rapid progress of society more and more strange. Many of the institutions which sprang up in that institutional era need to be explained, as Roman and Greek usages are explained. The study of an age now ancient alone can make intelligible the origins of many customs and laws that are still vigorous. T. S. WOOLSEY.

Feuerbach, foi'er-baakh, LUDWIG ANDREAS: philosopher; b. at Landshut, Silesia, July 28, 1804; son of Paul Johann Anselm von Feuerbach, the jurist; in 1822 went to Heidelberg to study theology, but removed in 1824 to Berlin, where, under Hegel's auspices, he devoted himself exclusively to the study of philosophy. From 1828 to 1832 he lectured at the University of Erlangen, but his public denial of immortality made his promotion impossible, and he retired to Ansbach, then to the castle of Bruckberg. The failure in 1860 of a manufactory from which his wife had drawn her income led to his going to Rochenberg, near Nuremberg. Meanwhile he developed a great activity in literature, and wrote in German, besides numerous minor essays in periodicals, *Thoughts on Death and Immortality* (1830); *History of Modern Philosophy from Bacon to Spinoza* (1833); *Criticism of the Philosophy of Leibnitz* (1837); *Pierre Bayle* (1838); *Philosophy and Christianity* (1839); *The Essence of Christianity* (1841; 4th ed. 1883; Eng. trans. by Marian Evans (George Eliot), London, 1854; 2d ed. 1881); *Principles of the Philosophy of the Future* (1843); and *The Essence of Religion* (1845). D. at Rochenberg, Sept. 13, 1872. A national subscription was raised for him shortly before he died.

Ludwig Feuerbach is the representative of the modern atheism in its German form. His polemic is often boisterous and uncouth, but his positive views are entirely free from that coarse or supercilious materialism which characterizes the English and French atheism. He dissolves the idea of God into that of nature; construes religion as the product of a merely psychological process—natural, perhaps necessary, at one stage of human development, ridiculous and injurious at another. His views on this last point contain many deep and striking psychological ideas, and it is not until he approaches Christianity, and begins to construe its doctrines too as resulting from the weakness and confusion of the human spirit, that he becomes crude, and sometimes even puerile. See his *Life* by C. N. Starcke (Stuttgart, 1885).

Feuerbach, PAUL JOHANN ANSELM, von: jurist and reformer of criminal law; b. at Jena, Germany, Nov. 14, 1775; educated at the gymnasium at Frankfort-on-Main and at the University of Jena, where he studied first philosophy and then law. His *Critique of Natural Law* (*Kritik des natürlichen Rechts*, 1796) and his *Anti-Hobbes* (1798) at once gave him prominence as a juristic thinker, and won a favorable reception for the course of lectures which he now began to deliver on criminal jurisprudence. The views set forth in these lectures and elaborated in his *Lehrbuch des gemeinen, in Deutschland geltenden peinlichen Rechts* (1801; 14th ed. 1847) placed him at the head of the new school of jurists called Rigorists, who maintained that the decisions of judges should be strictly subordinate to the text of the penal law and never rendered at discretion. In the *Lehrbuch* he was also the first to systematically develop the intimidation theory of punishment, which he had previously advanced in his work on the *Crime of High Treason* (1798). The effect of Feuerbach's works was not only to arouse a strong feeling against vindictive punishments, but ultimately to effect a reform of the entire system of criminal jurisprudence. In 1801 he was made a professor at Jena, but in the following year accepted a call to Kiel. In 1805 he filled an office in the department of justice and police at Munich, and in 1808 was appointed privy councilor. Having attracted the favorable notice of the Bavarian Government by his *Critique of Kleinschrod's Project of Criminal Law* for Bavaria, he was commissioned to plan a new criminal code, which was promulgated in 1813, and subsequently taken as a model for the reformation of the penal codes of several other countries. He published *Merkwürdige Kriminalsrechtsfälle* (1808–11), and *Betrachtungen über die Geschwornengerichte* (1813), pointing out in the latter work the defects of the jury system. He wrote a number of patriotic pamphlets in the war of liberation 1813–14, and in the latter year was appointed second president of the court of appeal at Bamberg. In 1817 he became first president of the court of appeal at Anspach. In 1832 he published his *Crime against a Soul*, presenting the first careful analysis of the remarkable case of KASPAR HAUSER (*q. v.*). D. at Frankfort-on-Main, May 29, 1833, just after having edited a collection of his *Kleine Schriften*. See *Leben und Wirken Anselm von Feuerbachs*, by his son Ludwig, the noted philosopher (2 vols., 1852). F. M. COLBY.

Feuillants, fö'yaañ' [so called from *Feuillans*, a village near Toulouse where their first abbey was situated]: the members of certain congregations of reformed Cistercian monks and nuns. Jean de la Barrière, abbot of Feuillans (d. 1600), began the reform in 1567. The reform was approved by the pope in 1586 and 1587. Their first house in Paris was instituted in 1588. Their severe rule was mitigated in 1595. The congregation was divided in 1630 into that of Notre Dame de Feuillans and the reformed Bernardines (the latter Italian). Nuns were admitted to receive the rule of the Feuillants in 1588.

The original abbey at Feuillans (*Folium, Fulium*), in Haute-Garonne, Languedoc, 18 miles from Toulouse, was founded in 1162. The club founded in Paris in 1790 by Lafayette, Sieyès, La Rochefoucald, and others, and which advocated moderate opinions, called itself Feuillants, from the convent in which they met. On Mar. 28, 1791, it was broken up by a mob. The name Feuillants was in 1791 given to the right and the extreme right in the French legislature.

Feuillet, fö'yā', Octave: novelist and dramatist; b. at St.-Lô, Manche, France, Aug. 11, 1822; educated at the College of Louis-le-Grand at Paris, where he distinguished himself; entered upon his literary career in 1844 under the name of *Désiré Hazard*, and since that time has been a constant contributor to various newspapers and periodicals, and subsequently wrote many novels, comedies, dramas, and farces, most of which were received with much favor. Among his dramas are *La Nuit Terrible, La Crise, La Tentation, Redemption*, and *Le Sphynx*; and of his novels, the best known perhaps are *Bellah, Le Roman d'un Jeune Homme Pauvre*, and *La Morte*. In 1862 he was elected to fill the chair in the French Academy left vacant by the death of Eugène Scribe. D. in Paris, Dec. 28, 1890.

Feuilleton, fö'ye-tōn' [Fr., dimin. of *feuillet*, sheet of paper, dimin. of *feuille*, leaf, sheet < Lat. *fo'lium*, leaf]: in French journalism, the name of that part of the sheet which contains the literary intelligence, criticism, and other similar matter. The feuilleton often contains tales, either complete or serial. Hence a light romance written for a journal is often called a feuilleton.

Féval, fā'vaal', Paul Henri Corentin: novelist; b. at Rennes, France, Sept. 27, 1817; admitted to the bar at his native place, but soon became an author. Among his novels the following have been translated into English: *The Lover of Paris* (1846); *The Duke's Motto* (1863); *The Woman of Mystery* (1864); and *Thrice Dead* (1869). Was made an officer of the Legion of Honor in 1869. D. Mar. 1887.

Fever [O. Eng. *fēfer, fēfor*: Mod. Germ., *Fieber*, from Lat. *febris* > Fr. *fièvre*]: a condition of the animal body characterized by a measurable and continuous elevation of the general temperature. This definition excludes short accessions of heat due to accidental and ephemeral causes, and purely local elevations of temperature, and limits the notion of fever to a state which is a concomitant of disease. In fever the functions of the body are disturbed, and usually in proportion to the variation from the normal heat of the body (37° C., 98·6° F.).

It is not exact to speak as if fever could occur as a distinct and particular disorder, for fever is always and only a condition dependent upon a disorder of some part or system of the body, although certain diseases are commonly called fevers because a rise of temperature is in them a constant symptom, as typhoid fever, scarlet fever, etc.

In the condition known as fever there is a definite order of events, spoken of in medical books as the stages of (1) invasion, (2) domination, (3) decline. In a typical fever the first stage is marked by a sensation of general *malaise*, of bodily as well as mental languor, sometimes of headache, with pains to the back and limbs, loss of appetite, an accelerated and rather small pulse, and great sensitiveness of the skin in the temperature of the surrounding atmosphere, and a *chill* may set in, causing involuntary shaking of parts of the body, with paleness of the surface and a bluish tinge of the nails and lips. This stage, after having lasted a certain length of time, gives way to a sensation of *heat* not merely felt by the patient himself, but also appreciable by others. The skin becomes turgid and congested, feels hot and dry, the pulse remains quick, but is fuller, the respiration is more hurried and irregular, there is general restlessness, the thirst is intense, the appetite is lost, the tongue is coated with a whitish film, the mucous membrane of the mouth and throat is dry, the urine is scanty, of a deeper color, and of a greater specific gravity: and the patient, who during the cold stage could hardly get on clothing enough, wants to free himself from every covering. After this stage of dry heat, the skin breaks out in a profuse *sweat*, the dryness of the mouth and the thirst diminish, the respiration becomes deeper, more regular, and less frequent, the pulse, still accelerated, is full and bounding, the patient grows calmer, and often falls into a sleep, out of which he awakes with a pleasant sensation of well-being, although more or less debilitated.

Not all the symptoms just described must necessarily be present. It is not always that fever is ushered in with a chill. Very often only slight horripilations, goose-flesh, and insignificant rigors precede the development of intense heat, which may pass off, scarcely moistening the skin by sweat. Instead of great muscular pain and a torturing sensation of restlessness, there may be not more than a rather voluptuous feeling of laziness, and, in place of a distressing confusion of ideas, a not unpleasant play of the fancy may exist. The appetite is not always wholly lost, nor is the thirst necessarily great. The pulse, never as slow as in health, either from individual peculiarities or from bodily enfeeblement antedating the fever, or from long duration of the fever, may show great frequency, and yet not denote a very grave febrile state, provided other symptoms are moderate. The symptoms vary, too, in consequence of the influence of local diseases, or according to the duration of the febrile process. With all these variations, producing the most different types of fever, the totality of symptoms so strikingly impresses the mind of even non-professional observers that hardly ever is a mistake made in pronouncing a patient "feverish."

There is one symptom which is never wanting in fever, which can be measured with mathematical exactitude, and which furnishes a standard of comparison between fevers of different degrees of severity: it is the *increase of the temperature* of the body as determined by the thermometer. The thermometer furnishes not only an indication of the progress of any fever, but is a valuable aid in discriminating between different diseases in which fever is a prominent symptom. This is due to the fact that in different fevers there are characteristic alterations of temperature, marked by an orderly progress of elevation or depression, occurring at regular intervals, and rising or falling within definite limits.

In a former edition of this cyclopædia it was stated that the classification of fevers is based partly on scientific, partly on practical, partly on purely arbitrary grounds, and that the principal and really scientific distinction is between *idiopathic* (primary) and *symptomatic* (secondary) fevers, the first class comprising those varieties in which the fever is the only, or at least the first (primary), morbid action, so that local disorders occurring in the course of the fever must be considered as depending upon it. This is not in accordance with the facts of pathology. As stated above, fever is only a symptom, and it is not correct to classify as idiopathic the zymotic or miasmatic fevers, for these are dependent upon disorders of tissues of the body (the blood is technically a tissue) as truly as are those fevers the names of which are derived from the *morbid process* which lies at their root; for example, inflammatory, catarrhal, rheumatic, hectic fevers, or fevers named after the organs whose diseased condition causes them—brain, lung, gastric, and enteric fevers.

An illustration of an inexact term is furnished by the name "bilious fever," which is a condition characterized by more or less depression, sometimes nausea, usually disturbance of the bowels, with coating of the tongue and loss of appetite. It is most common in persons whose skin is of a dusky color, and who are of the brunette type in general. It is so named because it is supposed to be dependent upon an excessive formation of bile. This, however, is not the case.

The name of some fevers is derived from some predominating symptom—e. g. typhus (Gr. τῦφος, stupor), eruptive, break-bone, spotted, scarlet, yellow fever. Sometimes the real or supposed *cause* is made use of to give the name—e. g. malarial, septic, hay, jail, ship fever. The febrile process, while having its stages of rise, height, and decline, does not run through them with an even tenor, but certain oscillations occur, the febrile symptoms showing an exacerbation and a remission every twenty-four hours, or even in a shorter time. The exacerbation in the greatest number of cases sets in in the evening and advances until about midnight, when the remission commences, so that in the morning hours the temperature is at its lowest point for any day. If the temperature never falls to the normal point, the fever is called a *continued* or *continuous* one. If at some time it falls nearly to the normal point, the fever is called *remittent*. If the febrile symptoms disappear altogether, to return on another day, the fever is called *intermittent*. An intermittent fever, in which the fever returns every day, is called *quotidian*; if it return on the third, fifth, or seventh day, and so on, it is called *tertian*; if on every fourth day (1, 4, 7, 10, etc.), it is called *quartan*. A fever lasting with certain well-marked symptoms for several days, then disappearing and returning after a few days' intermission, is called *relapsing* fever.

To understand fully what occurs in fever, conditions would have to be fulfilled which are either totally hidden or obscure, or the realization of which is surrounded by such difficulties that they have become only partially solved. Granted a thorough knowledge of the anatomical structure of the organs and the systems of the body in perfect health; of their chemical composition: their relative and total weight; of the quantity and quality of secretions and excretions; and testing the same individual just emerging from a fever in all these respects—the *ultimate* changes wrought by fever would be apparent.

To understand how these changes have been produced it would be necessary to know the quantity and chemical constitution of solid and liquid food consumed during the fever, the alternation of the circulation, the air inspired and expired, the quantity of force expended by voluntary and involuntary motion, the quantity and chemical composition of all secretions and excretions, and finally, the amount of animal heat generated during the fever. Moreover, to guard against any error vitiating the value of these facts, it would be necessary to eliminate all the influences of local diseases, producing the fever or being produced by it. Moreover, all the above occurrences would have to be gathered, not as a whole, but in parts, in regular intervals, some of them if not hourly at least twice a day, as it is known that periodical fluctuations take place in the physiological state during the night and day. Of all these matters only a very small part has been studied with such frequency and thoroughness that results have been gained which are beyond doubt.

Instead of philosophical speculations and the coining of a more or less ingenious hypothesis, a true scientific method of observation and experiment rules the science of pathology; and if no great advances have been made in clearing up the pathology of fever, it is not altogether because the ways are unknown, but because the means and time to unravel the complex maze of the febrile process are not furnished even to scientific institutions, not to speak of single individuals.

What is known with some degree of certainty is this: that the waste of organic material is not merely owing to a diminished supply of food or to an imperfect assimilation, but that of all organic substances the albumen of the body is disproportionately consumed. This is shown by the fact that more than double the quantity of urea is eliminated than is normal. The quantity of urea can not be increased unless a corresponding decomposition of nitrogenous substances by oxidation takes place. Further, more carbonic acid gas is given off, partly by breathing, partly by insensible loss, than under the same conditions in a state of health. The same is true of water. But neither of these substances is lost in so great a proportion as urea. The coloring-matter of the urine is increased in quantity, indicating disintegration of the red blood-corpuscles and of the muscles. The urine, too, contains a much greater proportion of salts of potash—another evidence of the waste of red blood-corpuscles and muscles. The changes which have been alluded to can not occur except by increased oxidation, and as oxidation is a source of heat, during fever more heat is produced. This increase of heat in the body takes place even during the cold stage, and although the outer parts are colder than they are normally, yet within the cavities of the body by use of the thermometer an increase of heat is demonstrated.

The increase of heat-production in fever is compensated to a certain extent by conduction, radiation, and evaporation from the surface, or by all three combined; but the wonderful regulation by which the body in the physiological state keeps its temperature at about 37° C. (98·6° F.), contracting the blood-vessels of the skin if the surrounding medium is cold, and causing evaporation by sweat if the surrounding medium is hot, is materially perverted in fever.

Limited and fragmentary as is the knowledge of pathology of fever, even less is known of its origin. It appears clear that irritation of the peripheral nerves, as of the intestines or of the skin, may produce impressions upon certain parts of the brain which result in changes in the bodily temperatures, and it seems to be proved that irritation or injury of a definite region of the anterior part of the cortex of the brain has a decided effect upon the process of heat-production, while psychological processes undoubtedly influence it. Fever can also be produced experimentally by injecting septic substances into the blood, and secondary fevers are probably generated in a similar manner, the original disease producing some substance which contaminates the blood.

Pathologists of the humoral school believed that organic and chemical changes in the blood are sufficient so to alter the whole process of nutrition and assimilation that a general disease, called fever, would result. According to their views, the nervous system would be a mere registering apparatus for changes of psychological conditions without originating or influencing them. The more recent opinion is that changes of temperature are brought about largely by the influence exerted upon portions of the nervous system by some irritant—irritants usually reaching these points by way of the blood. Like other functions, that of the production of heat is under regulation by the brain and its nervous prolongations. The most important varieties of fever are described under their several titles.

Revised by CHARLES W. DULLES.

Fever Bush: a handsome shrub (*Benzoin odoriferum*, or *Lindera benzoin*) of the family *Lauraceæ*; common in the Northern U. S. Decoctions of its bark and leaves have been used for aromatic and stimulant drinks in low fevers. Its red spicy berries have afforded a poor substitute for allspice. It is also called spice bush and benjamin-tree.

Feverfew [M. Eng. *fevyrfew* < O. Eng. *feferfuge*, *feferfugia* < Lat. *febrifugia*, the centaury, liter., a *febrifuge*]: a large perennial herb (*Pyrethrum parthenium*) of the family *Compositæ*, resembling chamomile, and a native of Europe, sparingly naturalized in the U. S. There are some fine cultivated varieties, which are prized in the flower-garden. It was formerly much used as a deobstruent, tonic, and febrifuge. A related species yields the so-called Persian insect-powder.

Feverwort, Wild Ipecac, Horse Gentian, or **Tinker's Weed**: a coarse perennial herb of the U. S., the *Triosteum perfoliatum* of the family *Caprifoliaceæ*. Its root is used as a cathartic and emetic. A smaller species, *Triosteum angustifolium*, grows in the Southern U. S.

Few, WILLIAM: U. S. Senator; b. in Baltimore co., Md., June 8, 1748; removed in 1758 to Orange co., N. C., and to Georgia in 1776. He was chosen to the State convention to form a constitution, as also to the assembly, and made one of the council. With the rank of colonel he served in the war of the Revolution; in 1778 he became surveyor-general, and also presiding judge of the Richmond County court. From Jan., 1780, to 1783, he was delegate to the old Congress, and also in 1786; a member of the national constitutional convention in 1787, and of those of the State of Georgia in 1796 and 1798; U. S. Senator from Georgia 1789–93, and then three years on the bench. He removed to New York in 1799, and was afterward in the State Legislature, commissioner of loans, and mayor of the city. D. at Fishkill, N. Y., July 16, 1828.

Fewkes, JESSE WALTER: See the Appendix.

Feyen, fā'i-ăañ, EUGÈNE: genre-painter; b. at Bey-sur-Seille, Meurthe-et-Moselle, France, Nov. 13, 1815. Pupil of Paul Delaroche; second-class medal, Salon, 1880; third-class, Paris Exposition, 1889; Legion of Honor 1881. His pictures of fisher-folk are meritorious, notable for delicate color. Studio in Paris. W. A. C.

Feyen-Perrin, -păr'răñ', FRANÇOIS NICHOLAS AUGUSTIN: genre-painter; b. at Bey-sur-Seille, Meurthe-et-Moselle, France, 1829. Pupil of Yvon and Léon Cogniet; medals, Salons, 1865 and 1874; Legion of Honor 1878. He generally painted pictures of fisher-life, and though his pictures are not without good technical qualities, they are weakly sentimental in expression. *Return of Fisher-girls at Cancale* (1874) is in the Luxembourg Gallery, Paris. D. in Paris, Oct. 14, 1888. W. A. C.

Fez: chief of the three capitals of Morocco and frequent residence of the sultan; 160 miles S. S. E. of Tangier, with which it is connected by only a bridle-path (see map of Africa, ref. 1–B). It is a beautiful and picturesque city from without, but filthy within. It is the commercial center of the country, and has important manufactures of silk, wool, and leather. There are sulphur baths in the vicinity. It was built probably in 793, and was long the capital of the Mohammedan states of West Africa. The Moors considered it the finest city in the world. It was once a great seat of learning, and is still held in great veneration. Pilgrimages were once made to Fez when the road to Mecca was considered unsafe. The Turkish cap or "fez" was, until recent times, made here exclusively. The population is 150,000.

Fezzan, fez-zaan' (anciently *Phasania*): in Northern Africa; between lat. 24° and 31° N. and lon. 12° and 17° E.; bounded N. by Tripoli, and on the other sides by the Sahara. It forms with Tripoli and Barka a province of Turkey. Most of Fezzan is a silent and barren desert with oases here and there. The northern part of the country is covered with bare hills of black quartz sandstone, without rivers and almost without vegetation. The southern part is level land, often consisting of dry sand. Only one-tenth of the soil is cultivable. The climate is in summer extremely hot, and at all seasons very dry. Wheat and barley are cultivated; dates, figs, and lentils are the principal articles of food. Horses and camels are reared, but cattle, and even sheep, are rare. Lions, tiger-cats, and jackals are abundant; also gazelles and ostriches. The inhabitants, whose number is estimated at about 50,000, are a mixed race of Berber Tuaregs, Arabs, and Negroes. They are governed by a sultan, who pays a tribute to the viceroy or *valy* of Tripoli. Murzuk is the capital, and the rendezvous for the caravans coming from Cairo, Tripoli, and Timbuctoo, which occasion a considerable trade.

Fiber, or **Fibre** [from Fr. *fibre* < Lat. *fibra*, fiber, filament]: a delicate, thread-like portion of the tissue of a plant or animal; also a substance composed of such filaments. Man has for ages availed himself of the filamentous character of various parts of plants to make clothing, domestic utensils, parts of instruments of the chase, and shelter for himself and his possessions. The animal kingdom has also been laid under contribution from the earliest times, and even the mineral kingdom contributes, in the substance known as asbestos, a fiber—in the general sense of the word—which has various uses in the arts. The history of the employment of these different materials, their uses, and the details of those processes of manufacture by which they are converted into fabrics for the use of man, belong properly to the different articles in this work in which they are severally described. (See SILK, WOOL, etc.) But the minute characteristics of the principal vegetable fibers, and the points on which their value for particular purposes depends, are most conveniently studied by grouping them under one subject. Anatomically considered, vegetable fibers may be referred to three different sources: viz., (1) plant-hairs, (2) fibro-vascular bundles, or (3) the separate constituents of the latter. (1) The important plant-hairs employed for textile purposes are the long, single cells which are attached to the seeds of certain species of *Gossypium* (cotton). (2) Fibro-vascular bundles are obtained from the stems of monocotyledonous plants, and consist chiefly of long bast-cells, with an admixture of spiral ducts (e. g. Manilla hemp). (3) The principal elements of fibro-vascular bundles of dicotyledons —namely, bast-cells and woody tissue—are used separately as fibers for spinning or for paper-making (e. g. flax and poplar-wood). These structures are cells of different shapes, sizes, and thickness of wall. Although they are derived from sources so different, they possess in common certain chemical and physical properties which must be considered before an examination of individual fibers is undertaken.

Chemical Characters.—The principal material of vegetable tissues consists of cellulose ($C_6H_{10}O_5$, or some higher multiple, $C_{18}H_{30}O_{15}$). This is generally accompanied by an incrusting substance which greatly reduces the flexibility of the fiber. Fibers are freed from this incrusting matter by the careful use of acids, alkalies, and bleaching agents. Cellulose dissolves in an ammoniacal solution of cupric oxide. For an account of other changes produced by chemical agents, see GUNCOTTON, and PAPER.

Physical Properties.—Fibers vary in color, from the snow-white of china-grass (*Böhmeria nivea*) to the grayish black of *Tillandsia*. All vegetable fibers are doubly refringent in polarized light. The conductive power of vegetable fibers for heat appears to be greater in the direction of the length of the fiber than perpendicular to it. The hygroscopic power of fibers is shown in the following table by Wiesner (*Rohstoffe*, § 293):

FIBER.	Percentage of water when air-dry.	Greatest amount of water.
Esparto	6·95	13·32
Belgian flax	5·70	13·90
Cotton	6·66	20·99
Fresh jute	6·00	23·30
Manilla hemp	12·50	about 40·00

Cotton.—Cotton fibers are the hairs which grow upon the seeds of species of *Gossypium*, plants belonging to the mallow family. Five species, now much mixed up, produce most of the cotton of commerce—*G. arboreum, barbadense, herbaceum, hirsutum, religiosum.* In India and China *G. arboreum* and *religiosum* are extensively cultivated; *G. hirsutum* is common in the West Indies; *G. barbadense* and *herbaceum* are those best known in the U. S. The seeds are numerous in the capsule (boll), which splits from the top into three or five parts as the fruit ripens. Each seed is clothed with delicate cells of variable length. Very short hairs are mixed thickly with the longer cells, which are used as fibers. The longer cells vary in length within certain limits in different species; the following measurements by Wiesner are averages:

Gossypium barbadense		3·89–4·05 cm.
"	*arboreum*	2·50
"	*herbaceum*	1·03–1·82 cm.

The cells are slender cylinders, with a slight enlargement a little above the base, after which they taper to the summit. The thin walls collapse and twist as the seed ripens, so that the slender, tapering tubes become spiral bands. The breadth of the flattened cells varies in different species. The measurements (from Wiesner) are given in fractions of a millimeter:

G. barbadense,	0·0192–0·0279,	most common	0·0252
G. arboreum,	0·0200–0·0378,	" "	0·0299
G. herbaceum,	0·0119–0·0220,	" "	0·0189
G. religiosum,	0·0255–0·0400,	" "	0·0333

The spiral is irregular, sometimes turning to the right and then abruptly turning in the opposite direction; occasionally there is simply a folding of one edge of the band over the other. These spirals adapt the cells for spinning. Contiguous fibers cling together slightly by interlocking their spirals as they are drawn out, and this slight grasp is strengthened by torsion of the thread at the spindle. Length of fiber is known in the cotton trade as length of "staple."

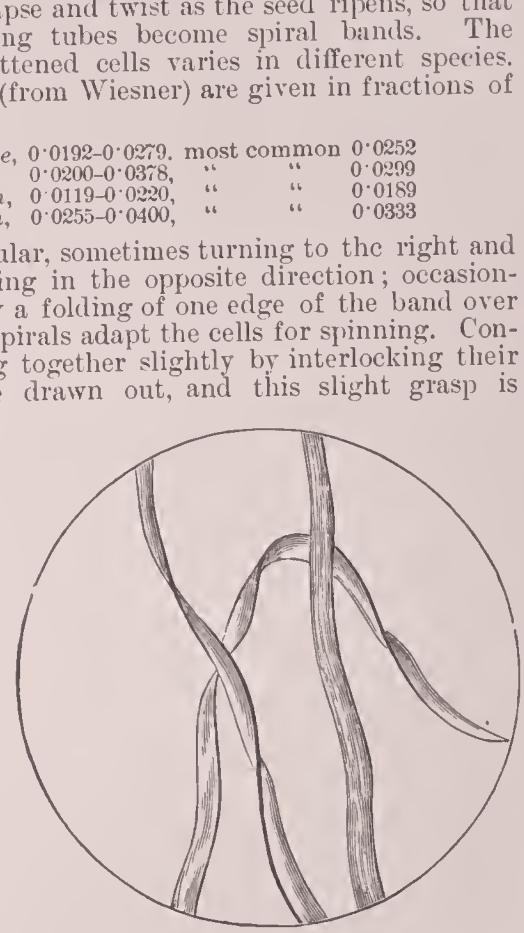

FIG. 1.—Cells of cotton (170 diam.).

Under a magnifying power of 200 diameters the flattened cell, if ripe, exhibits plainly the cell-walls and the space between them, which is filled with air. In exceptional cases the walls are thick, and then the air-space is reduced to a slender dark line. The surface of the wall has a cuticular layer, which may appear unevenly striated, somewhat granular, or nearly smooth. When a cotton fiber is placed in an ammoniacal solution of cupric oxide, the cell-wall dissolves, and leaves the cuticular layer somewhat altered in shape. The same phenomenon is observed in the case of other plant-hairs—for instance, vegetable silk—but never in bast-cells. This use of the solvent serves for the positive discrimination of the textile plant-hairs. The cotton fiber is usually white, but may be tinged yellow (*G. religiosum*). The finer short fibers are frequently colored green (*G. hirsutum*). This becomes rose-red on the addition of dilute acid, but the green color is restored by ammonia. The removal of the cotton fiber from the epidermis of the seed is effected without material injury to the hairs of black-seed cotton by means of the saw-gin. In green-seed cotton the fibers are more closely adherent. The shorter hairs which remain after the ginning are utilized in paper-making. The characters which determine the commercial grade of cotton are length of staple, fineness, and whiteness. In sea-island cotton, always black-seeded (*G. barbadense*), the latter qualities are found combined with great length of staple. The cotton of Louisiana is short-stapled, fine, and white; that from *G. religiosum* (and *G. flavidum*) is short-stapled, fine, and yellow.

Bombax Wool.—The mature seeds of many *Bombaceæ* are packed in their capsules in a mass of silky hairs which have become detached during ripening. These hairs are single cells of brilliant luster and a yellowish-brown color. It can not be spun except when mixed with cotton or other fibers, which it can in no way improve.

Vegetable Silk.—Under this name are grouped the fibers which grow on the seeds of many milkweeds (*Asclepiadaceæ* and the like). The remarkable fineness and luster of these fibers have led to many futile attempts to employ them, either alone or with cotton. The fiber is so weak and brittle that it would be useless for weaving even if it could be spun. A species of *Beaumontia* in India yields a vegetable silk of greater strength and almost pure whiteness. It is used in the manufacture of artificial flowers.

Fibro-vascular Bundles of Monocotyledonous Plants.—New Zealand Flax.—This fiber is obtained from *Phormium tenax*, now extensively cultivated in New South Wales. The leaves yield 22 per cent. of merchantable fiber. The fiber is yellowish, and composed of bast-cells mixed with ducts and cambium-cells. The bast-cells are 0·008–0·0189 mm. broad, and 2·7–5·65 mm. long. These form the raw fiber, which often exceeds a meter in length. New Zealand flax is fitted for cordage by its strength and resistance to the action of water and the atmosphere. According to Labillardière, the absolute strengths of the New Zealand flax, hemp, and flax are in the ratio of 60 : 48 : 34·5; silk = 100.

Aloë Fiber.—This is obtained from tropical species of *Aloë*. The fiber is white, of brilliant luster, and of nearly the same thickness throughout its great length of 20–50 cm. It is made up chiefly of bast-cells 1·3–3·72 mm. long, which do not readily separate from the bundle. The fibers are used in the rough state for cordage. The finest aloë fibers are spun and woven for fine muslins.

Manilla Hemp.—This fiber, known also in commerce under the names plantain fiber, Siam hemp, Menado hemp, and white rope, is obtained from the clasping leaf-stalks of *Musa textilis* of the Philippine islands. The fibers of other species of *Musa* have been employed, notably the plantain and banana. The outer parts yield coarse fibers 7 meters long—the inner, finer, about 2 meters. The fiber consists chiefly of bast-cells 2·7 mm. long and ·029 mm. thick. Manilla hemp is used for cordage.

Agave fiber, from *Agave americana*, now cultivated in many warm climates, is less tough and flexible than Manilla hemp. It is extremely light, and is capable of extensive use in rigging, but it has been more employed as an addition to bristles in the manufacture of brushes. "Sisal hemp" is the commercial name of the fiber of *Agave rigida*.

Cocoanut fiber, from species of *Cocos*, a tropical palm, is known in commerce under the name coir. It consists of the fibro-vascular bundles of the husk of the fruit. It is reddish-brown in color, very strong, and withstands the action of water for a long time. It is regarded by Grothe as the lightest of all fibers which can be used for making cordage. The raw fiber is 15–33 cm. thick, and consists of many structural elements. The bast-cells are the most important. These are from half a millimeter to a millimeter in length, and 0·016 mm. broad. The walls are unequally thickened. Coir is one of the most important vegetable fibers of the tropics. It is used for twine, cordage, tapestry, brushes, coarse paint-brushes, and even machine-belting.

Pineapple Fiber.—The fibers of the leaves of several species of *Bromelia* are employed for textile purposes. *Bromelia karatas*, of South America, yields a whitish, glistening fiber which resembles Manilla hemp, but is coarser, weaker, and less flexible. The fibers are cylindrical and about a meter in length, seldom exceeding 1·2 mm. in thickness. Its constituents are chiefly thin-walled bast-cells, with a few spiral vessels. When carefully prepared the finest fibers can be used for delicate fabrics.

Bast-fibers from Dicotyledonous Plants.—These are the inner layer of the bark. They are long, flexible cells, with thick walls, aggregated with parenchyma in bundles or bands which are separated by very narrow (or in some cases wide) medullary rays.

Flax.—This is the bast-fiber of species of *Linum*, chiefly *L. usitatissimum*, of which there are several varieties. The separation of the bast-fibers of flax, hemp, etc., from their contiguous tissues involves mechanical and chemical manipulations which are elsewhere described in detail. The stems are first subjected in mass to the action of water, either cold or warm. A kind of fermentation ensues, after which the bast-fibers can be separated from the surrounding tissues by mechanical means. The processes are known as "retting" and "scutching." The best results have been reached by what is known as warm-water rotting, followed by the use of a heckling machine, from which, according to the quality of the flax-plant, 15–20 per cent. of pure flax has been obtained. The length of flax fibers thus separated varies from a fifth of a meter to a meter and two-fifths; their width varies from 0·045–0·620 mm. The fibers are made up of regular cylindrical cells which taper toward the ends. The caliber of the cells is very minute, and is often reduced so that it appears a mere dark line. The cells are 2–4 cm. long and from 0·015–0·017 mm. broad. Here and there minute canals are to be detected in the walls, and by crushing the cell-wall exhibits spiral markings. The microscopic appearance of fresh flax bast-cells differs from that presented by manufactured fiber. The thickening layers of the cell-wall are more or less broken, and the cells are covered with dark lines which are nearly parallel to each other, and generally run in the direction of the length of the cell. This appearance is seen under a magnifying power of 200–300 diameters.

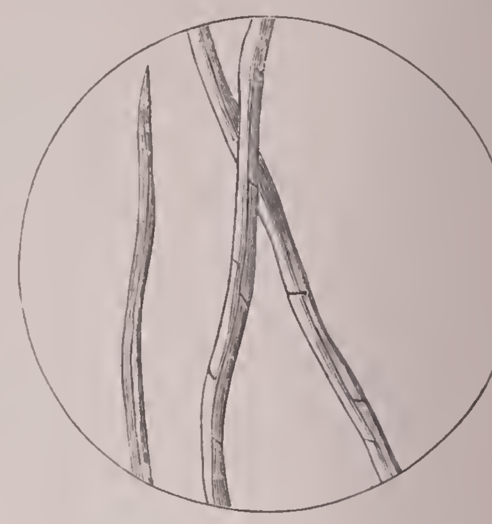

FIG. 2.—Bast-cells of flax (170 diam.).

The best flax fiber is whitish, and this absence of color is secured by the best methods of preparation. Much of the Belgian flax is steel-gray, and that of Egypt is grayish yellow. Flax has a delicate silky luster. The total absence of any luster is an indication that the bast-cells have not been wholly freed from surrounding tissues. Irish, Belgian, and Italian flax is regarded finest. The Irish fiber is very fine, soft to the touch, and strong. Many Belgian varieties are nearly as fine as the Irish, and exceed it in length. The longest fiber comes from Egypt. It is coarse and hard to bleach, but very strong. The use of flax in the manufacture of linen thread and linen fabrics can be traced further back than that of any other textile vegetable fiber. It is spun before bleaching.

Hemp.—This fiber consists of the bast-cells of *Cannabis sativa*, a plant of the nettle family. Hemp fiber is generally longer than flax fiber, sometimes reaching a length of 1 or 2 meters, or even more. Whitish and grayish fibers are best, the greenish come next, and lastly come the yellowish. Hemp fiber, even when finest, contains a mixture of parenchyma with the bast-cells. The latter are not so regular as those of flax. The walls are not always equally thick, but they are in general strongly thickened, and exhibit the canals which have been described under *Flax*. The air-space in the cells equals one-third of the whole breadth of the cell. Wiesner has shown that an ammoniacal solution of cupric oxide serves for the discrimination of hemp from flax. Under the influence of this agent the inner layer separates and becomes much crumpled, while the outer portion of the cell-wall becomes swollen and exhibits a fine parallel marking. Flax and cotton become blue by the action of iodine solution and sulphuric acid, but hemp turns somewhat greenish. The finest hemp is Bolognese, but by far the largest amount comes from Russia. It is not so fine as the hemp from Prussia or Austria. The hemp produced near Strassburg is used for spinning. Hemp is chiefly used for fine and coarse cordage.

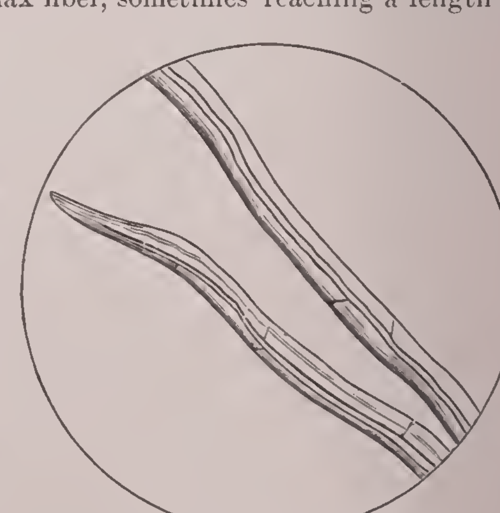

FIG. 3.—Bast-cells of hemp (170 diam.).

Mallow Hemp.—Several plants of the mallow family yield fibers which may be treated of in this place.

Hibiscus cannabinus of India, now cultivated in the West Indies, where it is called *ambaree*, has fibers of unequal length and differing greatly in their thickness. The bast-cells are 4–6 mm. long and ·020–·041 mm. thick.

Sida retusa and other species of *Sida* are much used in India as sources of fibers, which are coarse or fine according to the mode of preparation. The bast is without luster and of remarkable strength. The fibers consist almost wholly of flattened irregular cells, which in other characters much resemble the bast-cells of flax. Sunn hemp is produced from stems of *Crotolaria*, a plant of the pulse family. It is a fine and very strong fiber, only slightly hygroscopic. It is known in India also as Madras hemp. The flattened fibers are striated, and vary in width from 0·02–0·35 mm. Tercum fiber and Jetee fiber are from the stems of plants of the milkweed family.

China-grass and Ramie.—These are from plants of the nettle family—the first from *Böhmeria nivea*, and the second from *B. tenacissima*. China-grass is cultivated in India and Southern China. The bast is very tough, and can be finely divided into minute fibers, which are known as cottonized fiber. It is whiter and more lustrous than ramie fiber, but in other respects does not differ widely from it. *Ramie* is cultivated in China and Japan and in some parts of America. By the "cottonizing" process the fibers are broken up into the bast-cells, which are themselves sometimes broken. It is frequently possible to detect under the microscope traces of the mechanical injuries which they have received in the process. From the coarser fibers cordage is made, but from the finer the so-called *grass-cloth* or *grass-linen* is woven. The manufacture was long confined to India and China, but it has been undertaken in Germany as well.

Jute is the fiber of several Indian species of *Corchorus*, a plant of the linden family. *Corchorus capsularis* is the species most commonly employed in cultivation. In warm countries the culture of jute presents few difficulties. The seed is sown in April or May; in June or July the plant is in flower; in September or October the fruit is ripe. The strength and flexibility of this fiber, like those of flax, hemp, and ramie, diminish at the time the fruit matures. The bast-cells at that time become woody and more brittle, so that it is always desirable to cut the stems before the ripening of the fruit. The yield of jute is said to be from two to five times as great as that of hemp or flax. The stalk is 3 to 4 meters high. The fiber of jute is very silky, slightly colored, and composed almost wholly of bast-cells, which are cylindrical, somewhat flattened, or prismatic. The cells are 0·8–4·1 mm. long, and 0·016 mm. thick. The most striking peculiarity of its microscopic structure is the total lack of parallelism between the inner and outer surfaces of the wall. At many points the cell-wall is much thickened, while in others it is as thin as in vegetable silk. The same unevenness is seen in a few other fibers, but not in flax or hemp. Jute in its finest state has such a brilliancy of luster, and takes colors so well, that it has been much used to mix with silk. Much has been employed as a substitute for human hair in the manufacture of chignons, etc. Of late it has found an extensive use in papermaking. Jute is extensively exported from Calcutta, and is used chiefly in the manufacture of bagging. The term *gunny bagging* (*goni*, a Madras word) was applied not only to this, but to coarse fabrics made out of sunn, *Crotolaria juncea*. Much jute is brought into the market in the form of jute butts, in which state it is taken by the papermakers. A fiber much like jute, and frequently mixed with it, is obtained from *Abelmoschus* (*Hibiscus*) *tetraphyllos*, a plant of the mallow family from India. The bast-cells are 1–1·6 mm. long, and about 0·016 thick. See JUTE.

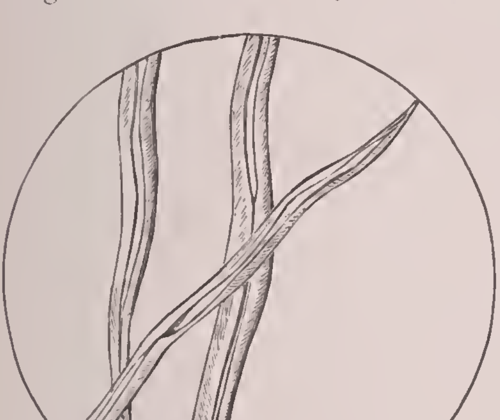

Fig. 4.—Bast-cells of jute (170 diam.).

Esparto Fiber.—This is obtained from the stems and leaves of *Macrochloa tenacissima*, a grass of Southwestern Europe. The fiber has been employed in the manufacture of coarse twine, but is now used wholly for papermaking.

Any of the fibers which have been spoken of can be used in the manufacture of paper, but only a few of them can be economically employed for this purpose at first hand. The fibers first serve in cordage or in woven fabrics, and then are turned over in the form of rags to the papermaker. Fibers for paper must be waste products or very cheap raw material (for instance, wood-tissue) which can be economically worked. *Zizania* (wild rice), *Phragmites* (reed), and the straw of cereals are used in the manufacture of different grades of paper.

Paper Mulberry.—This plant, which belongs to the fig family, furnishes the fibers of which the tapa cloth of Polynesia and the common paper of Japan are made. The inner bark is beaten to a pulp and spread out in thin layers. Much of the Japanese paper contains some vegetable mucilage by which the texture is rendered firmer, but in general the tissues cohere without the addition of any size.

Bast Tissue.—The bast of the linden and some other exogenous plants may be separated from the stem in broad and thick bands, which can be split up into thin ribbons. From these thin bands the coarse Russia matting is made.

Bast of the Linden (*Tilia parvifolia* and *T. grandifolia*).—Stems 30 to 40 cm. high are best for the purpose. From these stems strips 6 to 7 cm. broad can be taken. Their ultimate bast-cells are very thick-walled, and sometimes much widened in the middle. Cuba bast, used for tying up packages of cigars, is from *Paritium tiliaceum* and *elatum*, plants which may be referred to the genus *Hibiscus*, of the mallow family. *Lagetta lintearia*, the lace-bark tree, yields a delicate but strong white bast which has open meshes like coarse lace. *Daphne cannabina*, another plant of the same family (*Thymelaceæ*), has a tough, fibrous bast, which is employed in India for the manufacture of cordage and paper.

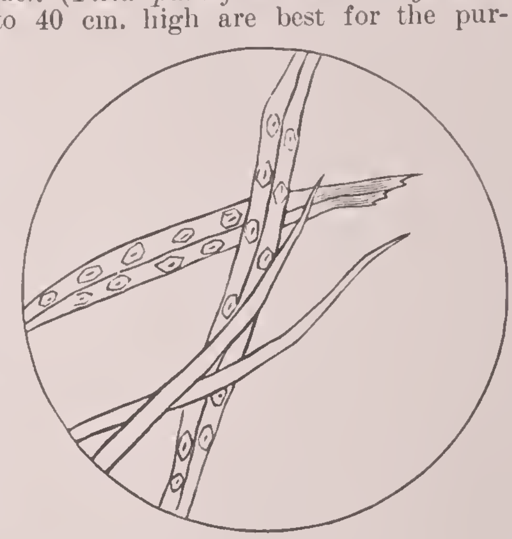

Fig. 5.—Spruce fibers (170 diam.).

Woody Fibers.—These are not used for spinning, but they are finding extensive application in papermaking, and their characters should now receive attention. Two important woods are selected, poplar and spruce, both of which are disintegrated either by mechanical means or by chemicals. In some mills the wood is boiled under pressure, with or without the presence of alkalies, after which it is easily broken down into its cells. In the Voelter process the wood is simply ground upon a rough surface, and the fibers are sufficiently fine for papermaking. The processes will be described in the article PAPER.

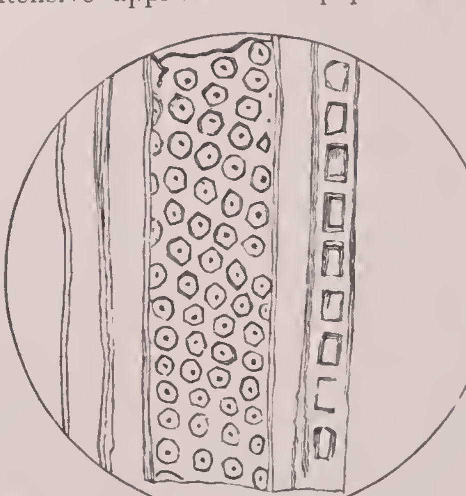

Fig. 6.—Poplar fibers and pitted vessel (170 diam.).

Chemical Tests for Vegetable Fibers.—A. Iodine in solution, followed by sulphuric acid. 1. Blue color: cotton; raw flax; cottonized china-grass and ramie (sometimes reddish to blue); raw hemp, greenish blue to pure blue. 2.

Yellow to brown: raw jute; raw esparto; bromelia; aloë and New Zealand flax.

B. Ammoniacal solution of cupric oxide. 1. Dissolves the cellulose: cotton, the cuticular layer remaining; cottonized china-grass and ramie; raw flax; hemp; sunn. 2. Colors the fiber blue, and causes it to swell up: raw jute; New Zealand flax; aloë; bromelia. 3. Simply colors the fibers: vegetable silk, blue; esparto, green.

C. Sulphate of aniline. Almost without effect on cotton, raw and cottonized china-grass and ramie; raw flax and New Zealand flax. Produces change of color in raw jute (gold yellow), raw hemp (light yellow), esparto (bright yellow), aloë and bromelia (gold yellow).

Microscopical Discrimination of Fibers as used.—Fibers of a single cell: cotton, vegetable silk, bombax wool (plant-hairs), cottonized ramie and china-grass (isolated bast-cells). Groups of cells chiefly bast: raw jute, flax, aloë. Groups of cells chiefly bast, with traces of parenchyma of the bast: raw sida, abelmoschus, and hemp. Groups of bast-cells mixed with ducts; New Zealand flax, Manilla hemp, esparto, coir. E. M. SCHAEFFER.

Fi'brin [from Fr. *fibrine*, deriv. of *fibre* < Lat. *fibra*, fiber]: an organic substance formed from the blood and lymph. From the former it is obtained in the proportion of two or three parts per thousand; in the latter in smaller quantity. Fibrin itself does not exist in the blood, but certain elements which together make fibrin do. These "fibrin factors" are increased in inflammatory conditions, and therefore the blood clots easily—a blood clot being largely fibrin. (See COAGULATION.) In wasting conditions fibrin factors are decreased, and clotting is slow.

Fibrin may be extracted from freshly drawn blood by whipping it with a bundle of twigs, to which, as it coagulates, it adheres. After washing, the coagulum presents a white, tough appearance, and upon placing it under the microscope it is found to consist of colorless and elastic filaments of considerable length, crossing each other in every direction, so as to form an irregular network. Within a few minutes after blood has been taken from the body it commences to lose its fluid condition, gradually becoming more and more solid until its coagulation is complete. It is then said to be clotted. The blood clots in the interior of the body after death; also during life when effused into the tissues, and also in a blood-vessel itself when a ligature is placed around it. This change depends wholly upon the presence of fibrin, for after its withdrawal the blood remains fluid indefinitely. With regard to the exact nature of coagulation there are many theories, but nothing is definitely known.

This clotting of the blood is of the utmost importance in the preservation of life. When a blood-vessel is wounded or cut across, the fibrin of the blood which is poured out coagulates upon the edges of the vessel, forming a plug, so that no more blood can escape. If it were not for this spontaneous coagulation, it would be impossible ever to arrest hæmorrhage. See BLOOD. Revised by WILLIAM PEPPER.

Fibrous Tissues: a name applied to a group of the connective tissues, and of great importance as structural elements. They are generally assigned to two groups—the white and the yellow fibrous tissues, the former found in tendons, fasciæ, and other unyielding parts, the latter elastic and found in many organs, notably in the middle coat of the arteries. Fibrous tissues, though so important to animal life, always play a merely mechanical part. Sparingly supplied with blood-vessels and nerves, they are not highly vitalized and have no active functions. They are composed of an albuminoid substance, which is changed into gelatin by boiling. Microscopically, fibrous tissue consists of a more or less dense or loose mesh of fibers with here and there a cell, the latter being of various shapes, sometimes round, again spindle-shaped, or in other cases star-shaped or stellate. White fibrous tissue exists also in many neoplasms, constituting fibromata or fibroid tumors.

Revised by WILLIAM PEPPER.

Fibro-vascular Bundles: See FIBER.

Fib'ula [=Lat. *fi'bula*, clasp, buckle, for **fivi'bula*, **figui'-bula*, deriv. of *fi'gere*, fix, fasten]: in the vertebrate skeleton, the outer of the two bones of the leg between the knee and the ankle, the inner bone being the tibia. In man the fibula is much smaller than the tibia, and does not quite reach the knee-joint. Its upper extremity is the styloid process; its lower, the outer malleolus. It is developed from three centers, and is regarded as the homologue of the radius in the upper extremity.

Fichet, fee'shā', GUILLAUME: educator; b. at Aunay, near Paris, France, early in the fifteenth century; was in 1467 rector of the University of Paris, teaching at the same time rhetoric, theology, and philosophy. He was employed by Louis XI. in making peace with the Duke of Burgundy, and was the patron by whose influence the first printing-press was brought from Germany and set up in the Sorbonne at Paris. Among the first books printed in France were his *Rhetoricorum Libri tres* (probably 1470) and *Epistolæ, in Parisiorum Sorbona* (1471). Fichet afterward held office at the papal court of Sixtus IV. The date of his death is unknown.

Fichte, fich'te, IMMANUEL HERMANN, von: son of the great Fichte; b. at Jena, July 18, 1797, and educated at Berlin, where he studied philology. He was early attracted to philosophy, however, especially by the ideas of his father, and made a comprehensive study of its history. He also heard Hegel's lectures, but he is said to have felt rather disgusted at them, and in his own philosophical writings the opposition to Hegel is often sharp and pointed. He spent the earlier part of his life as a teacher. In 1836 he was appointed Professor of Philosophy at the University of Bonn, and from 1842 to 1863 occupied the same office at the University of Tübingen. In 1863 he retired to private life in Stuttgart. His literary activity was very comprehensive and very prolific. The most important of his works are *System der Ethik* (1850–53); *Anthropologie, neubegrundet auf naturwissenschaftlichen Wege* (1860); and *Psychologie als Lehre vom bewussten Geiste des Menschen* (1864). One of the most interesting of his many essays and speeches is that with which he opened a meeting of philosophers at Gotha in 1847, *On the Philosophy of the Future*. He also wrote on politics, *Grundzüge zur Entwickelung der künftigen deutschen Reichsverfassung* (1848), and on theology, *Die speculative Theologie* (1846). I. H. v. Fichte taught that the world was created by God; he became a convert to Spiritualism. In 1867 he was ennobled. D. in Stuttgart, Aug. 8, 1879.

Fichte, JOHANN GOTTLIEB: the second of the four greatest philosophers of Germany; b. at Rammenau, in Upper Lusatia, May 19, 1762. He was of Swedish descent, and his father was a ribbon-weaver. In his earliest youth he exhibited the moral characteristics that appeared subsequently in the stern outlines of his philosophic system. When he was in his ninth year his excellent memory attracted the attention of the Baron von Miltitz, who interested himself in his education, and placed him successively in the family of a clergyman at Niederau, at the town-school of Meissen, and at the Princes' School of Pforta (1774–80). At the latter place he became acquainted with the writings of Goethe, Wieland, and Lessing. The latter writer exercised an overpowering influence on his mode of thinking and his literary style. He studied theology at Jena and Leipzig, and began to grapple with the problems that form the center of his philosophic system—those of free will and necessity. At this time he studied the systems of Spinoza and Wolff, and adopted a fatalistic view of life. While acting as family tutor in Zurich (1790) he made the acquaintance of Johanna Rahn, niece of the poet Klopstock, whom he subsequently married. Returning to Leipzig in 1790, he began the study of the Kantian critiques, which had been published, the critique of *Pure Reason* in 1781, of *Practical Reason* in 1788, and that of the *Judgment* in 1790. He now found a new world, and began to live a higher life. He saw free will to be the highest principle, and his fatalistic theories crumbled away at once. He visited Kant, and presented as his letter of introduction the manuscript of a *Critique of all Revelation*, a work composed in five days. It won him Kant's respect and esteem, and on its anonymous publication was taken for an original work of Kant by the philosophic public. Fichte, being announced as its author, found himself at once in the foremost rank of philosophers. After his marriage in 1793 he published a work in which he attempted to justify the French Revolution, and by this brought upon himself the suspicion of the German governments. Nevertheless, in 1794 he was called to the chair of Philosophy in Jena, to succeed Reinhold, and there came into personal contact with Goethe, Schiller, Wieland, Herder, Humboldt, and Jacobi, and carried on an extensive correspondence with Reinhold, Schelling, Tieck, Novalis, and the Schlegels. Fichte here elaborated the great central work of his system, in which he attempted to demonstrate the basis of the Kantian system by an *Analysis of Consciousness*. Kant had borrowed his categories from the traditions of formal logic, and thus, while he combated dogmatism, had grounded his system on a dogmatic basis. Fichte sought to correct this by supplying a strict deduction of the categories from pure consciousness, and thus to place philosophy forever beyond the reach of skepticism, and make it rival geometry in the certainty of its results. His *Science of Knowledge* (*Wissenchaftslehre*) appeared in 1794. Goethe, who had read it sheet by sheet as it passed through the press, wrote him: "In my opinion you will confer a priceless benefit on the human race, and make every thinking man your debtor, by giving a scientific foundation to that upon which nature seems long ago to have agreed with herself." It was the first attempt in the history of human thought to unfold dialectically from the Ego the *a priori* conditions of all knowledge. It was at once adopted by the leading thinkers of the Kantian school. In an essay *On the Ground of our Faith in a Divine Government of the World*, which he published in his *Philosophical Journal* in 1798, he used language in speaking of the moral order of the world implying its equivalence to the idea of God, and thus aroused the charge of atheism against him. This, strengthened by the prejudice created by his work on the French Revolution, resulted in his dismissal from his professorship, notwithstanding a vigorous self-defense. To add to his misfortune, Kant at this time saw fit to publish his disclaimer of Fichte's system as a true interpretation of his own. He declared that in his opinion the *Science of Knowledge* was an altogether faulty system, chimerical and ephemeral. Refused protection by neighboring states, but assured of toleration by Frederick William III. of Prussia, he repaired to Berlin, and came into intimate association with Schleiermacher, Frederick Schlegel, Novalis, Tieck, Schelling, and others. Here he published several eloquent popular expositions of his system, the most prominent of which are the *Destination of Man* (1800); *The Sun-clear Report to the Public upon the True Nature of the Latest Philosophy—an Attempt to Force the Reader to an Understanding of it* (1801); *The Way to the Blessed Life* (1806). An outline of the philosophy of history appears in his *Characteristics of the Present Age* (1806). In his *Addresses to the German Nation* he took a bold, patriotic stand against Napoleon (1808). He became rector of the University of Berlin upon its establishment, and exerted a powerful influence upon its constitution. The new career opening to him after the downfall of Napoleon was cut short by his death from typhoid fever on Jan. 27, 1814.

As a philosopher, Fichte's position is that of the immediate successor of Kant and the completer of the critical system. Kant had endeavored to obtain a critical insight into the nature of knowledge. It was for him the product of two factors—the Ego, or subject, and things-in-themselves. He endeavored to determine accurately the value of the subjective coefficient of our knowledge. The intuitions of Time and Space, and the categories of Quantity, Quality, Relation, and Modality, were found to be the results of the spontaneity (or original action) of the Ego; and these results formed the subjective coefficient of knowledge. Kant did not show how these determinations arise in the spontaneous activity of the Ego; he only inferred that they did thus arise from the demonstrated impossibility of their arising from experience. They were logical conditions of all experience whatsoever, and were presupposed by experience, instead of derived from it. The most obvious difficulties of Kant's theory were removed by Fichte's science of knowledge. They were two: 1. Kant held that the subjective factor of knowledge included the general forms or laws (Time, Space, Causality, etc.), while objective things *per se* furnished the contents of sensation, or in other words affected the sensory. But *to affect* is *to cause*, and hence Kant, while he denied all objective existence to the subjective factor of knowledge, was obliged to apply the category of causality to things in themselves, in order to justify their necessity in his theory. Thus his subjective coefficient belonged also to his objective coefficient of knowledge. Fichte avoided this glaring inconsistency by showing that the activity of the Ego furnishes the groundwork of the objective. In ordinary consciousness this phase of the activity of the Ego is not perceived, but by disciplined reflection the mind may acquire the power of seeing the mental genesis of the ideas of Time and Space and of the laws of Causality, Substantiality, etc., and the resulting objectivity which is given to the mere subjective feeling which is the basis of all sensation. 2. Kant's illogical attempt to destroy dogmatism by the critique of *Pure Reason*, as well as skepticism by the critique of *Practical Reason*, has been mentioned. He had not deduced the necessary basis of his categories, but had dogmatically assumed them from logic, without proving them, and hence had left his philosophy open to skepticism. Fichte made a searching analysis of Consciousness, and, starting from the self-identity of the Ego = Ego, or A = A, and proceeding to the self-distinction of the Non-ego not = Ego, or — A not = A, he reaches the idea of limitation or division of the totality by mutual exclusion of the self and the not-self. Thus the first analysis shows the genesis of the categories of Quality, Reality, Negation, Limitation. Pursuing this subtle psychological analysis, he arrives at the other categories, and establishes the fundamental distinctions between realism and idealism, between theoretical and practical. The most wonderful characteristic of this psychological analysis—which is valid for all time, although Fichte's concrete applications of his philosophy to the worlds of nature and history lack value by reason of his failure to study each department in its detailed developments—consists in his demonstration of the successive additions made by reflection in the endeavor to become self-conscious. For instance, in order to be conscious of feeling, the mind thinks it under the form of time; to be conscious of feeling *and* time, it thinks it under the form of space; to be conscious of the latter, it thinks the object under the form of causality. Thus it successively recognizes its own phases of formal activity as conditions of objectivity, and adds these, one after the other, to its sensation, and thereby arrives at the perception of an object in space which affects the organ of sensation. This process is present in all perception of external objects, but is rapid and unconscious. As with Kant, so with Fichte, the greatest stress was laid on the free will and the moral aspect of human nature.

Fichte's complete works were collected and edited in eight volumes by his son in 1845–46. Access to his system through English translations is now quite adequate. The *Life of Fichte* and his popular writings, including *The Nature of the Scholar*, *The Vocation of the Scholar*, *The Destination of Man*, *Characteristics of the Present Age*, *Way toward the Blessed Life*, *Outlines of the Doctrine of Knowledge*, were published in London, translated by William Smith (1848–49). *The Destination of Man* was also translated by Mrs. Percy Sinnett (London, 1846), and a portion of it by one of the contributors to *Hedge's German Prose Writers* (New York, 1856). The *Science of Knowledge* (ed. of 1794) and *Science of Rights* were translated by A. E. Kroeger (Philadelphia, 1868–70). In the *Journal of Speculative Philosophy* have appeared (*a*) *The Introduction to the Science of Knowledge* (ed. of 1794), (*b*) *Criticism of Philosophical Systems*, (*c*) *Sun-clear Statement*, (*d*) *New Exposition of the Science of Knowledge* (1801), (*e*) *Facts of Consciousness*. See articles on KANT, SCHELLING, HEGEL, LEIBNITZ, and PHILOSOPHY. WILLIAM T. HARRIS.

Fichtelgebirge, fich'tel-ge-beer'ge [Germ.; *fichtel*, dimin. of *fichte*, pine + *gebirge*, collect. of *berg*, mountain]: a short but broad range of mountains, covered with firs and pines, on the northern frontier of Bavaria. They are not remarkable for their height, the highest peak, Schneeberg (Snow Mountain), rising only 3,461 feet, but by reason of their central position they form the nucleus from which all the chief mountain-ranges of Germany diverge, and they separate the affluents of the German Ocean and the Black Sea, the Naab descending from them on the S. to the Danube, the Main on the W. to the Rhine, the Saale on the N., and the Eger on the E. to the Elbe.

Fici: plants of the genus FICUS (*q. v.*).

Ficino, fee-chee'nō, MARSIGLIO (*Ficinus*): reviver of Platonic philosophy in Italy; b. in Florence, Oct. 19, 1433; d. at Careggi, Oct. 1, 1499. When a youth he was selected and carefully educated by Cosimo de Medici with a view to placing him at the head of a proposed academy for the cultivation and dissemination of Platonic philosophy. The zeal of Cosimo for Platonism had been kindled by the enthusiasm of a learned Greek—George Gemistus Pletho—who had come from Constantinople with John Palæologus II. to the Council of Florence on the mission which resulted in the union of the churches of the East and West, in 1438. The academy which was founded in 1460 became in after years an asylum for the learned Greeks who had fled to Italy on the capture of Constantinople by the Turks (1453). About this time the invention of the art of printing contributed the necessary means for the rapid spread of classic study, by multiplying and rendering accessible the originals and translations of the same. Ficino translated into Latin the entire works of Plato (1484) and Plotinus (1492), accompanying them with a more or less complete commentary. Besides these, he made translations of many of the works of Proclus, Jamblichus, Porphyry, Dionysius Areopagita, Hermes Trismegistus, Alcinous, Speusippus, and Xenocrates. His translations are still of some value in restoring the original text, as it seems that he had before him manuscripts now lost. His Latin is pure and perspicuous. His work on the Platonic theology (18 volumes; 1482) treats of the nature of the soul, of spirits, and of God. It is especially devoted to the proofs of immortality and the refutation of the Averroistic doctrine of the World-Soul or Mundane Intelligence, which makes the latter to be immortal and the particular soul to be perishable, being cognizant of universals only through participation in the higher intelligence. The most important feature of the philosophy of Ficino is his claim to harmonize Platonic idealism with Christian doctrine. This gave rise subsequently to a school of mystics which numbers Pico of Mirandola, Reuchlin, Agrippa of Nettesheim, Patritius, Telesius, Ramus, and others. The supposed connection of Neoplatonism with Jewish mysticism through the Cabbala, and the discovery of a profound esoteric doctrine beneath the letter of the Bible, stimulated the enthusiasm of its votaries. Freedom in philosophy begins with the conflict of authorities, as Gibbon remarks. The conflict between the schools of Platonism and Aristotelianism at that time prepared the way for the original thinking of the following centuries. Ficino, with Bessarion before him and Pico after him, stands opposed to Pomponatius, the reviver of Alexandrian Peripateticism. The collected works of Ficino (not including the translations of Plato and Plotinus) were published at Basel in 2 vols. (1561–76); revised with additions, 2 vols., Paris (1641). Cf. J. A. Symonds, *The Renaissance in Italy* (ii., p. 324 ff.). W. T. Harris.

Revised by Alfred Gudeman.

Fick, Adolf Eugen, M. D.: physiologist; b. Sept. 3, 1829, in Cassel; educated at Universities of Marburg and Berlin; tutor and professor University of Zürich, 1852–62; Professor (extraordinary) of Physiology University of Würzburg, 1862–68, full professor since 1868. Author of *Lehrbuch der medizinischen Physik* (3d ed. 1885); *Anatomie und Physiologie der Sinneswerkzeuge* (1864); *Compendium der Physiologie* (4th ed. 1891); *Mechanische Arbeit und Warmeentwickelung bei der Muskelthätigkeit* (1882); has contributed papers to the leading German scientific journals.

Fick, August: philologist; b. at Petershagen, near Minden, Germany, May 5, 1833; studied philology at Göttingen, and remained there as teacher in the gymnasium, and later as professor in the university, till 1888, when he became professor in the University of Breslau. His most important work is *Wörterbuch der indogermanischen Grundsprache* (1868), which was republished (1870) as *Vergleichendes Wörterbuch der indogermanischen Sprachen* (4th ed. 1891–93). He has also published *Die Homerische Odyssee in ihrer ursprünglichen Sprachform wiederhergestellt* (1883), a similar edition of the *Iliad* (1885), and the poems of Hesiod (1887). His works, generally marked by independence and originality, are always rich in valuable suggestion even when the main thesis fails to carry conviction. B. I. W.

Fiction [from Fr. *fiction* < Lat. *fictio*, a shaping, making, pretending, deriv. of *fin'gere*, shape, feign (whence *figu'ra*)]: in law, in its ordinary meaning, an assumption that a thing is true which is either not true or which is as probably false as true. Best, an author on *Presumptions*, distinguishes it from a presumption, a mere rule of law established for the purpose of reaching a certain conclusion, though it may be arbitrary, which is based on public convenience or on the difficulty of arriving at the exact truth. Thus the rule that a child under seven years of age can not commit a felonious crime is a conclusive presumption, rather than a fiction. Some writers—as, e. g., Maine (see his work on *Ancient Law*)—use the word "fiction" in a broader sense, to signify any assumption which conceals, or affects to conceal, the fact that a rule of law has undergone alteration, its letter remaining unchanged while its operation is being modified. From this point of view fiction is a powerful agency in the improvement of law. By means of it new views more adapted to the age are introduced under color of observance of ancient forms. The agencies causing the progress of jurisprudence are fiction, equity, and legislation. Among these fiction has played no unimportant part. In some instances courts have even, by means of it, subverted the will of the legislature. A striking instance of this intentional employment of fiction is found in the early English statute of entailments. The history of this subject is so illustrative that it will be stated with some fullness. It is a well-known rule of English common law that a conveyance of land "to A and his *heirs*" gives him the complete ownership and power of disposal of the property. If, however, the words "*heirs of the body*" were used, instead of "heirs," the effect would be different. Such language points only to descendants; and as there might be none, the estate was deemed to be a conditional one. If "heirs of the body" should come into existence, the condition on which the estate was given was deemed to be performed, and the title of A for certain purposes became absolute. For example, he could sell, and thus cut off all claim on the part of his descendants, or he could forfeit the property by his treason, or encumber it by his voluntary act. If none of these acts were done, the estate would pass to surviving heirs of the body, and if there were no such persons, would revert to the original grantor.

The English landed proprietors being dissatisfied with this result, through their influence in Parliament caused a statute to be passed in the reign of Edward I. (13 Edw. I., c. 1) which was designed to prevent it, and to vest the ownership in A in the case supposed, and at the same time deny to him the power to sell or to encumber the property. The intention was that he should use it as owner, fell trees, mine, and do other proprietary acts, while at the same time the property should descend according to the line prescribed in the terms of the gift. From this violation of a cardinal rule of ownership mischievous consequences soon developed themselves. Creditors and purchases were defrauded, lessees were deprived of their leases, for the tenant in possession could make no deed, mortgage, or lease which should outlast his own life, though he appeared to all observers to be the owner. . Records of title were unknown, so that fraud was easily practiced by one who had all the outward badges of ownership. This state of things was endured for a long period, the nobility being unwilling to repeal a law which tended so strongly to the preservation of their estates.

In the reign of Edward IV., after the lapse of nearly two hundred years, the courts allowed a fictitious legal proceeding to be gone through with, which was declared to have the effect to destroy the entailment, and to enable A in the case supposed to become absolute owner. It was a pure fiction, called a "common recovery," and so understood by all parties to it. It was a fictitious lawsuit with regular and formal parties, and its effect was to destroy the entailment, and vest an absolute title in the first person named in the entailment (A). The rule soon became so perfectly settled that it was impossible for a conveyancer to frame a regular entailment without having it subject to this mode of disencumbering the title, so that a "common recovery" became a mere mode of conveyance. In later times the fiction had become so transparent and so cumbrous that the Parliament substituted in its place a mere deed of conveyance, known as a "disentailing deed" (3 and 4 William IV.; c. 74). The case is of interest and value as showing how the fiction, after being allowed for a time, is ultimately recognized as a change or modification of law, and tends to assume the form of a precise provision by means of a statute.

There are many fictions of law regularly resorted to, and having a powerful influence on the administration of justice. It is a cardinal maxim that a legal fiction must be consistent with equity. This doctrine has not been universally followed, particularly in the so-called doctrine of "relation." The meaning of that doctrine, so far as it refers to time, is that in some cases, when an act is done on a particular day, it shall be considered for legal purposes as being done on some earlier day. The act is then said to "relate back" to that prior day. One mischievous consequence of this rule was that if a law was passed during a session of Parliament, it "related back" to the first day of the session, although weeks or months might have elapsed. By this vicious retrospection an act which was perfectly lawful when committed might be treated as a crime. This result was done away with by the statute of 33 George III., c. 13, which enacted that the time when an act receives the royal assent shall be the date of its commencement, unless some other provision is made by law. The same rule prevails in the U. S. The doctrine of "relation" is resorted to in bankruptcy, referring the effect of the decree back to some date earlier than that of the commencement of the proceedings. It is also used in many other cases, not only as to time, but as to place, person, or thing, and in general is made to work consistently with right and justice. An instance of it may be noticed. Should a person deliver a deed conditionally, or in *escrow*, and subsequently, between the time of the first and the ultimate delivery, become disabled to convey, the law will refer the transaction back to the first delivery, for the purpose of upholding it. In other aspects of the case the conveyance would only take effect from the delivery transpiring after the condition had been performed.

Another instance of a fiction is the legal rule that "the law regards no fraction of a day." By means of this theory a person born on the seventh of the month becomes of full age twenty-one years later on the sixth. The fiction, however, gives way where justice requires that a distinction should be taken between two acts done on the same day. In this case a single moment may be decisive, as where two or more conveyances are left for record on the same day by parties having antagonistic interests.

Many attempts have been made to classify fictions, but without much practical success. They are said to be limited by three principal rules: *First*, the fiction must have the semblance of truth: that which is impossible is not to be feigned. *Second*, it shall not be allowed to work an injury. *Third*, it is only to be resorted to to accomplish the end for which it was introduced. To that extent it can not be contradicted; beyond that it may be impugned. "The law," says Gould, in *Lord Raymond's Reports*, 516, 517, "does not love that rights should be destroyed, but, on the contrary, for the supporting of them invents notions and fictions." When they are urged to an intent and purpose not within their reason and policy, a party injuriously affected by them may show the truth. T. W. DWIGHT.

Fiction: in literature. See NOVEL.

Fi'cus [Lat., fig > O. Fr. *figue*, whence Eng. *fig*]: a genus of plants belonging to the *Artocarpeæ*, or breadfruit family, in which it is associated with the breadfruit of the Pacific, the jack of the Indian Archipelago, the mulberry, the Osage orange of the U. S., and the upas-tree of Java; also, any plant of this genus. The common fig-tree (*Ficus carica*) is the most valued representative of this genus. (See FIG.) Many trees of the family yield a remarkable milky juice, which, inspissated, forms the caoutchouc of commerce. The original india-rubber plant, or *Ficus elastica*, of Java, is one of these. The celebrated banyan-tree (*Ficus indica*) of India yields the well-known resin gum-lac. Several of the *Fici* have poisonous qualities; as, for instance, the *Ficus toxicaria*, a native of the Malay islands. One of the most remarkable species is the peepul or BO-TREE (*q. v.*).

Fiddler Crab: See CRAB.

Fid'ei Commis'sum [Lat., committed to one's trust]: a species of trust existing under the Roman or civil law which was employed to effect the testamentary disposition of property to certain persons who by law were incapable of receiving it by direct device or bequest. Exiles, strangers, unmarried persons, those who had no children, and some other classes of persons were under this disability, and whenever a testator desired to evade this law and leave his property to one thus debarred, he selected some person as heir or legatee who was not incapacitated from taking; annexing a request to the gift that he who was thus constituted a recipient of the property should hold what he received in trust for him who was intended as the real object of the testator's bounty. When this form of trust was first adopted there was no means by which the duty imposed upon the immediate donee could be enforced against him. Its fulfillment depended entirely upon his good faith and honor. From this circumstance the trust received the name of *fidei commissum*. In later times, however, to prevent the frauds which were sometimes perpetrated by failure to fulfill such trusts, laws were enacted rendering their execution compulsory. In the time of Justinian a law was adopted by which a trustee could be compelled to disclose under oath the fact that a trust had been committed to him. From *fidei commissa* was derived the doctrine of uses in the English law. See the article USES.

Fide'næ: an ancient Latin city on the left bank of the Tiber, 5 miles above Rome. Livy erroneously calls it an Etruscan city. In Rome's early days Fidenæ was her powerful rival and enemy, but it declined as Rome increased, and before Cicero's time was an insignificant village, important only for its tufa quarries.

Fi'des [Lat., Faith (personified)]: in the religious system of ancient Rome, the personification of good faith or honor, and, as a quality fundamental to all social organization, Fides was represented as one of the oldest divinities, older even than Jupiter. In harmony with this conception, her shrine, the temple of Fides Publica, was reckoned among the oldest at Rome. She was especially revered as a goddess of international relations, and her temple was a depository of documents relating to such affairs. Represented variously; most commonly, however, in the older period as a matron bearing a wreath, carrying ears of corn and a calathus. G. L. HENDRICKSON.

Fief [from O. Fr. *fief*, *fien* (whence Eng. *fee*, estate), from O. H. G. *fihu*, cattle, property: O. Eng. *feoh*, cattle, property > Eng. *fee*, payment. See FEE]: an estate or dignity held of a feudal superior upon condition of military service. See FEUDAL SYSTEM.

Field: See DYNAMO-ELECTRIC MACHINES.

Field, CYRUS WEST: a son of the Rev. David D. Field, D. D. (1781–1867); b. at Stockbridge, Mass., Nov. 30, 1819; educated in Stockbridge; was a clerk in New York when fifteen years old, and a few years later became the head of a prosperous mercantile business. He traveled in 1853 in South America for six months, and on his return became interested in ocean telegraphy. Having been applied to for aid in building a land-telegraph across Newfoundland, to receive the news from a line of fast steamers to ply between St. John's and Ireland, he conceived the idea of carrying the wire across the Atlantic. In 1854 he obtained from the Legislature of Newfoundland the exclusive right for fifty years of landing telegraph cables from Europe and America on that island. Field next formed a company known as the New York, Newfoundland, and London Telegraph Company, with Peter Cooper, Moses Taylor, Marshall O. Roberts, and Chandler White, and in two years the lines were finished from New York across Newfoundland. The first cable to extend from Newfoundland to Cape Breton island having been lost in a storm while it was being laid in 1855, a second cable was laid in 1856. In that year he went to London and organized the Atlantic Telegraph Company, of which he furnished one-fourth of the capital. The U. S. and British Governments furnished ships for the enterprise. Field accompanied the expedition of 1857, the two of 1858, and those of 1865–66 for the laying of cables. Of these, the first two were failures, and the cable laid by the third worked but a short time. The public lost faith in the enterprise, civil war followed in the U. S., and Field could not obtain the capital to renew the attempt until 1865. In that year the Great Eastern laid 1,200 miles, when the cable parted, and was lost for the time. In 1866 a cable was successfully laid, and the cable of 1865 was picked up in mid-ocean by the Great Eastern and completed. Field was the recipient of many medals, of the thanks of Congress, and of other honors at home and abroad. He was subsequently engaged in other large enterprises, among which was the construction of elevated railroads in the city of New York. D. in New York city, July 12, 1892.

Field, DAVID DUDLEY, D. D.: clergyman; b. at East Guilford, now Madison, Conn., May 20, 1781; graduated at Yale College 1802; was settled at Haddam, Conn., from 1804 to 1818, and then at Stockbridge, Mass., from 1819 to 1837; then at same church as before in Haddam from 1837 until 1851, when he returned to Stockbridge to spend his last days, and where he died Apr. 15, 1867. Besides many published sermons, he was the author of a *Life of David Brainerd*, a *History of Middlesex County*, *Conn.*, and of *Berkshire County*, *Mass.*

Field, DAVID DUDLEY, LL. D.: jurist; b. at Haddam, Conn., Feb. 13, 1805; eldest son of Rev. David Dudley Field; entered Williams College in 1821. In 1825 he began the study of the law, and was admitted to the bar in 1828, and settled in New York, where he soon made his way to the front rank of his profession. Finding the practice of the law, which was after the English model, extremely complicated, dilatory, and expensive, he began to study how it could be revised and improved, and so entered upon those labors in favor of law reform which were to occupy so large a part of his life. In 1839 he published his first essay on the subject, which he continued to press upon the public attention until in 1847 he was appointed by the Legislature of New York one of a commission to reform the practice of that State. Upon this work he was engaged for two years, and the result was contained in two codes of procedure, the one civil and the other criminal. The code of civil procedure was in great part adopted by the State of New York, and has since been adopted by twenty-seven States and Territories. It is the basis of the legal reform established by the Judicature Acts in England, and of the practice in several of the British colonies, including India. After the completion of these codes he was in 1857 placed by the State of New York at the head of a new commission to undertake a codification of the whole body of the law. This was a work of years, but in 1865 the commission reported a civil code, a penal code, and a political code. These five codes, which were mainly the work of Mr. Field, covered the whole province of law in the U. S., both common and statute, and were designed to supersede the unwritten or common law—the object being to give the people in this compact form the whole of the laws by which they were governed. This body of law has been adopted in full and intact only by the State of California and the States of North and South Dakota. In 1867 he brought before the British Association for Social Science a proposition to frame an international code. This led to the preparation by him of what was really a complete work on international law, though modestly entitled *Outlines of an International Code*, one feature of which was the introduction of the principle of arbitration to settle disputes between nations. This work has attracted great attention in Europe, and been translated into French and Italian. The code of criminal procedure and the penal code have become a part of the law of New York, and the civil code has been twice passed by the Legislature, but has been defeated by the Governor. Mr. Field was one of the founders of an international association formed in 1873 for the purpose of reforming and codifying the laws of nations, the special object being the substitution of arbitration for war in the settlement of disputes between nations. He was a member of the peace conference at Washington in 1861, and of the House of Representatives of the U. S. in 1877. In 1890 he presided at the great peace convention in London. He published *The Electoral Votes of 1870* (New York, 1877), and *Speeches and Arguments before the Supreme Court of the United States, and Miscellaneous Papers* (New York, 1884). D. in New York, Apr. 13, 1894.

Field, Eugene: journalist and poet; b. in St. Louis, Mo., Sept. 2, 1850. He was educated at the University of Missouri; was connected with different newspapers in Missouri and Colorado from 1873 to 1883, when he joined the Chicago *Daily News*. Among his publications are *A Little Book of Western Verse* (1889); *A Little Book of Profitable Tales* (1889); *With Trumpet and Drum* (1892); *A Second Book of Verse* (1893). D. in Chicago, Ill., Nov. 4, 1895. H. A. B.

Field, Frederick, LL. D. (Cambridge. 1875): clergyman; b. in London, 1801; graduated at Trinity College, Cambridge, in 1823. He edited the Greek text of St. Chrysostom's *Homilies on St. Matthew* (3 vols., Cambridge, 1839); *Interpretation of the Pauline Epistles* (7 vols., 1849–62); and the Septuagint version of the Old Testament according to the *Alexandrian Codex*. In 1842 he was presented to the rectory of Reepham, Norfolk; resigned in 1863, and edited Origen's *Hexapla* (2 vols., 1867–74). He was one of the revisers of the Old Testament. D. at Norwich, Apr. 19, 1885.

Field, Henry Martyn, D. D.: author; a son of Rev. David D. Field, D. D.; b. at Stockbridge, Mass., Apr. 3, 1822; entered Williams College at the age of twelve; graduated at sixteen; studied theology three years at East Windsor, Conn., and one year at New Haven; at twenty took charge of a church in St. Louis, Mo., where he resided from 1842 to 1847, when he resigned, and spent the following year in Europe. In 1851 he was settled over a Congregational church in West Springfield, Mass., where he remained four years. In 1854 he removed to New York to become one of the editors of *The Evangelist*, of which he was sole proprietor until Feb., 1899. He is author of a number of volumes of travel, including *Summer Pictures: from Copenhagen to Venice* (1859); *From the Lakes of Killarney to the Golden Horn* (1876); *From Egypt to Japan* (1877); *Among the Holy Hills* (1884); *Old Spain and New Spain* (1888); and *Gibraltar* (1888). Travels at home furnished subjects for works entitled *Blood is Thicker than Water* (1886) and *Bright Skies and Dark Shadows* (1890). Other works include *The Irish Confederates and the Rebellion of 1798* (1851) and a *History of the Atlantic Telegraph* (1866).

Field, John: See the Appendix.

Field, Joseph M.: actor and dramatist; b. in London, England, in 1810; at an early age taken by his parents to the U. S.; was educated in New York city, and studied law; then became an actor, appearing first in 1843; settled in St. Louis, and, besides writing local plays, established the *Reveille*, a daily paper of which he was one of the editors. He published *The Drama in Pokerville and Other Stories, by Everpoint* (1847). Removed to Mobile, Ala., and died there Jan. 30, 1856.

Field, Kate: journalist; daughter of Joseph M. Field; b. in St. Louis, Mo., about 1840; educated in Massachusetts and in Europe; she was European correspondent of the New York *Tribune* and other journals; wrote for *The Atlantic Monthly* and other magazines; gave lectures and public readings, and in 1874 made her appearance as an actress in the character of Peg Woffington at Booth's theater, New York. In 1889 she established at Washington, D. C., *Kate Field's Washington*, a weekly journal. D. in Honolulu, May 19, 1896. Among her books are *Planchette's Diary* (1868) and *Ten Days in Spain* (1875). H. A. B.

Field, Richard Stockton, LL. D.: judge; b. at Whitehill, N. J., Dec. 31, 1803; graduated at the College of New Jersey in 1821; was professor in the New Jersey Law School 1847–55; for a long time attorney-general of New Jersey; U. S. Senator in 1862–63, in place of J. R. Thompson, deceased, and the judge of the district court of the U. S. for New Jersey until his death at Princeton, N. J., May 25, 1870. Published *The Provincial Courts of New Jersey* (1849), and contributed to the collections of the New Jersey Historical Society.

Field, Stephen Johnson: judge; son of Rev. David D. Field; b. at Haddam, Conn., Nov. 4, 1816; graduated at Williams College in 1837; studied law with his brother, David Dudley Field, in New York, and on his admission to the bar became his partner; went to California in 1849; in Jan., 1850, was elected first alcalde of Marysville, and in October was elected to the Legislature, and served one session; in 1857 was elected judge of the Supreme Court of the State, and in 1859 became chief justice; from 1863 to Dec. 1, 1897, was an associate justice of the Supreme Court of the U. S. In 1869 Judge Field was appointed Professor of Law in the University of California. In 1873 he was appointed by the Governor of California one of a commission to examine the codes of the State, and to prepare amendments to the same for the consideration of the Legislature. In 1877 he was a member of the Presidential Electoral Commission (*q. v.*), and voted with the seven in favor of Mr. Tilden against the eight in favor of Mr. Hayes. In 1880 he received 65 votes on the first ballot in the national Democratic convention as a candidate for President of the U. S. D. in Washington, D. C., Apr. 9, 1899.

Fieldfare: the English name for a species of thrush, *Turdus pilaris*, found in Europe, and commonly occurring in England as a bird of passage, although it sometimes breeds in the northern portions of Great Britain and Scotland. The fieldfare is variegated in color, but the general hue of the upper parts is chestnut brown; the head is gray, the quill feathers and tail blackish; the throat is reddish yellow streaked with black, the breast brown; the rest of the under parts white. F. A. Lucas.

Field-glass: a form of magnifying apparatus which is essentially a telescope of low power. It may have a single tube (like the antiquated spy-glass), or more frequently it is binocular, resembling in form the double opera-glass. See Telescope.

Fielding, Anthony Vandyke Copley: landscape-painter in water-colors; b. in England, 1787. He was a member of the British Society of Water-color Painters, and a clever and rapid workman. A large collection of his drawings is in the South Kensington Museum. D. at Worthing, England, 1855. W. A. C.

Fielding, Henry: dramatist and novelist; b. at Sharpham Park, near Glastonbury, Somersetshire, England, Apr. 22, 1707. He began his education at home under the care of Mr. Oliver, the family chaplain, said to have been the original of Parson Trulliber in *Joseph Andrews*. He studied at Eton, but, being destined by his father for the law, he was, at the age of eighteen, transferred to the University of Leyden. He was a diligent student for about two years, when, owing to the inability of his father to pay his expenses, he was compelled to return to London, where, at the age of twenty, he found himself dependent upon his own resources. His first effort, a comedy entitled *Love in Several Masques*, appeared in Feb., 1728, and was favorably received. Between his first appearance as a dramatic author and 1737, Fielding wrote twenty-three pieces for the stage, most of them comedies and farces. Of these only one proved decidedly successful—a burlesque entitled *The Tragedy of Tragedies, or the Life and Death of Tom Thumb the Great*, intended to ridicule the extravagant style of the tragedies of the day. *The Mock Doctor* and *The Miser*, translations of Molière's comedies, were also well received. In 1735 he married Miss Cradock, one of the belles of Salisbury, and possessed of a small fortune of £1,500. Fielding had succeeded, on his mother's death, to a small estate at East Stour in Dorsetshire, to which he now retired and assumed the character of a country squire of the first magnitude, by which his slender means were rapidly dissipated, and in a very short time he was compelled to break up and return to London and seek means for the support of his wife and child. Intending to apply himself to his profession, he was turned aside by an opportunity of producing a satirical drama—*Pasquin, a Dramatic Satire on the Times*; its success was so great that in 1737 he produced another, *The Historical Register for 1736*, which attracted so much attention that the Licensing Act, placing the stage under ministerial control, was passed. Resolving now to devote himself to the law, he entered himself (Nov. 1, 1737) as a student of the Middle Temple. In 1740 he was called to the bar, took chambers, and commenced practice. To the columns of *The Champion*, in which he was interested, he contributed largely. He also compiled a valuable work on crown law. Circumstances now led Fielding to turn his attention to the sphere in which he was destined to win enduring renown. In Feb., 1742, his first novel—suggested by Richardson's *Pamela*, which had appeared in 1740 and had created an extraordinary sensation—was published under the title of *The Adventures of Joseph Andrews and his friend Abraham Adams*. Its success was immediate; it soon became a universal favorite, and was regarded as the best work of fiction produced up to that time in the English language. *The Wedding Day*, a comedy written several years before, was produced in Feb., 1743. The *Miscellanies* appeared in 1743; *A Journey from this World to the Next*, in the second volume, is an admirably contrived satire, though in a fragmentary state: the third volume is entirely taken up with *The History of Jonathan Wild the Great*, the least agreeable of Fielding's works of fiction. In this year Fielding's affectionate wife died—a calamity that so deeply affected him that for a time his reason was endangered. As soon as he was sufficiently recovered he again applied himself to his profession. During the memorable events of 1745 he published a political journal, *The True Patriot*, which expired with the suppression of the rebellion. In 1747 he started another political paper, called *The Jacobite Journal*, which was discontinued toward the end of 1748, when he received the appointment of justice of the peace for Middlesex and Westminster—a sphere of duty in which he speedily earned for himself credit and distinction. The office was not at this time held in high estimation by reason of the trafficking in committals and convictions for the fees which formed the compensation of the magistrates, and for which practice they were termed "trading justices." Fielding refused to adopt these discreditable practices, and labored ardently to check the growth of depravity and crime; and his services in this department of life alone were of such importance as to entitle him to the respect of posterity. In 1749 he published his great work, upon which he had been long engaged, *The History of Tom Jones, a Foundling*, which placed him at the head of English novelists. Its success was decided, and it still maintains a prominent place among works of fiction. In 1749 Fielding was elected chairman of the sessions, which entailed upon him the additional duty of attending at the bench. In addition to these duties he published several valuable tracts, among which *An Inquiry into the Increase of Thieves and Robbers* attracted much attention. In 1751 he produced another work of fiction, *Amelia*, in which work the heroine is intended as a portrait of his first wife. This was Fielding's last production in fiction. In 1752 he published a literary journal called *The Covent Garden Journal*, and the following year several law reports. But the complication of disorders from which he had long suffered was fast undermining his strength, and a vigorous warfare which he successfully waged against the gangs of desperate ruffians then infesting London so wore upon his shattered frame that he was compelled to retire from the active performance of his duties. A trip to Bath was made without beneficial effect, and by the advice of his physicians he embarked for Lisbon on June 26, 1754. After a stormy voyage, of which he left an account, published in 1755 under the title of *The Journal of a Voyage to Lisbon*, he reached Lisbon in August. But his strength was too far declined to rally, and on Oct. 8 he expired. See Murphy's *Life and Genius of Fielding*; Sir Walter Scott's prefatory memoir in Ballantyne's Novelists' Library; *Life of Henry Fielding*, by Frederick Lawrence, 1855; and Austin Dobson in the Men of Letters series (1883; new ed. 1889).

Field-marshal: See MARSHAL.

Field Mice: those mice which live out of doors and do not frequent houses; especially mice of the genus *Arvicola*, of which there are more than six species in the U. S., besides many species of allied genera and similar habits. Europe has also several species, and in Great Britain these mice are in some years extremely destructive, not only to grain-crops, but to orchard and forest trees, whose bark they gnaw. At times the British Government has paid bounties for their destruction.

Field Officer: in the army, a colonel, lieutenant-colonel, or major of a battalion or regiment, as distinguished from general officers, who are superior to field officers in rank; from line officers, who are inferior; and from staff officers, general or regimental, who may be of rank superior, equivalent, or inferior to that of field officers.

Field of the Cloth of Gold: the place on the border of the territory of Calais where occurred the famous interview between Henry VIII. of England and Francis I. of France, in June, 1520. Francis I. and Charles I. of Spain, candidates for the imperial crown, sought the friendship of Henry VIII. At this interview the magnificence of the display on both sides gave to the scene the name it bears. Henry VIII. had interviews with Charles the same year, and Francis's object was not secured.

Fields, JAMES THOMAS, LL. D.: author and publisher; b. at Portsmouth, N. H., Dec. 31, 1817. He was a member of the publishing firm of Ticknor, Reed & Fields, and its successor from 1838 to 1870. In 1849, 1854, and 1858, respectively, he printed volumes of his poems for private distribution. He edited *The Atlantic Monthly* at Boston from 1862 to 1870, repeatedly visited Europe, and had wide acquaintance with literary men abroad. He also lectured in the U. S., and published *Yesterdays with Authors*—reminiscences (1871); *Hawthorne* (1876); *In and Out of Doors with Charles Dickens* (1876). D. at Boston, Mass., Apr. 24, 1881.

Field-sports: See SPORTS.

Fieldworks: See FORTIFICATION.

Fi'eri Fa'cias [Lat., you shall or may cause it to be done]: a writ of execution (usually termed a *fi. fa.*), to secure the satisfaction of a judgment recovered against a debtor, directing the officer to whom it is addressed *to cause to be made* of the debtor's goods and chattels or real estate the amount therein specified. By this is meant that he is to levy upon the property and sell sufficient to obtain the requisite sum. Personal property is first sold, and afterward recourse may be had to the debtor's real estate. In executing this writ the sheriff has no authority to break open the outer door of a dwelling-house after request for permission to enter is refused, as may be done on criminal process; but if he has once secured lawful admission into the premises he may break through inner doors, open chests, etc., to secure possession of the goods. When the property is within the debtor's store or barn, even the outer door may be forcibly entered; so, if it be upon the premises of a stranger and entrance is refused, the house may be broken, for a man's house is a protection only for his own property. If, however, the goods are not found upon the stranger's premises, the sheriff is liable as a trespasser. For further details, see EXECUTION.

Fies'chi, fee-es'kee, or **Fies'co**, GIOVANNI LUIGI, de': Count of Lavagna; b. in 1523 at Genoa of a celebrated Guelfic family of remote Bavarian origin. A wealthy and ambitious demagogue, he entered into a conspiracy to kill Andrea Doria, doge of Genoa, and to overthrow the government, but the scheme failed in both its objects, and Fieschi, striving to seize the public galleys, was drowned Jan. 2, 1547.

Fieschi, GIUSEPPE MARIA: b. on the island of Corsica, Dec. 3, 1790; entered the French army in 1808; served in

Russia in 1812; was imprisoned 1816–26 for theft and forgery; went to Paris in 1830; invented the infernal machine by which the attempt was made, July 28, 1835, to assassinate Louis Philippe, who escaped with a slight wound, though sixteen of his attendants were killed or mortally wounded. Fieschi was executed Feb. 16, 1836.

Fiesole, Fra Angelico, da: a Florentine painter; b. at Vicchio, 1387. In early life he entered the Church in the order of Dominicans, and for the remainder of his existence may be said to have lived in a state of ecstasy, painting the visions which came to him. He was the last of the ecstatic school, and the last of the pure Giottesques. He had studied painting before he entered the order, but was appointed to the work he was so well fitted for as that in which he could best serve the Church. Fra Angelico stands as the type of the purely religious painter, not merely in his devotion to sacred subject, but in the devotional manner of approaching his subject as one in which an act of worship was accomplished and in which divine assistance was to be asked. His painting was to him the record of inspiration, and he never changed what he had done, which in part accounts for the limitations and for some of the loveliest qualities of what he did, the purity of color, the simplicity and harmony of his design, and for the immense quantity of work he left. The best of it is that at Rome in the chapel of S. Nicholas of the Vatican, the vault of the Duomo at Orvieto, and the frescoes at S. Mark's in Florence, but all the galleries of art in Europe have examples of it. His pupil Benozzo Gozzoli was the first in whom is found the evidence of unmistakable reference to nature for the facts of his representations. The last ten years of Fra Angelico's life were spent in great rapture in Rome, where he died in 1455. He was buried in the church of S. Maria sopra Minerva. W. J. Stillman.

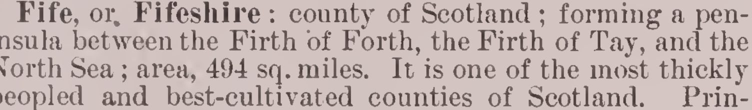
Fife [from Fr. *fifre*, from O. H. Germ. *pfîfa* > Germ. *Pfeife*, pipe, from Low Lat. *pi'pa*, deriv. of *pipa're*, chirp; cf. Eng. *pipe*, viâ Fr. from Low Lat. *pi'pa*]: a musical instrument chiefly used with the snare-drum in martial music. It is made in one piece, without keys, has six finger-holes, and a mouthpiece or hole for blowing upon one side, as in the flute. Its notes are shrill and somewhat harsh. The fife is variously pitched.

Fife, or **Fifeshire**: county of Scotland; forming a peninsula between the Firth of Forth, the Firth of Tay, and the North Sea; area, 494 sq. miles. It is one of the most thickly peopled and best-cultivated counties of Scotland. Principal towns, Cupar, Dunfermline, St. Andrews, Dysart, and Kirkcaldy. Pop. (1891) 187,320; (1901) 218,350.

Fife, Alexander William George Duff, Marquis of Macduff and Duke of: b. Nov. 10, 1849; educated at Eton; Liberal member of Parliament 1874–79; married July 27, 1889, Princess Louise Victoria Alexandra Dagmar, eldest daughter of the Prince of Wales, on which occasion he was created Duke of Fife.—The Duchess of Fife was born Feb. 20, 1867. She is president of the Edinburgh School of Medicine for Women, the first school of the kind in Scotland.

Fifteenth': in music, the interval of a double octave, comprising a distance of fifteen grades of the scale, from the lower to the upper note; also, the name of a stop in the organ, of which each pipe is tuned two octaves above the regular pitch as represented on the keyboard.

Fifth: in music, an interval comprising five degrees of the scale, or the distance, e. g., from C to G, D to A, etc. Fifths, according to their position on the scale or the influence of accidentals, are various in their compass, embracing from six to eight semitones. They are usually classified as *perfect*, *diminished*, and *augmented*. The perfect contains three whole tones and one semitone; the diminished, two whole tones and two semitones; and the augmented three whole tones and two semitones.



In counterpoint the progressions of the fifth are regulated by certain laws, partly arising from the harmonious nature and relations of this chord, and partly in view of the ease with which its use and abuse suggest themselves to the minds of young harmonists, who are unaware of the difficulties of its proper treatment. The restrictions, however, imposed by the old masters, have been so far relaxed in modern schools of music that certain progressions of fifths are now freely used which a century ago would have been strictly forbidden. Revised by Dudley Buck.

Fifth-monarchy Men: a small religious sect in England during Cromwell's protectorate and the first part of the reign of Charles II. They professed to believe that the time was near at hand when to the four great monarchies of Daniel's prophetic vision was to succeed the fifth, which was to break in pieces all others and to "stand forever." Of this Jesus was to be king, and in their eagerness to seize the fitting opportunity to proclaim him they conspired (Apr. 9, 1657) against Cromwell; and again (Jan. 6, 1661), on the prospect of Charles II. being fully restored to power, they rose in insurrection and attempted to sustain themselves, under a leader named Venner, by force of arms. The insurrection was promptly suppressed, and Venner and several others were executed. The Independents, Baptists, and Quakers formally disclaimed all sympathy with the insurgents, yet were made to suffer odium and civil hardships in consequence of the movement. Two years later another insignificant rising occurred, in consequence of which six persons are said to have been executed. The sect seems to have had no connection with Anabaptists on the Continent, but to have derived encouragement—however unwarrantably—from the views of some eminent men.

Fifth Nerve: See Facial Nerves and Trigeminus.

Fig [M. Eng. *fig*, from O. Fr. *figue* > Fr. *figue*: Ital. *fico* < Lat. *fi'cus*]: the fruit of *Ficus carica*, a deciduous tree of the *Artocarpeæ* or breadfruit family, 15 to 20 feet high, with rough and deeply lobed leaves, a native of Asia from Syria to the Caucasus and Kurdistan; also, the tree itself (see Ficus), which often lives to a great age. In the Scriptures the fig-tree is often mentioned, along with the vine, as a symbol of peace and plenty. Although unknown in Greece during the Homeric age, it was common in the time of Plato; it was early introduced into Italy, and thence in Spain and Gaul. Charlemagne ordered its cultivation in Central Europe, and it is now cultivated in most warm temperate climates. That it has succeeded even in England appears from the mention of the historian Matthew Paris that the year 1257 was so inclement that figs, cherries, and plums totally failed to ripen. Figs can be well ripened, and can be raised for preservation in the dried state, only where the summer and autumn are warm and dry. In the Eastern U. S. the main obstacle to their cultivation is the cold of winter, which frequently injures unprotected trees even in Florida. Figs are cultivated to some extent so far north as North Carolina, and the culture promises satisfactory results. On the Pacific coast they find a more congenial climate. The fig-tree bears two crops in a season—an earlier one from the axils of leaves of the preceding growth; a later and long-continued one from the axils of the leaves of the season. The fig is popularly said to fruit without flowering. This comes from the nature of this particular fruit—a hollow, pear-shaped receptacle, nearly closed or barely pervious at the broad apex, lined throughout the interior with innumerable small flowers, male and female. The so-called seeds are the ripened achenia (i. e. seed-like fruits) of the latter; the luscious pulp mainly belongs to the ripened and softened receptacle or hollow flower-stalk. A good idea of the botanical nature of a fig is got by comparing it with *Dorstenia*, of the same natural family; in this the flowers occupy the upper surface of a plate or saucer-shaped common receptacle. By imagining this saucer to deepen into a cup, and the cup to pass into the form of a jug by a contraction of the summit, the whole peculiarity of the fig-fruit will be apparent. In ripening, the acrid milky sap characteristic of the family is replaced by saccharine matter, chiefly grape-sugar, which serves to preserve them. Fresh figs, most agreeable to many, are too sweet and cloying for other palates, being destitute of acidulous flavor. In the fresh state, and still more in the dried, figs form an important article of food in the Levant, etc. Smyrna is the principal mart whence dried figs are exported to Northern Europe and America. Dried figs are said by the dealers to be *natural* when not compressed in the packing, but retaining their original shape, or *pulled* when after drying they are made supple by kneading, and then packed by pressure into drums or boxes. *Eleme* figs are merely those of superior quality, so called from a Turkish word meaning "hand-picked."

Figeac, fēe'zhaak': town of France; department of Lot; on the Sellé; 32 miles E. N. E. of Cahors (see map of Italy, ref. 8–E). It is a quaint old city, situated in a deep valley surrounded by rocky, vine-clad heights. It contains two Gothic churches, and has a trade in cattle and manufactures of cotton. Pop. (1896) 6,310.

Fighting-fish: a little fresh-water fish (*Ctenops pugnax*) of farther India, akin to the perch family. Two of these fishes placed in a vessel of water will attack each other with the utmost fury, and in India much money is often wagered upon the result of the combat.

Figig: See the Appendix.

Figueira da Foz, fēē-gā-ee'rāā-daa-fōs': seaport of Portugal; province of Beira, at the mouth of the Mondego; 23 miles W. by S. of Coimbra (see map of Spain, ref. 15–A). It has a lively trade in salt, oil, wine, and fruit, and is a favorite watering-place. Pop. 4,300.

Figueras, fēē-gā'rāās: frontier-town of Spain; province of Gerona; 25 miles by rail N. of Gerona (see map of Spain, ref. 13–L). On a height near the town is the citadel of San Fernando, one of the strongest fortresses of Spain and the key of the Pyrenees. There are manufactures of soap, paper, and leather. Pop. (1887) 11,912.

Figueras, Estanislao: statesman; b. in Barcelona, Spain, Nov. 13, 1819; received an excellent education; became at an early age one of the leaders of the liberal party in Catalonia; was elected to the Cortes in 1850; was a member of the revolutionary committee of Tarragona 1854; engaged in the liberal conspiracy of 1866, for which he was imprisoned in 1867, and took a prominent part in the organization of the republican party after the overthrow of Queen Isabella in 1868. On the abdication of King Amadeo (Feb. 11, 1873) he became provisional president of the republic, holding that post for about four months, when he retired from public life. D. at Madrid, Nov. 11, 1882.

Figueroa, fēē-gā-ro'āā, Francisco, de: a Spanish general and poet, often surnamed *El divino*; b. at Alcalá de Henares in 1540. During his long stay in Italy he acquired such a mastery of the Italian language that his Italian verse is as pure as that composed in Spanish. His poems, dating from the year 1572, but not published until 1620, rank among the best contemporary productions in Italian style. In his eclogue *Tirsis* he made successful use of the Italian blank verse, introduced into Spanish poetry by Boscan. D. at Alcalá de Henares in 1620. H. R. Lang.

Figueroa, Pedro Pablo: author; b. at Copiapó, Chili, Dec. 25, 1857. He was educated in his native place; was connected with various journals, and in 1885 established *El Imparcial*, a newspaper at Santiago. He has written numerous biographical works, sketches, and romances, among the best known being *Galería de Escritores Chilenos*; *Diccionario Biográfico Chileno*; *La Odisea del Desierto*; *La Cortesana* and *El Leñador* (novels.) H. H. S.

Figuier, fee'gee-ā', Guillaume Louis: chemist and scientific writer; b. at Montpellier, France, Feb. 15, 1819; became M. D. 1841; professor in the School of Pharmacy at Montpellier 1846; then scientific editor of *La Presse* at Paris. He published *Exposition et Histoire des Principales Découvertes Scientifiques Modernes* (3 vols., 1851–53; 5th ed. 1858); *Histoire du Merveilleux dans les Temps Modernes* (4 vols., 1859–60); *Vie des Savants Illustres depuis l'Antiquité jusqu'au XIXe Siècle* (1866); *Les Nouvelles Conquêtes de la Science* (1883–85); *Les Mystères de la Science* (1887), etc. D. in Paris, Nov. 9, 1894.

Figurate Numbers: those numbers which may be formed in the manner shown in the following table. The first column consists of the figure 1 simply; the second column is formed by adding one successively to each number, starting from the number 1. In the third column we also start from the number 1, and form each consecutive number by adding the next following number of the preceding column. All the following columns are formed in the same general way, starting with 1, and adding in succession the numbers of the column next preceding. This table is called

THE ARITHMETICAL TRIANGLE.

0th *order*....	1	1	1	1	1	1	1	1	.	.
1st *order*....	1	2	3	4	5	6	7	.	.	
2d *order*....	1	3	6	10	15	21	.	.		
3d *order*....	1	4	10	20	35	.	.			
4th *order*....	1	5	15	35	.	.				
5th *order*....	1	6	21	.	.					
6th *order*....	1	7	.	.						
7th *order*....	1	.	.							
. . . .										

This table may be continued to any desirable extent. The numbers in the first line are simple units; those in the second line are the natural numbers; those in the third line are called *triangular* numbers, because they express the numbers of balls that may be arranged in equilateral triangles as in the diagram:

o
o o o
o o o o o o
o, o o, o o o, o o o o, etc.;

those in the fourth line are called *pyramidal* numbers, because they express the numbers of balls that can be piled in the form of regular triangular pyramids; those in the fifth, sixth, and seventh lines have been called *trianguli-triangular*, *trianguli-pyramidal*, and *pyramidi-pyramidal* numbers. Hence the name *figurate numbers*.

It will be seen that the numbers of the table, read diagonally upward, are the numerical coefficients of the development of $x + a$ to a power whose exponent corresponds to the order of the series. This property, besides rendering the table useful in the formation of powers, enables one to use it, in the calculus of probabilities, to find the number of combinations of m things taken in sets of n. Thus to find the number of combinations of 7 things taken in sets of 1, 2, 3, etc., enter the table opposite the 7th order and read diagonally upward; the number in the second column is the number of combinations of 7 things in sets of 1; that in the third column is the number of combinations in sets of 2; that in the fourth column is the number of combinations in sets of 3; and so on.

It is this last property that connects the arithmetical triangle so closely with the logical *Abecedarium*. See Jevons, *Principles of Science* (London, 2d ed. 1877).

Revised by S. Newcomb.

Figured Bass: in music, a bass over or under which the harmony is expressed by ordinary figures, dashes, etc., instead of being written out in notes. These figures are not intended to represent the structure or *melodious movement* of the upper parts, but only the nature and elements of the *harmony* on which those parts depend. Nor do the figures usually determine the exact *positions* of chords as played by the right hand on keyed instruments; as such positions may be taken near the bass, or distant from it, or be in either close or dispersed harmony, at the discretion of the performer. The figures represent intervals counted *upward* from the bass; and generally those intervals which *exceed* an octave are expressed by figures denoting the same letter *within* the octave. Accidental flats, sharps, and naturals are used with the figures when necessary, but a sharp is frequently expressed by a stroke drawn through the figure. Figures standing one *over* the other indicate intervals to be struck simultaneously, but those standing one *after* the other are to be taken successively. The triad (or common chord), in its fundamental form, requires no figures, unless when succeeding a different chord on the same bass, or when there may be some ambiguity or obscurity in the progression. In keys having sharps or flats at the signature (at the beginning), those sharps or flats will of course affect the figures as well as the notes.

Dotted notes may be represented by dotted figures. Rests also may be introduced, though a small cipher (0) is preferable.

The words *tasto solo* imply that the bass is unaccompanied by harmony until the recurrence of figures.

For fuller information on the subject of figured bass, the student may consult J. G. Albrechtsberger's *General-bass-Schule*, Cherubini's *Treatise on Counterpoint*, and Beethoven's *Studien im Generalbass*.

Revised by Dudley Buck.

Figure of Speech: a peculiar or special use of words. The distinction between grammatical and rhetorical figures is of great importance in the logical construction of figurative language—a subject on which there is an extraordinary amount of confused thinking. The grammatical figure rests upon a *real* relation of the subject and predicate. "My Milton is in four volumes" involves a figure or form of speech departing from strict literalness; but it is a grammatical figure, for the relation on which it rests is real, objective, and undeniable: it is, according to the letter, the grammar, and hence has been styled the grammatical. Milton is literally the author of the works contained in the volumes. The two great grammatical figures are Metonymy (*q. v.*) and Synecdoche (*q. v.*). They may be at home in the plainest and most common-place prose—in the language of a will or of an advertisement. The rhetorical figure rests upon an ideal or an idealized relation between the subject and predicate. The mind makes it, and can unmake it; it can exist to one mind, and be denied by another; it may be conceded by the mind at one time and in one state, and denied at another time. "Milton is an eagle" involves a METAPHOR (*q. v.*), which is the chief rhetorical figure. Some of the most confused and persistent logomachies have arisen from failing to observe this distinction.

Figures: visible signs used to represent numbers. See NUMERALS.

Figworts: a family of flowering plants (*Scrophulariaceæ*) with two-lipped or irregular gamopetalous corollas, superior two-celled ovaries, and two or four (rarely five) stamens on the corolla-tube. They are mostly herbaceous plants, although some are trees. There are about 2,000 species, widely distributed throughout the world. Many species are cultivated for their fine flowers, e. g. snapdragon (*Antirrhinum*), *Mimulus*, *Pentstemon*, *Digitalis*, *Calceolaria*, etc. The Paulownia-tree (*Paulownia imperialis*) of Japan is planted in the Southern U. S. CHARLES E. BESSEY.

Fiji, fee'jēe, or **Viti Islands** (formerly written *Feejee*): a group of islands constituting a British dependency; in the South Pacific Ocean; between lat. 15° 30′ and 20° 30′ S., and lon. 177° E. and 178° W.; numbering over 200 islands, of which about 80 are inhabited; gross area, 7,451 sq. miles. They were discovered in 1643 by the Dutch navigator Tasman, but not fully explored until 1840, when they were visited by the American navigator Wilkes. The two largest islands are Viti Levu, having an area of 4,112 sq. miles, and Vanua Levu, of 2,432 sq. miles; the others are small. The Fiji islands are of volcanic origin; earthquakes are common and hurricanes periodical. The soil, which consists of a deep-yellow loam, and is well watered, is exceedingly fertile, and the moist and hot climate (the temperature ranging from 60° to 120°), calls forth a most luxuriant vegetation, consisting of bread-fruit trees, bananas, cocoanuts, sugarcanes, and tea-plants; cotton grows wild. The inhabitants are middle-sized, strong-limbed, short-necked, with a complexion between copper-color and black. Before the introduction of Christianity by Wesleyan missionaries in 1835 they were a fierce race of cannibals. The majority have become Christianized, about 100,000 being adherents of the Wesleyans and more than 10,000 of the Roman Catholics. In 1861 the king and chiefs of Viti Levu formally offered the island to Great Britain; but it was not until 1874 that the British flag was hoisted on Fiji soil. The population of these islands has greatly decreased since about 1845. Pop. (1895) 120,245, of whom 101,316 were Fijis and 2,872 Europeans, 9,861 Indian immigrants, the remainder being other Polynesians, half-breeds, Chinese, etc. Suva, in Viti Levu, is the capital. See FIJI ISLANDS in the Appendix.

Filament [from Fr. *filament* < Late Lat. *filamen'tum*, deriv. of Late Lat. *fila're*, spin, deriv. of Lat. *fi'lum*, thread. Or *filamen'tum* and *fila're* may both be derived by analogy from Romance derivatives]: in the descriptive botany of flowering plants, the support or stalk of the anther of the stamen; "it is to the anther what the petiole is to the blade of the leaf" (*Gray*). Elsewhere in botany the term has its usual meaning of a thread; thus the filament of a mould is a thread composed of a cell or a row of cells. See FLOWER.

Filangieri, fēe-lăăn-jēe-ā'rēe, GAËTANO: author; b. at Naples, Italy, Aug. 18, 1752; entered the army 1766; went to the royal court 1777; became a member of the supreme council of the finances 1787. He is chiefly remembered as author of *Scienza della legislazione* (1780–88, unfinished), a noble treatise on the principles of legislation. D. at Vico-Equense, July 21, 1788.—His son CARLO (1783–1867), Duke of Taormina, was a brave soldier under Napoleon, governor of Sicily under Ferdinand II., and Prime Minister under Francis II. of the Two Sicilies.

Filaria: See HÆMATOZOA and PARASITES (Human).

Filbert [formerly also *filbeard* < M. Eng. *filberde*, perhaps named from St. *Philibert*, the forms with *-d* arising from analogy with *beard*. Cf. the Germ. name *Bartnuss*, liter., beardnut]: the nut of the HAZEL (*q. v.*). The name is not often applied to the American wild hazel-nuts; and in commerce the round varieties of European hazel-nuts are called cob-nuts, the name *filbert* strictly belonging to the elongated sorts, which have also a finer-cut and more beard-like envelope; whence perhaps the name. Filberts are chiefly the product of *Corylus avellana*, the common hazel of Europe and Asia, which is extensively cultivated. Barcelona nuts are a variety of filbert, kiln-dried for better keeping. *Corylus colurna*, of Turkey, produces large, oily filberts. Filberts are used as dessert-nuts. Large amounts of oil (nut-oil) are also expressed from the kernels; it is a drying oil, much used by artists and makers of choice varnishes. But few filberts are grown in the U. S. Several species are known.

Fildes, SAMUEL LUKE: genre and portrait painter; b. at Liverpool, England, Oct. 14, 1844. Pupil of South Kensington Art School and Royal Academy, London; Royal Academician; second-class medal, Paris Exposition, 1889. He began his artistic career as an illustrator for the London *Graphic*, *Cornhill Magazine*, etc. *Applicants for Admission to a Casual Ward* (1874) is one of his most celebrated pictures. His work is technically of fair merit, but he inclines to story-telling in his pictures at the sacrifice of truth to nature. His portraits of women are graceful, but somewhat lacking in expression of character. Studio in London. WILLIAM A. COFFIN.

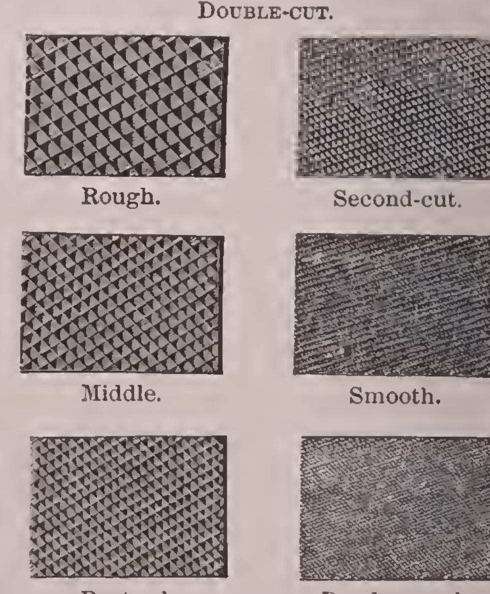
File [M. Eng. *file* < O. Eng. *fēol*: O. H. Germ. *fīhala* > Mod. Germ. *Feile*]: a tool used in shaping all kinds of materials of construction. It is a bar of steel, the size and shape of which are determined by the use for which it is intended. Its surfaces are covered with sharp cutting edges or teeth, the direction and number of the edges and the magnitude and distribution of the teeth varying with the nature of the material to be cut and the degree of smoothness of the surface which the file is required to produce. Where the surface has isolated sharp teeth separated by comparatively wide spaces the file is called a *rasp*.

Files are used upon surfaces of all kinds. Rasps are especially fitted for rapid work on surfaces of materials having slight resisting power. They are used by workers in wood and leather, and by the farrier. The effect of rubbing the file upon the surface of the metal, wood, ivory, or other material to be changed in form or dimensions, is to abrade it, cutting from it minute shavings or small particles, and reducing the mass by a gradual process. Files are therefore used only in shaping small pieces or in "finishing" surfaces which are already of approximately correct figure. The file usually follows the work of the lathe or the planer-tool.

The forms given to files, as well as their shapes and sizes, are almost numberless. Those files which have cutting edges extending unbroken from side to side are called "floats" or "single-cut" files. Those which have two sets of such edges, crossing each other at an angle, are called "double-cut." The effect of such crossing of edges is to produce points or teeth, rather than true cutting edges.

The coarseness or fineness of the file is known by the trade-terms: 1, rough; 2, middle-cut; 3, bastard; 4, second-cut; 5, smooth; 6, superfine or dead-smooth. The second grade is rarely found in the market. The most common are the "Sheffield cuts," rough, bastard, and smooth. These are shown in the accompanying sketches. In what are known as the Nicholson or "increment - cut" files the forms of the teeth and the cutting edges are very similar to those of ordinary files as just described. These are machine - cut files, but they differ from other machine-cut files by being cut with teeth slightly expanding or increasing in size and space from point to heel, thus avoiding the great regularity of teeth common to ordinary machine-cut files. The irregularity spoken of consists not only in the spaces between the teeth, but also in the heights of the teeth themselves.

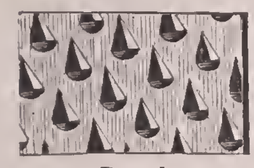
DOUBLE-CUT.



Rough. Second-cut. Middle. Smooth. Bastard. Dead-smooth.

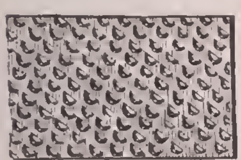
The regularity of the teeth, so characteristic of most machine-work, is not easily obtained by the hand-worker, who, seated with his blank firmly held on a stone block in front of him, strikes the chisel into the blank and raises the first tooth; the chisel is then lifted out of its groove, placed on the blank, and slid up until it comes into contact with the tooth previously raised, when the second blow is struck and another tooth is produced. If the force of these blows were alike in each case, the spaces would be equal; but as it is impossible for the most expert workman to strike the great number of blows required in the entire side of a file with exact uniformity, irregularity in the distribution of the teeth must exist.

RASP-CUT.



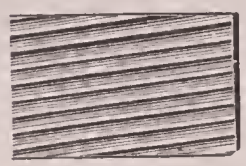
Rough.

Bastard.

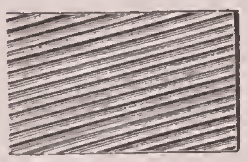


Smooth.

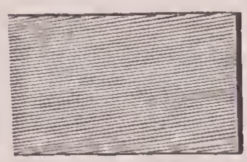
FLOAT-CUT.



Rough.



Bastard.



Smooth.

Possibly, the failure of many of the earlier enterprises may be traced in a measure to the defect in their machinery of producing this extreme regularity in the cut of their files. When a side or an edge of a file is left uncut, it is said to be "safe."

Watchmakers' files are often exceedingly delicate, measuring less than an inch in length, and having a thickness not greatly exceeding that of a coarse bristle. The larger files used by watchmakers seldom exceed 4 inches in length. Mechanics working on tools, small apparatus, and light machinery, use files of from 6 to 12 inches in length, and machinists employed on steam-engines and heavy machinery call for files of from 10 to 18 inches in length, and occasionally, for special purposes, use files of double these sizes. The shape of the cross-section of the file is usually either that of a square, a parallelogram, a circle, an oval, a triangle, or a combination of straight lines and arcs of circles. Fig. 1 represents the parallel hand file, called, when small, a pottance file, or if very slender a pillar file. This file is also called a verge or a pivot file, and when of large size a cotter file. Fig. 2 represents the square file, which is often, as is the case with all other forms of section, made with parallel sides. Fig. 3 represents the knife file. This form is usually small, and is of limited use. It is made for the purpose of cutting or enlarging narrow, triangular notches. Fig. 4 exhibits the half-round file, the section of which, as seen, is not a complete semicircle. The thickness of the file is usually from one-half to one-fourth the radius of the circle. Fig. 5 represents the round file. If of small size it is called, when tapering, a rat-tail file, and when parallel a joint file or gulleting saw file. Fig. 6 represents the triangular file, often called by the workman a three-square file. It is used for sharpening saws, for cutting internal angles, and for cleaning up corners. Fig. 7 resembles Fig. 1, but the file is thinner. It is known as a warding file, and was formerly much used by locksmiths in cutting the wards of the keys of locks. Fig. 8 is the cross or double half-round file, the two sides usually having different curvatures. The first name is derived from the fact that it was originally designed for trimming out the crosses or arms of small wheels. Fig. 9 is the slitting, feather-edge, or screw-head file, having two knife edges, and used for the same purpose as the knife file.

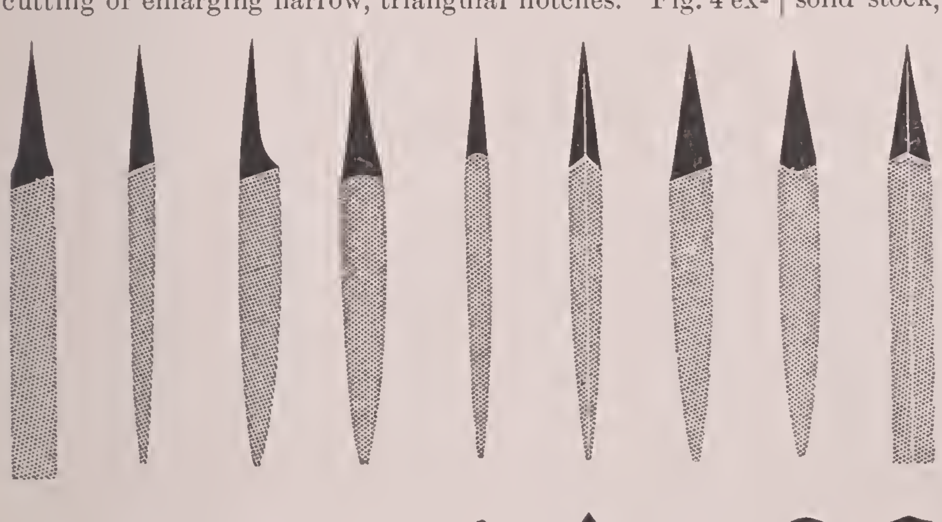


FIG. 1. FIG. 2. FIG. 3. FIG. 4. FIG. 5. FIG. 6. FIG. 7. FIG. 8. FIG. 9.

FIG. 10.

Equaling files are flat and thin. They are always uniform in thickness, and usually in width also. Two opposite surfaces are frequently left "safe." "Rubbers" are large, heavy, coarse files, usually of inferior quality, which are used for rough kinds of work. "Rifflers" or bent files are of the shape shown in Fig. 10, and have usually curved surfaces. They are used by sculptors and by makers of ornamental castings. They are double-cut, single-cut, or rasp-cut, and of various degrees of fineness, as required for different kinds of work. They are especially adapted for smoothing up irregular forms, such as are most frequently met with in bronze castings.

The common kinds of file are frequently bent for convenience in working upon curved surfaces. Bending is readily accomplished by heating to a red heat and shaping over a properly formed wooden block by striking it light blows with a wooden mallet. When the file has thus been given the desired shape, it is re-tempered and is ready for use. The file is bent to a smaller radius than that of the concavity in which it is to be used.

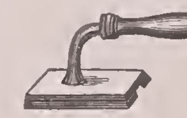

FIG. 11.

The tapering end of the file outside the shoulder, and upon which the handle is driven, is called the tang or the shank. The tapering form given the tang is not well adapted to give a firm hold to the handle, and it has probably been adopted and retained partly through conservatism and partly because workmen frequently use one handle for several files, and the tapering tang permits the file to be readily inserted into and withdrawn from the handle. To insure a good "hold," a tang of uniform section, and either cylindrical or prismatic in form, would be preferable. In the round screw-thread file the cutting edges are formed by making a ratchet-thread in the lathe, different pitches of thread thus making different grades of file. The cutting edges of these files are thus formed from the solid stock, and are said to possess remarkable endurance, and, acting like milling tools, do rapid and good work.

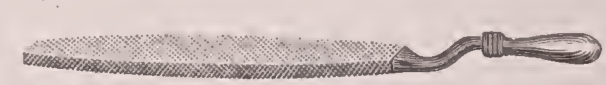

FIG. 12.

The handle of the file is usually driven directly upon the tang. It sometimes happens, however—as in filing extended flat surfaces, for example—that the file-handle interferes with the use of the file by bearing upon the surface and preventing the cutting portion of the file coming down to its work. In such cases the tang is bent or a "holder" is used, as in Figs. 11 and 12.

Files are usually made of the best of material, and great care is taken to select steel that is uniformly and highly converted. "Rubbers" for smiths' use are made from blistered steel, but all other files are made from better grades of steel. Files are forged into shape in a similar manner to all small work in steel, the smith taking care not to work the metal at a higher than a blood-red heat. Peculiar shapes are produced in dies or formers. Special care is taken to select good fuel for the fires in which the blanks are forged. It is usually coke, made from coals free from any trace of sulphur. The blanks are very thoroughly annealed after having been forged. The finer qualities are annealed or "lighted" in iron boxes, in which they are embedded in sand. Cheaper grades are annealed in ordinary annealing ovens—a less expensive method, but one in which the blanks are less completely protected against the access of air. The annealed blanks are next ground into the exact shape demanded, and the scale formed during the antecedent process is removed, leaving a clean and properly formed surface for the file-cutter to work upon. It was formerly customary to shape the blanks by filing, but the use of the grindstone is now much more usual. After grinding, the blanks are greased and sent to the file-cutter.

When *file-cutting* is performed by hand, the tools used consist of peculiarly shaped hammers and chisels, an anvil, and packing pieces of lead or pewter. The hammers weigh from 1 to 5 or 6 lb., the smaller sizes being used for very small and the heavier for very large files. They have a singular form, such as would be obtained by making the head first in the form of a truncated pyramid—the upper and lower bases having a breadth equal to about one-fifth and one-fourth its altitude respectively—and then bending it to an arc of a radius equal to about twice the altitude. The handle is inserted at a point considerably nearest the smaller end. In striking a blow the hammer is pulled toward the workman as it descends, the mass taking a direction approximating to that of the inclination of the chisel. The chisel is short and light, nearly a triangle in form, with a broad, straight edge. It is held between the finger and thumb of the left hand, much as a pen is held by the right hand in writing. The file-blank is placed upon the anvil, where it is held by a strap passing over each end and tightened by the workman, who places his feet in the "bight" of the strap as a horseman places his feet in his stirrups. As each blow is struck the workman moves the blank slightly to bring the chisel over the proper place for the next cut, the strap being loosened at the instant to allow the movement to take place.

In making small and smooth or dead-smooth files, the blows and these nearly simultaneous movements succeed each other with surprising rapidity. The smallest files are often cut by women or by boys and girls. The surface of the file being single cut, a second set of cuts is usually made at a large angle with the first, the two sets making angles of about + 50° and − 80° respectively with the middle line of the file. Before making the second cut the tops of the teeth already formed are smoothed off by lightly running over them a fine file. The blank is then turned over, and the opposite side and the edges are next cut. When a surface already cut is placed downward, a strip of lead or pewter is placed beneath it, to prevent injury of the teeth by contact with the hard surface of the anvil. By constant practice the workman becomes very expert, and the rapidity and accuracy of his work are quite wonderful, and are probably among the finest illustrations of the degree of perfection in workmanship which may be attained by the hand when guided by a delicate sense of touch.

After cutting, the files are next hardened, although those made for use on wood and other comparatively soft substances are frequently left unhardened, and several kinds which are made of peculiar shapes for some purposes, as for sculptors, are made of good iron and case-hardened. The files to be hardened are first besmeared with a mixture of salt and carbonaceous materials which are considered to be best adapted to preserve the teeth from decarbonization and oxidation, and which at the same time, by fusion upon the surface, may indicate the proper heat at which to temper. This surface-coating of comparatively non-conducting material also checks the first sudden change of temperature on immersion in the tempering liquid, and thus decreases the liability of the file to crack. The difficulty which might be experienced from the change of shape which invariably occurs to a greater or less extent on suddenly cooling the file is avoided by giving the untempered file a slight distortion in the opposite direction, so that the subsequent change of shape may leave it in the desired form. In all cases the general shape of the file is determined previous to the operation of hardening.

When the file has been heated in the fire to a temperature at which the surface-coating fuses, it is taken by the tang and suddenly immersed in a tank of water, the rapidity and particular direction of the immersion being determined by the size and shape of the file. Withdrawing it before it becomes cold, the workman inserts it between the jaws of a clamp or between a pair of iron bars, where he corrects by force any slight defect in form, while pouring water over it to cool it thoroughly. The tang is next softened by immersion in molten lead; the file is then scrubbed thoroughly and washed in lime-water to remove the scales of salt mixture. It is carefully dried and oiled, and is then ready for the market.

A careful system of inspection is adopted by the best makers, by which all imperfect files are detected and thrown out to be sold as "wasters." Those files which pass inspection are packed by dozens in papers.

The time at which files were first made is unknown. The manufacture of files was introduced into North America very soon after its settlement. File-cutters settled in Pennsylvania at the end of the seventeenth century. The firm of Broadmeadow & Co. began file-making in Pittsburg in 1820, and there are now a considerable number of file-manufacturers in the U. S.

File-cutting machinery was probably first proposed nearly two centuries ago. A Parisian mechanic, Duverger, presented a file-cutting machine to the Académie des Sciences in the year 1699, and a description of this apparatus appeared in the *Journal des Savants* in 1702. Thiout in his *Traité de l'Horologie*, published at Paris in 1740, describes another machine. Still later, Raoul, another French mechanic, made files by machinery, and obtained a report upon them from a committee of the Lycée des Arts in which it was stated that they were equal to the best English hand-made files. In 1812 Morris B. Belknap, of Greenfield, Mass., patented a file-cutting machine, and William T. James, who is said to have worked at Union Village, patented another. In 1836 Capt. John Ericsson, then in England, patented a file-cutting machine, which is described in Holzapffel's work on *Mechanical Manipulation*, where it is stated that one machine could do the work of ten men. In 1847 an ingenious machine was invented by George Winslow, of Boston, and was described in Appletons' *Dictionary of Mechanics.* Still later, a machine was invented by M. Bernot, of Paris, and was described in detail by Byrne. This machine was used to some extent with success in France and Belgium, and subsequent to 1860 was introduced into Great Britain and the U. S. In this machine the chisel is driven by a cam as the file-blank moves along beneath it, and the difference in height of teeth which is given by the hand-process in passing from the end to the middle of the file, and the reverse, is thus imitated. Considerable sums of money were expended in the effort to make this process a success in Birmingham, but in vain. File making by machinery is an important industry in the U. S., some of the plants having facilities for producing from 30,000 to 40,000 per day each, and for supplying over 3,000 varieties. This is done so cheaply that it no longer pays to recut worn files, a process in common use when all files were made by hand.

R. H. THURSTON.

Filefish: a fish of the family *Balistidæ* and the order *Plectognathi*. The filefishes have a conical muzzle, terminating in a mouth furnished with teeth in both jaws. In *Balistes* proper (see BALISTIDÆ) there are eight teeth in a single row in each jaw; their bodies are covered with hard rhomboidal scales, having the appearance of the teeth of a file; and they are furnished with spines in relation with the dorsal and other fins. The filefishes are brilliantly colored and abound in warm seas: several species occur on the Atlantic coasts of the U. S. The species represent several very distinct types of structure, varying in the development of the spinous dorsal fin, the position of that fin (which in some species is very far forward), the character of the scales, etc.

Revised by F. A. LUCAS.

Filelfo: See PHILELPHO.

Filibuster [from Span. *filibustero*, *flibustero*, from Fr. *flibustier*, *fribustier* (with silent *s*), from Dutch *vrijbuiter* (whence also Eng. *freebooter*); *vrij*, free + *buit*, booty, plunder]: a buccaneer or pirate. In 1849 and 1851 the name was applied by the Cubans to Narciso Lopez and his followers, and from that time it became a common name in the U. S. for the military adventurers who have fitted up expeditions from that country against the Spanish-American states. The most famous of the filibusters have been Lopez, above mentioned, and William Walker, who invaded Sonora, Mexico, in 1853, and afterward three times attempted to make himself master of Nicaragua: 1855–57, in 1857, and in 1860. See LOPEZ, NARCISO, and WALKER, WILLIAM.

Filicaja, fē̆e-lē̆e-kaa'yā̆a, VINCENZO, da: Italian poet; b. at Florence of a noble family, Dec. 30, 1642. Even in youth his ardent temperament was controlled by a clear judgment and high principles, and he returned to Florence, after his student-life at Pisa, with the character of an accomplished scholar and an earnest, upright man. Eminent as a jurist, and even consulted as a theologian, he occupied every leisure hour with poetry, and when at the age of thirty-one he married into the great Capponi family and was made senator by the grand duke, he was already known in Italy as a poet of distinguished genius. His noble *canzone* addressed to John Sobieski on occasion of the raising of the siege of

Vienna in 1683 caused his name to be known throughout Europe, and kings and emperors congratulated and honored him. His sonnets are models of purity of style, of vigor, and of sublimity of thought. Among the most celebrated of these are *La Providenza*, a sonnet of exquisite beauty, and *L'Italia*. The translation of the latter, introduced by Byron into the fourth canto of *Childe Harold*, and beginning with "Italia! oh Italia!" etc., is familiar to English readers. Filicaja held positions of high trust, and his life was in noble accord with the lofty sentiments of his poems. Tiraboschi says that "he died deeply lamented alike by rich and poor, and beloved by God and man." D. Sept. 24, 1707. See Tiraboschi, *Storia della letteratura Italiana*; Fabbroni, *Vite Italiane*; Crescimbeni, *Vite degli Arcadi*.

Filices [from Lat. *filix*, a fern]: See Fernworts (Filicinæ).

Filicinæ: See Fernworts.

Filioque, fil-i-ō'kwē [Lat., and from the son; *fi'liō*, ablat. of *fi'lius*, son + enclitic particle *-que*, and]: the clause of the Nicene Creed in its Western form which teaches the procession of the Holy Spirit from both the Father and the Son. The Council of Nice (325 A. D.) affirmed the consubstantiality of the Son with the Father, and simply declared its belief "in the Holy Spirit." The Council at Constantinople (381 A. D.) affirmed, in effect, the consubstantiality of the Spirit with both the Father and the Son, and taught the procession of the Spirit "from the Father." It was not affirmed that the Spirit proceeds from the Father *only*, but it became at last the established doctrine of the Greek Church. But at first the Greek Fathers were not agreed. Athanasius (d. 373), Basil (d. 379), and Gregory of Nyssa (d. after 394) were non-committal, neither affirming nor denying the procession of the Spirit "from the Father *and the Son*" (*filioque*). Marcellus of Ancyra (d. 373, 374), Epiphanius (d. 403), and Cyril of Alexandria (d. 444) affirmed it. But it was denied by Theodore of Mopsuestia (d. 429), and by Theodoret of Cyrus (d. 457–458). And this, as has been said, is the view which finally prevailed in the Greek Church.

In the Latin Church, on the other hand, the double procession of the Spirit appears never to have been denied. In St. Augustine's treatise on the Trinity, which was written between 400 and 416 A. D., it is clearly and emphatically taught that the Spirit proceeds from both the Father and the Son. And so firmly did this become the established doctrine in the West, that at the third synod of Toledo in Spain (589 A. D.) the clause *filioque* was added to the Niceno-Constantinopolitan Confession, and the doctrinal basis was laid for the schism—urged on by other influences—which permanently separated the Churches of the East and the West.

In the East the orthodox doctrine, confirmed by the influence of John Damascenus (d. between 754–787), rejected from the Creed the *filioque*; while in the West, at a synod convened by the Emperor Charlemagne, the introduction of the phrase into the Creed was indorsed especially through the influence of Alcuin, Theodulph of Orleans, and the Frank theologians. Pope Leo III. had already expressed his approval of the doctrine which the term implied, while he hesitated to approve its introduction into the Creed. He regarded it rather as speculative than practical. At length, when, in the ninth century, the controversy arose between Photius, Patriarch of Constantinople, and Nicholas I., which led to the rupture between the Churches, the doctrinal difference was made a topic of discussion, and the Western Church was reproached with having departed from the faith. Its position was defended by Æneas of Paris, Ratramn of Corvey, and especially by Anselm, Archbishop of Canterbury. In 1274 A. D. an attempt was made at the Council of Lyons to effect a reconciliation, but the effort proved futile. In 1439 A. D., at the Council of Florence, the attempt was renewed, but the formula proposed did not secure acceptance, although theologians of both parties were present, and had full opportunities to confer together. Plans of union between the two Churches have repeatedly been suggested, and hopes have been cherished that the breach might be healed. Possibly it might, if the question at issue had been limited to the phrase *filioque*, but in each instance in which its merits have been discussed other influences have operated to prevent the reunion. Although other characteristic differences separate the two Churches, their diverse views of the *filioque* have become historically the most conspicuous, if not the most important. The two Churches are equally committed to the maintenance of the doctrine of the Trinity. See Procession of the Holy Spirit. Revised by J. J. Keane.

Filipepi, Alessandro, called **Sandro Botticelli**: painter; b. in Florence, 1474. He took the name Botticelli from his first master, a goldsmith, but his teacher in painting seems to have been Fra Lippo Lippi (see Lippi). The earliest pictures of his which have been preserved are Madonnas of a melancholy and perhaps morbid expression of face; and a very peculiar slenderness of limb and remarkable type of head was characteristic of him, although not wholly unlike the work of his great contemporary, Ghirlandajo (*q. v.*). Before 1480 Filipepi had painted a remarkable *Birth of Venus*, now in the Uffizi Gallery of Florence, the *Adoration of the Three Kings*, in the Academy of Florence, and the large picture in the same gallery called *The Triumph of Spring*, *The Triumph of Venus*, and by other names. The last-named work is of mystical subject; it contains many figures, and is a very characteristic work of the Italian Renaissance. In 1480, in the Church of the Ognissanti at Florence, he painted a fresco of *Saint Augustine*, which still remains. At this time he was invited to Rome, and before 1484 he had painted on the walls of the Sistine Chapel several large frescoes, which still exist. Drawings of his exist illustrating the great poem of Dante, and he is thought to have engraved some of his own designs, many of which were probably followed by Baccio Baldini and other engravers. Botticelli's work from 1484 to his death is but little known, but he seems to have lived in Florence. In his prime he shared with Ghirlandajo the credit of being at the head of Florentine painting, and all the tendencies of advance and development of the epoch are to be seen in his work. D. at Florence, 1515. Besides the works named above there are many in the galleries of Europe, as, in the Pitti, Florence, a *Virgin with the Child and St. John*, and a portrait called *La Bella Simonetta*; in the Borghese Gallery, Rome, one of the fine circular *Madonnas* which he affected; in the Turin Gallery, a large allegorical picture and several smaller ones. Russell Sturgis.

Fil'lan (Irish, *Faelan*): the name of two saints, of whom the one has his festival on June 20 and his principal churches at Ballyheyland, Queen's County, Ireland, and at Loch Earn, Perthshire, Scotland; while the other has his festival on Jan. 9, and his principal churches at Cluain Maosena, Westmeath County, Ireland, and at Strathfillan, Perthshire, Scotland. The legend of the latter is found in *Act. Sanct.*, Jan. 9, tom. i., and in A. P. Forbes, *Kalendars of Scottish Saints* (Edinburgh, 1872, pp. 341–46). See also John Stuart, *Historical Notices of Saint Fillan's Crozier* in *Proceedings of Soc. Antiq. of Scotland* (1878, xii., 122–82).

Fillmore, John Comfort, A. M.: musician; b. at Franklin, Conn., Feb. 4, 1843; educated at Oberlin College and Leipzig Conservatory of Music; director of the Conservatory of Music, Oberlin College, 1867–68; Professor of Music, Ripon College, 1867–77, and at Milwaukee College for Young Ladies 1878–84; organized the Milwaukee School of Music 1884. Author of *History of Pianoforte Music* (1883); *New Lessons in Harmony* (1886); *Lessons in Musical History* (1887).

Fillmore, Millard: the thirteenth President of the U. S.; b. of New England parentage in the town of Sumner Hill (then a part of Locke), Cayuga co., N. Y., Feb. 7, 1800. He worked in youth upon his father's farm in Sempronius (now Niles) in the above county, and when fifteen years of age was apprenticed as a wool-carder and cloth-dresser. His school-education was scanty, but his leisure hours were occupied with study. He undertook when nineteen years of age the study of law with Judge Wood, of Montville, N. Y., teaching school a portion of the time. In 1822 he removed to Buffalo, N. Y., was admitted to the bar in 1823, and opened a law-office in East Aurora, N. Y.; commenced practice in the State Supreme Court in 1827, and in 1830 removed to Buffalo, where he became a partner of Solomon G. Haven and Judge Nathan K. Hall. He was sent to the New York Assembly 1829–32; was in Congress 1833–35 and 1837–41, where he was an active and useful member, favoring J. Q. Adams's views upon slavery, and in other public questions acting mainly with the Whigs. While chairman of the committee of ways and means he took the leading part in drawing up the tariff of 1842. In 1844 he was the Whig candidate for Governor of New York; in 1847 was chosen comptroller of the State and resigned in 1849; in 1848 was chosen Vice-President of the U. S. on the ticket with Gen. Taylor. On the death of the latter, July 9, 1850, Mr. Fillmore became President. The great events of his administration were the passage of the Compromise Acts of 1850 and the Japan expedition of 1852. Mr. Fillmore was in Europe 1855–56, and in the latter year was the candidate of the American party for the Presidency. He did not again enter public life. D. Mar. 8, 1874.

Filmer, Sir ROBERT: political writer; b. at East Sutton, Kent, England, toward the end of the sixteenth century; educated at Cambridge; d. about 1653. He was the most prominent of the early expounders of the DIVINE RIGHT THEORY (*q. v.*), which he presented in its most extreme form, asserting the absolute freedom of the king from human control. The *Patriarcha*, published after his death (1680), contains the most complete exposition of his views, and was answered by Locke in his *Treatise on Government*. Filmer also wrote *The Anarchy of a Mixed and Limited Monarchy* (1646); *The Power of Kings and in Particular of the King of England* (1648); and *Observations upon Mr. Hobbes's Leviathan, Mr. Milton against Salmasius, and H. Grotius De Jure Belli et Pacis, concerning the Originall of Government* (1652).

Filoplumes [from Lat. *filum*, thread + *pluma*, feather]: See FEATHERS.

Filter: See WATER.

Filth Diseases: a term introduced by Mr., now Sir, John Simon, in his report as medical officer of the Privy Council and Local Government Board of Great Britain, made in 1874, to include certain forms of disease upon whose prevalence and spread in a community he supposed the presence of putrescent refuse matter, solid and fluid, to exert a great influence. Among these diseases he included typhoid fever, cholera, dysentery, and various forms of diarrhœal disease, and also referred to septic diseases, such as erysipelas, pyæmia, puerperal fever, and septicæmia, as spread by the same cause. By "filth" in this connection is meant more especially human excrement and putrefiable garbage and refuse accumulated in, or in the immediate vicinity of, human habitations, either lying on the surface or stored in dust-bins, cesspools, privy vaults, obstructed or badly graded sewers, and the like. From such accumulations Mr. Simon held that "two chief sorts of danger to life arise: one, that volatile effluvia from the refuse pollute the surrounding air and everything which it contains; the other that the liquid parts of the refuse pass by soakage or leakage into the surrounding soil, to mingle there of course in whatever water the soil yields, and in certain cases thus to occasion the deadliest pollution of wells and springs." It is doubtful whether Mr. Simon supposed that either the filth itself or the ordinary volatile products of putrefaction were the active causes of the specific infectious diseases to which he referred, but such has no doubt been the opinion of many persons who accepted his teachings, and it is a very common idea that accumulations of filth are in themselves sufficient to generate epidemic diseases, and that not only typhoid fever, but also diphtheria, yellow fever, and even scarlet fever, may thus arise *de novo*. Discoveries in bacteriology and the application of exact methods of research have shown that the importance of filth as a causal factor in the production of disease consists mainly in two facts—first, that it furnishes a good medium for the growth and multiplication of certain forms of pathogenic bacteria when these gain access to it; and, second, that sooner or later such bacteria are very likely to find their way into it.

Of the micro-organisms which produce disease, some, such as the bacillus of typhoid, can grow and multiply in dead organic matter at ordinary temperatures, and a few of them may thus in the course of a few days make all parts of a foul solution dangerous, while others, such as the bacillus of tubercle, require temperatures near that of the living body for development, and hence under ordinary circumstances do not make accumulations of filth infectious. Although smallpox, scarlet fever, diphtheria, measles, and typhus may be conveyed by foul clothing or bedding, yet their spread is usually in no way connected with accumulations of filth, nor are they generated *de novo* by such accumulations. Typhoid fever is the typical filth disease, in the sense that it is mainly transmitted through human excreta, yet there is no evidence that a cesspool or water-supply can become the cause of this disease in any other way than by having the specific bacillus of typhoid added to it. It is possible that a common and under ordinary circumstances harmless form of bacillus may, in the course of time and under special conditions of food and temperature, be so changed in nature and functions as to be capable of producing a transmissible disease, but it is very improbable that such a change gives rise to the ordinary forms of specific disease as seen in practice.

The idea that specific disease of any kind is produced by gases or volatile products of any kind given off by decomposing filth is now generally abandoned, and it is known that the micro-organisms which cause such diseases do not pass into the air from the surface of fluids or from moist surfaces by simple evaporation. They are carried into the air by spray or dust, but not otherwise. Whether yellow fever is a filth disease, in the proper sense of the term, is as yet uncertain, but it is prudent to act on the supposition that its specific germ may be preserved in, and have its powers for evil intensified by, accumulations of human excreta and by water polluted with such excreta.

The various forms of septic disease, including puerperal fever and those produced by pyogenic organisms, are often due to want of cleanliness of the person, of clothing, of instruments, etc., and such want of cleanliness is apt to occur in connection with or to be produced by the presence of accumulations of filth, and in this sense they may perhaps be called filth diseases. The name "finger-nail fever," which has been applied to puerperal fever, is a very suggestive one.

Filth diseases are to be prevented, as Simon remarks, by preventing accumulations of filth rather than by trying to disinfect such accumulations, and one of the most important means of doing this for a city is a proper system of sewerage, which involves a good general water-supply and the regulation of the drainage systems in individual houses to insure proper connections and prompt disposal of liquid wastes. J. S. BILLINGS.

Fi'lum A'quæ [Lat., liter., a thread of water; *fi'lum*, thread + *a'quæ*, gen. of *a'qua*, water]: in law, an imaginary line passing along the middle of a river and dividing the soil underneath into two equal portions. In navigable streams above the point where the tide ebbs and flows, and in all streams which are not navigable, the *filum aquæ* designates the boundary to which the lands of owners along the river extend. If a grant be made of land adjacent to a river, it includes the soil to the center of the stream, unless the terms of the grant clearly indicate a contrary intention. If an island forms in the river so as to be divided by the *filum aquæ*, the parts thus separated belong respectively to the opposite proprietors. If there be a gradual deposition of earth upon one bank, and none or little upon the other, the thread of the stream will constantly vary, so as to always be midway between the banks. But if a large portion of land be detached from one side and carried to the other, the thread remains as before, so that the estate of each owner may extend to the same limits as previously. If a single person owns the land on both sides of a stream, of course the entire bed is also his sole property.

The *filum aquæ* in all cases only denotes the ownership of land forming the bed of a river or rising above the surface, but does not indicate any exclusive proprietary right in the water which is thus supposed to be divided. Each riparian owner along the whole course of the stream has a right to have the water flow in its accustomed manner and volume, and no one of the owners is justified in diverting the stream to his own uses, or in so materially diminishing the water-supply which it affords as to occasion unreasonable injury to the others. But any use of the water, as for purposes of irrigation, etc., which does not sensibly impair the rights of such other persons, is allowable.

In the case of public rivers, or those in which there is a flow of tide water, the soil underneath does not belong to adjoining owners, but to the sovereign or state, so that the doctrine of the *filum aquæ* has in general no application. It may, however, denote the boundary-line between two different States or two different counties. In some parts of the U. S. the doctrine is maintained that though there is no tide, the bed of a stream which is in fact navigable belongs to the State, and not to the riparian owners. See THE LAW OF RIVERS under the title RIVERS.

GEORGE CHASE.

Fin [M. Eng. *fin*, *finne* < O. Eng. *finn*: Germ. *Finne* < Teuton. *finna*: Lat. *pin'na*, fin, wing]: the principal organ of locomotion in fishes. A fin consists of a membranous expansion of the body, supported by bony spines or cartilaginous rays. Fins may be either median or paired, according as they lie in the middle line of the body or occur right and left of the median line. The median fins are the dorsal, caudal, and anal, the names of which sufficiently indicate their position. The paired fins never exceed four in number—a pair of pectoral fins, homologous with the fore limbs, and a pair of ventrals, with the hind limbs of higher vertebrates. The size and position of the fins may vary greatly, and these modifications are utilized in classifying fishes. Recent research tends to show that fins are derived from two lateral folds on either side of the body. The dorsal fold on either side moves upward and unites in the dorsal fin, while the lower fins behind the vent move downward in the same way, forming the anal, while the caudal fin is formed by both folds. The paired fins are portions of the lower fold, which continue to develop while the rest disappears. That this view is correct is shown, among other facts, by the Japanese goldfish, in which frequently both anal and caudal fins are paired. From structures similar to the paired fins have been derived the locomotor appendages of the higher vertebrates. J. S. KINGSLEY.

Final Causes: causes (see CAUSE) which are not also effects. All other causes are, on one side, caused; they come forth as well as go forth. Final causes do not come forth. The physical sciences, as such, have nothing to do with final causes. When they exhaust physical causes, they exhaust all with which they have to deal, for physical science is the science of second causes. They assume the simples and forces as existent, and the question *how* these simples and forces came to exist is not for them. In this sphere the objection of Bacon and Descartes to the investigation of final causes is well founded. It was too often an indolent or ignorant evasion of the real work of science. But, as it is no part of the distinctive work of physical science to determine final causes, it is equally remote from its province to assert that there are not final causes. The whole doctrine of final causes has been denied by materialism. (See Strauss's *Old Faith and New Faith*.) Ulrici shows that the argument of materialism at this point rests upon a confounding of "the *notion* of causality with the *mental law* of causality," and that the law of causality "does not affirm that whatever *exists* must have a cause, but only that all that *happens*, all that *comes into being*, must have a cause." See Ulrici's *Review of Strauss*, with an introduction by C. P. Krauth (1874), pp. 86–91, and pp. 56–58.

Finance [from O. Fr. *finance*, revenue > Fr. *finance*, finance : Ital. *finanza* < Low Lat. *finan'cia*, payment, money, deriv. of *fina're*, pay a fine, deriv. of *fi'nis*, settlement, fine, Class. Lat. *fi'nis*, end]: in general, pecuniary management, or the science of monetary affairs; in a strict sense that branch of the science of economics which treats of public revenue and expenditure. Finance in the latter sense has grown in dignity and importance as a separate department of the science of economics with the modern increase of government expenditure. The fact that $6,000,000,000 or over are annually received and spent by the national governments alone throughout the world indicates the far-reaching importance of this science.

Public Expenditure.—Government expenditure is naturally divided into *ordinary* and *extraordinary* expenditure. The former are the running expenses of government, which recur at stated intervals, and can readily be foreseen and calculated. The latter cover those expenses which the government may be suddenly or unexpectedly called upon to incur, or it covers investments of capital the returns or benefits of which are spread over a number of years. This distinction is important when taken in connection with the accepted principle of finance, that ordinary expenditure should be met with ordinary revenue and extraordinary expenditure with extraordinary revenue. In practice a proper distinction from this standpoint is often made with difficulty. Thus the cost of new men-of-war, of building custom-houses or schools, might be classed as items of extraordinary revenue, when in fact such items should be included among the government's running expenses in keeping its plant up to the proper standard. In the accounts both of corporations and of governments the tendency is strong toward apparently reducing ordinary by charging as much as possible to extraordinary expenditure. The distinction between *fixed* and *varying* expenditure is important as bearing on the powers of the legislative body which decides upon the spending of the public money. Fixed expenditure, as the name indicates, is fixed by an act of the legislature either permanently or for a series of years, such as the salaries of certain officials, or the expense of meeting the interest on the public debt; in a word, those expenses which need not or ought not to come up for revision at every legislative session. Varying expenditure is determined at each session of the legislative body, such as the cost of public improvements. A further classification of public expenditure is made according to the political unit which such expenditure concerns. Thus in the U. S. it is divided into *Federal* (national), *State*, and *local* expenditure, according as it concerns national, State or local interests. The Federal sphere of expenditure refers to those interests which all the States of the Union have in common; such are the preservation of the sovereignty of the U. S., to which the expense of maintaining army and navy is incident, and the cost of foreign intercourse. These items together formed 70 per cent. of the total Federal expenditure during the fiscal year ending June 30, 1891, which was as follows:

For army	$48,720,065
Navy	26,113,896
Pensions	124,415,951
Interest on debt	39,865,425
Foreign intercourse	2,028,715
Indians	8,527,469
Civil expenses	27,143,925
Miscellaneous expenses	67,035,740
Total ordinary expenses	$343,851,186

The civil expenses include particularly those of the executive, legislative, and judicial departments; the miscellaneous include particularly the cost of public buildings and public improvements, the cost of collecting the revenue, and the deficiency in the post-office revenue.

The sphere of State expenditure in the U. S. concerns interests which in general do not reach beyond the limits of the State, and are not purely local in character. The following table of the ordinary expenditure of the State of New York during the fiscal year 1891 is fairly representative of the expenditure of the other States, except for the unusual amount spent for educational purposes by New York:

For administrative departments	$789,183
Legislature	411,964
State judiciary system	670,375
Public works and buildings	2,373,590
Militia	530,214
Asylums and charitable institutions	2,571,582
Prisons and penitentiaries	749,723
Public education	4,577,615
Agricultural interests	212,528
Interest on the State debt	263,492
Moneys refunded	68,741
Miscellaneous expenses	111,130
Total ordinary expenditure	$13,330,137

Beside the Federal and State expenditures a local sphere of public expenditure is found in the minor political units, namely, in the counties, townships, boroughs, parishes, school districts, villages, and, most important of all, in the cities. The relative importance of these minor political units differs in different sections of the country. In the New England States the township is the most important; in the Southern States the county is more important; in New York and most of the Western States the so-called "compromise system" prevails, in which political power is more evenly divided between the county and the township. The ordinary expenses of the city and county of New York during the fiscal year 1891 were as follows:

For cost of administration	$2,123,387
City courts	1,461,060
Police	4,773,188
Asylums and charitable institutions	3,275,369
Public education	4,497,337
City parks	966,807
Streets and public works	5,802,592
Fire department	2,238,406
Judgments	730,657
Interest on city debt	5,084,804
Redemption of city debt	1,307,599
Miscellaneous expenses	444,460
Total ordinary expenditure	$32,705,666

These spheres of public expenditure in the U. S., the local, State, and Federal, do not find their exact counterpart in other countries. However, the expenditure on the one hand of a nation and on the other hand of a city are in general alike in character the world over, the former affecting the widest, the latter the narrowest public interests.

Budget.—A budget is an official forecast of public expenditure and revenue, on which the money-raising and money-spending laws are based—official, in the sense that it is made by a government official, the head of the government finances. A forecast of the public revenue and expenditure must be based on the experience of the past, and presupposes a review of the financial measures of the preceding fiscal years. Under constitutional governments the budget is of the greatest importance in the diets and the other representative bodies, where it is discussed and criticised by the legislators who control the appropriation of public money and devise means of raising public revenue. The leading example of budget legislation is found in Great Britain. The British Parliament controls all fiscal measures of the Government, but never originates them. The Chancellor of the Exchequer, the head of the Government finances, offers to the House of Commons his budget or estimates for the ensuing fiscal year, in the shape of a full statement of the amount of money required by the Government, and of his plans for meeting that expenditure. The spending and raising bills are discussed in committee of the whole, the Chancellor defending the proposed measures by reference to the experience of former years; the bills may be slightly amended, and after their passage in the House of Commons generally receive the approval of the House of Lords, which can only reject or accept them.

In the case of the U. S. Congress, the Secretary of the Treasury, a member of the cabinet, and head of the Federal finances like the British Chancellor of the Exchequer, sends his estimates to the Federal Congress. They are introduced in December, from six to seven months before the beginning of a new fiscal year on July 1. The Secretary of the Treasury, though responsible for the carrying out of the fiscal laws passed by the Congress, has but a small share in shaping those laws. He may be called upon to testify as to some item in his estimates before a committee of either house, but the financial policy of the Government is entirely in the hands of the Congress and of its committees. The money-spending and money-raising bills are framed by the committees irrespective of the Secretary's wishes, the committees, moreover, acting independently of each other. Money-raising bills must, and money-spending bills usually do, originate in the House of Representatives. After passing this lower house the bills are sent to the Senate for approval. There they are handled by similar committees, and are generally amended and returned to the House of Representatives for reconsideration. Finally, the bills pass both houses in the same form through the intervention of a so-called "conference committee," if they are otherwise unable to agree, and if approved by the President, become laws. The fiscal legislation of the States is similar to that of the Federal Government. In the lesser political units it lies more in the hands of the heads of counties, townships, etc., to frame the local fiscal laws under the supervision of the people's representatives, as, for instance, of the common council and board of aldermen in the case of cities.

In the finances of the U. S., Federal, State, and local alike, the carrying out of fiscal measures is in the hands of three distinct departments: The *director's* department, comprising the Federal Secretary of the Treasury and his assistants, the State and city comptroller, etc. These officials execute the fiscal laws, and draw warrants for the payment of public expenditure which are honored by the *cashier's* department, the treasurer, or chamberlain, who have direct charge of the public funds. The *auditor's* department verifies the warrants and claims, in a word, the public accounts. The accounts of the States and lesser units are complicated by the system of so-called *funds*. These are divided into *investment funds* and *account funds*. Investment funds are accumulations of money in the State or local treasuries, invested productively in bond and mortgage or otherwise, the interest being generally devoted to some special object. The school funds in various States are a leading example. Account funds are merely the names given to various accounts or divisions in government bookkeeping. The levee fund or the street fund is thus credited with the amounts appropriated for that particular purpose and debited with the amounts spent on those objects, and so with other account funds. The *general fund* has grown to be the most important, and includes all the items not embraced by the others. A further complication in the State and local public accounts in the U. S. arises from the fact that large transfers are frequently made in them from one account fund to another, and from an account fund to an investment fund, or *vice versa*, to supply a deficiency in one or the other.

PUBLIC REVENUE.—The expenditure of governments is met by their revenue. The sources of public revenue are domains, business enterprises, dues, taxes, and loans, the first four comprising the ordinary, the last the leading item of extraordinary public revenue.

Domains.—These are the public lands owned and managed by the various governments. The net receipts from this source, if they exist, figure among the receipts of the governments. In European countries the domains consist largely of forest lands; these are rented at such rates, or their products are sold at such prices, that they net the national or local treasuries considerable sums: in Bavaria, for instance, 11 per cent. of the total ordinary revenue; in Prussia, 5 per cent. Other than fiscal motives may lead to the retention of government domains, such as the desire to preserve the forests, or the desire to encourage agricultural settlers. The latter outweighs the fiscal motive in the U. S., and in consequence the immense tracts of Government lands have never proved a remunerative investment. From 1784 to 1883 the Federal Government spent $352,000,000 on the purchase, survey, and administration of the public lands; during the same period the receipts from the sale of land aggregated $234,000,000. Hence the Government has done a losing business with its land. Instead of disposing of it in such a way as to recover the amount it cost to acquire and manage it, the Government has pursued the policy of disposing of its land at such low figures that the investment has proved unremunerative. The desire to encourage the settlement of the West has been uppermost in Federal land legislation. The pre-emption, homestead, and bounty laws had disposed of 337,000,000 of acres up to 1883; grants of land in aid of road, canal, and railway construction, and grants to the individual States in aid of schools and colleges, took in addition 234,000,000 of acres. The public domain originally contained 1,849,000,000 of acres, of which it is estimated 620,000,000 had been disposed of prior to 1883, at an average price of $38\frac{3}{10}$ cents per acre. In the finances of the States and lesser units in the U. S., public land is similarly unremunerative, and though some cities own considerable amounts of real estate, the revenue derived from leasing or selling it is never large. This is not so much due to the influence of other than fiscal motives, as in the case of the Federal Government, but owing to careless management, the land being leased at low figures and for long terms of years.

Government Business Enterprises.—The second class of government revenue, that from business enterprises, is best represented by the operations of the *post-office*, which in all civilized countries is now a government monopoly. The penny post reform of Rowland Hill in Great Britain, beginning with the year 1840, was decisive in its influence on the postal policy of various nations. In accordance with Hill's recommendation the hitherto exorbitant charges for transporting letters were lowered to a uniform rate of one penny per letter for all distances within the United Kingdom. As a result of this change, the business transacted by the post-office increased enormously, but the net revenue fell off and did not reach the figure at which it stood prior to the reform until 1872. The postal reform of Great Britain has been copied in turn by every civilized nation. In the U. S. the policy of cheapening postal charges outweighs the fiscal consideration of deriving a net revenue from the post-office. Prior to 1841 the gross revenue exceeded the expenses of the post-office, but since 1852 the annual expenditure has exceeded the annual revenue. These ever-recurring deficits have been due to the cheapening of postal rates and to the necessity of supplying an enormous and thinly populated territory with postal facilities.

During the fiscal year 1891 the gross revenue of the Federal post-office amounted to $65,908,909; the total expenditure during the same year amounted to $72,069,115, resulting in a deficit of $6,160,205. While the post-offices in the New England and Middle States netted the Government $6,000,000, those in the other sections of the country did a losing business to the extent of $12,000,000. The post-offices of other countries, which are more favorably situated and which have pursued a less radical policy in fixing postal rates, have fared better and net the governments large sums. The policy of deficit financiering in the post-office is unjust in that the deficit is borne by the Federal taxpayers who are not coextensive with those who enjoy the benefits of cheap postage rates. The argument that the latter are desirable as an educational means—that is, as an encouragement to reading and letter-writing—has little weight, for those who gain by such cheap rates are, after all, but a small class of the population, and they enjoy the favors granted them at the expense of the body of taxpayers. The least the taxpayer can fairly ask for is that the postal revenue shall be made to equal the expenditure of the post-office. This does not mean, however, that postage rates shall be fixed strictly according to the cost of service, which is impossible, both on account of the need of simplicity and of uniformity of rates for the same kind of mail matter between all points within the country, and on account of the impossibility of calculating the cost of transporting the various classes of mail matter. Just as in the case of railway rates, so in general postage rates are fixed "according to what the traffic will bear," which in the long run has proved the easiest principle to realize in practice. Thus the Government charges two cents for transporting a letter weighing 1 oz., and one cent for transporting periodicals weighing 1 lb., not so much because it costs less to transport a periodical than a letter, as because any decrease of the former and increase of the latter rate would materially curtail the circulation of periodicals by the post-office and would not correspondingly increase the use of the mails by letter-writers.

Other forms of government business enterprises are found in the finance of European nations. Such are the *government telegraph* and *telephone* service, government *railways*, the manufacture of tobacco, powder, and matches, and government lotteries, *monopolies* which net the various governments more or less above their running expenses. In France $120,000,000, one-fifth of the ordinary revenue, are annually derived from the post-office and other Government monopolies, such as the manufacture of matches, tobacco, and explosives. In the U. S. the leading Government business enterprises, besides the Federal post-office, are the prisons and penitentiaries, the canals and highways when owned by the State or local governments, and the gas and water works of municipalities. None of these have ever proved a great success financially. One more business activity on the part of governments should be mentioned, that of lending their accumulated funds. Thus the investment funds of the States of the Union generally consist of municipal or other Government bonds, or of bonds and mortgages, the interest on these investments flowing into the State treasury.

Dues.—The next class of government revenue is included under the head of dues or fees—namely, *special* remunerations for *special* government services. Where the benefit of government to an individual is special in character and can be measured, he is charged a due or fee, that is, an amount equal to the cost of that service, but where the benefit of government is general and can not be measured in the case of an individual, taxes are raised—namely, *general* remunerations for *general* services. Coinage fees, court fees, and market fees are examples of such dues paid by individuals in return for special services done them by the government. The leading example of dues in the U. S. are the so-called *local assessments*, dues paid by real-estate owners for the rise in value of their property, owing to some action on the part of a municipal government. A city lays out, paves, and curbs streets, builds bridges, sidewalks, and parks, provides for street lighting, sewers, and water-mains. The adjoining real estate is increased in value thereby, and the owners of this real estate are fairly called upon to bear the expense of the improvement, as it specially benefits them and only incidentally benefits the public at large. In carrying out the principle that the cost of such improvements should be borne by the land-owners benefited, some standard on which to base the distribution of the cost must be adopted. This may be the assessed value of the property in question, or the same with due regard to its distance from the improvement, or it may be the frontage of the property on the street in the case of a street improvement.

TAXES.—The next class of government revenue, taxes, have little in common with dues or local assessments. Taxes are not special remunerations for special services; they are general forced contributions toward the support of the government—"general" in the sense that they are not based on any special relation the taxpayer may bear to the government, "toward the support of the government" in the sense that they are not payments for some particular acts on the part of government officials, but are contributions toward the cost of exercising those various functions which we call government, whose benefits are general and can not be measured by their effect on the individual, and can not be paid for accordingly. Taxes are not the equivalent of the protection the government gives the taxpayer; they are not insurance premiums against harm done to persons or property. The historical development of government revenue has in general followed the classification here given. At first the domains, the landed property of the sovereign, were sufficient to defray the expenses of the government, that is the court's expenditure. When they failed, business enterprises, monopolies of various kinds, were introduced. Then followed dues generally in the shape of licenses to trade. When all these failed to supply the growing wants of the modern bodies politic, general contributions were enforced. Thus taxes were originally an unusual or extraordinary means of raising revenue, necessary because the other means failed. The individual subject deemed it almost an infringement of his rights to be asked to contribute toward the cost of supporting the government, which he thought should be primarily borne by the private revenues of the crown. The *subject* has become the *citizen*, an organic part of the government; the people legislate and the people pay taxes, which have now become the primary means of revenue, while the others have lost in relative importance and have sunk to an insignificant figure in the U. S. Every individual, as a component of the body politic, pays taxes, not in virtue of a contract he enters into with the government, whereby he assures himself protection in return for the taxes he pays, but in virtue of the fact that he is born into a civilized community and thereby involuntarily has the obligation of paying taxes forced on him. It is a long step forward from the "voluntary contributions" of American colonial days to the complications of modern tax systems, with all the refined machinery for preventing evasion and enforcing the payment of taxes. With the growth of taxation has gone hand in hand the development of the last class of public revenue, of public loans. With the power to tax has come the power to borrow. A government which is successful with its tax system enjoys the confidence of the lending public: its credit is good, it can borrow on favorable terms whenever the occasion may arise.

Taxes are classed as *direct* and *indirect*. A tax is direct when it falls on the original or first payer; it is indirect when the original payer indemnifies himself at the expense of others. This distinction is one in economics, not in law. By constitutional provision, Federal direct taxes in the U. S. must be apportioned among the States according to their population. In the early history of the Federal Supreme Court it was held that only poll taxes and land taxes were direct in the meaning of the constitution. According to later decisions, taxes on income, on the note circulation of banks, and on inheritances, were held not to be direct. Such taxes, if direct, would have to be apportioned among the States, which would make their collection difficult, unfair, and in many cases impossible. A leading example of a direct tax, in the proper economic sense, is an income tax, which rests on the first payer and can not be shifted by him on others by charging more for his services; an example of an indirect tax is an import tax, which, though primarily paid by the importer, is shifted by him to the dealer in the advanced price of the article, and finally rests on the consumer. The distinction of direct and indirect taxes is a vital one, for on it depends the answer to the question of the *incidence* of taxation—namely, the question, who finally bears the burden of any particular tax or system of taxes. (See TAXATION.) Another important distinction is made between a real tax, one directed at a *thing*, and a personal tax, one directed at a *person*. As a matter of fact, of course, only a person can pay taxes; still in the finance of the U. S. the distinction is of great importance between taxes directed at a person as a taxpaying individual and those directed at things as representing an amount of wealth of which a certain part is claimed by the tax. The poll tax of the U. S. is eminently a tax on persons, the State and local property tax a tax on things; the former has only the personality of the taxpayer, the latter the extent of his property in view. The most useful classification of taxes divides them into those on *consumption*, or on what the taxpayer spends, on *revenue*, or on what he earns, and on *possession*, or on what he owns.

Taxes on Consumption.—These can rarely be levied on the consumer directly. The leading exception is the tax on householders. Such a tax is levied upon householders, whether owners or renters, and is proportionate to the amount of house rent paid. It is a tax on one line of consumption, and has been adopted by German cities in their systems of taxation, Berlin raising two-fifths of its ordinary municipal revenue in that way. Its advantages lie in the facts that it is easily assessed and collected, and that it is a tax on a person, directed at the householder as a member of the community, and not at his real property, a thing; its disadvantage lies in the difficulty of so framing the tax as not to unfairly burden the poorer classes, to whom the relative amount paid for house rent means much more than it does to the well-to-do classes. Instead of levying a tax on householders in proportion to the rent they pay, the tax may be based on some other criterion. For instance, the French door and window tax (*contribution des portes et des fenêtres*) taxes householders in proportion to the number of doors and windows their house contains. The use of some such external criterion avoids the necessity of inquisitorial methods in getting at the exact amount of house rent in each case.

Taxes on consumption levied on the dealer, with the intention of having him make good his loss in the price he charges the consumers, are of wide application in the U. S. So-called licenses are included under this head. A license, as the name indicates, involves a permit to carry on a certain trade or profession. When pedlers are required by law to take out a license to enable them to carry on their trade, it is done partly to keep this class of itinerant merchants under surveillance, to know their whereabouts and doings, and incidentally to limit their number; but, on the other hand, it is partly done as a means of revenue. The system of trade licenses has been adopted throughout the States of the Union, particularly in the Southern States, where license taxes, occupation taxes, business taxes, and privilege taxes net the State governments a large part of their ordinary revenue, in Mississippi 14 per cent., in Texas 33 per cent. In the North retail dealers in liquors and beers are particularly affected by the system of licenses. The cities derive large sums from this tax on consumption, New York, for instance, $1,500,000; but the municipal treasury is not benefited by this large revenue from liquor licenses, for on some theory of retribution the law provides that this revenue shall be distributed among the benevolent and charitable institutions of the city. All such license taxes have certain fiscal advantages in being easy to collect. However, in the U. S. their extension has been much hindered by the judicial interpretation of the Federal Constitution. In the first place it has been held that a license tax required for the sale of goods is in effect a tax upon the goods themselves. From this decision the step was easy to the one which held certain State license taxes unconstitutional, because they infringed upon the right of the Federal Congress to regulate commerce between the States. The trend of the decisions on this question has been toward a strict construction of the constitution, and the latter's interpretation now limits the levying of State and local licenses to businesses strictly within the State—that is, domestic in character.

Next to taxes on consumption levied on the dealer come those levied on the transporter—namely, import, export, and transit duties. This form of indirect taxation is the favorite form of national and Federal revenue, owing to the ease of collection and owing to the industrial advantages which are claimed for protective custom duties in fostering domestic industries. In fact, customs duties are looked upon in most cases not as purely questions of fiscal legislation, in which case we could truly speak of a "tariff for revenue only," but as questions of industrial legislation. (See TARIFF.) The amounts raised in this way by the nations of the world are considerable, as is seen from the following table, which gives the percentage of the total ordinary revenue of the various nations derived from taxing imports and exports (1890–91):

	Per cent.		Per cent.
Peru	73	Portugal	42
Mexico	68	Sweden	39
Argentine Republic	65	Germany	31
United States	56	Great Britain	27
Brazil	55	Italy	15
Norway	46	Russia	12
Switzerland	43	France	10

Import duties, however, are not levied at a nation's frontier alone. In many countries, notably in France, such taxes on consumption are levied at the gates of the cities. The *octroi* of French towns originated in the Middle Ages, and still taxes the importation into the towns of liquors, wines, and food products, fuel, and building material. In this way $27,000,000, more than half the ordinary city revenue of Paris, were raised in 1887. The constitutional law and economic development of the U. S. prevent the introduction of State or municipal customs duties.

Finally, taxes on consumption may be levied on the producer, with the intention of having him reimburse himself at the consumer's expense. Such a tax is based upon some external criterion, such as the amount of invested capital, horse-power, size and character of machinery, of boilers, size of factory or storehouse, or on some similar feature. In the U. S. the so-called *internal revenue system* involves such taxes on consumption levied on the producer. In extent it has been the most variable form of Government revenue. Beginning in 1789, it yielded but a small sum annually before the war of 1812, when the amount rose to above $5,000,000. During the following years of peace the internal revenue fell off, and disappeared in 1848. During the civil war (1861–65), the internal revenue system was again introduced, and has yielded large sums ever since. During and immediately after the war it amounted to a general tax on industry, the tax being directed at almost every kind of industry. When the necessity for an enormous Federal revenue declined, specific lines of industry were successively released from the tax, so that nowadays the production of spirits, fermented liquors, and tobacco are practically the only lines of industry affected. This is clear from the following table, which gives the highest amount paid by the following industries in any one of the years since 1862 (in millions of dollars):

Banks	4·9	(1865)
General industry	236	(1866)
Adhesive stamps	16	(1872)
Tobacco	47	(1882)
Spirits	83	(1891)
Fermented liquors	28	(1891)

The receipts of the Federal Government under the internal revenue system during the fiscal year 1891 were as follows (in millions of dollars):

Tax on spirits	83·3
Fermented liquors	28·5
Tobacco	32·7
Oleomargarine	1
Total	146

The taxation of the consumption of liquor, beer, and tobacco is a favorite financial expedient of modern nations; in fact, no tax is more easily collected and meets with less opposition, notwithstanding the attempts to evade the law, as in the case of illicit distilling. In general, the smokers and drinkers in the world bear the heavy taxation to which they are subjected without murmuring. In Great Britain $201,000,000, almost half the national revenue, are derived from taxing the importation ($69,000,000) and sale ($132,000,000) of tobacco and intoxicants.

Taxes on Revenue.—A tax upon the revenue from *land* is the earliest and most widespread form of taxation of revenue, because land is visible, tangible, and immovable, three qualities which make it pre-eminently serviceable as an object of taxation. Its value can readily be determined, and payment can be enforced by attachment. The earliest form in which a land tax appears is that of a tax of a specific sum on each acre of arable land or other unit of area. This method is of course grossly unfair, in that it does not properly distinguish between lands which differ in situation or productivity, and has been generally outgrown. A later method divides land into various classes according to productivity, and taxes each class uniformly per acre. A land tax of this kind was in vogue in the Southern colonies of Great Britain in America before the Revolution, but is extremely unfair. The next step forward was taken in taxing land according to its *gross* product. This is the principle involved in all tithes, which are still collected in less civilized countries. It is an extremely simple form of taxation, and amounts to taking from the agriculturist a certain fraction of all he raises. The serious objection to it is that it discriminates against enterprising farmers and in favor of those who dispense as much as possible with the use of capital, for by the law of diminishing returns the farmers can not increase their gross product in proportion to their increased application of labor and capital. The land tax reaches its fullest development when it is directed at the *net* product of land. This system is very general in European countries, where such land taxes furnish a large part of the revenue from taxation. In fixing the amount of net product subject to taxation two methods are adopted. In France the annual net product of each acre was established by an official survey, called a *cadastre*, made at heavy expense during the years 1807–50. Similarly strict surveys have been made in Prussia, Austria, Italy, Baden, and in other countries. The rigid assessments based on these surveys, which are completed at great cost, must necessarily become antiquated and inaccurate, owing to changes in the mode of production or in the kind of product. The mechanism of the cadastral system, however, when once established, is very simple and has the advantage of raising a fixed sum annually. The British tax on revenue from land and farmers' profits is more flexible, being based not on a permanent but on an annual assessment made by the landed gentry, who serve without pay.

Just as the revenue from land is taxed, so the revenue from capital invested otherwise is taxed. Such a system is carried out in France and Austria. Aside from the land tax, a tax on revenue does not often distinguish the various sources of revenue, but is aimed at revenue in general. The earliest and simplest form of a general tax on revenue is the *poll* or *capitation tax*, which demands the same sum from every taxpayer. Poll taxes were a favorite means of raising public revenue during the colonial period in North America, and have been retained to this day in most of the States of the Union, New York and Pennsylvania being the leading exceptions. Besides State poll taxes, the same are raised in the lesser political units, generally for educational purposes, the theory being that each taxpayer has an equal interest in the public-school system, and therefore should contribute the same sum to that object. Poll taxes must necessarily weigh heavily on people of small means. In fact poll taxes can not be consistently carried out, for the enforcement of payment by people of small means is impossible or politically inexpedient. Similarly to the steps in the development of the land tax, the poll tax is improved upon by the introduction of the *class tax*. This tax divides the population into classes, based on social position or some other criterion, and demands the same sum from those in the same class. Such a class tax has existed in Prussia since 1821. It divides the taxpayers into various classes and sub-classes, according to their presumable income, each sub-class being taxed a fixed amount per head. If the number of classes in the class tax is indefinitely increased, the tax approaches an *income tax proper*, in which the amount of the individual's income is determined by official or self assessment, and the rate of taxation, in percentage of that income, is fixed by law. By multiplying the amount of income, thus determined, by the tax rate, the amount of the tax is obtained. A proportional income tax is one in which the tax rate is the same for incomes of every size; a progressive income tax is one in which the tax rate increases as the income increases, relatively more is taken from large than from small incomes.

The leading modern income tax is that of the United Kingdom. It was adopted in 1798, distinctly as a war measure. It was repealed in 1816, when peace was restored, but was again introduced in 1842, and was renewed every few years. It was long unpopular, but it finally became a recognized part of British taxation. Its peculiar characteristics are its system of schedules, and its variable tax rate and exemption limit. By dividing taxable income according to its sources under five schedules, the assessment and collection of the British income tax is very much facilitated. Schedule A is directed at the income derived from the rent of land and houses—a form of land tax, as is shown above, which affects the landlord class. Schedule B is directed at the profits of land-renters, the farming class. Schedule C is directed at income derived from investment in Government bonds; in the case of domestic Government bonds the interest is retained by the treasury, and in the case of foreign government bonds the tax is collected from the authorized disbursing agents. Schedule D affects the largest class of incomes—namely, those from professions, trades, and from other sources, such as investments at home or abroad other than in Government bonds. Schedule E is directed at incomes from government salaries and pensions, the tax being withheld by the Government. In the case of Schedules A, B, and D the assessments are made by a board of assessors. The amount raised by the income tax is made to vary according to the needs of the Government by raising or lowering the rate of taxation, or by fixing the amount of income exempt from taxation at a low or a high figure. The other nations of Europe have with few exceptions followed the example of Great Britain, and have adopted income taxes as a regular feature of their systems of revenue. Unsuccessful attempts have frequently been made to introduce a French income tax; but the democratic principle, that an income tax is inquisitorial and interferes with the rights of a free people, has always prevailed. In the U. S. weak attempts have at times been made by the States to introduce income taxes, but without much success. In the Federal finances of the U. S. an income tax of large proportions was introduced as a war measure in 1862, and remained in existence ten years. During the civil war the rates were frequently raised and the exemption minimum lowered as a means of increasing the revenue. After the war, when the Federal public expenditure had fallen off, the opposite course was pursued; incomes of smaller size were freed from taxation and the rates were lowered. Finally, owing largely to the unpopularity of the system, the income tax went out of existence in 1872, but arrearages were collected as late as 1877. In all $347,000,000 were raised under this income tax, of which $73,000,000, the largest amount raised in any one year, were raised in 1866. But the amount raised in this way varied greatly: thus in 1867 it was but $27,000,000. By the first law incomes of $600 and less were exempted from taxation; on incomes between that sum and $5,000 5 per cent. was levied; on incomes between $5,000 and $10,000, 7 per cent.; and on incomes over $10,000, 10 per cent. Whatever was paid for rent or repairs was deducted. By subsequent laws the limit of exemption was raised from $600 to $1,000, and later to $2,000.

Taxes on Possession.—These tax a man not according to what he spends or earns, but according to what he owns. The leading feature of the State and local financial systems of the U. S. is the best and almost only example of a tax on possession in existence. The principle at the foundation of this property tax has always been the same since its origin in colonial days—namely, that every one should be taxed in proportion to the amount of property in his possession. Almost all the property of the colonists consisted of real estate, the valuation and taxation of which were easy matters. The property tax was in fact a real property tax, the most practical and equitable form of taxation under the economic conditions then prevailing. With the growth of the country, and the development of trade and industry, the relative importance of personal property grew. While real property can be seen and examined, and its value determined, personal property is in most cases mobile and often to all intents and purposes invisible, and can easily escape the notice of the tax official. Every attempt to remedy this difficulty, by making the oath of office of the assessors more stringent, or by direct interference of the State governments, has failed. Three points must be emphasized in the development of the property tax as imposed in the U. S.—namely, the change from a tax on *persons* to a tax on *things*, its connection with the *right of suffrage*, and the influence of the *Federal Government* on its development. In the colonial period the property tax was distinctly a tax on persons, and as property was in those days generally distributed, and the class of paupers was small, the tax reached the great mass of inhabitants. In the course of time the tax has become as distinctly a tax on things, directed not at persons, but at their property, more particularly at their real property. From once being a general tax on all property owners, it is approaching in character a fixed charge on real estate. Hand in hand with this change has gone a change in the relation between the taxpayer and the voter. During the colonial period the body of property taxpayers was practically coextensive with the inhabitants who enjoyed full rights of citizenship. This relation was recognized and maintained for two centuries. Property qualifications to the right of suffrage were the rule until well into the nineteenth century, and were then gradually done away with under the pressure of the democratic movement of the century. The only exceptions are the cases in which the law provides that the payment of a poll tax shall be a prerequisite to voting. In practice these petty restrictions amount to nothing. Property taxpayers are no longer coextensive with the voters; the voter often stands opposed to the taxpayer; the former lays the tax, the latter pays it. This conflict of interests comes up for instance in the matter of municipal finance. It makes any change in taxation difficult, for the voter, with whom the initiative lies, is not anxious for a change. Previous to 1789 each commonwealth was at liberty to derive a revenue from customs duties. This source of revenue was cut off by the Federal Constitution. Aside from this direct constitutional provision, the Federal and State and local taxes were left to compete with each other. The Federal Government secured the two most copious sources of revenue—customs duties and internal revenue—and compelled the States and lesser political units to extend more and more their general property tax; so that now opposite forms of taxation are represented on the one hand by the Federal taxation of consumption, and on the other by State and local taxation of possession. Moreover, the interpretation of the Federal Constitution by the courts interferes greatly with the consistent carrying out of the property-tax system. Under the clause of the Constitution which gives Congress sole power to regulate commerce between the States, or between a State and a foreign nation, large classes of personal property can not be taxed by the States or locally, because such goods are being transported from State to State or to some foreign country, or because they are still in their original packages. The taxation of corporations doing business in more than one State, such as railways, has been made difficult by a similar line of decisions.

The essential features of the property tax in the U. S. are as follows: All property is avowedly assessed at its market value, and is taxed at some uniform rate. Real estate includes all immovable, and personal estate all other property. Certain classes of property are exempt from taxation: 1. State and Federal Government property, the latter including all public buildings, forts, navy-yards, and Government land, but more particularly all U. S. bonds and notes. 2. The property of religious, charitable, and educational institutions, which when used for those purposes is generally exempt from taxation, on the theory that such institutions serve a public purpose and should therefore not bear the public burdens. 3. A minimum of property, which the law allows each taxpayer to withhold from taxation; this generally includes household furniture, tools, and growing crops, up to a certain amount. The assessment or valuation of taxable property is made by the assessors—officials elected by the people and generally in the smallest political units. The individual assessment lists of a township form the township assessment list; the lists of the various townships form the county list, which is controlled and corrected by a county board of review; the lists of all the counties form the State list, controlled by a State board of review. The amount to be raised for the State is divided among the counties in proportion to their corrected lists; each county adds its share of the State tax to its own county tax, and divides the amount among the townships in proportion to their corrected lists; the towns finally add to their share of county and State taxes their town taxes, and divide the amount among the taxpayers in proportion to their individual assessments.

The inherent difficulty in the property tax in the U. S. has reference to the uniform assessment of *all* property. *Real estate* can easily be found, and can be assessed, if necessary, at its true market value. But *personal property* generally escapes the assessors' notice, or is exempt because of constitutional objections. Uniform taxation of real estate is difficult but possible; uniform taxation of personal property is impossible. The difficulty of taxing personal property is particularly evident in the matter of *corporation taxation*. Corporations were at first included under the general property-tax system as persons, as individual owners of property. Corporate real estate is generally taxed wherever situated, and corporate personal estate is taxed in name at least in the taxing district where the principal office of the corporation lay. But the attempt to apply the principles of the property tax to the taxation of corporations has signally failed. Little by little possession is being discarded and product or earnings accepted as a criterion on which to base the taxation of corporations. This movement started at the beginning of the nineteenth century. First the banks, then the insurance, telegraph, telephone, and express companies were divorced from the property tax system and were taxed separately, if not on their property, then on their earning power. This movement is best illustrated in the case of railway corporations in the U. S. The simplest tax upon a railway is based on a valuation of its *property* by a local or a State board of assessors. Another method of railway taxation is based upon an assessment of the railway's *capital*, either at its par or at its market value, or the assessment may be based upon the market or par value of the aggregate *capital and bonded indebtedness*. This last method of corporate taxation is not on a line with the principles of the general property tax, for under that system of taxation the bonded indebtedness would have to be deducted from the aggregate amount of property to obtain the true value of taxable property. In taxing a railway on the amount of business transacted, a complete departure is made from the principles of the property tax. A tax on *gross earnings* is practically impossible, because when directed at railways, whose traffic is interstate—and the majority of railways come under this head—it has been held to be unconstitutional, in that it infringes upon the rights of the Federal Congress to regulate commerce between the States. A similar tax on the *net earnings* of railways may eventually meet the same fate. Finally, railways may be reached by a *franchise tax*. The franchise tax, though not satisfactorily defined in law, amounts to a tax on the excess of value of the corporate property as a whole above the aggregate value of the individual pieces. A variety of means are employed in the different States to determine this excess value. The possibility of developing franchise taxation lies in the fact that the law is likely to make a distinction between a franchise tax and a property tax; that while most State constitutions require all taxes on property to be uniform, this provision would not apply to franchise taxes, and would allow a freer development of that form of taxation than is now possible.

The desire to tax corporations by the State governments, independently of the local governments, and the difficulty of taxing personal property, owing to the facility with which it may be concealed or its value may be misrepresented, or owing to its exemption from taxation by constitutional provisions, has led in the U. S. to the introduction of State corporation taxes, which directly reach the corporations, without the intervention of the lesser political units. Pennsylvania took the lead in this development and now raises more than half her State revenue, $5,500,000 out of $10,700,000, by State corporation taxes; New York State has followed suit, and now raises one-eighth of her revenue in that way. Other States are falling into line. Moreover, collateral and direct-inheritance taxes are being adopted by the States. The introduction of such inheritance taxes, which demand a certain percentage of all moneys inherited, is the best illustration of the successful attempt to develop the tax system along other than the traditional lines. The tendency is strong to find other sources of revenue than the property tax for the State governments, and to leave the latter tax to the subordinate political units, which have greater facilities for securing correct returns of the amount of taxable property. Pennsylvania, for instance, derives only two-fifths of her State revenue from the property tax. This tendency is in keeping with the more general one of limiting the Federal Government to the taxation of consumption, by customs duties and the internal-revenue system, the State governments to the taxation of corporations, and the local and municipal governments to the taxation of property, more particularly of real property. This is illustrated in the following tables:

U. S. Federal Revenue, 1890–91.

From customs duties	$219,522,205
Internal revenue	145,686,249
Profits from coinage	6,714,344
Fees and fines	3,985,904
Public lands	2,518,064
National banks	1,236,043
Pacific railways	823,904
Sale of Government property	259,376
Miscellaneous receipts	6,513,338
Total ordinary revenue	$387,259,427

The great importance of the taxation of consumption in the Federal finances is seen from the fact that nine-tenths of the revenue is derived from that source. The profits from coinage—the so-called seigniorage—arise from the difference between the market value and the face value of the metals coined, the Government purchasing silver, copper, and nickel and turning them into coins, worth more on their face than the metal they contain. Strictly speaking, the public lands should not figure as netting the Government anything (see above). The tax on national banks is a tax of 1 per cent. on their circulation of bank-notes.

Pennsylvania State Revenue, 1890–91.

From corporation taxes	$5,564,072
Licenses	2,029,841
Collateral inheritance tax	1,227,302
Property tax	1,904,987
Miscellaneous receipts	66,444
Total ordinary revenue	$10,792,646

New York State Revenue, 1890–91.

From property tax	$8,031,401
Corporation taxes	1,535,875
Collateral inheritance tax	890,268
Interest on investments	761,811
Fees and fines	306,836
U. S. Government	109,903
Miscellaneous receipts	55,948
Total ordinary revenue	$11,692,042

The large amount Pennsylvania raises by its taxation of corporations, half of its ordinary revenue, and the large sum New York derives from its invested funds are noticeable.

New York City Revenue, 1891.

From property tax	$33,229,290
Water rent (gross)	3,272,080
Sale and rent of city property	2,837,254
Local assessments	2,715,851
Liquor licenses	1,459,830
Other licenses	675,857
State of New York	724,533
Interest on investments	475,303
Fees and fines	258,990
Miscellaneous receipts	133,104
Total ordinary revenue	$45,782,092

Almost three-quarters of the municipal revenue of New York is derived from taxing property. The rent and sale of city property net an unusually large sum, because of the large income from the rent of its docks. Liquor licenses bring in a large amount, as they do in most cities or States. While the gross revenue from the sale of Croton water seems large, the net revenue probably amounts to little, owing to the charge for maintenance and for interest on the bonds issued to provide a supply of water, which items must be covered by the gross water revenue. This is also true in most other cities of the U. S. In a few, however, the revenue from the city water-works is sufficient to cover running expenses and the fixed charges for interest on the debt incurred on account of the water-supply.

It was said above that the various spheres of Government expenditure in the U. S. do not find their counterpart in other countries. The same holds good, to an even greater degree, of spheres of Government revenue, especially as regards the character of the various sources of revenue. The national revenue of Great Britain during the fiscal year 1890–91 was as follows (in millions of dollars):

From excise duties	120
Customs duties	94
Stamp taxes	65
Income tax	64
Post-office and telegraph (net)	59
House and land tax	12
Fees	4
Government domains	2·5
Profits from coinage	2
Dividends from Suez Canal shares	1
Bank of England	0·8
Profits from savings-banks	0·3
Interest on advances	0·2
Miscellaneous receipts	2
Total ordinary revenue	427

It is seen from these figures that about half of the British revenue is derived from excise and import taxes; namely, from taxing the consumption of spirits, wine, beer, tobacco, and tea. These, with the exception of wine, are articles of general consumption; hence these taxes affect practically every one, but not uniformly, for the well-to-do spend relatively less on these articles of consumption than the poor do. The large amounts derived from the income tax and from the Government post-office and telegraph departments are noticeable—the figure $59,000,000 indicating the surplus of gross earnings over running expenses.

A somewhat different revenue system is presented by Prussia:

Prussian Ordinary Revenue, 1891–92 (in millions of dollars).

From Government railways (net)	90·6
Government mines, etc. (net)	5
Government domains (net)	11
Direct and indirect taxes	48
Lottery	2
Miscellaneous receipts	17
Total ordinary revenue	173·6

Almost two-thirds of the Prussian revenue are derived from Government property—the railways, domains, mines, etc.—and only about 28 per cent. from taxation. Customs duties are wanting, as they are in the revenue of the States of our Federal Union, and are reserved for the German empire. The leading Prussian taxes are an income tax, a house and land tax, and a license tax on industry. The fact that Prussia nets $2,000,000 from its Government lottery is to be noted; similar lotteries are maintained by many other European governments.

A still more striking difference is found between municipal revenue and the corresponding revenue of American cities.

Paris City Revenue, 1887 (in millions of dollars).

From octroi duty	27
Taxes	7
City property	6
Gas and water works	6
National Government	2
Miscellaneous receipts	3
Total ordinary revenue	51

The chief item of city revenue, it is seen, is the octroi duty. The city property, the markets, sewers, cemeteries, and the gas and water works bring in one-quarter of the entire revenue. The municipal taxes are based on and are in addition to the national taxes, much as the State taxes in the U. S. are based on and added to the local taxes on property.

Berlin City Revenue, 1888–89 (in millions of dollars).

From house and house-rent tax	4
Income tax	3·5
Gas and water works	2
City property	2
Miscellaneous receipts	6
Total ordinary revenue	17·5

The municipal tax on houses and on house rent is a tax on consumption and is directed at the householders; the income tax is based on the Prussian income tax, a similar arrangement to the one in Paris.

A comparison of the above tables suggests the great difference in the revenue systems of various countries; in some the governments derive large incomes from their property, or from business enterprises, and depend little on taxation; in other countries the opposite holds true. In the combinations of taxes, the tax systems, there is the same variety; some governments leaning to the taxation of consumption, like most federal and national governments, some to the taxation of revenue, and others, like the State and local governments of the U. S., to the taxation of possession. In examining the variety of tax forms adopted by different countries, the question naturally suggests itself, what are the proper principles of taxation? that is, in what proportion should each taxpayer contribute to the support of the government? Some hold that he should be taxed in proportion to what he spends; others, in proportion to what he earns; and still others, in proportion to what he owns. This leads to the question of an individual's ability to pay taxes. See TAXATION.

Public Loans.—The last class of public revenues are the public loans, the leading item of extraordinary public revenue. (See DEBT, PUBLIC.) When other sources of income fail, a government issues a loan, it borrows from the lending public. The first distinction to be made is that between *forced* and *voluntary* loans. In the case of forced loans, the government compels the public to accept its promises to pay in return for some article desired by it. The leading example of forced loans in modern times is the issue of legal tender paper money, which the creditors of the government are obliged to accept at their face value. In the case of voluntary loans the government enters the money market with its bonds, that is, with its promises to pay, and offers to sell them to the lending public. *Floating* and *permanent* loans or debts are distinguished. A floating or unfunded debt is due to unsettled accounts, outstanding warrants or notes issued in anticipation of revenue, which represent a temporary indebtedness. When these have been replaced by a regular issue of interest-bearing bonds, the debt becomes permanent, or funded. A large floating debt, in the case of governments, as well as of individuals, is usually a sign of financial weakness. Loans are classed as *productive* or *unproductive*, according to the productive or unproductive investment of the proceeds. Thus the public debt of Prussia was largely incurred for the purchase of railways, which investment has proved remunerative, the interest charge being more than covered by the net receipts from those railways. On the other hand, the public debts of the U. S. and of Great Britain are unproductive, inasmuch as the proceeds of the loans were wasted in wars—that is, they were unproductively invested. Whether loans are *redeemable* or *irredeemable* depends upon the ability of the government's creditors to claim repayment of the principal of the debt. In the U. S. Government loans are quite generally redeemable, the principal becomes payable after a certain number of years; in Europe there is a strong tendency toward irredeemable loans, the governments merely promise to the holders of their bonds the annual payment of a fixed sum in perpetuity, so-called "permanent annuities," however, reserving to themselves the right of repaying the principal of the loan when they see fit. Finally a public loan is said to be *secured* when some specific government property or revenue is pledged to the payment of the interest or principal. A financially weak government finds it necessary to secure its loans with its customs revenue, or with the revenue from some specific tax, established for that purpose; otherwise the lending public has no confidence in its promises. A financially strong government, however, need not secure its loans in this way; the good faith of the government, its credit, is sufficient, in the eyes of the lenders, without any such pledge. A sovereign power, in borrowing, enters into a contract relation with its creditors. But from its sovereignty it follows that it acknowledges no power above it, which can interpret and enforce that contract. Thus a national government can borrow, but it can also repudiate its debt with impunity—that is, it can break its contract and become bankrupt. Such national bankruptcies can readily occur in the case of financially weak governments, and may lead to wars. In the case of individual States of the U. S. repudiation and arbitrary reduction of interest have been of frequent occurrence; the delinquent States are protected in their quasi-sovereign capacity by the eleventh amendment to the Federal Constitution, adopted in 1798, which prevents their creditors from enforcing in the Federal courts the terms of the contract on which State loans are based.

The outstanding indebtedness of a government is indicated by the amount of principal of the debt, or of the annual interest charge. By the *conversion* of a public debt is meant a change in the amount of principal or of the annual interest charge of the debt, offered to its creditors by the government, and voluntarily accepted by them. A conversion generally amounts to a reduction of the interest charge. It appears in its simplest form when the government offers to the holders of its bonds, the principal of which has fallen due, the alternative of repayment in cash, or in new bonds bearing a lower interest. If the government's credit has improved—that is, if it can borrow at lower rates than formerly, a condition necessary to a successful conversion—the creditors will rather receive the new bonds than receive cash in payment for the old ones, and in this way the old loan, which may have borne a high rate, is converted or changed into a new one bearing a lower rate of interest.

The *redemption* or payment of a public loan is facilitated by providing that a part of the outstanding bonds shall be redeemed annually. Moreover, a so-called *sinking fund* is often introduced, with which the principal of a public debt is redeemed. A certain fraction of the debt is annually invested in some form of security, generally in the outstanding bonds themselves; the interest from these annual investments, together with the further investments from year to year, constitute a sinking fund, which it is planned shall accumulate to an amount sufficient to redeem the principal of the debt when it falls due.

Fin-back: a name given to the whales of the sub-family *Balænopterinæ* on account of their prominent dorsal fin, an appendage which in many whales is comparatively small, or rudimentary. They are comparatively slender, with a small, pointed head, the throat is longitudinally wrinkled, and the baleen is short and coarse. The fin-backs include some of the largest of animals, among them *Balænoptera sibbaldius*, which attains a length of 80 feet. On account of the great strength and power of endurance of these whales, coupled with their small yield of oil and the shortness of the baleen, they are but little sought after. In some localities, however, they are the object of inshore fisheries and the use of steamers, gun-harpoons, and bomb-lances makes their capture practicable. F. A. LUCAS.

Finch [M. Eng. *finch* < O. Eng. *finc*: O. H. Germ. *fincho* > Mod. Germ. *Fink* < Teuton. **finki-*: Celtic *pinc-*, whence Fr. *pinçon*: Ital. *pincione*, finch]: any one of various birds of the family *Fringillidæ*, but more particularly those of the sub-family *Fringillinæ*. The American finches are mostly of the genera *Carpodacus*, *Chrysomitris*, *Pipilo*, *Cyanospiza*, *Poocætes*, *Chondestes*, and *Zonotrichia*. They feed on seeds as well as insects, are generally bright, active birds, and some are good songsters. See FRINGILLIDÆ, GOLDFINCH, BULLFINCH, CHAFFINCH, etc.

Finch, DANIEL and HENEAGE: See NOTTINGHAM.

Finch, FRANCIS MILES: jurist and poet; b. at Ithaca, N. Y., June 9, 1827. He graduated at Yale College in 1849, practiced law at Ithaca, and in 1881 became a member of the New York State court of appeals. In 1892 he became dean of the law school, Cornell University. Among his poems are *The Blue and the Gray*, first published in *The Atlantic Monthly* in 1867, and *Nathan Hale*.

Finck, HENRY THEOPHILUS: See the Appendix.

Finding: the act of one who finds. In law this term has the same meaning as in popular language. The finder of lost property upon land who takes it into his possession becomes invested with a special property therein, which is superior to the claims of all persons except that of the true owner. He is under no legal obligation to take into his custody any articles he may thus discover, but if he does, certain important rights and obligations immediately attach to his possession. His primary duty is to preserve the property intact, and in as excellent condition as its nature and state at the time of finding will permit, in anticipation of the owner's appearing to reassert his title. A finder thus becomes a kind of bailee, and, like other bailees, he may defend his possession and interest by bringing action against any third person who injures the property, or asserts dominion over it, or interferes with his immediate ownership. If the absolute owner ever appears, restoration must be made to him, and the finder will be entitled to no reward if none had been previously offered, and can only claim to be remunerated for the actual and necessary expenses incurred in the proper care of the goods. But if a specific reward had been promised, of which the finder had knowledge, he would be authorized in demanding it, and would have a lien upon the property until such charges were satisfied. If at the time of making the discovery the finder knew, or had means of readily ascertaining to whom the property belonged, it would be his duty to seek out the owner and return whatever he had thus acquired; and if he failed to do this his retention of the goods would be a fraudulent appropriation of them which would constitute larceny. But in cases where knowledge of ownership could not be acquired no larceny could be committed. Retaining the chattels would then not be wrongful, but reasonable and obligatory. If the former owner can never be discovered or never asserts any claim to the property, it vests absolutely in the finder. The place where the finding occurred is immaterial as regards his rights. If an article which was lost in a store was picked up by any stranger, he would have the first claim to it, and if the owner never reappeared might enforce his title even against the storekeeper. This would not be the case, however, if the article was only left by accident, for it would then be regarded as confided to the keeping of the proprietor of the store, who might demand it from any one by whom it was discovered.

The finder of a chose in action, as a check or lottery-ticket, can not enforce payment of it if the party liable under it has notice that the applicant is not the real owner. If in such a case payment was made, the proper owner would not be debarred from a subsequent recovery. If, however, the finder transferred the instrument for value to a *bona fide* holder who was ignorant of his defective title, it would, if negotiable, be good in the latter's hands, according to general principles governing commercial paper.

At common law there were special rules concerning the finding of *estrays*—i. e. of cattle whose owner is unknown—but this matter is now generally provided for by statute. For the rules applying to TREASURE TROVE, see the article on that subject; in regard to goods found at sea, see the article SALVAGE.

Findlay: city and railway center; capital of Hancock co., O. (for location of county, see map of Ohio, ref. 2–D); 90 miles N. W. of Columbus. It has foundries, machine-shops, edge-tool works, flouring-mills, carriage-factories, spoke-factory, stave-factory, rake and handle factory, barrel-works, clay-pot works, an extensive pottery, brick, and tile works, and a large pressed-brick factory. It is the center of a natural gas-field, and since 1885 has become an important manufacturing center for glass-works, rolling-mills, nail-factories, etc. Pop. (1880) 4,633; (1890) 18,553; (1900) 17,613.

EDITOR OF "JEFFERSONIAN."

Fine [M. Eng. *fin*, end, fine, from O. Fr. *fin* < Low Lat. *finis*, end, settlement, fine (Lat. *finis*, end)]: a pecuniary mulct imposed by a court upon a criminal offender as a means of punishment. The precise amount of the fine is commonly left to the discretion of the court, though a maximum and minimum sum appropriate to each particular offense is, in general, designated by statute, and the exercise of judicial discretion must be confined within these limits. There is a provision in the U. S. Constitution that "excessive fines shall not be imposed."

Fine, feen, ORONCE, generally called **Orontius Finæus**: mathematician; b. in Briançon, in the department of Hautes-Alpes, France, in 1494. He received his first instruction from his father, who was a physician of great reputation. Afterward he studied philosophy and the sciences in the University of Paris, but finally he determined to devote himself wholly to the study of mathematics. Very few mathematical works were printed at that time, and the manuscripts were much scattered and not easily accessible. Furthermore, during the preceding centuries, mathematical science had been very much mixed up with cabbalistic elements, and it is Fine's great merit that by his numerous publications he not only made the study easier, but restored its scientific basis. Of his numerous works hardly more than half have been printed; the principal are *Quadrans astrolabicus* (1527–34); *Æquatorium planetarum* (1548); *La Théorique des cieux*, etc. D. in Paris, Oct. 6, 1555.

Fine Arts: the arts which address the sense of beauty or of sublimity or of grace, and are intended to give an exalted kind of pleasure. The fine arts are those which are calculated to serve not the daily needs of men in the way of food and other necessities and comforts, but their need of subjects of admiration and love, or, in a lower sphere, their need of that which shall charm the eye or the ear. The use of colors in simple combinations, as in stripes and zigzags, is not very lofty art, a popular tune is not very refined music, and from such art as these there results a pleasure which is high only in comparison with the purely sensual pleasures. But a great painting or a great musical composition may give pleasure of a very high and enduring kind, and will give the highest pleasure to the loftiest and most cultivated intelligence.

Of all the fine arts music is the purest, because the sources of pleasure in it are purely artistic. It tells no story, represents no fact, relates no incident, but merely excites and gratifies the sense of beauty by means of a combination of sequences of sounds. Painting, when especially directed toward beauty of form and color, and sculpture, when especially directed toward beauty of form, come next to music in dignity; but both these arts have more or less of a purely intellectual appeal to memory or to association in all or nearly all of their productions. Thus a painting of landscape is pure fine art so far as it is in itself a beautiful thing and a majestic or dainty composition, so far as it appeals to the sense of beauty and the kindred power of appreciation, and so far as it reveals natural beauty or grandeur in a way that verbal description can not do; but in so far as it shows some scene interesting for private or public associations it is not pure fine art, but rather a descriptive art partaking of the nature of history. But neither painting nor sculpture is capable of being separated from the suggestion of natural objects. This is because our human powers are not sufficient to enable us to make fine designs in color or form except by taking the suggestions of external nature. The most perfect combinations of line, of surface, of mass, of dark and light, or of color come as hints from the external world. The plastic and graphic arts, therefore, are less absolutely artistic than music, more complex, less capable, perhaps, of exciting great enthusiasm.

One art which appeals to the eye is almost absolutely pure fine art—namely, gardening in its higher branches. What is called LANDSCAPE GARDENING (*q. v.*), if including all laying out of grounds, large and small, with a single reference to beauty and grandeur of the resulting scenes, must be considered as ranking high among the fine arts. The mere study of the swells and sweeps of the ground and their accentuation and modification is a noble art akin to sculpture. Another art, seldom named as a fine art at all, must yet be classed as such in its purposes and capabilities at least—the making of fireworks. It seems a little strange that this and the art of illumination should not have been considered together as the single art of using fire decoratively. There are reasons why no very high development is possible to this art, but it is assuredly one of the fine arts.

Dancing also, which is not generally classed among the fine arts, has yet a claim to be considered as capable of becoming a very pure fine art. If looked at as a kind of moving sculpture, it is seen to have large capabilities. A sequence of stately or graceful attitudes of the body may certainly be a work of fine art. It may have been at different times in antiquity a statelier and more beautiful art than we know it, and Eastern dancing to-day points to such a probability. It has also been proposed to group and combine odors so as to produce a fine art appealing to the sense of smell, but this has never been done.

With these definitions in mind we are now able to qualify architecture, which is generally counted among those fine arts which appeal to the sense of sight. When a designer is composing a building so that its exterior shall be a beautiful and imposing mass or group of masses, he is doing fine art work. When he is arranging the statues in the porch and the floral sculpture in the canopies and molding, so as to bring these and the main lines of the porch itself into one harmonious whole, he is doing fine art work. When he is planning a hall and staircase (a most difficult subject) so that all the many points of view shall afford only graceful or imposing groups of line, and investing the whole with agreeable color, he is doing fine art work. So, in a smaller way, when he is arranging the colors for the wall and ceiling of a room, and deciding whether there shall be a dado at bottom and a frieze at top of the wall or not, and how the ceiling shall be paneled, he is doing fine art work so long as he is thinking only of the result as a piece of design as being beautiful, or at least comely and fitting. Fine art so used to beautify that which exists primarily for utilitarian purposes is called DECORATIVE ART (*q. v.*). Ordinarily, however, a number of considerations of material, utility, etc., come in and prevent the work of the builder from being fine art in any high sense, or even from being fine art at all. Thus it makes no difference whether there is plenty of money or not, the designer may make his design a good piece of fine art in spite of low cost; but if he has to provide very large windows in a certain part of the walls and a doorway and porch in another place, or to use a perfectly flat roof, this necessity may wholly destroy the artistic character of his work. Indeed there are many requirements of modern life which seem to tell directly against beauty of design. For these reasons the fine art in most buildings is of an inferior kind, and is not very impressive, consisting only in slightly pleasing or not displeasing proportions and color which is not disagreeable.

The fine arts are commonly said to be painting, sculpture, and architecture, excluding music, poetry, eloquence, and the dance. But if we in this way use the term "fine art" or "the fine arts" for the arts of color and form alone, there are really but two of them, namely, the art of molding and carving form, and the art of representing solids on a surface by means of form, light, and shade and color. Architecture is not a separate and distinct fine art at all, but a means of making buildings beautiful by adding to them the appeal to the sense of beauty by means of color and of form. The process of making a silver cup or a sword or a rug or a book-cover beautiful is exactly the same as that of making a building beautiful; and the art of the bookbinder, the weaver, etc., is a fine art to exactly the same extent that architecture is. It is therefore a mistake to speak of architecture as a separate fine art; it is indeed "the highest of the industrial arts," as is stated under ARCHITECTURE, and it may be called the most important manifestation of decorative art.

The act of creating a work of fine art is the carrying out the conception which arises in the mind. A painter has an oblong canvas or panel or piece of paper, and as he sits before a natural landscape, or as he looks at a sitter who has come to him for a portrait, or as he is struck by the beauty or the possible beauty of a group of children engaged in such or such occupation, he sees more or less clearly the future picture on the blank rectangle before him. He composes a group or a scene. Of course he may restrain himself and note down only what he sees, or only part of what he sees, but this is not producing a work of art in the high sense; it is only providing himself with material; it is *study*, like the study of any mental workman. It is true that an excellent work of fine art may be very like nature, but that is only when the conception of the artist does not take on a character further away from the natural facts; the resemblance to the natural fact is not necessarily a merit in the work of art; but because a tree is a more beautiful thing, with its grace and variety, its mystery of color, the visible signs of its growth and life upon it, than anything man's mind can create out of nothing, therefore it is generally the greatest artist who knows the most about his tree and is able to give the most essential facts about it, and does give them while trying only to express his artistic thought.

The fine arts which appeal to sight are often called the *graphic and plastic arts*; and these terms are sufficient for sculpture and for painting and its subsidiary arts, but do not seem to cover gardening nor architecture and the other decorative arts. They may also be characterized as the *arts of representation and expression* and the *arts of decoration*; for it is the chief business of sculpture, painting, drawing, etc., to give pleasure at once by revealing truths of external nature and of sentiment, and by the absolute beauty of the resulting work, while art in pottery, metals, architecture, etc., is charged with decorating that which would otherwise be merely useful. The term *arts of design* also applies with fair accuracy to all these arts.

This general theory of the nature of fine art, in which practically all modern artists agree so far as they have expressed in words their feeling about their art, is contradictory, or seems contradictory, to nearly all the writing about art in ancient times and in modern times down to the nineteenth century. When Homer, as in the famous description of the shield of Achilles, or Dante, as in the account of the sculptures or pictures (whichever they are meant to be; moving simulacra, perhaps) on the Mount of Purgatory, describes a work of art, the exactness of the representation of nature and of life is all that is insisted on. But the reason for this is simply that criticism was scarcely ever applied to works of the graphic and plastic arts before the nineteenth century. Men in Grecian republics admired a statue painted in vivid colors, with gilded hair, the nude parts of yellow-stained marble, the drapery blue, green, scarlet, or of the yellow stain covered thick with a pattern of dots or circles or small figures in vivid color; they told one another about the battle of the Centaurs and Lapithæ in the pediment of the Olympia Temple or the metopes of the Parthenon, and admired its artistic splendors, fancying all the while that what they admired was a representation of nature or the recording of an event. The tympanum of the thirteenth-century cathedral doorway set forth the Last Judgment, and the public and the priests cited the vigor and truthfulness of this representation of a scene which no man had seen, though each man expected to see it. But the artist who carved it and painted it in bright color and touched it with gold worked for art as single-mindedly as any self-conscious painter of our own day.

There is still the art of illustration and of pictorial description and record. There is art in the wood-cut of a new kind of steam-engine, and there is art in a picture of a juvenile book or on a postage-stamp of Columbus discovering America; but this descriptive and narrative art is not pure fine art, and it is very unusual that a good kind of fine art is found in combination with such a description or narrative.

The fine arts then are music, first and solitary, in appealing to the sense of hearing, and also in its almost complete abstraction; then the art of pure form in three dimensions, or sculpture, including all kinds of carving, modeling, chasing, and even engraving when it passes into sculpture, as in gem-cutting; then the art of color and form on a flat surface or painting, with its branches in which form alone, or form in connection with two or three tints only, is used—that is, drawing in all its forms and engraving of the usual sort with the needle or burin on smooth surfaces and the production of prints from engravings made for the purpose. Dancing may be a fine art, gardening is very often a fine art. And all these are fine arts proper, having no necessary application to any uses but those of beauty. But architecture and all those arts which are used only to adorn objects of possible utility and the great fine arts of sight themselves when so used are DECORATIVE ART (*q. v.*).

Poetry and eloquence are sometimes ranked among the fine arts. Neither of these can be absolutely separated from the other or from prose-writing.

Poetry, whether in the form of verse or not, is to be considered in the same manner as painting; it is the use of words in the noblest way to express and to excite emotion, and so far as this remains its work poetry is fine art. It is less a pure fine art than painting, because it always has something to relate or to urge; its appeals to the intellect are direct and constant, and its material or language is less artistic in itself; for we can not even conceive of poetry made up of words in unmeaning sequence, whereas colors put together without representing anything may be very lovely. On the other hand, the poetry consists not much in the subject-matter, but almost wholly in the way it is treated. A dozen men may tell a moving tale in prose and in verse, with but little poetry in any of their versions, when the same story told by a true poet is recognized quickly as a lofty work of art.

Eloquence is fine art only in so far as it gives high pleasure to the hearer by the dignity and beauty of the thoughts presented and the language in which they are presented. Argument is not fine art, convincing is not fine art; but appeals, consisting of lofty thoughts expressed in well-combined words and so addressed to the higher moral sense as to arouse men to noble deeds, can hardly fail to be considered fine art of a very lofty kind.

Writing in what is called prose may be eloquence and may be poetry, and as such becomes a work of fine art, though this is far more rarely the case than in the work of the versifier or the orator. RUSSELL STURGIS.

Fin de Siècle: a French phrase meaning end of the century, and used adjectively in the sense of peculiar to, or characteristic of, the close of the century or of the epoch; of such character as might be thought fitting to the end of the epoch—overwrought, overstimulated, artificial, and sophisticated.

Fine of Lands: a species of conveyance formerly in use in English law. It was in form a judgment of a court of justice. There was, however, no real litigation. The party against whom the action was apparently brought admitted upon the records of the court that the claim of the apparent plaintiff was just. This admission created a species of *estoppel*, so that he was prevented from afterward denying a statement thus solemnly made. This would be true, notwithstanding his title before the admission was perfect. In this way a fine might be resorted to as a conveyance. At an early day (18 Ed. I., § 4) it was required by statute that a married woman in making such an admission should declare before the court or an authorized officer, separately and apart from her husband, that she made the admission freely, and without fear or compulsion of her husband. A fine might on these principles be resorted to to "bar an entail" (see ENTAIL), though another fictitious proceeding, termed a "common recovery," was more effectual. (See RECOVERY, COMMON.) Another important use of a fine was to operate as a short statute of limitations. (See LIMITATIONS, STATUTE OF.) The rule is well expressed in the statute already referred to of 18 Ed. I.: "The fine is so high a bar and of so great force, and of a nature so powerful in itself, that it precludes not only those who are parties to the fine and their heirs, but *all other persons in the world* who are of full age, out of prison, of sound memory, and within the four seas the day of the fine levied, unless they put in their claim within *a year and a day*." In the reign of Henry VII. the time was extended to five years, and the claim must be made within that period, except in the case of persons under disability. In their case five years was allowed after the disability was removed. It was further required that there should be a proclamation of the fine in open court. This method of limitation has been in use in the U. S. with some modifications. An instance of it, when it became the support of an important title, is found in the case of *MacGregor* vs. *Comstock*, 17 New York Reports, 162 (decided 1858). T. W. DWIGHT.

Fingal, or **Fionn**: a hero of Gaelic legendary story; the father of Ossian, the heroic poet of the Gael. See MACPHERSON, JAMES.

Fingal's Cave: a remarkable cavern on the island of Staffa, off the west coast of Scotland, hollowed out in a mass of volcanic rocks. Two ranges of basaltic rocks are supported upon a lava-like mass beneath, and the unequal hardness of the materials, combined with the perfection of the columnar structure, has permitted the carving out, by the waves of the sea, of one of the most picturesque pieces of natural architecture in the world. The entrance is 42 feet wide, and 66 feet high; the length of the cave 227 feet. The Tertiary plants associated with the corresponding volcanic rocks on the neighboring island of Mull show that the eruption of these basalts occurred in the Miocene period. The beds of basalt on the coast of Antrim, Ireland, probably were but a part of the same great outpouring of lava. See GIANT'S CAUSEWAY.

Finger: See HAND.

Fingering: in music, (1) the mode or system devised for the proper use of the fingers in playing on certain instruments, as the organ, pianoforte, violin, etc.; (2) the application or practical use of such system. In elementary instruction-books and exercises for the organ or pianoforte the notes are "fingered"—i. e. accompanied by the marks x, 1, 2, 3, 4 (the x indicating the thumb), or by the figure 1 for the thumb, and 2, 3, 4, 5 for the fingers. This latter formula, sometimes spoken of as the "European fingering," has today practically superseded the "English or American fingering" with its thumb-mark x. Revised by DUDLEY BUCK.

Fin'ial [from Lat. *finis*, end]: the terminal ornament of a pinnacle, spire, or gable; also sometimes of a pointed arch. In the Middle Ages finials were important elements of architectural design, owing to the great numbers of buttresses, spires, pinnacles, turrets, and steep gables then employed, and were modeled with masterly skill in designs generally suggested by the vegetable world. The simplest and most vigorous were those of the thirteenth century in France and England; those of the fourteenth century were more elaborate and elegant; while those of the fifteenth partook of the general decadence of Gothic art. They were usually carved in stone, but leaden finials of great beauty were used on the wooden spires of churches and to terminate the ridge-crestings of hipped roofs.

Classic architecture made occasional use of roof ornaments similar to finials, the most famous examples being the florid marble *acroterium* on the summit of the choragic monument of Lysicrates at Athens. A. D. F. HAMLIN.

Finiguerra, fēē-nēē-gwăr'rāā, TOMMASO, or MASO: Italian niello-worker and goldsmith; b. at Florence, 1424; d. in 1475. To him is attributed the discovery of the art of taking prints from metallic plates on paper.

Fining, or **Clarification**: the process of clearing turbid liquors, generally used in connection with wines and malt liquors, though the process is resorted to for clearing a great variety of solutions, such as sirups, jellies, coffee, argol, etc. In the manufacture of wine and beer the yeast, which either rises to the surface as a scum or forms a deposit at the bottom, generally carries with it all suspended impurities, and leaves the liquid limpid. When this is not the case "finings" must be employed.

Filtering.—For fining small quantities of many liquors the process of filtration is the simplest. A funnel lined with porous filter-paper is the most convenient apparatus, though filters are made of a great variety of porous substances, such as cotton, flannel, earthenware, sand, charcoal, etc. Filtration is not always effective, as the impurities which render the liquid turbid are often so fine that they pass through the filter. This is generally the case with wines and malt liquors. Another objection to filtration is the difficulty of conducting it without exposing the liquor to the air, which in the case of light wines and malt liquors would be fatal.

Isinglass, or gelatin, is most frequently employed for beer and ale. "Brewers' finings" are made by softening the gelatin in four times its weight of cold water or sour beer. As the gelatin swells, more water or sour beer is added. The thick jelly thus obtained is dissolved in eight times its volume of the liquor to be fined, when it presents the consistence of a sirup; 1 lb. of isinglass makes about 12 gal. of finings. This is added in about the proportion of 1 to 2 pints to a barrel of ale or to a hogshead of cider or wine. The gelatin is coagulated, or rendered insoluble, by the astringent tannic acid of the liquor, and as the insoluble compound gradually settles to the bottom of the barrel, it inviscates and carries with it all the suspended impurities, and leaves the liquor clear. In some cases this removal of the astringent principle is objectionable, as it modifies the flavor and diminishes the keeping qualities of the liquor. In the case of red wines this is so important a consideration that albumen is employed instead of gelatin. Coffee is often clarified by the addition of a piece of the skin of salted codfish, which furnishes gelatin which is coagulated by the tannic acid present. Carrageen moss is sometimes used for clarifying beer, as are also the dried stomachs of the cod, called *sounds*. *Lime* in the water used is supposed to aid materially in the clarification of beer by combining with the acids of the malt, forming insoluble salts, which carry down the suspended matters. The spring water used in the breweries at Burton-on-Trent in England contains a considerable quantity of sulphate of lime, which is thought to aid in clearing the ales.

Albumen is coagulated either by heat or by alcohol. It is used in large quantities by sugar-refiners, who clarify or "defecate" their solutions of raw sugar with bullock's blood. The blood is added while the solution is below 140° F., and then, on raising the temperature to a boil by means of steam, the albumen of the blood is coagulated, and the coagulum, forming flocks, collects and envelops the suspended impurities, and partly rises to the surface as a scum, to be skimmed off, and partly settles to the bottom, to be separated by the "bag filters."

In making calf's foot jelly fresh egg-shells are often thrown in, that the adhering albumen may be subsequently coagulated by heat and clear the liquid, from which the shells and coagulum are separated by a bag filter of flannel. When albumen is added to wines it is coagulated by the alcohol, and operates as when coagulated by heat. Heat alone clarifies many vegetable and animal juices by coagulating the albumen which they naturally contain.

Vegetable acids clarify many expressed juices, and the juice of sour cherries will completely separate the pectin of currant and raspberry juice so as to fit them for sirups.

Alum is sometimes used. It is especially serviceable in clarifying waters which are rendered turbid by fine mud, a pinch of alum thrown into a barrel of water being sufficient to render it clear and limpid after a few hours' standing. The alumina is probably precipitated by the carbonate of lime, which is always present in river as well as in spring water.

Acetate of lead has been used for clarifying liquors, its precipitation being effected by a subsequent addition of half its weight of sulphate of potassa. It is a very dangerous agent on account of its poisonous character.

Plaster-of-Paris, clay, sand, and *marl* are often effective in clarifying turbid solutions, such as cider, etc.

Soluble salts, as a solution of sal-ammoniac, often cause the separation of finely divided precipitates, which remain long in suspension in pure water. They also greatly facilitate the filtering and washing of precipitates, which otherwise pass through the filter.

Finistère, fi'ni-stār', or **Finisterre** [Fr., from Lat., end of the land; *fi'nis*, end + *ter'rae*, gen. of *ter'ra*, land]: department of France, comprising the western part of the former duchy of Bretagne. Area, 2,595 sq. miles. Its coasts along the English Channel and the Atlantic are formed of rugged and broken granite rocks, but in the interior the soil is fertile and well cultivated. Its silver and lead mines are very valuable. Pop. (1896) 739,648.

Finisterre, Cape: a promontory at the northwestern extremity of Spain; lat. 42° 54' N., lon. 9° 21' W.

Finisterre Mountains: See the Appendix.

Finite Difference: in mathematics, the difference between two values of a variable quantity; generally the amount by which the quantity increases in consequence of an increase of unity in the variable on which it depends. For example, if the quantity is n^2, then an increase of n by unity changes the quantity to $(n+1)^2$. The excess of this over n^2 is the finite difference of n^2, found thus:

$$\begin{array}{ll} & (n+1)^2 = n^2 + 2n + 1. \\ \text{Subtract} & \quad n^2 = n^2 \\ \text{Finite difference of } n^2 = & \qquad 2n + 1. \end{array}$$

The finite difference of a quantity is represented by the symbol Δ before the symbol of the quantity. Thus the last result is written $\Delta(n^2) = 2n + 1$.

The increase of the original quantity (n in this example) is not necessarily unity; it may be anything whatever, and may be called Δn. We should then have, for the value of $\Delta(n^2)$,

$$\Delta(n^2) = (n + \Delta n)^2 - n^2 = 2n\Delta n + (\Delta n)^2.$$

A finite difference differs from a differential only in not being supposed infinitesimal. The calculus of finite differences treats of the theory of the subject, which has many practical applications. An excellent English treatise on the subject is that of George Boole (London).

Simon Newcomb.

Fink, Albert: civil engineer; b. near Frankfort-on-the Main, Germany, Oct. 27, 1827; studied at the Polytechnic School in Darmstadt, and in 1849 went to the U. S. He introduced the bridge system known as the "Fink truss," and in 1869 he built the great bridge over the Ohio at Louisville, Ky. (See Bridges.) For many years he was identified with the management of the Baltimore and Ohio Railroad and the Louisville and Nashville Railroad as superintendent and engineer. In 1875 he organized the Southern Railway and Steamship Association, and in 1877 he became the commissioner of the trunk lines centering at New York, which position he resigned in 1888 on account of failing health. In 1890 he was president of the American Society of Civil Engineers. D. near Sing Sing, N. Y., Apr. 3, 1897.

Finland [< O. Eng. *Finna land*, land of the Finns. Cf. Icel. *Finnland*; *Finnr*, Finn + *land*, land, but perhaps orig. *fenland*, transl. of the Finnish name *Suomenmaa*, lakeland, Finland]: a grand duchy of Russia, lying between lat. 59° and 70° N. and lon. 21° and 33° E., and bounded by Russia, Norway, Sweden, and the Gulfs of Bothnia and Finland. It includes a portion of Russian Lapland. Area about 144,255 sq. miles, one-third of which is occupied by lakes and marshes; pop. (1895) 2,483,249. The ground may be generally described as a table-land from 400 to 600 feet high, with occasional elevations, depressions, and ranges of hills covered with dense forests of fir and pine, which, in connection with the beautiful lakes, give the country a picturesque and romantic though somewhat somber aspect. The coast is low, except the southern part, which presents a line of rugged cliffs skirted with innumerable rocky islands. While Finland was united to Sweden it exported yearly a great quantity of rye and barley; indeed, it was called the "granary of Sweden." But since its annexation to Russia it has largely given up agriculture and has taken to cattle-breeding, for which the country in many places is eminently adapted. The most valuable exports are, however, the products of its forests, as timber, pitch, potash, tar, and rosin. It yields also some copper, iron, lime, and slate. Reindeer, wolves, elks, beavers, various kinds of game, and, among fishes, salmon, trout, and herring, abound. The climate is rigorous. A severe winter of seven or eight months passes through a short spring immediately into a hot, dry summer. About 84 per cent. of the population are Finns, the balance being Lapps, Swedes, Russians, Germans, and gypsies. The Finns are a branch of the Ugrian race, kindred to the Laplanders and the Magyars of Hungary, but different both from the Swedes and the Russians. They are tall, strongly built, and well proportioned, but the shape of their faces is nearer the square than the oval, and their features do not indicate any high degree of intellectuality. They are an honest, industrious, and energetic people, however, and their peculiar language and literature have attracted much attention. Along the coast the inhabitants have generally given up their peculiar dress and customs, but toward the interior primitive customs still prevail. The residences here greatly resemble the old American blockhouses. In olden times the Finns formed an independent empire, but in the twelfth century they were conquered and converted to Christianity by the Swedes. During the union with Sweden the Swedish language and civilization took deep root among the Finns, and when in 1809 Russia finally conquered and secured the country, she was met with great opposition and aversion by the people. The Swedish was the official language down to 1863. Russia has governed the country with great prudence, granting the Finns many privileges, and her attempts at eliminating the Swedish elements by supporting and developing the original Finnish foundation have been somewhat successful. In the popular schools, as a rule, Finnish is the medium of instruction. All the native population are able to read and write. The most important towns are Helsingfors, Åbo, Sweaborg, and Viborg. The Emperor of Russia is Grand Duke of Finland. The state Church is Lutheran. The government is nearly independent of the rest of the Russian empire, and is administered in accordance with the Finnish constitution of 1772. The country has an independent system of coinage, the unit being the mark = one franc. See Finland in the Appendix. Revised by C. H. Thurber.

Finland, Gulf of: the great eastern arm of the Baltic; situated between lat. 59° and 61° N. and lon. 22° and 30° E. Its water is only very slightly salt, having come from the great lakes Onega, Ladoga, Peipus, and Saima through the river Neva. At its east end is St. Petersburg, and along its coasts are Narva, Reval, Frederikshamn, Helsingfors, and Viborg.

Finlay, George, LL. D.: historian; b. of Scottish parents near Faversham, England, Dec. 23, 1799; studied at Glasgow and Göttingen. In 1823, before the death of Lord Byron, he joined the Greeks in their struggle for independence, and spent the remainder of his life in Greece, studying its history and antiquities. He wrote *Greece under the Romans, 146 B. C. to 716 A. D.* (1843; 2d ed. 1856); *History of the Byzantine Empire, 716–1057 A. D.* (1852; 2d ed. 1856); *History of the Byzantine and Greek Empires, down to 1453 A. D.* (1854); *History of Greece from its Conquest by the Crusaders to its Conquest by the Turks, 1204–1566 A. D.*, and of *The Empire of Trebizond, 1204–1461* (1851); *History of Greece under Othoman and Venetian Domination, 1453–1821 A. D.* (1856); *History of the Greek Revolution* (1861; rev. ed. 1877). D. at Athens, Jan. 26, 1875.

Finley, John Huston: See the Appendix.

Finley, Lieut. John Park: special student of and writer on tornadoes; b. at Ann Arbor, Mich., Apr. 11, 1854; educated at the State Normal School and State Agricultural College of Michigan; received the degree of M. S. from the latter. He has been assistant to the chief signal officer and officer in charge of the Pacific coast division of the Weather Service. Among his numerous papers may be mentioned *Tornadoes* (1887); *Manual of Instruction in Optical Telegraphy* (1889); *Sailor's Handbook of Storm-track, Fog, and Ice Charts of the North Atlantic and Gulf of Mexico* (1889); *Prize Essay on the Development of Tornadoes* (1890).

Finley, Samuel, D. D.: Presbyterian clergyman and president of the College of New Jersey; b. in County Armagh, Ireland, 1715; arrived in Philadelphia, Pa., Sept. 28, 1734; was licensed to preach Aug. 5, 1740, and was ordained at New Brunswick, N. J., Oct. 13, 1742. He began his ministry during the religious revivals of the time, and having preached at New Haven, Conn., in violation of a law forbidding itinerants to preach in the parishes of settled ministers without their consent, in Sept., 1743, he was seized and carried as a vagrant beyond the limits of the colony. From July 14, 1744, to 1761, he was pastor and teacher of an academy which he established at Nottingham, Md. In July, 1761, he was chosen president of the College of New Jersey at Princeton, N. J. He published sermons and edited those of his predecessor, President Davies. D. in Philadelphia, Pa., July 17, 1766.

Finmark [*Finn* + *mark*, boundary < O. Eng. *mearc* : Germ. *Marke* : Dan. *marke*]: province of Norway, comprising the northernmost part of continental Europe; between lat. 68° 30′ and 71° N. and lon. 17° and 31° E.; area, 24,000 sq. miles. Finmark is a high table-land, sometimes rising 3,000 feet above the level of the sea, indented by numerous deep, narrow, winding fiords, and skirted with innumerable islands. As agriculture becomes impossible at an elevation of 100 feet, at which height only a few wild berries will ripen, almost the only sources of wealth which the inhabitants possess are the reindeer and the codfish. Pop. (1891) 29,332, mostly Lapps. The principal town is Hammerfest, the northernmost city of Europe.

Finney, Charles Grandison: Congregational clergyman and college president; b. at Warren, Conn., Aug. 29, 1792; removed to Oneida co., N. Y.; studied law, but was ordained as a minister in 1824. He was specially noted as a revivalist. In 1835 Mr. Finney became a Professor of Theology at Oberlin College, Ohio, and its president in 1852, holding that office until 1866 and the former till death. In 1837 began his pastorate of the college church. In 1848–51 preached in England. Published *Lectures on Revivals* (Boston, 1835; ed. with notes, Oberlin, 1868); *Lectures to Professing Christians* (Oberlin, 1836); *Sermons on Important Subjects* (New York, 1839); *Lectures on Systematic Theology* (2 vols., Oberlin, 1847; London, 1851; n. e. Oberlin, 1878); *Character of Free Masonry* (Cincinnati, 1869); *Autobiography* (Oberlin, 1876); *Sermons on Gospel Themes* (1876). D. in Oberlin, O., Aug. 16, 1875. See his *Life* by G. F. Wright (Boston and New York, 1890).

Revised by S. M. Jackson.

Finnish Language (*Suomen Kieli*, lit., Finland's language): one of the chief representatives of the Ugro-Finnic group of tongues; spoken in Finland by about 1,750,000 people, and also in portions of Sweden, Norway, and Russia. While Finland was subject to Sweden, Swedish was the official language of the land, but since the conquest of Finland by Russia there has been developed a political and literary movement known as Fennomania, which is an effort warmly supported by the Russian Government to establish Finnish as the language of the land. The oldest written monuments of Finnish date no further back than to the year 1541, in which the Lord's Prayer was printed in Seb. Münster's *Cosmographey*. The first Finnish book was Michael Agricola's *Primer*, which appeared in 1542. The same author also published several religious and moral tracts. Later publications of importance to the student of Finnish language are the translation of King Kristoffer's *Law* (1610), and the Finnish version of the Bible begun by Bishop Agricola, but completed by other hands in 1642. See Finnish Literature.

The most conspicuous feature of the Finnish language is its wealth of vowels and diphthongs, a fact which led the celebrated linguist Rasmus Rask to proclaim it the most harmonious and sonorous of all tongues. Consonants are used most sparingly. In the written language phonetic spelling is employed with almost perfect consistency. The accent is always on the first syllable regardless of the length of the word. Nouns have no gender, and are declined in singular and plural through fifteen cases, six of which are local cases, e. g. *maalla*, on the earth; *maassa*, in the earth; *maalle*, to the earth; *maahan*, into the earth; *maalta*, from the earth; *maasta*, out of the earth. A suffix takes the place of the possessive pronoun, thus: *taloni*, my home; *talosi*, thy home; *talossani*, in my home; *talossasi*, in thy home. The negative is omitted with the stem of the verb and conjugated with it, thus, *en tule*, I do not come; *et tule*, thou dost not come; *emme tule*, we do not come. The verb has only two tenses, present and past, the future being formed periphrastically by the aid of the present. In the formation of words onomatopœic changes are made almost without end, e. g. the endless variations of a creaking, cracking, crashing sound are expressed by *ratisee*, *rätisee*, *ritisee*, *rotisee*, *rutisee*, *rotajaa*, *rutajaa*, etc. In terminal formatives Finnish is even far richer than Greek or Italian. Thus from *pieni* = little, we have *pienoinen*, *pienuinen*, *pienulainen*, *pienukainen*, *pienimminen*, *pienimäinen*, *pienemmäinen*, and several other modifications easily distinguished by a trained Finnish ear; besides, the above forms do not include the comparative and superlative degrees. This wealth of terminal formations is particularly important in connection with the verbs, which are made frequentative, factive, intransitive, momentive, etc., *ad libitum*.

There are several Finnish dialects, of which the East Finnish or Karelian, the Savolak, the East Bothnian, the Tavastland, and the West Finnish are the most important. In the capital, Helsingfors, there is a society for the promotion of the Finnish language (*Kotokielen seura*), the leader of which is the distinguished poet and linguist A. E. Ahlquist. The Tavastland dialect is now accepted as the basis of the written language, although the epic *Kalevala* is written in East Finnish, and C. A. Gottland desired the adoption of the Savolak dialect. Finnish and Swedish are now equally recognized in the schools, churches, courts, theaters, and newspapers of Finland, and Finnish is also employed in scientific works. The Finnish folk-songs consist of verses of eight syllables (four trochees), the foot being determined by the quantity, not by the accent. There is a peculiar periphrastic repetition of the same idea through several verses, similar to that found in Hebrew poetry. Rhymes rarely occur, but the verses abound in alliteration, which the Hungarian P. Hunfalvy regards as original, but which Ahlquist declares to be borrowed from old Norse literature. The first Finnish grammars were published by Eskil Petræus in 1649 and by Martinius in 1689. A vocabulary was collected by E. Schroderus and published in 1632. In 1821 appeared a new edition of Barthold Vhael's *Grammatica Fennica*, originally published in 1733. G. Renvall wrote treatises on Finnish orthoëpy, orthography, and meter, and published a Finnish dictionary in 1826 and a Finnish grammar in 1840. Lönnrot's great Finnish-Swedish dictionary was begun in 1866 and completed in 1880. Other dictionaries are that by G. E. Euréns (Finnish-Swedish), published in 1860, and that by F. Ahlman (Swedish-Finnish), of which the second edition appeared in 1872. Later grammars have been given by G. E. Euréns (1849), by A. W. Jahnsson (1871), and by Y. Koskinen (1860). Contributions to the history of the development of the Finnish language have been written by A. E. Ahlquist, S. G. Elmgren, and O. Donner.

Rasmus B. Anderson.

Finnish Literature: the literature of the Finnish people. This begins with the dedication of a university at Åbo in 1640 and the establishment of the first printing-press in Finland two years later. The scattered literary efforts during the preceding century were printed in other countries. The Lutheran Reformation was introduced in Finland about 1538, and there, as elsewhere, was followed by efforts to make religious knowledge accessible to the public. Thus came Bishop Michael Agricola's *Primer* (1542), his *Prayer-book* (1544), and his translation of the New Testament (1548), together with a number of other religious manuals and translations from the Old Testament. Another prayer-book and also a hymn-book appeared in 1583. In 1625 Ericus Erici published a book of sermons and in 1630 a *Catechism*. The learned Bishop Paulus Juusten (d. 1576) left an unpublished history of the Finnish bishops (*Chronicon episcoporum Finlandensium*), which was afterward printed in Nettelbladt's *Schwedische Bibliothec* (1728), and by Porthan (1784–99). This *Chronicon* is most valuable, and constitutes the chief source of Finland's early history. Klas Hermansson Fleming (d. 1616) and Johan Messenius (d. 1636) wrote extensively in Swedish on Finland, the latter devoting a tenth part of his *Scondia Illustrata* to this country, by reason of which he is usually styled "the father of Finnish history." In Sigfrid Aroni Forsius (d. 1627) Finland produced an eminent astronomer and mathematician, who prepared eleven almanacs, the last (1623) giving all the calculations for the Åbo latitude. Forsius wrote exclusively in Swedish. Another prominent scholar of this early period was the Bishop Eskil Petræus (d. 1657), the author of the first Finnish grammar.

As has been stated, the first printing-press was set up at Åbo in 1642. A second was established there in 1668, and in 1688 Viborg secured the third printing establishment. The literature that came from these presses was considerable in quantity, though usually inferior in quality. As early as 1642 the first complete translation of the Bible into Finnish left the Åbo press. This was the great folio edition; the translation was begun by Agricola and finished by Petræus. Thirty years later the founder of the second press at Åbo, J. Gezelius the Elder (d. 1690), and his son J. Gezelius the Younger (d. 1718) began the publication of a Swedish translation of the Bible, of which the New Testament appeared in 1713 and the Old Testament in 1728. The younger Gezelius also issued a new revised edition of the Finnish prayer-book, which appeared in 1701, and is still used in Finland without any subsequent revision. This period produced a large number of books of sermons by Eskil Petræus, Isak Rothovius (d. 1652), Olof Arenius (d. 1682), and Gabriel Vallenius (d. 1690). The scientific works of this age were usually written in Latin, and the chief topic was theology. Among writers of this class we find E. Svenonius (d. 1688), J. Terserus, J. Flachsenius, and the father and son Gezelius. The elder Gezelius also published a philosophical cyclopædia. Philosophy was represented by A. Thuronius, Axel Kempe, and the polyhistor M. Wexionius (d. 1670), whose *Etica* and *Politica* made their author famous. He also wrote a short geography of Finland. Philology was also studied, and brought forth the first Swedish and the first Finnish grammar. The seventeenth century produced one botanist of note, Elias Tillandz, and one antiquarian, Elias Brenner (d. 1717), who wrote a *Thesaurus nummorum Sveo-Gothicorum*. The conquest of Finland by Sweden in the twelfth and thirteenth centuries brought Swedish culture, and with it the Swedish language, into the country, and at the same time many Swedes settled in Finland. On the other hand, Finland has contributed much to the historical development of Sweden; and a number of the great men of Sweden—Arvid Horn, Armfelt, Reuterholm, and others—were Finlanders by birth. The university naturally had to look to Sweden for its professors, particularly in its infancy; and the university being the center of intellectual activity, Swedish influence became supreme. The Swedish element developed a literary activity in all directions, and in course of time produced poets and scholars of the highest rank. Indeed many of the native-born Finlanders, like Franzén, Runeberg, and Topelius, writing in Swedish, became the chief creators of the literature of Sweden. See SWEDISH LITERATURE.

In the seventeenth century the influence of the Swedish element was seen chiefly in the introduction of lyric poetry and the so-called students' dramas (J. Chronander, P. Carstenius, D. Achrelius, J. Paulinus, and T. Rudén).

The ravages of the great war against Peter the Great (1710–20) reduced Finland's population from three-quarters to one-quarter of a million, and caused a serious interruption in the development of Finnish literature. By the Nysted peace (1721) Viborg was ceded to Russia. Finland gradually regained her prosperity and former population, and Finnish literature entered upon a new era, in which particular attention was paid to practical, economic, and scientific subjects. Swedish and Finnish now became rivals of the Latin language in the presentation of these. The new epoch produced the eminent theologian and philosopher Johan Browallius (d. 1755); the botanist Peter Kalm (d. 1779), who was Linné's pupil, and who, at the request of Linné, visited North America (Sept., 1748, to Feb., 1751) for the purpose of studying its flora. He embodied the results of his researches in three volumes, called *En resa till Norra Amerika* (*A Journey to North America*); the chemist and mineralogist Peter Adrian Gadd (d. 1797); the economist Anders Chydenius (d. 1803), who has the honor of having defended in his published works the same principles as the celebrated Adam Smith. Poetry was represented in this epoch by Abraham Achrenius (d. 1769) and Gustaf Filip Creutz (d. 1785), the former writing hymns in Finnish, the latter pastoral poems in Swedish.

The Gustavian epoch so celebrated in Swedish literature did not begin to bloom in Finland until its flowers had already commenced to fade in Sweden. The chief Finnish poet of this period, Frans Mikael Franzén (b. 1772; d. 1847), was not only the first great poet of Finland, but he also attained the rank of one of the most eminent lyric skalds in the annals of the literature of Sweden. Other poets of this epoch were Mikael Choræus (b. 1774; d. 1806); Jakob Tengström (b. 1775; d. 1832), known also as an historian; and Henrik Gabriel Porthan (b. 1739; d. 1804), whose poems are forgotten, but whose labors in the cause of the Finnish language secured him undying fame. This age also produced the great jurist Matthias Colonius (1737–1817); the philosopher G. I. Hartman (d. 1809); the mathematician A. J. Lexell (d. 1784); the physicist G. G. Hällström (d. 1844); and the great chemist and mineralogist Johan Gadolin (d. 1852).

In 1809 all of Finland became a province of Russia. It seemed at the outset as if the Russian conquest would be a blow to Finland from which it would not soon recover; but after the university had been removed from Åbo to Helsingfors, the new capital, in 1828, Finland entered upon her most brilliant intellectual period, producing scholars, poets, and artists of whom any nation in any age might be proud. The first to kindle the new enthusiasm and activity was Adolf Ivar Arwidsson (1791–1858), the poet, publicist, and historian. His writings roused the people to a love of their country, their language, and their history hitherto never known. He fought for the rights of the Finnish tongue as the vehicle of Finnish thought, though the scientific study of the language itself had already been begun by G. Renvall (d. 1841) and by R. v. Becker (d. 1858). Scholars now undertook the collecting of songs and tales from the mouths of the common people, the grandest results in this direction being attained by the celebrated Elias Lönnrot (b. 1802; d. 1884), who published in 1835 the extensive popular epic *Kalevala* (see KALEVALA); in 1840 a collection of popular lyrics called *Kanteletar* (the Finnish harp is called *kantele*); and in 1880 a volume of troll-runes. The discovery and publication of all this popular poetry suddenly shed a flood of light upon the mythic past of the Finns, and gave a mighty impetus to the conflict which is still raging between the Fennomans and the advocates of Swedish. Much credit is due in this connection to the Finnish literary society (*Suomalaisen Kirjalisuuden Seura*) organized in 1831. Besides publishing the popular literature already mentioned, this society founded a magazine, the *Suomi*, of which more than forty volumes have appeared. In the meantime Finnish poetry began to flourish as never before. Its chief representative is August Engelbrekt Ahlquist (b. 1826), who is at the same time the foremost authority in Finnish philology. Swedish literature in Finland also felt the influence of the new movement. Its greatest ornament is Johan Ludvig Runeberg (b. 1804; d. 1877). By his imperishable verse he not only became the strongest pillar of Swedish culture in Finland, but he will forever be counted as one of the greatest poets that the whole North has produced, ranking easily with Tegnér, Oehlenschläger, or Welhaven. In his *Stories of Ensign Stål* he immortalized Finland's last conflict in a series of pictures of wonderful beauty. Next after Runeberg ranks Zacharias Topelius (b. 1818), a poet of the highest order, and Finland's most popular novelist. His *Surgeon's Stories* (6 vols.) have been translated into many languages, and are everywhere the delight of the reading public, but the discussion of Franzén, Runeberg, and Topelius belongs under Swedish as much as under Finnish literature. Other poets of this period are Fredrik Cygnæus (1807–81), a lyric and dramatic writer too deep to be popular; Lars Jakob Stenbäck (1811–70); Johan Jakob Nervander (1805–40); Emil von Quanten (b. 1827); Josef Julius Wecksell (b. 1838), author of the tragedy *Daniel Hjort*; Karl Robert Malmström (b. 1830); and Theodor Lindh (b. 1833). The removal of the university to Helsingfors also brought forth a number of distinguished scholars, among whom were Johan Jakob Nordström (d. 1874), an historian of great ability; Mathias Alexander Castrén (d. 1852), Professor of Finnish and translator of *Kalevala* into Swedish; Georg August Wallin (d. 1852), explorer and linguist; Gabriel Rein (d. 1867), Matthias Akiander (d. 1871), and G. Z. Forsman, the last three historians; Johan Vilhelm Snellman (d. 1881), philosopher; and Carl Gustaf Estlander (b. 1834), writer on arts and æsthetics.

Finnish literature has been exhaustively treated by S. G. Elmgren in his *Review of Finland's Literature* (1865), and by Gabriel Lagus in his *Lectures on the Development of the Finnish-Swedish Literature* (1867). Very comprehensive articles on Finland, its history, language and literature, are published in vol. iv. of *Nordisk Familjebok* (1881), and to this work the present writer is largely indebted for his materials.

RASMUS B. ANDERSON.

Finsbury, or **Fen Town**: See LONDON.

Finsch, FRIEDRICH HERRMANN OTTO, Ph. D.: German ornithologist and explorer; b. Aug. 8, 1839, at Warmbrunn, Silesia, Prussia. Educated for a mercantile life, he seized the first opportunity to indulge his love of travel and natural history by accepting a position with the Austrian consul at Rustschuk. From 1861 to 1864 he was assistant in the Museum of Leyden, Holland, and at the end of that time was appointed director of the Museum of Natural History and Ethnology at Bremen. In 1878, under the auspices of the Bremen Society for North Polar Exploration, he made a journey through Western Siberia accompanied by Dr. A. E. Brehm, author of *Das Thierleben*, and explored the tundra between the Obi and the Gulf of Kara, in the hope that it might be feasible to unite tributaries of the Obi and Kara rivers with a canal. Aided by the Humboldt Society of Berlin, Dr. Finsch spent the period of 1878–82 in Australia, New Guinea, and other islands in the Pacific, where he made large collections. On his way to Australia viâ the U. S. he supervised the transportation of live carp to Washington, the progeny of which, through the efforts of the U. S. Fish Commission, have been distributed throughout the U. S. In 1884–85 Dr. Finsch again visited New Guinea, this time in the interest of a Berlin syndicate, explored and surveyed the coast from Vulcan island to Humboldt Bay, the result being the establishment of the German protectorate over what is known as Kaiser Wilhelmsland. Among his many publications are *Monographie der Papageien*; *Die Vögel Ostafrikas* (in conjunction with Dr. Hartlaub, 1870); *Die Zweite deutsche Nordpolarfahrt.*, part iv., *Vögel* (1873); *Anthropologische Ergebnisse einer Reise in der Südsee* (1884); *Verzeichniss einer Sammlung von Maori Antiquitaten auf Neuseeland* (1884); *Über Bekleidung, Schmuck und Tättowierung der Papua auf der Südostküste von Neuguinea* (Vienna, 1885, mit Abbildungen); *Ethnologische Erfahrungen, etc., aus der Südsee* (1888, 1891, 1893); *Ethnologischer Atlas, Typen aus der Steinzeit Neuguineas* (1888).

Finsch Haven: See the Appendix.

Finsteraar'horn: the highest peak of the Bernese Alps, Switzerland, 14,026 feet high.

Fiords, fyōrds [from Dan. *fjord*: Icel. *fjörðr*, pl. *firðr*, whence Eng. *firth*, *frith*: Germ. *Furt*: O. Eng. *ford* > Eng. *ford* < Teuton. *ford-*: Lat. *portus*, harbor, whence Eng. *port* < Indo-Eur. *per-*, *por-*, go, cross, beyond > Sanskr. *par-*, cross, Gr. *πόρος*, passage, *περάω*, cross, *πόρθμος*, ferry, Eng. *fare*, ferry]: narrow and deep arms of the sea, penetrating a mountainous coast. Fiords characterize the coasts of Norway, Scotland, Greenland, Labrador, British Columbia and Southern Alaska, Southern Chili, and Southern New Zealand, and to a less degree the coasts of Maine, Nova Scotia, etc. They are produced by the submergence of valleys, excavated by atmospheric weathering during a former higher stand of the land, and frequently more or less modified afterward by glacial action. The irregular Austrian coast of the Adriatic and the ragged coast of Greece illustrate the effect of submergence of rugged lands, unaffected by glacial action. The great fiords of Norway differ from shallow inlets, such as those of Chesapeake Bay, chiefly on account of the difference in the relief of the two submerged regions. See COAST. W. M. DAVIS.

Fiore, PASQUALE: See the Appendix.

Fiorelli, fē̄e-ō-rel'lē̄e, GIUSEPPE: archæologist; b. at Naples, Italy, June 8, 1823; won early fame as a director of the Pompeian explorations, but was displaced on account of his liberalism. After Victor Emmanuel came into possession of Southern Italy, Fiorelli was made (1860) chief director of the operations at Pompeii, and later chief director of the excavations of the whole kingdom; also Professor of Archæology in the University of Naples. In 1865 he was elected senator. Was editor of the *Giornale dei Scavi*, and published maps and reports of his work, some of them extensive and important productions. D. Jan. 29, 1896.

Fir [M. Eng. *fir*, *fur*, from Dan. *fyr*: O. Eng. *furh* (in *furh-wudu*, fir-wood): O. H. Germ. *forha* > Mod. Germ. *Föhre* < Teuton. *forh-*; cf. Lat. *quercus*, oak]: the English name for all coniferous trees of the genera *Abies* and *Picea* (and in Great Britain even the native pine is called Scotch *fir*, but incorrectly); but there is a prevailing tendency to restrict the name to the group represented by the silver fir of Europe (*Abies pectinata*), the balsam firs of Atlantic North America (*A. balsamea* and *A. fraseri*), and the noble *A. grandis*, *A. amabilis*, and *A. nobilis* of Oregon and California; i. e. to those species which bear lateral and erect cones, the scales of which at maturity fall away with the seeds. Most of these yield fir balsam. (See BALSAM, CANADA.) The numerous species of the other main division properly take the name of *spruce*. These are known by their cones hanging from the tips of branches and their scales remaining permanently attached to the axis. There is a peculiar group of spruces or spruce-firs represented in the Northern Atlantic U. S. by the hemlock spruce (*Tsuga canadensis*), and in and W. of the Rocky Mountains by the noble Douglas spruce (*Pseudotsuga douglasii*). Fir timber generally is light, soft, and white; that of some species is excellent for masts and spars, but not otherwise of high value. That of the spruce is more valuable than that of the proper firs, excepting, however, the European silver fir. This genus furnishes some of the best and most available evergreen trees for ornamental planting. As to the Northern and Middle U. S., to which they are mainly adapted, the commonest and one of the best spruce firs is the Norway (*Picea excelsa*), much excelling the native black spruce (*P. nigra*), but it is excelled for all northern regions by the beautiful white spruce (*P. alba*) and by the Menzies spruce (*A. menziesii*) of the Rocky Mountains. As to the true firs, the balsam firs of North America are very short-lived; the European silver fir is apt to die down from the winter, at least when young; and it remains to be seen whether any of the magnificent Western species are sufficiently hardy to be generally planted with success.

Firdausī, fẹ̄er-dow'sē̄e (sometimes also *Firdusi* and *Ferdosee*): Persian epic poet of the tenth century A. D., and author of the *Shāh-Nāmah*, or Book of Kings, a national history of Iran. The poet's real name was Abū'l Kāsim Mansūr; the name Firdausī, Paradise, by which he is known to fame is apparently a *nom de plume* or complimentary title given him, it is believed, by his patron Sultān Mahmūd, but other explanations of the name are found.

The main facts of Firdausī's life are fairly certain. He was born near Tūs, in Khorassān, about A. D. 940 (Hijrah 329). By birth he came of good stock; his family, though perhaps in moderate circumstances, were of the Dihkan class, or old landed proprietors in Persia, whom the Arab conquest had not displaced. In the Dihkan families the old legends and historical traditions were kept alive; the name *Dihkan* became therefore synonymous with historian. Firdausī would thus naturally have an inherited aptitude for the subject he was destined so nobly to treat. That he had a good education is shown by his mastery of Arabic and Persian, and his evident familiarity with the obsolete PAHLAVI (*q. v.*). At the age of twenty-eight he married, and of his two children the younger, a daughter, survived him.

Firdausī's real literary career seems to have begun at the age of thirty-six, when he entered upon his life-work, the composition of the *Shāh-Nāmah*, to deal with which he was eminently qualified alike by his extended studies, his inherited sympathy, his devoted zeal, and his poetic talents. Abundant historical material must have existed in Firdausī's day out of which the annals of ancient Persia could be constructed. Chronicle histories of Media and Persia appear to have been kept from the earliest times, if Herodotus and Ktesias, Moses of Khorene, as well as the statement of the Bible, Esther vi. 1, x. 2, are to be believed. Under two of the last Sassanian monarchs, Nushirvan (Khosrav Anōshirvān, A. D. 550), and especially Yezdegerd (about A. D. 625), collections of these annals are said to have been begun. The historian Danishvar, one of the Dihkan class, under the last-mentioned ruler compiled a chronicle history, the *Khotai-Nāmak*, Book of Kings, in the Pahlavi language. Three centuries after the Moslem conquest a court poet, Daḵīḵī, who flourished about A. D. 975, under the last of the Sāmanian princes, had begun a national epic dealing especially with the reign of Gushtasp and the establishment of the religion of ZOROASTER (*q. v.*), but he had been murdered. There was an opening thus created for a national poet; Firdausī seems to have been filled with the ambitious design of striving to gain that honor. Through a friend, as he relates, he procured a copy of the old Pahlavi chronicle of kings, and immediately began work upon his cherished theme. For more than twenty years Firdausī seems to have worked upon the subject at his home in Tūs. His fame doubtless grew, and when in the poet's fiftieth year a new monarch and zealous patron of letters, Mahmūd of Ghazni or Ghazna (A. D. 997–1030), came to the throne, it is natural that not a long time should have elapsed before Firdausī was installed at court.

Many interesting anecdotes are preserved about Firdausī's life at court, and his skill shown in poetic contests. The delighted Mahmūd treated the laureate royally, and promised him 1,000 gold pieces for each thousand couplets of his epic as they were completed. Firdausī preferred to have the payment reserved until the great work was finished. His design was to spend the entire sum in improving the dikes of his native city.

For at least twelve years Firdausī lived at court and continued his work under Mahmūd's patronage; but jealousies were rife, and enemies had meanwhile arisen. The poet was seventy years of age when his monumental work of 60,000 couplets, or 120,000 lines, was finished. He presented it to the sultan through his friend Ayaz. The monarch ordered an elephant to be laden with 60,000 gold pieces and sent to the poet-laureate. But the sultan's jealous vizir, the knavish Hasan Meimendi, persuaded Mahmūd to change his decision and to substitute 60,000 silver dihrems for the gold. Firdausī, as the story goes, was in the bath when the gift arrived. He received it with joy, but on discovering the deception and the broken promise, he fell into a furious rage. He at once divided the money into three parts, giving 20,000 to Ayaz, and distributing the remaining 40,000 silver pieces equally between the bath-steward and a servant who brought him a glass of cordial. He then sent back a reproachful message to Mahmūd. The latter, incensed, ordered Firdausī to be put to death, but on the morrow revoked this cruel mandate. The aged poet, however, in bitter despair fled from Ghazni, leaving behind him a satire which on the spur of the moment he had composed against Mahmūd. This satire, which has been preserved, destroyed all the effect of the poet's former noble panegyric on the prince, and has ever lasted as a tarnish upon the name of Mahmūd.

For the ten years that remained of his life, Firdausī seems to have been a wanderer. He went first to the region of Māsandarān; thence he betook himself to the Khaliph Kader-billah of Baghdad, by whom he was hospitably received, and for whom he composed a poem of 9,000 couplets on the love of *Yūsuf and Zuleikha*, a version of the story of Joseph and Potiphar's wife as found in the Koran. Obliged again to flee, he sought refuge ultimately with the governor of Kohistan. The latter made efforts for a reconciliation between the wronged poet and the angry sultan, and not without success. Firdausī, however, had meanwhile returned to his old home in Tūs. Thither Mahmūd sent to him, it is said, the once-promised gold pieces, together with a robe of honor, and a handsome apology. The reconciliation came too late. The aged poet had just died, A. D. 1020 (A. H. 411) in his eightieth year, or some eleven years after the completion of his great work.

To the story is added a statement that the Sheikh of Tūs at first hesitated to grant Firdausī's body the proper funeral obsequies, on the ground that he was an infidel, and leaned toward the old faith of the fire-worshipers. Warned in a dream, however, the sheikh revoked the decree and Firdausī was honorably interred. The gift sent him by Mahmūd of Ghazni was ultimately accepted by the dead poet's relatives, and employed in carrying out the design, which in his lifetime he had cherished, of improving the dikes of Tūs.

Firdausī's *Shāh-Nāmah*, or Book of Kings, is one of the great epics of literature. It is really the national chronicle of Iran, narrating the achievements of the ancient kings from the mythical days of Kaiūmers, the first King of Persia, down to the Mohammedan conquest, A. D. 641. The most interesting portion of the poem is its first half or two-thirds, down to the invasion of Alexander. Though much of the material is legendary, fabulous, and romantic, Firdausī seems in general to have followed quite faithfully his sources referred to above; and in the poem there is unquestionably a vast store of real history. The *Shāh-Nāmah*, for example, has thrown much light on many historical allusions in the AVESTA (*q. v.*). The language of the *Shāh-Nāmah* is in general a pure Persian, comparatively free from Arabic elements; and the style is worthy of the subject and not overladen with an excess of Oriental richness and coloring. The nature of the poem, a sort of rhyming chronicle, precludes real epic unity; but the composition of the book is interesting as being the work of one person. Some of the best parts of the poem are the episodes. The most famous perhaps is that of Sohrab and Rustem.

The best editions of the text are by Turner Macan, *Shāh-Nāmah, an Heroic Poem* (4 vols., Calcutta, 1822–29); by Jules Mohl, *Le Livre des Rois* (6 vols., Paris, 1831–68); Vullers, *Schahname* (3 vols., Leyden, 1877—continued by Landauer). There is a complete French translation by J. Mohl, *Le Livre des Rois traduit et commenté* (7 vols., Paris, 1876–78); also an Italian one by Pizzi, *Firdusi, Il Libro dei Re* (8 vols., Turin, 1886–88), and an unfinished German translation by Ruckert, *Firdosis Königsbuch Schahname*, hrsg. von E. A. Bayer (Berlin, 1890). Selections in German are by A. F. von Shack, *Heldensagen des Firdusi* (3 vols., Stuttgart, 1877); and there is a convenient English translation and abridgment by James Atkinson, *Shāh-Nāmah*, (London, 1832), of which a handy reprint has been published (New York, 1886). Consult also Ouseley, *Persian Poets, Ferdusī* (London, 1846), and Görres, *Heldenbuch von Iran* (Berlin, 1820).

An edition of the *Yūsuf and Zuleikha*, of which an extremely rare manuscript is to be found in the British Museum, is being prepared by Ethé. Furthermore, regarding the genuineness of some minor poems attributed to Firdausī, consult Ethé in *Münchner Sitzungsber* (1872–73).

A. V. WILLIAMS JACKSON.

Fire: See FLAME and COMBUSTION.

Fire-alarms: devices used for giving notice of the occurrence of a fire, classified as fire-alarm telegraphs, automatic electric fire-detectors, and mechanical fire-detectors. In the first named a system of signal-boxes is distributed over a given district, and connects by electric circuits with a central station, and thence with a series of alarm-bells on a second circuit. By giving a signal at one of the boxes the place of the fire is telegraphed to the central station, and from the latter to the signal-bells at the local stations, to direct the engines to the place where needed. The first practical trial of a fire-alarm telegraph system was made in 1851 in Berlin and New York, but the plan was much modified in succeeding years, and as thus changed was fully adopted in some of the cities of the Eastern States before being put into regular use in New York in 1871. Although simple in principle, the details of the system are somewhat complex, and for a full description the reader is referred to the U. S. patent of Farmer and Channing, dated May 19, 1857. It is well known that different substances or mechanical devices change their volume or position with change of temperature; and if we imagine one of these substituted in lieu of human fingers to break or close, by such changes, an electric circuit connected with alarm mechanism, we have an idea of the essential principle of a self-acting electric fire-detector. Mechanical detectors depend for their action upon agencies altogether mechanical; such, for example, as the burning of a string to set the annunciating appliances in motion.

The fire-alarms of most interest are those of the automatic electric variety, of which in recent years a number have been devised. In each of these a thermostat, acting, when heated, by change of form or position, is used to break or close a circuit; but the arrangement of the circuit wires, the thermometric devices, and the accessory mechanism in the different plans are widely different.

The earliest record of an electric fire-alarm appears to be the British patent of N. Rutter (1847), in which the mercurial column of a thermometer closes the circuit when the temperature is high enough to be dangerous. A galvanometer, alarm-bell apparatus, and electro-magnetic coil are included in the circuit. Thermometers properly fitted with wires are placed in important parts of the building, so that any unusual increase of temperature becomes instantly known. On the completion of the circuit a soft iron bar, detached from a permanent magnet, falls upon the detent of a spring or other alarm, putting it into action, and at the same time deflects the galvanometer needle, so as to show the place of the danger. Rutter also proposed the modified use of his invention as a "burglar-alarm" and for the detection of undue pressure of steam in boilers, etc. In 1852 one John Hunter suggested applying fusible or combustible conductors to render electric telegraphs self-communicating in case of fires. In the same year Price patented a thermometric circuit-actuating device, the principle of which has been, and still is, in practical use. Lloyd describes an indicator for completing the circuit by means of a curved compound metallic strip made of steel and hammered zinc, connected with one battery pole; the other battery pole is fixed to the opposite part of the instrument. On elevation of temperature the strip straightens itself and completes the circuit. Lloyd describes an alarm in which a detent lever, actuated from the circuit, releases a toothed wheel, which is then rotated by a cord and weight, whereupon a suitable escapement causes a hammer to strike a bell. In 1857 Greenhow patented a valuable modification, in which, instead of setting the alarm in action by completing the circuit, the same effect is produced by breaking it.

In 1865 Charles Dion, of Montreal, Canada, patented in France fire-alarms embracing contrivances both electric and mechanical, and of simple and scientific construction. Other apparatus brought forward about the same time included the use of thermometric devices that under ordinary conditions themselves form a portion of the circuit, so that elevation of temperature will break the circuit and transmit the alarm, the same also occurring when the circuit is broken by accident. Some automatic fire-alarms have been so constructed that only one line-wire is required for any number of rooms in a building, and the signal-boxes of the ordinary alarm telegraph are retained. The thermometric devices or thermostats employed for initiating the action of the alarm mechanism are of various kinds, but are too numerous for detailed description here.

The ease and convenience with which electricity may now be applied tend to render merely mechanical fire-alarms obsolete, but there may be places where they may be employed to some advantage. There have been numerous plans for their employment.

Joseph Smith patented in Great Britain in 1802 a fire-alarm set in motion by the burning of a string. In another device for the same purpose all the apartments of a building were connected with a single one by means of tubes. It was expected that the occurrence of a fire in any apartment would send a current of air through the corresponding tube, and thus make it manifest. Still another device employed the rupture of a brass wire softened by mercury, brought into contact with it by expansion to start a train of wheels, and thus ring a bell. In what is known as Tunnicliffe's invention a small cylinder of gunpowder is furnished with a fuse igniting at 200° F., the device being hung to the ceiling of the room and the explosion sounding the alarm. In 1872 F. F. Herman combined with an alarm a gun-cotton cord connecting with the wick of a lamp, to light the latter when the alarm was started. In 1873 William A. Barnes patented an alleged improvement in alarm cartridges, acting on the same plan as Tunnicliffe's, but not so liable to fly into dangerous fragments when exploded. Also in 1873 Henry L. Brown patented a contrivance which the Patent Office brief describes as follows: "The detent lever of a wound-up alarm-bell mechanism is connected with the arm of an inflated bellows or air-chamber, which is in air-tight communication with a tube of fusible metal running through the rooms to be protected. On the melting of the closed tube by a fire at any point, the escape of air collapses the air-chamber and the alarm is sounded." This *modus operandi* is reversed in the contrivance patented in the same year by Charles H. Lehnis, consisting of one or more U-shaped tubes containing mercury, one arm being in connection with a closed and exhausted fusible tube extending to the locality to be guarded. In Dion's mechanical application of his funnel thermometric device the balanced lever was made hollow, and a sphere of some heavy substance was placed therein above or near the point. On the tilting of the lever by the upward movement of the funnel the ball rolled out against the detent of a bell-sounding device, and thence into the mouth of an inclined tube that conducted it to a receiver in the office of a hotel, for which class of buildings the apparatus was more especially designed, the balls being marked with the numbers of the rooms.

The subject of automatic fire-alarms has received much attention from inventors, and numerous improvements calculated to extend their application, or to remedy real or apparent defects, have been secured. In 1881 was patented an ingenious combined fire-alarm and gas-lighting mechanism. In the same year Peter H. Van der Weyde patented the combination "with a pneumatic fire-alarm tube of a plunger retained by a piece or plate of fusible alloy, which by its melting will cause the plunger to be propelled by a weight or spring and act upon a diaphragm bellows or on an air-pump, and operate the signal." In the same year another inventor patented an apparatus in which the alarm is given by a horn or trumpet adapted to be operated by a blast of air, this used in connection with a source of supply of compressed air, a suitable valve, and means for operating the device from a distance. In 1892 twenty-four patents relating to fire-alarms were issued in the U. S. Among the patents hitherto issued have been combined electric fire-alarms and call-bells, combined fire-alarms and extinguishers, combined fire and burglar alarms, a combined fire-alarm and time-detector, combined fire and police alarms, a combined fire and telephone telegraph system, and an apparatus for testing fire-alarms and an apparatus for preventing false alarms. The patents of course include fire-alarm devices of the several classes already designated, and comprise a wide variety in structure and method of operation. One of the inventions in this field (patented Aug. 8, 1893) comprises the combination with the gas pipes containing illuminating gas in a building of—with other mechanism—pressure-inducing devices, which are normally inert until heated in such a manner that the gas becomes the medium for actuating the alarm by transmission of impulses imparted by such devices.

The importance of automatic fire-alarm apparatus is but beginning to be adequately appreciated. Contrivances operating on similar principles are capable of being successfully applied to many other purposes; as, for example, the detection of "heating" in grain-bins, and for the maintenance of desired temperature in various industrial operations.
JAMES A. WHITNEY.

Fire-armor: appliances designed to protect the respiratory organs against smoke, heat, gases, etc. The idea of fire-armor was naturally derived from that of submarine armor, and the first apparatus of the kind was adapted for either use. The U. S. patent of W. H. James, granted in 1828, describes a diving-dress which the inventor stated could be employed "in mines and other places filled with deleterious gases, wherein it may be used with perfect safety and very great advantage." In this apparatus air was supplied from a receiver placed around the waist to a helmet which inclosed the face of the wearer. Suitable devices were provided by conducting the air to the mouth and for preventing too great pressure from the air compressed in the receiver. It was calculated that an apparatus within a manageable compass could be made to hold air enough to last one hour, but to do this a pressure of 15 atmospheres, or about 225 lb. to the sq. inch, was required. This, together with the somewhat cumbrous character of the apparatus, seems to have led to its abandonment. The simpler apparatus of M. Galibert (see p. 344 of Dr. Barnard's *Rep. Paris Exp.*, 1867) has an air-receiver of india-rubber cloth, from which the air passes by a tube to the mouth of the wearer, the expired air passing out through a valvular device attached to the nostrils. A somewhat similar appliance has been used in England, the air being in this case contained in a sheet-metal cylinder strapped to the back like a fire-extinguisher.

Eye and lung protector.

After the James device just described a British miner named Roberts designed a "hood and mouthpiece," which attracted considerable attention, and, as a writer of that time avers, "its efficacy was repeatedly proved in the presence of numerous scientific individuals, amid the most dense smoke arising from the combustion of wool, wet hay, straw, shavings, and large quantities of sulphur, in temperatures varying from 90° to 240° F." It differed somewhat in details of construction from those that had preceded it, but involved no material change of principle in its operation.

One apparatus brought out in New York city in 1873–74 was termed an "eye and lung protector," and comprised a mask of novel construction held over the face by an elastic band passing about the head. A duplex shell, formed of thin steel covered with india-rubber, fits over the eyes of the person using the device; the external edges of the rubber being flexible, and so shaped as to fit tight around the eyes to exclude dust, smoke, etc., from the eyes: while the eyeholes provided in the shell have flexible lips, with a groove between, which receive plates of transparent mica, a tight joint being formed between the mica and the rubber. Provision is thus made for the protection of the eyes, independent of the respiratory organs. To protect the latter the duplex shell is provided with a curtain of porous cloth, which, being gathered in at the bottom by means of a string around the neck of the wearer, forms a semi-elastic bag over the lower portion of the face. In this is placed a wet sponge of suitable size and shape, held by the bag against the mouth and nostrils. The wearer breathes through the moist sponge, which eliminates from the air passing through it the dust, noxious gases, foul odors, etc., with which it may be impregnated, and also cools the air during such passage. This contrivance has been used on several occasions very effectively.

In San Francisco, on July 28, 1874, a small room was filled with smoke of "pulo" and tobacco until daylight could not be seen through the glass doors; four men provided with the "protector" remained in this atmosphere during more than half an hour without inconvenience. On Aug. 6, 1874, at a trial at Toronto, Canada, persons remained for twenty-three minutes in an atmosphere of smoke from damp straw and tobacco-stalks, in which the chief of the city fire brigade found it impossible to remain more than one minute without the protector. The necessity of wetting the air-filtering material on each occasion when desired for use could perhaps be obviated by some hygroscopic treatment of the sponge; for this purpose glycerin or some other neutral absorbent of moisture probably would prove efficacious.

A dust-muzzle or respirator is used where grain handled in large quantities in loading vessels from elevators or warehouses gives off clouds of almost impalpable dust. It comprises a metallic chamber shaped at its inner end to fit the mouth and nostrils and with its outer end provided with perforations which admit the air, and from which it passes to the respiratory organs through a filtering material placed within the chamber. The device is held in place when in use by a band which passes over the head of the wearer. The addition of a covering for the upper part of the face would make this device a cheap and simple fire-mask.

In 1888 an improvement in supplying a fireman's mask with fresh air comprised an air-pipe carried along the hose of the engine to the fireman holding the hose-nozzle. In another apparatus, patented in 1889, provision is made for breathing at will direct from the atmosphere, or through a suitable filter, or from an air-supply pipe suitably arranged. Another, made public in 1893, contemplates an armor to be worn by a fireman, the armor supplied with air and having external pipes, each provided with a mask capable of being placed over the head of a person in a suffocating condition to renew respiration during transport to a place of safety.

JAMES A. WHITNEY.

Firearms: arms loading with powder and ball; all arms which expel their charge by the combustion of powder, whether cannon, such as guns, howitzers, mortars, or small-arms, such as muskets, rifles, pistols, and fowling-pieces. See ARTILLERY, CANNON, and SMALL-ARMS.

Fire-brick: brick made from very refractory clay and used for the lining of furnaces, stoves, grates, etc. As they are largely consumed in iron-making, the manufacture is an important branch of industry which has been carefully perfected by experience, and is now largely carried on at certain localities where the somewhat rare materials used for the purpose are most easily attainable. Fire-brick are usually made from FIRE-CLAY (*q. v.*), but other materials are used in their manufacture; as, for example, the "Dinas brick," the fire-brick most esteemed in Wales, is made of pulverized quartzose rock cemented with a little lime. In the U. S. the best fire-brick are made from the "Amboy clay" (a cretaceous clay found in New Jersey) and from the fire-clays of the coal measures of Pennsylvania, Ohio, Illinois, and Missouri. In the manufacture of fire-brick both plastic and non-plastic clays are employed. In the use of a plastic clay like that of New Jersey this is first burned in a kiln, losing its plasticity by the process, and becoming what is known as "cement." This is then coarsely ground, mixed with from one-sixth to one-tenth of plastic clay, molded, and burned. The Mt. Savage fire-brick are made at Mt. Savage, Md., from two varieties of carboniferous fire-clay; one of which is non-plastic, in its natural state has the properties of the "cement" before mentioned, and is treated in the same way. The Mt. Savage brick are of great excellence—being equally esteemed with the Amboy brick—and are extensively used throughout the U. S. At Mineral Point, Tuscarawas co., O., a non-plastic clay is found similar in appearance and properties to that used at Mt. Savage. It is here manufactured in the same way, and the brick made from it are scarcely inferior to those before mentioned. In all factories of fire-brick the refuse of the kilns is ground over and cemented with a little fresh plastic clay, and in this way brick are manufactured which have great power to resist fire. From their mode of manufacture the most refractory fire-brick are necessarily tender and have little power to resist mechanical strain or violence. They are therefore employed only for the central portions of furnaces, where they are exposed to the greatest heat. Higher up in the blast furnace and near the doors of puddling furnaces brick of greater strength and less resistance to fire are used. These are made in large part of plastic clay, to which more or less sand is added. In the various parts of the different kinds of furnaces used in smelting operations brick of different shapes and qualities are required; hence at all factories may be seen bricks of various forms and sizes, and those in which the materials are differently mixed. As all iron furnaces frequently require to be relined with fire-brick, the impression generally prevails that they are rapidly destroyed by the action of the heat. This, however, is not true, as the best fire-brick are infusible by ordinary means. The rapid destruction of fire-brick which takes place in a furnace is for the most part due to the union of the iron with the silica of the brick, forming a fusible slag; in this way the brick are eaten or dissolved away. In the selection of clay for fire-brick it is important that it should contain as little iron, lime, soda, potash, etc., as possible, as these readily combine with the silica, forming fusible silicates. The price of the best fire-brick in the U. S. varies from $35 to $60 per 1,000 at the kiln, and these are made at comparatively few localities. Cheaper brick, and those of somewhat inferior quality and yet adapted to most purposes for which fire-brick are used, are or may be manufactured at a thousand different localities; wherever, indeed, a reasonably good fire-clay can be obtained. See BRICK.

J. S. NEWBERRY.

Fire-clay: the name specifically applied to the beds of clay which underlie most of the coal-seams in the Carboniferous strata. They are so called because as a class they are very resistant to the action of fire. These clay-beds are fine sediments which accumulated at the bottom of shallow pools of water, subsequently filled up by growing vegetation. The roots of aquatic plants penetrating this clay have generally abstracted its potash, soda, lime, iron, etc., and have removed such a percentage of silica as to leave it with a larger relative quantity of alumina than it had before being subjected to their action. Thus they have taken from it its more fusible ingredients, and have imparted to it the peculiar property it possesses of remaining unchanged at a high heat. Clays very like fire-clays are found underlying many beds of peat, and in such circumstances the formation of fire-clay may be seen going on.

In the U. S. there are two varieties of fire-clay—the one non-plastic, and specially adapted to the manufacture of fire-brick; and the other plastic, and used also for fire-brick, and for pottery, glass-pots, etc. In the first class are the clays of Mt. Savage, Md., Mineral Point and New Lisbon, O., and from these large quantities of superior fire-brick are made. The second class includes most of the fire-clays of the coal measures. These differ much among themselves as regards purity and excellence, but they are very largely employed for the manufacture of stoneware and second-quality fire-brick. Analyses are given below of some of the best and best-known fire-clays, Nos. 2 and 3 being non-plastic and Nos. 4 and 5 plastic clays:

ANALYSES OF FIRE-CLAYS.

SUBSTANCES.	No. 1.	No. 2.	No. 3.	No. 4.	No. 5.
Water	17·34	12·74	11·70	5·34	5·45

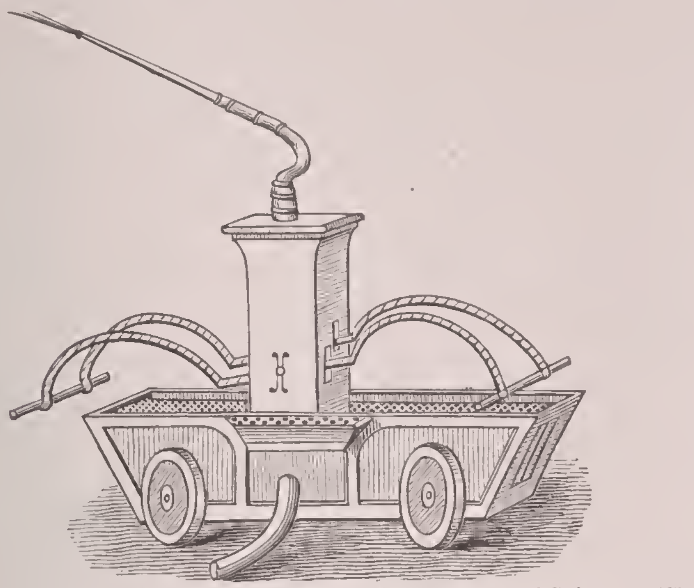
J. S. NEWBERRY.

Fire-damp: See MARSH-GAS.

Fire-eater: a term the invention of which is ascribed to Col. Howell Rose, of Coosa co., Ala., who in the Southern Rights convention at Montgomery co., Ala., in 1851, applied this epithet to the avowed Disunionists of that body. The term was afterward applied in political parlance to extremists among the Southern Rights men, whether Disunionists or not.

Fire-engines: machines for extinguishing fire. The earliest fire-engines were huge squirts or syringes mounted upon wheels. These are known to have been used in Augsburg as early as 1618. The transition from the squirt to the pump on wheels initiated the fire-engine. The improvement of the pump was a matter easily reached, but by slow stages, and by the middle of the eighteenth century the fire-engine embodied a practically valuable, though mechanically crude, machine, such as is shown in the Newsham engine. Two of these were taken to New York in 1732, and were doubtless the first in use in the U. S. Floating fire-engines with rotary pumps were in use in England before the close of the eighteenth century. Floating steam fire-engines were proposed by an English writer in 1834, and in

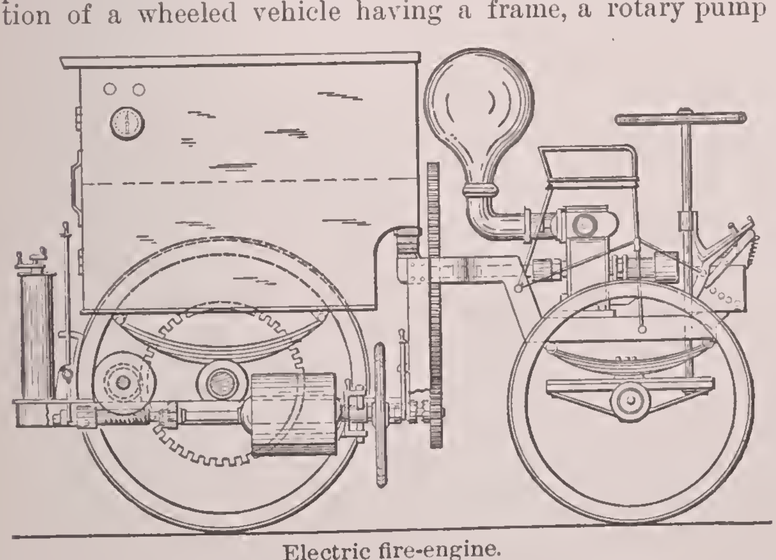


Newsham's fire-engine. From a dictionary of Arts and Sciences, 1754.

1850 a pump was placed upon a propeller and geared with the engine. It threw 600 gal. per minute to a height greater than any of the buildings on the East India Docks, London. The utility of steam-power for the purpose in land engines had been demonstrated eleven years before by Braithwaite and Ericsson, but these engines met with less favor than they deserved. The first steam fire-engines in the U. S. were made in 1840, although the earliest American patent on improvements was that of A. B. Latta, of Cincinnati, O., May 22, 1855. Self-propelling steam fire-engines have been constructed at various times, but thus far experience has approved the use of horses for the transfer of engines from place to place in the exigencies of practical use.

The improvement of manually operated fire-engines had, however, early attracted attention in the U. S. The earliest American patents relating to the art were those of J. Kersey, Apr. 13, 1797; S. E. Hamlin, Aug. 30, 1799; and S. E. Steward, Dec. 6, 1803. With the destruction of the Patent Office by fire in 1836 knowledge of the structure or character of the inventions of these patentees perished, and a like remark applies to the improvements covered by patents, of which there was one in 1807, three in 1812, one in 1813, and others in subsequent years. Successive improvements, fitting the machine for all the vicissitudes of use in large cities, have made the steam fire-engines used in the U. S. the best examples of their class in the world.

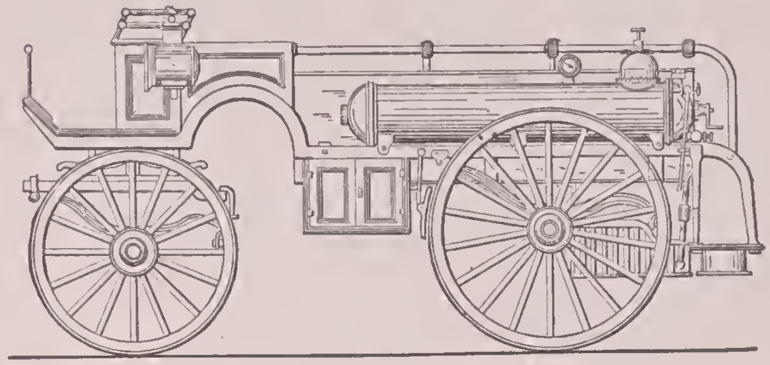
The great development of electricity as applied to the arts has led to its proposed use for the propulsion of fire-engines. The accompanying cut illustrates an engine embracing the principle indicated. It was patented Dec., 1891. It comprises in its construction among other things the "combination of a wheeled vehicle having a frame, a rotary pump



Electric fire-engine.

fixed upon the front part of the frame and having its driving-shaft extending lengthwise of the vehicle, an electric motor supported upon the vehicle nearer the rear axle, means to connect said motor either with the wheels of the vehicle to propel the same or with the pump, as desired," the engine being thus self-propelling and the motor used for propulsion serving also to throw the water-jet through the hose.

Another invention, patented on the same date, relates to chemical fire-engines so called (see FIRE-EXTINGUISHERS), and has for its object due provision for carrying hose, so as



Combined chemical fire-engine and hose cart.

to dispense with a separate hose-wagon, and also the convenient placing and support of the tanks which contain the extinguishing agents. The hose for the chemical tanks is carried in the depressed baskets suspended at the rear. The chemical tanks are of cylindrical form and are placed longitudinally one at each side of the frame, and between them is a receptacle for the desired quantity of water-hose.

JAMES A. WHITNEY.

Fire-escapes: devices to facilitate the escape of persons from burning buildings. The common fire-escape is simply a system of fixed iron ladders attached to a building to permit descent from the upper windows, ordinarily with a platform or balcony provided for each story. Scores of complex machines intended for use as fire-escapes have been projected, but reliance is still had by firemen upon sectional ladders manipulated at a great disadvantage by hand. These were in use previous to A. D. 385, as also were flexible ladders with hooks at the ends, which were thrown to catch upon walls and window-sills. Telescopic tubes raised perpendicularly from a base-frame by means of a screw, and carrying a basket large enough to hold several persons, also lazy-tongs, or jointed superposed bars lifting a platform, were also known at that date. Both of these principles of operation are embraced in numerous fire-escape apparatus projected in recent times.

Apart from fixed ladders attached to the building, and the sectional ladders of the hook-and-ladder companies, fire-escapes may be classified as of six varieties. Of the first class, one of the most efficient was brought forward about the middle of the nineteenth century and was known as the "sling" fire-escape. It comprised a rope passed over a sheave temporarily hooked to the window-sill, the rope being furnished at one end with a sling or loop serving the purpose of a seat, and also with a belt passing around the waist; the opposite portion of the rope being grasped by the hand, and slowly paid out until the person was let gently to the ground. The same principle has been reapplied with various additions and modifications. In the second class a number of ladders lie flat upon a vehicle during transport from place to place, and when required for use are lifted to a nearly vertical position, and then moved out longitudinally, one from the other, until their utmost limit is reached. In the third class the apparatus comprises a strong sail-cloth tube distended by a hoop at the upper end, attached to a window, the diameter of the tube being such that a person sliding down could regulate his speed by passing his elbows outward against the sides. The tube should be stretched from the window to the front at an angle of 45°. That it provides for the safe descent of persons from a great height without danger has been often demonstrated by experimental trials; among others, by one in the neighborhood of the city hall in New York in 1869. Another apparatus is constructed with a telescopic tube to be elevated from the sidewalk, and formed at its lower end with a curved outlet to gradually check the rapidity of the descent. The fourth or lazy-tong system is open to the apparent objection of being somewhat complicated, but its practical operation dates from the fourth century, when the plan was employed for raising soldiers to the tops of walls. The "lazy-tongs" have been actuated by various combinations of screws, gearing, etc. A tolerably efficient device of the fifth class was proposed, and to a slight extent adopted, in England in the beginning of the nineteenth century. It consisted of a strong pole of from 36 to 40 feet in length, surmounted by an iron cross-bar designed to rest against the side of the building and to keep the pole from turning. About 3 feet from its upper extremity the pole carried a pulley, over which was a rope having at one end a basket, the rope being worked from the pavement to raise and lower the basket. The rope, pulley, and basket have been frequently combined with a ladder, the last taking the place of the pole previously described. The most useful example of the sixth class is the fire-escape of Ranald Macdonald, of Brooklyn, N. Y., in which thin wire ropes are joined by rounds formed of gas-pipe, thus forming a flexible ladder which is wound on a portable reel when not in use, but which may be readily extended from an upper window in case of emergency.

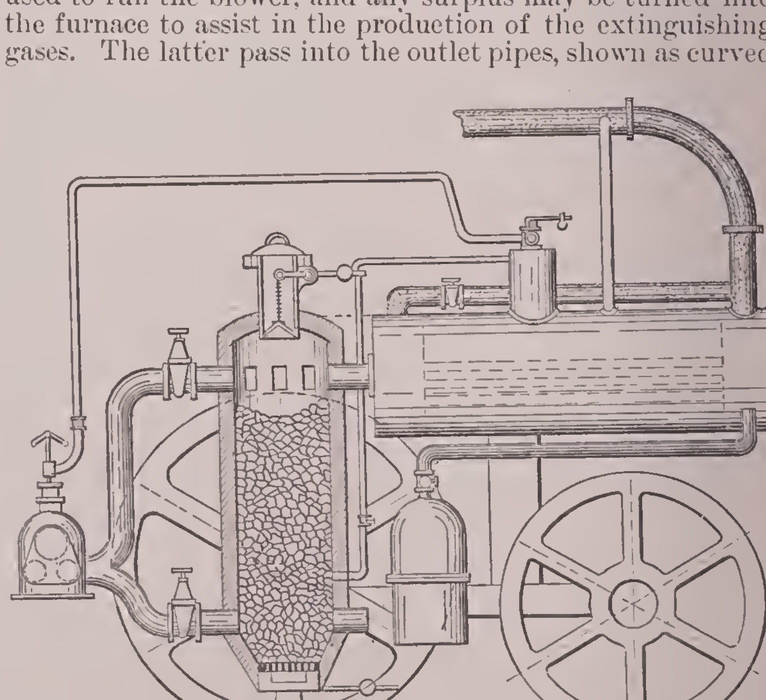
A fire-escape apparatus preferably should be a fixture of the building and so arranged as to permit the rescue of persons from the dwelling as well as to permit their voluntary escape. An apparatus invented by Dr. Abraham W. Lozier, of New York city, and patented in 1884, has been carefully designed to meet these conditions. A fixed ladder is surrounded by a protecting case which can be opened from the street, an alarm being automatically sounded within the building when the case is thus opened. It may also be opened from within to afford access to the ladder to the occupants of the building, the ladder being arranged in convenient relation with a window platform. Interest in the subject appears to be greatly on the increase with inventors. During the years 1888–1892 inclusive no less than 333 U. S. patents were granted on fire-escapes. JAMES A. WHITNEY.

Fire-extinguishers: apparatus for extinguishing fires either by means of water or by non-combustible gases. The term technically considered excludes fire-engines, although the principle of operation may be similar in both.

The original fire-extinguisher, in the sense in which the term is now generally used and understood, was the invention of William A. Graham, of Lexington, Va., who filed his applications for a patent in Nov., 1837. The patent was issued more than forty years later, in July, 1878, and its validity was sustained in a Federal decision six years after. Among other things Graham claimed as his invention "the method of extinguishing fires by means of a properly directed stream of mingled carbonic acid gas and water projected by the pressure or expansive force of the mingled mass from which the stream is derived"; also "the combination of fixed pipes or tubes arranged by or through a building with a stationary or fixed fountain or tank, for forcing mingled carbonic acid gas and water by its own elasticity through said pipes"; also "the combination of a strong vessel for containing the mixture of carbonic acid gas and water under pressure, with a stop-cock, flexible hose-tube, and a nozzle." The carbonic acid gas was compressed in the liquid either by artificial pressure or by generation therein. Graham claimed to be the discoverer of the fact that "carbonic acid gas compressed in water in the proportion of ten or more volumes of gas to one of water, in portable fountains or fixed reservoirs, could be usefully applied to extinguishing fires"; and that he had "devised suitable apparatus by which a stream of gaseous water, by the elastic force of the gas, would be projected a distance of 40 feet, so as to quickly, cheaply, and effectually subdue the fire." Graham died in 1857 after twenty years of vain endeavor to convince the Patent Office of the patentability of his invention. Twelve years later certain foreign inventors, who probably had no knowledge of Graham's invention, received a U. S. patent embracing its principle, but were unable to carry back the date of their discovery of it beyond 1861, whereas it was shown that Graham, aside from his application for a patent in 1837, had successfully made and used an apparatus embodying the discovery as early as 1853. This appeared in long subsequent litigation. In 1876 the administrators of Graham filed a new application for a patent, which was rejected on the ground of delay and long public use. On June 14, 1878, an act of Congress was passed which revised the original application of forty-one years before, and upon this the patent was finally issued. Drawings which accompany his patent specification show the mechanical structure of the apparatus to have been somewhat crude, but Graham appears to have been beyond question the originator of that class of fire-extinguishers which depend for their operation upon the combined use under pressure of carbonic acid and water. In 1851 what was known as the Philips fire "annihilator" was tested with experimental success. Its operation depended upon the chemical evolution of certain non-combustible gases in connection with the vapor of water.

Among the various modifications of, and practical improvements upon, the Graham extinguisher was the employment in 1867 of a sealed glass vessel to hold the acid, which is fractured on occasion by suitable mechanical devices; also the use (in 1870) of one or more perforated plates, partitions, or diaphragms arranged within a portable fire-extinguisher and below the acid vessel, to distribute the acid through the alkaline solution previously provided therein, to facilitate the chemical action, and to prevent the accumulation of the acid at the bottom of the vessel. Previous to this, in 1868, an apparatus was made that when used was inverted, having the effect of mixing dry acid on a foraminous internal shelf with the water already charged with the opposite material, thus producing and charging the water with carbonic acid gas, which, upon the opening of the cock, forcibly discharged the water from the vessel." In an apparatus patented in 1888 a charge of peculiar composition is placed in the upper part of the closed chamber containing the liquid, and being ignited produces a gas which, accumulating until a high pressure was reached, remains to exert a constant pressure upon the water. The apparatus is kept continually under pressure, and in this respect acts mechanically, upon the same principle as that of the first fire-extinguisher ever made, the compressed gas in the one case being simply an equivalent for the compressed air in the other. The Babcock extinguisher is filled with a solution of bicarbonate of soda, and has in its upper part a vessel of acid suspended by lateral pivots to a stirrup depending from the top of the apparatus. The stopper of this vessel is worked by a rod through the top of the extinguisher. By withdrawing the stopper the vessel tilts over, and mingles the acid with the solution, thereby discharging the carbonic acid from the latter. An improved method of generating gas in fire-extinguishers, patented in 1890, consists in first mixing hydric sulphate with a solution of sulphite of soda or other sulphite, and then throwing the mixture into a solution of a carbonate contained in the main vessel of the extinguisher.

As carbonic acid at ordinary temperatures is heavier than air, and much heavier than air heated by conflagration, it has been contended that the extinguishing agent tends to descend through the burning material before fully accomplishing its purpose. To meet this difficulty an elaborate apparatus operating with heated extinguishing gases was patented in 1888. In this a furnace is so combined with a blower and air-conducting pipe that air for the combustion of the fuel is found below the latter to provide for its conversion into carbonic oxide, and above the fuel to convert this oxide into carbonic acid. The latter passes into the flues of a steam-boiler, shown horizontally at the right of the figure, and generates steam in the boiler. The steam is used to run the blower, and any surplus may be turned into the furnace to assist in the production of the extinguishing gases. The latter pass into the outlet pipes, shown as curved

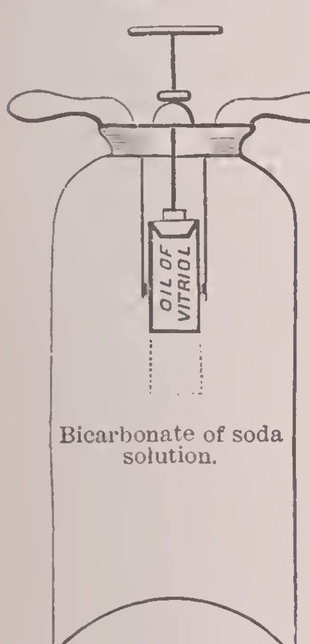


Fire-extinguisher using hot gases.

in the figure, from which they are passed to the fire to be subdued. A supplemental carbonic acid reservoir is so arranged that its contents may pass to and mingle with the extinguishing gases from the furnace, there being sufficient heat to expand the carbonic acid to the requisite relative degree of lightness. The apparatus is intended to be supported upon a suitable wheeled frame, so as to be readily transported from place to place.

Numerous accidents have occurred on railways resulting in the burning of the wrecked cars from fire communicated from the heating stoves. To provide against this various plans for automatically extinguishing the fire in the stove in the event of derailment or collision have been devised. In one of these, patented in 1888, a reservoir filled with water or other extinguishing agent is so suspended that it retains its normal vertical position when its supporting frame or casing is tilted. In the upsetting or wreck of a car the change from a vertical to an inclined position on the part of the frame produces a corresponding change in the relative positions of the reservoir and the casing. This, through suitable mechanism, is caused to actuate a valve which opens the reservoir, and through a suitable connecting pipe causes the water or other extinguishing material to be directed into the fire-box of the stove to extinguish the fire therein.

The transition from a fire-extinguisher small enough to be carried on the back to one sufficiently large to require wheels was easy and natural, and under the name of chemical fire-engines these latter have been put in practice, with a measure of success. Among the alleged improvements is one (1869) in which there is arranged upon a truck or carriage "two or more cylinders or reservoirs, connected by pipes which are controlled by stop-cocks, and which connect with an issue-pipe or nozzle common to all the pipes, so that in extinguishing a fire one reservoir may be re-supplied while another is being exhausted, and thus a continuous supply and stream be kept up and thrown upon the fire." Another apparatus, produced a year or two previous, was constructed with a chamber, in the upper part of which was placed the gas-generating material, determinate portions of this latter being brought automatically from the chamber and mingled with the stream of water ejected by a forcing pump. In another a stream of carbonic acid gas from a separate receptacle was caused to mingle with the jet issuing from an ordinary fire-engine. Grenades or bombs, so called, filled with suitable fire-extinguishing substances and designed to be thrown by the hand, and to fracture on falling in the fire, have been made, and are claimed to operate with success.



Babcock's fire-extinguisher.

Numerous methods have been proposed for insuring the automatic action of fire-extinguishing apparatus through the inevitable increase of temperature. Pipes extending from a central reservoir charged with water or extinguishing gases, and provided with fusible plugs or actuated by a thermostat, have been largely and successfully introduced of late years. JAMES A. WHITNEY.

Fireflies: nocturnally luminous coleopterous insects of the families *Lampyridæ* and *Elateridæ*, the former including the glowworms. According to some writers, some of the *Fulgoridæ*, which are hemipterous insects, are luminous also, but the weight of the evidence is quite to the contrary. The luminous organs of fireflies and glowworms are composed of yellow masses of cells filled with granular matter and traversed by many tracheæ. It is now generally held that the light is produced by the slow combustion of granular and perhaps fatty matter, oxygen being abundantly supplied by the tracheæ. Phosphorus does not appear to be present in any noteworthy amount in the luminous matter. Spectroscopic examination of the light of insects of both families gives a very beautiful continuous spectrum without lines. The fireflies of Central and South America are chiefly *Elateridæ* of the genus *Pyrophorus*. They generally give a very intense light, which comes from two spots on the prothorax. The U. S. have some *Elateridæ* with luminous larvæ (*Melanectes*). The common "lightning-bugs" of the U. S. are of numerous species, all *Lampyridæ*, and mostly of the genera *Photinus* and *Photuris*. *Photuris pennsylvanica* is the most common. Both sexes are winged. *Photinus* is distinguished from the old genus *Lampyris* by the females being winged. See GLOWWORM.

Fire-hole River: a river of Wyoming; the main fork of Madison river; flows from Madison Lake, a sheet of water of some 60 acres area, N. W. through the Fire-hole Basin, one of the most remarkable geyser regions of the National Park. See YELLOWSTONE NATIONAL PARK.

Fire Island Beach: a low, sandy spit of land broken by a few inlets; separates the Great South Bay of Long Island from the Atlantic. It is some 30 miles in length, and belongs to the township of Brookhaven, Suffolk co., N. Y. At its western extremity is Fire island inlet and a lighthouse of brick 166 feet high, with a flashing light of the first order; lat. 40° 37′ 54″ N., lon. 73° 12′ 48″ W.

Fire-insurance: a form of business enterprise in which for a consideration called a premium, and under suitable conditions, compensation to a specified extent is guaranteed to property-holders for loss arising from fire. Like other kinds of insurance, it is the bearing of the losses of the few by the contributions of the many. If this is done simply by and among the members of an organization the plan is called mutual; if it is done by a corporation issuing its policies to applicants who pay an agreed premium and shift the hazard over upon the company it is called joint stock. The practice of fire-insurance is modern. Marine insurance preceded fire by at least two centuries, and apparently it was not until 1609 that fire-insurance was established, when a scheme was suggested in Germany for insuring the houses of subjects by the Government. Count Anthony von Oldenburgh, to whom the plan was presented, admitted its merit, but feared if he engaged in it that Providence might be tempted, his people displeased, and himself accused of avarice. As Walford, the historian of insurance, remarks, "but for this superstitious fear the Germans might have claimed the credit of laying the foundation of the present system of fire-insurance." There does not appear to be any public record of definite action in regard to fire-insurance until the year 1681, when on Oct. 15 an English insurance fund was formed by act of the corporation of London; but the first regular fire-insurance office was not started until 1696, thirty years after the great London fire. The name of the company was the Amicable Contribution. This name was changed in 1718 to the Hand-in-Hand. This was a mutual company and is still in existence. Thus fire-insurance existed in England for seventy years before it first developed in organized form in North America. To some extent it was practiced through agencies or individuals prior to 1752; but on Apr. 13 in that year the subscribers to the first American insurance scheme met in the court-house in Philadelphia and elected twelve directors, Benjamin Franklin's name standing at the head of the list. This was the Philadelphia Contributionship, and the company is still extant. From this small beginning has grown a volume of business as startling in its magnitude as it is important and beneficent in its reach. The amount covered in 1893 by fire-insurance in the U. S. is approximately ten times as great as was the entire property valuation of the country when the first company was organized, the fire-policies extant covering $24,000,000,000! Early figures are not available, but the more recent development of fire-insurance in the U. S. is indicated by the following table:

YEARS.	Property valuations in the U. S.	Amounts insured.	Percentages insured.
1860	$16,159,616,068	$1,681,255,609	10·41
1870	30,068,518,507	5,044,884,495	16·78
1880	43,642,000,000	9,132,162,479	20·90
1890	62,610,000,000	19,091,231,250	30·41

Thus in thirty years fire-insurance in the U. S. multiplied more than eleven times, while property multiplied less than four times. The *amount* of the increase is not so very astonishing when it is remembered that every industry in the U. S. enlarges phenomenally, but the *ratio* of increase or the values to be insured is illustrative of the vigor and industry with which the business has been prosecuted. If one-half of the above valuations represents land and other incombustible properties or improvements, then two-thirds of the burnable property of the U. S. is protected by insurance, a fact which throws an important light on the business possibilities of the present era through the protection of credits and the enlargement of enterprises which would be impracticable but for the re-enforcement which insurance affords. This is of universal application wherever insurance is generally practiced.

According to the best information obtainable there are (1893) over 600 companies prosecuting fire-insurance in the U. S., as follows:

U. S. joint-stock fire-insurance companies	338
U. S. mutual fire-insurance companies	212
U. S. marine insurance companies	14
Foreign marine insurance companies	12
Foreign fire-insurance companies	41
Total	617

The marine companies do but little fire-insurance, and the mutuals (except the factory mutuals) confine their operations mainly to the insurance of farm and village risks. The great bulk of the business is covered by those known as the "agency companies"—the domestic joint-stock and the foreign fire companies.

The Agency System.—When offices were few and confined mainly to the seaboard, inland towns and cities were without facilities for insurance except as they were obtained through correspondence. Gradually agencies were planted in the hands of merchants and bankers, but the rapid spread of the business, as tabulated above, soon drew to it men who made insurance their vocation, and in due time the entire country became covered with a network of agencies, until there are not less than 50,000 persons now engaged in the various branches of the agency business in the U. S. Some of the larger companies employ 3,000 agents each, and many of them 500 or more. The local agent, a resident of the town where domiciled, is a sort of resident autocrat. In the larger places he employs solicitors and sub-agents, and has an office with clerks and assistants. Next to the local agent comes the special agent. He is a trusted representative of the company, selected for his knowledge of the country and his professional skill. He establishes new agencies, stimulates old ones, and supervises the business generally in his district. Next to and above the special is the manager. Most of the agency companies sustain at least four departments—Eastern, Western, Southern, and Pacific coast—and often more, and over each of these a manager is appointed who is an experienced underwriter and competent to oversee several States, occupied perhaps by several hundred local agents.

The adjuster is an important figure on the company's staff. There are in the U. S. between 20,000 and 25,000 fires annually, large and small, involving an insurance loss each year of from $60,000,000 to $70,000,000. The settlement of these losses has called into existence a profession of great importance, and the adjusters are, as a rule, not only professional experts in their particular line but men of more than ordinary sagacity, business knowledge, and general ability. The incentives to fraud growing out of the easy obtaining of large lines of insurance and the comparative ease with which the crime of arson may be concealed have led to numerous incendiary fires, and the companies have been compelled to defend themselves by the employment of sharp adjusters, the offering of rewards for the detection of incendiaries, the use of bureaus for the interchange of reports concerning dishonest men, the employment of detectives, and other means of a similar nature. All these expenses, which add materially to the cost of insurance, grow out of what is familiarly known as

Moral Hazard.—There are two hazards in an insurance risk, the physical and the moral, both of which are prominently considered in determining upon its acceptance or rejection. The physical hazard includes the natural causes of fire, the combustibility of the risk itself growing out of its construction, occupancy, and exposure to other risks. For all this class of hazards reasonable estimates of the proper premium to be charged can be made; but for the moral hazard, which includes the dishonesty of owners and employees, the jealousy of rivals, the revenge of enemies, and all like causes, no price can be named, and where a risk is known or suspected to be tainted in this regard it is promptly declined by intelligent underwriters. In 1891 there were in the U. S. 2,602 fires attributed to incendiarism, with 1,956 exposed risks burned by the incendiary fires. These 4,558 cases involved an aggregate loss of $15,020,747, with insurances of $8,348,157.

Factory Mutuals.—What is known as the factory mutual system originated in Rhode Island about 1840, and grew out of dissatisfaction with the high rates charged for textile factories and other manufacturing risks which were regarded as excessively hazardous. A mutual insurance company was organized, which was soon followed by others in Rhode Island and Massachusetts. The prime object of these organizations has been not so much the payment of losses as the prevention of losses. To this end buildings accepted must come up to a certain standard, popularly known as "Mill Construction and Sprinkler Equipment." While these companies are important factors in the region where they work and among the classes of risks which they cover, their operations are necessarily very limited as compared with the whole field of fire-insurance. The total risks now covered by them do not exceed $650,000,000, mainly within the area of New England and the Middle States. Efforts have been made in the Western States to establish factory mutuals, but the frequency of manufacturing risks and the organized effort prevailing in New England being absent, these efforts have not been to any considerable extent successful.

Fire-insurance Lloyds.—A recent phase of fire-insurance in the U. S. is the "Lloyds plan," so called. It differs from the marine practice of individual underwriting, so familiar in Great Britain, and is partly the outgrowth of an existing dearth of large insurances and partly of a desire to avoid the onerous taxation laid upon corporations. Subscribers, usually a hundred or more, contribute a sum of $1,000 to $5,000 each, and appoint a representative whom they designate as an attorney. This person is an insurance expert, and he manages the business much as an ordinary executive of a regular company would do.

Individual underwriters are very much the same as the Lloyds, except that they insure only for members. Each member subscribes $2,000 or more, and his liability on each other member's policy is *pro rata* with the several subscriptions. All these schemes are modifications of mutual plans. The last two mentioned are quite modern, and like other insurance projects will prove their fitness as they are tested by time and fire.

Insurance Legislation.—Insurance being a business of a beneficent nature whose function is to sustain the credit of the merchant, manufacturer, and shipper, and add to the business stability of the state, it would seem as if it ought to be approached with more than usual intelligence and should enjoy the fostering care of the legislatures; but, being carried on by corporations, it has been divorced from public sympathy and made the subject of hostile legislation to an extent not easily explained. In various States laws known as "Valued Policy Laws" have been enacted, compelling the companies to pay the full amount of a policy on a building, regardless of its value at the time of the fire. Other laws have been passed making it a misdemeanor for the companies to form boards or associate together for the establishment of rates. In some States the form of policy is dictated by statute. Many of them require large deposits, and in nearly all "retaliatory laws," so called, exist; and taxation of various forms is laid heavily on the companies in almost all the States; those which levy upon the gross premiums sometimes taxing in excess of the net income—the residue after paying losses and expenses. Official figures tabulated for ten years show that the taxation in one State amounted to 220 per cent. of the net; in three States it was over 100; in four over 60; in seven over 30; and in ten others it ran from 2 to 17 per cent. of the net income. There were, of course, individual companies that were more fortunate than others, but this was the result of the aggregate business.

Co-insurance.—In marine insurance practice a man insures as large or as small a proportion of his vessel or shipment as he chooses and carries his own risk on the remainder, bearing his proportion of losses, total or partial. But in fire the practice has prevailed of collecting the whole of a partial loss from the insurers, even though the owner has paid premiums on only a small fraction of the value. This has induced economical owners of good buildings to take out only as much insurance as would catch the probable losses, compelling the companies to pay in full the partial losses which the whole property produced, while the owner saved the expense of insuring the whole value. This, in turn, has constrained the insurers to adopt what is popularly known as the "co-insurance clause," usually a provision that the owner must be insured on, say, 80 per cent. of the value, or else stand as the co-insurer of any uncovered proportion up to the agreed proportion. Under this clause the companies pay in full on a total loss without regard to the proportion actually insured, but on partial losses the owner contributes with the others, if he has neglected to procure the required amount of insurance.

Fire Prevention.—Intimately connected with the occurrence of fire is the prevention of it; and none are more directly concerned than insurers in such cognate matters as water-supplies, fire departments, building laws, and fire limits, electric and automatic alarm systems, and salvage corps, or "insurance patrols," as they are called in many places. In some of the large cities of the U. S. the insurance companies maintain at their own expense a service whose special duty it is to protect and save goods. A "patrol" consists of a chief and a number of men who occupy premises not unlike a first-class engine-house, which is connected with the local system of fire-alarms and is equipped with horses and wagons to carry men, tarpaulin covers, and other apparatus. Each wagon has one or more chemical extinguishers, and the patrol runs to fires as a supplement to the fire department, where it protects goods from water damage by spreading covers, and otherwise saving property. Measures have been introduced in a number of the States looking to the extension of the duties of coroners by making a fire a casualty calling for the official examination of the coroner for the purpose of ascertaining its cause, and devising means for amending the building laws with a view to fire prevention.

Rating, Classification, Fire Maps.—To what extent fire-insurance is a science and what an art is a question not yet settled. There are those who hold that through a combined experience of the companies rates of premium can be fixed on a basis which would be more or less scientific; while others hold that although it is obvious that some hazards demand a higher rate than others, yet the only safe guide to a proper rate is individual inspection of each particular risk. Many of the companies classify their risks and keep an account with each class, but no effort has yet proved successful to bring the experiences of the different companies into combined form. Schedule rating is the nearest approach to a scientific basis for fixing premiums that has yet been attempted. This, in brief, is assuming a building for a standard which is as nearly perfect as may be in its fire-proof construction, and then making additional charges for each defect or departure from the standard. A comprehensive plan, known as the "Universal Mercantile Schedule," is (1893) attracting much attention among the companies. Fire maps or diagrams have been in use for a great many years. These are ground plans drawn to a scale with various symbols and colors to indicate the material of which each building is constructed, the location of fire-walls, the number of stories, the sort of roof and other things desirable for insurers to know in regard to the locality mapped.

Boards: National, Local, and Otherwise.—As early as 1845, soon after the second "great fire" in New York, an association was formed in that city under whose auspices the first national congress of fire underwriters was called in the following year to devise means to reform existing evils, to adopt bases of remunerative rates, and formulate rules of practice for the more harmonious conduct of the business. It was developed at these early meetings that the profits for the twenty years preceding had been less than 3 per cent. of the premiums, and the danger of continuing a business of such fluctuations as fire-insurance on so narrow a margin was evident. The next attempt of which there is any record was in 1849, when nine principal companies of New York and New England agreed upon a uniform tariff and rules for the government of their agents throughout the country. In 1850 this tariff was modified and so improved that it remained the standard of the U. S., so far as any standard was recognized, for a dozen years or more. Meantime the civil war, which began in 1861, brought confusion to insurance as well as other branches of business, and at the close of that conflict the rates had run down to the lowest recorded point, while the burning line had gone up to the highest recorded point. In 1865 the average rate obtained by the companies was only 74 cents per $100 insured, and losses the following year reached the unprecedented height of 81 cents. Expenses added to this heavy loss resulted in a state of affairs scarcely short of panic. Accordingly, a meeting was called on July 18, 1866, when fifty-seven New York companies and thirty-five from other States met and formed the famous National Board. While the call for this meeting was out, and just two weeks before it convened, a great fire occurred in Portland, Me., wherein $6,000,000 of losses were added to the already crushing burdens resting on the companies. It was life or death, and the utmost harmony prevailed in the meeting. An organization was formed having four objects: (1) the establishment of uniform rates; (2) the fixing of uniform commissions; (3) the repression of incendiarism; (4) the protection of common interests. To an executive committee was intrusted the principal work of the organization, and for two years it was the supreme factor in fire-insurance in the U. S.; but with returning prosperity came jealousies and malpractices, and as soon as that cohesion which seems to be dependent on adversity was relaxed the board fell into decay. The great conflagrations of Chicago and Boston in 1871–72, however, not only revived it but emphasized its necessity, and for several years after those notable conflagrations it controlled fire-insurance with imperial sway. The Chicago fire department yielded to its demands, and was remodeled at its dictation. The private judgment of companies was almost abandoned, and "board rules" were substituted. Company agents were disciplined by men who did not employ them, and numerous acts of arbitrary power finally brought on a reaction which resulted ultimately in a collapse. It still retains its organization, does duty as a bureau of statistics, and awaits the day in which it may again be useful to the companies. The National Board movement was not without fruit, for a number of powerful local associations have grown out of the sentiment and experience generated by that association. The New England Exchange in the Eastern States, the Western Union, centering at Chicago, the Southeastern Tariff Association, and the Pacific Insurance Union are the most notable examples. These all have the same general object of conservative practice over the agency field in regard to rates, rules, and practice. State boards exist also, working on the same lines, and local boards are very numerous.

Compacts.—A remarkable outgrowth of the widespread agency business of the U. S. is a comparatively recent expedient known as the "compact." Originally this was merely a voluntary arrangement among the agents, first at Kansas City in 1882 and afterward at other points. Later on it was taken up in the general interests of the companies, and compacts have been established at a great many important points. To the compact manager the local agents submit their daily transactions, and nothing can go forward to the companies until he has "stamped" it; his stamp indicating that the local requirements as to rate, form of policy, and otherwise have been complied with. Much has been done through the compact to make good practice not only uniform, but easy. A chapter of great interest to insurance men might be written concerning the details of planning and working a compact.

Societies, Journalism.—Germane to the organizations just mentioned, but separate from them and working on other lines, are the literary and semi-literary associations of fire-insurance men. The most notable of these are the Fire Underwriters' Association of the Northwest, the Underwriters' Association of the South, and the Fire Underwriters of the Pacific. These have annual meetings lasting two days or more, at which papers are read and discussions prosecuted which take high rank both for professional and literary excellence. Eminent scientists have lectured and the most notable men in the insurance world have delivered addresses before these associations, but the major part of their work comes from domestic talent which is stimulated by the honor of a public hearing and the publication of papers in the annual proceedings. Insurance journalism is no insignificant factor in the everyday work of insurance in the U. S., where class journalism has had such remarkable development during the last score of years. These journals are usually conducted with great independence, and are useful in spreading abroad among the agents and the companies the current discussions immediately affecting the practice of insurance, thus stimulating and warning in regard to the prevalent practices of the day. The insurance journal takes the place to a considerable extent of book literature in the craft, and furnishes the main supply of professional reading to its various members. Many books are published, however, particularly on the legal side of insurance, so that by reason of these several agencies fire-insurance is not by any means without a literature of its own.

State Departments.—These have been established by the governments of very many of the States, and, while they are usually managed by political incumbents, have had a marked influence upon the insurance business of the country. Between the examinations by the departments and the exposures by the journals, it has become well-nigh impossible for fraudulent insurance schemes to make much permanent headway. The annual statements required under oath from the officers of all the companies by these departments is in the same line and has the same tendency. The commissioners of the several States meet in annual convention for conference, and these gatherings are illuminated not only by discussions of members on current topics of insurance, but by the reading of papers by experts which are usually of a high order of merit.

LITERATURE.—Joseph K. Angell's *Law of Fire and Life Insurance* (Boston, 1855); *Insurance Law Journal* (22 vols., New York, 1870–93); Edmund H. Bennett's *Fire Insurance Cases* (5 vols., Boston, 1872–77); Charles J. Bunyon's *Law of Fire Insurance* (London, 1875); Ostrander's *Law of Fire Insurance* (Chicago, 1892); George A. Clement's *Digest of Fire Insurance Decisions* (New York, 1893); Walford's *Insurance Cyclopedia* (5 vols., London, 1876), and his *Fires and Fire Insurance* (London, 1877); *Insurance Blue-book* (New York, 1876); *Insurance Year-book* (New York, 1880–93); Fowler's *History of Insurance* (Philadelphia, 1888); Griswold's *Fire Underwriters' Text-book* (Montreal, 1889); Relton's *An Account of Fire Insurance Companies* (London, 1893). C. C. HINE.

Fireless Engine: a successor to the ammoniacal gas-engine. Dr. Émile Lamm, a native of France, but for many years a citizen of New Orleans, La., was the inventor and patentee (July 19, 1870) of an engine in which the power was derived from the vapor of ammonia. The ammonia, on escaping from the engine which it propelled, was recondensed (absorbed) by water, over which it was passed. This ammoniated reservoir of water, on being heated to the temperature of about 135° F., gave up the ammonia in the form of vapor. The same vapor was again returned to the engine, and was again allowed to escape, to be absorbed by its bath of water. The detail of the construction of the engine and water-bath need not be given, since the engine has been superseded by the incidental discovery, by Dr. Lamm, of a convenient method of using detached steam for the like purpose. Suffice it to say that the ammonia engine was successfully used in propelling street-cars in the city of New Orleans on the Canal Street railway at the rate of about 8 miles per hour, and with decided economy as compared with horse-power. This was used in the year 1871. While perfecting the methods of applying the ammonia-propelling power, and studying heat in its latent and active forms, Dr. Lamm was impressed with the facility with which the vapor of water may be condensed, even at high temperature, in water under high pressure; and following up the experiments, he was led to the invention of the fireless engine, patented Apr. 9, 1872, and afterward in complete use in New Orleans, but first perfected by Dr. Lamm himself, and applied to the selfsame engine used for driving the ammonia cars.

Fire-proof Building: the science of constructing an edifice not only incombustible, but capable of resisting, without injury to its stability or serious damage to its structure, the action of any fire originating either within its contents or from without. The destructive effect of long-continued and fierce flame upon incombustible materials, such as stone and iron, renders the problem of fire-proof building a difficult one. The burning of stored merchandise, and even the radiated heat of a great conflagration, may suffice to melt exposed iron-work, or at least to soften it until it collapses, dragging floors and walls down with it in a general ruin; it may even fuse the surface of wall-tiling (Athletic Club fire, Chicago, 1892), crack and destroy solid granite masonry from across the street (Boston post-office building, 1872), and cause zinc and copper to burst into flame (Constantinople [Pera], 1870). The gutting of many edifices alleged to be fire-proof, among which have been not a few constructed almost entirely of incombustible material, has led to a popular distrust of fire-proof construction not justified by the real facts; while the experience acquired in these disasters has finally made it possible to reduce the principles involved to clear and definite statement.

The distinction should be carefully drawn between *fire-proof* and merely *incombustible* buildings. The latter, although wholly composed of material incapable of combustion, may be completely gutted by the spread of the fire among their contents from one part to another through hatchways, stairways, and other openings; and may even suffer serious structural damage by the collapse of their metal beams and columns. A *fire-proof* building should suffer no structural damage from either internal or external fire, and should offer an effectual barrier to the spread of the flames from one story or section to another. There is also a third class of buildings which, though built with incombustible walls, floors, roofs, and partitions, are finished with inflammable fittings and decorations. The damage by fire to "fire-proof" buildings has mainly been in structures of this class, which includes a large proportion of modern "fire-proof" hotels, apartment-houses, and office-buildings. Yet the gutting of structures of this class is comparatively rare, because of the difficulty with which the flames acquire mass or headway in them, which would justify their being classed among "slow-burning" buildings, and it is doubtless a fact that the multiplication of such edifices greatly diminishes the danger of general conflagrations in large cities.

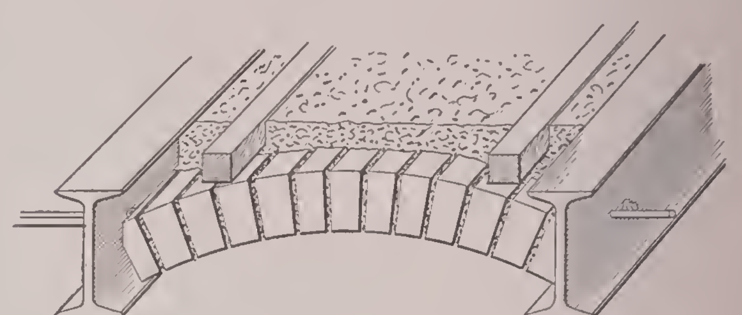


FIG. 1.—Floor-arch of solid brick.

Purposes.—It should be the aim in any system of fire-resisting construction (1) to build wholly of incombustible materials; (2) to protect by non-conducting coverings all exposed structural metal-work; (3) to dispense absolutely, if possible, with inflammable material even for the finishing and minor embellishments; and (4) to oppose every possible barrier to the passage of fire from one part of the building to another.

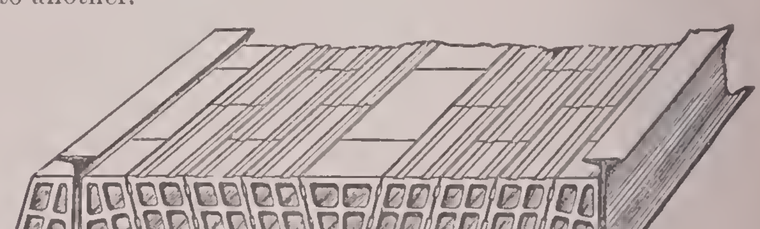

FIG. 2.—Horizontal floor-arch of hollow brick protecting beam-flanges (Maurer's).

Methods.—Burnt clay in the form of brick, terra-cotta, and tiles, is the best fire-resister of all building materials. In its highest form—that of fire-brick—it is practically infusible as well as uninflammable, while even common hard brick will endure a very high temperature. A completely fire-proof building might therefore be composed of brick walls and piers carrying vaulted ceilings and roof of brick, with tile flooring and roof covering. Systems of light and nearly flat vaults of thin, hard-burned tiles have been used in several buildings erected in the U. S., which, by avoiding the excessive cost, weight, and waste of space of ordinary vaulting, have brought this method of construction within the range of practicability for warehouses, libraries, and similar depositories of valuable and inflammable material. But the use of iron and steel for beams and columns, by reason of their economy of space and ease and rapidity of erection, has become practically indispensable for the framing of roofs, stairs, and elevator-ways, and for spanning wide distances without intermediate supports; and modern ingenuity has devised various means for protecting these metallic members from damage by fire. This is usually effected by means of fire-proof and non-conducting coverings or jackets, generally of terra-cotta or fire-brick, though sometimes special compositions of plaster or cement are applied to the metal, either directly or upon casings of wire netting.

Floors.—Floors are usually built of I-beams spaced from 3 to 6 feet, anchored to the walls, tied by continuous tie-rods to prevent spreading, and supporting incombustible fillings or arches, leveled on top with concrete in which are buried sleepers to which the finished flooring is nailed. The fillings, which were in the earlier examples arches of solid brick, as in Fig. 1, usually consist in more recent

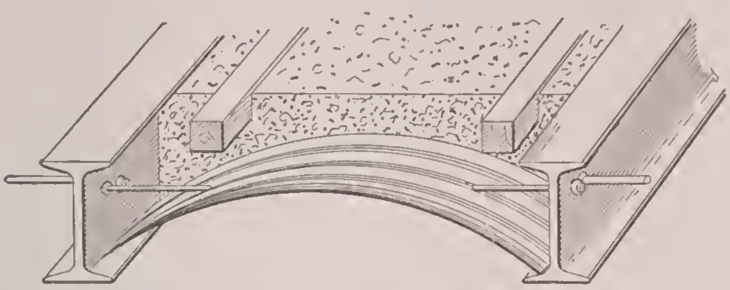

FIG. 3.—Concrete fillings on corrugated-metal arches.

work of flat arches of hollow brick made specially for the purpose, the soffit of the beam being in the best work protected by overlapping "skew backs" (Fig. 2). Such arches may be built of 6 to 8 feet span with a thickness of but 6 inches, capable of resisting a very heavy center-load. Fig. 3 shows a not uncommon system of concrete fillings on corrugated-metal arches, and Fig. 4 an inexpensive but strong arch used in 1870 in Robert College at Constantinople. Fig. 5 shows the common French (Thuasne) system, employing plaster-of-Paris carried by light bars wired to transverse hangers between the beams, a system having little strength and inferior fire-resisting qualities, as was proved by the fearfully rapid destruction of the Magasins du Printemps in Paris in 1880. A New York company has introduced a modification of this system, in which a patented composition capable of resisting both fire and water is molded or cast over wire netting stretched between the beams. It is reported to possess great strength as well as lightness. The "Guastavino" system of light vaults of thin tiles laid flat in cement permits of dispensing

FIG. 4.—Floor-arch of thin hollow brick, laid flat, used in Robert College, Constantinople.

with iron beams, which are replaced by low-crowned transverse arches of tile

Partitions and Roofs.—For light partitions hollow brick are commonly used; while a material called "porous terra-cotta," made in slabs by baking clay mixed with saw-dust,

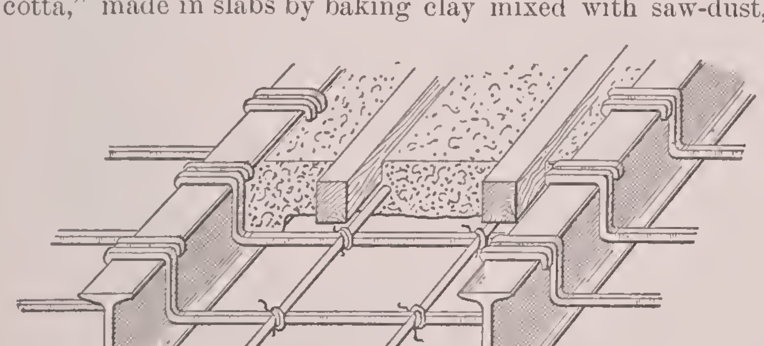

FIG. 5.—Common French (Thuasne) system.

is sometimes used for this purpose, and for filling-in between iron rafters and purlins in roofs; tiles and slates can be nailed to it precisely as to boards. Wooden sheathing should never be tolerated for roofs; if porous terra-cotta is not used, the tiles or slates may be wired to iron rods, or bedded in mortar applied to wire netting secured to closely spaced iron purlins. Roofs are sometimes covered with sheet copper or galvanized corrugated iron, secured directly to light iron purlins, or to a filling of porous terra-cotta or similar material. For covering roofs nearly or quite flat, concrete is often employed, and is in some cases covered with a paving of hard brick, especially when the roof is to serve as a terrace or promenade.

Furrings and Linings.—Wooden furring-strips should be sedulously avoided, and be replaced either by linings of hollow brick or by iron furring-strips and metallic lathing. The latter, of which many kinds are obtainable in the U. S., made of wire netting or of perforated sheet steel, should be used wherever it is desired to apply plastering otherwise than directly to the masonry.

Precautions.—Special attention should be bestowed upon all openings and passages from floor to floor. Every shaft, stair-well, and pipe-chase may serve as a flue to carry the flames from cellar to roof. The architect should plan to reduce all such passages as far as possible, both in area and number. All pipe-chases and passages for wires should be completely stopped at each story by packing with asbestos or plaster. Everything combustible should be kept away from stair-wells and elevator-shafts, and no metal left unprotected in their construction. Especially should hollow spaces be avoided under wooden flooring and behind wainscotings, by applying the woodwork as closely as possible to the surface of concrete or masonry beneath or behind it. Wherever the use of wood for interior finish is unavoidable it should be treated with some fireproofing solution like tungstate of soda. This is a somewhat expensive precaution, seldom observed; but not otherwise can the fire-proof quality of a building be preserved where wood enters into the interior finish, as it must in hotels and apartment-houses. Every large building should be divided into sections by solid brick walls rising some feet above the roof and penetrated by doors, which should be double and made of metal or of two thicknesses of plank entirely covered—the edges as well as the sides—by bright tin, experience having proved the excellent fire-resisting qualities of such doors. Every building containing inflammable contents—such as books, merchandise, records, and the like—should also be provided with fire-proof shutters to all windows as a safeguard against external fires. Such shutters should, if possible, be double, made of steel or wrought iron, and provided with loopholes having pivoted covers to allow of the introduction of hose for extinguishing internal fires. There should also be outlets at each floor for the escape of water thrown in by the engines in case of such fire. And the fire-proof character of the edifice should by no means be an excuse for dispensing with extinguishers, hose, self-sprinklers, and other approved appliances for promptly extinguishing any fire that might start among its contents.

History.—Ancient records teem with surprising tales of the destruction of monumental edifices of solid masonry by the burning of their wooden roofs, floors, and contents. The Roman systems of vaulting were partly a result of the effort to guard against such calamities, yet in 217 A. D. a fire kindled by lightning in the wooden superstructure of the Coliseum destroyed a large part of the masonry of its upper stages. The Romans, in the Baths of Caracalla, anticipated the modern systems of metal beams with concrete fillings, as proved by Lanciani in 1873. The Byzantines sought in the magnificent Church of the Divine Wisdom (Santa Sofia), in 532 A. D., to replace by a fire-proof structure the earlier basilica destroyed by fire; and the whole history of mediæval architecture is that of a constant effort through five centuries to translate into a stone-vaulted and fire-proof structure the traditional forms of the early Christian basilicas. With the development of palace architecture in the Renaissance came a more general use of timber in floors, roofs, and ceilings, and of lath and plaster for interior finishing. These practices, handed down and, in the U. S. especially, fostered by the cheapness of wood and the costliness of mason-work, have led to a great extension of wooden construction and to many vicious and defective methods of building. In regions where timber is scarce, however, the more ancient practice of building vaulted ceilings of masonry still prevails, as in some districts of Italy and Hungary where wooden floor-beams and roofs are the exception. The public buildings of the Old World are in great measure solid and well-built edifices, and the development of metallurgy, leading to the increasing adoption of iron and steel for posts, beams, and trusses, has led to improvements amounting to a revolution in the art of building, in which the most rapid progress and the greatest inventiveness have been displayed in the U. S. Floors of brick arches carried by heavy timbers may be seen in Spain and Southern France, dating from the seventeenth century, but the modern development of this principle dates only from the general introduction of rolled-iron beams into building practice between 1840 and 1850. In the Berlin Museum, by Stüler (1843–55), trussed beams of cast and wrought iron were used with brick arches; during the same period Bunnett's, Fox & Barrett's, and Cheyne's patent fire-proof floorings were invented in England, and the Thuasne and Vaux systems generally adopted in Paris. The Cooper Institute in New York was the first building in the U. S. to employ American rolled-iron joists with brick arches. Since 1876 the progress in methods of fire-proof building has been especially great. This period has also witnessed the adoption, especially in New England, of the so-called "slow-burning" or "mill-construction" system of heavy wooden floors on widely spaced beams of heavy section, described in the articles FLOOR and MILL-CONSTRUCTION.

A. D. F. HAMLIN.

Fireproofing: the process or means of rendering textile fabrics or other materials incombustible. On Mar. 17, 1735, one Obadiah Wyld obtained an English patent for "making or preparing paper, linen, canvas, and such like substances which will neither flame nor retain fire, by mixing alum, borax, vitriol, or copperas dissolved," and dipping the fabrics "into a strong infusion of the said materials in water or thin size made hot." Impregnation with alum, borax, or copperas, as the case may be, is by far the best treatment for fireproofing and preserving wood, which thus treated has been strongly recommended for railway cars subjected to risk of fire from overturned stoves and lamps in cases of collision, etc. The use for fireproofing of sulphate of ammonia was proposed by De Breza in 1838; that of soluble glass by Bethell in the same year; that of hydrochlorate of ammonia by Froggant in 1851, but this last does not appear to have received serious attention. The use of tungstate of soda and phosphate of ammonia was at a later date found by Dr. Versemann, after a series of the most careful experiments, to be the best adapted for common use with cloths, etc., either of these rendering the lightest muslins uninflammable. The tungstate of soda, however, has this advantage over the other, that it may be used with starch and does not interfere with ironing. A mixture of this salt with starch is sold in London under the name of fire-proof starch. The tungstate of soda should be used in preference to the others for light articles of apparel, curtains, upholstery, etc.

A German recipe for fire-proof coating is three successive applications of a hot solution of 3 parts alum and 1 part copperas, and after this of a solution of copperas brought to the consistence of paint by the admixture of pipe-clay.

The disastrous results of fires in theaters and like places of amusement have led to the invention of fire-proof drop-curtains, the material of which could undoubtedly be employed for other but similar purposes. In some of these asbestos is the material most relied upon for the desired fire-resisting properties.

JAMES A. WHITNEY.

Fire-proof Safes: in general, movable receptacles of iron or steel, lined with non-combustible materials, and used for the preservation of papers, money, or other articles of value. The fire-proof safe originated in New York city between the years 1829 and 1832, when James Conner made an iron box filled in with plaster-of-Paris for use in his office. He made no attempt to benefit the public by his invention and the safe was almost forgotten until 1843, when one Fitzgerald invented a similar receptacle. From this date the manufacture of fire-proof safes received a lasting impetus. Numerous new compounds were devised for filling. Although Conner was the first to make a fire-proof safe, William Marr, of London, was the first to patent and make public a method of construction. This he did in 1834. Marr's invention differed materially from Conner's; the former filling the spaces between the inner and outer shells or casings of the safe with sheets of mica pasted upon paper, and crowding the space between with burnt clay and powdered charcoal, or in lieu of these with powdered marble. The next alleged improvement was that of Charles Chubb, also of London, in 1838, who used a series of concentric linings of iron plates, the intermediate spaces filled with baked wood-ashes, or "such other slow-conducting materials as will retard the transmission of heat." In 1843 three gentlemen named Tann originated safes made fireproof by filling the spaces with ground alum, finely sifted, and gypsum, also finely pulverized. The alum and gypsum were intimately mingled, heated to liquefaction, and after cooling to a hard and brittle condition comminuted to a coarse powder for use. This mixture, when subjected to an extreme heat, would give off water from the plaster; but the calcination of the alum of course detracted from its utility. In 1855 George Price, of Wolverhampton, used powdered alum and sawdust as a filling. During the previous use of alum it had been discovered that various other salts containing water of crystallization would serve the same purpose in the filling.

The construction of fire-proof safes has for many years formed a very important branch of manufacture, and many improvements have been made which in the aggregate have much increased their utility. But the essential features remain the same, so that these fire-proof receptacles may still be classified as, 1, those having a filling of some simply non-conducting material, like clay or concrete; 2, those fitted with plaster capable of giving off water by calcination, though only in moderate quantities; 3, those in which alum or other salt yielding a large percentage of water by decomposition is mingled with the plaster; and 4, the steam-safes, in which vessels either of glass or metal and filled with water are arranged between the inner and outer walls to give off steam when subjected to a high heat.

Very many inventions relating to fire-proof safes have been developed in the U. S. since 1850, the greater number relating to the filling upon which the fire-proof quality depends. Among these was one, in 1864, which comprised a filling of alum in small lumps rolled in plaster and then bedded in dry clay. In 1865 a filling of Epsom salts was used, either alone or combined with sulphate of lime or plaster-of-Paris (this also is the filling used in a celebrated fire-proof safe); in 1866, a novel arrangement of vessels containing water between the inner and outer walls to form a steam-safe. In 1868 nearly a score of patents for fire-proof safes were granted; among others, upon wood imbedded in the plaster filling to enhance its non-conducting power, the introduction of non-conducting material between the plates of the door and the door-casings, the use of fine (common) salt as a filling, water-vessels stopped with glue or mucilage inserted in the cement filling, the construction of the set filling with cells for the reception of a vaporizing substance; also several novel forms of steam-safes, in one of which a space external to the water-filling was provided to receive the steam from the filling, and thus provide a non-conducting jacket to the whole. From 1869 dates the use, external to an alum or similar filling, of cans containing steam or vapor-producing substance placed between such filling and the outer casing of the safe; also, the construction of safes with a water-supply from an elevated head. These embody the leading varieties of fire-proof safe construction, although various improvements of more or less merit have been from time to time proposed. It must always be remembered that no safe is absolutely fire-proof, although several manufacturers make them capable of withstanding an exceedingly high temperature. Wherever possible, a safe should be imbedded in brickwork, which experience has shown to be one of the most effective of all protections against the injurious transmission of heat.

JAMES A. WHITNEY.

Fire-ship: a vessel, often old and unseaworthy, which is laden with combustibles, fired, and sent into the midst of an enemy's fleet for the purpose of setting it on fire. This ancient device has been frequently tried in modern warfare, and though sometimes of much service, as in the war of Greek independence, it can never be of much effect when employed against a well-managed steam-marine; moreover, this service is fraught with great danger to the aggressive party.

Fireworks: See PYROTECHNY.

Firishta: See FERISHTAH.

Firkowitsch, feer'kō-vitch, ABRAHAM: Jewish archæologist; b. at Lutzk, in the Crimea, Sept. 27, 1786. He was the son of Karaite parents, and was reared in the faith of his forefathers. (See KARAITES.) Of a ready mind and eager for learning, he was afforded all the advantages which the Jews of the Crimea had at their command. These were but scanty; most of his knowledge consisted, therefore, of a thorough mastery of the Hebrew of the Old Testament canon and of tradition, acquired mainly at Eupatoria, where he had enjoyed the use of a manuscript library belonging to the Karaite congregation. He became a rabbi, and distinguished himself in his connections at Cherson and Koslov. His study of the MSS. at Eupatoria had instilled in him a love for ancient Jewish authors, particularly Karaites, and a desire to see the study of Hebrew literature and of Karaism revived among his nation. His opportunity to urge the matter successfully came in 1825, when the Karaites of Eupatoria established a printing-press. Firkowitsch finally became the principal guide of the Crimean Karaites not only in the reproduction of ancient MSS., but also in the selection of modern works worth printing. Unsatisfied by the meager supply in the Crimea, Firkowitsch visited the scattered Karaite communities in Turkey, Syria, Palestine, Persia, and the Caucasus, not shunning any danger or privation, determined to unearth the treasures of the past. He penetrated into the very depths of Asiatic wildernesses, searching wherever he might hope to find a fragment of Karaite antiquity. He deposited in the Imperial Library at St. Petersburg no less than 1,500 MSS.—a collection said to rival, if it does not surpass, the fine collection of Hebrao-Arabic codices at Oxford. In the deciphernent of these MSS. Rabbi Samuel Pinsker assisted and frequently guided Firkowitsch. They are not yet as widely known as they deserve to be. Neubauer, the Jewish savant at Oxford, and others have drawn attention to the great value of the Firkowitsch fragments of ancient MSS. of the Old Testament, both for the various readings of the Hebrew text and for the Masora. Firkowitsch died at Shufut-Kale, in the Crimea, June 7, 1874. See his *Life* by A. Jellinek (Vienna, 1875) and by H. L. Strack (Leipzig, 1876).

J. H. WORMAN.

Firmament: See STARS.

Firman [from Turk. *fermān*, from Pers. *farmān*; cf. Avest. *framāna*, authority, decision, deriv. of prefix *fra-*: Skr. *pra-*, Gr. *προ-*, Eng. *for-*, forth + *mā-*, measure: Lat. *metior*, whence Eng. *measure*]: in Oriental countries the certificate or written mandate of a sovereign or government. It is especially applied to the passports issued to travelers in Turkish countries.

Fir′micus Mater′nus, JULIUS: a writer on mathematics and astrology; b. in Sicily; flourished in the time of Constantine and his successors. He followed at first the profession of an advocate. He wrote in Latin a work entitled *Matheseos libri VIII.* (about A. D. 354), which treated of astrological subjects, such as nativities, the influence of the stars on human life, etc., more than of mathematics. The work is still extant, and was first printed in Venice (1497) in a purer text than that of Aldus (1499) and of subsequent editors. A new edition is promised by K. Sittl. Evidently, from several passages of his work, the author was a heathen. If the treatise *De errore profanarum religionum*, which is ascribed to Julius Firmicus Maternus, be by the same author, he must in his later years have become a Christian. But it is more probable that this work is by another writer of the same name, who flourished at the same period, as his book is dedicated to Constantius and Constans, the sons of Constantine, and bears internal evidence of having been composed about 347. It is a vigorous defense of the Christian religion against the errors of paganism, which he exhorts the emperors to destroy. The best edition is by C. Halm (Vienna, 1867) along with Minucius Felix. See Hertz, *Dissert. de Julio Firmico Materno* (Copenhagen, 1817). Revised by M. WARREN.

Firozpur: a district (and city) of the Lahore Division, Punjaub, British India; on the left bank of the Sutlej river; between lon. 74° 5′ and 75° 29′ E. Area, 2,752 sq. miles. The country is level, and in part subject to fertilizing overflows of the Sutlej. A railway runs through the district. Pop. 650,000, about one-half Mohammedans. The capital is Firozpur, a city of 25,000 inhabitants, on the old bank of the Sutlej (see map of N. India, ref. 4–D). It is very prosperous and has a military cantonment adjacent to it.

First-born (in Heb. בְּכוֹר, בְּכוֹרָה; Gr. *πρωτότοκος*, LXX. and N. T.; Lat. *primogenitus*, Vulgate): among the Hebrews, the first child of the father and the mother; hence he is spoken of in regard to the father as "the beginning of his strength" (Gen. xlix. 3; Deut. xxi. 17), and in regard to the mother as "the opening of the womb" (Ex. xiii. 2). Before the establishment of the Hebrew theocracy the rights of primogeniture were recognized, but they were sometimes transferred from the eldest to a younger son, as from Esau to Jacob (Gen. xxv. 29–34; xxvii. 18–40), and from Reuben to Joseph (1 Chron. v. 1–3). After the Mosaic economy was established such a transfer was forbidden (Deut. xxi. 15–17). The birthright consisted in a double portion of the inheritance; that is, the eldest son received twice as much of the patrimony as any one of the younger sons (Deut. xxi. 15–17; 1 Chron. v. 1, 2). When Elijah was about to be translated, Elisha said to him, "I pray thee let a double portion of thy spirit be upon me" (2 Kings ii. 9). He meant that, like a first-born son, he might inherit a double portion of Elijah's prophetic prerogatives; not that he should be twice as great a prophet as his master, but, like him, be at the head of "the sons of the prophets"—their superior in office; and so he became. It is nowhere said in the Bible that the birthright embraced the family priesthood and government. As to the family priesthood, nothing specific is recorded. It is likely that the eldest son officiated in place of the father when he was absent, or after his death while the family remained together. To commemorate the destruction of the first-born of the Egyptians, God required that the first-born males of the Hebrews should be consecrated to him; also the firstlings of their cattle and the first-fruits of their ground. After the Exodus their first-born sons, numbering 22,273, were substituted by 22,000 Levites, and the 273 surplus were redeemed at five shekels a head (Num. iii.). The tribe of Levi thus became the priestly tribe for the nation. But how this affected the family priesthood does not appear. So the right of government naturally inhered in the eldest son in the absence of the father, or in the case of his death while the family remained together. This pre-eminence attached to the eldest son in the royal family, as he succeeded to the throne (2 Chron. xxi. 3), though in special cases this rule was reversed; as, e. g., Solomon, who for theocratic reasons was substituted for his eldest brother (1 Kings i.). The first-born son seems to have had authority over the rest of the family from the earliest times; but this appears to be distinguished from the peculiar birthright prerogative, for Esau says of Jacob, "Is he not rightly named Jacob [a supplanter]? for he hath supplanted me these two times: he took away my birthright, and behold now he hath taken away my blessing" (Gen. xxvii. 37). In the blessing, Isaac said, "Let people serve thee, and nations bow down to thee: be lord over thy brethren, and let thy mother's sons bow down to thee" (Gen. xxvii. 29). So it is said that the birthright was taken from Reuben and given to Joseph: "For Judah prevailed above his brethren, and of him came the chief ruler, but the birthright was Joseph's" (2 Chron. v. 1, 2; cf. Gen. xlix. 8–10; Mic. v. 2; Matt. ii. 6). As the first-born was considered more vigorous than younger children, having been begotten and brought forth before the parents had lost their strength, and first developing into manhood, he was naturally invested with superior prerogatives in the family. This has been the case among almost all people. Hence the destruction of the first-born of Egypt was considered so great a calamity, and hence so much importance was attached to the first-born of man and beast that by the Levitical law they were consecrated to Jehovah. The male first-born of men, being represented by the priestly tribe, were redeemed. When the child was a month old the father paid five shekels of the sanctuary to the priest, and so redeemed him. If the child died before he was a month old, the rabbins say the father was excused from the payment. The firstling of an unclean beast was also redeemed, as not fit to be offered in sacrifice. The firstling of an ass, for instance, was to be redeemed by a lamb, otherwise his neck was to be broken. The firstlings of clean animals were not to be redeemed, but offered in sacrifice (Ex. xiii. 11–15; xxii. 29, 30; Num. viii. 16–18; xviii. 15–17).

The term first-born is used metaphorically for the first, or chief, or pre-eminent; thus (Job. xviii. 13), "the first-born of death shall devour his strength"—i. e. the most deadly disease shall destroy him. "The first-born of the poor" (Isa. xiv. 30) are the poorest and most wretched. God said of David (Ps. lxxxix. 27), "I will make him my first-born, higher than the kings of the earth," where the second clause explains the first. David, as the royal representative of the theocracy, enjoyed a higher prerogative than any heathen monarch. In the New Testament *prōtotokos* occurs nine times. Thrice it is used literally (Matt. i. 25; Luke ii. 7; Heb. xi. 28). Christ is "first-born among many brethren" (Rom. viii. 29), as he is "the Son of God" in a peculiar sense—pre-eminent among the sons of God, who are made so through him by adoption and regeneration. He is called "first-born of every creature" (Col. i. 15) or of all creation, as he is "Lord of all," being the Creator of all (cf. Col. i. 16; Heb. i. 1–6). He is called "first-born from the dead" (Col. i. 18) and "first-begotten of the dead" (the same word, Rev. i. 5), because he was the first "raised from the dead to die no more," and so is "become the first-fruits of them that slept" (Rom. vi. 9; 1 Cor. xv. 20). He is called "the first-begotten" (same word, Heb. i. 6), as he was destined to occupy the highest position of honor in the universe (cf. Ps. lxxxix. 27; Phil. ii. 9–11). The righteous are spoken of as "a society of first-borns, registered in heaven" (Heb. xii. 23), because they enjoy the freedom of the city of God, the heavenly Jerusalem: it expresses their pre-eminent dignity and distinguished prerogatives. (Cf. Ex. iv. 22; Jer. xxxi. 9.)

For the subject of the first-born's rights under the English law of primogeniture, see PRIMOGENITURE.

Revised by S. M. JACKSON.

First-fruits (in Heb. רֵאשִׁית; Gr. ἀπαρχαί; Lat. *primitiae*): the earliest gathered fruits of the season. The offering of the first-fruits of the season, with more or less of religious ceremony, is a natural expression of pious gratitude in acknowledgment of the Divine bounty, and was practiced by the ancient Egyptians, Greeks, and Romans, as well as by the Hebrews. The form in which it is first expressly commanded by Moses (Ex. xxii. 29) implies a custom already existing. It may be traced back, perhaps, to the very beginning of history (Gen. iv. 3, 4). Under the Mosaic ritual these offerings were of two kinds—the one national, the other individual. The national offerings were in connection with two of the great national festivals; the first, a sheaf of barley at the Passover, when the barley-harvest began; the second, two loaves of bread at Pentecost, when the wheat-harvest ended. These national offerings, which had a solemn representative character, were to be made, of course, at Jerusalem, and ceased with the destruction of the Temple. The rules to be observed are laid down in Lev. xxiii. Still more minute directions are given in the Talmud. Individual offerings were not merely in acknowledgment of dependence upon God, but also for the sustenance of the priesthood, and were to be made throughout the country, as well as at Jerusalem. Specific directions, bringing out the religious significance of the act, are contained in Deut. xxvi. 1–11. Some kinds of offerings were expressly devoted to the priests' use (Num. xviii. 12), as the best of the oil, wine, and wheat, in addition to which mention is also made (Deut. xviii. 4) of the fleece of sheep. Of young trees no fruits could be taken till the fourth year, in which they were offered to the Lord; after this they might be eaten. Of every kind of produce of the earth, as it ripened, a basketful was to be presented by each Israelite, some in their natural, and others, as wine and oil, in their prepared state. The amount of the gifts of the first-fruits was not specified in the Law, and the field was thus left open for Talmudic casuistry to busy itself in deciding what was proper or obligatory. The gift was not to be taken from the portion designed for tithes, nor from the corners left for the poor. One-fortieth (or, according to the school of Shammai, one-thirtieth) was accounted a liberal proportion of the entire produce, while a moderate portion was a fiftieth, and a scanty portion a sixtieth. But whatever was offered must be the produce of the Holy Land. Beyond Palestine it might be converted into money, and thus sent to the Temple. See Spencer, *De Legibus Hebræorum Ritualibus*, iii. 9.

Fir-wool: a fiber prepared to some extent in Germany from the leaves of *Pinus sylvestris* (Scotch fir), and made into cloth and wadding which are believed to be useful in the treatment of rheumatism and skin diseases. Fir-wool oil is an oil of turpentine made from these leaves. Fir-wool extract is a residual substance prepared from the leaves, and used to some extent in medicine.

Fiscal Departments: See FINANCE.

Fisch, GEORGES, D. D.: a French Protestant clergyman; b. in Nyon, Switzerland, July 6, 1814; educated in the academy at Lausanne. After entering the ministry he preached for nearly five years to a German-speaking congregation at Vevey, and then emigrated to France and joined the French Evangelical Church. Became in 1846 the successor of the celebrated Adolphe Monod at Lyons. In 1854 removed to Paris, as pastor of the church Taitbout, where he was the colleague of his brother-in-law, Edmond de Pressensé, the learned French Protestant ecclesiastic. In 1863 Dr. Fisch became president of the Union seeking the coalition of French Protestants, and was a director of the Evangelical Society of France, a powerful auxiliary to the Union. He figured prominently at the Evangelical Alliance meeting held in New York in 1873. D. in Vallorbe, Switzerland, July 3, 1881.

Fischart, JOHANN: satirical writer; b. (according to some accounts, at Strassburg; according to others, at Mentz, Germany) about 1550; studied law at Strassburg, where he received a doctor's degree in 1574; became advocate to the imperial chamber at Spires in 1581, and in 1583 was made bailiff of Forbach, near Saarbrücken, where he died in the spring of 1590. His numerous writings, comprising both prose and verse, were published under a great variety of pseudonyms, and with strange, fantastic titles. Almost all of them, though satirical in form and abounding in humorous thoughts and oddly coined words, have in general the serious purpose of holding up to public contempt the vices and follies of all classes of society, and especially of vindicating Protestantism against the charges of its enemies. Perhaps the best known of his writings is his free imitation of the first book of Rabelais's *Gargantua* (1575). Of his other works may be mentioned *Aller Practik Grossmutter* (1572); *Eulenspiegel Reimensweiss* (1572); *Flöhhatz und Weibertratz* (1573); and *Bienenkorb das Heilig. Römischen Imenschwarms* (1579), the last a sharp attack on the lives of the dissolute clergy.

Fischer, KUNO: philosopher; b. July 23, 1824, in Sandewald, in Silesia; educated at the Universities of Leipzig and Halle; Professor of Philosophy at the University of Jena 1856–72; since 1872 Professor of Philosophy in Heidelberg. Author of *Diotima, the Idea of the Beautiful* (1849); *History of Modern Philosophy* (1852–72); *Kant* (1860); *System of Logic and Metaphysics* (1865); *Spinoza* (1865); *Francis Bacon and his Successor* (1876); *Lessing* (1882); *Critique of Kantian Philosophy* (1885); *Goethe's Faust* (1886); *Schiller* (1892).

C. H. THURBER.

Fish [M. Eng. *fisch*, *fisc* < O. Eng. *fisc* : Goth. *fisks* : O. H. Germ. *fisk* > Mod. Germ. *Fisch* < Teuton. *fiskos* : Ir. *iasc* : Lat. *piscis* < Indo-Eur. *pisk-*]: any one of many various and widely differing animals having the common characteristic of living in water. The word fish is also used as a collective plural to designate a number of fishes without distinct reference to the individuals. See FISHES and FOOD.

Fish, HAMILTON, LL. D.: lawyer and politician; b. in New York city, Aug. 3, 1808; a son of Nicholas Fish; educated at Columbia College in his native city; graduated in 1828; was admitted to the bar in New York in 1830; was in 1837 chosen to the State Legislature; then served in Congress in 1843–45; was Lieutenant-Governor of New York 1847–49; Governor of New York 1849–51; and from 1851 to 1857 was one of its U. S. Senators. He was in 1862 one of the U. S. commissioners to visit soldiers confined in Confederate prisons, and rendered valuable service in negotiating for the exchange of prisoners. In 1869 he was appointed Secretary of State in the cabinet of President Grant, his term of office commencing in March. Mr. Fish suggested the joint high commission between the U. S. and Great Britain which met in 1871 to settle the various difficulties between the two nations, including the famous Alabama claims. In 1872 he became president of the order of the Cincinnati. In 1873 he was reappointed Secretary of State at the beginning of President Grant's second term, and served till Mar., 1877. D. at Garrisons-on-the-Hudson, N. Y., Sept. 7, 1893.

Fish, NICHOLAS: soldier and politician; b. in New York, Aug. 28, 1758; entered the College of New Jersey at Princeton, N. J., at the age of sixteen, but left, and commenced the study of law with John Morin Scott, with whom he served in 1776 as aide-de-camp, and subsequently as major of brigade; Nov. 21 major of the Second New York Regiment, and at the close of the war was a lieutenant-colonel. Col. Fish was in both battles of Saratoga, commanded a corps of light infantry at the battle of Monmouth, served in Sullivan's expedition against the Indians in 1779, was with the light infantry under La Fayette in 1780, and in 1781 was active with his regiment in the operations which resulted in the surrender of Cornwallis at Yorktown, Va. He was adjutant-general of the State in Apr., 1786, and thereafter for many years. He was revenue supervisor under Washington in 1794, and a New York alderman from 1806 to 1817; president of the New York Society of the Cincinnati in 1797, and a prominent member of many literary and benevolent institutions of New York city. D. in New York city, June 20, 1833.

Fish-culture: a term which in its widest sense means the increase, distribution, and protection of useful and ornamental aquatic animals and plants. The methods and ends involved receive a more nearly adequate expression in the synonymous term "aquiculture," now current in France, since the modern fish-culturist gives attention to many important objects of fishery besides fish, for example, the seals and their allies, the lobsters and other crustaceans, the oysters and other mollusks, corals, sponges, algæ, and the various economic forms of life in the waters.

The Chinese from a remote date have collected, distributed, and hatched naturally impregnated fish-eggs, but the practicability of stocking waters by means of fish developed from artificially impregnated eggs was first made known by Lieut. Stephen Ludwig Jacobi, of Westphalia, in 1763, and the processes were first publicly explained in 1772, by Prof. Adanson in the Royal Garden of Paris. This art was practiced only by private individuals for their own amusement or profit for nearly a century after its discovery. Public fish-culture dates from 1850, when France established, at Hüningue, the first fish-hatchery under Government direction.

The methods and results of the French and British fish-culturists were promptly made known in the U. S. through the publications of Dr. Theodatus Garlick and William H. Fry, whose contributions to the history of fish-culture in Europe were nearly simultaneous; but Dr. Garlick gave the first practical application of the art in the development of eggs of the brook trout. Massachusetts appointed the first State Fish Commission, but New Hampshire, in 1865, first began public fish-culture by importing and hatching salmon-eggs from Canada. A commission was established by Vermont in the same year. The first public fish-hatchery erected in the U. S. was the shad station of Massachusetts at Hadley Falls, on the Connecticut river. At the present time forty States and Territories have fish commissions in more or less active operation, with annual appropriations ranging from $1,500 to $34,000, and the aggregate annual appropriation nearly $250,000.

The U. S. Fish Commission was established by Congress in 1871, and began the artificial propagation of fish in 1872. Prof. Spencer F. Baird was the first commissioner under the Government, and served until his death in 1887, when he was succeeded by Dr. George Brown Goode. The later commissioners have been Marshall McDonald, 1888–97; J. J. Brice, 1897–99; and George M. Bowers, 1899–. The commission has thirty-six stations in operation in twenty-four States. The appropriations for the fiscal year ending June 30, 1900, aggregated $446,500.

The impregnation of fish-eggs is effected by gently pressing a female fish in the spawning condition along the sides of the belly with the thumb and forefinger, and letting the eggs flow into a clean, dry pan. In a similar way the milt from a male is squeezed upon the eggs, the pan being kept swaying until fertilization is effected. A little water is sometimes added before fertilization is complete, and this is continued until the eggs become hard and increased in size. Hatching takes place in glass jars, wooden troughs, or some other form of apparatus, through which there is a constant flow of water.

The extent of the work accomplished by the States is shown in the reports of their fish commissions: Wisconsin distributed 50,000,000 of young fish in 1891 and 36,000,000 in 1892, besides planting some fertilized eggs on the spawning-grounds. New York deposited more than 38,000,000 in 1891. Pennsylvania, during the three years ending with 1891, distributed upward of 152,000,000, averaging about 51,000,000 a year. Michigan furnished more than 136,000,000 in 1891 and upward of 135,000,000 in 1892. Six States have cars specially constructed for the transportation of fish and eggs to and from their hatcheries, and the U. S. has four cars for the same purpose. From 1872 to 1882 the U. S. Fish Commission distributed 341,096,977 fish; from 1882 to 1892 the number distributed was 2,391,389,410; in 1900 1,164,336,754 were distributed, an increase of about 100,000,000 over the preceding year.

Among the many results accomplished by fish-culture may be mentioned the introduction of European salmon and trout into New Zealand and Australia; the successful transfer of trout from the U. S. to Japan, Great Britain, and the continent of Europe; the acclimation of the black bass in Great Britain and Germany; the introduction of several species of European trout into the U. S.; the transfer of shad and striped bass from Eastern rivers to California; and the remarkable increase in the catch of shad in the Eastern U. S. since 1880. The number of shad taken in 1890 was nearly two and a half times as great as in 1880, and the increase in the yield was worth $823,965, notwithstanding that the average price per pound in 1890 was only eleven cents as against nineteen cents in 1880.

The number of species of fish to which the methods of fish-culture are now applied by the general Government and the States is not far from forty. The shad, whitefish, pike-perch, cod, and several members of the salmon family receive the greatest amount of attention. The Dominion of Canada appropriates about as much annually to public fish-culture as all Europe, while the U. S. devote to the work many times the amount granted in Europe and the Dominion. A full description of the history, methods, results, and literature will be found under PISCICULTURE.

TARLETON H. BEAN.

Fisher: the largest of the martens; the *Mustela pennantii*, a carnivorous quadruped of the family *Mustelidæ*, found in Canada and the U. S., arboreal in its habits, and named, as it is said, from its fondness for fish, which it often steals from the traps of fur-collectors, who use fish as a bait for the pine-marten. It is some 3 feet long, inclusive of the tail. In color it is chiefly black, often with gray or brown tints toward the head. It is a fierce nocturnal animal, living chiefly upon birds and small quadrupeds. Its fur in winter is good, and is much used.

Fisher, Hon. CHARLES, D. C. L.: politician; b. at Fredericton, New Brunswick, Canada, Sept., 1808; graduated at King's College, New Brunswick; studied law and was admitted to the bar; was elected to the provincial Parliament in 1837. In 1848–57 he was a member of the executive council; in 1852 a commissioner to codify the provincial statutes; from Oct., 1854, to May, 1856, was attorney-general, again in 1856–61, and again Apr., 1866. He advocated the union of all the provinces of British America, and in 1867 was a member of the conference in London which arranged the terms of the union. He was a judge of the Supreme Court of New Brunswick from 1868 to his death, Dec. 8, 1880.

Fisher, FRANCES C.: See the Appendix.

Fisher, GEORGE JACKSON, M. D.: b. in Westchester co., N. Y., Nov. 27, 1825; graduated in medicine at the medical department of the New York University, Mar. 1, 1849; physician and surgeon of the departments of the New York State prisons at Sing Sing in 1853–54; resigned (after twenty years' service) surgeon Seventh Brigade N. G. S. N. Y. 1873; president of Medical Society State of New York 1874. Author of *Biographical Sketches of Deceased Physicians of Westchester County, N. Y.* (1861); *On Animal Substances employed as Medicines by the Ancients* (1862); *Diploteratology, an Essay on Compound Human Monsters*, (pp. 200, 33 lithographic plates of 126 figures, 1865–68); *On the Influence of Maternal Mental Emotion in the Production of Monsters* (pp. 55, 1870). After the death of the distinguished Dr. Gross, of Philadelphia, Dr. Fisher was chosen his successor to write a *History of Surgery* for the *International Encyclopædia of Surgery*. D. at Sing Sing, N. Y., Feb. 3, 1893.

Fisher, GEORGE PARK, D. D., LL. D.: b. in Wrentham, Mass., Aug. 10, 1827; graduated at Brown University in 1847, and studied theology at New Haven (1848–49), at Andover, where he graduated in 1851, and in Germany. Became Professor of Divinity in Yale College in 1854, and in 1861 was transferred to the chair of Ecclesiastical History. The degree of D. D. was conferred on him by his alma mater (1866), by the University of Edinburgh (1886), and by Harvard College (1886), and the degree of LL. D. by the College of New Jersey (1879). Has published *Essays on the Supernatural Origin of Christianity* (1865); *Life of Benjamin Silliman* (1866); *History of the Reformation* (1873); *The Beginnings of Christianity* (1877); *Faith and Rationalism* (1879); *Discussions in History and Theology* (1880); *The Christian Religion* (1882); *The Grounds of Theistic and Christian Belief* (1883); *Outlines of Universal History* (1885); *History of the Christian Church* (1888); *Manual of Christian Evidences* (1890); *Colonial History of the United States* (1892); and many articles in the *Bibliotheca Sacra*, *North American Review*, *British Quarterly* and *New Englander, etc.*; in 1892 became one of the editors of *The Yale Review*. He was for several years after 1886 one of the editors of *The New Englander*.

Fisher, JOHN: Bishop of Rochester; b. at Beverley, Yorkshire, about 1459; took his M. A. at Cambridge University in 1491; in 1501 became vice-chancellor of the university, and in 1504 chancellor and Bishop of Rochester. In 1505 was president of Queen's College, Cambridge, and on May 12, 1521, preached against the Reformation on the occasion of burning

Luther's writings; besides this, in opposition to the Lutheran doctrines, he wrote several treatises. In 1530 he opposed the divorce of Henry VIII. from Catharine of Aragon, was imprisoned in the Tower of London in 1534, and, receiving the cardinal's hat from Pope Paul III. May, 1535, was convicted for denying the royal supremacy on June 17, and executed at London, June 22, 1535. See his *Life* by J. Lewis (2 vols., London, 1855) and his *Life* by T. E. Bridgett (1888).

Fisheries: those industries which consist in the taking for commercial purposes of fish or of any other kind of aquatic animals, such as seals, whales, clams, corals, and sponges. The term fishery means fishing for business, as distinguished from angling, which is fishing for sport, and implies the use of fine tackle for the capture of active, well-flavored fish.

In an article like this the most general treatment only is possible, and the most important fish and fisheries can alone be treated of at length, while a mere enumeration of others must suffice. It is hardly too much to say that almost every common fish is somewhere caught and used for food, often in considerable numbers, without being the object of any particular "fishery." It may also happen, as is pre-eminently the case on the Great Lakes of North America, that large fisheries may be carried on having as their object the catching of fish in general and no one species in particular. The subject of the fisheries of the U. S. is dwelt on at special length in this article, not only because of their importance, but because detailed information concerning them is much more accessible than it is for other countries.

It has seemed best to discuss the fishes in their natural groups, giving under each some of the more important methods of capture, and to preface this with a description of the general types of apparatus used.

Apparatus.—Under this head come hooks and lines, nets, traps, and spears. Hooks and lines are naturally proportioned in their sizes and lengths to the various kinds of fish and various depths of water for which, and in which, they are used. They may be classed as hand-lines and set-lines, long lines or trawls. These three names are applied to long lines having attached to them at regular intervals short lines armed with hooks. At either end is an anchor to hold the trawl in place, furnished also with a line and buoy to indicate its position.

For cod-fishing trawls usually have the hooks 6 feet apart, and are set in lengths of 3,000 feet, although two or three of these lengths are frequently combined.

A full set of trawls for a fishing-schooner is 72,000 feet, or over 12 miles, long, and is furnished with 14,000 to 15,000 hooks. The difficulty of hauling trawls in deep water (and they are used at depths of from 600 to 1,500 feet) is so great that boats are provided with little winches, known as hurdy-gurdies. Trawls were first used on the Grand Bank of Newfoundland by French fishermen and it was a long time before they were adopted by North American fishermen. Although usually allowed to rest on the bottom, the Italian fishermen use trawls having at alternate intervals a float and an anchor, this arrangement causing the main line to assume the form of triangles, the hooks at the base taking such fishes as dwell at or near the bottom, while those near the apex capture such species as swim nearer the surface. The terms trawl and trawling have such different significations in different localities that it is often necessary to specify just what is meant. In the U. S. trawl always means a long line as described above; in England it means beam trawl, a kind of net; and in Scotland trawling is applied to the use of haul-seines for catching herrings. Trolls, drails or trails are modifications of hand-lines used from boats in rapid motion for taking active, predatory fish, such as the bluefish and barracuda.

The hook either has its upper part imbedded in lead or tin, or has attached to it a piece of bone, bright metal, rag, or bait of some kind.

The most important nets are gill-nets and seines. These are both long, straight nets kept in a vertical position by having the lower edge weighted with lead or stones, while the upper edge is buoyed up by means of cork, wood, or glass floats. Glass floats, which are now so extensively used, seem to have originated in Europe, and as they are made of strong green glass in the shape of hollow balls and are covered with netting, they are extremely durable. They have the merits of never becoming water soaked, and of being much cheaper than cork floats of equal buoyancy. Gill-nets are either anchored in position or set across the current of moving water and allowed to drift with stream or tide, the object in either case being to capture fish by their becoming entangled in the meshes of the net. Gill-nets are used not only at the surface but at the bottom, as in the cod gill-net fishery, the sinkers used being sufficiently heavy to overcome the resistance of the floats. Or, as in the European herring-fishery, the upper rope of the net may be attached to buoys by ropes and lowered to any desired distance below the surface.

Seines are long nets which are drawn around a shoal of fish, or around a locality where fish are supposed to be, in order to surround them. When set from shore, one end of the net is fixed, while the other is carried around to form an immense circle, and then drawn in by man, horse, or steam-power, according to the size of the seine. Some of the Albemarle Sound shad-seines are nearly 1½ miles in length, while one used at Stony Point, on the Potomac, had a length of 3,400 yards, or nearly 2 miles. Seines are used in localities where the bottom is comparatively level and free from rocks or other obstructions, as otherwise, as the foot of the seine is dragged over the bottom, fish would escape beneath it or the net would be torn. In purse-seines, such as are used in the mackerel and menhaden fisheries, a rope is run around the bottom of the net in such manner that the lower part of the net can be drawn together so as to form an immense bag or pocket. Mackerel purse-seines are from 900 to 1,500 feet long and from 160 to 180 feet deep, and are naturally used only in deep water. They are not set directly from the vessel carrying them, but from large row-boats.

The beam-trawl, which is so characteristic of the North Sea fisheries of Europe, is a triangular, bag-shaped net, whose wide, open end is attached to a beam supported on iron runners. The lower edge of the bag is weighted, and, as the apparatus is dragged over the bottom of the sea, the low-swimming or ground-haunting fishes are swept up by it and pass into the hinder end, which forms a pocket from which they can not escape. A large trawl-net is about 80 feet long, and has a beam of 30 to 50 feet. The beam-trawl can be used to advantage only where the bottom is comparatively smooth, and it is particularly adapted for taking flat fishes. Related to the beam-trawl is the drag-net or paranzella of the Italian fishermen, now coming into use on the Pacific coast. This is a bag-shaped net with wings or leaders, but the upper edge is kept clear of the bottom by floats, and the net is extended by having the drag-lines attached to spars projecting from the sides of a boat. Or it may be dragged between two boats, or, even when small and used in shallow water, between two men.

The term traps includes a large number of devices, from small wickerwork affairs, constructed on the plan of a rat-trap, up to pound-nets and weirs and the deadly fyke-net. This consists of a rather long, cylindrical net, kept open by hoops, and terminating in a pocket entered by a funnel-shaped opening. From the open end of the net are stretched long, straight nets, termed leaders, their object being to *lead* the fish to the mouth of the trap. Fyke-nets are set at or near the bottom, being supported by stakes, and are very extensively used both on the coast and in lake fishing, being subject to almost endless modifications in the arrangement of pockets and leaders, according to the locality in which they are used and fish that they are intended to catch. Pound-nets are long, straight nets, usually leading from near the shore into deeper water, and having at the outer extremity a square or bag-like net so arranged that fish once within its bounds can not escape. Fish moving along the shore reach the leader, as the straight net is called, and follow it down to the trap. Pound-nets are set in water of moderate depth, rarely as much as 75 feet, and are supported by stakes. The leaders are from 500 feet to 1,400 feet long, and very long nets may have two or more pockets. Among the advantages of pound and fyke nets is the fact that the fish are kept alive and not lost if the fishermen are prevented by rough weather or other causes from visiting their nets regularly.

A weir is practically a structure on the principle of a pound net, built largely or entirely of stakes, boards, or brushwood. Weirs are generally used in salt water, where there is considerable rise and fall of tide, which allows such structures to be readily built, while the use of brushwood obviates the expense of a net. They are extensively used along the coast of New England.

Although limited in its use to rivers with a swift current, and practically restricted to the Columbia river, Oregon,

AMERICAN FOOD FISHES

the fish-wheel deserves mention from the ingenuity of its construction and its deadly effects. It is a large undershot wheel, whose buckets or floats are represented by large wire nets or scoops with their mouths facing down stream. As the fish come swimming up stream they are scooped up by the ever-turning wheel, and, as it revolves, tumbled out on an inclined plane and slide into a receptacle at its base.

While the cormorant can hardly be called a fish-trap, as is well known this bird is successfully employed in China and Japan for the capture of certain kinds of small fishes.

Spears, grains, or gigs of various patterns are used to a considerable extent for taking some fishes, and on the New England coast play an important part in the capture of flounders and eels. The use of spears for taking fish swimming at or near the surface, and the hook and line for catching those below it, are the most primitive methods, and the progress of a fishery is marked by the abandonment of devices for taking fish singly and the employment of nets and traps by which scores or thousands are caught at a time.

Fishing-gear of various sorts, such as trawls, nets, seines, and very often hand-lines, is tarred or tanned to preserve it from rotting, and especially in Europe the sails of fishing-boats are also tanned.

The subject of fishing-boats can not be treated in the same general manner as fishing-gear, for not only does each nation have its own types of vessels, but almost every locality has its own peculiar craft. In a very broad way the fore-and-aft rig may be said to be characteristic of North America, luggers of the north of Europe, and feluccas of the south of Europe. The schooner is pre-eminently *the* fishing-vessel of the U. S., and has been greatly improved in size, speed, and safety. Steamers are extensively used in the fisheries of Great Britain, and have been introduced on the Pacific coast of the U. S. They are important factors in the fisheries of the Great Lakes, and in the capture of menhaden along the coast. The majority of the British whaling-vessels and one-tenth of the whaling fleet of the U. S. are steamers, and the extensive seal-fisheries of Newfoundland are carried on by their aid.

Specific Fisheries.—The sharks (*Squali*) are regularly caught along the shores of Japan and at various localities in the East Indies, notably Kurachi, the fins being salted, dried, and exported to China, and the skin being used for the manufacture of fancy articles. Off the coasts of Norway and Iceland the sleeper-shark (*Somniosus microcephalus*) is systematically taken with hand-lines for the sake of its liver, which yields a large quantity of oil. During the winter, when the sharks approach the shore, the fishery is partly carried on in open boats; but in summer it is necessary to go farther from land, and schooners of from 20 to 80 tons are employed. The oil-shark (*Galeorhinus galeus*) is taken in some numbers on the coast of California, and quantities of dogfish (*Squalus americanus*) are captured on the New England coast with hand-lines and trawls for the oil yielded by their livers. Skates and rays (*Raiiæ*) are comparatively little used for food in the U. S. on account of their ugly appearance; but they are brought into some markets, and in 1889 the quantity brought into San Francisco was 75,000 lb., valued at $3,750. In many countries of Europe and Asia skates are more extensively used, *raie au beurre noire* being in France justly considered a delicacy; while in Japan, in addition to being eaten, the extremely rough skin of some species is in demand for covering boxes, sword-hilts, and other articles.

The chief species of sturgeons (*Acipenseridæ*) used for food are the Chinese sturgeon (*Acipenser sinensis*), the lake sturgeon of the U. S. (*A. rubicundus*), the California sturgeon (*A. transmontanus*), the Russian sterlet (*A. ruthenus*), and the common *Acipenser sturio* from Europe and Eastern North America. The flesh is used fresh and salted, but is rather coarse and oily. It is extensively used after having been smoked, when it is often sold as smoked halibut. The swimming bladders are made into isinglass, the roe salted into caviare, and the heads, skins, and refuse made into fertilizer. In the U. S. the most important fishery for sturgeon alone is on the Delaware, but vast numbers are taken on the Great Lakes, in connection with other fish. On the Delaware large gill-nets are used, but sturgeon are taken largely in pound-nets also. The Chinese have a barbarous and destructive mode of catching these fish, which they have introduced into California, by suspending bunches of barbless hooks at short intervals from a long line so hung as to just clear the bottom. The sturgeon catch on the hooks, and in their struggles to escape usually become caught in other adjacent hooks. The catch of sturgeon in the U. S. for 1888 was 11,031,539 lb., valued at $231,780, while the Dominion of Canada is credited with sturgeon to the value of $102,127.

The caviare manufactured in the U. S. is largely exported, one firm having shipped 50 tons in a single season. In 1885 477,020 lb. of caviare and 7,297 lb. of isinglass were made on the Great Lakes. In 1888 the product of caviare in the U. S., aside from the Great Lakes, was 318,960 lb.; value, $35,619. These figures seem small when compared with those for Russia, which exports caviare and isinglass to the extent of $1,500,000.

The catfish family (*Siluridæ*), although containing many species which are eaten, is rarely the special object of any fishery, its members being taken with other fish in pound and fyke nets. Small trawls, or trot-lines as they are termed, are, however, employed in some localities. The aggregate catch is large, that of the Great Lakes alone amounting in 1889 to 1,930,050 lb., worth $61,017, more than two-thirds coming from Lake Erie.

The suckers (*Catostomidæ*) are taken with other fish in pound-nets, but their flesh is as a rule so coarse and insipid that their market value is comparatively small, although with other "refuse" fish they form one of the sources of fish-oil. Neither can the carps (*Cyprinidæ*) be very highly commended as food-fishes, although the species are widely distributed, especially in the Old World. The common carp, however, is largely used, since it can be easily propagated on an extensive scale, and has for a long time been semi-domesticated in China and Germany, where it furnishes a cheap and abundant article of food. This species has been extensively introduced into the Southern and Western U. S., being particularly adapted to shallow, sluggish, and warm waters.

The herring family (*Clupeidæ*) is of great commercial importance, not only because many species are used as food, but because they furnish a part of the natural food of such fish as the cod and halibut, and are hence extensively used for bait in some fisheries.

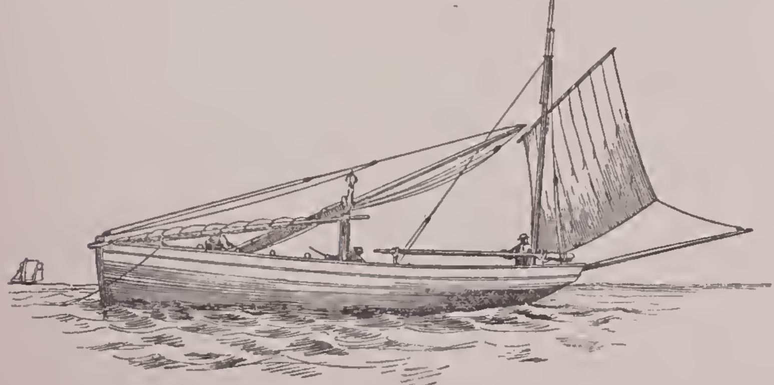
A prominent member of the herring family, and perhaps the most toothsome of all, is the shad (*Alosa sapidissima*), which occurs on the Atlantic coast of North America, from Florida to the St. Lawrence, and has been introduced into the Mississippi and some of the rivers of the Pacific coast. It ascends the rivers in spring to spawn and is taken in seines, gill-nets, or pound-nets, according to the abundance of fish and the conditions under which the fishery is carried on. An allied species is taken in the Yang-tse-Kiang, China, and two others, the allice shad (*Alosa alosa*) and twaite shad (*A. finta*), ascend the rivers of Europe. None of these, however, equal in flavor or importance the American fish. The alewife, often termed herring or branch-herring (*Clupea vernalis*), is the object of extensive fisheries from Maine to North Carolina, being taken with seines, pound-nets, and in some small streams even with dip-nets. Two allied species of much less importance are *Clupea æstivalis* and *C. mediocris*. The alewife is salted on a large scale, used fresh and smoked. The catch for 1888 was 46,601,167 lb., worth $505,281.

The sea herring (*Clupea harengus*), the herring *par excellence*, is taken abundantly on the northwestern shores of Europe and on the coast of North America from Maine to Labrador. This fish is found during the spawning season in such vast shoals that 1,000 barrels are sometimes taken at one haul of a seine. The frozen-herring trade is peculiar to North America, the fish being taken in winter on the coasts of Newfoundland, New Brunswick, and Nova Scotia, frozen solid, and transported to the U. S. where they are used as food, and for bait in the winter cod-fishery. The trade is financially somewhat hazardous from the fact that while herrings may be abundant at the fishing-stations, if the weather is mild they can not be frozen, and, on the other hand, the temperature may be low and fish totally lacking. Artificial freezing has, however, been successfully accomplished. In 1889 forty-six U. S. vessels brought to the New England States 22,524,000 lb. of frozen herring, having a value of $279,297. An important use of herring in the U. S. is in the preparation of "sardines," these being simply small herrings cooked and put up after the manner of the true sardine (*Clupea pilchardus*), a fish which occurs in the Mediterranean and on the western coast of Europe. This industry, which is chiefly carried on in the eastern part of Maine, ranks first among the shore fisheries, the product in 1889 being valued at $1,676,105. The Canadians also have interested themselves in the "sardine" industry, and the product of their canneries for 1891 amounted to $71,412. Incidentally, canned herring appear under the disguise of "brook trout." The majority of small herring as well as many others are taken in weirs built of brush, but seines and gill-nets are extensively used, and in some localities numbers are taken at night by "torching." In "torching" a boat is provided with an iron frame projecting from the bow in which a fire is kindled. The fish are attracted by the light, and scooped up with a dip-net as the boat is rowed rapidly forward. The bulk of the herring catch is disposed of fresh, but vast quantities are also smoked or salted, and in this form exported, largely to Europe.

While the herring-fisheries of North America are to a great extent shore-fisheries, those of Great Britain, Norway, and Sweden are mostly carried on from boats, and the herring are taken almost exclusively in gill-nets by the method known as drift-net fishing. Some fishing has been done with seines on the west coast of Scotland, but has always met with bitter opposition from the majority of the fishermen. The boats employed in drift-net fishing vary in size and rig according to locality, but those of the first-class are luggers of from 15 to 20 tons and decked over. Several nets are used, fastened to one another in a long line, 80 to 130 nets being used, the whole forming a "train" a mile to a mile and a quarter in length. As the floats on the upper edge of the nets are not sufficient to support them they are attached to buoys by ropes varying in length according to the depth at which the fish are supposed to be swimming. A strong rope or warp is fastened to the lower edge of the nets for the purpose of hauling them in, as well as to secure the nets in case the upper part should be torn by a passing vessel. The foremast is lowered in order that its weight may not add to the rolling of the vessel, and the boat rides by the warp with just enough sail set to steady her.

Yarmouth, which furnishes large quantities of red herrings, besides the well-known "bloaters," is the chief port of the English herring-fishery, and Lowestoft comes next in importance. Scotland exports large quantities of pickled or white herring, and Ireland has a herring-fishery which in ordinary years excels that of the New England States. It requires the aid of figures to convey an adequate idea of the importance of the herring. Great Britain takes herring to the value of $8,584,908, Norway to the value of $3,000,000, France reports a catch worth $1,969,600, and Holland $1,600,000, while $1,000,000 is a low estimate for Denmark, Russia, and Germany. The British provinces of North America are credited with herring to the extent of $2,639,000, and New England with the comparatively low sum of $330,000, making in round numbers an aggregate of $19,125,000, an amount well within the mark.

The true sardine (*Clupea pilchardus*), known in England as the pilchard, and the well-known sprat (*C. sprattus*) are also important members of the herring family, and another



Lowestoft herring-drifter.

species (*C. toli*) occurs abundantly on the coast of Sumatra, 14,000,000 or 15,000,000 being taken annually, the fish being dried and the smoked roes exported to China. Local but comparatively undeveloped herring-fisheries also exist in the vicinity of the Canary islands. The abundance of sardines may be inferred from the fact that the Spanish fishermen take annually about 100,000 tons of these little fishes, having a value of from $400,000 to $600,000. A peculiar method of capturing sardines at night prevails in the Adriatic. The location of the shoals of fish is literally felt out by a light sounding-line, and by means of the attraction of a fire of resinous pine the fish are slowly coaxed into some creek or estuary and surrounded with a seine. The demand for wood for use in this and other night fisheries causes a serious drain on the pine-forests around the shores of the upper Adriatic.

Another valuable member of the herring tribe is the menhaden, mossbunker, or porgy (*Brevoortia tyrannus*), which is the object of important fisheries peculiar to the Atlantic coast of the U. S., New York, Connecticut, and Rhode Island being foremost in this field. The menhaden is very erratic in its movements, as is well shown by the Maine fishery, which, formerly prosperous, was practically abandoned between 1880–86 owing to absence of fish, and is again assuming considerable proportions. Menhaden approach the coast in immense shoals, swimming at or near the surface of the water, and great numbers are taken in purse-seines, although pounds and weirs play an important part, and gill-nets are also used, especially by the smaller craft. One peculiarity of the menhaden-fishery is the employment of steamers, which have great advantages over sailing craft, not only in cruising for fish but in transporting them to the factories where they are ground and pressed. A small portion of the catch is used fresh, canned, or salted, but most of the fish are used for the manufacture of oil and fish guano, this being particularly rich in nitrogen. In 1888 55 steamers and 66 sailing vessels were engaged in the menhaden fishery; the products were 2,818,097 gal. of oil and 918,211 tons of scrap; total value, $2,393,629.

The members of the salmon family (*Salmonidæ*) are mostly confined to the northern hemisphere, and many species are anadromous, residing the greater portion of their time in the sea, but ascending rivers to spawn. Large numbers of salmon are taken with gill-nets and traps in Great Britain, Norway, Russia, and other parts of Europe, and there are extensive fisheries in Eastern Asia, including Japan. A small number of salmon are taken in Maine, many more in the British provinces, but the most valuable of the salmon-fisheries are on the northwest coast of North America, and especially on the Columbia river.

The most important species is the quinnat or king salmon (*Oncorhynchus chouicha*) but the blue-back salmon (*O. nerka*), and the white salmon (*O. kisutch*), and Gairdner's trout (*Salmo gairdneri*), are also commercially valuable. The fish are taken on their run up the rivers by gill-nets, seines, pound-nets, traps, and fishing-wheels, and are chiefly used for canning, "Columbia salmon" being exported to all parts of the world.

The extent of this industry is shown by the fact that in 1888 the value of salmon canned in the Pacific States was $3,703,838. In 1891 the Dominion of Canada reported salmon canned to the value of $1,522,508, nearly all from British Columbia.

The future of these great salmon-fisheries appears to depend largely on the possibilities for artificial propagation on an extensive scale, coupled with rigid protective laws, appliances for taking fish having so multiplied that the salmon have decreased in an alarming manner. The value of protection is well shown by a comparison of the returns from the salmon-fisheries of Great Britain with those for the Eastern U. S., where salmon were formerly abundant. The reports of England and Wales for 1887, and of Scotland and of Ireland for 1888, show that the value of salmon taken was respectively $464,095, $1,166,490, and $1,622,987, the total $3,253,572, nearly equaling the value of the product of the Pacific coast fisheries of the U. S. In 1889 the salmon-fishery of the Eastern U. S. yielded $34,118, all but $288 worth coming from Maine. In 1891 Canada and Newfoundland took salmon of the value of $1,712,762, exclusive of salmon used for canning.

The smelt (*Osmerus mordax*), although but a small relative of the salmon, is of considerable importance, the catch of this little fish in the rivers of Maine alone amounting in 1889 to 1,055,385 lb., worth $74,977, while the catch of salmon was but 152,740 lb., worth $34,118. The figures for Canada are even more striking, being $298,951 for the same year. The smelt occurs on both coasts of North America in cold waters and is taken in weirs, by small seines, dip-nets, and hook and line.

The eulachon, or candle-fish (*Thaleichthys pacificus*), and the surf smelt (*Hypomesus pretiosus*) are two abundant and toothsome relatives of the smelt, found on the northwest coast of North America. Another valuable little fish is the capelin (*Mallotus villosus*) which occurs in vast numbers on the northern shores of the Atlantic and Pacific during the spawning season. Although it is dried in great quantities for winter's use both in Kamchatka and on the shores of the U. S., the importance of the capelin is largely due to the fact that it furnishes subsistence to the cod and halibut, and at certain seasons is extensively used as bait for taking those fishes. The whitefishes (*Coregonus*), of which about forty species are known from the lakes of north temperate Europe, Asia, and America, are prized for food, and are the objects of numerous local fisheries with seines, pounds, and gill-nets. The pollan (*Coregonus pollan*) of the Irish lakes is, at the spawning season, very abundant, and the cisco or lake herring (*Coregonus artedi*) of the Great Lakes sometimes occurs in such enormous numbers that the pound-nets are completely filled with them.

The most valued species, however, is the whitefish of the Great Lakes (*Coregonus albus*), of which 15,326,488 lb., worth $691,563, were taken in 1889 by fishermen of the U. S., while the catch of the Dominion of Canada amounted to $685,096. This fish is unfortunately decreasing to a serious extent, probably on account of over-fishing, for the catch of 1880 was more than 6,000,000 lb. greater than that for 1889, and this, too, with a less number of fishermen and appliances.

The pike family (*Esocidæ*) furnishes a limited number of edible species which are taken with other fish in pounds and fyke-nets, to some little extent with trolling-gear, and in winter are caught through the ice on lines baited with minnows, or speared. The pike (*Esox lucius*) found in Europe, Asia, and North America, is the most abundant species, while in North America the pickerel (*Esox reticulatus*), and to a less extent the muskellunge (*E. nobilior*), come into market also.

The eels (*Anguillidæ*) comprise several locally important species, among them the great conger (*Conger conger*), a fish of rather wide distribution, which is taken, as on the coast of England, with hand-lines or with trawls. The common eel (*Anguilla rostrata*) is taken in great numbers, both in Europe and the U. S., by means of close wickerwork traps, made on the principle of a rat-trap, while on the New England coast many eels are caught with long-handled spears while hibernating in the mud. In European markets eels are customarily kept alive. Sweden has important eel-fisheries, those of Blekingen and Schonen literally netting $40,000 annually, and so has Italy, the eels being caught in the numerous lagoons along the coast. In the U. S. the catch of the eel-fisheries of the Atlantic coast amounts to about 3,500,000 lb., worth $223,323.

The swordfishes (*Xiphiidæ*), although large and good eating, whether fresh or salted, are, except in a few localities, not sufficiently abundant to be the objects of regular fisheries. On the New England coast, however, they are taken with the harpoon from small schooners, while on the coasts of Greece and Sicily they are pursued and harpooned from large row-boats or caught in strong gill-nets. The Italian boats have, or had, a long projecting figure-head, like the sword of the fish they seek for. The product of the New England fishery for 1889 was 1,230,339 lb., worth $55,242.

The representatives of the mackerel family (*Scombridæ*) are widely distributed in temperate and tropical waters, the most valuable species (*Scomber scombrus*) occurring in great shoals upon the coasts of Europe and eastern North America. Although in the U. S. the hook and line fishery for mackerel has practically given way to the big purse-seine, by means of which many barrels of fish are taken at a single haul, it is still carried on along the coast, and deserves at least a brief description. The peculiar hooks, known as "jigs," have the shank embedded in a cylindrical, tapering piece of lead, tin, or pewter, and are baited with strips of fresh mackerel. The fish are attracted to the surface of the water by throwing out quantities of finely ground menhaden, termed chum, whose oily portion spreads over the water, while the heavier particles sink. If hungry, the mackerel will follow up the chum, and are then attracted by the baits on the jigs and by the glitter of the jigs themselves. Each man has two lines, which are alternately thrown out and drawn in, the work when in a large school of hungry fish being very lively. Some mackerel are taken on the coast of the U. S. with gill-nets, and this mode of fishing is the one chiefly relied upon by European fishermen, the mackerel being taken like herrings by drift-net fishing. The train of nets employed often reaches the enormous distance of 2 miles. In Europe the catch of mackerel is little more than sufficient to supply the demand for the fresh fish, but in the U. S. a large proportion ot the catch is salted. England has mackerel-fisheries to the value of $853,835, and the figures for Ireland reach the sum of $1,062,745, but the Dominion of Canada leads with canned mackerel worth $19,917 and salt mackerel to the extent of $1,949,654 The mackerel-fishery of the U. S. is practically confined to the New England States, which in 1889 produced 3,074,441 lb. of fresh mackerel and 5,286,967 lb. of salt, worth respectively $256,550 and $474,874.

The huge tunny, horse-mackerel, or albacore (*Orcynnus thynnus*), which often attains a weight of half a ton, is taken in considerable numbers in the Mediterranean, chiefly along the shores of France, Spain, and Italy. It is also taken on the coast of Portugal and the Atlantic coast of France, while it is one of the most common and largely consumed fishes of Japan. On the Atlantic coast of the U. S. the tunny is frequently taken in weirs, but is deemed of comparatively small value, and was formerly usually thrown away. The catch for 1889 in New England amounted to but 74,000 lb., with a value of only $291. These figures are insignificant when compared with those for Portugal, which exports about 500,000 lb. of prepared tunny, worth over $57,000.

The bonitos, which belong in the mackerel family, are mostly deep-water fishes of warm seas, but they are taken in some numbers with hook and line, and combine with other species to swell the total of "miscellaneous fish." Nearly related to the mackerel are the crevalles (*Carangidæ*), among which is the delicious pompano (*Trachynotus goreensis*) of the West Indies and South Atlantic and Gulf States; these too are mostly caught with hook and line.

The Spanish mackerel (*Cybium maculatum*) occurs in the warmer waters on both sides of North America, and is highly esteemed as food; it is taken in seines, pounds, and gill-nets, and also to some extent with hook and line, and its relative, the kingfish (*Cybium regale*) of the Southern States and West Indian waters, is caught with trolling-gear.

The gray mullets (*Mugillidæ*), found in brackish waters or along the coasts in warm latitudes, furnish a number of important species, two of them (*Mugil albula* and *M. brasiliensis*), being of special importance in the Southern U. S., where great numbers are taken with cast-nets and seines. In Italy mullet-roes, salted and dried, are considered as delicacies, and this industry is being carried on to some extent in the U. S., the product for 1888 being 138,800 lb., worth $7,112. The catch of mullet for that year amounted to 9,752,107 lb., with a value of $227,798, more than two-thirds of this being credited to Florida. The fishermen of the Adriatic take mullet, like herrings, by "torching," the fish in their eagerness to reach the light actually leaping into the boats.

The bluefish (*Pomatomus saltatrix*), although widely distributed in the warm portions of the Atlantic and Indian Oceans, is of little commercial importance except on the coast of the U. S., where it has become very abundant. The bluefish is caught to a considerable extent in pounds and gill-nets, but probably more than half of the entire catch is taken on hand-lines by trolling from sail-boats. In 1888 13,416,389 lb. of bluefish were taken, having a value of $664,862, over half of this coming from New Jersey and New York.

The fresh-water bass and perch, contained in the families *Centrarchidæ* and *Percidæ*, are the objects of lake and river fisheries carried on largely by pound and fyke nets, and partly by seines and hand-lines. Among the more important species taken are the black bass (*Micropterus salmoides* and *M. dolomieu*), the grass bass (*Pomoxys sparoides*), the black gills (*Lepomis pallidus*), the yellow perch (*Perca fluviatilis*), common to both Europe and North America, the pike perch (*Stizostedium americanum*), and the European zander (*Lucioperca zandra*).

The sea-bass family (*Serranidæ*) includes such forms as the striped bass (*Roccus lineatus*), a well-known and important food-fish of the Atlantic coast of North America and its European ally, *Roccus labrax*, the white perch (*Morone americana*), taken abundantly in the estuaries of the eastern coast of the U. S. south of Cape Cod, and making up in numbers what it lacks in size, and the black sea bass (*Serranus atrarius*). In this family, too, are found the "groupers" of the Southern U. S., among them the huge jewfish (*Epinephelus nigritus*) and the guasa (*Promicrops guasa*), which respectively attain weights of 300 and 500 lb. The "groupers" are taken with hook and line on rocky reefs, and on the Florida coast are caught extensively for the Havana market. The fish are kept alive in wells, and at Key West and other ports are transferred to floating cars until wanted.

Closely related is the snapper family (*Sparidæ*), a group of marine fishes which includes the gamy and well-flavored red-snapper (*Lutjanus blackfordi*) and sheepshead (*Diplodus probatocephalus*). In 1888 the catch of the red-snapper amounted to 4,022,266 lb., worth $118,575. The other members of the group, although mostly small, are largely used for food. Among them are the snapper of Australia (*Pagrus unicolor*), an important food-fish, the sargo of the Mediterranean, and the sailor's choice (*Pomadasys fulvomaculatus*).

The true mullets (*Mullidæ*) are marine fishes of warm or tropical waters, whose most important member is the red-mullet of the Mediterranean (*Mullus barbatus*). The ancient Romans paid fabulous prices for this fish, and it is still considered a delicacy.

The drums (*Sciænidæ*) form an important family of edible fishes, including many large species, whose members with a single exception dwell in salt water and in warm regions. As they frequent rocky places, keep near the bottom, and, as a rule, do not go in shoals, they are mostly taken by hand-lines. The squeteague, or weakfish, or trout (*Cynoscion regale*), and sea trout (*Cynoscion maculatum*), of the Atlantic coast of the U. S., however, are largely taken in seines and weirs, and are valued not only for their flesh but for their sounds (swimming bladders), which furnish a fine quality of isinglass. The red-drum (*Sciænops ocellata*) is a valued fish of the Southern waters of the U. S., and the king-fish and whiting (*Menticorrus nebulosus* and *M. alburnus*), which are taken in nets, rank in flavor next the pompano and sheepshead. The catch of these two species amounted in 1889 to 12,146,000 lb., which brought $413,000.

The maigre (*Sciæna aquila*) and the corvo (*Umbrina cirrhosa*) are caught on the European coasts, the former occurring also at the Cape of Good Hope and on the coast of Southern Australia.

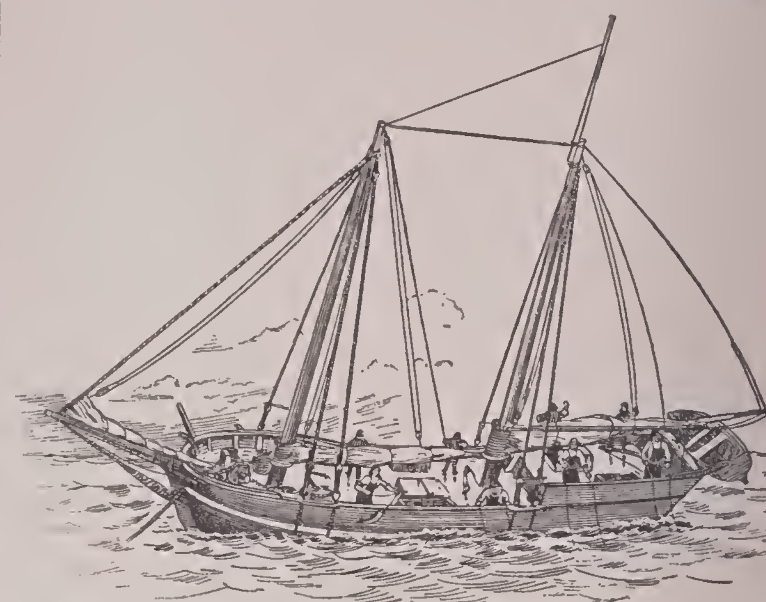
The wrasses or rockfishes (*Labridæ*) comprise nearly 500 species, mostly tropical, inhabiting rocky shores, where they feed on mollusks. Many of the species especially those brightly colored, are dry, but others, like the tautog or blackfish (*Tautoga onitis*) and cunner (*Ctenolabrus adspersus*), are excellent pan-fish. Of these two fish, well known along the New England coast, the catch for 1889 was reported at 557,195 lb. of tautog, worth $22,451, and 1,072,630 lb. of cunners, valued at $43,417. The scare of the Mediterranean (*Scarus cretensis*), the butterfish of New Zealand (*Coridodax pullus*), and the hogfish of the Gulf of Mexico (*Lachnolæmus falcatus*) are important forms. The parrot-fishes (*Pseudoscarus*) attain a considerable size, but unfortunately the flesh of these is sometimes poisonous. The rockfishes are largely taken with hand-lines, but the clap-net is also used to advantage in their capture, while in some localities pounds and gill-nets and occasionally seines may be used.

The rockfishes (*Scorpænidæ*) are residents of temperate or cold seas, often found at considerable depths, and are taken with hand-lines or trawls. The rosefish or Norway haddock (*Sebastes marinus*) is of considerable importance in Greenland and Northern Europe, and is also caught to some extent by fishermen of the British provinces and Northern New England. The group is particularly well represented in the North Pacific, between twenty and thirty species occurring on the northwest coast of North America, the rock-fish brought into San Francisco alone in 1888 amounting to 860,000 lb., with a retail value of $68,000.

The cultus cod (*Ophiodon elongatum*), a large fish reaching a weight of 30 or 40 lb., belonging to the allied group of *Chiridæ*, is an important fish of the North Pacific.

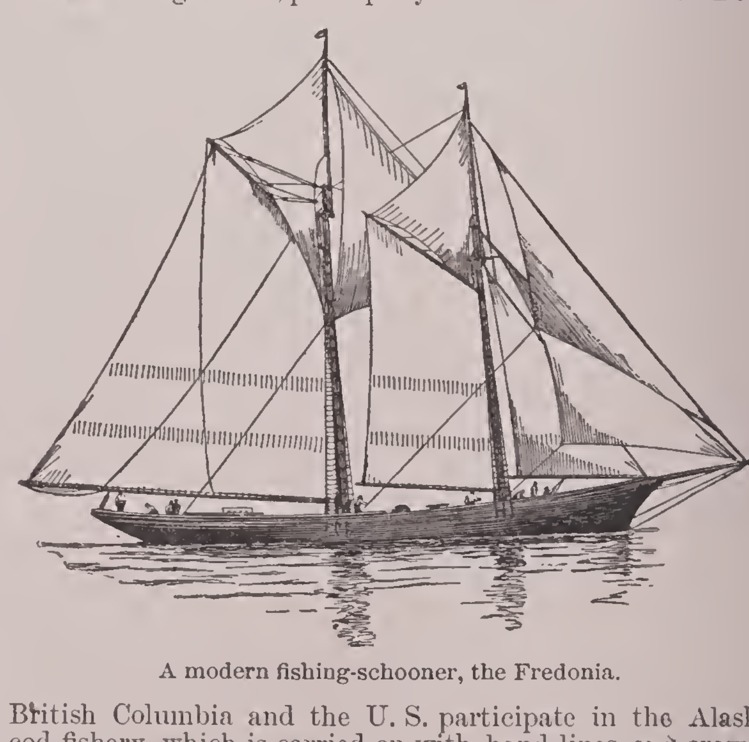
The cod family (*Gadidæ*), commercially the most important among fishes, is mainly confined to north temperate and arctic seas, being well represented both in the North Pacific and North Atlantic Oceans. Its leading member is the common codfish (*Gadus morrhua*), which has for centuries been the object of extensive fisheries along the northern shores of Europe and America, on the Grand Banks, near the Lofoden islands, and on the shoals of the German Ocean. The enterprise of the early fishermen is well shown by the fact that those of Normandy, Brittany, and the Basque Provinces visited Newfoundland in 1504, only seven years after the discovery of the island, while by 1578 not less than 400 sail of Spanish, French, and English vessels were engaged in the Newfoundland fisheries. The cod-fishery of eastern North America may be divided into the bank and inshore fisheries, the former being carried on by vessels of from 50 to 125 tons, and supplying the bulk of the salt fish, the latter being prosecuted from smaller craft, in some parts of the British provinces even from row-boats. In the British provinces the larger part of the fish taken inshore are salted, while on the coast of the U. S. the inshore fishery supplies a great part of the fresh fish for market.

Prior to 1860 the bank fishery was carried on by clumsy craft of 40 to 70 tons, and the fish were taken from the vessel, using salt clams or salt mackerel for bait. The schooners anchored on the banks, and remained in one place so long as fish bit well. Since 1860 larger and faster vessels have been introduced and trawls employed, or where hand-lines are used they are used from small flat-bottomed boats



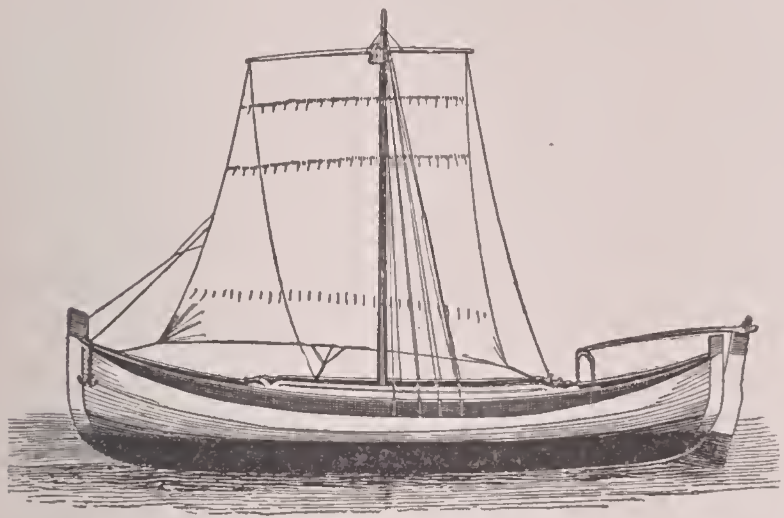
Bank fishing-vessel of the old type.

termed dories, which are eminently characteristic of the New England fisheries. Trawls are used in deep water, hand-lines where it is under 300 feet, and the bait is frozen herring, salt herring or mackerel, capelin, or squid, according to season. The fish are split, cleaned, and salted on board the fishing-schooners, the drying being done on the return of the vessel to a home port. The George's Bank cod-fishery is, in winter, one of the most hazardous of occupations, and is carried on by stanch schooners of 50 to 75 tons. The fish are taken with hand-lines, one to a man, directly from the vessel, and the gear is of the heaviest character on account of the rapid tides on the shoals. The line is steam tarred, 900 feet long, provided with two hooks and a lead weighing 8 or 9 lb. A considerable number of halibut are taken in connection with this fishery; these are packed in ice, but the cod are split and salted. Hand-lines and trawls are used in the inshore cod-fishery, and some cod are taken in gill-nets, principally when bait is scarce. Both



A modern fishing-schooner, the Fredonia.

British Columbia and the U. S. participate in the Alaska cod-fishery, which is carried on with hand-lines and trawls. This latter gear can not be used in some localities owing to the abundance of sea-fleas (*Amphipods*), which swarm over the bait and eat holes in the cod after they have been hooked. The cod-fisheries of Norway and Sweden are mainly carried on with hand-lines and gill-nets from large, open boats, and the catch per man is small when compared with that of the U. S. The fish are extensively dried, forming the stockfish of commerce. The English cod-fishery is peculiar in that the fish—taken with hand-lines or trawls—are to a great extent brought to market alive. This is effected by transferring the fish when caught to a "well," this being a portion of the vessel's hold, separated from the rest by transverse, water-tight partitions, to which water is freely admitted by holes in the bottom. A vessel thus provided is technically known as a smack.



Norwegian fishing-boat.

While the English fish are mostly used fresh a large portion of the catch of Scotland is dried.

France has important cod-fisheries about Newfoundland and Iceland, the former employing about 180 vessels and 7,200 men, the latter 240 vessels and 4,300 men. These fisheries have been looked upon as training-schools for the French navy, and are subsidized to the extent of 60,000,000 to 80,000,000 francs. Holland, too, carries on a cod-fishery, and many of the boats which are engaged in summer in catching herring are employed during the winter in taking cod on the Dogger Bank.

The value of fish taken by the countries most extensively engaged in the cod-fishery is as follows: Newfoundland (1891), \$5,092,623; Dominion of Canada (1890), \$3,827,708; U. S. (1889–90), \$2,760,000; France (1890), \$2,645,412; Great Britain (1887), \$1,853,197; Norway and Sweden, \$1,500,000; Holland (1886), \$291,600: total, \$17,970,540.

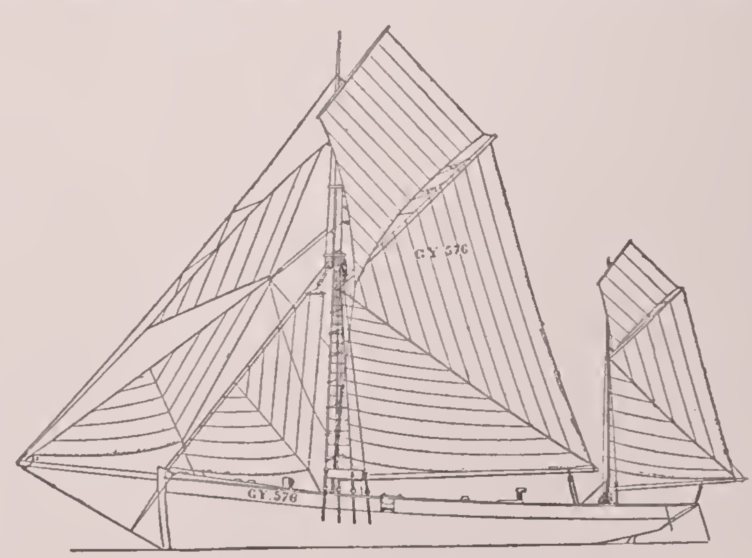
The haddock (*Melanogrammus æglefinus*), the hakes (*Phycis*), the cusk (*Brosmius brosme*), the pollack (*Pollachius carbonarius*), and the tomcod (*Gadus tomcodus*) are important food-fishes of the North Atlantic, while other allied species are found in the North Pacific. Some of these fishes, notably the hakes, are largely used in the manufacture of "boneless codfish," while the haddock produces the Scotch Finnan haddies (so-called from the town of Findon), which owe their flavor to the peat-smoke with which they are cured. The air-bladders of the cod and its relatives are salted as sounds, or made into isinglass, the tongues are looked upon as good eating, cod-liver oil is used according to its purity in medicine or in manufactures, and the skins yield a valuable quality of glue. The roes of some are used for bait, and have even been utilized as a source of albumen for the manufacture of sensitized paper. The importance of the so-called secondary products of the fisheries may be appreciated from the fact that one firm engaged in the manufacture of glues used in one year nearly 2,000 tons of fish waste, and produced about \$180,000 worth of material.

The family of flatfishes (*Pleuronectidæ*), from its wide distribution and the size and flavor of most of its members, is commercially an important one. The giant of the family is the halibut (*Hippoglossus vulgaris*), which not infrequently attains a weight of 250 lb., and is found in both the North Atlantic and North Pacific. It has been said of the halibut-fishery that "there is no other food-fishery in the world in which fish are sought at so great a depth," and this can easily be realized when it is stated that trawls are habitually set in water 600 to 1,200 feet deep, while halibut have even been taken at depths of 3,000 and 4,000 feet, three-quarters of a mile. The largest and fastest fishing-schooners are used in the fresh-halibut trade of the U. S., and the fish, which are taken on the outer slopes of George's Bank, the Grand Bank, and other noted grounds, are packed in ice and brought to market with all possible speed, sail being carried to the utmost, winter or summer. For the smoked-halibut trade, in which the fish are dressed and salted before being taken to home ports, schooners resort to the more distant portions of the Grand Banks, to the west coast of Greenland, and even to the distant shoals about Iceland. Halibut are continually becoming scarcer, and although they were formerly abundant in Massachusetts Bay and were regarded as a nuisance on George's Bank, it is now necessary, as stated above, to go long distances in search of them and to fish in deeper and deeper water. In spite of all exertions, the catch of halibut for 1889, by vessels from New England ports, although amounting to 10,740,843 lb., worth \$723,002, was nearly 4,000,000 lb. less than the catch for 1879. This loss was partly compensated for by the growth of the Pacific fishery, the State of Washington taking 1,220,000 lb.

The Greenland turbot (*Platysomatichthys hippoglossoides*) is a fine large fish which is brought to market in winter, in limited numbers, by vessels engaged in the frozen-herring trade, and another large species, the Monterey halibut (*Paralichthys californicus*), is an important food-fish on the Pacific coast of the U. S.

The numerous and smaller flatfishes, commonly known as plaice and flounders, found along the shores of the U. S., are taken by almost every kind of apparatus, the special sort employed depending on the local conditions under which the fishery is prosecuted. In Maine the majority are caught by haul-seines, while in Massachusetts pounds and trap-nets take the lead. Flounders are among the few fishes in whose capture spears play an important part, several hundred thousand pounds of these bottom-haunting fish falling victims to these instruments.

In European waters the turbot (*Rhombus maximus*) is held in high esteem, and is taken on hand-lines as well as by beam-trawls. This latter piece of apparatus is the chief means of capturing the various flatfishes of the North Sea, among them the justly celebrated sole (*Solea vulgaris*), a species not found on the North American coast. Great Britain leads in the beam-trawl fishery, the value of her catch being \$13,000,000, or between one-third and one-half the total product of all her fisheries. The bulk of the fish thus taken are naturally flatfishes, but whiting (*Gadus merlangus*), haddock, skate, and other species are caught in considerable numbers.



A Grimsby trawler.

The beam-trawl fishery is carried on mainly by stanch cutters and yawls of from 25 to 50 tons, but steamers of from 40 to 120 tons are also used and possess great advantages over sailing vessels, not only in towing the nets but in heaving them up. The task of hauling up the beam-trawl by hand-power is extremely laborious, and under the most favorable conditions takes from three-quarters of an hour to an hour, while in rough weather it may take even two or three hours. The steam trawler does the same work in from fifteen to thirty minutes. In order to avoid the loss of time that would be occasioned by each boat bringing home her catch steam carriers are employed which regularly collect the fish from the various vessels and transport them to market. France, Belgium, and Germany all participate in the beam-trawl fishery, and Holland, the originator of the apparatus, has quite a number of vessels so employed, among them some of the most peculiar craft that float. The low, sandy shores of the Netherlands call for vessels of light draft, while the lack of good harbors makes it desirable to have boats that can be drawn out on the beach. These conditions have given rise to the *bomschuit*, a stout, almost flat-bottomed craft, blunt at either end and more than half as broad as long, furnished with lee

A Dutch bomschuit.

boards and capable of being run on the beach and dragged out by oxen, to be dragged down again at low tide when wanted.

The flatfishes conclude the list of edible fishes, and it remains only to show some of the total results of the fisheries, and in the most general way to note some of the causes affecting them.

The following table shows the total value of the fisheries of some of the most important maritime nations, but it should be said that owing to the difficulty of gathering fishery statistics the figures can not be implicitly relied on. The reports of the U. S. and of France are very complete, but the returns for the Dominion of Canada and for Great Britain are avowedly incomplete in details. The official estimate of the fisheries of the United Kingdom for 1890 was £5,815,000 ($28,260,900). Dr. G. Brown Goode's estimate in 1883 was $40,000,000, and $32,000,000 is doubtless safe.

Total Value of Fisheries of all Kinds.

New England States	$8,133,600
Middle Atlantic States	10,550,640
Southern Atlantic States	11,601,760
Gulf States	2,438,675
Pacific States	6,387,805
Great Lakes	2,615,785
Other inland Fisheries	1,400,000
Total for U. S.	$43,128,265
Great Britain	$32,000,000
Japan	26,000,000
Russia	22,000,000
France	21,256,292
Dominion of Canada	18,977,878
Norway	8,000,000
Newfoundland	6,679,574
Portugal	3,400,000
Spain	2,500,000
Holland	2,225,000
Sweden	2,300,000
Italy	1,216,000

Dr. Goode's estimate of the total value of the fisheries of the world is $420,000,000.

The value assigned the fisheries of Japan seems high, but the Japanese both consume and export large quantities of fish, and not only carry on fisheries along their own coast, but along the adjacent shores of Asia, a fleet of some 4,000 boats being employed on the Korean coast alone, the annual catch being worth from $1,320,000 to $1,760,000. About 187,000 boats and over 1,500,000 people are said to be employed in the Japanese fisheries, but of this latter number only one-third are *bona fide* fishermen, the balance being engaged as helpers or in the preparation of fishery products.

China has vast fishing interests, and is extensively engaged in taking cuttlefishes, the city of Ningpo alone having 1,200 boats thus employed. It may be said, in passing, that cuttlefishes are coming into use in the U. S., and that there is a demand for them not only among the Chinese of the Pacific coast, but in the Eastern markets. The high rank of France is partly due to the extent of the subsidized cod-fisheries and partly to extensive and successful oyster cultivation.

Norway is peculiar from the fact that a comparatively small portion of the products of her fisheries is consumed at home, very nearly 80 per cent. being exported.

The fisheries of New Zealand and Australia are being rapidly developed, and, although confined to supplying the local markets, will undoubtedly attain considerable proportions. The Dutch East Indies have large local fisheries, Java and Madura counting about 50,000 fishermen, and the Philippine islands export great quantities of trepang (dried sea-cucumbers), pearl shells, and shark-fins, mainly to China.

The figures for the U. S. are smaller than they were ten years previous, partly owing to certain differences in the manner of tabulating the value of the products of the fisheries, and partly on account of a falling off in certain fisheries, notably in those for fur seals, whales, and mackerel. The returns from the New England and Southern Atlantic States are less than in the last decade, but other sections of the country have gained. Increase in the value of total catch does not, however, always indicate a desirable state of affairs, as it may be due to increase of apparatus, or to the taking of undersized fish, or those which have become marketable through the absence of larger or better species. The reports for the U. S. show that the percentage of increase in value of fish taken is proportionately much less than the increase in the amount of capital invested, although greater than the increase of men employed.

There is a steady growth in the value of the secondary products of the fisheries by the utilization of refuse in the manufacture of glue, oil, and fish guano, although unfortunately, and often unavoidably, large amounts of material still go to waste. Improved methods of transporting and handling fish, such as the use of steamers, fast-sailing vessels, refrigerator cars, and warehouses, have been important factors in the development of many fisheries, the one by speedily carrying the fish from their place of capture to the points of distribution, the other by keeping them in good order while in transit. The red-snapper furnishes a good illustration of these facts, for while in 1880 it brought $1 to $1.50 per lb. in New York markets, it can now be purchased for 15 cents. This is partly due to better knowledge of the fishing-grounds, but without facilities for transportation the catch could not have been utilized.

What the fisheries of the U. S. most need is not development but conservation. Halibut have grown scarce on the more accessible grounds; the supply of lobsters has in some localities dwindled; and the seemingly inexhaustible beds of oysters in Chesapeake Bay have become greatly depleted. The salmon has almost disappeared from the waters of the Eastern U. S., and, from the Potomac northward, the shad would have followed the salmon but for the efforts of the U. S. Fish Commission.

Anadromous fishes are often practically prevented by a multiplicity of nets from reaching their spawning-grounds; fishing is carried on at seasons when it should be prohibited; and fine-meshed nets are used which take fishes so young as to be of little or no value.

The erection of dams and the pollution of water by mines, manufactories, and sewage are other, and often preventible, causes for the decline or ruin of some fisheries.

Much of this might be remedied by good laws well enforced, but unhappily the fishermen who would be most benefited are too often bitterly opposed to any laws for the protection of fisheries, and they are carried on in a wasteful and destructive manner.

It is by fish-culture only that many of the fisheries of the U. S. can be preserved, and while its effects are most readily appreciable in lakes and rivers, there is good reason to believe that some coast fisheries, like those for lobsters and cod, may be sensibly benefited.

LITERATURE.—The various reports and bulletins of the U. S. Fish Commission contain a vast amount of information, including statistics relating principally to the fisheries of the U. S., but also contain many facts pertaining to those of other nations. The series of quarto volumes, *Fishery Industries of the United States*, prepared through the co-operation of the U. S. Commissioner of Fisheries and the Superintendent of the Tenth Census, forms an exhaustive treatise on the subject. The fisheries of Great Britain are discussed at some length by E. W. H. Holdsworth in the article *Fisheries*, in the last edition of the *Encyclopædia Britannica*, and under the captions *Fisheries* and *Fishery Treaties*, in Lalor's *Cyclopædia of Political Economy*, Dr. G. Brown Goode treats very fully the economical and political aspects of fisheries. Statistics for Great Britain may be found in various "blue-books," reports of inspectors and fishery boards for England and Wales, Scotland and Ireland, and these contain also much general information. The yearly *Fisheries Statements* of the Dominion of Canada contain the facts and figures for that vast region. *Statistique des Pêches Maritimes* is the title of the very comprehensive annual report of France, while the periodical *Circulare* and *Mittheilungen* of the Deutscher Fischerei Verein give much general information concerning not only the fisheries of Germany but of Northwestern Europe. The various reports, papers, and catalogues of the Berlin and London Fisheries Exhibitions of 1880 and 1883 are replete with interest, and *Bulletin 27* of the U. S. National Museum, which contains the catalogues of the collections of the U. S. exhibited at London, forms a comprehensive report on that section. For general reading may be recommended *American Fishes*, by G. Brown Goode; *Commercial Products of the Sea*, by P. L. Simmonds; *Fisheries of the Adriatic*, by George L. Faber; and *Deep Sea Fishing and Fishing Boats*, by E. W. H. Holdsworth. The catching of crabs, lobsters, seals, turtles, and whales, and the method of obtaining pearls and sponges, will be treated of under those heads. F. A. LUCAS.

Fisherman's Ring (in Lat. *annulus piscatorius*): a seal-ring worn by the pope, who with it seals certain briefs, which are said to be "given under the fisherman's ring." It bears a figure representing St. Peter fishing, is borne by the popes as St. Peter's successors, and has been used since the thirteenth century. The origin of this custom is not known. The habit, however, of wearing rings, either as token of authority (for instance, Pharaoh's ring), or as the token of a promise, a pledge (the wedding-ring), is extremely old. A ring similar to that worn by the pope belongs to the official costume of a Roman Catholic bishop.

Fishery Laws: the laws which define and regulate the rights of the public or of individuals to fish in natural or artificial bodies of water, public or private. The rules of the English common law regulating the subject of fisheries are of a twofold variety, since navigable waters—by which is meant, in legal usage, those in which the tide ebbs and flows—are distinguished, as regards the right to fish, from those which are not navigable. In streams above the reach of the tidal flow the soil to the center of the river-bed belongs to the riparian proprietors upon the opposite banks (see FILUM AQUÆ), and each of them possesses an exclusive right of fishery in that half of the stream over which his independent ownership exists. If the land upon both sides is vested in the same person, his fishing privilege pertains to the whole width of the river as far as the boundaries of his property along the course of the river may extend. But this exclusive right must be exercised so as not to interfere with the public convenience in passing along the stream in boats or rafts, and no dams or other obstructions can be made which would prevent the free passage of the fish, unless such privilege be given by statute. In navigable or tide waters, on the contrary, the soil is vested in the sovereign, and the right of fishery is common to the entire public. A special or exclusive privilege can only be created by legislative grant or by prescription, which must be clearly proved. This, however, is very unusual. This right of all persons to fish in public waters is called a *common fishery*. When several have a right to fish in a private stream in derogation of the owner of the soil, it is termed a *common of fishery* or *of piscary*. The designation *free fishery* is applied to an exclusive right in a navigable river arising by grant or prescription, without any right in the soil, while the term *several fishery* is employed when, in connection with such an exclusive grant, a property in the soil is also given. These various terms are, however, often employed without precision of meaning.

The doctrines of the English law concerning fisheries have been generally adopted in the U. S. In some few States, however, the common right of the public to take fish has been extended to streams ordinarily considered private, being above the flow of the tide. Thus in Pennsylvania and North and South Carolina it is declared that the great rivers of those States, even above tide-water limits, are subject to no exclusive privileges, but open to the general public. The regulation of fisheries by statutory provisions is very general, because great attention is given to the breeding of choice varieties of fish and the stocking of lakes and rivers. The modes and times of taking fish are often thus appointed, and penalties imposed for any violations of the restrictions created.

In the absence of any special statutory prohibition, it is supposed the inhabitants of one State may exercise the same right of fishing in the waters of another as the citizens of the latter possess. But the important question has come before a few of the courts for adjudication whether, if any State imposes upon the citizens of other States restrictions in regard to the power of fishing within its limits which are not imposed upon its own citizens, that clause of the U. S. Constitution is not violated which provides that "the citizens of each State shall be entitled to all the privileges and immunities of citizens in the several States." The U. S. Supreme Court has held, in opposition to some earlier cases, that the right of fishing is in the nature of a right of property incident to the right of territory, and that the legislation of any State appropriating it to the use of the citizens of that State, either exclusively or with the grant of peculiar privileges, would therefore not be unconstitutional. Compare *McCready* vs. *Virginia*, 4 Otto's Reports, 391; *Corfield* vs. *Coryell*, 4 Washington Circuit Court Reports, 380; *Bennett* vs. *Boggs*, Baldwin's Reports, 60; *The State* vs. *Medbury*, 3 Rhode Island Reports, 138; *Dunham* vs. *Lamphere*, 3 Gray's Reports, 276.

The U. S. Government at an early period adopted important measures of legislation to promote cod-fishing along the coast, providing for the payment of bounties to those persons who would engage in the business. Thus a law was passed in 1819 establishing the following bounties, which continued to be paid annually until the year 1866 to the owners of all vessels employed in the cod-fisheries for at least four months in the fishing season: For vessels between 5 and 30 tons, $3.50 per ton; for those above 30 tons, $4 per ton, except that the allowance to any vessel was not to exceed $360. But in 1866 fishing-bounties were abolished, and the only privilege now granted to the cod-fishermen is that duties shall be remitted on imported salt in bond which they take on board for curing purposes.

In the prosecution of the cod, mackerel, and other fisheries along the coast of Newfoundland and the other British possessions much hostility was created between British fishermen and those of the U. S. on account of the practices of the latter in fishing unlawfully in bays and inlets, and in drying and curing their fish upon British shores. The high seas are free and open to all nations, and people of any nationality may fish therein without restriction, but this right ceases at the mouths of rivers and in bays and harbors along the coast of any country, to the distance of a marine league from the shore. Foreigners can acquire a privilege to catch fish in places of this kind only by grant of the state or sovereign. At times the colonial authorities have used force to drive away U. S. fishermen from the Newfoundland and Canadian coasts. In order to remedy these difficulties, various treaties have from time to time been negotiated between the U. S. and Great Britain granting certain privileges reciprocally to the inhabitants of either country. For the provisions of these treaties, see FISHERY RELATIONS OF THE UNITED STATES.

GEORGE CHASE.

Fishery Relations of the United States: The right to catch fish on the high seas, on banks in the same, on the coasts, or in the bays and rivers of lands not pertaining to the jurisdiction of any organized state, is open to all; but by international law, as the sea for a marine league is under the jurisdiction of the sovereign of the adjoining land, no one can lawfully fish there without liberty expressly given or conceded by law or treaty. Much less has any one a right to dry and cure fish on the soil belonging to any organized state without permission.

In the treaty of 1783, by which Great Britain acknowledged the independence of those North American colonies which now form the U. S., the right of their inhabitants to take fish on the banks of Newfoundland was admitted, as well as in the Gulf of St. Lawrence and at all other places of the sea where they had been wont to fish in earlier times. *Liberty* also was conceded to them to take fish without drying or curing them on parts of the coast of Newfoundland used by British fishermen, and "on the coasts, bays, and creeks" of all other British dominions in America; and also to take, cure, and dry fish in any of the unsettled bays, harbors, and creeks of Nova Scotia, Magdalen islands, and Labrador, so long as they should remain unsettled, but to dry and cure fish after the settlement of such coasts, etc., "only with the consent of the inhabitants, proprietors, or possessors of the ground."

The treaty of Ghent (1815), terminating the war of 1812–15, said nothing of the right of fisheries. The U. S. Government claimed that the old treaty of 1783 survived the war, and the British Government denied such a claim, on the general principle that war dissolves ordinary provisions of treaties. In 1818 a convention made at London conceded to fishermen from the U. S. the right to take fish on the southwestern and western coasts of Newfoundland within certain limits, on the shores of the Magdalen islands, and on those of Labrador from Mt. Joly eastward and northward. The liberty of drying and of curing fish was confined to the southern coasts of Newfoundland and the coast of Labrador, as defined in the treaty, so long as they should continue unsettled, but afterward only with the consent of proprietors, as before. These grants were expressly made perpetual, and therefore suspended only, but not terminated, by war. On the other hand, the U. S. renounced for ever the right to take, cure, or dry fish within 3 marine miles of any coasts of the British dominions not named in the treaty. Liberty to enter bays or harbors thus excepted from the right of fishing was granted for purposes of shelter, repairing damages, and obtaining wood and water.

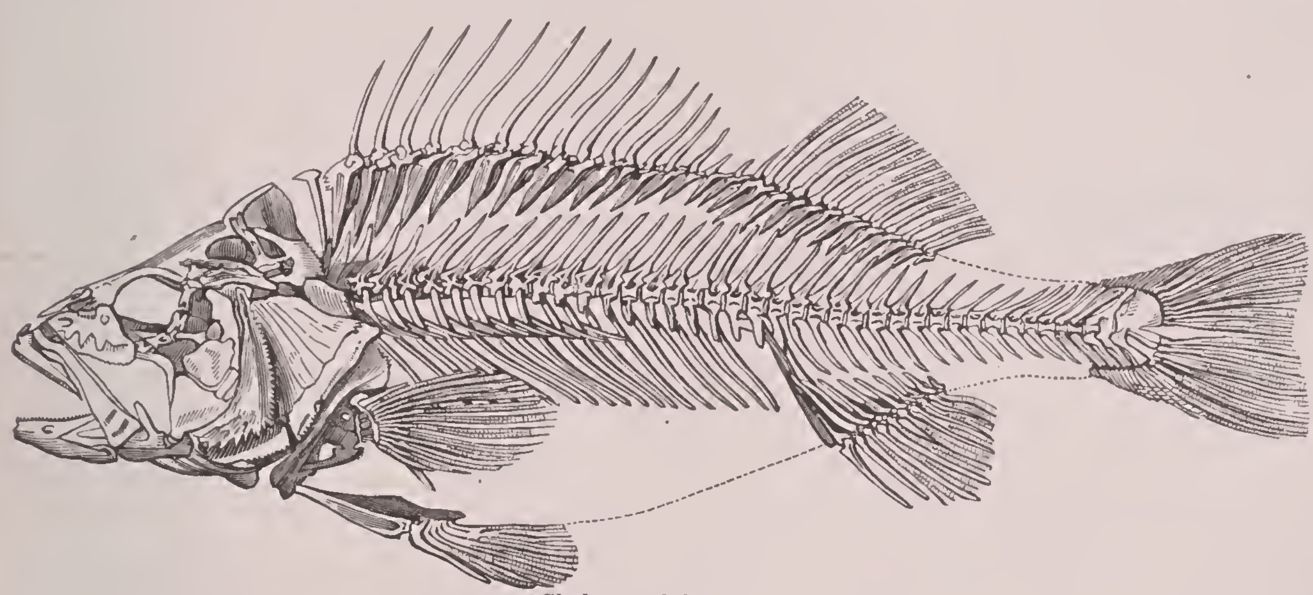
In 1854 a new treaty relating to the fisheries on the eastern coasts was negotiated, which went by the name of the Reciprocity Treaty, and considerably enlarged the liberties conceded to fishermen from the U. S. The rights created by the old treaty remained untouched and unenlarged; this treaty granted the additional right of taking fish, except shellfish, of every kind on the seacoasts and shores and in the bays, harbors, and creeks of Canada, New Brunswick, Nova Scotia, Prince Edward island, and of the islands thereto adjacent, and the permission of landing to dry their nets and cure fish on all these coasts, as well as on those of the Magdalen islands; provided it be done without interference with private property. From the permissions given by this treaty those of catching salmon and shad and of fishing in the mouths of rivers were excepted. On the other hand, similar liberties were given to British fishermen to fish along the shores of the U. S. as far S. as the 36th degree of latitude, with similar permission to dry and cure, and with the reservation of fisheries similar to those already mentioned. Other rights, such as the free navigation of Lake Michigan by both parties, and that of using the St. Lawrence within British territory, were provided for, as well as the free exportation of a number of its products by either country into the other. Among such products were lumber, coal, and fish, which latter was the chief equivalent for the free fishing granted the fishermen of the U. S.

This treaty, terminable after ten years on twelve months' notice, was actually terminated by the action of the U. S. Mar. 17, 1866, in pursuance of notice given a year before. Consequently, the treaty of 1818 alone regulated the fisheries on British American eastern coasts, and many irritating exercises of power and claims that the Americans had surpassed their rights occurred on the part of the authorities of the British dominions. Five years passed away before the treaty of Washington of 1871 put the fisheries on a new basis. In this treaty most of the particulars which enter into the intercourse of border states were considered, and form a system in which the advantages were intended to be equal. The fisheries were again placed substantially, as far as rights of fishing, curing, and drying were concerned, on the basis of the reciprocity treaty of 1854; only the southern limit of British rights of fishing, etc., along the coasts of the U. S. was moved northward to the 39th parallel. An important feature of the treaty was that of article 21, the admission of fish-oil and fish (except fish of inland waters and fish preserved in oil) into the territories of the U. S. from those of the Dominion of Canada and of Prince Edward island, being the produce of their fisheries, and *vice versa*, free of duty. Another provision of the treaty arose from the claim on the British American side that the concessions were of more value to the U. S. than to themselves. In order to determine this, article 23 provides for the appointment of commissioners to meet at Halifax and determine what gross sum, if any, ought to be paid to the British Government as a compensation for excess of advantages conceded to the U. S. Such a commission met at Halifax in 1877, and awarded $5,500,000 to Great Britain. This part of the treaty of Washington was by article 33 made terminable after ten years, and after one year's notice. Such notice was given in 1884, causing these treaty provisions to terminate on July 1, 1885. The treaty of 1818 has thus again come into force, and this has given rise to serious difficulties between the U. S. and Canada. An attempt in 1888 to settle this vexed question by a new treaty failed, owing to the non-concurrence of the Senate in the treaty proposed. It is probable that no form of reciprocity which balances the free entry of fish against the freedom of the inshore fisheries can be permanently satisfactory. For the conditions of the mackerel fishery, which is the one principally concerned, are constantly changing, and its importance accordingly fluctuates, while the free entry of Canadian fish is of constant value. The two are not proper equivalents. It is suggested, therefore, that a fair solution of the problem would be to secure through yearly licenses or outright purchase the fishery rights of the provincial shores for U. S. fishermen, and then settle the question of the free importation of Canadian fish on its own merits separately as a domestic matter. Until some such settlement is made difficulties will always arise.

Under the head of fishery relations with Great Britain should also be mentioned the sealing difficulty, the U. S. claiming the right to forbid all captures of seals in the Bering Sea, by any persons of whatever nationality, except the employees of a single company, under penalty of confiscation of ship and outfit. See BERING SEA CONTROVERSY. This claim was at first mainly based upon an exclusive jurisdiction over the eastern portion of the Bering Sea, which the U. S. was asserted to have derived from Russia with the Alaska purchase in 1867. Such exclusive jurisdiction was denied by Great Britain, since (1) the Bering Sea was part of the high seas, and since (2) Russia by formal treaty in 1824 with the U. S. and with Great Britain in 1825 had renounced the claim. It was also asserted that the U. S. had a property right in the seals accustomed to resort to its islands, and that their indiscriminate killing was *contra bonos mores*. As the sealskins are dressed in London, both countries have a sufficient reason for desiring the preservation of this animal, and toward the end of the first Cleveland administration an attempt at an amicable settlement was made to include several states and preserve the species threatened with extinction. This arrangement was prevented by the protests of Canada. Upon the failure of this plan, the Bering Sea was again patrolled by U. S. vessels, and pelagic sealing checked by force. At the same time negotiations were resumed which ended in an agreement to submit certain mooted points to arbitration, along with the question of proper international protection to the seals and rules therefor. This court of arbitration sat in 1893 at Paris. The main question before it was whether the U. S. on any ground possessed the *right* to prevent pelagic sealing in the Bering Sea exclusively; and also, if such protection could only arise by agreement with Great Britain, what rules were reasonable and necessary to make it effectual. The claim to an exclusive jurisdiction over a portion of the Bering Sea as being territorial waters of the U. S. was not strongly pressed by the counsel for the U. S., but the question of a property right in the seals resorting to the Pribyloff islands was very ingeniously and forcibly urged. The award, however, published in Aug., 1893, denied all the pretensions of the U. S. to prevent sealing in the Bering Sea as a matter of right. It denied any property right in the seals. It did more. It attempted to preserve the seal herd by prescribing rules to be binding upon and enforced by both nations which limit in time and place and method the pelagic seal-fishery. In brief, pelagic sealing is permitted only between Aug. 1 and May 1 to sailing vessels, using no nets or guns, and operating under license. It is forbidden the entire year throughout a zone of 60 miles around the Pribyloff islands. The regulations were applied not only to the Bering Sea, but also to the Pacific Ocean, east of 180°, from the latitude of a point two-thirds way down the coast of California northward to the Bering Straits. These rules may or may not be effectual. It should be remembered that they bind only subjects of the two nations which are parties to the agreement, and that owing to fogs, to the difficulty of guessing a ship's distance from the Pribyloffs, and to the organized systems of evasion which are sure to grow up, they may well fall short of absolute protection. Moreover, the question of damages for the seizure of sealers has not been taken up, though the liability of the U. S. is made clear by the award. But the main, the international, difficulty is settled. Revised by T. S. Woolsey.

Fishes: a name applied, in a popular sense, to the vertebrated and all other inhabitants of the waters; in a scientific sense, restricted at first to vertebrates dwelling in water and inspiring air from it by means of branchiæ or gills, and later to a still more limited group, the lancelets, hagfishes, lampreys, sharks, and rays being assigned to separate classes, and not included among the true fishes. See Ichthyology.

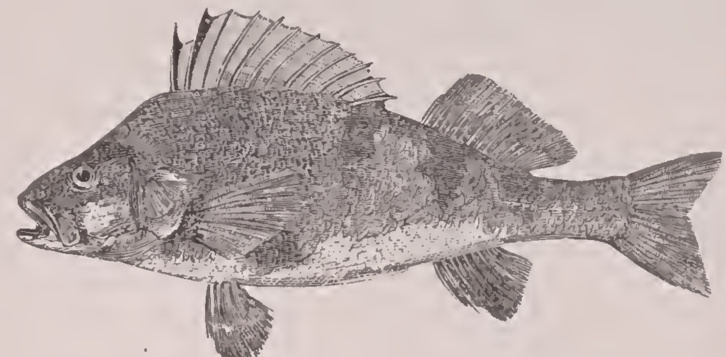
General Characters.—Fishes, in the last acceptation of the term, may be defined as *lyriferous vertebrates, with a skull provided with membrane or dermal bones.* In these the shoulder-girdle forms a lyriform or furcula-shaped apparatus, like a bird's wish-bone, the scapular bones and their adjuncts of the two sides being connected below at the median line; an air-bladder (sometimes lung-like) is, as a rule, developed, and either connects with the œsophagus by a single duct (as in Ganoids and most soft-finned fishes), or is entirely closed (as in the spine-finned fishes); the skull is highly developed, and is provided with membranous bones, or with dermal shields which are homologous with them; the shoulder-girdle is formed, in great part, by large furcula-like bones, which bound the region behind the head, and which, beside meeting at the median line, are generally connected, by means of intervening bones, with the skull. These external scapular bones are also membrane or dermal bones, and are not developed in the Selachians; to their internal surfaces are attached smaller ones or cartilages (homologous with the shoulder-girdles of sharks), which support the pectoral fins.



Skeleton of the perch.

The gills and branchial apparatus are contained entirely within the cephalic cavity, in front of the scapular arch, and consist of five arches, the hindmost of which are, however, generally modified into pharyngeal bones; the gills are free at their distal margins. The brain is well developed, and has generally approximately equal cerebral and optic lobes and a moderate cerebellum. The heart is also well developed, and in all the forms (except some Dipnoi) is divided into an auricle and a ventricle. The members, anterior or pectoral, and posterior or ventral, whenever present, are developed as fins. In addition to these there are also generally median or unpaired fins sustained by rays (peculiar to lyriferous vertebrates), and of which the dorsal and anal are connected by the intervention of interspinal bones with the dorsal and inferior spines (neurapophyses and hæmapophyses) of the vertebral column; these fins are respectively termed dorsal, anal, and caudal. The caudal must by no means be confounded with the "tail" or "flukes" of the whales, which are to a certain extent homologous with the hind limbs.

Such are the characters which are common to all true fishes; that is, the classes Fishes and Ganoids of Agassiz,



European perch.

etc., embracing such forms as the flatfishes, codfishes, perches, mullets, billfishes, pikes, herrings, carps, electrical eels, mormyroids, catfishes, true eels, ganoids, etc. There is, however, much variation in other respects among these numerous constituents of the class. The skeleton may be bony or cartilaginous; the caudal, ventral, and even pectoral fins present or absent; scales, of very various character, present or absent; the air-bladder, either membranaceous or lung-like, present or absent; and, in fact, every portion of the framework and organization generally is liable to modification of some kind. The character and mode of association of some of these modifications may be best exhibited in connection with the systematic relations of the class.

In the typical fishes, known as teleosts, or bony fishes, the skeleton is ossified (whence the name); the optic nerves cross (decussate) each other; the heart has only two opposite valves, the outer elements of the scapular arch (proscapula) are simple, the inner elements are mostly ossified, and usually three or two in number; the pectoral member is destitute of any representatives of the humerus, and connected with the scapular arch by several (generally four) narrow bones (actinosts). To this great division belong by far the largest number of species and those most familiar; they are grouped in a number of orders, which have been named plectognaths, lophobranchiates, pediculates, hemibranchiates, teleocephals, scyphophores, nematognaths, apodes, and opisthomes.

In the remaining fishes, united by most recent naturalists under the name of ganoids, the skeleton is variable in its composition; the optic nerves do not cross, but are united by a commissure; the heart has a thickened bulbus arteriosus, provided with several rows of valves (but with those of each row sometimes united into a ridge, as in the lepidosirenids); the elements of the outer portions of the scapular arch (proscapula) are in some double, in others united; the inner scapular element is cartilaginous and simple; the pectoral member is provided with two basilar elements (bounding the insertion of the pectoral fin on each of its sides), or with a single pedicle corresponding with the humerus. The fishes combined under this last division, although not now numerous in species, exhibit extreme differences when compared with each other, and have been even considered (and with a very great degree of propriety) as constituting several subclasses. Commencing with those types which are most nearly related to the typical fishes, the characteristics may be briefly given and contrasted as follows:

In the first group (hyoganoids) the skeleton is ossified:

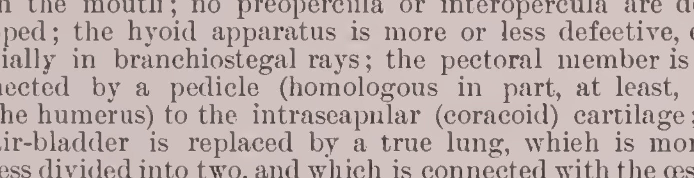
the skull also exhibits well-ossified bones; supramaxillary and intermaxillary bones are well developed; the nasal apertures are both external; preopercular and interopercular bones are present; the hyoid apparatus is well developed; the ceratohyals sustain a number of branchiostegal rays; the pectoral fin has two external cartilaginous basilar elements entirely separated from each other; and the air-bladder connects with the œsophagus by a duct which enters it from above. This group contains the orders *Cycloganoids* (represented in the U. S. by the bowfins or Amiids) and *Rhomboganoids* (represented by the alligator-gars or Lepidosteids).

In the second group (brachioganoids) the skeleton is also in great part ossified, but the centra or bodies of the vertebræ may be either osseous, or (in extinct types) represented by a persistent notochord; the skull is provided with well-ossified but superficial bones; supramaxillary and intermaxillary bones are distinguishable; the nasal apertures are external; preopercular and interopercular bones are both wanting; the hyoid apparatus is defective in the branchiostegal rays; the pectoral member is connected with and interposed at its base between two bones converging and uniting at their base with a cartilage representing a humerus; the air-bladder is highly cellular, and connects by its duct with the floor of the œsophagus. The group is represented in the present age of the earth by a single order (crossopterygians) with two genera (*Polypterus* and *Calamoichthys*), but was in ancient times rich in species.

In the third group (dipnoans) the skeleton is in part

Lepidosiren paradoxa.

ossified and in part cartilaginous, and the bodies of the vertebræ, instead of being ossified, are represented by a simple notochord; the skull is in great degree cartilaginous, but is also encased with superficial and thin membrane bones; no supramaxillary or intermaxillary bones are distinguishable; the posterior nasal apertures are internal, i. e. in the mouth; no preopercula or interopercula are developed; the hyoid apparatus is more or less defective, especially in branchiostegal rays; the pectoral member is connected by a pedicle (homologous in part, at least, with the humerus) to the intrascapular (coracoid) cartilage; the air-bladder is replaced by a true lung, which is more or less divided into two, and which is connected with the œsophagus by a duct or rudimentary trachea, which enters it from beneath. This type is represented at present by three very distinct genera—viz., *Lepidosiren* in South America, *Protopterus* in Africa, and *Ceratodus* in Australia, the members of this last genus being locally called *salmon* and *barramunda*. Formerly, the members of the group were among the principal representatives of the class, and in the Triassic period of Europe the *Ceratodus* of Australia was represented by several typical species of that genus, which was originally established on fossil dental plates.



The common sturgeon.

In the last group (chondroganoids) the skeleton is almost entirely cartilaginous (and from this circumstance the group has been named); this is the case especially with the vertebral column and its appendages; the skull is also cartilaginous, but is covered by dermal bones; no supramaxillary or intermaxillary bones are differentiated; the nasal apertures are external; both the preopercular and the interopercular elements are wanting; the hyoid apparatus, as in the last types, is defective in branchiostegal rays; the pectoral member, as in the Hyoganoids, has external cartilaginous basilar elements entirely distinct; and the air-bladder connects with the œsophagus by a duct which enters from above. To this group belong the sturgeons (constituting the order *Chondrostei*) and the "shovel-noses" or "paddle-fishes" of North America and Eastern Asia (constituting the order *Selachostomi*).

While the four groups just enumerated are the only great primary types of ganoid fishes that have members in the waters of the present epoch of the earth, in ancient times there were some very strange and peculiar forms which are not referable to any of those divisions, but which appear to stand isolated and afar from all others, and thus necessitate still another primary group. The types alluded to flourished among the first-known fishes, and in the Silurian and Devonian epochs. So strange are some of these in their appearance that remains of them have been referred to the crustaceans. Such are the forms which have been called *Cephalaspidæ*. Others (*Placoganoidea*) are almost equally aberrant in appearance, and their relations would not be suspected from their external characters; but the dental armature and scapular arches of a species discovered by Prof. Newberry in Ohio have convinced the writer that they were closely allied to the order *Sirenoidei*, and with them formed the super-order *Dipnoi*. The vomerine and palatine dental plates were contiguous, and seem to be homologous with the palatine plates of the *Sirenoidei*.

Limitations of Characters.—The student of the fishes, more than of any other class of vertebrates, must dissipate all prejudices with regard to the value of form in determining the relations of members of the class. Forms as diverse, almost, as any among all the quadruped mammals or among all the birds are found combined in the same natural family among fishes, and on the other hand there are forms that are very similar associated with structural characteristics that are very dissimilar. The student must also dismiss prejudices respecting the constancy of members (fins in fishes) in weighing their systematic relations. The members, for example, may vary in the same family, and ventral fins may be present or absent in closely related genera; scales are also by no means invariably characteristic of fishes, for they likewise may be present in one genus and absent in another in other respects very closely related. But although the presence or absence, *per se*, of parts may be comparatively immaterial, their structure, when present, is all important. The pectoral and ventral members, for example, are always constructed on the same *general* plan, and contrast markedly with those of the higher vertebrates. The character and mode of development of the scales, too, though not so distinctive as the fins, are *sui generis* in fishes.

Geographical Distribution.—About 9,000 species of living fishes are now known, variously distributed and found in greater or less numbers in almost all the waters of the globe, fresh and salt; the greatest numbers of species, however, are found in the tropical waters, and especially in the seas of the Indo-Moluccan Archipelago. The distribution of the types, especially of the marine species, to a considerable degree coincides with thermometrical conditions. In the polar and northern temperate regions, for example, are found representatives of the families of gadoids or codfishes, lycodoids, stichæoids, liparidoids, cottoids or sculpins, and others less known; in the tropical regions many forms are distributed throughout the entire zone (and therefore designated as tropicopolitan), this being especially the case with many genera of labroids (of which the tautog is a northern type), scaroids or parrot-fishes, pomacentroids, gerroids, serranoids or groupers, sparoids (of which the porgy is a representative), carangoids or horse-mackerel, and others; numerous species of these families being found in torrid waters, while very few extend far northward or southward. In the antarctic regions, again, there is another combination of forms; typical codfishes and the other types characteristic of high northern latitudes are wanting, but are replaced by several peculiar groups, which seem to fill an analogous place in the economy of nature, having a superficial resemblance in general aspect, although they are not at all (comparatively speaking) related in structure. The gadoids, for example, are replaced by notothenioids, the lycodoids by peculiar genera, the cottoids by harpagiferoids, etc. In the contrast between these antarctic and the arctic forms there is evidence of the absence of any paramount causal relation between temperature and structure; and it is necessary to remark here that, in addition to the tropicopolitan types, each great region has a number of characteristic and peculiar types.

But the distribution of the inhabitants of the great open seas and those of the inland waters is determined by different conditions, as might *a priori* be supposed. While, for example, the inhabitants of the opposite sides of converging continents are, to a great extent, similar, the fresh-water species of those continents are mostly quite dissimilar, the greatest difference being manifest in the most southern part of those continents.

There are numerous families of fishes which are represented in the fresh waters, some exclusively so, others with marine species. The geographical limitation and relation in space of these families may be exhibited under combinations in several categories—viz.:

(1) Peculiar to North America: *Centrarchidæ, Aphredoderidæ, Elassomidæ, Amblyopsidæ, Percopsidæ, Hyodontidæ*, and *Amiidæ*.

(2) Peculiar to tropical Asia: *Platypteridæ, Helostomidæ, Osphromenidæ, Nandidæ, Luciocephalidæ, Ophiocephalidæ, Notopteridæ, Salangidæ, Homalopteridæ*, and *Sisoridæ*.

(3) Peculiar to Africa: *Kneriidæ, Mormyridæ, Gymnarchidæ*, and *Polypteridæ*.

(4) Peculiar to tropical America: *Centropomidæ, Polycentridæ, Sternoptygidæ, Electrophoridæ, Hypophthalmidæ, Trichomycteridæ, Callichthyidæ, Argidæ, Loricariidæ*, and *Aspredinidæ*.

(5) Peculiar to Australia: *Gadopsidæ, Ceratodontidæ*.

(6) Peculiar and common to the cis-tropical hemisphere—that is, Northern America, Europe, and Northern Asia: *Gadidæ* (*Lotinæ*), *Cottidæ* (*Etheostomatinæ*), *Percidæ* (*Percinæ*), *Gasterosteidæ* (*Gasterosteinæ*), *Esocidæ, Umbridæ, Catastomidæ* (America and Eastern Asia), *Salmonidæ, Acipenseridæ*, and *Polyodontidæ* (America and Eastern Asia).

(7) Peculiar and common to Europe and Asia: *Cobitidæ*.

(8) Peculiar and common to South America and Australasia: *Percophididæ, Haplochitonidæ, Galaxiidæ*, and *Osteoglossidæ*.

(9) Peculiar and common to tropical and sub-tropical America and Africa: *Cichlidæ, Characinidæ*, and *Lepidosirenidæ*.

In addition to these, the family *Cyprinidæ* is represented in the entire cis-tropical or "arctogæan" hemisphere as well as in tropical Africa and Asia; and there are several monotypic families limited to very small regions, such as the *Comephoridæ*, the single species of which is only known from Lake Baikal. There are, further, a number of families (in addition to several already mentioned) which are chiefly represented by marine species, but which have also a greater or less number of representatives in fresh water in different regions of the earth: such are the *Brotulidæ, Blenniidæ, Gobiidæ, Atherinidæ, Mugilidæ, Cyprinodontidæ, Microstomidæ, Clupeidæ, Dorosomidæ*, etc.

Others, again, were represented in former epochs in parts of the world where they are not now found, and especially to be noted among these are two families characteristic in their distribution: the first of these is the *Cobitidæ*, which, in the early Tertiary, were inhabitants of Western America, and which thus increased the similarity of the fauna of the (cis-tropical) continent of North America with that of Northern Asia; the second is the *Ceratodontidæ*, a family whose representatives have been long known from fossil teeth found in Palæozoic and Mesozoic deposits (and which were referred by Prof. Agassiz to the sharks), and had been supposed to have expired toward the end of the Triassic epoch; yet since 1870 two species, closely allied to those found in the Triassic beds of Europe, have been discovered living in Australia; and thus another ancient type preserved in that continent illustrates the past life of North America.

If knowledge thus gained is applied to the appreciation of the different fish-faunas of the globe, the following conclusions are inevitable:

Inasmuch as the cis-tropical hemisphere shares in common the same families, and to a considerable extent the same genera, and even some species, it is presumable that the different regions of that hemisphere have derived their inhabitants from a common primitive source, although North America has quite a large proportion of forms peculiar to it. The relations of those peculiar forms, however, are in all cases rather with some found in the northern hemisphere (fresh-water or marine) than with any found elsewhere; but at the same time, toward the southwestern limits of the U. S., occur representatives of families which are characteristic of tropical America.

Tropical Asia also nourishes a number of peculiar forms, but the relations of those are either intimate with cis-tropical ones or with marine types.

Africa likewise has cyprinoids and anabantids in common with tropical Asia, and cyprinoids in common with the cis-tropical hemisphere, but it also supports several very peculiar families whose relations must be sought in other continents.

In tropical America are to be found the nearest relations of some of those African types, and several almost or quite limited to those two continents; on the other hand, in South America are found several families having no analogues in the parts of the world yet mentioned, but in Australasia are found representatives of not only the same families, but even, it has been contended, one of the same species. Under these circumstances one is almost compelled to believe that the first fauna of South America was derived, at a distant epoch, to some extent, from a common source with that of Africa and that of Australia. There are, however, at first sight contrary indications, but they are not irreconcilable; the most conspicuous and, as it were, obtrusive types of South American fishes are analogues of African forms, members of the families *Cichlidæ* and *Characinidæ*, but the species belong to widely different genera. On the other hand, although the types common to South America and Australia are not conspicuous in numbers or importance, they are much more nearly related to corresponding Australian species than the former, and, in common with other facts, somewhat tend to verify Huxley's views respecting an "Austro-Columbian" fauna.

In fine, dividing the earth into regions distinguished by general ichthyological peculiarities, several primary combinations may be recognized—viz.: (1) an *Arctogæan*, embracing Europe, Northern Asia, and Northern America; (2) an *Asiatic*, embracing the tropical portions of the continent; (3) an *African*, limited to the region S. and E. of the desert; (4) an *American*, embracing the America *par excellence* dedicated to Amerigo Vespucci, and including the tropical and trans-tropical portions; and (5) an *Australasian*. Further, of these (*a*) the first two have intimate relations to each other, and (*b*) the last three others among themselves; and some weighty arguments might be adduced to support a division of the faunas of the globe into two primary regions coinciding with the two combinations alluded to—(*a*) Pliogæa and (*b*) Eogæa.

Chronological History.—The earliest known remains of fishes occur in the lower Silurian of North America. The most ancient known fishes belonged to types entirely distinct from any that are in existence at the present time. As mentioned in the remarks on the primary groups of fishes, the Placoganoids, first of known fishes, heralded the advent of the class, and these were the predominant species apparently in the Devonian epoch; from somewhat later formations have been obtained the remains of representatives of orders still existing, but in very small numbers; such were especially the dipnoans, which were then represented by numerous genera and species; coeval with these were various Selachians or sharks. Almost all of the true fishes existing during the Mesozoic epoch have been referred to the great group of ganoids, but it is probable that some have been erroneously identified, and that they belonged to the subclass of teleosts. No universally recognized species of that group, however, have been found in deposits lower than the Cretaceous; in that epoch they began to culminate, and in time became the greatly prominent forms; and in the present epoch almost all the species (excluding the selachians) belong to this great group; and, so far as numbers go, all of the living ganoids might disappear, and yet the loss would scarcely be apparent in the sum-total of the class. Of about 9,000 existing species of fishes or teleostomes, less than 100 do not belong to the teleosts, and that number alone represents the various primary groups of the ganoid fishes, and yet, great as is the number of the teleostomes, and small as is that of the ganoids, the latter exhibit much greater differences in contrast with each other than do all the teleosts among themselves. Such is the character of the difference between the animals of the present and the distant past periods of the earth's history; and it is fortunate that, although with few lineal heirs left, most of the ancient types are still represented by some examples of their organization.

THEODORE GILL.

Fish-glue: a species of isinglass not sufficiently refined for culinary and medicinal purposes, but suitable for making cements, etc. It is prepared from the offal of the fisheries, and sometimes has a strong fishy odor.

Fish-hawk: a common name of the osprey (*Pandion haliaëtus*), one of the birds of prey, so called from its feeding upon fish which it captures by swooping down upon them when they are near the surface. The general color of the fish-hawk is vandyke brown above, the quill feathers are blackish, and the head, neck, and under parts are white. The outer toe, as in owls, can be turned backward and the powerful feet are furnished with sharp spicules which aid in holding the bird's slippery prey. The length is about 2 feet, the spread of wing 4½, and, as in most birds of prey, the female is larger than the male. By preference the fish-hawk nests in tall trees near the water. The nest, which is a bulky affair of sticks and weeds, repaired and added to yearly, is so large that small birds frequently build their nests in its interstices. The fish-hawk ranges over the greater portion of the warm and temperate parts of the globe, the American birds being frequently separated as a distinct geographical race or sub-species, *Pandion haliaëtus carolinensis.* The bird is systematically plundered by the bald eagle, and in some southern localities by the frigate bird. F. A. LUCAS.

Fish-hook: a curved, barbed, and pointed steel wire used in angling and the fisheries. The most important seats of the fish-hook manufacture are Limerick in Ireland and Redditch, Worcestershire, England, but fish-hooks of the best quality are made in the U. S., not inferior to those of Limerick except in reputation and cost. The Limerick hook has a barb which is forged solid and then filed into the proper shape, while the English and other ordinary hooks have a barb which is raised by cutting into the wire. These are inferior in temper and durability to the best hooks.

Fishing-bounties: bounties varying from $1 to $2.50 per ton, given during the period of British rule over North America to all vessels employed for the term of four months at least in each year on the Newfoundland Banks or other fisheries. Three-eighths of the bounty went to the owner of the vessel, and the remaining five-eighths to the fishermen. During the Revolutionary war this system fell out of use, but by act of Congress, 1792, it was re-established, on the ground that the state received great benefit from the fisheries as nurseries for seamen. Fishing-bounties were finally abolished in 1854.

Fishing-frog: See ANGLER.

Fishkill on the Hudson, or **Fishkill Landing**: village; Dutchess co., N. Y. (for location, see map of New York, ref. 6–J); on the N. Y. C. and H. R. and N. E. R. Rs., and on Hudson river, opposite Newburg, with which it is connected by steam ferry; 58 miles by rail N. of New York. It has three churches, an excellent public school, the De Garmo Institute, a hat-factory, machine and boiler shop, and an insecticide-factory. Pop. (1880) 2,503; (1890) 3,617; (1900) 3,673. EDITOR OF "FISHKILL STANDARD."

Fish-louse: a name applied to numerous parasites (generally entomostracous crustaceans of the order *Copepoda*) which infest fishes. The genera *Argulus*, *Caligus*, *Nicothoë*, *Dichelestium*, *Lernœodiscus*, *Chondracanthus*, *Achtheres*, *Anchorella*, and *Lerneotoma* are best known.

Fishmoth: See ENTOMOLOGY.

Fish-plates: a pair of plates placed upon opposite sides of a joint in a beam, and connected by bolts passing through the beam. The fish-joint for railway rails was first used in England in 1847, the plates being 18 inches long, 3 inches wide, three-fourths of an inch thick, and bolted through the rails by four bolts in oval holes, so as to allow for changes in length of the rails due to temperature. This joint is deficient in stiffness and has mostly passed out of use, the angle-bar joint having taken its place. See RAILWAYS.

Fisk, CLINTON BOWEN: soldier and politician; b. in Griggsville, N. Y., Dec. 8, 1828; became a merchant and banker at Coldwater, Mich.; entered the Union army in 1861 as a private, and became brevet major-general of volunteers in 1865. He devoted himself to the improvement of the colored race, was assistant commissioner in the Freedmen's Bureau, and founded the FISK UNIVERSITY (*q. v.*). He was a member of the Indian commission in 1873; held many other important offices; was a Republican until 1884, when he became a Prohibitionist. In 1886 he was a Prohibition candidate for Governor of New Jersey, and in 1888 the Prohibition nominee for President of the U. S. D. in New York city, July 9, 1890.

Fisk, WILBUR, D. D.: b. in Brattleboro, Vt., Aug. 31, 1792; joined in 1812 the sophomore class in the University of Vermont, but spent his senior year at Brown University, where he graduated with high honor in 1815. Entering with great zeal upon the study of the law, he was arrested in his course by what threatened to be a fatal illness, and in 1818 was licensed as a local preacher in the Methodist Episcopal Church. He soon took high rank as a pulpit orator. He was in 1825 chosen first principal of the Wilbraham Academy, Massachusetts, removing thither in 1826; in 1830 was chosen first president of the Wesleyan University, Middletown, Conn., and entered upon the duties of this office in 1831. He declined a bishopric in 1839. D. in Middletown, Vt., Feb. 22, 1839. He was a man of the Fénelon type of character. Published *Calvinistic Controversy* (New York, 1837); *Travels in Europe* (1838); *Sermons and Lectures on Universalism*, *Reply to Pierpont on the Atonement*, and other tracts and sermons. See his *Life* by Rev. Joseph Holdich, D. D. (1842) and by Prof. George Prentice (1890).

Fiske, JOHN, M. A., LL. D.: historian; b. in Hartford, Conn., Mar. 30, 1842; graduated at Harvard 1863; lecturer on philosophy 1869–71; instructor in history 1870; assistant librarian 1872–79, all in Harvard College; overseer of the same institution 1879–91; Professor of American History, Washington University, St. Louis, 1884. He was engaged mainly in lecturing and writing, making his home in Cambridge. His lectures and books were received with great favor not only in the U. S., but also in Great Britain. He also devoted himself to the exposition of Herbert Spencer's philosophy. His principal works are *Tobacco and Alcohol* (New York, 1868); *Myths and Myth-makers* (Boston, 1872); *Outlines of Cosmic Philosophy, Based on the Doctrine of Evolution* (2 vols., London, 1874; republished in Boston); *The Unseen World* (Boston, 1876); *Darwinism and other Essays* (London, 1879; new and enlarged edition, Boston, 1885); *Excursions of an Evolutionist* (Boston, 1883); *The Destiny of Man Viewed in the Light of his Origin* (Boston, 1884); *The Idea of God as Affected by Modern Knowledge* (Boston, 1885); *American Political Ideas Viewed from the Standpoint of Universal History* (New York, 1885); *The Critical Period of American History* (Boston, 1888); *The Beginnings of New England* (Boston, 1889); *The War of Independence*, for young people (Boston, 1889); *Civil Government in the United States* (Boston, 1890); *The American Revolution* (2 vols., Boston, 1891); *The Discovery of America* (2 vols., Boston, 1892); etc. D. July 4, 1901. C. H. THURBER.

Fisk University: an institution at Nashville, Tenn., for the education of colored persons of both sexes; founded in 1865 largely through the efforts of Gen. Clinton Bowen Fisk, for whom it is named. It has, besides the regular course of study in liberal arts, normal, industrial, and preparatory departments, and schools of theology and music. The original endowment was not large, but additions have been made from time to time, including a theological hall, which was completed in 1891, and the Fisk memorial chapel. The college is well attended by the colored race, and has done much for its advancement.

Fissirostres [Mod. Lat., from Lat. *fissus*, cleft + *rostrum*, beak, in allusion to the width of gape]: a term applied by Cuvier to a "tribe" of birds comprising the goat-suckers, swifts, and swallows, and so extended by G. R. Gray as to include the trogons, kingfishers, and a number of other wide-mouthed birds. The group, which was contrasted with *Dentirostres* and *Tenuirostres*, was purely artificial and the birds comprising it are now distributed in various orders. The adjective fissirostral, however, remains as a convenient term. F. A. LUCAS.

Fis'tula [Lat., reed, pipe, fistula]: in pathology, an abnormal canal, usually of small length and diameter, leading from one organ to another (vesico-vaginal fistula), or from some cavity of the body to the external world (gastric or biliary fistula, fistula in ano).

Fistula is called (1) complete, when it has two orifices; (2) incomplete or blind, when it has only one; (3) external, when the opening is through the skin; (4) internal, when it opens only into a cavity of the body. The two most prominent characteristics of a fistula are the constant discharge from it of a thin purulent fluid, with which the secretions of the organ affected are mixed, and the obstinacy with which it resists the healing process. This latter results from the nature of the wall of the fistula, which in recent cases is formed of soft, unhealthy granulation-cells which have no tendency to unite to form either cicatrix or cuticle. In older cases the walls consist principally of condensed connective tissue, inseparable from the surrounding parts. A fistula of long standing also exerts a change in the tissues through which it passes, these becoming more dense, and finally indurated, and the integument around its orifice callous and sometimes warty.

Fistula is caused (1) by wounds which penetrate passages giving natural exit to the secretions, or those which follow a long and deviating course through many tissues; (2) by ulceration and the sloughing process; (3) by abscess. The last is the most frequent cause.

The passage of a bullet through any region of the body sometimes leaves a canal which fails to unite; and whenever a necrosis of bone occurs there are usually one or more tracks following a winding course from it to the outside of the body. These passages are often called fistulæ, but the more appropriate name for them is *sinus*.

Fistula commonly occurs in persons of an enfeebled constitution. Where it results from abscess it is more frequently the chronic than the acute form which gives rise to it. Fistulæ were formerly supposed to furnish exit for morbid humors, and surgeons hesitated to attempt their cure. Some surgeons refuse to operate on a fistula in ano in a patient having phthisis, but this is evidently an error.

The cure of fistula depends upon producing union of its walls through the agency of healthy granulation-cells. This may be brought about by stimulating applications, as the injection of nitrate of silver, etc., in solution, or the application of the red-hot iron. Where the walls are old and indurated it is necessary to dissect them out and remove them altogether, bringing the lips of the wound together by sutures. The most common treatment consists in laying the fistula and soft parts above it freely open by an incision, and keeping the orifices of the wound apart, so that it may slowly heal by granulation from the bottom. There are other modes of cure, but they are less serviceable than the above, or else only applicable to special cases.

Revised by Roswell Park.

Fistula: the farrier's name for a deep-seated chronic abscess in horses, usually situated upon the withers, and discharging pus through fistulous pipes or sinuses. When seated upon the top of the head it is called poll-evil. Blows and strains of the tendon of the nape are the most fruitful causes of the disease, which most frequently attacks old or ill-kept animals. The thorough application of hot caustic solutions is often curative; but sometimes it is well to lay open the sinuses and retrench unhealthy masses of granulation-cells.

Fit: See Apoplexy, Convulsion, and Epilepsy.

Fitch: See Vetch.

Fitch [either abbrev. of *fitchet*, *fitchew*, polecat, or from O. Dutch *vitsche*, polecat, whence O. Fr. *fissian*]: the commercial name of the fur of the European polecat (*Putorius fœtidus*). It is collected in Northern Europe, and though in general inferior in quality to the fur of martens and sables, it is very handsome and serviceable, and when it is in fashion brings a good price. The animal which affords it is often called *fitchet*. See Polecat.

Fitch, John: inventor; b. in East Windsor, Conn., Jan. 21, 1743. In his twenty-sixth year he established himself at Trenton, N. J., as a silversmith. During the early part of the Revolutionary war he had large contracts for the repair of arms, but when the British army entered Trenton his shop and its contents were burned. He served as lieutenant in the New Jersey volunteers, and afterward resumed the business of repairing arms. Having procured an appointment as deputy surveyor for Virginia, he journeyed through a part of Kentucky, making surveys.

The thought of propelling vessels by steam, he claimed, originated with him in 1784. He matured his plans, and in Aug., 1785, petitioned Congress for aid in constructing his boat. In his statement before a committee appointed by the Assembly of Pennsylvania he averred that he had seven different plans and four different models of steamboats. The records of the American Philosophical Society of Philadelphia show that "a model, accompanied by a drawing and a description of a machine for working a boat against a stream by means of a steam-engine, was laid before the society by John Fitch on Sept. 27, 1785." With the pecuniary assistance of several gentlemen, Fitch immediately undertook to build a steamboat. The engine of Fitch was the first double-acting condensing engine, transmitting power by means of cranks, ever constructed.

On May 1, 1787, Fitch's steamboat, the Perseverance, was put in motion on the Delaware river, and made 3 miles per hour. Improvements were made, and the steamboat, with its greatly increased power, was successfully tested in the fall of 1788. With thirty passengers the vessel left Philadelphia and, moving against the current of the Delaware, reached Burlington, a distance of 20 miles, in three hours and ten minutes. Subsequently the Perseverance made 80 miles in one day.

Fitch was sent to France by the steamboat company, under the auspices of Consul Aaron Vail, who was anxious to have a steamboat built in that country; but finding all the machinists engaged on Government work, Mr. Vail furnished Fitch with means to return to his native country. He crossed the British Channel, and during his stay in London, in 1793, he published his pamphlet entitled *An Explanation for Keeping a Ship's Traverse at Sea by the Columbian Ready Reckoner*. He returned to Boston in 1794 in a state of destitution. From that time to 1796 he resided at Sharon, Conn. In the *Documentary History of New York*, vol. ii., p. 585, will be found an interesting account of experiments subsequently made by Fitch in propelling a small boat by steam on the Collect Pond, formerly existing in the lower part of the city of New York. This boat was arranged with side wheels, and a screw propeller at the stern. In 1797 Fitch went to Kentucky to obtain possession of lands he had purchased there. D. at Bardstown, Ky., July 2, 1798. See the *Life* by Westcott (1857).

Fitch, John Lee: See the Appendix.

Fitch, Ralph: one of the first English travelers in India; lived in the latter half of the sixteenth century. He was a merchant dealing in East Indian products, and it was for the purpose of advancing his business that he undertook the great voyage (1583–91), crossing from Tripoli to Bagdad, sailing from Bagdad to Ormus, and visiting both Indies and Ceylon. A description of his tour (*The Voyage of Mr. Ralph Fitch*) is found in Pinkerton's *Collection of Travels*.

Fitch, Simon Walbrooke: surgeon; b. in Horton, Nova Scotia, Jan. 2, 1820; graduated M. A. at Acadia College, Nova Scotia, and M. D. at Edinburgh University in 1841. He began practice in St. John, New Brunswick, in 1842; removed to Portland, Me., in 1855; to New York city in 1874; and afterward to Halifax, Nova Scotia, where he became consulting surgeon of the Victoria General Hospital. He was surgeon to the Fifth Corps Military Hospital, Fredericksburg, Va.; surgeon to the troops at Fort Preble, Me.; is a member of the council of Edinburgh University; and connected with various medical societies in Europe and America. He invented the dome trocar, the dome transfuser, and dome aspirator needle in 1875, the clamp cyst forceps in 1876, the trocar prostate catheter in 1882, the intra-uterine forceps in 1886, the handy aspirator in 1887, and at different times other surgical and gynecological instruments. Among his published works are *Lithotomy* (1858); *Excision of Uterine Tumors* (1862); *Medical and Surgical Practice in Great Britain* (1872); *Paracentesis, Aspiration, and Transfusion* (1886). Neil Macdonald.

Fitch, Thomas: Governor of Connecticut; b. in Norwalk, Conn., in June, 1699; graduated at Yale College 1721; practiced law, and filled the offices of counselor, judge of the Supreme Court, chief justice (1750–54), Lieutenant-Governor, and Governor. In 1766 he was driven into retirement for having taken the oath of office prescribed in the Stamp Act in 1765. D. in Norwalk, July 18, 1774.

Fitchburg: city and railway center; one of the capitals of Worcester co., Mass. (for location, see map of Massachusetts, ref. 3–F); situated on a branch of Nashua river, 25 miles N. of Worcester, the other county-seat. It has fine churches and schools, a public library, three parks, extensive manufactories, excellent water-works, sewers, street railways, and electric lights. The census of the U. S. for 1890 showed 285 industrial establishments, with a capital of $6,120,050, giving employment to 4,195 persons at an annual wage of $2,268,221. The cost of materials was $5,381,910; the value of products, $9,349,993. Among the leading industries are the manufactures of paper, machinery, woolen goods, ginghams, cotton yarns, and bicycles. Pop. (1880) 12,429; (1890) 22,037; (1900) 31,531. Editor of "Sentinel."

Fitzgerald, Augustus Frederick: third Duke of Leinster; b. in London, Aug. 31, 1791; succeeded to the title on the death of his father in 1804, and took his seat in the House of Lords; in 1831 was appointed lord-lieutenant of the County Clare in Ireland, and member of the queen's privy council. Was the grand master of the order of Freemasons in Ireland. For many years he was the sole Irish duke, and he also held the rank of first marquis and earl among the Irish nobility. In politics he was a Liberal, but conservative on the question of a repeal of the union with England. In 1818 the duke married the daughter of the Earl of Harrington, by whom he had four children. D. in London, Oct. 10, 1874. His eldest son, known as the Marquis of Kildare, succeeded to the dukedom, but died in 1887, and was succeeded by Gerald Fitzgerald.

The Fitzgerald family of Ireland is a very ancient Anglo-Norman one, long thoroughly Hibernicized, and derives its descent from the Barons of Offaly, first ennobled in 1205. In 1747 the family was elevated to the British peerage, and in 1766 the then head of the family was created Duke of Leinster.

Fitzgerald, Edward: author; b. at Bredfield House, near Woodbridge, Suffolk, England, 1809; d. 1883. He was educated at Trinity College, Cambridge, and spent his life mostly in his native county in study and literary pursuits. He made translations from Æschylus, Sophocles, and Calderon, and published a selection from the writings of his father-in-law, Bernard Barton, the Quaker poet. His fame rests, however, on his translation (1859) of the *Rubáiyát* (quatrains) of the Persian poet Omar Khayyam, which went through many editions and achieved a remarkable success. Fitzgerald's *Letters and Literary Remains* (3 vols.) were published in London in 1889. H. A. Beers.

Fitzgerald, Edward: a bishop of the Roman Catholic Church; b. in Limerick, Ireland, 1833. He removed to the U. S. in 1849; was educated at the College of the Barrens, Missouri, and at Mt. St. Mary's College, Emmettsburg; ordained priest in 1857; and in charge of a parish in Columbus, O., till 1867, when he was consecrated Bishop of Little Rock, Ark. While in Columbus he restored harmony between his parishioners and the Archbishop of Cincinnati, on which his church was relieved of an ecclesiastical interdict; and in Arkansas he promoted immigration to the State, and introduced several orders of brothers and sisters to conduct missionary, educational, and charitable work. He took part in the Vatican Council in Rome 1869–70, and in the Third Plenary Council in Baltimore 1884.

Fitz Gerald, James Newbury, D. D., LL. D.: a bishop of the Methodist Episcopal Church; b. in Newark, N. J., July 27, 1837. He was educated and fitted for the profession of law, and was from 1858 to 1862 an attorney and counselor. He entered the ministry in the Newark conference in 1862, and was pastor, or presiding elder, until 1880. He was recording secretary of the missionary society 1880–88, and elected bishop in 1888.

Fitzgerald, Rt. Hon. John David, P. C., Q. C., LL. D.: b. in Dublin in 1816; educated at Trinity College, Dublin: called to the bar in 1838, and became a Q. C. in 1847. In 1855–56 was solicitor-general of Ireland, and in 1856–58 and in 1859–60 attorney-general. In the House of Commons he represented Ennis from July, 1852, to Feb., 1860, and was then made a judge of the court of queen's bench in Ireland, where he was a commissioner of national education, of charitable donations and bequests, and of endowed schools. In 1856 he became a privy councilor. D. Oct. 16, 1889.

Fitzgerald, Oscar Penn, D. D.: a bishop of the Methodist Episcopal Church South; b. in Caswell co., N. C., Aug. 24, 1820; educated at Oak Grove Academy, Rockingham co., N. C.; held successively the positions of pastor, editor, college president, and superintendent of public instruction in California. He was elected bishop in 1890, and resides at Atlanta, Ga. He has published a number of books, including *California Sketches* (2 vols., 1879–81); *Christian Growth* (1883); *Centenary Cameos* (1884); *Bible Nights* (1888); *Judge Longstreet: a Life Sketch* (1891).

Fitzgerald, William, D. D.: Anglican Bishop; b. in Lifford, Limerick, Ireland, Dec. 3, 1814, and educated at Trinity College, Dublin; B. A. 1835. In 1840 he wrote in opposition to *The Tracts for the Times.* In 1847 was appointed Professor of Moral Philosophy in Trinity College, and in 1852 Professor of Ecclesiastical History. He edited *Constable's Ethics* and *Butler's Analogy*, and was author of one of the answers to *Essays and Reviews.* He was joint editor of *The Irish Church Journal* with Dr. Abeltshauser, was consecrated to the see of Cork in 1857, and transferred to that of Killaloe, Kilfenora, Clonfert, and Kilmacduagh, in 1862. D. at Clarisford House, Killaloe, Nov. 24, 1883.

Fitzmaurice, Henry Charles Petty: See Lansdowne.

Fitzpatrick, Charles: See the Appendix.

Fitzpatrick, John Bernard, D. D.: b. of Irish parents, in Boston, Mass., Nov. 1, 1812; educated at Boston, at the College of Montreal, and the Sulpitian Seminary, Paris. In 1840 he was ordained a Roman Catholic priest; in 1844 was consecrated coadjutor bishop of Boston; and in 1846 succeeded Bishop Fenwick in the bishopric. D. Feb. 13, 1866.

Fitzroy, Robert: British naval officer; b. at Amton Hall, Suffolk, July 5, 1805. He entered the navy in 1819, and in 1828 was placed in command of the Beagle brig, then engaged in surveying the coasts of Patagonia under Capt. King of the Adventure. The ships returned to England in 1830; in 1831 Fitzroy was commissioned to continue the surveys in the Beagle, Charles Robert Darwin (*q. v.*) going with him as naturalist. The cruise lasted until Oct., 1836, and included thorough surveys of the southern and western coasts of South America, and the running of a chronometric line around the globe. In 1837 Fitzroy received the gold medal of the Royal Geographical Society. In 1839 he published his *Narrative of the Surveying Voyages of H. M. Ships Adventure and Beagle* (3 vols., 8vo; the 3d vol. by Darwin). In 1841 Fitzroy was elected to Parliament; he was governor of New Zealand 1843 to 1845, and superintendent of the Woolwich dockyard 1846 to 1849. In 1850 he retired from active service. In 1851 he was elected to the Royal Society, and in 1854 was appointed chief of the meteorological department of the Board of Trade. D. in London, Apr. 30, 1865. Besides the *Narrative* referred to, he published several well-known works on navigation and meteorology, *Barometer Manual* (1861), and *Weather-book* (1863), and was practically the founder of the modern weather-signal service. Herbert H. Smith.

Fitzsim'mons, Thomas: b. in Ireland in 1741; became a merchant in Philadelphia, Pa., and commanded a volunteer company in the Revolutionary war; was for many years a member of the Pennsylvania Assembly; in 1782–83 delegate to the Continental Congress; in 1787 to the Federal constitutional convention; and 1789–95 member of Congress. D. in Philadelphia, Pa., Aug., 1811.

Fiume, fi-oo'mā: free imperial city of Hungary; on the coast of the Adriatic, at the mouth of the Fiumara, where it falls into the Gulf of Quarnero; 40 miles S. E. of Trieste (see map of Austria-Hungary, ref. 8–D). It is an important seaport; has large ship-building industry, and manufactures of paper, machinery, tobacco, etc. The harbor is excellent and the quay admirable. The exports and imports are considerable. Pop. (1890) 29,001.

Five Forks, Battle of: a battle between the Union forces under Gen. Sheridan and the Confederates under Gen. Pickett, fought in Dinwiddie co., Va., Apr. 1, 1865.

Gen. Grant, extending his left around the right of Lee's line near Petersburg, advanced the Fifth Corps (Warren) and the cavalry under Sheridan to the vicinity of Five Forks. Warren on Mar. 31 struck the right of the enemy's line on the White Oak Road, where, supported by Humphreys, he fought the action of White Oak Ridge with a loss of about 1,400 killed, wounded, and missing from his corps. Sheridan's advance, moving farther to the left, met a superior force near Five Forks, and was driven back to Dinwiddie Court-house.

On Apr. 1 Sheridan was placed in command of the movement, and having connected his forces with Warren's he decided to attack the left (east) flank of the Confederate position at Five Forks, overlap their line, strike their rear, and thus cut them off from the rest of the army, while the cavalry was to strike their front and right flank so soon as the infantry was fully engaged. The attack was made at about 4 P. M. and was carried out as planned; but, owing to the exact position and shape of the Confederate line not being known, some confusion arose in one of Warren's divisions, and the direction of the march of the other two had to be changed. The necessary steps were taken under the personal direction of Gens. Sheridan and Warren; the Confederate left wing was enveloped by the infantry, the cavalry attacked in front at the same time, and the Confederate line was rolled back from its intrenchments and completely routed, with the loss of a number of prisoners, estimated by different authorities from 2,600 to 4,500, together with six guns and thirteen colors. The number of killed and wounded is not exactly known, but was probably about 600. On the Union side the chief losses were those of the Fifth Corps, and amounted in killed and wounded to 634. An unfortunate controversy between Gens. Sheridan and Warren led to the latter being relieved from command immediately after the battle. On the next morning (Apr. 2) the final successful assault upon the lines at Petersburg was undertaken. A detailed description of this action, together with a *résumé* of the points involved in the controversy mentioned, is given in *The Virginia Campaigns of 1864 and 1865*, Humphreys, Scribner's War Series. See also the *Battles and Leaders of the Civil War*. JAMES MERCUR.

Five Islands: the northern end of the Philippine Archipelago. See BABUYAN.

Five Islands: post-village of Colchester co., Nova Scotia; on the Basin of Minas (for location of county, see map of Quebec, etc., ref. 2–B). It has considerable mineral wealth and manufactures of baryta paint, which is an imitation of white lead, and carries on ship-building. Here there is a cataract with a fall of 90 feet. Pop. 1,000.

Fixed Air: a name given by Dr. Black to CARBONIC ACID (*q. v.*). That this gas was liberated in the burning of lime was known to Van Helmont, who called it *gas sylvestre*, but Dr. Black's name came into more general use. Fixed air is properly carbon dioxide, CO_2.

Fixed Oils: See OILS.

Fixed Stars: See STARS.

Fixing: See PHOTOGRAPHY.

Fixtures [formed from *fixure* (either by analogy of *fixed* or of words in which, as is usually the case, the suffix *-ure* is preceded by *-t-*) from Low Lat. *fixu'ra*, a fastening, deriv. of *fi'gere*, *fixum*, fix, fasten]: things which, in themselves being personal property, have been annexed to or made accessory to real estate. There has been a bewildering variety of legal definitions given to the term, and it is hardly possible to fix upon any which would reconcile their various discrepancies and receive general acceptation; but the one here stated will probably make as near an approximation to accuracy and completeness as any that have been suggested. Annexations of this nature, when made under certain conditions and circumstances, still continue to be considered chattels, while in a different class of cases they are regarded as constituting a part of the realty, merely as a result of the change that has been effected in their situation and relations. Two structures identical in every respect, not only in construction, but also in the manner of their attachment to a house or land and in the uses to which they are applied, may be treated in law at one time as personalty, at another as realty; and as the rules as to management and disposition would be essentially diverse in the two cases, and additions to real property are very common for purposes of improvement, trade or manufacture, agriculture, etc., the "law of fixtures" is manifestly of great importance. The subtlety of the distinctions resorted to makes the subject one of exceptional intricacy, and has been the cause of much conflict in the decisions.

The question to be determined in every instance is, Has an addition to land become itself real property? It was formerly a well-established legal principle that such a result was consequent upon every case of attachment, and the rule was stated in a concise Latin maxim, as if universally applicable (*quicquid plantatur solo, solo cedit*—whatever is affixed to the soil belongs to the soil—i. e. becomes a part of it), but the exceptions which have been established have become so numerous that the formerly received doctrine, though still applicable as a general principle relating to fixtures, can no longer be regarded as of much practical value. In the elucidation of the subject the primary and fundamental inquiry must be whether there has been a true annexation in the legal meaning of the term. This annexation may either be *actual*, as where there is some real substantial attachment to land or buildings, or it may be merely *constructive*, as in cases where, though there is apparently no connection, and the articles are easily portable or removable, they are yet properly considered as appurtenant to certain real property and indispensable to its integrity. Thus machinery attached to buildings, furnaces, mirrors fastened to walls, etc., would be illustrations of actual fixtures, while door-keys, window-blinds, or bells temporarily detached, fences that have been removed but are to be replaced, etc., would constitute *constructive* fixtures. Such articles as the latter kind are, by common consent and necessarily, considered essential to the complete idea of a dwelling or a plot of land, as being requisite for its ordinary and proper use. But if, on the one hand, things originally chattels have been completely incorporated into real property, as where boards are fashioned into floors or plaster wrought into walls, or, on the other hand, chattels are merely suffered to rest upon land or lie within buildings, but are not naturally considered as essential thereto, no difficulty can arise as to whether the articles are real or personal. They are real in the former instances, and personal in the latter, beyond any possibility of doubt.

After the subject of annexation has been considered, another leading inquiry is the presumable intention with which the erections or additions were made, and by the establishment of what principles the requirements of a wise and judicious public policy would best be promoted. As the standard of "public policy" is necessarily very indefinite and general, it might be expected that the conclusions to be derived from its application would be largely determined by the more specific inquiry as to "intention," if the results which the latter afforded were entirely consistent with public welfare; and such seems to have been the case, since the rules referred to both these criteria mainly coincide. One test, however, serves to supplement and modify the other. In examining into the intent with which fixtures were erected, the actual purpose is not so much in question as the reasonably and justly *presumable* intention which the law can gather from all the attendant circumstances and the relations of the parties concerned to have been the instigating and guiding motive. When, for instance, a person sells land with certain additions upon it of the equivocal nature of fixtures, and which the purchaser may naturally have presumed to pass with the grant, and to have been intended for the permanent improvement of the property, the law will not permit the vendor to claim that his actual intent, though secretly indulged, was to consider the articles as personalty and remove them for his own use. An intent is fastened upon his conscience which his acts fairly and justly warranted, and which alone is consistent with any understanding which the opposite party could have formed under the circumstances. The dictates of public policy also support the same rule, since otherwise fraud could be readily committed, and free transfers of property would be hampered by suspicion and uncertainty. But if a vendor's actual intention is made known to the purchaser at the time of sale in regard to additions strictly within the class of fixtures, or if a chattel mortgage has been made in regard to them, which the purchaser can ascertain, presumed intent will coincide with actual intent, and the relations of the parties will be determined accordingly. Again, when additions for purposes of trade are made upon leased property by a tenant for years, it is necessarily presumable that he does not intend that they shall be permanent attachments, but that he only purposes their maintenance during the time of his tenancy. Considerations of public policy also support this conclusion, since the establishment of a prohibition upon tenants to erect fixtures which they could remove when their interests expired would materially interfere with the leasing of property and with commercial enterprise and progress. In all cases, however, in which specific contracts are made, or persons have a clear understanding of the terms upon which their interests are created, no opportunity for presumption can exist, and if the agreements be legal public policy can interpose no obstacle. The parties may determine upon what stipulations they will.

On these grounds has been made a division of the parties in regard to whom questions concerning fixtures most generally arise into two great classes: (*a*) One class consists of those interested in property on which fixtures have been erected by one having a *permanent* interest therein; (*b*) the second class is where the fixtures were annexed by one having only a *limited* interest in the land. Under the first class questions arise (1) between heir and executor of one adding fixtures to land; (2) between mortgagor and mortgagee of property on which fixtures had been erected by the former; (3) between vendor and vendee of land with fixtures thereon; (4) between vendor and contractor to buy land under similar circumstances. Under the second class questions occur (1) between landlord and tenant where the latter erects fixtures after the commencement of his lease; and (2) between tenant for life and remainder-man or reversioner. When the interests of all those varieties of parties grouped under the first class are concerned, the presumption is quite rigid that attachments to the land constitute a part of it, and consequently are governed by all the rules appertaining to real estate. Fixtures, therefore, which the law would presume to have been attached for permanent continuance will pass to heirs rather than to executors, will be conveyed under a deed or mortgage of the property to the vendee or mortgagee, or will be included within the contract of one who agrees to purchase the land. But a large number of annexations may, even in this class of instances, be considered as personal property, for those additions, as has been stated, are alone treated as realty in regard to which the legal presumption is that they were added for the *permanent improvement and habitual enjoyment* of the premises. In order to determine whether such a presumption can justly be entertained regard is had to a variety of tests, as, for instance, to the nature of the annexation, whether bulky and unwieldy or light and easily removable; to the adaptability of the attachment to the proper and natural use of the building in which it is placed, or of the land with which it is connected; and to many diverse considerations which must evidently depend upon the circumstances of each particular case. If a building were erected in such a location and with such peculiarities of construction that it could only be used to advantage by the employment of certain machinery which had been placed within it, or could be adapted to different purposes only at great expense, the deduction would be necessarily made that such machinery was intended to be no mere temporary attachment, but that it was designed for permanence.

One test of considerable importance and frequent application is to consider the manner in which the fixture is joined to or connected with the property to which it is attached—whether it can be removed without injury to the premises, or whether its fastenings can be readily detached. This was formerly said to be the chief distinguishing test in all questions concerning fixtures, the statement being made that all objects firmly fastened were real property, while those not so annexed remained chattels; but this rule would exclude all constructive fixtures from the category of realty, and can not be upheld. The criterion is only valuable as indicative of intention to have the articles remain constant attachments to the land. But it is so indefinite and general in its character, and leaves so much room for fine-drawn distinctions and delicate subtleties of discrimination whose reasonableness is oftentimes difficult to discern, that to this cause alone is attributable much of the confusion in the legal decisions upon the subject of fixtures. Thus machinery attached to a building by means of rods passing through joists and there secured by nuts has been held to be real estate, while looms merely fastened to the floor by screws have been considered personalty. Some courts have gone so far as to hold that articles fastened by bolts or nails would become realty, when if fastened by screws they would still remain chattels, since screws can be so much more readily removed that it is natural to believe that in the latter case a removal was intended. Other courts deny the distinction. In regard to such objects as stoves, boilers, kettles, and various articles of machinery of moderate size, the cases have exhibited much discrepancy. Buildings erected upon wooden blocks merely are generally considered chattels. A statue resting upon a pedestal in the garden of a dwelling-house has been decided to be real property as between a mortgagor and a mortgagee, as probably erected for permanent continuance. The rolling-stock of railroads is by some courts considered real, by others personal property, in perplexing variety. As between mortgagor and mortgagee the decisions preponderate that it may be treated as real estate. But by a decision rendered in New York it has been held to be personal property (*Hoyle* vs. *Plattsburg and Montreal Railroad Company*, 54 New York 314 [1873]).

But it would be useless to multiply illustrations; only the general principle can be satisfactorily stated. The common law rule is that trade-fixtures, in regard to the rights of those classes of persons that have hitherto been considered, are not to be treated differently from fixtures of other kinds, but in the relations of landlord and tenant it will be seen that they attain to great importance.

In regard to the rights of those persons forming the second class above mentioned—viz., landlord and tenant and tenant for life and remainder-man—the law concerning fixtures is very different. Both the question of presumed intent and the dictates of public policy, as has been seen, lead to conclusions essentially diverse from those which have been stated as applying to other cases. But the doctrine of presumed intention is not carried so far as to permit a tenant to erect anything he may choose upon his landlord's premises, with the privilege of removing it when his tenancy is ended, since the landlord's interests, which are equally deserving of protection, might be unduly sacrificed. The tenant therefore may only take away additions he has made when they belong to one of these special classes. (1) He may remove all fixtures which he has erected for purposes of trade or manufacture. This rule is established to promote business enterprise. Thus brewing-vessels, cider-mills, closets, shop-counters, engines, presses, etc., may all be rightfully removed. The rule has also been extended to buildings constructed by the tenant for purposes of trade, as, e. g., additions to an inn, tavern-keeping being deemed a species of trade. The removal must be made by the tenant so as not to injure the landlord's premises. (2) In the U. S. the general rule is established that fixtures annexed for agricultural purposes may be removed. In England a contrary rule was maintained at common law, but some exceptions have been established by statute. Nursery trees would be an illustration of agricultural fixtures. (3) Articles erected for domestic use and convenience and the necessary enjoyment of the premises are, in general, removable. This privilege probably would not extend to objects of mere ornament. In any case, it is necessary that the tenant should exercise his right of removal before the expiration of his interest and his yielding up possession, as otherwise he will be deemed to have abandoned the fixtures to his landlord. But the executor of a tenant for life, as the necessity of the case demands, has a reasonable time after the tenant's death to take away the fixtures.

The rights of landlord and tenant may be variously modified by mutual agreement. They may contract to consider certain articles chattels which would otherwise become real estate according to general rules, and *vice versa*. It is quite common to find a provision in leases that the fixtures at the end of the term shall be taken by the landlord at a valuation made in a specified manner; as, e. g., by appraisers selected by the parties. By such an agreement matters which, legally speaking, would be real estate may be made to appertain so far to the tenant as to entitle him to compensation. Consult Amos and Ferard on *Fixtures*; Washburne on *Real Property*; Chitty on *Contracts*, etc.

George Chase.

Flac'cus: a cognomen of several Roman families, of which the most important belonged to the gentes Fulvia, Valeria, and Pomponia. The poet Horace (*q. v.*) also bore this name. Among the illustrious men of the name were (1) Lucius Valerius Flaccus, consul with C. Marius in 100 b. c., censor in 97, and again consul in 86 b. c., when he was murdered by Fimbria. (2) Q. Fulvius Flaccus, consul 237, 224, and 212 b. c., often prætor, and distinguished in the Second Punic and many other wars, in which he was fortunate; but his character is stained by his cruel treatment of the Campanians. His family produced many public men, among whom his son, Q. Fulvius Flaccus (d. 173 b. c.), and his grandson, M. Fulvius Flaccus, were the most renowned. The former was a distinguished general in Spain; the latter, a partisan of the Gracchi, was put to death 121 b. c.

Flaccus, Gaius Valerius: an epic poet who flourished in the reign of Vespasian. He is not to be confused with Martial's poet-friend Flaccus, a native of Padua. The name given in the Vatican manuscript (C. Valerius Flaccus Balbus Setinus) makes it probable that he was born at Setia. He died in the reign of Domitian, probably about a. d. 89, and Quintilian speaks of his death as a loss to literature. He was the author of a poem entitled *Argonautica*, on the expedition of the Argonauts, in imitation of the poem of Apollonius of Rhodes, which extended to eight books, but was left unfinished. His style is an imitation of that of Vergil, but more declamatory and artificial. He often produces obscurity by the use of involved constructions and too crowded figures, and too frequently and on too slight occasions calls in the aid of the gods. The best editions are those of Burmann (Utrecht, 1702; Leyden, 1724); J. A. Wagner (Göttingen, 1805, 2 vols.); G. Thilo (Halle, 1863); and C. Schenkl (Berlin, 1871). Revised by M. Warren.

Flaccus, Siculus: a writer on land-surveying, who lived probably soon after the reign of Nerva. Nothing is known of his life. His extant work, *De Condicionibus Agrorum*, in its present form refers only to Italy, and is full of legal learning and valuable information. It is included in Lachmann's edition of the *Gromatici* (Berlin, 1848–52).

gustus. He was so successful in his method of instruction that the emperor placed his own grandsons under his charge, and allowed him to bring his other pupils into the Palatium, on the condition that no additions should be made to their number. At his death, under Tiberius, a statue was erected to him in the forum at Præneste. He was the author of several works, historical, antiquarian, and grammatical, the most important of which, and the one the loss of which is most deplored, was entitled *De Verborum Significatu*. This is referred to occasionally by later grammarians, and a few extracts from it (and the other writings of Flaccus) have been collected by O. Mueller in his edition of *Festus* (see *Præfatio*, p. xiii.), but it was superseded in general use by the abridgment of Festus, which no doubt caused the final disappearance of the larger treatise. (See FESTUS, SEXTUS POMPEIUS.) A brief notice of Flaccus is given by Suetonius in his *De Grammaticis et Rhetoribus*. See also Nettleship's articles entitled *Verrius Flaccus* in *Am. Journal of Philology*, vol. i., pp. 253–76, and ii., 1–19.

Revised by M. WARREN.

Fla'cius, MATTHIAS (surnamed ILLYRICUS): scholar and polemic; "the Achilles of pure Lutheranism," of the second generation of the era of the Reformation; b. at Albona, in Venetian Illyria (hence *Illyricus*), Mar. 3, 1520. His right name was Vlacich Francowitz. He desired to become a monk, but was dissuaded by Lupetinus, provincial of the Minorites, who put into his hands some of Luther's writings and counseled him to study theology in Germany. He went to Basel 1539; became private teacher at Tübingen 1540; went to Wittenberg 1541. Out of great spiritual darkness and distress, connected with his views of election, he was led by Luther, of whose faith he became one of the most earnest defenders. He received the chair of Hebrew 1544; in 1545 he married; in 1549 the Schmalcald war compelled him to leave Wittenberg. In the time of theological conflict on the Adiaphora which followed the INTERIMS (*q. v.*), Flacius took a position of uncompromising fidelity to the principles of Luther, which Melanchthon and his school were periling by indecision. He was a defender of the faith against open enemies and misjudging friends. (See OSIANDER, MAJOR, SCHWENKFELD, and SYNERGISM.) In Magdeburg he began (1557) his immortal church history, the *Magdeburg Centuries*, in which he was the main worker, though he had a body of able colaborers, among whom were Wigand, Judex, Faber, and Nicholas Amsdorf. Brischar, a Catholic divine, says: "It is impossible to ignore the erudition, the acuteness, and the gift of combination which express themselves in this book." The *Catalogus testium Veritatis* (1556) was meant to trace in a long line of witnesses the evangelical protest of the ages against the errors of Rome. In the same interest he published the *Missa Latina* (1557), a copy from a missal of about A. D. 700. In 1558 he was appointed a professor in the newly founded University of Jena; but in 1561 he was dismissed for his resistance to the encroachments of the state on the liberties of the Church. His whole after-life was one of wandering and suffering, amid which he finished his other great works, the *Clavis Scripturæ Sacræ* (1567) and his *Glossa on the New Testament*. He died in the hospital at Frankfort, Mar. 11, 1575, at the age of fifty-five, having displayed a tenacious courage, mostly for the truth, not unlike that of Luther. "He was," says Kling, "a man of faith, one of that cloud of witnesses of whom the world was not worthy." A lack of metaphysical accuracy in the use of language—which, however, he finally modified—involved him in a controversy which arose from his assertion that ORIGINAL SIN (*q. v.*) is a substance, and not accidental. This view, called "Flacianism," was condemned, in the strict sense of its phraseology. (See CONCORD, FORMULA OF.) Its adherents were styled Flacians and Substantialists. See the *Life* by A. Twesten (vindicating Flacius; Berlin, 1844), and that by W. Preger (the best; 2 vols., Erlangen, 1859–61).

Flad, HENRY: civil engineer; b. in Bavaria in 1823; graduated at the University of Munich in 1846. From 1849 to 1861 he was engaged in railway construction, mostly on the Ohio and Mississippi Railroad. He served in the civil war (1861–65), enlisting as a private and being promoted to the rank of colonel. Since 1865 he has been actively engaged on many civil engineering works, among which may be mentioned the water-supply of St. Louis, the arch bridge over the Mississippi at St. Louis, and the large park on the western border of that city. He has been president of the board of public improvements of St. Louis for many years; during 1886 he was the president of the American Society of Civil Engineers, and in 1892 he was one of the members of the Mississippi River Commission.

Flag [M. Eng. *flegge*, from Dan. *flæg*, flag. Perhaps akin to *flag*, droop]: any one of various long-leaved aquatic plants, such as sweet-flag (*Acorus calamus*), blue-flag (*Iris*), and cat-tail flag (*Typha*).

Flag [prob. from Dutch *vlag* < O. Dutch *vlagghe* (perhaps deriv. of *vlaggheren*, flag, droop): Dan. *flag*: Germ. *Flagge*]: an ensign. Webster defines *flag*, as "that which *flags* or hangs down loosely," "an ensign or colors"; a cloth usually bearing certain devices and attached to a staff; it is synonymous with the French *drapeau*. It is, in fact, one of the forms of *insignia* by which nationality is distinguished—by which the sway or jurisdiction of a political power is asserted. Hence its predominating use in those organizations of a country by which its sovereignty and jurisdiction are asserted and maintained—i. e. the army and navy. Hence, too, its powerful appeal to the patriotism of all those who see in it the symbol not only of their country's power, but of its claim upon themselves. Pendent over a fortress or ship, and throwing out, with the varying breeze, its folds to the four quarters of the heavens, it seems to hold above them the imperial ægis of a nation's power. A history of such "insignia" would occupy volumes. The Chinese flags or banners are said to have been, in essentially their present forms, in existence at a date earlier than the siege of Troy. The term "vexillum" of the Romans applies to anything that is *borne as an ensign*, whether it be a flag or banner, or some other device; but it became specifically applied to the *drapeau à croix* (i. e. a flag suspended to a horizontal cross-piece, attached by cords to the upright staff, with which arrangement the term "banner" has become identified) after the time when the Emperor Constantine introduced the LABARUM (*q. v.*); and this form of flag has been used ever since by the Church. It is also the most usual form of the banners of lay societies.

During the early days of the Revolution in North America the colonists made use of flags of various devices; the first legally established national emblem was that adopted by Congress June 14, 1777, which provided that the flag of the thirteen United States should be thirteen stripes, alternately red and white; that the union be thirteen stars, white in a blue field, representing a new constellation: this form was altered by act of Jan. 13, 1794, which provided that after May 1, 1795, the flag of the U. S. should consist of fifteen stripes, etc., and fifteen stars, etc.; in 1818, however, act of Apr. 4, the flag was re-established as thirteen horizontal stripes, alternately red and white; the union to consist of twenty stars, white, in a blue field; one star to be added to the union on the admission of every new State; the addition to be made on the fourth day of July succeeding such admission. This flag was first used July 4, 1818, and is still the recognized national emblem of the U. S. of America.

In the U. S. army the garrison flag is the national flag, 36 × 20 feet; the post flag is 20 × 10 feet; and the storm flag 8 feet by 4 ft. 2 in., used also as a recruiting flag. The colors of the engineer battalions consist of a national flag 6 ft. 6 in. by 6 feet, with the words U. S. Engineers embroidered in silver on the center stripe, and a battalion color of the same size, scarlet, having in the center a castle with the letters U. S. above, and the word Engineers below, all embroidered in silver. Fringe white, cords and tassels red and white silk intermixed. Each artillery regiment has two silken colors—the first, the national emblem, 6 ft. 6 in. fly and 6 feet deep on the pike; the number and name of the regiment embroidered with yellow silk on the center stripe. The second, or regimental color, is of scarlet, of same dimensions as the first, bearing in the center two cannon crossed, with the letters U. S. above and number of regiment below, both in scarlet in a yellow scroll. Fringe yellow, cords and tassels yellow and red intermixed. Infantry regiments have likewise two colors of silk and of similar size—the first of which is the national flag, with the number and name of the regiment in white silk on the center stripe; the regimental color is of blue, with the arms of the U. S. embroidered in silk on the center; the number and name of the regiment embroidered in white in a red scroll underneath the eagle. Fringe yellow, cord and tassels blue and white intermixed. Each mounted regiment has a yellow silken standard 4 × 3 feet, bearing the arms of the

U. S. embroidered in silk, with the number and name of the regiment embroidered in yellow in a red scroll underneath the eagle. Each company has a swallow-tailed silken guidon 3 ft. 5 in. × 2 ft. 3 in., half red, half white, divided at the fork, the red above: on the red the number of the regiment in white, and on the white the letter of the company in red.

The hospital and ambulance flags are of white bunting 9 × 5 feet, 6 × 4 feet, and 28 × 16 inches, with a cross of red bunting in the center; the arms of the cross are of equal length. Camp colors are national colors, as described for garrison flags, printed upon bunting 18 × 20 inches, mounted on an ash pole 8 feet long, armed at its butt with a pointed ferrule so that it may be easily driven in the ground.

The supreme royal standard of the United Kingdom of Great Britain and Ireland was hoisted for the first time on the Tower of London Jan. 1, 1801. It is a square flag or banner on which are emblazoned the arms of England, Scotland, and Ireland, the field of the first and fourth quarters being red, the second yellow, and the third blue. This flag is displayed over the residence of the sovereign or any other member of the royal family, as well as on certain fortresses and stations throughout the empire on state occasions or royal anniversaries, and is hoisted at the masthead of any vessel on which a member of the royal family is embarked. The second or admiralty flag in the British navy bears an anchor and cable on a red ground, and characterizes the presence on board ship of the lord high admiral or the lords commissioners of the admiralty. It came into use during the reign of Henry VIII. The third flag in the British navy is the national or union flag. Originally it bore the cross of St. George combined with that of St. Andrew, but on the legislative union with Scotland in 1707 a new design was adopted, to which the red cross of St. Patrick was added at the union with Ireland in 1800. This device forms the canton or upper corner next the staff in the British naval and commercial flags. The union flag is generally also called the union jack, but according to some authorities the name jack should be restricted to the small union flag displayed from a staff at the end of the bowsprit of war-vessels. The union flag is carried at the main, and is appropriated to the admiral of the fleet of the United Kingdom. On certain occasions it is displayed on shore as well as on sea. The fourth flag is a white flag divided into four quarters by a red cross. This flag is carried at the main by admirals, at the fore by vice-admirals, and at the mizzen masthead by rear-admirals. The ensign in the British navy is a large flag with a white, blue, or red field, bearing the union in the upper inner corner or canton. The white ensign is, in addition, divided into four quarters by the red cross of St. George, and is used exclusively by the royal navy and the royal yacht squadron. The blue ensign is appropriated to the use of the naval reserve and certain yacht clubs, and the red ensign is carried by the merchant marine, by most vessels not connected with the navy, and is commonly used on shore. The flag of the Lord-Lieutenant of Ireland bears the device of the union, with a blue shield in the center charged with a golden harp. It is hoisted at the main of the ship on which the Lord-Lieutenant may embark within Irish waters or on St. George's Channel.

Flags are used as the symbols of rank and command, the officers using them being designated *flag-officers*. Such flags are square, to distinguish them from *broad pennants* and *narrow pennants*.

There are flags also which are symbols of individual authority. Among such are royal standards, flag officers' flags, etc. In the navy of the U. S. the President's flag is rectangular in shape and blue in color, with the arms of the U. S. in the center, surmounted by thirteen stars in the arc of a circle, and is carried in the bows of his barge or hoisted at the main of the vessel on board of which he may be. The flag of the Secretary of the Navy is similar to that of the President in shape and color, but smaller, and has four stars, one in each corner with a vertical foul anchor in the center. The flags of an admiral, vice-admiral, and rear-admiral are rectangular in shape and blue in color, having four stars in the center for an admiral, three for a vice-admiral, and two for a rear-admiral. A commodore's broad pennant was swallow-tail in shape and blue in color, with one star in the center. In the event of two or three flag-officers being present, the senior's flag is blue, that of the second in rank red, and the junior's white.

To strike the flag is to lower the national colors in token of submission.

Flags, signal, are described under NAVAL SIGNALS.

Flag-captain, or *fleet-captain*, the chief of staff of a flag-officer or commander-in-chief; generally the captain of the flag-ship.

Flag-lieutenant, a lieutenant on the staff of a commander-in-chief.

Flag of truce, a white flag displayed to an enemy to indicate a desire to communicate. See INTERNATIONAL LAW.

In monarchical countries the royal standard is worn at ceremonies in honor of the sovereign and at those at which the sovereign may be present.

The white flag is the symbol of peace, and is used as the flag of truce or in token of surrender.

The red flag, bidding defiance, is often used by revolutionists. In the U. S. service, when hoisted at the fore of a vessel, it shows that she is receiving or discharging her powder.

The yellow flag shows a vessel to be in quarantine.

Flags are said to be at half-mast when they are hoisted but half the height at which they are ordinarily worn, and in this position designate mourning.

Dipping the flag is a salute to a fort or passing vessel by lowering it slightly and hoisting it again.

A pennant is a flag much longer in the fly than in the hoist. The *narrow* or *long* pennant, also called *coach-whip* and *streamer*, is carried at the masthead of a government vessel in commission. The *broad* pennant, such as carried by a commander's vessel, is sometimes pointed, and usually has its fly about twice its hoist. See FLAG-OFFICER.

Revised by JAMES MERCUR.

Flag′ellants [from Lat. *flagel'lans*, pres. partic. of *flagella're*, to whip, deriv. of *flagel'lum* (whence Eng. *flail*), dimin. of *flagrum*, a whip, scourge]: a name given to companies of persons in the Middle Ages who marched and sang and scourged themselves in public places for their own and others' sins. Self-flagellation, as a penance, had its origin in the monasteries, and is of early date. It was first recommended to others than monks about the year 900 by Reginō (d. 915), Abbot of Prüm, in Rhenish Prussia, in his *De Disciplina Ecclesiæ*, ii., c. 442, but it did not become a popular penance till after the time of Peter Damiani (1007–72 A. D.), by whom it was earnestly advocated. During the thirteenth, fourteenth, and fifteenth centuries the Flagellants became a sort of intermittent order of fanatics, frequently reappearing here and there in times of extraordinary declension or distress. Three such outbreaks are specially prominent: 1, in Upper Italy, 1260 A. D., in connection with the struggle between the Guelphs and the Ghibellines; 2, in 1349 A. D., while the black plague was raging; 3, in 1414, when many were beginning to be dissatisfied with the papal Church. The Flagellants generally enrolled themselves for the term of thirty-four days—a day for each year in the life of Christ. Stripped to the waist and scourging themselves with knotted whips, they marched with songs and banners from town to town. In market-places they would fling themselves upon the ground, with arms extended in the form of a cross, plying their whips till the blood came. Blood so drawn was thought to have an atoning efficacy. Other wild notions were entertained. The celebrated John Gerson (1363–1429) wrote against them, and they were condemned by the Council of Constance (1414–18). Their last appearance in Germany was in 1481. In spite of all their extravagances, their existence served as a sort of protest against the blind ritualism of the age. See the standard authority on the subject, E. G. Förstemann, *Die christlichen Geisslergesellschaften* (Halle, 1828); cf. W. M. Cooper, *Flagellation and the Flagellants* (London, 1870). Revised by S. M. JACKSON.

Flagella′ta: a group of Protozoa. See INFUSORIA.

Flagel′lum, pl. **Flagella** [from Lat. *flagellum*, a whip]: a name given to the long, whip-like, vibratory organ possessed by many microscopic animals and plants, and serving for purposes of locomotion, etc. A flagellum is simply a single, long cilium. See CILIA. F. A. L.

Flageolet′ [from Fr. *flageolet*, whistle, flute, dimin. of O. Fr. *flageol* < Lat. **flauti'olus*, dimin. of *flauta*, flute]: a musical instrument consisting of a wooden or ivory tube with a mouthpiece at one end, the other end being open. It has one large aperture near the mouthpiece and six or more finger holes. Its invention is ascribed to one Flavigny in 1580, but the flutes of the ancients, like those of some modern barbarous nations, were simply flageolets.

Flaget, flaa'zhā, BENEDICT JOSEPH, D.D.; Roman Catholic bishop; b. in Contournat, Auvergne, France, Nov. 7, 1763; received his first education in France; emigrated to America, and was consecrated Bishop of Bardstown Nov. 4, 1810. The name of the diocese was changed, and he became in 1848 Bishop of Louisville. D. in Nazareth, Ky., Feb. 11, 1850.

Flagg, GEORGE WHITING: See the Appendix.

Flagg, ISAAC, Ph. D: educator; b. in Beverly, Mass., Sept. 7, 1843; A. B., Harvard, 1864; A. M. 1887; Ph. D., Göttingen, 1871; tutor Harvard College 1865–69; Professor of Greek, Cornell University, 1871–88; associate Professor Classical Philology, University of California, 1891–; author of *Demosthenes's Hellenic Orations* (1880); *Versicles* (1883); *Æschylus's Seven against Thebes* (1886); *Euripides's Iphigenia among the Taurians* (1889). C. H. THURBER.

Flagler, ISAAC V.: See the Appendix.

Flag-officer: a generic term signifying a naval officer of rank high enough to command a fleet (see NAVAL TACTICS) or one of the sub-divisions of a fleet, and the naval equivalent of the military term *general officer*. The symbol of his rank is a FLAG (*q. v.*), as distinguished from the *broad pennant* of a commodore, or the *coach-whip* (long pennant) of a captain or commander. There are three grades of flag-officers—viz., *admiral*, ranking with general of land forces; *vice-admiral*, ranking with lieutenant-general; and *rear-admiral*, ranking with major-general. The ship of a flag-officer is called the *flag-ship*—a designation applied to the ship of a commodore when commanding more than one ship.

Flagstaff: See the Appendix.

Flagstone [*flag* < M. Eng. *flagge*, akin to Icel. *flaga*, flake, slab]: stone separable into broad flat slabs suitable for sidewalks, curbing, doorsteps, etc. In Great Britain the word *flag* is used in the same sense. Flagstones are derived from various sandstones and limestones of the sedimentary series and slates and schists of the metamorphic, all of which are sometimes divided by natural partings into layers of convenient thickness. Availability is further determined by breadth between the cross-partings called joints, by durability under wear, and by inability to acquire a high polish. Rocks readily polished are objectionable because slippery when wet. The rocks in greatest demand are sandstones of fine grain in which the cementing material is at the same time strong and less hard than the grains. Slate, although less durable, is much used for interior flooring, and limestone of open or crystalline structure is also employed. As there is no sharp line of separation between flagstones and building-stones, and as they are frequently obtained from the same quarries, the statistics of the flagstone industry have never been separately gathered. A variety of sandstone called *bluestone*, occurring at various horizons in shales of Devonian age and obtained from many localities in New York, New Jersey, and Pennsylvania, is largely used for this purpose.

Flagstones do not belong to any particular geologic age, and they occur at so many localities that the extent to which they are quarried in any region depends largely on the local demand. Prominent among the present sources of supply are the bluestone just mentioned, the Medina sandstone (Silurian) of New York, the Waverly sandstone (Devonian) of Ohio, and the Triassic "brownstone" of Connecticut and New Jersey.

The purpose of flagging is also subserved by various other materials. Various massive rocks, including sandstones, granites, and crystalline marbles, are sawn to the required thickness; and a variety of concretes and artificial stones are likewise employed. G. K. GILBERT.

Flahaut de la Billarderie, flaa'ō'de-laa-bēel'yaard'ree', AUGUSTE CHARLES JOSEPH, Count de: French general and diplomatist; b. in Paris, Apr. 21, 1785; entered the army at the end of 1799, became a colonel in 1809, and was aide-de-camp to Napoleon in 1813. In Oct., 1813, he distinguished himself at Leipzig, and was made a general of division and count of the empire; in June, 1815, fought at Waterloo, and after the battle advocated the succession of Napoleon's son. He left France after the second restoration, but returned in 1827, and in 1830, by the Revolution, was restored to his peerage and rank in the army. He was ambassador to Berlin in 1831, to Vienna in 1841–48; was made senator in 1853; was ambassador to London Dec., 1860. D. in Paris, Sept. 2, 1870.

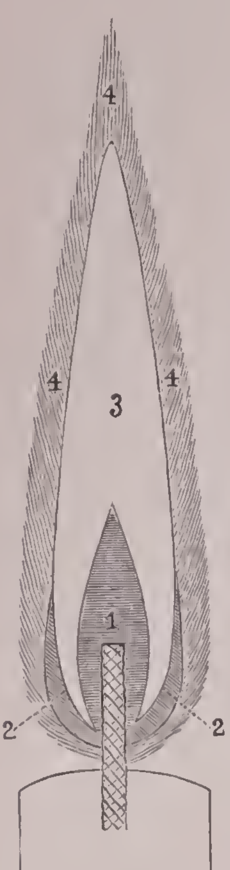
Flamborough Head: a promontory on the Yorkshire coast, England. It is formed by a range of steep, almost perpendicular chalk-cliffs, from 300 to 450 feet high, and bears on its headland a lighthouse whose revolving light (lat. 54° 7′ N., lon. 5′ W.) can be seen at a distance of 30 miles. Across the peninsula runs a ditch with ruins of old fortifications, called "Danes' Dyke."

Flamboyant, flăm-boi'ant [Fr., flaming, pres. partic. of *flamboyer*, to flame < O. Fr. *flambeoir*, deriv. of *flambe*, flame]: in architecture, a term used to designate generally a florid and showy style of design and decoration, and in particular that phase of mediæval French architecture which prevailed during the fifteenth century. During this period the rigid constructive logic of the earlier French Gothic architecture gives way to an unrestrained exuberance of decorative fancy, accompanied by great ingenuity and skill in executing details of extraordinary richness and complexity. Minute open-work tracery, with flowing lines and "fish-bladder" or "palm-leaf" openings, whose flame-like outlines gave rise to the name of the style; arches of various forms inclosed under hood-molds of ogee outline, terminating in rich finials; a general laxity of profiles in the moldings; the frequent suppression of interior pier-caps, and a thoroughly realistic and pictorial treatment of decorative sculpture, are characteristic of this period, which corresponds to the "Perpendicular" in England. Among its masterpieces are the façades in Rouen of the cathedral, the Church of St. Maclou, and the Palais de Justice; of the churches of St. Wulfrand at Abbeville and St. Jacques at Dieppe; the choir of St. Séverin in Paris, and many splendid choir-screens and inclosures at Troyes, Amiens, Chartres, and elsewhere. In Belgium, which was architecturally a province of mediæval France, the cathedral of Antwerp and the town-halls of Louvain and Ypres are a few among many examples of flamboyant design. A corresponding phase of Gothic architecture prevailed in Germany throughout the fifteenth century and well into the sixteenth, with extravagances even less restrained by a refined taste than in France. A. D. F. HAMLIN.

Flame [M. Eng. *flame*, *flaume*, *flaumbe*, from O. Fr. *flambe*, by-form of *flamme* < Lat. *flam'ma*, deriv. of *flagra're*, burn]: a mass of visibly glowing gas; ordinarily, of a gas in process of combustion with air or oxygen. But flame may accompany the combination of any gaseous bodies, provided the action be sufficiently intense to produce luminosity; or it may even result from the intense heating of a gas whose nature is not thereby changed. As a consequence of their high temperature, the gases constituting a flame will have a tendency to rise and form upward currents; this fact, and the circumstance that combustion as well as cooling proceeds from the outside inward, determines the erect and tapering form of undisturbed flames.

Structure of a Regular Hydrocarbon (candle, lamp, or gas) *Flame.*—In a candle-flame four distinct portions are readily distinguished, differing both in their aspect and in the nature of the processes producing them: 1. Immediately surrounding the wick there is a dark space of conical shape (No. 1 of figure) filled with the combustible gases formed by the first action of the heat on the fuel (wax, tallow, etc.), together with those flowing in through the base of the flame. The temperature in this dark space is quite low, and it is void of oxygen, so that neither will gunpowder explode nor phosphorus burn in it. 2. Surrounding the base of the dark cone and the lower portion of the luminous part is a cup-shaped zone (No. 2), of a blue tint, faintly luminous, but sharply defined. It results from the sudden and complete combustion of the gases of the dark cone, with a full supply of air (or oxygen) striking them from without. When the natural draught is artificially increased beyond a certain limit, the edges of the blue cup contract, and finally coalesce above, suppressing the luminous part, and forming a short conical blue flame; or if the blowpipe be used, there results an elongated cone, forming part of the "oxidation flame" of blowpipe practice, but itself possessing a slight reducing action. Its temperature is high. 3. Above the dark cone (1) lies the brightly luminous portion of the flame (No. 3), when it exists at all; its extent depending (other things being equal) upon the relative amount of carbon present in the fuel. In a wax, tallow, or coal-gas flame it forms a slender rounded cone with hollow base; while in that of alcohol it appears as a thin paraboloid (inverted cup-shape) zone. Its prominent characteristic is the separation of highly heated and therefore luminous carbon, out of its combinations with hydrogen, by the intense heat of No. 4, the exterior zone of final and complete combustion.

The latter, a faintly luminous halo (the "outer veil"), surrounds the flame on all sides, and is its hottest portion. The maximum of temperature is a little *above* the point of the luminous cone, where also is found the highest *oxidizing* power; while just *within* the luminous point high temperature and the presence of free carbon co-operate to produce the most energetic *reducing* action.



Flame.

Luminosity of Flames.—The luminosity of flames varies between wide limits, from the faintly luminous and (in daylight) almost invisible flames of hydrogen, carbonic oxide, or sulphur, to the intense brilliancy of the "Bude light," in which coal-gas is burnt with pure oxygen, and of the magnesium flame. Frankland has shown that faintly luminous flames may become intensely so when the gases are strongly compressed during combustion. Under ordinary circumstances, however, useful luminosity is dependent upon the presence in the flame of a sufficient (yet not excessive) amount of a highly heated solid: usually carbon, which in ordinary candle, lamp, or gas flames is liberated from the combustible gases by the influence of the high temperature of the exterior portions of the flame, through which no free oxygen can pass inward. But when illuminating gas is, previous to combustion, mixed with air or oxygen sufficient for the complete combustion of all its ingredients, the separation of carbon, and consequent luminosity, will be suppressed, while the temperature is greatly increased. This is the principle upon which the "Bunsen burner" is based, the body of whose flame represents the blue cup (No. 2) or the "oxidation cone" of the blowpipe. By varying the supply of air the flame may thus, at will, be made to exert an oxidizing or a reducing effect—a principle of most important practical application in the management of the reverberatory and gas furnaces used in metallurgical operations, where the flame, urged either by draught or blast, or by both combined, is readily varied in character to suit the requirements of any stage or kind of process.

The temperature of flames depends primarily upon the nature of the fuel, upon the rapidity and completeness of combustion, and upon the amount of inert gas mixed with the active ingredients. The hottest flame is that of pure hydrogen burning with half its bulk of pure oxygen; but a hydrogen flame burning in air is less hot, because four-fifths of the air is an inert gas (nitrogen), which has also to be heated. Still less hot is the flame of coal-gas in air, because it consists in part of carbon, whose combustion generates less heat than does that of hydrogen.

The measurement of flame temperatures is a matter of very great difficulty. The following are the values for the hottest portions of a few flames which have been subjected to experiment:

Bunsen flame (non-luminous)....	1,360° C.	(Rossetti).
Stearin candle-flame............	940° C.	"
Locatelli lamp-flame............	835° C.	"
Alcohol flame..................	1.180° C.	"
Gas flame (argand burner)......	1,373° C.	(Crova).

According to Rogers (Silliman's *Journal*, 43, p. 301), the flame of the common blast-lamp is about 150° hotter than that of the Bunsen burner, while the flame of burning magnesium occupies an intermediate position, being at least 50° lower than the blast-lamp flame.

The color of flames depends in part upon the substances that are vaporized within them, and is very characteristic, especially when observed with the spectroscope. Thus compounds of sodium (such as common salt) produce a yellow tint; copper, green and blue; calcium (lime), orange-red; strontium, crimson; potassium, violet, etc. Such flames show bright line spectra; the spectrum of ordinary illuminants, however, is simply that of solid incandescent carbon heated to a temperature of rather more than 1,000°. It is a continuous spectrum with the maximum of energy in the infra-red. Of the apparent light-giving area of ordinary gas-flames, only about 1 per cent. is actually occupied by luminous particles. A bat's-wing burner, for instance, of 5 sq. inches apparent area will not exceed in candle-power an incandescent lamp of the same temperature the area of the filament of which is ·05 inches.

Revised by E. L. NICHOLS.

Fla'men [Lat., priest, connected either with Goth. *blōtan*, worship, or with Sanskr. *brahman-*, priest]: a Roman priest devoted to the service of one deity. They were at first three (established by Numa), but were increased ultimately to fifteen, constituting two distinct classes—viz.: (1) the *Flamines majores*, consisting of only three, the *dialis*, *martialis*, and *quirinalis*, consecrated the first to Jupiter, the second to Mars, and the third to the deified Romulus, and selected from the descendants of patricians only; and (2) the twelve *Flamines minores*, who usually were of the plebeian order. The office was for life, but a flamen could forfeit it by neglect of duty, and was liable to removal if an ill-omened event disturbed any of his sacred performances. Their characteristic dress was the *apex*, a cap either conical or close-fitting, having at the top a pointed piece of olive-wood, surrounded at its base by a lock of wool (*filum*, whence, according to Varro and Festus, the word *flamen* was obtained, but by Plutarch derived from *pileum*, hat), the *læna*, or mantle, and the laurel wreath. The most distinguished of the flamens was the *dialis*, who was required to be the son of parents united in marriage by confarreation. The *flamen dialis* immediately after his appointment, though a minor, was relieved from parental control, and became a *sui juris*. He was never required to give oath, had a seat in the Senate *ex officio*, and, like the highest officers of state, had the use of the *sella curulis* (or chair of state) and of the *toga prætexta*, the assistance of a lictor, the right of sanctuary for his house, and the high prerogative of procuring pardon or respite for criminals. On the other hand, the *dialis* suffered numerous restrictions and deprivations; as, e. g., he was not allowed to mount, or even to touch, a horse, wear a ring, or to touch a dead body. He was forbidden to sleep out of his own bed for three consecutive nights, to leave the city even for a single night (a rule modified by Augustus and Tiberius), and was obliged to resign and remain single upon the decease of his wife, who assisted him in the performance of some of his sacred functions. She was called *flaminica*, and was subject to restrictions like those by which her husband was fettered. The *flamen dialis* was chosen by the Pontifex Maximus from three candidates, nominated by the pontifices. See Marquardt, *Römische Staatsverwaltung* (vol. iii., pp. 313–323).

Revised by G. L. HENDRICKSON.

Flameng, flaa'meng, FRANÇOIS: figure-painter; b. in Paris in 1859; pupil of his father, Leopold Flameng, the engraver, and of Cabanel, Hedouin, and Jean Paul Laurens; second-class medal, Salon, 1879; medal of honor, Paris Exposition, 1889; Legion of Honor 1885. An artist of fine ability; among his most important works are *The Girondins Summoned* (1879) and *The Bowlers* (1886). *Grolier and Aldus* is in the Grolier Club, New York. Studio in Paris. W. A. C.

Flamingo, flă-ming'gō [from Portug. *flamingo*: Span. *flamenco*; cf. Prov. *flamant*, flamingo, pres. partic. used as noun of *flamar-*, to flame]: a bird of the genus *Phœnicopterus*; distinguished by a bill bent downward for half its length and provided with tooth-like projections, or lamellæ, similar to those of a duck's bill. The neck and legs are long, the feet webbed. On account of their long legs the flamingoes were formerly classed with the waders, but they seem rather to be aberrant ducks, and are now placed with those birds in the order *Anseres* or *Chenomorphæ*, or occasionally set apart in the order *Odontoglossæ*. Several species are known inhabiting tropical or warm countries, the most familiar being *Phœnicopterus antiquorum* of Southern Europe and Northern Africa, and

Flamingo.

P. ruber of tropical America, the latter still occasionally found in Florida and along the Gulf coast, although it has been practically extirpated in those localities. Flamingoes build a nest of mud in wet localities, or even in the water, and as these nests are built on year after year, they vary in height from 6 to 18 or 20 inches. The statement, based on an old account of Dampier's, that the birds sit or stand astride of the nest is erroneous, for their legs are doubled beneath them in the usual manner of birds. A curious, small flamingo (*Phœnicoparrus andinum*) is found in the Andes. F. A. Lucas.

Flamin'ian Way [translation of Lat. *Via Flaminia*; *via*, way + *Flaminia*, fem. of *Flaminius*, pertaining to Flaminius]: the principal northern road which led from ancient Rome. It was laid out from the Flaminian gate of Rome to Ariminum by C. Flaminius the Elder in 220 B. C., during his censorship, and with its subsequent extensions and branches finally reached nearly all the large towns of Northern Italy. Its remains are still visible at various points.

Flamini'nus, Titus Quintius: a general of the Romans; b. about 230 B. C.; became quæstor in 199 and consul in 198; invaded Epirus, which he subjugated; gained in 197 the great battle of Cynoscephalæ over Philip, the last King of Macedon; proclaimed at the Isthmian games, in 196, the independence of Greece; overthrew the tyrant Nabis in the Peloponnesus in 195; triumphed in 194; was ambassador to Greece in 192–190; censor in 189; envoy to Prusias of Bithynia 183, designing to arrest Hannibal, who was an exile there. D. about 174 B. C.—His brother, Lucius Quintius Flamininus, was an able general and admiral, notorious for vice and cruelty.

Flamin'ius, Caius: a Roman of plebeian birth; became tribune 232 B. C., and carried an agrarian law against the strongest opposition; was prætor in 227; as consul in 223 defeated the Insubrian Gauls and triumphed, but was deprived of his office by the senate; was magister equitum to M. Minucius Rufus 221, but both had to resign immediately, on account of the squeaking of a mouse, an evil omen; was one of the censors in 220, and constructed the Flaminian Way and the Flaminian Circus; again consul in 217; marched against Hannibal, and was defeated and slain in the battle of Lake Thrasymene, June 23, 217 B. C. Flaminius was a man of singularly bold and decided character, hated by the aristocrats and idolized by the common people. —His son, Caius Flaminius, was an able general, consul in 187 B. C.

Flammarion, flaa'maa'ri-ōn', Camille: astronomer; b. at Montigny-le-Roi, Haute-Marne, France, Feb. 25, 1842; studied in the imperial observatory from 1858 to 1862, when he became editor of *Cosmos*. In 1865 he was appointed scientific editor of the *Siècle*; in 1868 made several balloon ascensions to study the atmosphere at great altitudes. He has written a number of books, some of which are of a popular character, including *La Pluralité des Mondes Habités* (1862); *Les Mondes Imaginaires et les Mondes Réels* (1864); *Les Merveilles Célestes* (1865); *Dieu dans la Nature* (1866); *Histoire du Ciel* (1867); *Contemplations Scientifiques* (1868); *Voyages Aériens* (1868); *Astronomie sidérale* (1879); *Astronomie populaire* (1880); *Dans le Ciel et sur la Terre* (1886); *Uranie* (1889).

Flam'steed, John: first English astronomer royal; b. at Denby, Derbyshire, Aug. 19, 1646; graduated at Cambridge University, taking M. A. there in 1664; early began the study of the stars; was ordained a clergyman, and obtained the living of Bristow, Surrey, in 1684. He had been appointed astronomer royal in 1675, and finished the observatory of Greenwich in 1676. Here he passed his life in observation, determining the position of 2,934 stars; erected a mural arc in Sept., 1689; quarreled with Sir Isaac Newton, but ultimately adopted his philosophy. His great work was *Historia Cœlestis Britannicæ*, published in 1725 in 3 vols., the first trustworthy catalogue of the fixed stars. D. at Bristow, Dec. 31, 1719.

Flanders: the territory formerly comprising two provinces of Belgium (East and West Flanders), the southern portion of the province of Zealand, in the Netherlands, and two departments of France (Nord and Ardennes). In the latter part of the ninth century this territory was given by the French King Charles the Bald as a fief to his son-in-law, Baldwin with the Iron Arm, Count of *Vländergau*, who gave the country its name, and who by his prudent management laid the foundation of that agricultural, industrial, and commercial prosperity which soon afterward made it powerful. A spirit of independence and republicanism sprang up with material success, and the relations between the Flemish towns and the Counts of Flanders was often very loose. On the marriage of Marguerite of Flanders to Philip the Bold of Burgundy (1384), Flanders became united to Burgundy, and a century later (1477), on the death of Charles the Bold, it passed, together with that country, to the house of Hapsburg by the marriage of Mary of Burgundy to the Archduke Maximilian. On the abdication of Charles V., in 1556, Flanders and Burgundy came into the possession of the Spanish line of the house of Hapsburg with Philip II., but the territory of Flanders was soon considerably diminished, a northern portion of it being transferred to the States General by the Peace of Westphalia (1648), and a southern portion being conquered by Louis XIV., and secured to him by the Peace of Utrecht (1713). The remainder of Flanders fell again by the Congress of Rastadt (1714) to the Austrian line of the house of Hapsburg, but in 1794 it was conquered by the French and incorporated with the French republic, and afterward with the empire, until the Congress of Vienna (1814) conferred the territory on the kingdom of the Netherlands, to which it remained united until the formation of the kingdom of Belgium in 1831, when most of it was incorporated in that country. But under all these changes Flanders was always rich and prosperous, for it was industrious and enterprising, and it was always independent or fighting for its independence. Flemish influence on commerce and industry, on literature and art, on morals and fashions in Europe, has been very considerable, and to the student who wishes to understand the relation between energy and prosperity, and between prosperity and morals, its history is a rich source of information. See Flemish Language and Literature.

Flanders, East, province of Belgium, bounded N. by Holland; area, 1,158 sq. miles. Pop. (1896) 1,002,300; 865·5 to the sq. mile. It is the most thickly peopled region in Europe. Its surface is a low and level plain belonging to the Scheldt basin. Its soil, though in many places sandy, has been made exceedingly fertile by spade cultivation and an excellent system of manuring. Flax and hemp are its most valuable productions; linen, laces, damasks, and bobbinet its most valuable manufactures. The principal towns are Ghent and Dendermonde.

Flanders, West, province of Belgium, bounded N. by the North Sea and W. and S. by France; area, 1,249 sq. miles. Pop. (1896) 781,261. The surface is flat, for the most part belonging to the Scheldt basin, but with a range of low sandy hills along the coast. Its soil is sandy, but well cultivated and fertilized, though not so productive as that of East Flanders. The principal towns are Bruges and Ostend.

Flandrin, flaañ'drăñ', Jean Hippolyte: historical and portrait painter; b. in Lyons, Mar. 23, 1809. Pupil of the sculptor Legendre, of Revoil at Lyons Academy, and of M. Ingres; Grand Prix de Rome (1832); officer Legion of Honor (1853). He was very poor in the earlier part of his career, but obtained recognition on his return to Paris from Rome in 1838. His portraits are excellent, and his decorative work is notable for its attention to form, and is strong in color quality. He executed frescoes in St.-Germain-de-Prés (1842–61) and St. Vincent de Paul (1850–54), Paris, St. Paul, Nîmes (1847-49), and other churches, and in the Conservatoire des Arts et Métiers, Paris (1854). One of his important pictures, *Dante and Vergil* (1835), is in the Lyons Museum, and a *Study of a Figure* (1855) and *Portrait of a Young Girl* (1863) are in the Louvre. Other portraits are in the Versailles Museum. D. in Rome, Mar. 21, 1864. —His brother Jean Paul (b. in Lyons, May 8, 1811) is a landscape-painter whose works are in the museums of Lyons and Nîmes. William A. Coffin.

Flannel [Fr. *flanelle*: Ital. *flanella*, derived from Celt. *vlan-*, wool, or possibly from Lat. *filum* + *lana* (?)]: a fabric formerly made of wool alone, and still chiefly made of that fiber; but there are silk-mixed, linen-mixed, cotton-mixed, and all-cotton flannels. Flannels with a cotton warp are called dometts. All-cotton goods, baize-woven and having a dense nap on one side, are called canton or cotton flannels. In general flannels have a loose-twisted yarn, and hence their superior warmth. There are many varieties—some twilled and others not—from the translucent gauze undershirting to heavy homespun flannels. Choice flannels are used for men's suits and for ladies' opera-cloaks. Many fancy flannels are now printed in colors. The best flannel is made in the neighborhood of Welshpool and Newtown, in Wales, from the wool of the Welsh mountain-sheep, and is commonly known as Welsh flannel. Large quantities are also made in West Lancashire, West Yorkshire, and the neighborhood of Leeds. Fine light flannel is also made in France and Belgium, approaching in quality to French merinos, though much softer.

Flat: a musical character (♭), the effect of which is the lowering of the note to which it is prefixed a semitone. On the organ and other keyed instruments each black (or short) key is the *flat* of the white key on the right hand, and also the *sharp* of the white key on the left. But as E and F, B and C, are only a semitone apart, and have therefore no intervening black key, F♭ and C♭ are produced by striking the white keys E and B, being the next on the left hand respectively. A double flat (♭♭) lowers a flattened note two semitones. An *accidental* flat is one which affects only a single note or its repetitions in the same bar, except when the first note of the next bar is a mere prolongation of the preceding one. One or more flats placed at the clef, as B, E, A, D, etc., affect all the notes of similar name in every octave throughout a movement, unless contradicted by a natural (♮). Revised by DUDLEY BUCK.

Flatbow Indians: See KITUNAHAN INDIANS.

Flatfish: See DAB, FISHERIES, and PLEURONECTIDÆ.

Flathead Indians: See SALISHAN INDIANS; also SIOUAN INDIANS.

Flathead River: See CLARKE RIVER.

Flattery, Cape: See CAPE FLATTERY.

Flatworms: translation of the scientific name PLATHELMINTHES (*q. v.*), a grand division of the animal kingdom containing the flukeworms, tapeworms, etc. Most of the species of flatworms are parasitic.

Flaubert, flō'bãr', GUSTAVE: author; b. at Rouen, Dec. 12, 1821. He first studied medicine, but afterward devoted himself entirely to literary studies. Originally a pupil of Victor Hugo and Byron, he broke off from the romantic school and became one of the forerunners or first representatives of the realistic or naturalistic school. His first book, *Madame Bovary* (2 vols., 1857), was an unqualified literary success, but met with great opposition on account of its moral bearings. His second book, *Salammbo* (1862), which has Carthage at the time of the Second Punic war for its scene, also made a great sensation, though also encountering considerable opposition from the archæologists. D. in Paris, May 10, 1880. See his *Life* by Tarver (London and New York, 1895).

Fla'vel, JOHN: English Nonconformist clergyman; b. in Bromsgrove, Worcestershire, about 1630; was educated at Oxford, and became rector of Dartmouth in 1656, but was ejected for nonconformity in 1662, and afterward preached in private houses. His works are highly prized, and among them are *Husbandry Spiritualized* (London, 1669); *A Saint Indeed* (1673); *Divine Conduct* (1678); *The Touchstone of Sincerity* (1679); *Personal Reformation* (1691); *Exposition of the Assembly's Catechism* (1693); *The Soul of Man* (1698). His complete *Works* were published in Newcastle (6 vols., 1701; 3d. ed. 1797). D. at Exeter, June, 29, 1691.

Flavia'nus: patriarch of Antioch; b. about 309 A. D. In early life he was a lay monk, zealous for the faith, and according to Theodoret, he, with Diodorus, his associate, first devised the choir and introduced the responsive singing of the Psalter. In 381 A. D. he was chosen Bishop of Antioch to succeed Meletius, but was not fully acknowledged by all factions until 390. In 387 he interceded with Theodosius the Great for the seditious people of Antioch. He strongly opposed Arianism and the Messalians, and died in 404 A. D. Chrysostom was one of his pupils.—Another Flavianus was Bishop of Antioch from 498 until in 512 he was banished to Petra, where he died in July, 518 A. D. He is commemorated as a confessor by the Roman Catholic Church July 4.

Flavianus, SAINT: ecclesiastic; became Bishop of Constantinople 446 A. D., and was from the first opposed by Theodosius II., the emperor, who favored the Eutychian heresy. Flavianus called a synod which deposed and excommunicated Eutyches (448), but in 449 the emperor convened a council at Ephesus (the robber council), presided over by Dioscurus, Bishop of Alexandria, who was the enemy of Flavianus. The latter, who was present, was deposed and ordered to be banished, but was set upon and so beaten by the Egyptian party that he died at Hypepe, Lydia, Aug. 11, 449 A. D.

Fla'vine: a preparation of QUERCITRON BARK (*q. v.*).

Fla'vius: the name of many eminent Romans, mostly of the gens Flavia, an ancient plebeian stock, but many of the Flavii who figure in history were undoubtedly not of this gens, and were indeed not even Romans in a strict sense.—GNÆUS FLAVIUS, a Roman jurist who was curule ædile in 304 B. C., was the son of a freedman and secretary to Appius Claudius Cæcus. His publication of the *Jus Flavianum*, embracing the secret rules of judicial procedure, hitherto known only to pontiffs and patricians, caused great indignation, and made him exceedingly popular with the common people.—Vespasian, Constantine the Great, and many other Roman emperors bore the name of Flavius.

Flax [O. Eng. *fleax*: Mod. Germ. *Flachs*]: a plant important as the source of the fiber from which linen cloth is made, and of flax seed. Like the more important cereal grains, flax was known throughout the ancient seats of civilization in the East. It is therefore impossible to determine where it originated. It is known throughout the civilized world, and is valued as an almost indispensable adjunct of civilization. Its botanical name is *Linum usitatissimum*. The genus *Linum* contains several species, of which this is the only one of especial value or of commercial importance. The *plant* is an annual of quick growth, and probably a race which originated from a species still indigenous to Southern Europe. It grows from 1 to 3 feet high. The leaves are alternate upon the straight slender stem and branches. The flowers, which are in loose terminal panicles, are blue, about an inch in diameter, having a calyx of five sepals, a corolla of five petals, five stamens, and a pistil having five styles. The petals drop within a few hours after the flowers open, and the seed-heads, called *bolls*, form rapidly, becoming finally nearly globular. These consist of ten cells, each containing a flat oval seed of a reddish-brown color, very smooth and glossy. When the plant grows by itself in good soil, it branches freely, blossoms profusely, and yields a proportionately large quantity of seed. When, however, many plants are crowded together, each one grows as a single upright stem, bearing a few blossoms and little fruit at the summit. The valuable portions of the plant are the fibrous coating of the stalk, and the seed. The *stalk* is a woody cylinder, more or less pithy and hollow when dry, and inclosed in a bark consisting of long, strong, silky fibers cemented together by a kind of glue, and encased in an outer bark or skin, which adheres as if glued to the fiber. The *fiber*—when freed from all else, so far as possible, by the processes of rotting, to destroy the glue; breaking, to free it from the woody part of the stalk; scutching, to whip out the small particles of bark and stalk adhering; hatcheling, to straighten it and free it from tangles—is nearly pure bast, of a light grayish-brown color inclining to green, exceedingly tough, adapted to spinning and weaving, capable of being bleached to snowy whiteness and of taking a variety of colors in dyeing, which it holds faster than cotton, though it does not take readily so many dyes.

Flax (*Linum usitatissimum*).

The ultimate filaments are hollow, thick-walled, and thus nearly solid cylindrical cells, which are terminated by exceedingly attenuated points. They are semi-transparent, of a silky luster, and under the microscope the walls of the tube appear like a double line through the center. These filaments vary in thickness from $\frac{1}{650}$th to $\frac{1}{5000}$th of an inch, according to the measurements of Mr. John Phin, who describes the cells as jointed, apparently like the stalks of the bamboo cane. (See FIBER.) When the fiber is separated from the bark and wood of the stalk, as above indicated, it appears in market in two principal forms—namely, "dressed flax" and "tow," which are each of several qualities.

The *seed* consists of the embryo or kernel and its outer coverings, principally its reddish-brown shell, which is very mucilaginous, yielding, particularly to hot water, a thick, glairy gum, becoming quite viscid when cold. The kernel is rich in a valuable oil, which possesses the property of "drying" or hardening on exposure to the air to a remarkable degree (see LINSEED OIL), by which process of drying it gains, instead of losing weight. Powdered flaxseed and powdered oil-cake (linseed meal) are much used in medicine and surgery for poultices, epithems, etc., and are useful on account of their long retention of heat and moisture. The cake remaining after the oil is extracted from the seeds makes when ground an exceedingly palatable and nutritious food for animals, largely used in the U. S. and Great Britain for fattening animals and milch cows.

FLAX-CULTURE.—Flax is a plant of rapid growth, and is sown in April or May and harvested early in August. When raised for seed it makes considerable drafts upon the soil, which should therefore be rich and in fine tilth. As it is almost impossible for manure to be evenly distributed through the soil the first season, it is best to grow flax upon land heavily dunged the previous year as for a corn-crop, but dressed the same season with wood-ashes or some other "hand manure" which can be evenly applied and is adapted to the wants of the land. Good wheat-soils are especially favorable to flax. Heavy clays, coarse gravels, light sands, and peaty soils are not so. Moderately stiff soils should be plowed in autumn, light ones early in the spring. As soon as weeds begin to germinate and grass to grow the land should be thoroughly and evenly plowed and harrowed. If the weather be not favorable to sow, the harrowing may be repeated, and thus successive crops of weeds killed in the seed-leaf. Finally, when the ground is warm in spring the seed should be sown. The practice in Europe is to sow very early; in the U. S. flax should not be sown until after the oat-crop is in—say from Apr. 15 to May 1 in the Middle States. The quantity of seed sown to the acre depends upon the object for which the crop is raised; if principally for seed, half a bushel to three pecks is used; if for fiber mainly, a bushel to a bushel and a half is employed. It is very important that the sowing should be even, for otherwise the tendency to branch is great, and those plants which are less crowded will grow coarser and larger, ripen their seed unevenly, and cause the crop of lint to be of unequal fineness, and to leave much more of the fiber in the tow than otherwise need be. Flax should be sown as carefully as fine grass-seed, and to enable the sower to handle it more easily it is sometimes soaked a short time in cold water and then rolled in plaster. It should be harrowed in evenly with a light harrow, or, better, put in with an improved grain drill. Some farmers, who raise flax for the lint principally, preferring that no horse should tread upon the land after sowing, brush the seed in with a heavy hand bush harrow, made like a stable broom by inserting short pieces of brush in a hard-wood head 5 or 6 feet long. This is drawn over the ground by means of handles attached at right angles, or nearly so, to the brush. It is most important that the flax should get the start of the weeds, and when it is about 3 or 4 inches high it should be carefully examined, and if necessary weeded at once—an operation best done in moist weather and by women and children, who go upon the crop without shoes, and work facing the wind, so that the breeze may favor the downtrodden plants to rise again. It is better to let the weeds grow than to weed the crop after the plants are 6 or 8 inches high, or to do this hurriedly, mashing and bruising the plants. After this the crop is "laid by" until pulling-time.

Pulling.—Flax is ready to pull when it changes color decidedly after blooming, becoming of a yellowish or golden-brown color, two-thirds of the bolls being plump and beginning to turn brown, and the leaves having shriveled and dried upon the lower half of the yellow stalks. Pulling should take place a little earlier than we describe if lint be the principal object, but a little later if the seed pays best. This is done by grasping a handful of stalks in one hand near the tops, and then pulling them with both hands, giving a *steady jerk*, so to speak. This handful is not laid down, but held while other handfuls are pulled, until as much is gathered as can conveniently be grasped: then it is bound after "butting" the roots even. Stalks which fall out and scatter are used for bands. These bundles are set up in long shocks, to become cured thoroughly before stacking. The drying process is greatly shortened if, instead of binding as soon as pulled, the gavels are spread out on the ground, so as to be turned and sunned on both sides before binding.

If the fiber is an important object with the farmer, the flax should be pulled as described, but otherwise it may be mowed with a scythe or cradle, or with a reaper, cutting close as possible to the ground, and harvested and threshed in the same manner as any other grain crop.

Threshing.—After drying and standing in the stacks, or not, as the case may be, the seed may be threshed off by a flail or by beating the heads of the sheaves against a block of wood, which easily removes the bolls. On a large scale the seed is most easily removed by holding the bundles spread out, fan-shaped, upon the cylinder of a threshing-machine, the "concave" being taken off. After this the flax is ready to be subjected to the process called

Retting (*rotting*).—This is conducted either under water, or upon the grass, where the flax is exposed to the action of the dew and sunshine. In "water-rotting" the flax is subjected in the bundles to the action of *soft* water in pools called "dams." The methods of setting or laying the bundles are various, and the rapidity of the action depends upon the warmth and softness of the water, varying from four to fourteen days. It is more uniform if it does not progress very rapidly. During the whole process it must be kept submerged, being weighted with stones. Waters containing iron or other mineral matters are likely to stain the fiber and to hinder the action. It requires some experience to know exactly when to remove the flax, for a few hours may make a considerable difference in the amount of fiber realized. If too much rotted, the lint will break and tangle, and be lost in the tow. If too little rotted, the fiber will break up with the stalk, and be scutched out with the shives. When the rotting (or retting) has been continued long enough, the woody part of the haulm separates easily and completely from the fibrous bark, which itself is easily divided upon the finger into individual fibers. When, however, the process has gone too far, the fiber is weakened, but this can only be quickly detected by the most experienced. When sufficiently rotted, the flax bundles are lifted from the water, opened, and spread upon the grass until perfectly dry. Then they are rebundled and housed until they can be conveniently subjected to the next process, which is

Breaking.—This is accomplished by machines called flax-breaks, which are variously constructed, but all accomplish the same end—namely, the breaking up of the stalks without doing violence to the fiber. A flax-break in common use and easily constructed consists of several hickory slats hinged at one end upon a form, and fastened at the other end into a heavy wooden head. These slats when let down occupy a horizontal position, and shut in between other similar fixed slats, but do not touch them. By means of a handle attached to the head the movable slats are raised up and down by one hand, while the flax held in the other is thrust in and drawn through, and thus "broken," so that the "shives," or pieces of broken stalk, or "boon," may be whipped or "scutched" out.

Scutching or *swingeing* is the next operation, and one performed both by simple hand-appliances and by more complicated machinery. The essential implements are the scutching-block and the scutching-knife. The former is an upright hard-wood board set in a block or fixed in any convenient place. It has in it a large notch, with one edge horizontal and cut to a sharp edge, the bevel being altogether upon one side. This notch is to receive a handful of flax, which, resting upon the sharp wooden edge, hangs over upon one side. The scutching-knife is made of hard wood also, and must be 9 or 10 inches broad and very thin. With this the "hand" of flax is struck sharp blows as it is turned in the notch, the knife being brought down close, parallel with the side of the board. Thus the fiber is freed from most of its adhering impurities, and in this condition is usually baled and marketed in the U. S., but before it can be spun much more is necessary. In this condition the lint and the tow remain together, only the coarsest tow being separated from the fiber by the scutching process.

Hatcheling or *heckeling* consists in drawing the hands of flax-fiber through combs of long iron teeth set filling a circle or a square. The instrument is called a "hatchel" or "heckel," and there are usually two hatchels used—one coarse, for a preliminary operation, the other fine, for finishing. The hand of flax is hatcheled from the tips to the middle—first one half, and then the other, the tow being left in the teeth of the hatchel, and the teeth being frequently cleaned of the same. The ends accomplished by this process are three—namely, the subdividing of the fibers into their finest filaments, the separation and removal of all broken or short fibers (the tow), and the laying of the lint parallel and untangled. The operation requires considerable skill, and upon it depends to a great extent the value of the result. It will be long before American farmers to any great extent will prepare their flax-fiber for market by the careful dressing practiced in Germany, Holland, and Great Britain, but until this is done the value of the crop will be greatly less than it might otherwise be. In general, this crop is and will be cultivated in the U. S. almost solely for the seed, the lint being roughly treated and sold for cordage and for coarse fabrics. The product of flax-seed in the U. S. in 1899 was 29,601,000 bush.: the exports, 2,830,991 bush. The world's product was 68,553,000 bush. Minnesota, Iowa, South Dakota, Nebraska, Kansas, and Missouri were the largest producers in the order named. No statistics were collected for the production of fiber in the U. S. During the "cotton-famine" caused by the civil war greatly increased interest was manifested in flax-culture, and great efforts were made to treat the fiber so that it could be worked upon cotton machinery; but these experiments resulted in no marked success, and were given up when cotton again became abundant. Russia is the largest flax-producing country in Europe, her yield being about two-thirds of the whole production. The total quantity of flax fiber produced in the whole of Europe in 1899 was 1,123,943,000 lb., distributed as follows: Russia, 876,788,000 lb.; Austria-Hungary, 112,809,000 lb.; Italy, 41,917,000 lb.; Belgium, 32,309,000 lb.; France, 27,834,000 lb.; Ireland, 16,034,000 lb.; all other countries, 16,252,000 lb. The total area in Europe sown with flax aggregates about 5,700,000 acres, of which more than 3,700,000 are in Russia. See FLAX, NEW ZEALAND.

Revised by L. H. BAILEY.

Flax, False: See GOLD OF PLEASURE.

Flax Family: the *Linaceæ*, a family of mostly herbaceous flowering plants, with regular flowers, and superior compound ovaries. There are about 135 species widely distributed in temperate and tropical climates. The most important species is the flax (*Linum usitatissimum*) cultivated from time immemorial for its bast fibers. In North America there are twenty-two native species of flax (*Linum*).

CHARLES E. BESSEY.

Flax, New Zealand: a large perennial, liliaceous plant (*Phormium tenax*), native of New Zealand, and grown for its fiber, which is exported to some extent, and used as a substitute for hemp, which is inferior to New Zealand flax in strength, but superior in durability. The fiber is obtained from the long and flag-like leaves, which are 2 to 6 feet long and 1 to 3 inches broad. In the U. S. the plant is cultivated for ornament. See FIBER.

Flaxman, JOHN: sculptor; b. in York, England, July 6, 1755; the second son of John Flaxman. When he was only six months old his father, who had gone to York from London, where he had failed to find sufficient work in his trade of modeler in plaster, returned to the capital, taking his family with him. The elder Flaxman was a good workman; his plaster casts were in great favor with artists, and, although not an artist himself, he had sense and perception enough to encourage the early indications of talent in his afterward famous son. Among the early works of the younger Flaxman were his own portrait-bust, quarter size, modeled in his twenty-third year, two statues, *Grecian Comedy* and a *Vestal*, and many portrait-busts of his friends. During his youth he derived a large part of his support from making models for the use of Wedgwood, the famous maker of fine pottery. In 1787 Flaxman went to Italy, and remained there seven years, living the greater part of that time in Rome. While in Italy he made for Mrs. Hare Nayler the well-known series of designs in outline for the *Iliad* and *Odyssey*; for the Countess Spencer the illustrations to *Æschylus*; and for Mr. Thomas Hope the illustrations for the *Divina Commedia* of Dante. While in Rome he executed several works in marble, but none of them of much importance, if we except the *Cephalus* and *Aurora*, a commission from Mr. Thomas Hope. Shortly after his return to England he made his statue of Lord Mansfield. In 1797 he was elected an associate of the Royal Academy, and in the same year he sent to the exhibition three sketches in bas-relief from the New Testament and the statue for the monument of Sir William Jones. In 1800, being then in his forty-fifth year, Flaxman was elected a member of the Royal Academy, and on this occasion he presented to the Academy a marble group, *Apollo and Marpessa*, in compliance with the rules of the institution, which require from each new member a specimen of his skill. He now produced in rapid succession many of his best works—the monument in memory of the Baring family; the Lushington monument; the monument to the Countess Spencer; to Mrs. Tighe, the poetess; with others to the memory of the Tarborough family, to Mr. Edward Balme, and to the Rev. Mr. Clewe.

Among other statues made by Flaxman were those of Sir Joshua Reynolds, of Sir John Moore, of Pitt, of Joseph Warton, of George Stevens, of the Rajah of Tanjore, of the missionary Schwarz, of Lord Cornwallis, and of Warren Hastings. In his sixty-third year he modeled the group of the *Archangel Michael Vanquishing Satan*. In 1810 the Royal Academy created a professorship of Sculpture, and requested Flaxman to fill the chair. He gave in all ten lectures, and these are the subjects: 1, English sculpture; 2, Egyptian sculpture; 3, Grecian sculpture; 4, Science; 5, Beauty; 6, Composition; 7, Style; 8, Drapery; 9, Ancient art; 10, Modern art. They were published in 1829 in one volume, with 52 plates. D. Dec. 7, 1826. See his *Life* by Allan Cunningham in *British Painters, Sculptors, and Architects.*

Flea [O. Eng. *flēah*: Mod. Germ. *Floh*]: the common name of the insects of the family *Pulicidæ*, wingless creatures constituting an order, *Aphaniptera*, but by some considered as degraded forms referable to the *Diptera*, or two-winged insects. (See ENTOMOLOGY.) They grievously infest the higher animals, the common flea (*Pulex irritans*) attacking man as well as beast, while other species attach themselves to the dog, cat, mole, and various other mammals. The *Sarcopsylla penetrans*, or chigoe, is another flea which seriously troubles man. Most of the fleas are distinguished by great powers of leaping. Accounts are given of fleas trained to perform curious feats which have been often exhibited in public. It is doubtful whether there is any training in the case. The feats which seemingly evince intelligence are rather acts necessitated by the mechanical conditions to which the insect is subjected.

Flea.

Fleabane [*flea* + *bane* < M. Eng. *bane*, destruction < O. Eng. *bana*, murderer]: a name given to various herbs of the family *Compositæ*, especially to those of the genus *Erigeron*. The *Erigeron canadense* and *E. philadelphicum* yield strong-smelling, volatile oils which are sometimes used in medicine as diuretics. The allied genera, *Pulicaria* and *Conyza*, are called fleabanes in England. The destructive powers of various composite plants upon insects appear to reach their maximum in *Pyrethrum carneum* and *roseum* of Asia and Europe, the leaves of which are largely used as an ingredient of the Persian insect-powder, so deadly to insect vermin. The plant has also been used to cure dysentery, and for other medicinal purposes. See OIL OF ERIGERON.

Fleawort Seed (in Lat. *Semen psyllii*): the seeds of *Plantago psyllium*, a kind of plantain of Europe and Barbary. The seeds are mucilaginous, like flaxseed, and are sometimes used for the same purposes in medicine.

Fléchier, flā'shi-ā', ESPRIT: ecclesiastic; b. at Pernes, France, June 10, 1632; was educated by the Fathers of Christian Doctrine at Avignon; taught rhetoric at Narbonne; went to Paris in 1659, where his talents as a preacher won him great preferments. In 1673 he was admitted to the Academy; in 1685 became Bishop of Lavour, and in 1687 was translated to Nîmes, where he was beloved alike by his own Church and by the Huguenots. D. at Montpellier, Feb. 16, 1710. He wrote *Oraisons Funèbres*, *Panégyriques des Saints*, and *Lives* of Theodosius the Great and of Ximenes, etc. See his *Life* by A. Delacroix (Paris, 1865; 3d ed. 1883).

Fleck'eisen, ALFRED: Latin scholar; b. Sept. 23, 1820, in Wolfenbüttel, Germany; studied in Göttingen. After teaching in various cities, he was appointed director of a gymnasium in Dresden in 1861. He is best known by his critical editions of *Plautus* (ten plays), *Terence*, and *Cato*. Since 1855 he has been the editor of the *Jahrbücher für Philologie und Pädagogik*. ALFRED GUDEMAN.

Fleet-captain: See FLAG.

Fleet Marriage: a marriage performed at the Fleet prison in London, which, like Gretna Green in later times, and May Fair and the Savoy at a somewhat earlier date, was long a famous resort for clandestine marriages. Fleet marriages are first mentioned in 1613, and in 1754 were forbidden by statute. The officiators were Church of England clergymen in prison for debt. The most famous Fleet marriage was that of Henry Fox, afterward Lord Holland, to Georgina Caroline Lennox, daughter of the Duke of Richmond. See J. S. Burn, *History of the Fleet Marriages* (1834).

Fleet Prison, or **The Fleet**: a debtors' prison in London. Before 1200 it was in use both as a debtors' and king's bench prison, and remained such until 1641, when, on the abolition of the Star Chamber, it became, like the Marshalsea, a debtors' prison. It was burned in 1381 by Wat Tyler, in 1666 at the great fire of London, and in 1780 by the Gordon rioters. In 1842 it was abolished by statute, and in 1845 pulled down. It was the scene of many disgraceful abuses.

Flegel, flā'gel, EDUARD ROBERT: African explorer; b. in Wilna, Russia, in 1855. His explorations were confined to the Niger-Benue basin. In 1875 he settled as a trader at Lagos. His journey on the steamer Henry Venn, the first steam-vessel to ascend the great Benue tributary of the Niger, resulted in an admirable report on that region in all its aspects. In 1880 the German-African Association supplied the funds needed for an expedition which was to complete the knowledge of the basins of the Benue and Lake Chad. Traveling from the middle Niger to Sokoto by land, he followed an unexplored route to Adamawa, and in Aug., 1882, discovered the source of the Benue. In 1885 he led another expedition up the Benue, under the same auspices, to carry on scientific research and study commercial possibilities, and he died while engaged in this work in 1886. Flegel's work had the effect of stimulating German colonial enterprise, and of directing attention to the Benue, the only African river which affords steam-navigation from the sea to the central portions of the continent. C. C. ADAMS.

Fleischer, HEINRICH LEBERECHT: Orientalist; b. at Schandau, Saxony, Feb. 21, 1801; studied theology and Oriental languages at the University of Leipzig 1818–24, and then went to Paris, where he applied himself to the study of Persian and Arabic. Returning to Germany in 1828 he was made a professor at the Kreuzschule in Dresden in 1831, and in 1836 filled the chair of Oriental Languages at the University of Leipzig, where he died Feb. 10, 1888. He edited Abulfeda's *Historia Moslemica* (1831–34); *Ali's Hundred Sayings* (1837); Baidhavi's commentary on the Koran (1846–48); and among other works wrote a *Critical Dissertation on Habicht's Glossary to the First Four Volumes of the Thousand and One Nights* (1836); an account of the Arabic, Turkish, and Persian manuscripts in the town library of Leipzig, printed in Naumann's *Catalogue* (1838); *Grammar of the Modern Persian Languages* (1875); and *Kleinere Schriften* (1885–88).

Fleming, JOHN: Scotch clergyman and naturalist; b. near Bathgate, Linlithgowshire, 1785; preached in Shetland and at Flisk, Fifeshire; appointed to the chair of Natural Philosophy at King's College, Aberdeen, 1832; resigned the position in 1843, and became Professor of Natural Science in the Free Church College of Edinburgh 1845. D. Nov. 18, 1857. The *Philosophy of Zoölogy* was published about 1822; *History of British Animals*, in 1842.

Fleming, JOHN AMBROSE: See the Appendix.

Fleming, SANDFORD, C. M. G., LL. D: Canadian surveyor; b. at Kirkcaldy, Scotland, Jan. 7, 1827, and educated there. He removed to Canada in 1845; in 1852 was appointed on engineering staff of Northern Railway, and subsequently commissioned to visit Red River to ascertain the advisability of connecting it by railway with Canada. In 1863 he proceeded to Great Britain to present memorial of the inhabitants of the valley of the Red River, petitioning for railway communication with Canada, but was unsuccessful in his mission. Upon his return he was commissioned by Canadian Government to make preliminary survey of projected line of railway to connect maritime provinces with Canada, which work he successfully accomplished. In 1871 he was ordered by the Dominion Government to survey a line that would connect Eastern Canada with the Pacific Ocean, and had successfully prosecuted part of the work when political exigencies led to his resignation. He was created a companion of the order of St. Michael and St. George in 1877; elected chancellor of Queen's University in 1880, an office he now (1901) retains; in 1881 he represented the Canadian Institute and the American Meteorological Society at the International Geographical Congress at Vienna; and in 1884 represented Canada at the International Prime-meridian Congress at Washington, D. C. In addition to engineering reports, etc., he wrote *England and Canada* (1884); *Time and its Notation*; and *The New Time Reckoning*. NEIL MACDONALD.

Flemingsburg: town; capital of Fleming co., Ky. (for location of county, see map of Kentucky, ref. 2–I); on railway; 17 miles S. of Maysville. It has churches of six denominations, a very large graded high school, Masonic and Odd Fellows' hall, two large flouring-mills, and an extensive tobacco-factory; chief products, wheat, corn, and tobacco. Pop. (1880) 811; (1890) 1,172; (1900) 1,268.

EDITOR OF "TIMES-DEMOCRAT."

Flemington: borough and railway junction; capital of Hunterdon co., N. J. (for location, see map of New Jersey, ref. 3–C); 50 miles W. by S. of New York. It is in a rich agricultural district, and has an extensive trade. Pop. (1880) 1,751; (1890) 1,977; not returned separately in 1900.

Flemish Language and Literature: The literal meaning of Flemish (or Vlæmish) is "dialect of Flanders." But the term is generally (although not always) used in a wider sense, in being applied to the language of the Low German inhabitants of Belgium, or, in other words, to "Belgian Dutch," as distinguished on the one hand from "Belgian French" (the so-called "Walloon") and on the other hand from "Hollandish Dutch."

Early Flemish.—It has been mentioned in the article on DUTCH LANGUAGE (*q. v.*) that it is the Flemish dialect that the Middle Dutch literature was based upon. "Flemish literature" and "Dutch (or Dietsch) literature," as far as the Middle Ages are concerned, are synonymous terms, the province of Flanders then being the recognized center of literary culture in the Netherlands. As the Southern Dutch language was adopted for literary purposes by the authors of the northern provinces, Flemish may be said to be the basis not only of Middle Dutch, but to some extent also of Modern Dutch (i. e. the modern literary language, not, of course, the modern Dutch dialects). Still it is from the time of the general adoption of Southern Dutch or "literary Flemish" by the Netherlandish authors that the Dutch literature ceased to be Flemish. After the conquest of Antwerp in 1585, and the political separation of the southern from the northern provinces, the former (viz., East and West Flanders, Antwerp, South Brabant, and Limburg) lost the leading position in Dutch literature, the development of the literary language being from this time more closely connected with that of the Northern Dutch dialects. Literary Flemish, as distinguished from its legitimate successor, the literary Dutch, was not at once abandoned in the southern provinces, but it was then confined to a rather small and unimportant area, and in being later on in official and literary use superseded by French, Flemish was once more reduced to what it had been before, viz., a Low Frankish dialect.

Modern Flemish.—It was not until the early decades of this century that in Belgium a literature which goes under the name of "Flemish" again arose. After the reunion in 1815 of the southern and northern provinces under the name "United Kingdom of the Netherlands," King William I. endeavored to introduce the Dutch literary language into Belgium. He was not, however, successful in his efforts. The people looked upon Dutch as a foreign language, different from their own dialect, and among the cultivated classes the position held by French was too strong to easily submit to another language. When after the revolution of 1830 Belgium and Holland were again separated, and French was made the only official language of Belgium, the fate of the Low German element in Belgium seemed to be decided. But it is just at this time that a new and successful attempt was made at regaining for the Low Frankish part of Belgium a literary language, and at securing for it a position similar to that which Flemish had formerly held. Under the leadership of Frans Willems the so-called "Flemish movement" started, whose followers advocated the adoption by the Belgian authors and the

Belgian Government of Dutch as a literary and as an official language. In their opinion—and this opinion was on the whole correct—the literary Dutch was a modified and more recent form of the language, in which the early Flemish literature was written, so that by adopting Dutch they could hope to regain their connection with the earlier Flemish authors, and to prove themselves the legitimate and worthy heirs of this old and important literature. While in the time of William I. the attempts to introduce Dutch into Belgium had seemed to be made for political purposes, in order to bring Belgium under the influence of Holland, under the "Flemish movement" the same attempts gained a patriotic and a specific Belgian character, and soon became popular. J. F. Willems, who was keeper of the archives of Ghent, published in his quarterly review, *Belgisch Museum* (1837–46), and in separate editions several of the earlier Flemish literary works. In his efforts to awaken the interest of the Belgian people in the adoption and the literary use of the Dutch language, he was supported by several Belgian authors, poets like Ledeganck, Van Rijswijk, Van Duyse, and novelists like Hendrik Conscience writing their works in Dutch. Willems died in the year 1846. In 1851 the Willemsfonds was erected in his honor, whose members, under the guidance of J. F. J. Heremans (d. 1884), and at present of Julius Vuylsteke, have been carrying on the work begun by Willems. A few statements will illustrate the steadily growing success of the "Flemish movement" and the close union which, as one of its consequences, has taken place between the Flemish and Dutch writers and scholars. A *Taal- en Letterkundige Congress* was established in Ghent in 1849, in the interest of the literary language. The congress has since assembled yearly, or at least every second or third year, in one of the chief towns of Belgium or Holland. It is this association which suggested the spelling reform of 1863, and the comprehensive Netherlandish dictionary by De Vries and Te Winkel. In three official regulations by the Belgian Government in 1873, 1878, and 1883, the Dutch language has been acknowledged in Belgium alongside of French as an official language, and the Belgian officials are now obliged to make themselves acquainted with it. The foundation in 1886 of the Koninklijke Vlaamsche Academie was another important step in the same direction. Numerous daily papers and weekly and monthly periodicals are published in Belgian Dutch, the best known of which is the *Nederduitsch Tijdschrift*, commenced by E. Hiel in 1862.

It is important to bear in mind that the modern literary language of Belgium, whose introduction is connected with the Flemish movement, was not based upon the present Flemish dialect, but is identical with the Dutch literary language. However, as the latter originated in the earlier Flemish dialect, there is still a strong connection between Belgian Dutch and the Flemish dialect, although since then more than five centuries have passed; and it seems only natural that the present Belgian dialects should exert some influence on the literary language, the more so as the latter is at the same time (as in Holland) the conversational language of the educated classes. There are other circumstances that tend to differentiate Hollandish and Belgian Dutch to a certain extent—e. g. Belgian Dutch is more likely to be influenced by French and to admit French idioms than its northern sister-language. The Belgian Dutch indeed, for these and similar reasons, differs somewhat from the literary language of Holland, and it is stated by Dutch scholars that even the best Belgian authors, who are most anxious to avoid any traces of dialect, can not write a single page without being recognized by the northern Dutchmen as southerners. However, most of the Belgian peculiarities are confined to the vocabulary, and interfere little with the Dutch character of the Belgian literary language. There is no difference in spelling between Belgian and Hollandish Dutch, as the proposals made in 1863 for a spelling reform have since been generally accepted in both countries.

REFERENCES.—Most of the literature on Flemish is found in the article on the Dutch language. In addition to these the following works may be mentioned: L. W. Schuermans, *Algemeen Vlaamsch Idioticon* (Louvain, 1856–70); L. L. de Bo, *West Vlaamsch Idioticon* (Bruges, 1870–73; 2d ed. Ghent, 1892); K. Brämer, *Nationalität und Sprache im Kgr. Belgien* (Stuttgart, 1887); O. Delepierre, *Sketch of the History of Flemish Literature* (London, 1860); J. v. Düringsfeld, *Das geistige Leben der Vlamingen* (3 vols., Leipzig, 1861.)

HERMANN COLLITZ.

Flemming, WALTHER, M. D.: anatomist; b. Apr. 21, 1843, at Sachsenberg, Germany; educated at Universities of Göttingen, Tübingen, Berlin, Rostock; assistant in physiological laboratory, Amsterdam, 1869–70; tutor in anatomy, Rostock, 1871–72, in Prague 1872–76; Professor of Human Anatomy and Histology, University of Kiel, since 1876. Author of *Studien in der Entwicklungsgeschichte der Najaden* (Vienna, 1875); *Zellsubstanz, Kern und Zelltheilung* (Leipzig, 1882); *Beiträge zur Kenntniss der Zellen u. ihrer Lebenserscheinungen* (*Archiv f. Anat.*, 1879–81); *Neue Beiträge u. s. w.* (in same, 1887–91); *Studien über Regeneration der Gewebe* (Bonn, 1884–85). C. H. THURBER.

Flensborg, flens'bōrch: handsome and thriving town of Schleswig, Prussia,; at the west end of Flensborg Fjord (see map of German Empire, ref. 1–E). It has good ship-yards, excellent oyster-beds, some tobacco manufacture and spinning, and sugar-refining industry. One of the most interesting features of the town is the great tomb in which the Danes buried their dead after the battle of Idsted, July 25, 1850. Pop. (1890) 36,894.

Flesh [M. Eng. *flesch, flesc* < O. Eng. *flǣsc* : O. H. Germ. *fleisc* > Mod. Germ. *Fleisch*, meat, flesh]: ordinarily, all solid animal tissues, excluding the bones; in a narrow sense, the muscular tissue of animals, especially of the vertebrates. In a still narrower popular sense the muscular tissues of fishes, reptiles, and birds are excluded. In the broadest sense the flesh of animals comprises not only muscles, but fasciæ, fibrous, adipose, and other tissues, cartilage, nerve-substance, the parenchyma of the viscera, etc.; each of which is described under its alphabetical head.

Fleshfly, or **Blowfly**: any one of the various insects of the order Diptera, family *Muscidæ*, of which the best known is the *Sarcophaga carnaria*, the common fleshfly. The *Musca* (or *Lucilia*) *cæsa*, *Musca* (or *Calliphora*) *vomitoria*, and other species are common to both continents, and deposit their already hatched larvæ upon fresh meat and decaying animal matter—sometimes on the wounds of soldiers—giving rise to a crop of maggots.

Fletcher, ANDREW, OF SALTOUN: publicist; b. at Saltoun, Scotland, in 1653; had for his first teacher the celebrated Gilbert Burnet, who at that time was minister of the parish, and finished his education on the Continent, where he spent several years in travel and studies. As a member of the Scottish Parliament in 1681 he opposed the royal court, and was forced to retire to Holland. Returned to England in 1683; took part with the Duke of Monmouth in 1685; served in Hungary against the Turks in 1686; returned to England with William of Orange in 1688; brought forward the bill of security in the Scotch Parliament in May, 1703; and opposed the terms of the union in 1706, proposing a measure of limitations which would have failed to effect a complete and permanent union of the two kingdoms. D. in London in 1716. His *Political Works* were published in 1737.

Fletcher, JOHN: dramatist; b. in Northamptonshire, England, in 1579. He was the son of the Bishop of London, was educated at Corpus Christi College, Cambridge, and devoted his life to writing for the stage. He produced alone, or in conjunction with Francis Beaumont, fifty-two dramas, among the best of which are *The Maid's Tragedy*, *Philaster*, *The Faithful Shepherdess*, *The Knight of the Burning Pestle*, *The Scornful Lady*, *Rule a Wife and Have a Wife*, and *The Spanish Curate*. "Such a total of work," says Saintsbury in his *Elizabethan Literature*, "so varied in character and so full of excellences in all its variety, has not been set to the credit of any name or names in English literature if we except only Shakspeare." Fletcher died in London in 1625 of the plague. H. A. BEERS.

Fletcher, JOHN WILLIAM, originally **de la Flechère**: theologian; b. at Nyon, Switzerland, Sept. 12, 1729; studied at Geneva; served in the Portuguese and Dutch armies; visited England, and became a minister of the Established Church in 1757, becoming vicar of Madeley 1760. He wrote in defense of Wesley's Arminianism. The Countess of Huntingdon appointed him president of her theological school at Trevecca, Wales, 1768. His principal work was *Checks to Antinomianism* (1771). He was one of the founders of Methodism, and a man of great industry and piety and of most amiable and saintly character. He was also a keen polemic. D. at Madeley, Aug. 14, 1785. His complete works have been published (London, 1800–04; 8th ed. 1826, 7 vols.). See his *Life* by Luke Tyerman (London, 1882) and by F. W. Macdonald (1885).

Fletcher, PHINEAS: poet; b. in England in 1582; entered Cambridge University in 1600, and became rector of Hilgay, Norfolk, in 1621. He wrote various poems—*The Locustæ, or Apollyonists*, a satire against the Jesuits (1627), rare; *Sicelides, a Dramatic Piece* (1631); *Joy in Tribulation* (1632); *The Purple Island, or The Isle of Man*, together with *Piscatoric Eclogues and other Poetical Miscellanies* (1633), etc. D. at Hilgay in 1650. He was a cousin of Fletcher, the dramatist, and a brother of Giles Fletcher (1588–1623), a clergyman, and author of the fine poem *Christ's Victory and Triumph* (1610).

Fletcher, ROBERT, M. D.: anthropologist; b. at Bristol, England, Mar. 6, 1823; educated at private schools, at the Bristol Medical School, and the London Hospital; member of the Royal College of Surgeons of England; M. D., Columbian University, Washington, D. C.; surgeon of First Ohio Volunteer Infantry 1861, and later surgeon of volunteers; assistant to Dr. J. S. Billings in the preparation of the *Index Catalogue* of the library of the surgeon-general's office, U. S. army; co-editor with Dr. Billings of the *Index Medicus*; vice-president of the Philosophical Society of Washington; for four years president of the Anthropological Society at Washington; was Professor of Medical Jurisprudence in Columbian University; author of *Paul Broca and the French School of Anthropology* (1882); *On Prehistoric Trephining and Cranial Amulets* (1882); *Human Proportion in Art and Anthropometry* (1883); *A Study of Some Recent Experiments in Serpent Venom* (1883); *Tattooing among Civilized People* (1883); *The New School of Criminal Anthropology* (1891), and other works.

Fleur de Lis, flēr'de-lēēs', often Anglicized into **Flower de Luce** [Fr., lily-flower; *fleur*, flower + *de*, of + *lis*, lily]: the flower of the *Iris sambucina* (family *Iridaceæ*), a plant native in the South of Europe and cultivated for many centuries in gardens. This flower is famous as the emblem of the French kings, whose arms in later times were azure, three fleurs de lis, or, borne two and one. Many curious legends were related as to the origin of this emblem. The historical fact appears to be that the Frankish kings employed the fleur de lis as a kind of badge long before the proper rise of heraldry.

Fleurus, flö'rüs': town of Hainaut, Belgium; 7 miles N. of Charleroi (see map of Holland and Belgium, ref. 11–E). Here Gonsalvo of Cordova was defeated by the Duke of Brunswick and Count Mansfeld Aug. 29, 1622; Waldeck was defeated by Marshal Luxembourg July 1, 1690, and the Prince of Coburg, having gained here a virtual victory over Jourdan, June 26, 1794, lost its fruits, and indeed the whole of Belgium, by bad strategy after the fight. The battle of Ligny, 1815, took place a mile or two north of Fleurus. Pop. (1891) 5,148.

Fleury, flö'ree', ANDRÉ HERCULE, de: cardinal; b. at Lodève, France, June 22, 1653; studied at the Jesuit College, Paris; was made Bishop of Fréjus 1698; in 1715 became preceptor to Louis XV.; in 1721 was admitted to the Academy; in 1726 assumed the position of Prime Minister of France, and was made a cardinal. His policy was to foster the sciences and arts, to increase the internal prosperity of France, and to reduce the expenses of the Government; hence he favored peace, but he lacked the vigor to carry out this policy and was dragged into two wars, whose unsuccessful issue was due in no small measure to his mismanagement and parsimony. D. in Paris, Jan. 29, 1743.

Fleury, CLAUDE: abbé; ecclesiastic and historian; b. in Paris, France, Dec. 6, 1640; was advocate to the Parliament of Paris 1658–67, and tutor to the Princes Conti in 1672; in 1689–1707 sub-preceptor with Fénelon to the Dukes of Burgundy, Anjou, and Berri; became member of the French Academy 1696. He was prior of Argenteuil in 1707 and confessor to Louis XV. 1716–22. Published *Morality of Christians, Ecclesiastical Law, Historical Catechism* (1683), etc., but his greatest work is his *Ecclesiastical History* (20 vols., 1691–1720). D. in Paris, July 14, 1723.

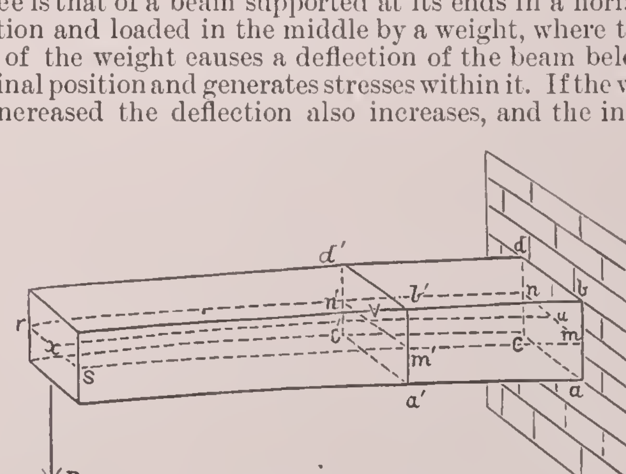
Fleury, ÉMILE FÉLIX: general; b. in Paris, France, Dec. 23, 1815; entered the army in 1837; served eleven campaigns in Algeria; was sub-lieutenant in 1840, captain in 1844, major in July, 1848, and on his return to France a general of brigade Mar. 18, 1856, and general of division Aug. 13, 1863. He was a thorough Bonapartist, and became officer of the Legion of Honor in 1849, and grand officer Aug. 13, 1859. Was summoned to the French senate by decree Mar. 15, 1865; was chief equerry to Napoleon III. Dec., 1865. In 1866 was sent on a diplomatic mission to King Victor Emmanuel and in Sept., 1869, became ambassador at St. Petersburg. In Sept., 1870, he resigned this position, and retired to Switzerland. He was placed on the retired list of the army in Oct., 1879. D. in Paris, Dec. 11, 1884.

Fleury, LOUIS, Chevalier and Viscount de: soldier; b. in Limoges, France, about 1740; joined the Revolutionary army of the British colonists of North America, having received a captain's commission from Washington; served at Fort Mifflin on the Delaware and at the battle of Brandywine, and was promoted to be lieutenant-colonel Nov. 26, 1777. In the winter of 1777–78 he was sub-inspector under Steuben; June 4, 1778, adjutant-general of Lee's division; in July, 1778, was second in command of a battalion of light infantry in the Rhode Island expedition, and then commanded a battalion of light infantry under Washington. He received the thanks of Congress and a silver medal for gallantry in the storming of Stony Point, July, 1779. He returned to France 1780 with Rochambeau, and became one of his officers. He was executed in Paris in 1794.

Flexibility [viâ Fr. from Lat. *flexibil'itas*, deriv. of *flexi'bilis*, flexible, deriv. of *flec'tere, flex'um*, bend]: that quality by which certain bodies may be made temporarily or permanently to change their form under the influence of mechanical forces. Thus a long leaden rod held by one end in a horizontal position is bent downward by its own weight. Flexibility, though not the opposite of brittleness, can not be predicated of brittle bodies.

Flexible Sandstone, sometimes called **Itacol'umite**: a metamorphic siliceous rock found in the Southern Alleghanies, and especially in Brazil. It occurs in thin layers, which are to a certain degree flexible, but are not elastic. Such sheets may be bent forward and backward hundreds of times without breaking. The cause of this peculiar property of itacolumite has been much discussed. Prof. Wetherell, of Philadelphia, after a careful microscopic examination of the granules of quartz which compose this rock, announced that he had discovered that they are elongated and interlocked, each particle working in a kind of joint. This statement has been denied by subsequent observers, but the weight of authority is in favor of its acceptance. Gold and diamonds are frequently found with itacolumite, and it has been thought that the association of the two latter was something more than accidental. No relationship has, however, been proved to exist between them.

Flexure [viâ Fr. from Lat. *flexura*, a bending, deriv. of *flectere, flexum*, bend]: the bending of a beam, plate, or column under the action of applied forces. The simplest instance is that of a beam supported at its ends in a horizontal position and loaded in the middle by a weight, where the action of the weight causes a deflection of the beam below its original position and generates stresses within it. If the weight be increased the deflection also increases, and the internal



Flexure of beam projecting from wall.

stresses finally become so great that rupture occurs. The theory of the flexure of beams enables the amount of deflection to be computed, provided that the internal stresses do not exceed the elastic limit of the material.

It is found by experiment that when a beam is subject to flexure one side assumes a concave and the other a convex form. The fibers on the concave side are compressed and those on the convex side are extended. Between the compressed and extended fibers lies a surface which is unchanged in length, called the neutral surface, and the intersection of this with a vertical plane is called the elastic curve. Thus a beam projecting from a wall, and loaded with a weight, *P*, at the end, as in the figure, has its upper surface convex and elongated, while its lower surface is concave and compressed. The neutral surface is $m\ n\ r\ s$, and the central line of this, $u\ v\ x$, is the elastic curve. The intersection of the neutral surface with a cross-section of the beam is called the neutral axis of that section; thus $m'\ n'$ is the neutral axis of the section $a'\ b'\ d'\ c'$. By the fundamental principles of statics it is proved that the neutral axis always passes through the center of gravity of a section, provided the elastic limit of the material be nowhere exceeded.

The practical discussion of a beam with respect to strength consists largely in the use of the formula

$$M = \frac{RI}{c}, \qquad (1)$$

in which M is the bending moment of the loads and reactions on one side of the section, c the distance of the remotest fiber of the section from the neutral axis, I the least moment of inertia of the cross-section, and R the unit-stress of tension or compression on the fiber distant c from the neutral axis. This formula, although only strictly true when the stress R is less than the elastic limit of the material, is often used for the rupture of beams, in which case R is called the modulus of rupture.

The following values of c and I for the most common cross-sections are needed in applying the above formula:

SECTION.	c	I
Rectangular	$\frac{1}{2}d$	$\frac{bd^3}{12}$
Square	$\frac{1}{2}d$	$\frac{d^4}{12}$
Circular	r	$\frac{\pi r^4}{4}$
Triangular	$\frac{2}{3}d$	$\frac{bd^3}{36}$
Hollow rectangular	$\frac{1}{2}d$	$\frac{bd^3 - b'd'^3}{12}$
Hollow square	$\frac{1}{2}d$	$\frac{d^4 - d'^4}{12}$
Hollow cylindrical	r	$\frac{\pi(r^4 - r'^4)}{4}$
I cross-section	$\frac{1}{2}d$	$\frac{bd^3 - b'd'^3}{12}$

in which b denotes breadth, d depth, and r radius, the same letters accented being the inner dimensions for the hollow sections; for the I section b' denotes the breadth minus the web thickness, and d' the depth minus the two flange thicknesses.

The average values of R, both for the case of rupture and for a safe degree of stability, are given in the following table in pounds per square inch:

MATERIAL.	Modulus of rupture.	WORKING UNIT STRESSES FOR—	
		Buildings.	Bridges.
Wood	9,000	2,000	1,200
Cast iron	35,000	5,000	3,000
Wrought iron	55,000	14,000	8,000
Steel	120,000	25,000	13,000

As an example of the use of the formula, let it be required to find what load will break a wooden beam 4 inches wide, 6 inches deep, and 108 inches long when supported at the ends and loaded in the middle. Here let the load be P; then the bending moment $M = \frac{1}{2}P \times 54 = 27P$, and $R = 9{,}000$ lb. per sq. inch, $c = 3$ inches, $I = 72$, and inserting all these in the formula there is found $P = 8{,}000$ lb.

The equation of the elastic curve of a beam and the amount of deflection are determinable by the theory of flexure, provided that the stresses in the material are within the elastic limit. If E be the coefficient of elasticity of the material, and x and y the linear co-ordinates of any point of the curve with respect to rectangular axes, the general equation of the elastic curve is

$$\frac{d^2y}{dx^2} = \frac{M}{EI}, \qquad (2)$$

in which M and I have the same significations as in formula (1). Applied to the case of a cantilever beam of length l having a load, P, at the free end, this becomes, for an origin at the free end,

$$6EIy = P(3l^2x - x^3),$$

which shows that the curve is a cubic parabola. If x be made equal to l the value of y is $\frac{Pl^3}{3EI}$, which is the deflection of the end of the beam due to the load P. The following table gives the values of the maximum bending moment and the maximum deflection for beams of uniform cross-section, W being the total load whether uniform or concentrated. It is seen that a concentrated load produces a

KIND OF BEAM AND LOAD.	Maximum moment.	Maximum deflection.
Cantilever beam, load at end	Wl	$\frac{1}{3}\ \frac{Wl^3}{EI}$
Cantilever beam, uniform load	$\frac{1}{2}Wl$	$\frac{1}{8}\ \frac{Wl^3}{EI}$
Simple beam, load at middle	$\frac{1}{4}Wl$	$\frac{1}{48}\ \frac{Wl^3}{EI}$
Simple beam, uniform load	$\frac{1}{8}Wl$	$\frac{5}{384}\ \frac{Wl^3}{EI}$
Beam fixed at both ends, load at middle	$\frac{1}{8}Wl$	$\frac{1}{192}\ \frac{Wl^3}{EI}$
Beam fixed at both ends, uniform load	$\frac{1}{12}Wl$	$\frac{1}{384}\ \frac{Wl^3}{EI}$

greater bending moment and a greater deflection than the same load uniformly distributed.

Columns.—If a column supports a load P the average compressive unit-stress upon it is $P \div A$, where A is the area of the cross-section. If the length of the column be considerable compared with its thickness, a slight sidewise deflection may occur, in consequence of which the compressive stress on the concave side becomes greater than the average value $P \div A$, and that upon the convex side becomes less. The exact determination of the maximum stress can not be made theoretically unless the deflection is known, but the subject is one of great practical importance, and many empirical formulas have been proposed for this purpose. The curve assumed by the central line of a column when thus subject to flexure is a sinusoid, and its equation is

$$y = \Delta \sin n\pi\frac{x}{l},$$

in which Δ is the maximum deflection, l the length of the column, y the deflection at a distance x from the end, and n is 1, 2, or 3, according to the number of times the sinusoid crosses the axis. The value of Δ, however, is indeterminate, and can not be expressed theoretically in term of the load.

A long column fails usually by sidewise flexure rather than by direct compression, and the load which causes incipient failure is given by the formula

$$P = EI\frac{n^2\pi^2}{l^2},$$

in which n and l are as just defined, E is the coefficient of elasticity of the material, and I is the least moment of inertia of the cross-section. If the load be less than this formula gives, the deflection of the column tends to decrease; if it be greater, the deflection tends to increase, and in this sense P is the load which causes the failure.

HISTORY AND LITERATURE.—The problem of the flexure of a beam was first discussed by Galilei in 1638; he regarded the fibers as inextensible, but nevertheless some of his conclusions were correct. Hooke's discovery of the law of elasticity in 1678 rendered it possible for a better theory to be developed, and this was done during the following fifty years by Mariotte, Varignon, and others. The elastic curve was first investigated by James Bernouilli in 1694, but its complete practical application was not made until the subject was treated by Navier more than a century later. Among those who have made important contributions to the theory of flexure during the nineteenth century may be mentioned Lamé, Saint-Venant, Clapeyron, and Weyrauch. The flexure of columns was first treated by Euler, and little theoretical advance has since been made. A synopsis of writings on the theory of flexure previous to 1850 is given in Todhunter's *History of the Theory of Elasticity* (1886). In modern text-books the subject is usually treated in works on the resistance of materials. Among these may be mentioned Wood's *Resistance of Materials* (1875); Merriman's *Mechanics of Materials and of Beams, Columns, and Shafts* (1885); and Church's *Mechanics of Engineering* (1889). The flexure of continuous beams is fully developed in Weyrauch's *Theorie der einfachen und continuirlichen*

Träger (Leipzig, 1873). See also BRIDGES (*Continuous Bridges*), GIRDER, MOMENT, STATICS, and STRENGTH OF MATERIALS. MANSFIELD MERRIMAN.

Fliedner, fleet′ner, THEODOR, D. D.: philanthropist, and founder of the institution of Protestant deaconesses; b. at Eppstein, Prussia, Jan. 21, 1800. He studied at Giessen, Göttingen, and Herborn, was for one year tutor in a family at Cologne, and in Nov., 1821, accepted a call from a small Protestant colony at Kaiserswerth, a Roman Catholic town of 1,800 inhabitants on the Lower Rhine, below Düsseldorf. The failure of a silk-factory having soon afterward thrown most of his parishioners out of employment, to relieve their distress he started on a tour for the solicitation of charity, and had soon collected a considerable sum. In June, 1823, he made a tour to Holland and England, which not only resulted in a permanent endowment of his congregation, but suggested to him the idea of founding benevolent institutions in his own country. Accordingly, upon his return he set on foot a number of charitable projects, the most important of which was the establishment of the House of Deaconesses at Kaiserswerth.

King Frederick William IV. of Prussia and his queen Elizabeth took much interest in his labors for the sick and poor, granted him several audiences, furnished him liberally with means, and founded a Christian hospital with deaconesses at Berlin (Bethany) after the model of Kaiserswerth.

Fliedner made two more journeys—to Holland, England, and Scotland (in 1832 and 1853), in the interest no more of his congregation, but of his institutions. He also visited the U. S. in 1849. Twice he traveled to the East—in 1851, to aid Bishop Gobat in founding a house of deaconesses in Jerusalem, and again in 1857, when he was, however, too feeble to proceed farther than Jaffa. D. at Kaiserswerth, Oct. 4, 1864.

Fliedner's Institutions.—The most important of these is the institution of Evangelical Deaconesses, founded in 1836. It was intended to be, and is in some sense, a revival of the apostolic office of deaconesses which continued in the Church for several centuries, but it resembles more the active sisterhoods of the Roman Church, and may be regarded as a Protestant counterpart of the Sisters of Charity, divested of all ascetic and monastic features. The apostolic deaconesses, such as Phœbe, were congregational officers, and visited the sick and the poor at their homes. The Kaiserswerth deaconesses may also be employed for parochial activity (*Gemeindepflege*), but they are usually connected with hospitals, orphan asylums, prisons, and other public institutions.

With the House of Deaconesses at Kaiserswerth are connected a hospital, an infant school, an orphan home, and an asylum for insane females. In 1850 more than sixty Kaiserswerth deaconesses were at work in different places. At the time of Fliedner's death the number of deaconesses exceeded 400, and in 1890 about sixty institutions similar to that at Kaiserswerth were reported, with about 6,000 sisters. In the Austro-Prussian war of 1866 the various deaconess houses of Germany furnished 284 nurses to the military hospitals, besides receiving a large number of sick and wounded into their own establishments; and of these nurses forty-six were from Kaiserswerth. The mother house fulfills the mission of a large normal school for the training of women to the care of the poor and suffering, and has given rise to many similar institutions in Germany and other lands. There Florence Nightingale was inspired for her noble mission in the Crimean war, and Dr. Passavant for the establishment of a Christian hospital in Pittsburg.

LITERATURE.—Fliedner, *Collectenreise nach Holland* (2 vols., Essen, 1831); *Buch der Märtyrer der evangel. Kirche*, (1852, *seq.*, with a supplement, in 3 vols.); *Kurze Geschichte der Entstehung der ersten evang. Liebesanstalten zu Kaiserswerth (des Asyls. der Diakonissen-Mutter-Hauses und des Hospitals)* (1856); Jul. Disselhoff (Fliedner's successor), *Nachricht über das Diakonissenwerk in der christlichen Kirche . . . und über die Diakonissen-Anstalt zu Kaiserswerth* (5th ed. 1867); Catherine Winkworth, *Life of Pastor Fliedner of Kaiserswerth* (translated from the German, which first appeared in the *Kaiserswerth Almanac* for 1866), London, 1867); Florence Nightingale. *Account of the Institution for Deaconesses* (London, 1851); Dean Howson (of Chester), *Deaconesses* (London, 1862); W. F. Stevenson, *Praying and Working* (1862; republished in New York); J. M. Ludlow, *Women's Work in the Church* (London, 1866); also the annual reports and other periodical publications of Kaiserswerth. Revised by S. M. JACKSON.

Flies: See FLY.

Flint [O. Eng. *flint*: Dan. *flint*, stone, flint, gun (whence Germ. *Flinte*, gun); cf. Gr. πλίνθος, brick]: a variety of quartz, massive, dull-colored, and dark, with translucent edges, found especially in nodules in chalk-beds, and on microscopic examination found to consist largely of the fossil frustules of diatoms, the spiculæ of sponges, and the like. Its nodules frequently inclose a large fossil. Specific gravity, 2.6. In prehistoric times it was extensively used as the material for knives, arrow-heads, and other weapons, its peculiar conchoidal fracture and sharp edges fitting it well for such uses. Its use for kindling tinder by striking fire with steel is a thing of the past, as is its employment for a similar use in firearms. Flint is employed in making some kinds of glass, and ground flints are an ingredient of porcelain-ware. Flint is in some places used as a building-stone. In the U. S. the hornstones of the Palæozoic limestone strata pass into flint, and have been shown to be of precisely similar origin to the true Cretaceous flint.

Flint: seaport and parliamentary borough; Flintshire, North Wales; on an arm of the Dee river; 13 miles N. W. of Chester (see map of England, ref. 8–F). It has a large trade, exporting coal and lead from extensive mines near by, and importing much lumber. It contains remains of ancient intrenchments and of Flint Castle, built by Edward I., and dismantled in 1647, and is noted as the place where Richard II. surrendered to Bolingbroke in 1399. Pop. (1891) 5,247.

Flint: city; capital of Genesee co., Mich. (for location, see map of Michigan, ref. 7–J); on Chi. and Gr. Trunk and Flint and P. Marq. R. Rs.; 61 miles N.W. of Detroit. It is the seat of the Michigan Institution for the Deaf and Dumb and of Oak Grove Home, a private institution for the care of mildly insane persons. The city has a large union schoolhouse, a ladies' library association, a large number of steam saw-mills (manufacturing about 50,000,000 feet of lumber annually), gas and electric lights, water-works, etc. Pop. (1880) 8,409; (1890) 9,803; (1900) 13,103. EDITOR OF "NEWS."

Flint, AUSTIN, M. D., LL. D.: physician and author; b. in Petersham, Mass., Oct. 20, 1812; graduated in the medical department of Harvard University 1833; was one of the founders of the Buffalo Medical College, and Professor of Theory and Practice in it from 1847 to 1853; also established the Buffalo *Medical Journal*. In 1844 he was called to the Rush Medical College in Chicago. He occupied for four years the chair of Theory and Practice in the medical department of the University of Louisville, and for three winters (1858–61) was Professor of Clinical Medicine in the New Orleans School of Medicine. He removed to New York city in 1859, was made one of the attending physicians to Bellevue Hospital, and appointed to the chair of Principles and Practice of Medicine and Clinical Medicine in the Bellevue Hospital Medical College, a position he held till his death, and from 1861 until 1868 was a professor in the school of the Long Island Medical College Hospital. From 1872 until 1885 he was president of the New York Academy of Medicine. Dr. Flint was the author of many standard works in the profession. He published the clinical reports *On Continued Fever* (Buffalo, 1852); *Chronic Pleurisy* (1853); and *Dysentery* (1853); *Physical Exploration in the Diagnosis of Disease of the Respiratory Organs* (Philadelphia, 1856; 3d ed. 1868); *Diseases of the Heart* (1859–70); *Principles and Practice of Medicine* (1866; 5th ed. 1881); *Essays on Conservative Medicine and Kindred Topics* (Philadelphia, 1874); *Clinical Medicine* (1879); *Physical Exploration of the Lungs by Means of Auscultation and Percussion* (1882). D. in New York, Mar. 13, 1886.

Flint, AUSTIN, M. D., LL. D.: physician; son of Austin Flint; b. in Northampton, Mass., Mar. 28, 1836; was for one year at Harvard; 1854–56 at University of Louisville, Ky.; graduated from the Jefferson Medical College, Philadelphia, 1857; editor of Buffalo *Medical Journal* 1857–60; Professor of Physiology and Microscopic Anatomy, University of Buffalo, 1858–59; became Professor of Physiology in New York Medical College 1859, and in New Orleans Medical School 1860; studied in Europe under Bernard and Robin, and in 1861 became Professor of Physiology and Microscopical Anatomy in Bellevue Hospital; has held the chair of Professor of Physiology in Long Island College Hospital 1862–68; and has been connected with other institutions as consulting and visiting physician. His chief works are *Physiology of Man* (5 vols., 1866–74); *Chemical Examination of Urine in Disease* (1870); *Effects of Severe* *and Protracted Muscular Exercise* (1871); *Service of Muscular Power* (1878); *Text-book of Human Physiology* (1875). In addition to these he has written a large number of pamphlets, memoirs, etc., on professional subjects.

Revised by C. H. THURBER.

Flint, ROBERT, D. D., LL. D.: a theologian of the Church of Scotland; b. near Dumfries, 1838, and educated at Glasgow. He was in the pastorate 1859–64, was Professor of Moral Philosophy and Political Economy at the University of St. Andrews 1864–76, and then became Professor of Divinity in Edinburgh University. Among his published works are *The Philosophy of History in France and Germany* (Edinburgh, 1874); *Theism* (Baird lectures for 1876–1877; seventh ed. revised 1893); *Anti-Theistic Theories* (Baird lectures for 1877; 1879 and three subsequent editions).

Flint, TIMOTHY: clergyman; b. in Reading, Mass., July 11, 1780; graduated at Harvard University in 1800; was a Congregational minister at Lunenburg, Mass., from 1802 to 1814; was missionary in the Mississippi valley, and was afterward farmer and teacher at Cincinnati, O., and in Louisiana. Returned to Massachusetts in 1825; from 1825 till 1828 edited at Cincinnati the *Western Review*. In 1833, at New York, edited the *Knickerbocker*; in 1827–30 edited *The Western Monthly Magazine*; subsequently lived in Alexandria, Va. He published *Geography and History of the Western States in the Mississippi Valley* (1828), besides various novels (the best known of which is *Francis Berrian*, 1826); *Lectures on Natural History*, etc. D. in Salem, Mass., Aug. 16, 1840.

Flint Glass: one of the varieties of glass which contain a large percentage of lead. Powdered flint was formerly used in the manufacture, whence the name. The best of white sand (51 parts), a tolerably pure carbonate of potash (16 parts), minium or litharge (28 parts), and saltpeter (4⅔ parts) are used as principal ingredients; a little manganese, arsenic, baryta, and lime are added to correct any discoloration. Flint glass is used largely in the manufacture of achromatic lenses, and grades inferior to the very finest are used in making bottles, table-ware, and other glass goods, either blown or molded. The Venetian and Bohemian glass articles are especially celebrated. See GLASS.

Flint Implements: See STONE, AGE OF.

Flint River: a river of Georgia; rises in Clayton County and flows first in a S. S. E. and then in a S. S. W. course to the S. W. corner of the State, where, joining the Chattahoochee, it forms the Appalachicola river. It is 300 miles long and navigable during high water to Albany by light-draught steamers, and at all times by larger steamers to Bainbridge, 50 miles from its mouth.

Flint River: a river of Michigan; rises in Lapeer County; flows 100 miles W. and N. W., and falls into the Shiawasee, an affluent of the Saginaw. Its lower part is navigable.

Flintshire: maritime county of North Wales; situated between the Irish Sea and the river Dee; area, 253 sq. miles. The coast is low and sandy, except along the estuary of the Dee. Parallel with the Dee runs a range of hills, rising in Garrey to 825 feet. The plains and the vales are fertile, and produce wheat, oats, and barley. The hills yield coal and ores of iron, zinc, copper, silver, and especially lead; one-fourth of the lead produced in Great Britain is supplied by Flintshire. As the county has a mild climate, moderate elevation, and shelter, it is well adapted to agriculture, and three-fourths of its area are under cultivation. Cotton is the main manufacture. Flint, Mold, St. Asaph's, and Hawarden are the chief towns. Pop. (1901) 81,487.

Flipart, flee'paar', JEAN CHARLES: engraver; b. in Paris in 1700. His best works are a portrait of René Chopin, after Jacnet: *The Virgin and Child* and *Christ in the Garden of Olives*, after Raphael; also *The Penitent Magdalen*, after Lebrun; and *Apollo Teaching Daphne*, after René Houape, for the Crozat collection. He was father of JEAN JACQUES FLIPART (b. in 1723; d. 1782), more famous than himself, and of CHARLES FRANÇOIS FLIPART, both engravers who learned their art of him; the former was also a painter and a skillful draughtsman, and left many engravings after Greuze, Giulio Romano, Natoire Vier, and Dietrick and others.

W. J. S.

Floating Batteries: See SHIPS OF WAR.

Floating Breakwater, Docks, etc.: See BREAKWATER, DOCKS, etc.

Flodden Field: the last point of the Cheviots, the place where King James IV. of Scotland, after crossing the Border on Aug. 22, 1513, with an army of over 30,000 men, encountered the Earl of Surrey at the head of an English army of 32,000 on Sept. 9. The battle was stubbornly contested till after nightfall, but resulted in the complete defeat of the Scottish army, and the loss of from 5,000 to 12,000 men, including the king and many of the nobility.

Flodoard, flō'dō'aar', or **Frodoard**: Canon of Rheims; b. at Épernay, 894 A. D.; opposed the intrusions of the civil power into the affairs of the Church, and was imprisoned therefor; author of French annals (*Chronicon*, 919–966); a history of the Rhemish Church; the *Triumphus Christi*, a metrical work, etc. He became an abbot, and died Mar. 28, 966. *Chronicon* is valuable to the historian. Large portions of his writings are extant, and have been printed.

Floeberg Beach: See the Appendix.

Floersheim, OTTO: journalist and composer; b. in Aix-la-Chapelle, Mar. 2, 1853; studied there under local teachers, and then at Cologne under Ferdinand Hiller; went to New York in 1875, and contributed musical articles and criticisms to various German periodicals. In conjunction with Marc A. Blumenberg he established the *Musical Courier*, to which he has since confined his writing. In 1892 he returned to Germany, where he still remains (1893). His compositions comprise orchestral pieces, songs, and pianoforte pieces.

D. E. HERVEY.

Flogging: the infliction of stripes or blows by a whip or scourge, especially when directed by a court of justice or other public authority. Corporal punishment has from the earliest ages been inflicted as a punishment for various offenses. In the form of the bastinado it is still extensively employed in the East. In ancient Rome scourging might not be administered to a citizen, for it was looked upon as giving the deepest dishonor to its victim. It was, however, frequently employed as a punishment for those who were not citizens, and was administered with a rod. In modern Europe it is not quite extinct; in many places where it had been abolished it has been reintroduced. Its severest form is by the knout in Russia, where it is much less frequent and severe than it formerly was. In Great Britain it exists as a means of prison discipline, but has been abolished in the army and navy. In the U. S. army and navy it has been abolished, as well as in most of the States, Delaware being a noteworthy exception.

Flood, Rt. Hon. HENRY: orator; b. in Ireland in 1732; educated in Dublin and Oxford; first entered the Irish Parliament in 1759; was sworn a member of the privy council for Great Britain as well as for Ireland in 1775; was vice-treasurer of Ireland, 1775–81; and entered the British Parliament in 1783. His speeches are noteworthy for their fine style and logical method. He was an eloquent advocate of reform for Ireland, but the purity of his motives has been questioned. Author of some poems and a volume of *Speeches* (1787). D. at Farmley, Ireland, Dec. 2, 1791. See his *Life and Correspondence*, by W. Flood (1838.)

Flood-plain: a broad river-made plain, formed by successive layers of silt, sand, or gravel, at times of river overflow. The even surface of the plain commonly ascends very gently from either margin to the river-banks, where the greater amount of deposit is laid down by the overflow. For this reason settlements are often made on the higher ground close to the river, to avoid the "back swamps"; for the same reason lateral tributary streams emerging from higher land frequently turn down the flood-plain for many miles before entering the main river. A river meanders or swings in a serpentine course through an alluvial flood-plain, the radius of its curves increasing with the volume of the stream. The current cuts away the concave bank and builds out the convex bank, and thus the channel shifts about the plain. Narrow necks of land between meanders are often cut off, leaving an abandoned channel as a stagnant "ox-bow" lake. The flood-plains of the the lower Mississippi (mapped by the Mississippi River Commission), Amazons, middle Rhine and Danube, lower Po, Nile, and Ganges are well known. They are extremely fertile, and are generally covered in the natural state by swampy forests or meadows. When occupied by man, protection by dykes or levees is needed against overflow. Gravelly flood-plains are made by rivers emerging from a steep course among lofty mountains upon a lowland; the river then splits into a network of shifting channels, like those of the Duranse in Southeastern France or the Tagliamento in Northern Italy. See RIVERS, DELTA, and LAKES.

W. M. DAVIS.

Floods: temporary invasions of the land by bodies of water. Coasts of seas and lakes are sometimes inundated. By the bursting of dams, artificial or natural, the water of reservoirs deluges neighboring valleys. Most rivers, either periodically or occasionally, are so enlarged as to spread beyond their banks.

Coastal Floods.—Floods sometimes occur along coasts from the wave accompanying an earthquake. During the great Lisbon earthquake of Nov. 1, 1755, a wave rushed over the land covering it to a depth of 80 feet, causing great destruction. They are also caused by the storm-waves accompanying tropical cyclones of great energy. Such was the Backerganj flood from the Bay of Bengal. The delta of the Ganges river was inundated to a depth of 40 feet, and more than 100,000 lives were lost. Floods of this nature, but less intense, occur at rare intervals along the coast of Texas. Of nearly the same nature are the floods that sometimes devastate Holland. A great part of the country is protected by dikes from the encroachment of the sea. Violent storm-winds heap up the sea, which in some cases overtops or breaks the dikes.

Floods due to rise of lake-level occur only over restricted areas, and are of slight importance. They result from more than the usual amount of rainfall in a season, and occur only on some of the lakes of Central Asia. The rises are slow and not very great, and but little damage is ever done. Of the class of lake floods, however, seiches are important. A seich is a sudden rise of the water surface, or a slow moving wave. On the Great Lakes of the U. S. the rise sometimes is as great as 6 feet, and at times causes great damage.

Reservoir Floods.—A very important class of floods is that due to the bursting of reservoirs, from the giving way of embankments, the yielding of ice-dams in rivers, and the releasing of glacier lakes. The Johnstown flood of May 31, 1889, in Western Pennsylvania, was a memorable example of the first kind of flood. The breaking of the dam of the South Fork reservoir precipitated a volume of water 3 miles long, a mile wide, and 100 feet deep, on the valley below, destroying everything in its course for a distance of 18 miles and killing 5,000 people.

At the breaking up of ice in the spring river channels sometimes become blocked by the accumulation of ice in bends or narrow parts of the river, or at places obstructed by bridge piers. The water backs up behind the dam or ice-gorge thus created, causing damage above it and also below it when the barrier breaks. Floods of this class, however, do not usually prove very destructive. If foreseen they can in many cases be provided against. The greatest loss is commonly to boating interests, damage being done to craft that can not be gotten out of the way. Ice-jam or ice-gorge floods may cause great damage in a flat country.

A flood of a peculiar kind sometimes arises from an advancing glacier crossing and blocking a stream and creating a glacier lake back of it. This occurs at times in Switzerland, and more frequently in the region of the Himalaya mountains in Northwestern India, especially on the tributaries of the Indus. In the valley of Bagnes, south of Martigny, the winter of 1818 being very severe, the Gintroz glacier advanced and blocked the Drause river, making a lake back of it a mile long, 700 feet wide, and 200 feet deep. The ice was pierced artificially and the lake about half drained off when the barrier broke and caused a great flood.

River Floods.—The most frequently occurring floods are river floods due to overflow of river-banks caused by inadequacy of river channel to carry off the rainfall water as fast as supplied. Rivers are a product of rainfall. The periodicity of rainfall over a country is reflected in the rise and fall of its rivers, sometimes nearly dry and at others overflowing their banks. Floods in rivers are rarely the result of a single great downpour of rain, except over a very restricted area of a few hundred square miles in extent. They are usually the result of a series of moderate rainstorms gradually filling the river channels until there is an overflow. A very disastrous but rare species of river flood occurs when a river cuts its banks, taking an entirely new course to the sea. This has occurred on the delta of the Hwang Ho in China on nine occasions in historical times. In 1853 the river broke from its course and entered the Yellow Sea, 350 miles farther north than formerly, entailing enormous loss of life through drowning and starvation. See CHINA and YELLOW RIVER.

In the most common species of flood, where the water rises gradually and overflows the low-lying lands, damage occurs from the submerging of property, the destruction of growing crops, and the impossibility of working the land in time to raise a harvest. At times buildings are destroyed, cattle are drowned, and human lives lost. In cities subject to overflow great damage is at times wrought to merchandise. Railroads are flooded, bridges carried away, commerce is impeded, and business interrupted.

The amount of rise above low water that will produce overflow is different in different rivers, and also along different parts of the same river. The overflow stage varies from 20 feet or less in some rivers to as much as 86 feet in others.

Run-off.—Of the rain that falls a part goes directly into the rivers; a part sinks into the ground and flows out slowly through springs at a lower level than it entered. A great part of what sinks into the earth evaporates into the air, either directly or through the vital processes of plants. About one-fourth of all the rain that falls reaches a depth of 3 feet in the ground. The depth of water in the ground to bed-rock is about one-third of the depth of the soil covering the rock. Thus only a part of the rain reaches the rivers and the sea. The proportions vary greatly in different regions, and even for the same region in different seasons and different rainstorms. The average run-off for rivers of the temperate zone is about one-fourth of all the rainfall. For the drainage area of the Darling river in the dry climate of Australia the run-off is on the average only 1·5 per cent., some years being as low as 0·1 of a per cent., and in others as high as 6 per cent. The run-off varies greatly with the permeability of the ground. Some soils absorb the water more readily than others. In the case of snow on hard-frozen ground the run-off may be 75 per cent. of the melted snow. In the case of hard-frozen ground covered with glare ice by a light rain, the run-off in the case of a succeeding heavy rain may be as much as 90 per cent. The greater the rate of downpour of rain the greater the run-off; the water not sinking into the earth rapidly forms a thin layer over the surface, which promotes the rapid transfer of a great part of it to the streams. After a season of drought, a month or more with little or no rain, it requires a fall of 2 or 3 inches of rain to saturate the ground. Such a rain falling slowly might produce no effect on a river, but if it fell in a few hours it might produce a great rise. The estimated flow of water from all the land surface of the earth is 7,000 cubic miles annually. The outflow of the Mississippi river is 120 cubic miles annually on the average, and 200 in flood years. The outflow of the Amazon is 600 cubic miles.

Levees.—River floods are not without beneficial effects on the land overflowed. The fine silt deposited renders it very fertile. Alluvial land is therefore highly prized, but when it has once become occupied by the farmer the flooding by which it was originally enriched becomes an impediment to its utilization. Protection from overflow is commonly sought by embankments called levees. Along the lower course of the Mississippi river, below the junction of the Ohio, there is an area of 30,000 sq. miles subject to overflow which is protected by 1,300 miles of levees. The yield of cotton and sugar from this region is large, and when the water breaks over the levees, as it sometimes does, the damage is great. The whole area is never flooded at the same time. Were it not for the levees a great part of the area would be flooded every year.

The levees do not entirely prevent floods, but greatly diminish their frequency. The greatest high waters that occasionally occur override everything. Breaks in a levee are known as crevasses. When the water once gains an outlet through a levee it carries away the earth of the embankment very rapidly, deepening and widening the break every instant, until it is hundreds of feet wide, and in some cases even miles in width. When crevasses occur, the first care of the levee engineers is to secure the ends of the opening and prevent the break extending. Crevasses are sometimes successfully closed.

Levees are apt to break when from long contact with high water the embankment becomes softened by the water percolating through. When the water is near the top, wave-wash caused by high winds is a source of danger. Crevasses are sometimes attributed to crawfish. Improperly laid rice-flumes are apt to be a source of weakness and make a starting-place for water to come through. During the continuance of high water vast interests may be at the mercy of the slightest accident to the levees. See LEVEE and RIVERS.

Mode of Occurrence of High Water.—High waters in rivers occur in various ways in different parts of the world, depending on the climate, the annual distribution of rainfall, the temperature, and especially on the topographical features of the drainage areas of the rivers, particularly the slope of the ground and the way different tributaries combine to form a great river. Of the dependence of river floods on meteorological laws little more is known than that certain high waters depend on the rains of the equatorial belt of calms, on the rains associated with the bursting of the monsoons, and on the locking of water by frost in northern latitudes.

Rivers may be roughly classified according to the way high water occurs. In land-locked areas the rivers flow to the lowest part of the drainage basin and form a lake. The water rises to the lowest part of the inclosing ridge, provided the evaporation from the lake surface is less than the inflow, and overflows as a river to the sea. In rivers that take their rise in lakes the flow of water is nearly constant, and there is very little variation of stage, year in and year out. Floods never occur on these rivers. The variation in the height of the St. Lawrence river, which takes its rise in Lake Ontario, ordinarily is only 4·5 feet. High winds cause variations of a few feet from the extremes of low and high water lake-levels which, however, last for only a short time.

In the rivers of Siberia and British America that flow into the Arctic Ocean high water occurs as the result of snow melting in the spring along the lowlands and up to a height of 3,000 feet above the level of the sea. The rivers flow from south to north. The Obi, Yenessei, and Mackenzie are of this type. Along the upper courses the snow melts first. As the water flows down it is met by the water from the snow farther north melting later. The consequence is excessive high waters along the lower courses of these rivers, and great areas of land are flooded. The blocking of river-channel by the formation of ice-gorges also adds greatly at times to these floods.

One class of rivers derive their water almost exclusively from snow melting in the mountains. The melting is a slow process, and high water occurs gradually and with great regularity. The Indus, which rises in the Himalaya Mountains, is a river of this type. The Rocky Mountain region of the U. S. abounds in small streams of this kind. In some instances such rivers show a small diurnal fluctuation of stage corresponding to the greater melting of snow that takes place in the day as compared with the cooler night.

Rivers in the tropical countries receive water from rainfall only, and have high water in summer. The greatest rivers of the world belong to this class, the Amazon, the Congo, the Ganges, the Yang-tse, and the Nile. In some of these rivers the high waters depend on the rains of the belt of calms at the equator. In those of Asia the rises come from rains that occur at the bursting of the monsoon. The Amazon does not vary greatly at different times of the year, because when the northern tributaries are in flood the southern ones are low, and when the southern ones are in flood the northern ones are low. The great floods of the Yang-tse sometimes last from June to December. The rises show that the monsoon winds penetrate to the interior of Asia to a greater extent than was at one time supposed.

In rivers that are dominated by the sub-tropical rains—that is, little or no rain in summer-time—the rivers are low or nearly dry in summer, and high water occurs in winter. The rivers of Italy and Spain are of this class, also the rivers of California and Oregon. These latter, however, derive some water from melting snow in the mountains. Rivers of the temperate zone receive their main supply of water from rains directly, and are high in winter and spring, the seasons of great rainfall. Of this class are the Elbe, Rhine, and Seine of Europe, the Ohio, Arkansas, and Mississippi in the U. S. High water in these rivers is added to very materially at times by the melting of accumulated snow. The smallness of evaporation in winter as compared with summer tends to make the water high.

Some rivers receive most water from rain, but high water is due to the additional amount coming from melted snow. Melted snow is relatively more efficient than the same amount of rain in causing a rise, because a much greater part of it goes into the rivers when melted, frozen ground being impermeable to water. The rivers of New England are of this type. With great depth of snow on the ground, floods occasionally occur in some rivers not otherwise subject to overflow. About once a century the river Somme in France overflows from this cause. The flood of 1658, which was preceded by several weeks of excessively cold weather, came from the melting of snow which lay on the ground to the depth of 6 feet. Preceding the great flood of 1740 the conditions were similar.

High water, besides depending on great rain, depends also on the topographical features of the drainage area in combination with the sequence of rainfall over its different parts. Rainfall is not usually uniform in depth over a wide area in great rain-storms. When the distribution of a fall of rain in time and space is such that the freshets in tributaries from several regions coincide in reaching the main channel of a river at the same time, excessively high water results.

Floods in the lower Mississippi river are due mainly to water from the Ohio river. The Ohio alone is not sufficient to cause a stage of more than 40 feet in the lower Mississippi. To carry it 8 feet farther to the flood-line requires that the Arkansas, the Missouri, or the upper Mississippi shall send out a flood to be opportunely superposed on the high water from the Ohio. Variation in distribution of rainfall in different years may cause flood-waves from the various tributaries to pass through the lower river in succession, producing moderately high stages of water lasting a long time, but no great high water.

For any particular river many different combinations of flood-waves from the various tributaries are possible, so that the occurrence of a flood may in a certain sense be considered as fortuitous. Caution has therefore to be exercised in passing from records of high water to conclusions as to changes in river regimen and increased flood-heights due to extension of land cultivation or the clearing of forests.

Forests and High Water.—Where forests are cut away from a drainage area, especially on hillsides, the amount of silt carried to the streams is increased. By filling up the bed of a river this may cause the heights of high waters to gradually increase without any greater quantity of water passing through the river. A notable case of rising of river-bed due to deposit of silt is that of the Sacramento river. This, however, is not due to cutting away of the forests, but to the washing down of mining *débris*. The rise in bed of river, which is 20 feet higher now than it was in 1849, is partly due to restricted tidal scour caused by reclaiming of overflowed land by levees. Bushes that grow spontaneously on hillsides are as serviceable as forests in checking soil waste and consequent clogging of streams, so there is no necessity to plant trees. That forest over a drainage area diminishes the flood-heights of its rivers by conserving the rainfall, and causing it to pass to the streams more slowly, is highly improbable. That forests have any influence in increasing or diminishing rainfall has never been proved. That forests do conserve the water by diminishing evaporation, giving greater outflow at low water, and preventing the occurrence of very low stages or the absolute drying up of streams, seems very likely.

Records of River-stages.—Daily records are kept of the stages of water in rivers at various places. A river-stage is the vertical height in feet of the river-surface above the local plane of low water. The stage of water is ascertained by means of a river-gauge, which usually consists of timbers or stones suitably graduated, laid along the incline of a river-bank. When a bridge pier is available, a gauge is made of a graduated plank fastened to it vertically or by the cutting of marks on the stone. River-stage observations are mainly valuable at very high stages of a river in case of a threatening flood; they are also of use at the lowest stages of water, as indicating available channel depths for boating.

A flood condition in a river is sometimes graphically presented to the eye by a device called a hydrograph. On a sheet of cross-section paper the squares from left to right are taken to represent successive days, and the squares from below upward are taken to represent units of gauge height. The gauge readings for the days are then plotted as points, and these are joined by a curve, which is called a hydrograph. In this way a rise in a river at a place is shown on paper as a wave. There is a gradual increase in height to the highest stage or crest and then a falling off. A hydrograph exhibits the condition of a river at only one point. To show the conditions all along a river requires hydrographs for a great many points. Another method of graphically showing a flood condition in a river is by means of isopleths. On a sheet of cross-section paper the squares from left to right represent successive days; the squares up and down represent distance of various places along the river from some initial point. On the line for a place there is written in for each day in figures the number of cubic feet of water per second passing the place on that day. Lines are drawn through the points of equal quantity of water discharge for discharges differing by 100,000 cubic feet or so. These lines are called isopleths. In this way a graphic relief chart is produced which shows a flood-wave along a river.

Another method of representing a flood is to write in place of the discharge of water, as described above, the stage of water on the day expressed as a percentage of the total range in stage from low to high water. Joining the points of equal percentages by lines, say 10 per cent. apart, a chart is obtained which shows the magnitude and movement of a flood-wave.

Flood-wave Movement.—The greater the drainage area above a place the slower and more regular the rise and fall of the water. Where the drainage area is not more than 200 sq. miles the rise and fall runs its course in a day or a few hours, especially if the country is hilly. With a drainage area of many thousand square miles, as in the case of Pittsburg, for instance, with 17,000 sq. miles above it, the rise and fall on the average covers about six days. For Cincinnati, with 71,000 sq. miles above it, the time is fourteen days; for Vicksburg, with an area of 1,137,000 sq. miles above it, the time may be forty days or more.

A flood-wave in a river moves down stream with a moderate velocity, from 3 to 5 miles an hour, which renders it possible to foretell the occurrence of high water along the lower course of a river when the rises along the upper course are known. There is a dependence of the stage at one place with that of another above it. Warnings of a coming high water can be given by telegraph in many cases to interested districts a considerable time ahead. Such warnings have become of great importance.

So long as the water remains in the channel the rate of progress of a flood-wave crest does not differ materially from the velocity of the water forming it. When the water overflows the banks the wave-crest time is very much retarded. The wave-crest velocity is also retarded as compared with the velocity of the water, from the fact that the empty river channel has to be filled as the river rises. The time of a flood-wave crest in the Ohio river, from Parkersburg to Cincinnati, a distance of 286 miles, is three days; from Cincinnati to Cairo, 498 miles, it is six days. On the Mississippi river, from Cairo to Vicksburg, 599 miles, the time of crest-wave travel is seven days while the river is within banks; when the river overflows it may be as great as twenty days.

River-stage Predictions.—The following account of the method employed in the prediction of river-stages is based primarily on the usage of the U. S. Weather Bureau:

For two places on a river 100 miles or so apart, with no large tributaries coming in between them, the relation of the gauge readings for the two places is derived as follows: From the records of stages the highest stages reached during rises at the upper place are selected, and also the corresponding highest stages occurring a day or so later at the lower station. By taking the averages of corresponding stages for the two places in groups differing in stage about 5 feet, a series of corresponding values for the two places is derived. These are arranged in the form of a table, or a curve is made with the stages at one of the places as abscissas and the stages at the other as ordinates. From this the high water that may be expected at a place can be derived when the high water that occurs earlier at the place above it is known. For Cincinnati and Louisville, for instance, on the Ohio river, 132 miles apart, a 40-feet crest stage on the gauge at Cincinnati corresponds to 16·9 feet one day later at Louisville; 50 feet correspond to 26·0 feet; 60 to 38·2; and 70 to 46·4. These are the averages. The individual cases may differ a foot or two. The relation of the gauges is closer the nearer the two gauges are together and the less the quantity of water coming into the river from tributaries between them. In some cases better results in the prediction of stages are obtained from the comparison of corresponding rises rather than by corresponding stages. In case the rise at a place is the result of rises in several large tributaries, the best method of deriving a rule for predicting the highest stage is to compare the rise at the place with the rises preceding it at places on the tributaries. At Cairo, Ill., for instance, on the Ohio river, a rise may be the result of a rise in the upper Mississippi river as shown by the river-gauge at St. Louis, a rise in the Wabash as shown by the Mt. Carmel gauge, a rise in the Ohio river as shown by the gauge at Cincinnati, or on rises in the Cumberland or Tennessee as shown by the gauges at Nashville or Chattanooga.

The higher the stage at a place the greater the effect of a rise in causing a rise at places below it, on account of the greater quantity of water passing. For high stages at a lower station, rises at upper stations are not as effective in producing rises as when the stage at the lower station is low. The greater area of cross-section of a river and the greater velocity of the water at a high stage require a greater quantity of water to produce a given rise at a high than a low stage. In deriving prediction rules it is considered that for a place the rises multiplied by the mean stages during the rises are comparable throughout different stages. This is taken as a rough approximation to the truth where there are no local discharge measurements to give exactly the relation of rises at different stages.

In case the rise in a tributary stream at a place near its mouth is partly due to back water from a rise in the main stream, the rise multiplied by mean stage during the rise is not a measure of effectiveness in producing a rise farther down, and allowance has to be made for it.

From observations of stages at a single place, some idea can be formed of a coming stage of high water. The difference of stages gives a rate of rise which can be used in calculating a stage for some time ahead. When the rate of rise is diminishing, it is a sign that the crest of the wave or greatest stage of water is near at hand.

Rainfall and River Rise.—Observations of rainfall over a drainage area are of little practical value in estimating a river rise quantitatively. A rain-gauge collects the rain over an area of only 50 sq. inches, which is but a small sample, and is not accurately characteristic of what occurs in the way of rainfall over a broad area. Moreover, the conditions affecting run-off are too complicated to be readily allowed for. To estimate river rise from rainfall it is necessary to consider the distribution of rain in time and space over a drainage area. By dividing a drainage area on a map into a number of parts over which the time of water travel to a gauge station by the river is nearly the same, and by subdividing these parts into a number of other parts, 1,000 sq. miles or so in extent, over each of which the rain may be taken to be nearly uniform in depth and equal to the mean of the depth as shown by all the observations of rainfall within it, and by taking into account the average run-off, an approximate estimate can be made of the quantity of water that reaches a place on the river simultaneously from the various parts of the drainage area and from the rainfalls on different days. Comparing these amounts with the rises that have occurred in various instances, some idea can be formed of the relation of the two. This method of estimating a river rise is, however, not comparable in accuracy or ease of application with the method by comparison of river-stages, and is only resorted to where up-river gauge records are not available for prediction.

Thomas Russell.

Floor [M. Eng. *floor*, *flor* < O. Eng. *flōr*: M. H. Germ. *flur* > Mod. Germ. *Flur*, floor, field, plain < Teuton. *flōrus* < Indo-Eur. *plārus*, deriv. of *plā-*, flat; cf. Gr. πλατύς: Lat. *plānus*, whence Eng. *plain*]: the lower surface of a room; the upper surface of the horizontal structure which separates one stage or story of a building from another, and whose under surface forms the *ceiling* of the story beneath; hence also the structure itself. In naval architecture the various floors are called *decks*. The construction of floors over wide spaces, and in structures where they are subjected to excessive strains of weight or vibration, presents problems of considerable difficulty which have engaged the skill and ingenuity of builders in all ages.

Wooden Floors.—The simplest form of floor is that in which beams called *joists*, stretching from wall to wall at short intervals, carry a *flooring* or covering of boards or planks nailed to them. In ancient and mediæval work the joists were usually heavy square timbers, widely spaced, and carrying a flooring of broad planks. Modern builders, recognizing that the transverse strength of a beam is as the square of the depth, employ deep and narrow joists, or stout planks set on edge, and concealed from view below by a ceiling of wood or plaster. To secure greater stiffness and freedom from vibration cross-bracing or bridging is resorted to, by means of which any strain upon one joist is distributed over several. When the span is too great for single joists, intermediate *girders*, carried on piers or columns, support the meeting-ends of adjacent rows of joists; or heavy beams or trusses span the area, and carry joists laid parallel to the walls. When it is desired to bring the tops of the joists flush with the top of the beam or girder, they are mortised into the latter, or hung to it by iron "hangers" or "stirrups." In frame buildings the joists are carried by the sills, girts, and wall-plates of the frame, and by intermediate girders, trusses, or partitions. Where openings exist for stairs, hearths, or chimneys, the joists abutting against the opening, called "tail-beams," are mortised or hung to transverse pieces called "headers," which in turn are framed to girders or double joists called "trimmers" on either side the opening. Single floorings are nailed directly to the joists, and in all but the cheapest work are composed of narrow boards, tongued and grooved to each other; the large number of narrow boards reducing the possible shrinkage of the flooring at each joint to a minimum. Better floorings are composed of an under-flooring next the joists, and an upper flooring of superior quality "blind-nailed" to it. Ceilings are made upon *furring-strips* nailed across the joists underneath, for the purpose of securing a perfectly even horizontal bearing for the laths or woodwork of the ceiling. When floors are to be *deadened* (or "deafened"), an intermediate surface of boards or of lath and plaster is formed between the joists at about half their depth, and sometimes leveled up to the top of the joists with "mineral wool" or simply with shavings, plaster, or other non-conductor of sound.

In the "slow-burning system" of mill-construction recommended by the Boston Manufacturers' Mutual Insurance Company, and widely adopted in New England, the floor is composed of 3-inch or 4-inch planks of Southern pine or oak, carried by heavy beams 8 or 10 feet apart, without cross-bracing or ceilings. The flooring-planks are grooved on both edges and joined by splines of hard wood. An upper flooring of $\frac{7}{8}$-inch stuff is often added.

Fire-proof Floors.—For description of floors with iron beams and brick arches or other filling, see article FIRE-PROOF BUILDING. Sometimes wooden joists are used, filled in between with slabs of fire-proof material, and protected on the under side by plastering applied to wire-lathing; but such floors do not possess the highest fire-resisting qualities.

Floors on Vaulting.—The Romans and Byzantines were masters in the art of building floors upon vaults of brick, stone, or concrete, an art which the mediæval builders carried to even higher perfection. In some parts of Italy and Hungary vaulting is still employed for this purpose, even in ordinary dwellings. But this method of construction is too costly, too heavy, and too wasteful of space to be often used in these days of steel beams. The so-called "Guastavino" system in large measure avoids these objections by the use of very thin vaults of hard tiles laid flat in cement, edge to edge, in two or three layers breaking joints, and with but little "rise" or curvature to the vault. The weight these thin elastic vaults will support is extraordinary. They are leveled on top with concrete to receive wooden or tile floorings.

Stone floors are rarely used, because of the great weight and relatively low transverse strength of slabs and beams of stone. Though frequent in ancient and mediæval buildings, their place is taken in modern work by the various kinds of fire-proof construction already referred to.

Floorings.—The most common materials used for finishing the upper surface of floors are wood, tile, flag-stones, mosaic, and concrete, or asphalt. Common floorings are of pine or spruce, laid as already described. Finer floorings are made with narrow strips of hard wood tongued and grooved, or splined, blind-nailed to the under-flooring, planed to a perfect level, and oiled, varnished, or waxed. Floorings of wood mosaic and parquetry are made of small pieces of hard wood of different colors, fitted together in decorative patterns and nailed to the under flooring. Tiled floors and floorings of marble mosaic require a firm and unyielding structure to carry them. The tiles, or the fragments of stone and marble composing the mosaic, are bedded in strong cement spread over a layer of concrete. The mosaic is then rubbed to an even surface and polished. Flagstones of marble or coarser material are laid in the same way. In France and in some other parts of Europe the floors of ordinary houses are not uncommonly laid with small hexagonal tiles of fine hard brick, which are varnished from time to time. Cement and asphalt are used for flooring basements, cellars, stables, and other places requiring a hard surface absolutely impervious to moisture. Such floorings are made by spreading a layer of pure cement, or of cement and sand mixed, or of asphalt, over a well-hardened bed of concrete of crushed stone, sand, and cement.

The Greeks, and after them the Romans, adorned their temples and public buildings, and even their private dwellings, with floors of marble and of mosaic of great beauty of design and workmanship. (See MOSAIC.) The floors of the early Christian basilicas of the East were often finished in a combination of *opus Alexandrinum* or mosaic of minute triangles of bright-colored material, and *opus sectile*, or patterns in which each area of color was of a single piece of marble cut to the required shape. The Byzantine architects also wrought splendid floorings of the same kind for their churches, as in the church (now mosque) of Agia Sophia in Constantinople, and the Italians have for centuries excelled in this sort of work. Floorings of fine material and artistic design are far more common in Europe than in the U. S., where, however, they are now more frequently used than formerly.

Weight on Floors.—This varies greatly for different classes of buildings. In calculating the strength of floor-beams it is customary to allow for a weight of 80 lb. per sq. foot in dwellings, schools, and hay-lofts; 120 lb. in churches, theaters, and places of public assembly. But the experiments of B. B. Stoney, in England, have shown that this is sometimes largely exceeded in "crushes" such as occur in the vestibules of theaters, etc. For granaries, 100 lb. per sq. foot may be allowed; for warehouses, 250 lb.; for factories, 100 to 400 lb. To these weights should always be added that of the floor itself, varying from 18 lb. per sq. foot in ordinary wooden floors with plaster ceilings under them to 35–60 lb. in fire-proof floors with brick arches.

Formulas for Beams.—The requisite size and strength of iron and steel beams for floors are calculated by means of tables furnished by the manufacturers of the various patterns used. For wooden beams, however, the calculations may be made by the architect or builder by the use of the formulas

$$d = \sqrt{\frac{scl^2(W+w)}{2Ab}} \qquad (1)$$

$$c = \frac{2Abd^2}{sl^2(W+w)}, \qquad (2)$$

in which $W =$ assumed load per square foot on floor; $w =$ weight of floor itself per square foot; $l =$ length of beam in feet; $b =$ breadth of beam in inches; $d =$ depth of beam in inches; $c =$ distance apart on centers in feet; $s =$ factor of safety assumed (usually from 3 to 5); and A is a constant determined by experiment, viz., 240 for white pine, 270 for spruce, 315 for oak, and 375 for hard pine. Formula (1) gives the depth of beam required for a given span, thickness, and spacing of the joists; and formula (2) the proper spacing on centers for beams of a given dimension.

When, however, it is desired to calculate the load which a given beam will carry without exceeding a deflection of $\frac{1}{40}$th of an inch per foot of space, the following formula should be used:

$$L = \frac{8bd^3e}{5l^2},$$

in which $L =$ safe load required; b, d, and l are the same as in (1) and (2), and e is a constant, viz.: 62 for white pine, 72 for white oak, 75 for spruce, 103 for yellow pine.

Special Floors.—Special kinds of floors and flooring are required by certain industries and for particular purposes. Thus theaters, amphitheaters, lecture-halls, and sometimes churches, require inclined floors in order to bring the remoter spectators within sight and hearing of the speaker or performer on the stage or platform. Such floors are usually built upon stagings from a level floor forming the ceiling of the space or story below. Ship-builders make use of a vast draughting-floor of pine on which to plot the curves of the ship-frames; it serves as a drawing-board, on which the lines are erased by scraping or sandpapering when no longer required. Molding-floors in foundries are of sand, upon which the molds for casting are laid, or in which they are formed. Floors of piazzas and balconies are made of slats set slightly apart to allow rain-water to drain away, or are covered with duck or canvas, tightly stretched and painted, to exclude the water; in either case the floor should be inclined with a pitch outward of an inch in every 6 to 10 feet, and the boards be laid lengthwise across this slope. It is hardly necessary to enumerate other varieties of floors, of which the list might be indefinitely prolonged. Consult article cited, and MILL-CONSTRUCTION; also Hatfield's *American House-carpenter*, Kidder's *Architect's and Builder's Pocket-book*, and general text-books on construction.

A. D. F. HAMLIN.

Floor-cloth, or **Oil-cloth**: oil-painted canvas, both sides of which are painted with one or more coats, one side being subsequently printed with designs in colors. Floor-cloths are usually printed by hand by the old method of block-printing. The compounds linoleum, kamptulicon, and the like are substitutes for common floor-cloths, and are made by patented processes. India-rubber is an ingredient of some of these, and they are often stiller under foot and warmer, but sometimes less durable than good oil-cloth.

Floquet, flō′kā′, CHARLES THOMAS: politician; b. Oct. 5, 1828, at St.-Jean-de-Luz, France; studied at the Collège St. Louis; called to the bar 1851; 1867 offended the Czar Alexander II., when a guest of Emperor Napoleon III., by crying, "Vive la Pologne"; consequently was under the Russian ban until 1888; 1871 radical member of the National Assembly; 1876 member of the Chamber of Deputies; 1883 Prefect of the Seine; 1885–88–89 president of the Chamber; 1888–89 Prime Minister; in July, 1888, fought his famous duel with Gen. Boulanger, severely wounding Boulanger in the throat. In 1892–93 he was implicated in the Panama scandals, to the injury of his political standing. D. Jan. 18, 1896.

C. H. THURBER.

Flo′ra [= Lat. *Flora*, goddess of flowers, deriv. of *flos*, *floris*, flower]: (in mythology) a deity early worshiped among the Romans as the goddess of flowers and of spring, and identified with the Grecian Chloris. A temple was vowed to her by Tatius, and a flamen appointed to serve at her altar. Her temple was situated near the Circus Maximus, and an annual festival was held in her honor between Apr. 28 and May 3, when every licentious extravagance was indulged in by the populace. She was represented bearing the cornucopia filled with flowers.

A late tradition says that Flora was a wealthy courtesan who bequeathed her riches to the city on condition that she should be worshiped; but stories of that kind generally originated with people who liked to bring the Roman religion into contempt, either atheist philosophers or Christian Fathers. Lactantius seems to have been the first who knew the story of Flora. The Romans themselves identified her with the Greek Chloris—not the wife of Neleus, but the daughter of Niobe. Her true name was Melibœa, and she and her brother Amyclas were the only ones of Niobe's children who escaped Apollo's revenge, after which her name was changed into Chloris.

Flora: in botany, the aggregate vegetation of a country or region; thus when the "flora of the Black Hills" is spoken of, reference is made to the natural vegetation of that portion of the country, just as the animal life of a country is referred to when its fauna is spoken of. A catalogue or description of the flora of any country is often called simply the "flora" of the country, as Gray's *Synoptical Flora of North America* (1878–84); Hooker's *Student's Flora of the British Islands* (1884); Gremli's *Flora of Switzerland* (1889).

CHARLES E. BESSEY.

Flora: city and railway junction; Clay co., Ill. (for location of county, see map of Illinois, ref. 9–F); 94 miles E. of St. Louis, Mo. There are 40,000 acres of apple-orchards in the county, and Flora is a great fruit-market. Immense coal-beds underlie the soil. The climate is fine. Pop. (1880) 1,494; (1890) 1,695; (1900) 2,311.

EDITOR OF "DEMOCRAT."

Floréal, flō′rā′ăăl′ (the flowery): the eighth month in the republican calendar of France, which from Nov. 24, 1793, to Sept. 9, 1805, was used in place of the Gregorian. Floréal began Apr. 19–22, and ended May 18–21.

Flore, Order of [so called from *Floris* (a place near Cosenza), the seat of the first abbey]: a branch of the Cistercians, including convents of nuns as well as those of monks. The order was founded by Joachim of Floris in 1189, and, being suspected of maintaining the heresies of its founder, it never flourished. In 1505 most of its convents joined the Cistercians and other orders.

Flor′ence (Ital. *Firenze*): province of Italy; area, 2,144 sq. miles. It is one of the most fertile provinces of the country; wheat, wine, and silk are extensively produced. Pop. (1891) 813,031.

Florence [from Lat. *Florentia*, deriv. of *florens*, *floren′tis*, blooming, prosperous, pres. partic. of *flore′re*, bloom]: a city of Italy; situated 195 miles N. W. of Rome, in the beautiful valley of the Arno, mostly on the northern bank (see map of Italy, ref. 4–D). Pop. of commune (1895) 204,000. It is one of the most beautiful and interesting cities of Italy, an archbishop's see, and a principal seat of art and science. The industry of the city was formerly more flourishing, and comprised extensive manufactures of silk, velvet, and woolen; it is now remarkable only in works of art, mosaic, and jewelry.

The inner part of the city was formerly surrounded by a wall, but gardens, palaces, and monasteries cover the neighboring hills. The city has been made brighter by the construction of new and wider streets, and new and beautiful palaces are added to the great number of old and celebrated monuments. The Arno, dammed up to 100 paces breadth, is provided with quays, called *Lungarni*, and six bridges connect the different parts of the city with each other. These bridges and quays, with the Via della Scala and Via Maggio, form the liveliest parts of the city, and more than twenty public squares, surrounded by beautiful buildings, adorn it. Among these public squares the most remarkable is the Piazza del Granduca, now called the Piazza della Signoria, which is very rich in works of art. It contains the great fountain, adorned with twelve bronze statues by Giovanni of Bologna: the beautiful equestrian statue in bronze of Cosmo I., by the same artist; the colossal Neptune and the Tritons of marble by Ammanato; and the statue of Hercules by Bandinelli. The old palaces stand generally among common houses in narrow streets, and their heavy and massive architecture gives them a gloomy character. In the Middle Ages they served as strongholds. They were built of large blocks of freestone with battlements, and often with towers, but without any exterior embellishments. They are now, moreover, blackened by age. In the interior they contain courtyards, with arcades from which stairs lead into the halls. One of the most interesting palaces is the Palazzo Vecchio, or Palazzo della Signoria, at one time the seat of the Florentine magistrature, and from 1865 to 1871 of the Italian Parliament. The Palazzo Pitti, built by Brunelleschi, and the residence of Victor Emmanuel while in Florence, is one of the most magnificent palaces in existence. It contains the Galleria Pitti, the finest collection of pictures in the world, and the Pitti and Uffizi collections are connected by a long gallery, passing over the Ponte Vecchio.

Remarkable among the ecclesiastical buildings is the cathedral, 555 feet long, 340 feet broad. Arnolfo da Colle commenced the building, and continued it until 1310; Giotto succeeded him, and Brunelleschi finished it in 1436. The marble covering of the cathedral is rich and varied; especially is that of the campanile delicate and fine in color. The construction of the vaults of the baptistery of San Giovanni is very interesting, and the three doors of bronze, especially that of the eastern gate by Ghiberti, are widely known. The Church of Santa Croce, commenced in 1294 by Arnolfo di Cambio, 371 feet long and 113 feet wide, has eleven chapels, and contains the tombs of Michael Angelo, Alfieri, and Machiavelli, and a monument of Dante. A most interesting building is the Loggia dei Lanzi, a hall commenced in 1376, and finished by Benci di Cione and Simone di Francesco Falenti after a plan by Orcagna. It contains masterpieces of marble and bronze—the Vestals, the Centaur, Ajax with the corpse of Patroclus. Between the Loggia dei Lanzi and the Palazzo Vecchio is situated the Palazzo degli Uffizi, containing the world-famous collections of statuary in marble and bronze (the group of Niobe and the Medicean Venus), of cameos, pictures (*Venus*, by Titian, the *Holy Family*, by Michael Angelo), and crayons.

History.—Florence, originally a Roman colony in Etruria, was a flourishing city at the time of Christ. Under Totila it was destroyed, but it was rebuilt under Charlemagne. The German emperors, especially Otho the Great, favored the city in many ways; and as its position was of much consequence in military respects, many knights settled here, and the nobles early gained the ascendency. Parties fought in Florence as in other cities; nevertheless, in the ninth and tenth centuries it became a center of civilization, and increased its political importance by conquering the neighboring cities and towns. In the beginning of the twelfth century it threw off the authority of the German emperors and established a republic, and in 1198 it headed the union of the Tuscan cities against Philip of Suabia. In the beginning of the thirteenth century Florence was governed by a podestà, who, however, held the supreme authority only in matters of justice; the administration and the political power depended on six consuls and a municipal council of 100 citizens. The republic had an oligarchical character, but although it was convulsed by the civil wars between the Guelphs and the Ghibellines the city still increased in power. In 1078 the enlargement of the city made a second wall necessary, and between 1284 and 1327 the third wall, the present one, was built. In 1222 Florence conquered Pisa, and gained great commercial advantages; in 1332 it conquered Pistoja, in 1333 Massa, and soon it ruled over the whole of Tuscany. The authority of the nobility began to decrease; the citizens acquired ascendency, and in 1378 the democracy gained a decided victory, Salvestro de Medici, a plain citizen, becoming gonfaloniere. It was, however, Giovanni de Medici, the banker of the pope and a man of immense wealth, who founded the house. At his death in 1428 he left two sons, Cosimo and Lorenzo, from the latter of whom the dukes of the sixteenth century descended. Cosimo acquired great fame during the Council of Florence in 1439, and his grandson, Lorenzo the Magnificent, added still more to the splendor of the house. In 1478 the conspiracy of the Pazzi against the Medici failed, and in 1492 Pietro succeeded his father Lorenzo as gonfaloniere. He was expelled, however, and Savonarola established a kind of theocracy, but was burnt as a heretic in 1498. By the victory of Alessandro of Medici (Aug. 12, 1530) the republic was finally overthrown, and Alessandro was declared Duke of Florence, July 29, 1531. He was killed in 1539, but his son succeeded as grand duke. After the death of the last Medicean grand duke the government of Tuscany, of which Florence was the capital, fell to Francis, Duke of Lorraine, afterward Emperor of Germany. His descendants were expelled by the French in 1799. In 1801 Tuscany became a part of the kingdom of Etruria under Louis of Parma. In 1808 it came under the sway of France. In 1814 the Grand Duke Ferdinand III. once more took possession of the country, but in 1859 his son, Ferdinand IV., had to abdicate, and on May 22, 1860, Tuscany was incorporated into the kingdom of Italy, of which Florence was the capital until 1871, when the seat of government was transferred to Rome.

Florence: city and railway center; capital of Lauderdale co., Ala. (for location of county, see map of Alabama, ref. 1–B); situated on the north bank of Tennessee river, at the head of deep-water navigation and at the foot of Muscle Shoals Canal. It has the Southern Female University, Synodical Female College, Paxton's Military and Classical Academy, State Normal College, fine city schools, sawmills, and extensive manufactures of cotton and iron. Pop. (1880) 1,359; (1890) 6,012; (1900) 6,478. EDITOR OF "HERALD."

Florence: city; Marion co., Kan. (for location of county, see map of Kansas, ref. 6–H); on the Atchison, Topeka and Santa Fé Railroad; at the junction of the Cottonwood river and Doyle creek. It is situated in a wheat-producing district, and has quarries of building-stone. Pop. (1880) 954; (1890) 1,229; (1900) 1,178.

Florence: town and railway junction; capital of Florence co., S. C. (for location of county, see map of South Carolina, ref. 5–F); 102 miles N. of Charleston. It has railway shops, a mill, machine-shops, and a large trade in cotton. Pop. (1880) 1,914; (1890) 3,395; (1900) 4,647.

Florence, WILLIAM JERMYN (real name BERNARD CONLIN): actor; b. in Albany, N. Y., July 26, 1831. He joined a dramatic association in New York city 1847; made his first appearance in Richmond, Va., Dec. 6, 1849, as Peter in *The Stranger*. He played in Providence, R. I., Macduff to Booth's Macbeth. At Brougham's Lyceum in New York he afterward appeared in Irish characters. He married in 1853 Mrs. Malvina Littell, a dancer attached to Wallack's theater, and subsequently the two appeared at the National theater, New York, as the Irish Boy and the Yankee Girl. In 1856 Florence and his wife went to England, traveled through the British provinces, and were well received. On returning to the U. S. they acted regularly every season in the principal towns and cities of the Union. In 1887 Mrs. Florence practically retired from the stage and Florence joined Joseph Jefferson, playing with him in some of the old comedies. His best-known parts are Capt. Cuttle in *Dombey and Son*, Bardwell Slote in *The Mighty Dollar*, and Robert Brierly in *The Ticket-of-leave Man*. D. in Philadelphia, Pa., Nov. 20, 1891. B. B. VALLENTINE.

Florence, Council of, 1439–42 A. D.: the continuation of the Council of Basel, the seventeenth of the twenty œcumenical councils acknowledged by the Church of Rome. The Council of Basel was opened July 23, 1431. Called in the interest of reform, the attendance at first was small, the pope, Eugenius IV., being hostile. In 1434 a reconciliation was brought about, and the pope took the direction of affairs into his own hands. On Jan. 8, 1438, the council was transferred to Ferrara, and in Feb., 1439, to Florence, where its sessions continued at intervals until 1442. But its interest culminated in the summer of 1439, when the reunion of the Greek and Latin Churches was thought to have been accomplished. More than 500 Greeks, including the Greek emperor and the Patriarch of Constantinople, were in attendance, having joined the council at Ferrara. Four points were under discussion: 1, the Filioque of the Latin Creed; (2) the use of unleavened bread in the Eucharist; (3) purgatory; (4) the papal supremacy. The first three points were settled by compromise; the fourth by the submission of the Greeks. But the impulse of this settlement was imperial, the Greeks desiring Occidental assistance in beating back the Turks. The "reconciliation" had no root in the hearts of the people, and in 1443 the patriarchs of Alexandria, Antioch, and Jerusalem united in denouncing the Council of Florence. Meanwhile the remnant of the council summoned by Eugenius IV. continued to sit at Basel; in 1440 it elected an antipope (Felix V.), who resigned in 1449; removed to Lausanne, July 24, 1448, and dissolved May 25, 1449. See Mansi's *Councils* (vol. xxix.); Harduin's *Councils* (vols. viii. and ix.); and Hefele's *Conciliengeschichte* (vol. vii., part 2, 1874). Revised by S. M. JACKSON.

Florence, University of: See the Appendix.

Florencia, FRANCISCO, de: Jesuit author; b. in Florida (probably in St. Augustine), 1620. He studied in the College of San Ildefonso, Mexico; took the Jesuit habit in 1643; acquired considerable fame as a teacher and pulpit orator; was procurator of his province at Madrid and Rome 1688, and subsequently procurator-general for the Indies at Seville. His *Historia de la provincia de la Compañía de Jesus de Nueva España* was the first Jesuit history of Mexico (1st vol. only, Mexico, 1694). He also published several biographical works relating to the Jesuits, and numerous theological treatises. D. in Mexico, 1695.

Florentine Academy (in Ital. *Accademia Fiorentina*): a learned association of Florence, founded in 1540. It is famous as successor of the Accademia della Crusca. See DELLA CRUSCA.

Floren'tius: the name of several men eminent in history and in letters. Among them are FLORENCE (Florentius) OF WORCESTER, a learned monk who died in 1118; author of a Latin chronicle, the first written in England after the Norman Conquest; English translation edited by Thomas Forester, London, 1854 (in Bohn's Library).—FLORENTIUS RADENIUS; b. at Leerdam in the Low Countries in 1350; was educated at Prague; succeeded Gerhard Groot as director of the Brethren of the Common Life. D. 1400. See his *Life* by Thomas à Kempis.—Another FLORENTIUS (*François Florent*) was a Burgundian jurist, who died Oct. 29, 1650; author of *Dissertations* on the canon law (1632), etc.

Flo'res: a central department of Uruguay; created in 1885 from the northern part of San José; bounded N. and N. E. by Durazno, S. by San José, and W. by Soriano. Area, 1,745 sq. miles. The river Yi borders the department on the north. The land is generally rolling and open, suited for pasturage, and grazing is the principal industry. Wheat and maize are cultivated to some extent. Pop. (1890) about 20,000. Capital, Trinidad, 123 miles N. E. of Montevideo, with about 2,500 inhabitants. HERBERT H. SMITH.

Flores: the westernmost island of the Azores; in the Atlantic Ocean; in lat. 39° 25′ N. and lon. 31° 12′ W. Area, 54 sq. miles. Its name was given it by the Portuguese in allusion to the flowers with which it is covered. Pop. 9,000. Chief town, Santa Cruz.

Flores: an island of the Malay Archipelago, and the largest of the chain that extends from Java to Timor. Its length is 230 miles, its breadth about 35 miles. Area, 8,900 sq. miles. It is hilly, with some lofty volcanic peaks on its south side. It exports sandal-wood, beeswax, and horses. The aborigines are Papuans, but the Malays outnumber them by far. Pop. estimated at 250,000.

Flores, ANTONIO: Ecuadorian statesman; son of Gen. Juan José Flores; b. in Quito, 1833. He studied in Paris, and subsequently graduated in law at Lima. He early took part both in civil and military affairs, and has occupied important diplomatic positions, including the ministry to Washington 1861 and again 1868–69; in 1885 he signed the treaty with Spain in Madrid. He succeeded Caamano as president of Ecuador, June 30, 1888, serving until 1892. His term was commendably quiet and prosperous. HERBERT H. SMITH.

Flores, JUAN JOSÉ: Spanish-American general and statesman; b. at Puerto Cabello, Venezuela, July 19, 1800. In his youth he was taken prisoner by the Spaniards, and on his escape in 1815 joined Bolivar; rapidly rose in rank, and took part in the principal events of the war for independence in Venezuela and New Granada. In 1823 he was colonel, and civil and military chief of Pasto; the Spaniards drove him back to Popayan, but he regained the ground as second in command under Salom, and subsequently commanded in the final defeat of the Spaniards in that region (1824). In 1825 he was made commandant-general of Ecuador, and in 1828 commander-in-chief of the Ecuadorian army, defending the country against the Peruvians 1828–29. Bolivar made him civil and military chief of the south in the latter year, and when, in 1830, Ecuador became independent Gen. Flores was elected president. During his term he put down several revolts, including one headed by Rocafuerte, 1833–34; Rocafuerte was captured, but Flores pardoned him, gave him important civil and military posts, and in 1835 supported him for the presidency, to which he was elected. Under Rocafuerte Flores was nominally commander-in-chief of the army, but virtually governed the country; in 1837 he was elected to the senate, and in 1839 was again elected president; by re-election in 1843 he retained the office until 1845. In 1840 and 1841 he interposed in the affairs of New Granada, marching in person against the revolutionists in Pasto and defeating them. In 1845 a revolution broke out in Ecuador, and, though Flores twice defeated the insurgents, he found it prudent to resign; he left the country, traveled extensively in Europe and America, and only returned in 1863 to take part in the movement by which Franco was overthrown; he then accepted the post of vice-president. D. in Quito, 1864. HERBERT H. SMITH.

Flores, VENANCIO: Uruguayan general and politician; b. in 1809. He was the son of a wealthy landed proprietor, and for many years lived on the pampas, where he gained great influence with the gauchos. He supported the *Colorados* in their revolt against Oribe 1853; on Oribe's overthrow he became one of the governing triumvirate, and in Mar., 1854, was elected president for two years. Oribe headed a counter revolt in Sept., 1855, and at length both claimants to the presidency agreed to resign; Pereira was then elected president, and soon after Flores retired to Buenos Ayres, where he served under Gen. Mitre, and took a prominent part in the battle of Pavon Sept. 17, 1861. In Apr., 1863, he secretly returned to Uruguay, and initiated a revolt of the *Colorados* against President Berro. A desultory war was carried on against Berro and his successor, Aguirre; Brazil, having declared war against the government of the latter, joined forces with Flores; Aguirre was defeated, 1865, and forced to resign. Flores was made provisional governor, and in 1866 was elected president. He at once signed with Brazil and the Argentine Republic the treaty of alliance against Paraguay, called the Triple Alliance, taking part in the campaigns of 1865 and 1866. He was assassinated at Montevideo during a political disturbance, Feb. 19, 1868. HERBERT H. SMITH.

Flo'rian, SAINT: patron saint of Poland; was a Roman soldier; b. in Noricum of Christian parentage, and drowned in the river Enns in Austria during the Diocletian persecution, on account of his voluntary confession of the Christian faith. He was buried where now stands the magnificent Augustinian abbey of St. Florian, 3 miles S. W. of Enns, but his relics were transferred to Rome, whence in 1183 they were taken to Cracow. In legendary lore St. Florian is honored as the extinguisher of conflagrations. He is commemorated on May 4.

Florian, flō'ri-aăn', JEAN PIERRE CLARIS, de: b. at the Château de Florian, in Gard, France, Mar. 6, 1755; entered the service of the Duc de Penthièvre; was patronized by Voltaire, and attained fame as a writer of fables, romances, comedies, and pastoral poems; was imprisoned in Paris by the republicans, and d. at Sceaux, Sept. 13, 1794. Some of his plays still keep the stage, but his romances *Galatée* and *Estelle*, his *Fables*, and his translation of *Don Quixote* are his best works.

Floriculture [from Mod. Lat. *floricultu'ra*; Lat. *flos*, *floris*, flower + *cultu'ra*, cultivation, deriv. of *co'lere*, cultivate]: the cultivation of ornamental plants for their individual uses. The cultivation of ornamental plants for their uses in the landscape is a part of LANDSCAPE-GARDENING (*q. v.*), or more properly of landscape-horticulture. Floriculture is now an important industry in the U. S., and no rural pursuit offers greater attractions, whether in the business itself or in its pecuniary rewards. The business readily divides itself into two features, growing plants for sale, which really belongs to the nursery trade (see NURSERY), and growing cut flowers and plants for decoration. The eleventh census made an investigation of the floricultural interests of the U. S. The business is found to be in a thriving condition, as evidenced by the fact that the number of establishments is rapidly increasing. In 1800 there was but one commercial florist in the U. S. Between 1810 and 1820 3 establishments started: 8 more were started in the next decade, 25 in the next, 45 between 1840 and 1850, 96 in the next, 313 in the next, 998 between 1870 and 1880, and 1,797 between 1880 and 1890. In 1890 there were 4,659 commercial establishments, using 38,823,247 sq. feet of glass and heated with apparatus valued at $38,355,722.43. The tools were valued at $1,587,693.93. New Jersey has the largest floricultural business of any State in proportion to its size. There is not one establishment, so far as learned, in Idaho, Nevada, and Indian Territory. Three hundred and twelve of these establishments are owned and conducted by women, and 1,958 women are engaged in the business in the U. S. The total value of the floricultural product for one year was $26,211,805.77, of which $14,175,328.01 was for cut flowers and the remainder for plants. Of the plants sold, 49,056,253 were rose-bushes and 38,380,872 were hardy plants and shrubs, while the total number of all plants sold was 240,272,417. It required 18,805 people to grow these plants and cut flowers, at an aggregate wage of $8,483,657. All this business required an outlay of $1,161,168.31 for advertising and the issuing of 21,055,694 catalogues, and the estimated freight and express bills on outgoing shipments amounted to $1,086,904.60.

The census report for 1890 states that "of the plants sold the demand in the Northern and Eastern U. S. is greatest for geraniums, coleus, roses, pansies, verbenas, heliotrope, carnations, chrysanthemums, palms, ferns, and fuchsias, nearly in the order named. In the Southern U. S. the demand is for roses, chrysanthemums, geraniums, coleus, palms, and ferns; while California shows the demand to be largest for roses, carnations, chrysanthemums, geraniums, palms, and pansies. For cut flowers roses lead, followed closely by carnations."

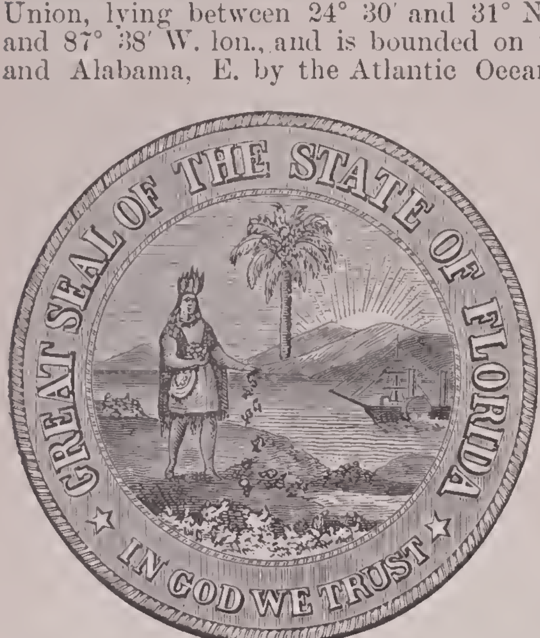
Besides the capital invested in commercial floriculture there is a very large interest in amateur flower-growing, and it is probably safe to say that no other avocation attracts so many people. Amateur gardening is most conspicuous, as a rule, in the Eastern States, but almost every village in the land affords some example of devotion to flowers for the pleasure which they afford. The passion for flowers is one of the refinements which comes from a love of home and rural life. L. H. BAILEY.

Florida: a central department of Uruguay; bounded N. by Durazno, E. by Minas and Treintaitres, S. by Canelones, and W. by San José; area, 4,280 sq. miles; pop. (1890) 29,516. The mountains or hills of the Cuchilla Grande form the eastern border; the general surface is rolling, with but few high hills, and there are extensive grassy plains bordering the river Yi, which forms the northern boundary. Cattle-raising is the principal occupation; the number of horned cattle alone is estimated at 1,500,000, and vast flocks of sheep are raised. Owing to the rich pastures, many other departments send their cattle here during the winter. Florida, the capital, on the river Santa Lucia Chico, has 4,000 inhabitants. Sarandi Grande, on the Central Uruguayan Railway, is a new town of considerable commercial importance.

HERBERT H. SMITH.

Florida: one of the U. S. of North America (South Atlantic group) and the second largest of the group E. of the Mississippi river. In shape it is somewhat like an inverted L.

Situation and Area.—It is the southernmost State of the Union, lying between 24° 30′ and 31° N. lat. and 79° 48′ and 87° 38′ W. lon., and is bounded on the N. by Georgia and Alabama, E. by the Atlantic Ocean, S. by the Gulf of Mexico and Straits of Florida, and W. by the Gulf of Mexico and Alabama, the Perdido river forming the extreme western boundary. From the northern boundary to the southernmost outlying island the distance is 450 miles. From the Atlantic Ocean to the Perdido river the distance is 400 miles, and from the northwestern corner of the State to Key Largo it is nearly 600 miles, the line running diagonally across the Gulf of Mexico. The peninsula proper is about 375 miles long, and has an average width of 90 miles. The actual area is 58,680 sq. miles, or 37,555,200 acres. Lakes, rivers, bays, and estuaries cover nearly 3,000,000 acres, an area often quadrupled in extent during a rainy season.



Seal of Florida.

Name.—The name is abbreviated from the Spanish *Pasqua Florida* (Easter, or the Feast of Flowers), so called from its discovery by Ponce de Leon on Easter Day, 1513. "The Everglade State" is perhaps the most generally accepted nickname.

Topography.—The general impression received by the traveler is that Florida is mainly a monotonous level, but this is strictly true only as regards wide areas along the coast, the land rising only a few feet above the sea-level. These "flatlands" are irregularly distributed in open grass-grown savannas, pine forests, cypress swamps, and "cabbage hammocks," the latter being the local name for extensive native growths of the cabbage-palm. The general level rises toward the interior until, almost insensibly, the low pines give way to high pines, and these again to hills of considerable altitude. The highest part of the peninsula proper is along the central ridge, where, according to the railroad surveys, an elevation of nearly 300 feet is reached; the rise, however, is so gradual that only the engineer's level can define it. In Western Florida the land is decidedly hilly, excepting along the coast, and is very heavily wooded. Topographically, it belongs to Georgia and Alabama. The southern part of the peninsula proper is occupied by a vast tract known as the Everglades (probably an adaptation of the English word "glades" with the prefix ever to indicate its extent).

In general terms this southern portion of the peninsula has been formed by successive dikes of coral built in bygone ages and inclosing most of the space that now forms "subtropical Florida." The upper part of this is occupied by the shallow waters of Lake Okeechobee, which merges into the Everglades proper to the S. and E., and is destined eventually to be filled up and become a part of the grass-grown tract now the abode of the remnant of the once powerful Seminole Indians, whose name for it is *Pa-ha-yo-kee*—much grass in water. They are penetrated in all directions by tortuous open channels of water only a few feet in depth, and at short intervals over the whole tract are wooded islands possessing great fertility of soil and usually covered with a dense growth of sub-tropical vegetation. These islands no doubt were once surrounded by the sea, and stood in the same relation to the mainland as do the present Florida reefs and keys. The Everglades are separated from the Gulf of Mexico by wide tracts of cypress swamp. These forests extend toward the southern point of the peninsula, but are narrowed as they turn the cape and extend up along the Atlantic coast. The Everglades approach the ocean most nearly on the eastern coast at Biscayne Bay, where the distance across is barely 5 miles, the intervening elevation being an ancient dike of coralline rock, crossed at short intervals by streams of considerable volume, navigable for small boats and flowing out from the Everglades in strong currents of clear, sweet water. The Everglades, far from being a stagnant swamp as has been popularly supposed, are in reality a not unhealthful region.

At frequent intervals throughout the lowlands, particularly along the coast, are extensive swamps, some of which have never been explored, owing to the impenetrable character of the undergrowth and the impassable holes and sinks that break the surface. Prominent among these great swamps are the Big Cypress near the southern extremity of the peninsula, several of great extent farther to the north, as the Fen Holloway and Wakulla swamps; there is also an extensive swamp near the mouth of the Appalachicola river. The largest of the inland swamps is the Okefenoke, which extends far to the northward beyond the Georgia line.

Almost the entire shore of the mainland is separated and protected from the ocean by outlying sand-bars, which eventually become islands and peninsulas as vegetation covers them. The inner or sheltered sea-beaches consist for the most part of rather soft sand, not easy to walk upon, impracticable for vehicles, and often of the nature of quicksand. The outer beaches are often for scores of miles as hard and level as a macadamized road. Along the tidal rivers of sub-tropical Florida the mangrove is ever encroaching on the sea, and often absolutely prohibits passage along the water-side. Elsewhere the underlying coralline or limestone rock crops up, forming a natural sea wall; this is notably the case at intervals along the Indian river, Lake Worth, and Biscayne Bay on the Atlantic coast, and at the mouths of nearly all the principal rivers of the Gulf coast. Where these rivers break through the coral dikes extraordinary formations are found. In many instances natural bridges exist, and there are often deep rock cuttings of great beauty and interest to the geologist.

Springs, Streams, Lakes, etc.—Some of the most remarkable springs in the world exist in Florida. The most famous is Silver Spring near Ocala in Marion County, but there are many others that are only less celebrated because they are out of the line of travel. Among these is Blue Spring, also in Marion County, Wekiva Spring, in Orange County, and Wakulla Spring, near Tallahassee. The extraordinary clearness of the waters of these springs is as remarkable as their size. In several instances navigable streams burst full-grown from the earth. The volume of Silver Spring is over 300,000,000 gal. daily (D. G. Brinton's estimate). The clearness of the water is such and its refractive powers so great that it is almost impossible to believe that objects lying on the bottom at a depth of 30 or 40 feet are not actually magnified by the water. Along the coast are found countless springs of fresh and sulphuretted water. One of these of large volume bursts upward through the sea itself not far from St. Augustine, boiling so violently to the surface 2 miles from shore that the ocean rollers break against the column of fresh water as if it were a sunken reef. The total volume of water discharged by these multitudinous springs baffles computation, and where the supply comes from, with only a narrow peninsula for a watershed, is a perplexing problem.

The lakes are largely aggregations of smaller springs, sometimes being themselves the direct sources of rivers and sometimes members of lacustrine systems. There are several principal lake groups, one lying along the head waters of the St. John's river, including Lakes Munroe, George, Dexter, Crescent, and others. The Oklawaha river, a tributary of the St. John's, finds its source in a fine group of lakes including Apopka, Dora, Harris, Eustis, and Griffin. S. of these again is the Kissimmee group including the Tohopekaliga lakes, Kissimmee, and others. This group unites to form the great Kissimmee river flowing southward through vast tracts of swampy wilderness until it discharges into Lake Okeechobee, the largest body of open fresh water in Florida. This great lake is quite shallow, barely exceeding more than 12 or 15 feet in depth. Its area is about 1,250 sq. miles. It is for the most part surrounded by a wide belt of almost impenetrable "big saw-grass," so that it is only accessible by the natural waterways leading from the higher levels. Its main outlet is by the Caloosa river, which flows into the Gulf of Mexico at Charlotte harbor. The surface of the lake is only 20·24 feet above the sea-level, and its distance from the coast is sufficient to prohibit artificial drainage. In general the Florida lakes are shallow, save where chasms and fissures occur in the bed-rock, and these are often springs discharging enormous volumes of water. Of

smaller lakes named and unnamed there are hundreds, perhaps thousands, scattered everywhere among the "flatwoods" as well as among the hills. The water is generally pure and hard, with traces of magnesia and sulphur, and usually the bottoms are clean and sandy. Fish are found in almost all of them in great abundance. Many of the Florida lakes are subject to remarkable fluctuations, rising or falling at regular or irregular intervals, sometimes even running dry for longer or shorter periods. These phenomena are chargeable almost always to the freaks of subterranean rivers which from time to time change their channels. Lake Jackson suddenly ran dry about the time of the Charleston earthquake. After a few weeks, however, the water began returning to it, and it resumed its natural proportions. Similar phenomena on a smaller scale are of frequent occurrence wherever the underlying rock strata are liable to erosion, and this condition prevails over almost the entire State. Where the openings are apparent on the surface they are called sinks, and often appear without warning and in the most unexpected places. These sinks are frequent in the northern Gulf counties and in parts of Western Florida. They are often merely breaks exposing the currents of underground rivers, but sometimes they open down into still pools of wonderfully limpid water. These are called wells, as contradistinguished from the ordinary sinks.

Rivers.—The peninsula proper has three large river systems, two of which run N., namely, the St. John's along the Atlantic coast and the Withlacoochee along the Gulf coast, while the Kissimmee, having its sources between the two, runs far S. into Lake Okeechobee and the Gulf. This intersection of river systems is very remarkable, considering the generally level character of the country. The St. John's river is navigable for large steamers some 220 miles from the sea, and the other rivers named for smaller craft. The St. Mary's river (navigable) separates Florida from Georgia on the N. E., but hardly belongs to the Florida system.

West Florida is traversed by three large rivers, all having their sources in the States lying to the N.; these are the Suwannee, the Appalachicola, and the Chattahoochee; all are navigable, and, as they drain extensive watersheds, are subject to high freshets. Besides those named, there are countless small streams navigable for small boats, and of more or less use commercially for rafting lumber and for traversing otherwise almost impenetrable regions.

Bays, Harbors, etc.—The harbors of the Atlantic coast are mostly shallow and difficult of access, owing to shifting sand-bars and the varying conditions induced by slight changes of the wind. The best are at Fernandina, at the mouth of the St. Mary's river, and at the mouth of the St. John's river, where artificial improvements have been made. At St. Augustine is a natural harbor, but it is only at the most favorable times that sea-going vessels can enter it. S. of this there are only shallow inlets until Biscayne Bay is reached, where vessels drawing 9 or 10 feet of water can at all times gain access to a secure anchorage. Along the Florida reefs are numerous harbors of refuge among the keys. Conspicuous among these is Turtle harbor, shown on the coast survey charts, but most of them are known only to local pilots. At Key West is an excellent harbor. On the Gulf coast of the peninsula are Charlotte harbor and Tampa Bay, both accessible for large sea-going craft. Pensacola, on the northern Gulf coast, has a superb natural bay and harbor where vessels of large size can enter at all times. Along the greater part of the Florida coast are islands and reefs lying a short distance from the main land and forming sheltered inlets that are called rivers, lakes, harbors, or bays according to individual conformation. These are mostly shallow, but are generally navigable for vessels of light draught; such are Indian river, Lake Worth, Charlotte harbor, and Sarasota Bay.

The Florida Keys.—(The name "key" is from the Spanish *cayo*, island.) This remarkable coral formation marks the northern limit of the Gulf Stream, where it rushes out from its source in the Gulf of Mexico and begins its northern course through the Atlantic Ocean. The Straits of Florida are among the most dangerous known to navigators, although they are well lighted and charted. The islands are nowhere more than 8 or 10 feet above the sea, but they are often covered with a luxuriant growth of tropical vegetation. From the Dry Tortugas to Sand's Key, at the entrance to Biscayne Bay about 200 miles, is a continuous reef of coral, upon the whole extent of which the little coral-builder is still industriously at work. The reef is broken here and there by channels of greater or less depth, and within the outer line are many habitable islands. The whole space within the outer reef is no doubt slowly filling up, just as the islands are slowly growing through the accretion of floating substances that become entangled in the roots of mangrove-trees. The present Florida reef is no doubt an example of the way in which a large part of the peninsula was formed. No less than seven old coral reefs have been shown to exist south of Lake Okeechobee, and the present one, being at the very edge of the deep water of the Gulf Stream, is probably the last that can be formed, since the coral-builder can not live at a greater depth than 60 feet. The current of the Gulf Stream is so swift now along the outer reef that there is no longer a solid foundation upon which to build.

Geology and Mineralogy.—The Upper Eocene, or Vicksburg limestone, forms the substratum throughout most of the State, but along the coasts and to the southward are extensive formations of Postpliocene coralline limestone. Important discoveries of high grade phosphate rock were made in 1888, and an extensive export trade has since developed. The phosphates are classified as "hard rock," soft rock, land pebble, and river pebble. The hard rock is found in a belt sweeping to the S. and E. from the vicinity of Tallahassee to the southeastern part of Pasco County. To the S. and E. of this belt are great islands of the land and river pebble. Vertebrate remains occur in abundance, and the proportion of phosphate of lime is from 50 to 80 per cent.

Soil, Productions, etc.—To the superficial observer the soil of Florida is a vast tract of sand, but out of this spring all kinds of vegetation in great luxuriance. The surface soil, in fact, depends largely on the character of the underlying rock, which is everywhere limestone, varying in its constituents, but often rich in phosphates. These mingling with vegetable humus cover wide tracts with a soil of unsurpassed productiveness. Classified by the natural tree-growths three general divisions of land are indicated:

1. Oak, hickory, and pine uplands, mainly the northern tier of counties, but with detached examples in Middle Florida.
2. The long-leaved pine regions, including the best parts of peninsular Florida (28,000 sq. miles).
3. Pitch-pine, treeless, and alluvial. Mainly coastwise, but including swamps, everglades, savannas, and flatwoods, largely worthless, but partly arable or reclaimable.

The agricultural productions include cotton, pears, and peaches for the northern counties; vegetables of all kinds for the middle peninsula region; and oranges and citrus fruits of all kinds for the entire State, except the extreme northern portion. The best oranges are grown in the semi-tropical region of Middle Florida, where there are occasional frosts. In sub-tropical Florida pine-apples, cocoa-palms, mangoes, guavas, and almost all tropical fruits either grow naturally or are cultivated with great success. Hammock lands, considered the best for all agricultural and horticultural purposes, are easily distinguishable from pine lands by the prevailing growth of hard woods and cabbage-palms. "Hammock" is the sole survival of the Lucayan tongue and should not be confounded with hummock. Its alleged meaning is "a place where hard wood grows."

Zoölogy.—Among animals, deer, bear, panther, wildcat, raccoon, opossum, squirrels, otter, wolves, foxes, etc., abound in the sparsely settled tracts. Of birds, there are the turkey, duck, quail, pigeon, and nearly all varieties of snipe and plover. Birds of brilliant plumage have been nearly exterminated in the interests of millinery. The roseate spoonbill, the flamingo, the rarer curlews, egrets, paroquets, etc., are found only in the heart of the wilderness. The manatee, or sea-cow, is found in the salt and fresh waters of Middle and Southern Florida. It has been practically exterminated by wanton gunners in the more frequented regions. Crocodiles (*Crocodilus acutus*) exist in considerable numbers in one or two localities in the extreme south. The common alligator (*Aligator mississippiensis*) is found in all the lakes, streams, and swamps of the State, though comparatively rare since the introduction of breech-loading firearms and the growing demand for alligator hides. Fish abound in all the waters of Florida. Mullet, shad, sea-trout, bass, pompano, red-snapper, and sheepshead are among the most valuable food-fishes, and are largely exported for foreign consumption. From the sportsman's point of view tarpon and kingfish are chief among the game varieties, but they are not valued for the table. Pompano may be taken with the rod, and are among the most delicious of table fish. Sea-turtles abound along all the coasts during the egg-laying season, and terrapin are found in the inland waters. A large species of land-turtle, locally known as "gophers," frequent the forests, burrowing into the earth for refuge from their many enemies. Rattlesnakes and moccasins are the only venomous varieties of snakes, and these are rarely seen except during the warm months, say from May to October inclusive.

Climate.—Though Florida extends over six degrees of latitude, its climate is very uniform. The extreme range of temperature in Northern Florida is from 90° to 26° F., and in central and Southern Florida from 90° to 43° F., the summer average nowhere exceeding 84° F. The rainfall exhibits greater variations. At Tarpon Springs it averaged 84.5 inches for five years.

The following table, compiled from the U. S. Weather Bureau reports, shows (1) the average number of clear or fair days in the year, (2) the annual average rainfall, and (3) the annual average temperature at five of the Weather Bureau stations:

PLACE.	Annual average number of clear days.	Annual average rainfall in inches.	Annual average temperature in degrees Fahr.
Jacksonville	280·1	54·70	69·30
Sanford	322·0	45·72	71·75
Cedar Keys	311·0	55·86	71·12
Key West	307·7	40·31	77·57
Pensacola	274·6	67·31	68·42

Divisions.—Topographically the State naturally divides itself as follows: 1, The Atlantic coast; 2, the Gulf coast; 3, Middle Florida (including the "orange belt" and the best agricultural tracts); 4, sub-tropical Florida (S. of lat. 27° N., generally defined as the habitat of the cocoa-palm); 5, West Florida (including the northern Gulf coast and that part of the State not belonging properly to the peninsula).

For administrative purposes the State is divided (1900) into forty-five counties, as follows:

COUNTIES AND COUNTY TOWNS, WITH POPULATION.

COUNTIES.	* Ref.	Pop. 1890.	Pop. 1900.	COUNTY TOWNS.	Pop. 1900.
Alachua	3-I	22,934	32,245	Gainesville	3,633

* Reference for location of counties, see map of Florida.

Principal Towns (*1900*).—Tallahassee (capital), 2,981; Jacksonville, 28,429; Pensacola, 17,747; Key West, 17,114; Tampa, 15,839; St. Augustine, 4,272; Lake City, 4,013; Gainesville, 3,633; Ocala, 3,380; Palatka, 3,301; Fernandina, 3,245; Appalachicola, 3,077; and Orlando, 2,481.

The industrial and business interests of Florida depend largely upon the crops. First in importance is the orange crop, which in round numbers approximates two and a half million boxes annually for export. The raising of early vegetables, including strawberries, for the Northern market is a large and profitable business. Pineapples and cocoanuts are largely exported from the sub-tropical section. Tobacco-growing and the manufacture of cigars employ several thousand operatives. The cotton crop is annually increasing, and factories are springing up in the western counties. The chief crops in 1900 were: cotton, 41,855 bales, value $2,189,805; oats, 378,211 bush.; potatoes, 104,280 bush.; hay, 6,418 tons. The lumber interests are of great value, Pensacola being the chief port of shipment. Considerable business interests have recently developed in the manufacture of textile goods from palmetto fiber. The sponge-fishery is carried on from Cedar Keys on the Gulf coast to and along the Florida Straits, and as far up the Atlantic coast as Biscayne Bay. Key West is the principal market and shipping-point for sponges. The manufacture of "koonti," or "coontie," a flour resembling corn-starch, is largely carried on in sub-tropical Florida. This is made from the root of a wild plant (*Zamia integrifolia*), and is exported in considerable quantities. See Florida in the Appendix.

Finances.—Assessment returns for 1899 showed the following valuations: Real estate, $59,177,137; telegraph lines, $252,736.15; railways and rolling stock, $18,759,125.64; and personal property, $15,338,355—total, $93,527,353.79. The total assessed valuation for 1900 was $96,518,953.73. The tax rate for all purposes was $5 per $1,000 of valuation. The total bonded indebtedness of the State in 1899 was $322,500. This amount has since been greatly reduced.

Banks.—On June 30, 1900, there were 15 national banks with a combined capital of $1,150,000; surplus and undivided profits, $772,902.74; and individual deposits, $6,431,-498.44; 23 State banks with $742,500 capital; $234,510 surplus and profits; and $3,489,436 deposits; and 1 savings bank with $20,000 capital stock; $9,883 surplus; and $225,-395 in savings deposits. Five of the State banks are savings banks or have savings departments.

Means of Communication.—Natural means of communication are the waterways partially described under *Topography*. These have in some cases been improved, as by jetties at the mouth of the St. Johns, by several canals along the Halifax and Indian rivers, and by improvements in several of the rivers and harbors. In 1900 there were in the State 3,109.70 miles of railroad. The principal lines are Jacksonville, Tampa and Key West, with branches; Jacksonville, St. Augustine and Indian River; Florida Central and Peninsula; Louisville and Nashville; Florida Southern. Besides these there are numerous smaller roads intersecting the northern and central parts of the State. In 1900 there were 3,148.40 miles of telegraph lines.

Churches and Schools.—The Methodist Episcopal Church South is the strongest denomination in the State. The census of 1890 gave the following statistics of the Churches: Methodist Episcopal Church South—organizations, 389; churches and halls, 370; members, 25,362; value of church property, $333,824; African Methodist Episcopal—organizations, 152; churches and halls, 269; members, 22,463; church property, $168,473; Baptist, colored—organizations, 327; churches and halls, 330; members, 21,711; church property, 137,578; Baptist, white—organizations, 403; churches and halls, 403; members, 18,747; church property, $208,933; Roman Catholic—organizations, 44; churches and stations, 38; members, 16,867; church property, $225,100; African Methodist Episcopal Zion—organizations, 61; churches and halls, 61; members, 14,791; church property, $90,745; Methodist Episcopal—organizations, 117; churches and halls, 112; members, 5,739; church property, $219,000; Protestant Episcopal—organizations, 100; churches, 84; members, 4,225; church property, $390,-561; and Presbyterian in the U. S.—members, 3,444; Colored Methodist Episcopal, 1,461; Disciples, 1,306; Congregational, 1,184; and Presbyterian in the U. S. of America, 1,042.

The school census for the school year 1899–1900 gives the number of children of school age as follows: White males, 48,023; white females, 45,328; total white, 93,351. Negro males, 33,689; negro females, 34,388; total negro, 68,077. Total males, 81,712; total females, 79,716. Grand total, 161,428. In 1897–98 there were 108,455 children enrolled in the public schools; white males, 35,116; white females, 32,541; negro males, 19,632; negro females, 21,116. Total revenue, $630,733; expenditure, white, $565,465, colored, $171,486. Number of schoolhouses, 2,121: value of school property, $755,824; number of teachers, male 1,121, female 1,671; average pay of male teachers a month, $35.04, female teachers, $32.40.

Other public institutions are: East Florida Seminary, at Gainesville; Duval High School, at Jacksonville; Osceola High School, at Kissimmee; high school, at Lady Lake; Jefferson Collegiate Institute, at Monticello; high school, at Palatka; high school, at St. Augustine; West Florida Seminary, at Tallahassee; academy, at Union; and academy at Waukeenah. There are also a State Agricultural College at Lake City; Normal College for White Teachers, at De Funiak Springs; Normal College for Colored Teachers, at Tallahassee; John B. Stetson University, at De Land; Florida Conference College, at Leesburg; Rollins College, at Winter Park; Cookman Institute, at Jacksonville; Convent of Mary Immaculate, at Key West; and Convent of the Holy Names of Jesus and Mary, at Tampa.

Charitable, Reformatory, and Penal Institutions.—The principal ones are the State Lunatic Asylum, at Chattahoochee; the State Institute for the Deaf and Dumb, at St. Augustine; and the State Prison, the inmates of which, since Jan. 1, 1890, have been leased to contractors, and put to work on farms, on turpentine farms, and in the phosphate mines.

History.—It is not unlikely that Florida was seen by Europeans as early as 1497 (by Sebastian Cabot) and during the decade following by Spanish and Portuguese traders. But the accepted date of discovery is Mar. 27, Easter Sunday of 1513, when Juan Ponce de Leon sighted the coast near St. Augustine, and named it in honor of the day. In a search for gold and for the fountain of perpetual youth Ponce de Leon and his successors explored a large part of Florida. He met his death in a fight with the natives in Feb. or Mar., 1521. In 1528 Panphilo de Narvaez, with a fleet of five vessels and a force of 400 men, landed on the west coast, perhaps at Clear Water harbor. The fleet was sent along the coast while the army marched inland and perished, all save four who escaped after eight years of captivity. In 1539 Fernando de Soto landed at Tampa Bay with a force of nearly 600 men. He marched northward and westward, passing soon beyond the confines of Florida. He treated the Indians, friend and foe alike, with great violence, and laid the foundation for the distrust and hatred with which the Spaniards were ever after regarded. In 1564 the French, under René de Laudonnière, a Huguenot, attempted permanent settlement near the mouth of the St. Johns river. Two years afterward this colony was exterminated by Pedro Menendez d'Aviles, who hanged such of the garrison as were not killed in the action. Fortune also enabled him to capture other detachments of the French who were absent in their ships, and were shipwrecked on the coast south of St. Augustine. These men, too, he ruthlessly put to death, confessedly because of their Protestant faith. The fort built by the French was made a permanent post by the Spaniards, who fortified and garrisoned the headlands at the mouth of the river. The story of Menendez's atrocities was received with indignation in France, but such was the fear of Spain that the king dared do nothing in revenge. A private gentleman, however, Dominique de Gourgues by name, organized a force at his own expense, captured the Spanish forts on the St. Johns river, and hanged the survivors of the fight on the very trees that had been employed by Menendez for a like purpose. The French from this time practically withdrew from Florida, and, excepting occasional descents by Drake and other English freebooters, the Spaniards enjoyed uninterrupted possession. They reduced many of the natives to slavery, and treated them with such outrageous cruelty that the race rapidly deteriorated. Nominally, however, the whole period of Spanish occupation was sanctioned by the Church, and many zealous missionaries perished at the hands of the Indians while endeavoring to carry their religion into remote regions. New settlements were made at Pensacola and at various points elsewhere along the coasts. In 1687 the first large consignment of Negro slaves was brought to Florida. In 1702 the British, under Gov. Moore, of South Carolina, laid siege to St. Augustine by land and sea, and during the twenty years that followed hostilities were frequent between the Spanish, French, and British along the Florida coasts. No formal declaration of war was made, however, until 1739, when active hostilities were opened, and in 1740 St. Augustine was formally besieged by the English. A defense was successfully conducted by the Spanish garrison under Don Manuel de Monteano. Hostilities continued until 1748, when a truce was agreed upon between Great Britain and Spain, which lasted until 1762, and war was renewed, resulting in the exchange of Cuba for Florida, and the British immediately took possession. Then began for Florida a period of prosperity, during which a number of industrious settlers established homes in the new colony. The wonderful productiveness of the soil, unsuspected by the Spaniards, was promptly recognized, and there was every indication that a prosperous agricultural community would be permanently established. The American war for independence scarcely affected Florida. Shortly after the independence of the American colonies was recognized, Florida was ceded back to Spain, greatly to the disadvantage of the British subjects, who were allowed eighteen months to remove their effects, and were assisted by the crown. Those who remained were treated most abominably by the Spaniards, and were practically expelled from the country, often with the loss of their property. A new period of decadence under Spanish rule immediately set in. In 1795 Spain sold West Florida to France. In 1811, in view of probable war with Great Britain, the U. S. resolved to seize Florida in order to prevent the British from taking possession. A British force occupied Pensacola with the consent of the Spanish authorities in 1814, but in November of that year the place was captured by Gen. Andrew Jackson, and the British garrison expelled. Then followed a long series of wars with the native tribes, and in 1819 the whole of Florida was finally ceded by Spain to the U. S. On July 10, 1821, the Spanish flag was hauled down and the U. S. flag hoisted at all military stations. In 1822 Florida was organized as a Territory of the U. S. From 1835 to 1842 the State was the scene of almost constant Indian wars. The Seminoles were a gallant and warlike race, and inaugurated hostilities by waylaying a detachment of U. S. troops under Maj. Dade, 110 strong. Four of this detachment escaped by feigning death. Eventually the Seminoles surrendered and were removed to a special reservation. About 360 of them, however, remained in the Everglades, where their descendants still reside. In 1845 Florida was admitted to the Union as a State. In Jan., 1861, the various U. S. posts were seized by State troops under authority of the Governor, and on the 10th of the month the ordinance of secession was adopted in convention at Tallahassee. Fort Pickens, at Pensacola, the only garrisoned fort, was held and eventually re-enforced, and after sustaining a severe bombardment by the Confederates became a base of operations for the Union forces in the vicinity. Various minor engagements occurred at different places along the coast and on the navigable streams. Jacksonville was several times occupied and evacuated by the contending forces. St. Augustine was seized by a Union force early in the war and held until its close. The most considerable engagement was the battle of Olustee, near Ocean Pond, Baker County, on Feb. 20, 1864, which resulted in the defeat of the Union force. The Confederates under Gen. Joseph Finnegan lost 934 men, the Union troops under Gen. Truman Seymour 1,828 men. On July 4, 1868, the Fourteenth Amendment to the Constitution of the U. S. having been adopted with a constitution comporting with the new order of things, Florida was readmitted to the Union.

GOVERNORS OF FLORIDA.

Territorial.		David S. Walker	1866–68
Andrew Jackson	1821–22	Harrison Reed	1868–Dec. 31, 1872
William P. Duval	1822–34	O. B. Hart	Jan., 1873–Mar., 1874
John H. Eaton	1834–36	M. L. Stearns	1874–77
Richard K. Call	1836–39	George F. Drew	1877–81
Robert R. Reid	1839–41	Wm. D. Bloxham	1881–85
Richard K. Call	1841–44	Edward A. Perry	1885–89

Madison S. Perry	1857–61		
John Milton	1861–65		
Wm. Marvin, *Provisional.*	1865–66		

Antiquities.—There are evidences in various parts of Florida that the country was once occupied by an industrious and almost semi-civilized race. Mounds and cultivated tracts, "old fields" so called, show that the people must have been numerous, and have had some ideas as to engineering and agriculture. There are one or two very large works, apparently canals, now overgrown with luxuriant vegetation, but which were apparently intended to facilitate the commerce of some prehistoric time. The accounts of the early explorers, especially the French, who established far more friendly relations with the natives than did the Spaniards, point to quite a high degree of cultivation. There are at St. Augustine some collections of relics that show the skill of the natives as artisans. Early evidences of European civilization are found in several old forts, notably that at St. Augustine, built of coquina. After various vicissitudes of siege and storm, it has been made a military post and measures have been taken for its preservation. Elsewhere, as at Biscayne Bay, there are ruins of stone buildings, no record of which has been preserved, and which were probably the work of settlers afterward exterminated by the Indians. Similar ruins are found on several of the keys. Perhaps the most noteworthy antiquities consist of the enormous shell-mounds that exist all along the coast. These are of great magnitude, and are evidently mainly the natural accumulations of oyster-shells thrown here in vast quantities by the Indians, who made shellfish a principal article of diet. Besides these there are so-called domiciliary and burial mounds, in which have been found stone implements and other proofs of mechanical skill.

Brinton, *Notes on the Floridian Peninsula* (Philadelphia, 1859); Francis Parkman, *Pioneers of France in the New World* (Boston, 1865); George Rainsford Fairbanks, *History of Florida* (Philadelphia, 1871); James Wood Davidson, *Florida of To-day* (New York, 1889); Charles Ledyard Norton, *Handbook of Florida* (London and New York, 1890). CHARLES LEDYARD NORTON.

Florida Agricultural College: an educational institution situated in Lake City, Fla.; organized in 1884; president, W. F. Yocum, D. D. It has thirteen professors, a military department, and four courses of instruction in classical and literary, agricultural, mechanical, and civil engineering, and is supported partly by State appropriation but mainly by endowment from the general Government. A State experiment station is located on the grounds, which comprise 112 acres. The college has six buildings, a full equipment of apparatus, a library, museum, etc. In 1900 there were 226 students. Tuition is free to residents of the State.

Florida Blanca, JOSÉ MOÑINO, Count of: statesman; b. in Murcia, Spain, 1728; graduated at the University of Salamanca and studied law; became a successful advocate, and secured an appointment as fiscal to the tribunal of Castile. While administering this office he wrote a report on the subject of the Jesuits which brought him to the favorable notice of the Government and led to his appointment as ambassador to Rome in 1777, where his skillful diplomacy established friendly relations between his country and the holy see. Soon after his return he was appointed by Charles III. his chief minister of state. His administration, especially in domestic affairs, was remarkably successful. He reformed abuses in the administration of justice, improved the means of transportation, reduced the taxes, promoted industries, and encouraged learning and art. While his foreign policy bore good fruit in the treaties of commerce with the Porte, in the alliance with Portugal, and in the repression of Algerine piracy, his enemies accused him of bringing on the disastrous war with England 1779–83, and the bombardment of Algiers and attempt on Gibraltar cost his country 80,000 lives without advantageous result. After the death of Charles III. he retained his position with the imbecile Charles IV., but lost much of his influence, though a strong supporter of monarchical rights, and when in 1792 he tried to destroy the queen's influence with the king, his enemies procured his dismissal from court. He was imprisoned in the castle of Pampeluna and treated with great cruelty, but finally allowed to retire to his estates. At the time of the French invasion in 1808 he was chosen president of the Junta, Sept. 25. D. Nov. 20, 1808. F. M. COLBY.

Florida, Cape: See CAPE FLORIDA.

Florida Keys: See FLORIDA.

Florideæ: the only order of the class *Rhodophyceæ* or RED SEAWEEDS (*q. v.*).

Flor'in [from O. Fr. *florin*, from Mediæv. Lat. *flori'nus* (whence Ital. *fiorino*), deriv. of Lat. *flos, floris*, flower, because of the lily-flower stamped on the coin]: a Florentine coin first struck in gold in 1254. Gold and silver coins called florins, and of various values, have since been coined in many countries. England struck a gold florin in 1343. At present the British two-shilling silver piece, first coined in 1849, bears the official name of florin. It has nearly the value of the Austrian new silver florin, a unit of account, worth 48·6 cents of U. S. money.

Flori'nus: a Roman presbyter and heresiarch in the latter half of the second century, who was deposed by Eleutherius. His heresy was a form of Gnosticism (see GNOSTICS), and was essentially the same as that taught by Valentinus.

Flo'rio, JOHN: philologist and grammarian; was b. in London about 1552 of Italian parents, who, as Waldenses, had sought refuge in England from religious persecution; resided for a time at Oxford, and in 1578 published his *First Fruits which yield Familiar Speech, Merry Proverbs, Witty Sentences and Golden Sayings*, which was accompanied by *A Perfect Induction to the Italian and English Tongues*. This was followed by a similar work in 1591, and by an Italian and English dictionary in 1598 under the title of *A World of Words*. He enjoyed the patronage of several persons of high rank, and after the accession of James I. was appointed instructor to the young prince, and later gentleman of the privy chamber and clerk of the closet to the queen. He is best known for his English translation of Montaigne's *Essays*, published in 1603. D. at Fulham in 1625.

Florio, CARYL: composer, organist, and teacher; b. in Tavistock, England, Nov. 3, 1843; went to New York with his parents in Sept., 1858. In his boyhood he had a remarkable soprano voice, and was a member of Trinity church choir 1858–1860, under the family name of Robjohn. Studied under Dr. Edward Hodges and Dr. Henry Stephen Cutler, successively organists of Trinity church. He has been organist of Zion church and the "Brick" Presbyterian church in New York. His compositions include two operas, two symphonies (all in MS.), several cantatas, many anthems, services, and hymn tunes for church service, and he has edited a volume of *Children's Hymns with Tunes*. He resides in New York city. D. E. HERVEY.

Flo'ris, FRANÇOIS, called *Franc-Flore*, or *Franc-Floris*: b. at Antwerp in 1520; the family name was *De Vriendt*. He began studying sculpture with his father, but at the age of twenty, preferring painting, he became a pupil of Lambert Lombard, at Liége. Soon surpassing his master, he was elected member of the Antwerp Academy, and went to Rome, where he studied the antique and adopted the manner of Michaelangelo. On his return to his country his skill and rapidity of execution acquired fame and riches immediately for him. When Charles V. made his entry into Antwerp Floris designed and executed the triumphal arches erected in honor of this monarch. He was again called upon for similar work for Philip II., and Philip desired to engage him for his court painter, but he refused to leave his own country, where he died of drunkenness at the age of fifty. His chief works are *St. Michael*, for the confraternity of St. Michael at Antwerp, *The Last Judgment*, for a church at Brussels, now in the Louvre, and a triptych at Ghent representing the life of St. Luke; also the nine muses in Middelburg. D. in 1570. W. J. STILLMAN.

Flo'rus: a Roman historian, whose full name is a matter of dispute. In the earlier editions of his history he appears as L. Annæus Florus, and is supposed to have been a member of the family to which Seneca belonged. Duker, following Vossius (*Hist. Lat.*), infers from his style, family name, and the age in which he lived, his identity with the poet Annius Florus, who interchanged sportive verses with the Emperor Hadrian. In the preface to his work he speaks of a revival of Roman vigor under Trajan, and would seem therefore to have lived in his reign or in that of Hadrian. Titze, however, rejecting the passage as an interpolation, maintained that he is the Lucius Julius Florus to whom two of Horace's epistles are addressed, and places him therefore in the time of Augustus, a view no longer tenable. Wölfflin, in the *Archiv für Lat. Lexikographie*, vol. vi., pp. 1–7, has shown new ground for believing that the historian came from Africa, and is to be identified with the rhetorician and poet P. Annius Florus, the author of the dialogue as to whether Vergil was rather an orator or poet (*Vergilius orator an poeta?*), and probably also of the extant poem entitled *Pervigilium Veneris*. Florus's history is a concise and highly rhetorical account of the Roman people from King Romulus to Augustus Cæsar. In the earlier editions the work was entitled *Epitome Rerum Romanarum*, and was divided arbitrarily into four books. But Jahn and Halm, following the Bamberg codex, give the title *Epitomæ de Tito Livio Bellorum omnium Annorum DCC. libri duo.* The first book contains the account of the external wars of Rome, while the second deals chiefly with the domestic contentions and the seditions of the people, and the wars in which Augustus was engaged, ending with the closing of the temple of Janus as the token of universal peace. The work of Florus, taken, as the name indicates, in the main from Livy, is a concise but interesting record of the progress of the Roman people, written in a rather ambitious style, without much regard to accuracy of facts or of dates, and is to be regarded rather as a panegyric than a history. The best of the earlier editions are those of Duker (Leyden, 1722), and Titze (Prague, 1819); more recent and critical those of Otto Jahn (Leipzig, 1852), and of Halm (Leipzig, 1854). See *Das Geschichtswerk des Florus*, von J. Reber (Freising, 1865); C. Heyn, *De Floro Historico* (Bonn, 1866).

Revised by M. Warren.

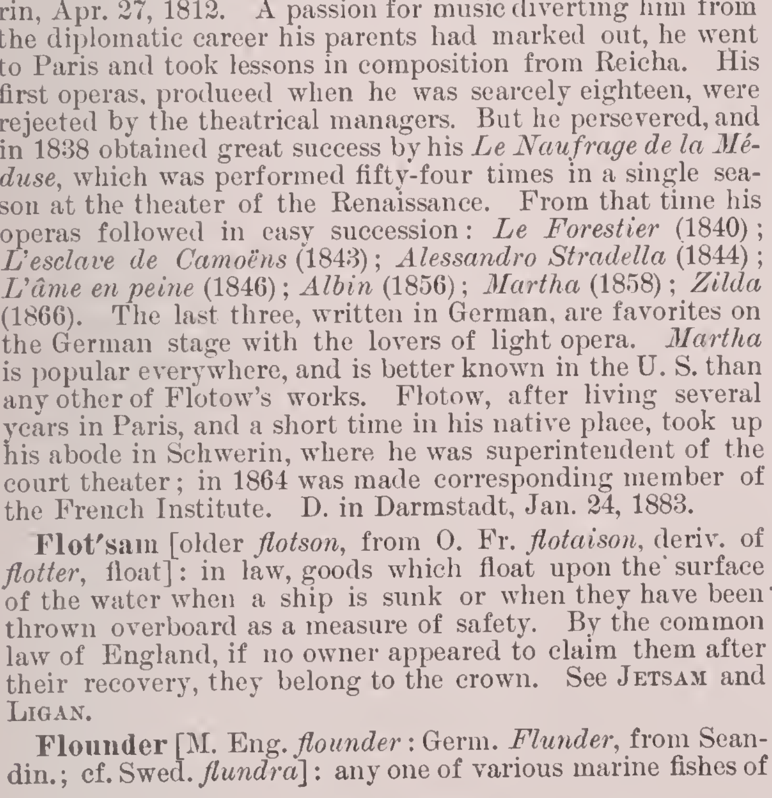
Florus, Drepanius: a Gallo-Roman divine of the ninth century, and a deacon at Lyons; remembered as the opponent of Gotteschalk and Scotus Erigena; against the latter he wrote *Liber de Predestinatione* (852). D. about 860.

Floss Silk [*floss* is from O. Fr. *flosche*, weak, soft, Ital. *floscio*, apparently descend. of Lat. *fluxus*, fluid, weak, under influence of *floccus*]: the soft, downy part of the silk which remains on the cocoon after all that can be reeled off has been reeled off. It is steeped in water, pressed, dried, oiled, carded, and spun into soft, loose yarn, used chiefly in embroidery.

Flotow, flō'tō, Friedrich Ferdinand Adolph, von: a German composer; b. at Teutendorf, in Mecklenburg-Schwerin, Apr. 27, 1812. A passion for music diverting him from the diplomatic career his parents had marked out, he went to Paris and took lessons in composition from Reicha. His first operas, produced when he was scarcely eighteen, were rejected by the theatrical managers. But he persevered, and in 1838 obtained great success by his *Le Naufrage de la Méduse*, which was performed fifty-four times in a single season at the theater of the Renaissance. From that time his operas followed in easy succession: *Le Forestier* (1840); *L'esclave de Camoëns* (1843); *Alessandro Stradella* (1844); *L'âme en peine* (1846); *Albin* (1856); *Martha* (1858); *Zilda* (1866). The last three, written in German, are favorites on the German stage with the lovers of light opera. *Martha* is popular everywhere, and is better known in the U. S. than any other of Flotow's works. Flotow, after living several years in Paris, and a short time in his native place, took up his abode in Schwerin, where he was superintendent of the court theater; in 1864 was made corresponding member of the French Institute. D. in Darmstadt, Jan. 24, 1883.

Flot'sam [older *flotson*, from O. Fr. *flotaison*, deriv. of *flotter*, float]: in law, goods which float upon the surface of the water when a ship is sunk or when they have been thrown overboard as a measure of safety. By the common law of England, if no owner appeared to claim them after their recovery, they belong to the crown. See Jetsam and Ligan.

Flounder [M. Eng. *flounder*: Germ. *Flunder*, from Scandin.; cf. Swed. *flundra*]: any one of various marine fishes of



Flounder (*Pleuronectes* or *Pletessa plesus*).

the family *Pleuronectidæ*. They are flat, and swim with one side, not one edge, uppermost; both eyes are on the upper side, and the lower side is much whiter than the other. Many species occur in American waters. See Fisheries.

Flour [from Fr. *fleur de farine*: Span. *flor de la harina*, lit. *flower of meal*]: the finely ground meal of wheat or of any other grain; especially the finer part of meal separated by bolting. When dry wheat is crushed as in mortar, or between revolving mill-stones, the product is a powder mixed with scales, known as whole meal. The process of sifting or bolting separates the whole meal into two portions, known as flour and bran. The latter consists of the outer woody portion of the grain, with adhering portions of the interior; and flour is the name given to the remainder. The latter is white, the former is reddish or grayish. This simple nomenclature was suited to the earliest forms of milling. It applies as well to rye, except in the matter of color, as to wheat, and more or less to other grains, and to some extent to seeds.

With refinements in the art of making bread, cake, and pastry came a demand for finer flours. New modes of milling were introduced, and the product was separated into more numerous grades. It was at one time customary in the U. S. to divide the product into three grades—flour, connell, and bran. The flour, including so much as could be separated of the requisite whiteness, amounting to some 70 per cent., was removed by bolting from the remainder; and this remainder, by passing over a coarser sieve, was divided into larger scales and fragments called bran, and lesser scales and fragments called connell. The latter is also known as shorts and middlings. These three have been further increased by improved appliances both in the U. S. and in Great Britain, and especially in Hungary. The grades of flour produced by the best mills are ten in number.

The principles which have guided the inventor of milling devices will be best understood after a study of the *structure of the wheat grain.* The grain of wheat has the form of an irregular oblong spheroid, having a longitudinal groove on one side, and terminating at one end in minute vegetable hairs or bristles, and at the other in a slightly corrugated surface covering the germ. If this grain be moistened and rubbed with a dry rough cloth there will be detached from the surface two outer coats composed of woody fiber. Within there is a thin coat, also composed of woody fiber, which, from the peculiar network of fibers and tubes, suggesting the appearance of cigars placed side by side, has been called the cigar-coat. This is succeeded by another coat of exceeding tenuity, like the others chiefly composed of woody fiber. Within these is the nutritious portion of the grain. There is first a framework of cells entirely enveloping the white portion of the flour. The cells are filled with a class of nitrogenous bodies of albuminous character and certain mineral salts, almost wholly phosphates, of which the chief is the phosphate of potassa, with much smaller proportions of phosphates of magnesia, lime, soda, and iron, the whole, with the cell framework, being known as the gluten coat. At the germ end of the berry, opposite the brush end, there are certain organic forms, constituting the embryo of the grain. The whole of the remaining interior is occupied by a framework of coarse, open cellular tissue, filled with starch grains, which are coarse, and others, exceedingly minute, containing albuminoid or nitrogenous constituents. If a sharp knife be passed through a plump berry of wheat perpendicular to its axis halfway from end to end, and the section so exposed be treated with solution of iodine, the entire surface bordered by the gluten coat, but not including it, will be changed from whiteness to dark purple, demonstrating the presence and extent of the starch. If another section be exposed to the action of a solution of blue vitriol in ammonia (ammonio-sulphate of copper), the starch of the interior will be but little affected, but the gluten coat which surrounds it will have become green, from the formation of phosphate of copper. A solution of ammonio-nitrate of silver (nitrate of silver dissolved in ammonia) will color the gluten coat yellow, from the formation of phosphate of silver. If the crushed berry be treated with weak acetic acid, and the result of the digestion be filtered and ammonia added to the clear liquor, there will be separated from the solution on standing minute crystals of phosphate of magnesia and ammonia. If a drop of nitrate of silver dissolved in water be poured upon the flour, no change will take place, but if nitrate of silver dissolved in ammonia be poured upon the flour it will yield, as already observed, the yellow compound of phosphate of silver. Strong nitric acid will color the flour orange, from its action on the albuminoid substances. If a quantity of flour intimately mixed with water to a stiff emulsion is set aside at a temperature of about 70°, it will after a while begin to evolve bubbles of gas, and after a longer time it will become acid and offensive to the taste, and the liquid will contain phosphoric acid, readily recognizable by chemical tests.

The phosphatic and nitrogenous constituents and the starch all have nutritive value, and are indispensable as elements of food. Of these the starch is far the most abundant, constituting about 70 per cent. of the whole grain. The nitrogenous constituents or the albuminoid bodies constitute from 11 to 18 per cent., and the phosphatic salts about 2 per cent., the rest being mainly woody fiber. Of the nutritious portions, weight for weight, the phosphatic constituents are undoubtedly entitled to the first rank. The portion of the nitrogenous constituents lodged with the phosphates in the cells of the gluten coat have been shown by Mègé Mouriés to be peculiarly susceptible to fermentation when exposed to a moist atmosphere. They are encased in capsules impervious to the air in the berry. If these capsules be ruptured or crushed, exposure to the air is inevitable.

On this structural peculiarity of the grain rests the foundation of a philosophical system of milling. The larger the percentage of the interior of the berry in flour, the less must be its nutritive value; and correspondingly, the larger the percentage of the gluten coat in flour—the chief deposit of the phosphates—the greater its nutritive value; and in bran, the smaller the percentage of adhering gluten, the more nearly worthless as an article of food the bran would be. If it were practicable to reduce the percentage of pure starch and increase the percentage of phosphatic and nitrogenous constituents, the nutritive value of the flour would be augmented.

The presence of minute particles of woody fiber in the flour gives to it a yellow shade. That system of milling which most nearly removes all the woody fiber, and none of the gluten or phosphates, from the flour, accomplishes one of the chief ends to be gained.

To appreciate the difficulties that present themselves to the inventor of milling machinery the berry should be considered as it is found in commerce. It is very rare that any considerable quantity of wheat is to be found in the market absolutely free from foreign ingredients, such as chaff, fragments of straw, oats, chess, mustard, cockle, grass-seed, sand, etc.; it is rarer still to find wheat grains uniformly filled out and without shriveled or blasted kernels. Wheat is sometimes plump, the starch of the interior being mealy, so that if the berry were cut in halves it would be easy with a pin to detach all the white interior, leaving two cups lined with the gluten coat and invested with the woody bran-case. The wheat is sometimes slightly shrunken, hard, and brittle from the surface to the center, and cuts like the rind of old cheese. It is sometimes shriveled, as if its growth had been arrested at the commencement of the period when the berry is in what is technically called "the milk," or as when it has been struck with rust—a microscopic vegetable growth accompanying the loss of milk from the berry. It is plain that shriveled berries in the process of milling would for the most part be resolved into fine bran, and so be with difficulty separated from the flour, and thus the flour be discolored and rendered less nutritious. It is plain, too, that the plump berry with the mealy interior would be easily mashed in the process of grinding, while the hard, brittle berry would more easily be cracked.

Purification of Commercial Wheat.—Two principles underlie most of the devices for separating the light grains from the heavy, and the foreign seeds, grains, and other impurities from the wheat. The one is the process of sifting—the other, that of exposing a thin cascade of falling grain to a current of air. To these a third has been added, that of centrifugal force, taking advantage of unequal specific gravity and unequal extent of surface. In the sifting process advantage is taken of the unequal sizes and of the different shapes of the bodies to be separated from each other. It is easy to see how light grains and chaff and bits of straw and dust would be further diverted from a perpendicular in falling through a stratum of air driven by a revolving fan. This principle was illustrated in the earliest times, when the mixed wheat and chaff were tossed together into the air, to be separated by the wind before reaching the ground, and is the principle underlying the ordinary fanning-mill. The separation of mustard and cockle and grass-seed from the wheat may be easily affected by passing the mixed grains over inclined plates perforated with holes large enough for the smaller seeds to pass through, but not large enough for the wheat. The oat grain is separated by taking advantage of its elongated form. The mixed oat and wheat grains are discharged in a thin sheet upon an inclined thin iron plate perforated with round holes at intervals nicely determined by experiment, abundantly large for the ready passage of both the wheat and oat grains if presented end foremost perpendicularly to the surface of the plate. But as the plate is inclined each berry must be tipped forward in order to enter a hole. An individual hole is of such diameter that when the wheat grain, sliding forward, carries its center of gravity beyond the support of the upper edge of the hole, the forward end of the grain has not reached the lower margin, and thus the wheat falls through. The oat grain, however, in sliding down the inclined plane, before its center of gravity has passed beyond the support of the upper margin of the hole, will, by reason of its prolonged keel, extend over the lower margin of the hole. As the oat advances the center of gravity will pass beyond the lower edge of the hole, and gain the support of the continuous surface before the tail of the berry will have lost the support of the upper edge. Fragments of straw and chaff pass on with the oats.

The dust, smut, and rust which may cling to the berry are separated by discharging the impure grain into the space between what may be regarded as a vertical cylinder, the surface of which is covered with brushes, and a closely fitting iron case perforated with numerous slits or holes, which serve the double purpose of making the surface rough and providing an escape for the separated dust. Round seeds are separated by taking advantage of the superior velocity they acquire in rolling down an inclined plane as compared with the long grains, which slide. The former leap an opening into which the latter drop.

By these and kindred processes it is now practicable to obtain good wheat from a sample of spring wheat of which not more than one-half is fit for making flour, by the complete separation of every foreign matter from the sound, serviceable wheat grains.

The wheat thus prepared is a structure the chemical, physiological, and mechanical composition of which has already been glanced at. If the grain of wheat be subjected to pressure, as in a vise, so that its diameter shall be lessened by a certain definite amount, the interior may be partially pulverized without rupturing the surface. If the pressure reducing its diameter by the same amount be of the nature of impact or of a blow, the interior will be cracked, but not pulverized, with the probable rupture of the surface. If the pressure of the vise be continued until the grain is flattened, the product will be large scales and powder. If the blows be repeated with change of position of the berry, the product will be dust, fragments including the inner layers of the bran, the gluten coat, and starch extending to the center of the berry, and the outer scales of the woody covering more or less separated from the gluten coat. The product derived from pressure may by sifting be separated into its constituents of scales (or bran) and powder (or flour). The bran will contain a large proportion of the gluten coat; the flour will consist of starch, with associated albuminoids, and gluten-cells detached from the bran. In the case of reduction by blows the dust will be chiefly composed of starch (which, it will be understood, though by far the largest constituent, may contain a larger percentage of the nitrogenous constituents than the gluten coat), the scales will be mainly of woody fiber, and the lumps or groats will be composed of starch, with the associated albuminoids on the interior, more or less of the bran coat on the exterior, and the gluten coat between. The dust may be easily removed by bolting; the outer scales of bran, mainly of woody fiber, may be easily separated by a current of air directed upon a thin cascade of the mixture—the bran-scales, with a given weight of material, presenting a greater extent of surface to the blast than the compact granules from which they are to be discharged.

It is plain that, weight for weight, the groats contain much more nutritive matter relatively than either of the two portions which have been separated from them. If, now, these groats be subjected to attrition among themselves, their corners will be rounded off, the scales on the outside of the gluten coat will be more or less detached, and the starch on the interior will be more or less worn off. The tenacity of the gluten coat will tend to preserve its integrity, while the relative friability of the starch in the interior and the fibrous texture of the outer covering of the gluten coat will facilitate their separation under the influence of attrition. If, now, the process of attrition be intermittent and alternating with the process of bolting and the use of the fan-blower, the groats will ultimately assume the form of little concave disks, largely freed from the bran without, and for the most part freed from the starch within. As these alternating processes have been worked, there will have been produced successively a series of brans growing richer in gluten, and a series of starches growing richer in gluten, and a final result of groats consisting mainly of gluten, with scarcely any starch or bran.

The two plans of reduction thus illustrated may be regarded as exhibiting the principles underlying the extremes of high and low milling; in practice, however, no such extreme is attained. The best forms of low milling include more or less of the principle of impact, and the best forms of high milling take advantage more or less of the principle of pressure without impact.

Milling.—Old Process.—The trituration of wheat was formerly almost universally accomplished between what are called millstones, two short cylinders of hard stone placed one over the other, having the two horizontal surfaces between them peculiarly grooved to fulfill the office which they are expected to perform. To understand this office account must be taken of a property of the gluten to which no allusion has as yet been made. If a handful of flour be moistened with water and fashioned into dough, and then continuously kneaded in a slender stream of falling water, the starch will gradually be separated from the dough, and there will remain at length pure gluten, a singularly tenacious and homogeneous substance. On drying, this body will become quite hard and somewhat brittle. On subjecting it to moderate heat after it has been thoroughly dried at common temperatures, it will be found to lose weight. It will have parted with water of hydration. On withdrawing the heat the gluten will reabsorb this water of hydration from the air at common temperatures, and recover its original weight. In the same manner the gluten of the flour subjected to heat will part with its water of hydration; and this escape of water will be accompanied more or less with the rupture of the cells in which the gluten is encased. The openings through which the moisture has escaped will permit the air to enter, and with it more or less the germs of microscopic vegetation, which, taking root in the gluten, produce the well-known effect described in the term *musty*, the flour acquiring an unpleasant odor and an inferior taste, the gluten at the same time losing an appreciable portion of its tenacity, and the bread made from it acquiring a less palatable flavor and being less light.

It is obviously desirable, therefore, that in the process of grinding the wheat the wheaten meal should be subjected to as little friction with the millstones as may be, or within certain limits, successively to interrupt the process and allow the materials to cool. The surfaces of the millstones present a series of grooves, or lands and furrows. These are oblique in some instances, and curvilinear in others. Great ingenuity has been displayed in the conformation and arrangement of the grooves with a view to attaining the best results. If it were the sole object to have the wheat pass through the stones without abrasion, it is manifest that the best form of the groove would be that which a grain of wheat would pursue discharged from the hopper and traversing the surface of the millstone under the influence of the centrifugal force. This path has been ascertained by allowing grains of wheat coated with plumbago to fall upon a smooth millstone, the surface of which has been chalked, so as to receive the marking of the plumbago as the stone was revolved with its determined velocity. The calculated direction of this curve has been found to coincide very precisely with the path as ascertained by experiment. The curves of the upper (the running) stone being reversed, as compared with the curves of the lower stone, the action of the edges of the opposing curves is to some extent like that of shears, and when the grains have been broken they fall into the grooves of the lower stone, and are gradually pushed to the periphery with but little further friction. Among the best results that have been attained in this direction are those of the Istvan steam-mills at Debreczin in Hungary, in which with a stone 54 inches in diameter the width in grinding surface from the periphery inward is only 9 inches. This gives nearly 80 per cent. of flour, with 20 per cent. of bran and 3 per cent. of waste.

The primary function of the grooves is that of trituration. As the grooves present one vertical surface, from the bottom of which the depth lessens by an ascending inclined plane, it will be seen that the grooves in the upper and nether stones provide that in the process of milling the action shall be in some degree like that of shears, in some degree that of impact, and in some degree that of mashing; and the relative measure of these will be determined by the distance of the stones from each other when in service. The stones may be placed so far asunder that the wheat will pass through without being crushed at all. In this case the interval must exceed the greatest length of the kernel of wheat. With the distance a little less than this the brush at the end of the kernel opposite the embryo will be cut off. As the distance is further lessened the grains will be cracked, until they may be brought so near that the gluten cells will be crushed, and the moisture evolved from them, in consequence of the heat produced by friction, will soften the gluten and cause the stones to adhere and the milling to be arrested. Between these extremes the art of the miller so adjusts the distance and velocity that, taken in connection with the other mechanical appliances of his mill, he is enabled to turn out the best product, in condition and quality, which the grain submitted is capable of yielding.

New Process: *Grinding between Grooved Rollers.*—By experiments made at Minneapolis in 1878 and 1879 it was found that a system of gradual reduction upon rollers similar to what had for some time been used in Hungary and France was of advantage in milling spring wheat. This system received a great impetus at the Millers' Exposition at Cincinnati, O., 1880, and by 1887 the gradual-reduction system had been widely adopted in the U. S. In this process the millstones are replaced by pairs of small horizontal rollers, the surfaces of part of which are traversed by small, sharp grooves parallel to the axis of the rollers. These pairs of rollers are arranged in sets of three, one above the other, with considerable intervals between, so that the heat produced by the slight crushing will be counteracted as the product passes through the air on its way from one pair of rollers to the next. These pairs of rollers are adjusted so that the crushing effect of any one pair is slight, and as many as six or seven sets, making from eighteen to twenty-one pairs of rollers, are necessary to produce the various grades of flour.

The powerful and progressive movement of modern milling is due to several causes. Among these may be mentioned the increasing demand for high grades of flour free from bran and from woody fiber. The demand for this glutenous middlings flour becomes larger from year to year. It is not only desirable but necessary that, as a matter of economy, the yield and quality of wheat flour shall be improved, the cost of manufacture lessened, and the less available kinds of wheat be brought into use; and as a matter of business prudence each miller should keep as near as possible to the front rank in his trade. Competition, stimulated by ample rewards for successful invention, is fierce, intelligent, well organized, and backed with abundant capital; hence systems, processes, and devices follow each other with wonderful rapidity, and with marked and beneficial effects upon the rapidly advancing science of milling. A division line may be made between methods, and "old" and "new" process may be spoken of as meaning whole wheat milling and middlings milling, no matter by what machines effected; the terms "low" and "high" milling may represent the same distinction, and the latter may be divided into "single-reduction" and "gradual-reduction" processes. The term "Hungarian system" is loosely applied to roller middlings milling by gradual reduction, whereas the original Hungarian system was middlings milling by gradual reduction with burrs. As both "high" and "low" milling are effected with rollers, the matter is further complicated; and when it is considered that the various operations in any one method as a whole—say middlings milling—may be effected by combinations of successive devices, the entire process is so complicated that it can not here be described in detail. Thus the breaking of the wheat may be done on rolls or on burrs; the middlings reduction has equal choice, and the bran dressing may be by burrs, rolls, beaters, or brush machines. In general, it may be said that the harder the wheat is the better high grinding pays in connection with the roller system. The leading features of this system, sometimes called the Hungarian roller system, are as follows: 1. Systematic separation, scouring, and brushing of the wheat. In this it does not differ from any other good system of milling. 2. Wheat granulation by grooved chilled-iron rollers, employing at least five breaks, and rolls having from eight to thirty grooves to the inch, making but little flour and leaving the bran finished. 3. Separation of the light chaff from the breaks by aspirators. 4. Thorough and systematic grading and purifying the middlings by purifiers. 5. Sizing the large middlings by equally speeded, smooth, chilled-iron rolls, thus reducing their size and taking out germs and bran specks. 6. Reducing the fine clean middlings to flour by differentially speeded rollers. 7. Full and complete bolting or sifting after each of the above.

The present methods of manufacturing flour in a modern flouring-mill in the U. S. are identical with Hungarian process milling, excepting that in mills in the U. S. all manual labor is reduced to a minimum, and that machinery is employed in all stages of the process of manufacture to such an extent that the modern mill is practically automatic. Improvements are being constantly applied in simplifying the process of manufacturing, saving of power, and cheapening the cost of production. The mills of the U. S. generally make three principal grades of flour—viz., patent or middlings flour, bakers' or break flour, and low-grade or bran flour. Of 100 lb. of flour manufactured from ordinary milling wheat, 72 to 76 per cent. is middlings flour, 18 to 22 per cent. is bakers' flour, 4 to 7 per cent. is low-grade flour. Of 100 lb. of good wheat there is produced 76 lb. of flour of all grades, and 24 lb. is in the weight of bran, shorts, and waste. To make a barrel of flour 258 lb. of clean wheat are required. One indicated horse-power in a modern flouring-mill in 1893 is required for every three barrels of flour in twenty-four hours. The cost of water-power in the Western States to make a barrel of flour is between 1½ and 3 cents. The cost of steam-power is between 4½ and 6½ cents per barrel.

Grading Flour.—The relative quantities of the several grades of flour vary with the kind and excellence of the wheat employed. The following list, taken from the record of a mill near Trieste, will illustrate the refinement to which the art of milling has been brought:

Groats, A and B		2	per cent.	41 per cent. of extra flour.
Flour,	No. 0	5	"	
"	" 1	12	"	
"	" 2	6	"	
"	" 3	6	"	
"	" 4	5	"	
"	" 5	5	"	
"	" 6	14	"	38 per cent. medium and common flour.
"	" 7	9	"	
"	" 8	5	"	
"	" 9	10	"	
Bran		18	"	79 per cent.
Loss		3	"	

Of these quantities, in a comparison with a view to determine the best work of a system of milling, a mixture of the first total 45 per cent. is taken.

Judging Flour.—The excellence of flour may be judged in some degree by its shade of color—the presence of minute particles of bran tending to give it a yellowish hue; by its freedom from musty odor or taste—proving that it has not been overheated and is comparatively new; and by the elasticity and tenacity of the dough which it yields when mixed with a small quantity of water and kneaded. To this may be added the odor which the dough in thin layer yields when submitted for a brief time to a sharp baking temperature of about 400° F.

Composition of Flour.—It has been convenient to treat of the composition of wheat as including the outer envelope, bran; the inner envelope, the gluten coat; and the mass of the interior, the starch and associated albuminoids. Proximate physical analysis and detailed chemical analysis have shown a much greater variety than would be indicated by these three. Of the outer coats there are five that may be readily separated from each other—the gluten coat, consisting of the framework of cells and the capsules and their contents of minute grains that fill the cells, the loose cellular tissue spanning the whole interior of the berry and supporting the starch-cells and their contents: opposite the brush end, distinguished as a tuft of vegetable hairs, there is the complete structure of the embryo. The outer coats contain, besides the woody fiber and cellular tissue of their structure, various inorganic substances, including silica. The gluten coat contains, besides the framework of cellular tissue, various nitrogenous substances, the chief of which is gluten—albumen, gluten, mucin, and cerealine, which differ from each other mainly in their solubility in water and in their susceptibility to fermentation and disintegration. Besides these there are contained bibasic phosphates of potassa—the most abundant—then magnesia next—lime, soda, iron, in combination with which the nitrogenous bodies above mentioned seem more or less to play the part of bases; and in addition to these oil and sugar.

The interior, besides the open cellular tissue and starch-granules, contains albuminoid bodies, kindred with those of the gluten coat, and in some grains in larger proportion; and a small percentage of phosphates. The ratio of phosphates in the interior to the salts in the bran and gluten coats is about as 1 : 10. The embryo contains, besides its organic texture, the nitrogenous and phosphatic constituents found in the gluten coat.

The following analyses by Dempwolff show the percentages of the proximate constituents of the wheat, the nitrogen and phosphates in the different grades of wheat flour:

IN 100 PARTS ARE—	Water.	Ash phosphates.	Nitrogen.	Albuminoids.	Starch.	Cellulose.
Groats and extra imperial	10·6	0·41	1·80	11·7	70·0	7·29
Roll flour	10·5	0·60	2·08	13·3	67·2	8·40
Bread flour	10·7	0·96	2·40	15·4	63·4	9·80
Dark flour	8·5	1·55	2·30	14·9	61·0	14·05
Bran	10·7	5·46	2·20	14·3	43·6	25·95

The following analyses of the flour of the Pesth Walz Muhl (cylinder mill), made by the writer, show the relations of the phosphoric acid to the nitrogen in the different grades into which the flour is resolved in that renowned mill. It should be remarked that the so-called "groats" are masses of the interior of the berry:

NUMBERS.	Water.	Ash.	Phosphoric acid.	Nitrogen.	Albuminoids calculated.
Groats	10·57	0·42	0·20	2·24 / 2·27	14·65
No. 0	10·37	0·43	0·14	1·68	10·76
" 1	10·23	0·41	0·21	1·68 / 1·68	10·76
" 2	10·47	1·03	0·22	1·72	11·02
" 3	10·07	1·02	0·17	1·72	11·02
" 4	10·24	1·19	0·25	1·74	11·15
" 5	9·66	0·69	0·35	1·80	11·54
" 6	11·12	1·04	0·24	1·84	11·79
" 7	10·99	0·81	0·21	1·80	11·54
" 8	9·86	1·01	0·36	1·90	12·18
" 9, coarse bran	9·71	7·32	2·14	1·98	12·69
" 10, fine bran	11·01	4·21	0·70	2·20	14·16

The constituents of the gluten coat when moistened with water spontaneously undergo chemical changes. The starch and sugar by themselves, similarly treated, experience no change. But when the starch and gluten are mingled together and mixed with an adequate quantity of water, the changes which the nitrogenous bodies experience are transferred to the starch, and that is also converted into new substances. At a moderately low temperature the starch is converted into lactic acid. At a temperature of from 70° to 80° F. the starch is converted first into a kind of dextrin, then into grape-sugar, and then this grape-sugar into alcohol and carbonic acid; at a more elevated temperature butyric acid, succinic acid, hydrogen, with carbonic acid and other volatile products, are produced. In the art of bread-making advantage has been taken of this susceptibility to fermentation, producing volatile products, to give to the moistened flour or dough, and ultimately to the loaf, the quality of porosity or cellular structure. This quality of the loaf, as is well known, facilitates digestion. The later refinements in the production of fermented bread have been directed to securing from sound flour that kind of fermentation only which yields mainly alcohol and carbonic acid, and is called vinous fermentation. Incidentally with these products there is yielded a certain amount of gum, and sometimes of sugar, beyond that converted into alcohol and carbonic acid, and also an agreeable volatile essential oil or ether, which imparts to the fresh loaf a pleasant aroma. See BREAD, COOKERY, and FERMENTATION.

Revised by CHARLES A. PILLSBURY.

Flourens, floo'răăn', GUSTAV: *littérateur* and politician; son of Marie Jean Pierre; b. at Paris, Aug. 4, 1838; deputy professor at College of France in 1863; fought in Crete against the Turks, and was sent as minister plenipotentiary from Crete to the Greek Government 1865–68; took part in electoral movement at Paris 1868; was arrested Apr., 1869, and same year was wounded in a duel with Paul Granier de Cassagnac; took part in the communal insurrection in Mar., 1871, and was killed near Paris on Apr. 3, 1871. Author of *Discours du Suffrage Universel* (1865); *La Question d'Orient et l'Insurrection Crétoise* (1867); *Paris Delivrée* (1871), etc.

Flourens, Marie Jean Pierre: physiologist and author; b. at Maureilhan, France, Apr. 15, 1794; became M. D. 1813, and a resident of Paris 1814; admitted to the Academy of Sciences in 1828; Professor of Comparative Anatomy in 1832; perpetual secretary of the Academy of Sciences in 1833; member of French Academy in 1840. His *Researches on Irritability and Sensibility* appeared in 1822; *Researches on the Properties and Functions of the Nervous System in Vertebrate Animals* in 1824; *Analysis of the Labors of Cuvier* in 1841; *Buffon, Histoire de ses Idées et de ses Travaux*, in 1844; *Theory of the Formation of the Bones* (1847); *Course of Comparative Physiology* (1854), etc. Became peer of France 1846, and grand officer of the Legion of Honor Aug. 11, 1859. D. at Montgeron, near Paris, Dec. 6, 1867.

Flower [M. Eng. *flour*, from O. Fr. *flour*, *flur*, *flor* > Fr. *fleur* < Lat. *flos*, *flo'ris*, flower]: the aggregation of reproductive organs and accessory parts in the highest division of the vegetable kingdom (Anthophytes). In its derivation it is a shoot in which the stem is short, while the leaves have undergone more or less modification for special reproductive purposes. Thus there are usually one or more whorls of green or colored leaves (the *perianth*), which may often be distinguished into an outer whorl (the *calyx*, composed of *sepals* commonly of a green color) and an inner whorl (the *corolla*, composed of *petals*, commonly white, red, yellow, blue, etc.). Within or above the calyx and corolla are found one or more whorls of slender pollen-bearing leaves (the *stamens*), and within or above these one or more seed-bearing leaves (the *pistils*). In the simpler flowers these parts are all present in the order given, and are separate from one another (Fig. 1, A). There are, however, many modifications of this simple type. On the one hand, the parts become more and more united (Fig. 1, B to F), while at the same time they may become more irregular as to size and shape, and every part may exhibit a wide departure in size, shape, and texture from the original type. On the other hand, there have been considerable modifications, by the omission of one or more parts, sometimes resulting in a reduction to a single organ, as in the willows, where some flowers have been reduced to a pistil only.

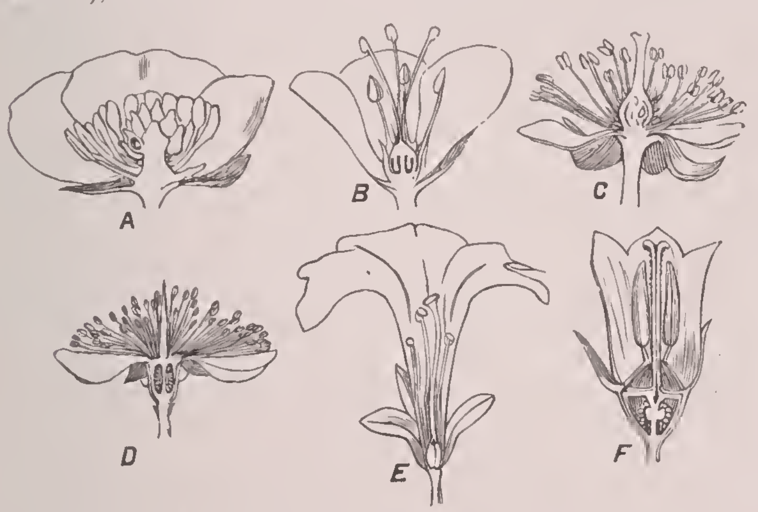


Fig. 1.—A, crowfoot; B, flax; C, linden; D, myrtle; E, petunia; F, bellwort.

In the stamen two parts can generally be distinguished—viz., the stalk (called the *filament*), and the pollen-sacs (*anthers*) at its summit. The anther is usually two-celled (sometimes one-celled), and at maturity contains a quantity of minute rounded cells, the *pollen*.

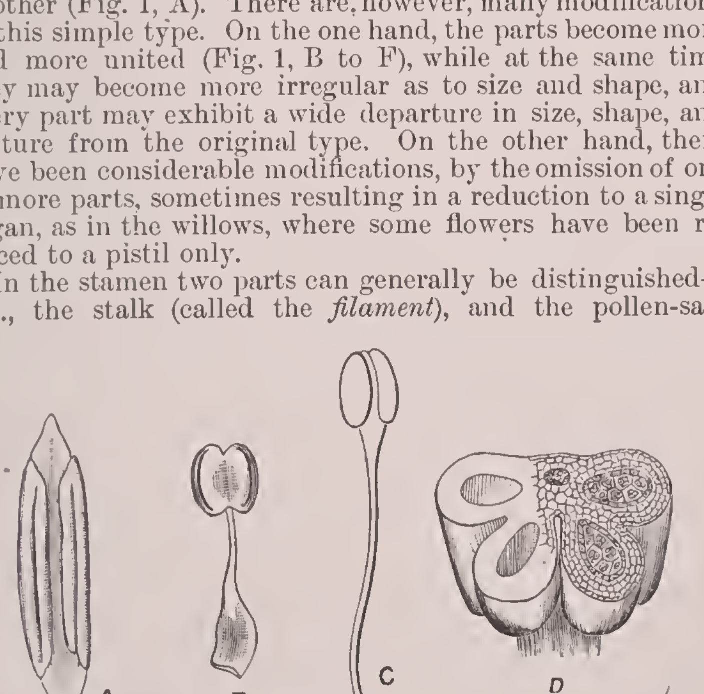

Fig. 2.—A, stamen of magnolia; B, aconite; C, anemone; D, cross-section of a young anther.

The pistil generally consists of three parts—viz., the lower, enlarged part, the *ovary*, containing the young seeds (*ovules*), a slender and often elongated stalk-like projection (*style*) usually from the upper part of the ovary, which bears the *stigma* upon its summit (Fig. 3). The pistil is a folded leaf, with the ovules normally growing from its margins. When two or more pistils grow together, the result is a compound pistil (Fig. 3, B).

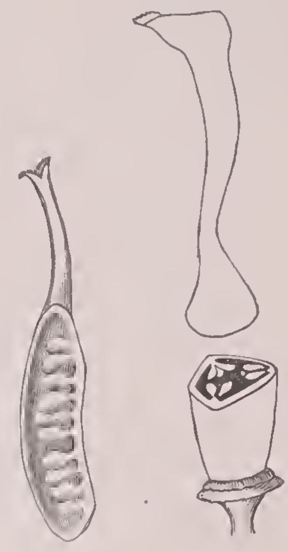

Fig. 3.—A, longitudinal section of a simple pistil of aconite; B, cross-section of a compound pistil of violet.

The purpose of the flower in the economy of the plant is the production of new plants, or, what amounts to the same thing, the production of perfect seeds. Every detail as to form, color, odor, honey-secretion, etc., has to do with this prime object. While the only parts which are directly engaged in the production of new plants are the stamens and pistils, yet the part played by the petals and sepals is often of equal importance. In order that a new plant may be produced, the protoplasmic contents of a pollen-cell must unite with an egg-cell in the ovule. This can be accomplished only when the pollen-cell has been placed upon the stigma, where it is able to germinate into a long tube which, penetrating the style, finally reaches the egg-cell of the ovule where the two protoplasms unite. See Embryology (in plants), and Physiology (of plants). The placing of the pollen upon the stigma (pollination) is thus a matter of the greatest importance, and accordingly flowers have many devices intended to insure its performance. Not only is pollination all-important, but it is almost equally necessary that it should be done in a particular way; thus it is usually better that the pollen should come from another plant, or at least from another flower, than from the same plant or the same flower. To tell how the winds, insects, and birds are made the agents for carrying the pollen from flower to flower; how color, odor, and honey serve as baits or lures; how special forms of calyx, corolla, stamens, and pistils, all take part in this work, would exceed the limits of this article.

For a full discussion of this subject, the reader is referred to Charles Darwin's *The Various Contrivances by which Orchids are Fertilized by Insects*; *Different Forms of Flowers on Plants of the Same Species*; *Effects of Cross and Self-Fertilization in the Vegetable Kingdom*; Asa Gray's *How Plants Behave*; and Hermann Müller's *Fertilization of Flowers* (which includes a list of 825 papers and books treating of pollination). See also Embryology (in plants) and Flowers, Colors of. Charles E. Bessey.

Flower, Roswell Pettibone, LL. D.: banker; b. in Theresa, Jefferson co., N. Y., Aug. 7, 1835. In early life he worked on a farm, in a brick-yard, and in a country store; after taking a course in the Theresa high school became a teacher; engaged in the jewelry and brokerage business in Watertown, N. Y.; and since 1869 had been in the banking business in New York city. He was elected to Congress, to fill the unexpired term of Levi P. Morton, resigned to become U. S. minister to France in 1881; was re-elected for a full term in 1882; was a Democratic candidate for the nomination for Governor of New York in 1882; declined the nomination for Lieutenant-Governor in 1885; was appointed one of the electric subway commissioners of New York city in 1886; was re-elected to Congress in 1888 and 1890; and was elected Governor in 1891. He received the degree of LL. D. from St. Lawrence University in 1893. D. in Eastport, Long Island, May 12, 1899.

Flower, Sir William Henry, K. C. B., F. R. S., D. C. L.: anatomist; b. at Stratford-on-Avon, England, Nov. 30, 1831; educated at University College, London; assistant surgeon Sixty-third Regiment in Crimean war 1854–55; assistant surgeon and Demonstrator of Anatomy, Middlesex Hospital, London, 1858–61; conservator of the Museum of the Royal College of Surgeons of England 1861-86; Hunterian Professor of Comparative Anatomy and Physiology 1870–86; president of the section of anatomy at the International Medical Congress held in London in 1881; president of the Anthropological Society 1883–85; director of the natural history departments of the British Museum since 1885; president of the Zoölogical Society of London since 1879; president of the British Association for the Advancement of Science 1889; president of the Museums Association. Author of *Diagrams of the Nerves of the Human Body* (1861; 2d ed. 1872); *Introduction to the Osteology of Mammalia* (3d ed. 1885); *Fashion in Deformity* (1881); *Introduction to the Study of Mammals, Living and Extinct* (with R. Lydekker, 1891); *The Horse, a Study in Natural History* (1892); *Catalogue of the Osteological Specimens in the Museum of the Royal College of Surgeons* (1886); and numerous memoirs and lectures on anatomical, zoölogical, and anthropological subjects in the transactions of various societies and journals. D. in London, July 2, 1899. C. H. THURBER.

Flower de Luce: See FLEUR DE LIS.

Flowers, Artificial: imitations of natural flowers and foliage formed from various materials, and used for personal adornment or for decorative purposes. This art or branch of manufacture is of very old date. Flowers and leaves of painted linen have been found in tombs at Thebes, and the Egyptians also invented flowers of horn shavings stained in various colors. The Chinese have made artificial flowers of the pith of a kind of bamboo from very remote times. Crassus was the first in Rome who had them made of real gold and silver. During the Middle Ages they were much used, not only in the Roman Catholic Church and with a symbolical signification, but also at secular festivals and merely as ornaments. They were generally made of paper, satin, silk, metal, and wax, and the most celebrated were made in Italy. But in 1728 Seguin, a botanist and chemist, began the manufacture in Paris, employing parchment for the flowers and bristles of the wild-boar for the stems, and his imitations were so successful as to arouse the jealousy of the painters. From this time the manufacture steadily increased and developed in France, which still stands at the head of this kind of industry. The French wholesale houses engaged in this business have each some special branch. Thus one makes only roses; another, wild flowers; a third, leaves. The work-people earn from two to six francs a day according to their skill. Of the money received by the Parisian manufacturers, three-fifths are paid to the work-people, one-fifth covers incidental expenses, and one-fifth defrays the whole cost of materials. Artificial flower-making was introduced into Great Britain during the French Revolution of 1790 by refugees, who employed the art as a means of subsistence.

The principal tools used by artificial florists are *stamps*, a kind of knives of various sizes and shapes, by means of which leaves and petals are cut out very rapidly. The material to be shaped is laid, folded several times, upon a leaden table, and the stamp is driven through it with a hammer. This part of the work is done by men. Stamps (or, as they are often called, *irons*) were invented in Switzerland at the beginning of the eighteenth century. Leaves and petals had previously been cut out with scissors. *Goffering-irons* of different kinds, the commonest being a ball of polished iron fastened to a handle, are used to hollow the petals. *Molds* called *veiners* are, as the name indicates, employed to vein the leaves. *Burnishers* of glass or agate give the petals the polished appearance of most real flowers. Many other tools exist, but their use has greatly diminished. The florist's fingers, guided by skill and taste, are found better than any mechanical appliance. The best flowers are carefully painted by hand. Harvard University possesses a unique collection of flowers, made entirely of glass, illustrating chiefly the flora of the U. S. See *Dictionnaire Universel du XIX^e Siècle*, Larousse, art. *Fleurs Artificielles*, and *Art of Making Paper Flowers*, by Mrs. Bartlett (New York).

Flowers, Colors of: although the coloring principles contained in many of the most important vegetable dyestuffs have been isolated and their composition and chemical relations clearly established, as in the case of madder-root, Brazil-wood, logwood, quercitron bark, indigo, weld, archil, etc., and some of them, as the alizarin of madder, have been produced artificially, the colors of flowers have, with few exceptions, thus far resisted all attempts at isolation. This is perhaps partly owing to their fleeting character and the changes which they so readily undergo. The colors of flowers often change spontaneously during the life of the flower. The flowers of *Myosotis versicolor*, the common garden weed forget-me-not, open with a yellow tint, but soon change to blue. The *Cheiranthus mutabilis* opens yellow, then changes to orange, red, and finally to purple. Some flowers even change color during the day. Garden phlox is blue in the early morning and pink in the middle of the day. *Hibiscus variabilis*, which is white in the morning, is pink at noon and bright red toward night. The colors of flowers are very sensitive to chemical reagents. The petals of the purple or violet dahlia are reddened by acids, the purple being restored by alkalies, but changed to green by an excess of alkali; a red rose is bleached by sulphurous acid, but the color is restored by dilute sulphuric acid.

Many flowers contain more than one coloring-matter. The petals of the safflower yield a yellow color to water and a red principle to alkalies. The orange-colored *Tropæolum majus* yield a purple coloring-matter to boiling water, becoming yellow; boiling alcohol then extracts a purple substance. When the purple is absent the flowers are yellow; when present they exhibit various shades of brown. The flowers of the brown *Calceolaria* yield two similar colors under like treatment.

In but few cases have the coloring-matters of flowers been isolated and their nature determined with any certainty. The coloring-matter of the saffron crocus (*Crocus sativus*) has been isolated, though not in a pure state. It is known as *polychroite*, and is supposed by Roehleder to be identical with *crocin*, $C_{58}H_{86}O_{31}$, the coloring principle of Chinese yellow berries. (See SAFFRON.) The red coloring principle of the safflower (*Carthamus tinctorius*) is a very important dye. (See SAFFLOWER.) It is called *carthamin*, $C_{14}H_{16}O_7$. The blue and red pigments of flowers are generally soluble in water, while the yellow matters are often resinous, and dissolve only in alcohol and ether. They are generally very fugitive, and consequently of little value in dyeing.

Floy, JAMES, D. D.: preacher and author; b. in New York, Aug. 20, 1806; studied for a time in Columbia College and afterward in London; became a preacher in the Methodist Episcopal Church in 1833; preached in New York, Brooklyn, N. Y., New Haven, Conn., etc.; edited *The National Magazine* and *Good News*; edited the works of Stephen Olin, and served on the "committee on versions" of the American Bible Society. *Old Testament Characters*, *Guide to the Orchard and Fruit-garden*, etc., were from his pen. He was prominent as an anti-slavery leader. D. in New York, Oct. 14, 1863.

Floyd, JOHN: U. S. general; b. in Beaufort, S. C., Oct. 3, 1769; removed to Georgia in 1791; was brigadier-general of the Georgia militia Aug., 1813, to Mar., 1814; commanded at the battle with the Creek Indians at Autossee, Ala., Nov. 29, 1813, and at the battle at Camp Defiance, Ala., Jan. 27, 1814. Was often in the State Legislature; M. C. in 1827–29; and also major-general of the State militia. D. in Camden co., Ga., June 24, 1839.

Floyd, JOHN BUCHANAN: statesman and soldier; b. in Montgomery (now Pulaski) co., Va., 1805; graduated at South Carolina College 1826; studied and practiced law; removed to Helena, Ark., 1836, returning to Virginia in 1839; member of Congress from Washington co., Va., 1847–49; Governor of Virginia 1850–53; took an active part in favor of the nomination and election of James Buchanan as President, by whom he was appointed Secretary of War Mar., 1857. During his term of office he used his power in dispersing the U. S. army to distant and not easily accessible parts of the country, in transferring arms and ammunition to Southern arsenals, and generally in preparing for the conflict which it now appears he must have been aware was impending between the North and the South. On the secession of South Carolina he became a zealous sympathizer with the secession movement, opposed the reenforcement of the forts and troops in Charleston Harbor, and upon President Buchanan's refusing to withdraw the U. S. forces from that harbor resigned his office. He was indicted by the grand jury of the District of Columbia as being privy to the withdrawal of a large amount of bonds from the Department of the Interior, but having left Washington was never brought to trial. Was appointed brigadier-general in the Confederate army, and commanded in 1861 in Western Virginia. His operations there were unsuccessful, and severely commented upon by the Virginia press. He was subsequently transferred to Kentucky, and at Fort Donelson commanded a brigade, being senior officer, but abdicated his command and withdrew, the night previous to the surrender, with Gen. Pillow and some 5,000 men. He afterward held several unimportant commands. D. at Abingdon, Va., Aug. 26, 1863.

Floyd, William: b. in Brookhaven, Suffolk co., L. I., Dec. 17, 1734; was in the Continental Congress 1774-83, and signed the Declaration of Independence; was again in Congress 1789-91; was a presidential elector 1800, 1804, 1820, and was a prominent State legislator. He served actively in the Revolutionary war 1775-83, in which he lost much property. At the close of the war he was appointed major-general of militia. In 1803 he removed to Weston, Oneida co., N. Y., where he died Aug. 4, 1821.

Floyer, Sir John: physician; b. at Hinters, in Staffordshire, England, in 1649. He studied medicine at Oxford, and practiced as a physician at Lichfield. It was he who sent Dr. Johnson, when a child, to be touched by Queen Anne for the king's evil (1714), and he was the author of a number of more or less curious writings, including *The Sibylline Oracles, Translated from the Best Greek Copies and Compared with the Sacred Prophecies* (1713). D. at Lichfield, Feb. 1, 1734. Dr. Johnson speaks highly of his learning and piety.

Fludd, Robert (in Lat. *Robertus de Fluctibus*), "The Searcher": an English Rosicrucian and alchemist; b. at Bearstead, Kent, in 1574; entered St. John's College, Oxford, in 1591; studied five years on the Continent; took his medical degree at Oxford 1605. He was a famous physician, and the author of numerous obscure Latin works, theosophical, philosophical, and mathematical, but his enigmatical style prevents the intelligent study of his works. His doctrine was a refined dualism; his writings have only an historic value. Kepler, Gassendi, and P. Mersenne were his adversaries. D. in London, Sept. 8, 1637.

Flüe, flü'e, Niklaus, von, generally known under the name of **Brother Klaus**: patriot and hermit; b. at Flüeli, in the canton of Unterwalden, Switzerland, Mar. 21, 1417. He was a man of great practical energy and ability, the father of a household consisting of ten children, and he took active part in the business of the community to which he belonged. But the deepest instinct of his nature was asceticism, and on Oct. 16, 1467, he retired to a lonesome place among the Alps, where he built a cell and spent the rest of his life as a hermit. Thousands of pilgrims visited him; miraculous powers were ascribed to him, and for twenty years he exercised a wide influence by his exhortations and warnings. At the diet of Stans (1481) he saved the confederation from civil war, and brought about an agreement which formed the foundation of the Swiss constitution for 300 years. D. in his hermit's cell at Ranft, near his native place, Mar. 21, 1487. After his death his countrymen made great exertions to have him canonized, but in spite of subscriptions, heavy taxes, etc., it proved impossible to raise the sum which Clement IX. demanded for a canonization; the canton of Unterwalden had to content itself with a beatification. See his *Life* by J. Ming (Lucerne, 3 vols., 1861-71).

Flue: See Chimney.

Flüelen, flü'e-len, or **Flühlen**, flü'len: village of Switzerland; in the canton of Uri; on the southern arm of Lake Lucerne; 2 miles N. of Altorf (see map of Switzerland, ref. 4-G). Here is a chapel which was erected in 1388 to the memory of William Tell, and is annually visited by a large number of persons in Ascension week. According to one version of the old Swiss legend, the chapel is situated on the very spot where William Tell jumped to the shore, thrusting the boat, with the crew and Gessler, back into the surf. There are, however, as is well known, other points along the shore for which the same claim is made, and, as it would seem, on equally good authority.

Fluents: See Fluxions.

Flü'gel, Gustav Lebrecht: Orientalist; b. at Bautzen, Germany, Feb. 18, 1802; educated at Leipzig; became the pupil in 1827 of Von Hammar at Vienna. The *Arabic Anthology of Thâalibi* (fugitive poetry), published in 1829, led to his appointment on a scientific mission by the Austrian Government, and for three years he traveled in Hungary, Styria, parts of Germany, and in France. Became professor in the College of Meissen in 1832; resigned 1850; published his *History of the Arabs* in 1833, and an edition of the Koran, and subsequently a concordance of the Koran. In 1835-54 appeared, at the expense of the London Oriental Society, his Latin translation of *The Encyclopædia and Biographic Dictionary of Hadschi-Chalfa*, with commentary. He wrote also *Mani und Seine Lehre* (1862), published Arabic, Turkish, and Persian MSS., and other works. D. at Dresden, July 5, 1870.

Flügel, Johann Gottfried: lexicographer; b. at Barby on the Elbe, Germany, 15 miles from Magdeburg, Nov. 22, 1788; spent ten years in the U. S. (1810-19); was Professor of the English Language in the University of Leipzig 1824-38, when he was appointed U. S. consul at Leipzig, where he died June 24, 1855. He published, besides other works, a *Merchants' Dictionary, in German, English, and French* (3 vols., 1840; 2d ed. 1854), but is best known by his *Complete English-German and German-English Dictionary* (2 vols., 1830), in the last edition of which (1852) he was assisted by his son, Dr. Felix Flügel.

Fluidity: See Fluids.

Fluids [from Fr. *fluide*: Ital. *fluido*, representing Lat. *flu'idus*, fluid, flowing, deriv. of *flu'ere*, flow]: substances in which there is an entire absence of any tendency to resist change of form (in the case of liquids) or change of form or volume (in the case of gases) under the action of applied forces, which characteristic is called fluidity.

Liquids are frequently called "incompressible fluids," but a better criterion by means of which to distinguish a liquid from a gas is the presence of "surface tension" and a surface film.

In point of fact the gaseous and liquid forms approach each other by insensible gradations as a certain critical temperature and pressure are approached (differing widely with the substance experimented upon), until finally they become identical.

A similar continuity of solid and liquid states has been observed under conditions less easily attained. See Carl Barus, *Am. Jour. Science*, vol. xli., p. 325.

The properties of matter in all three states, as regards the effects of forces in producing change of forms, vary widely according to the suddenness of application.

Thus solids, generally rigid, show themselves plastic under the action of forces gradually applied, changing form without rupture. Liquids and even gases, on the other hand, when subjected to sufficiently sudden stress exhibit a property closely allied to rigidity of form. See Gas, Hydrodynamics, and Hydrostatics. E. L. Nichols.

Flukeworms: a common name applied to different members of the Trematode genus *Distomum*, and more especially to the liver fluke (*Distomum hepaticum*) of the sheep. They are, as a rule, flat and oval, smooth, soft, and not jointed, and are mostly hermaphrodite, having sexual organs which constitute a large part of the organism. They pass through the following history: The eggs are laid in the liver, and pass with the gall to the intestine and thence to the exterior. They hatch on the wet grass, producing a small larva which bores into the body of the snail *Lymnæa*. Here it secretes a capsule, and the contents of this break up into so-called spores. These develop into a worm-like embryo, the so-called redia, which possesses a mouth. Inside of the redia are developed other redia, as well as a new tadpole-like larva, the cercaria. These latter escape from the snails, and, crawling about on the grass, are eaten by the sheep. Inside the stomach they are set free from a new capsule they have secreted, and then they bore their way through the tissue to the liver, where they become sexually mature. As will be seen, there is here an alternation of one sexual with two asexual generations, as well as a change in hosts. The presence of these parasites in the liver causes the disease commonly known as "sheep-rot" and "liver-rot," which, fortunately, is rare in the U. S. In 1879-80 it caused the death of over 3,000,000 sheep in the British kingdom. Several varieties of fluke infest the biliary passages in man, especially in Japan. Another form is found in the blood of man and causes hæmaturia. (See Hæmatozoa.) In Japan and China a form of Distoma is found which infests the bronchial tubes, and leads to hæmorrhage from the lungs and chronic cough. For allied forms, see the article Trematoda. J. S. Kingsley.

Flume, The: a cleft between two walls of rock in the Franconia Mountains; in the town of Lincoln, Grafton co., N. H. A small stream flows through it and just below falls over 600 feet in a cascade. The Flume is a favorite resort of tourists in the White Mountain region.

Fluohy'dric (or **Hydrofluor'ic**) **Acid** [derived from *fluorine* and *hydrogen*]: See Fluorine.

Fluor: a less common name of Fluor Spar (*q. v.*).

Fluoresceïn, floo-ō-res'sē-in: See the article PHTHALIC ACID.

Fluorescence [deriv. of Eng. *fluor*, fluorite or fluor-spar, of which fluorescence is a notable property; *fluor* is originally a Lat. word meaning a flowing, flux, applied to fluorite on account of its use as a flux]: an action of certain substances upon light by which they absorb light-energy of shorter period or wave-length and re-emit it in waves of greater length, thus under certain conditions appearing self-luminous with brilliant and various colors.

The simplest and most striking illustration of this action is the following:

On the surface of water in a clear-glass jar let fall a few particles of the coal-tar color known as fluoresceïn. As the particles of this brick-red powder slowly dissolve, root-like filaments of intense green color will descend into the water, soon producing the appearance of a bunch of delicate seaweed. If the vessel is placed between the eye and the source of light, however, these opaque green filaments will appear perfectly transparent and of a reddish-orange color. The reason of these appearances is that the light of shorter wavelength (i. e. the blue and violet and even invisible rays) is absorbed by the solution and re-emitted in longer waves constituting green light, while the light which passes through this solution, being deprived of these shorter waves, has a resultant or residual color-effect of reddish orange.

A few other substances like the above possess this property in such a high degree that it can be exhited in the same simple manner; but there are a great number which require some special arrangement to make it manifest.

One of the simplest of such arrangements is to provide a pencil of light in a dark room, consisting solely of the very short rays, including the blue and violet and yet higher invisible rays of the spectrum. This may be done by reflecting sun-rays into a dark room by means of a "porte lumière," and then passing them through a glass tank filled with a solution of ammonio-sulphate of copper. A large number of substances placed in the path of the faintly visible purple-blue light thus obtained will glow as if on fire, with their peculiar tints. Thus a block or a vessel made of "canary glass" will glow as if it were made of self-luminous emerald; an acid solution of quinine sulphate will gleam with vivid sky-blue; a solution of "chlorophyl" (the green coloring-matter of plants) will show blood-red.

The light of burning magnesium or of the electric arc, similarly filtered through the same solution or through sheets of cobalt glass, will act in like manner. By these means very striking illustrations of fluorescence may be made on the large scale.

A substance, thallene, discovered by the writer (London *Chem. News*, 1872, vol. xxvi., p. 273), especially lends itself to such use. On various occasions screens 20 feet square, made of orange-colored muslin on which were attached designs in paper, coated with thallene, have been used in the largest auditoriums. Illuminated by light from burning magnesium or an electric arc inclosed in a box with a sheet of cobalt glass, such a screen appears as though made of black velvet with designs of self-luminous and vivid color upon it.

Another means of exhibiting fluorescence is furnished by the electric discharge through rarefied gases, which produces light rich in waves of small length. This is availed of in many of the structures known as "Geissler tubes." In these, portions of the tubes through which the electric discharge takes place are made of "canary glass," or are surrounded by jackets of glass which may be filled with fluorescent solutions. When the electric discharge, from an induction coil or from a Holtz machine, is passed through these, we have, in addition to the variously colored light produced by the discharge itself, a great variety of luminous colors, due to the fluorescence of the glass and of the solutions in the jackets.

Fluorescent actions are also developed in many of the experiments made by Dr. William Crookes where he employed the electric discharges from an induction coil in high vacua.

Having thus considered the more obvious and familiar phenomena of fluorescence, we may next take up the history of its discovery and investigation, which will involve some reference to more recondite actions.

The first recorded observation of a definitely fluorescent action is found in the Edinburgh *Philosophical Transactions* for 1833, vol. xii., p. 542, where Sir David Brewster describes some phenomena which are now recognized as belonging to this subject. In volume xvi. of the same journal he describes other appearances, as also in the *Philosophical Magazine*, vol. xxxii., p. 401, 1848. In 1845 Sir John Herschel described the luminous appearance of some solutions of quinine, under the name of "superficial color," or "epipolic diffusion." In none of these papers, however, was the true nature of the action recognized.

In the *Philosophical Transactions* for 1852, part ii., p. 466, appeared a paper by Prof. G. G. Stokes, F. R. S., occupying more than 100 pages, pointing out the true nature and relations of this remarkable action, to which he gave the name fluorescence, because he first observed and studied it in the mineral fluor spar, which possessed this property in a marked degree, although vastly less than other bodies more recently discovered. This research of Prof. Stokes was a model for thoroughness and accuracy, and exhausted the subject as far as the materials and means of research known at that date were concerned.

In 1850 Edmond Becquerel published in the *Annales de Chimie et de Physique*, 3d series, vol. lvii., p. 101, an investigation of a number of substances which he designated as "phosphorescent"; but nearly all of them are the same or similar to those studied by Stokes, and the actions with a few exceptions are simply those of fluorescence, as recognized and defined by Stokes. In his extensive work entitled *La Lumière*, published in 1867–68, Becquerel devotes over 200 pages to the same subject. In the *Comptes Rendus* of Aug. 3, 1872, Becquerel published an abstract of a research on what should be called the fluorescent properties of certain uranic salts, and in the *Ann. de Chim. et de Phys.*, 4th series, vol. xxvii., 539–579, of the same year, the entire memoir. Hagenbach, in the *Ann. Phys. und Chim.*, 1872, vol. cxlvi., pp. 65, 232, 375, and 508, has discussed the fluorescent properties of a great number of substances. (See also *Journal of London Chem. Society*, 2d series, vol. x., p. 1058, and *Lond. Chem. News*, vol. xxvi., p. 173.) He has also published many other papers on the same subject in more recent columns of the *Ann. Phys. und Chim.* Eugen Lommel has also published many papers in the last-named journal, as in vol. cxliii., p. 26, 1871; vol. clix., p. 514, 1876; and new series, vol. x., pp. 449 and 631, 1880.

The writer of this article has also made a number of investigations on the spectra of the fluorescent light emitted by the salts of uranium and by certain products obtained in the destructive distillation of petroleum, and others like them, and also on the absorption spectra of the same substances. These were published during the years 1872–74 in the London *Chemical News*, the American *Chemist*, the *Moniteur Scientifique*, the London *Philosophical Magazine*, and Poggendorff's *Annalen*.

In addition to pointing out the true nature of the fluorescent action, Stokes announced the law (since known by his name) that the wave-length of the light emitted by a fluorescent body was always greater than that of the existing light. This law has been called in question in a few instances by Lommel and some others, but the objections have been met by Hagenbach in what appears to be a satisfactory manner. From this law or mode of action flow curious consequences. Thus light waves too short to affect the eye under ordinary conditions (such as the supra-violet rays of the solar spectrum) falling on a fluorescent body may develop in it visible rays. Thus Stokes, by throwing a solar spectrum on a screen of turmeric paper, canary glass, etc., was able to trace its upper end far beyond the H. H. lines, which are its ordinary visible limit, and to map out many lines in this upper portion otherwise only recognizable by photography. Considerable development was given to this subject later by Stokes (*Phil. Trans.*, 1862, ii., p. 599), when with the light of the electric spark and quartz prisms he produced, on fluorescent screens, spectra five times as long as the ordinary solar spectrum. Again Stokes pointed out that there were usually certain wave-lengths in the exciting light which had greater effect in exciting fluorescence than others. Thus if a solar spectrum is thrown on a screen or surface of fluorescent material, the latter will not be made to emit fluorescent light equally under all parts of the spectrum, but will show bands of maximum brightness which will vary in number and position with the fluorescent substance acted on. Also, as might naturally be expected, those wave-lengths of the exciting light which most powerfully excited fluorescence are the most rapidly absorbed by the fluorescent substance, so that if the light transmitted through such a body is examined by the spectroscope absorption bands or dark spaces will be seen, corresponding in position with the maxima of fluorescence.

Both these actions are well illustrated by applying one of Stokes's methods of observation to a solution of "thallene," a hydrocarbon discovered by the present writer (*Chem. News*, 1876, vol. xxxiv., p. 188). For this purpose a pure solar spectrum is thrown against the vertical side of a square tank containing the solution. This side of the tank is best made of quartz, which has no fluorescence of its own, but in most cases ordinary thin plate-glass will serve very well.

Fig. 1 represents the appearance of such a tank, seen from above and filled to the depth of an inch with the solution named.

The scale and letters below the figure indicate the parts of the spectrum falling on the vertical side or face of the tank.

The green part of the spectrum from E to *b* and beyond excites a faint fluorescent light in the solution, then come rays which have no effect until, at F and above, a powerful fluorescence is excited, giving the bright blade *b* which reaches far into the tank. Then comes a space of no action and again one of maximum effect, producing the blade *c*. Then again a space of no action, until at *G* suddenly begins another maximum gradually fading out to the right.

Looking at the opposite side of the tank, it will be observed that dark blades are located exactly over against the maxima of absorption, and indicate that, looking into the tank from that side, we should see dark bands or spaces corresponding with the maxima of fluorescence on the other side of the tank.

Again, Stokes showed that the fluorescent light, or light emitted by the fluorescent substance, was in many cases composed of a few groups of wave-lengths, so that when viewed through a prism it would exhibit a spectrum made up of bright-colored bands with dark spaces between them. This effect is exhibited in the most decided and beautiful

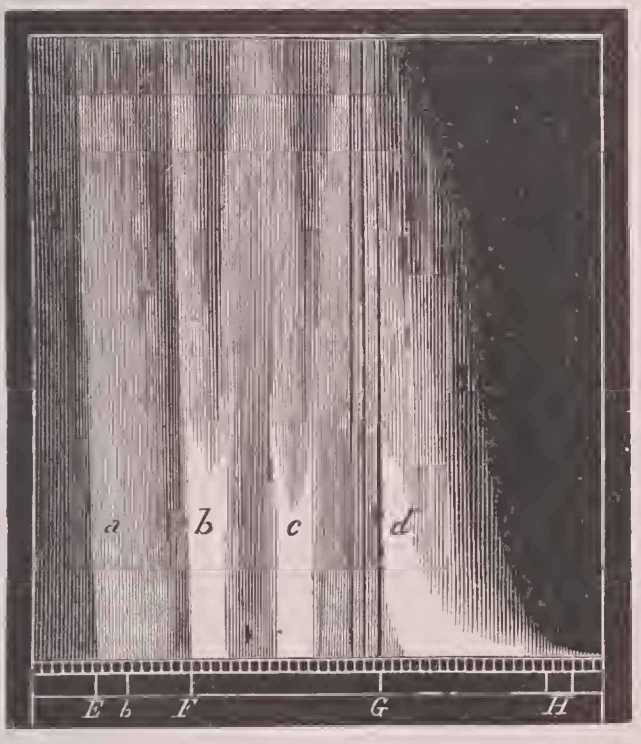

Fig. 1.—Thallene in benzole.

degree by the salts of uranium, and its study has enabled the present writer to discover and distinguish a number of new compounds whose existence would otherwise have been quite unsuspected. For example, if some crystals of the ammonio-uranic sulphate are placed in the path of a pencil of sunlight, concentrated by a lens and deprived of its less refrangible or longer waves by passing through a layer of ammonio-sulphate of copper in a glass tank about a quarter of an inch thick, and the fluorescent light which they emit is examined through a spectroscope, the appearance presented will be that shown in Fig. 2, stripe 1.

There will then be seen a banded spectrum having a band of bright red at C, orange-red at 4, orange between 4 and D, then yellow, yellow-green, blue-green, and blue in the succeeding bands up to F, at the right. The upper edges of all these bands, except the last to the right, are sharply defined, but they shade off gradually on their lower or left-hand edges. If these crystals are gently heated, so as to expel some water, their spectrum will change to that shown in the sec-

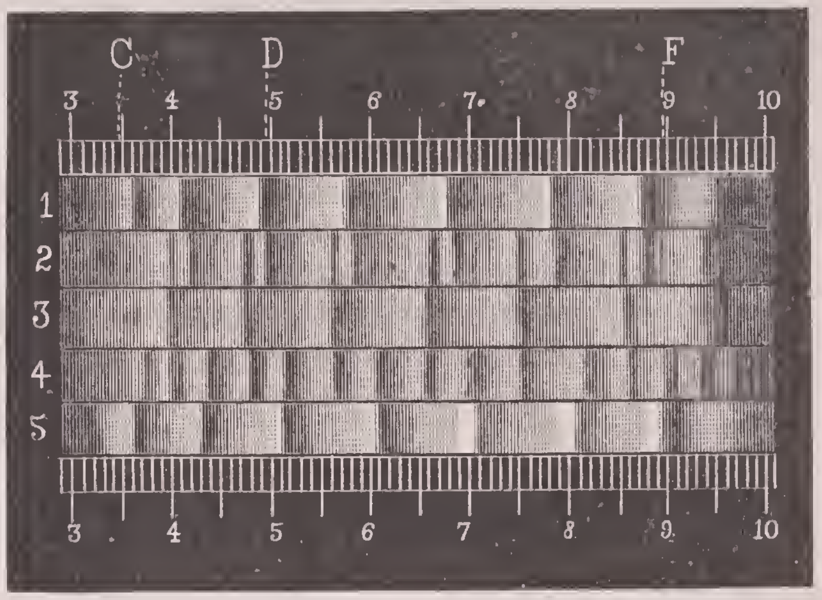

Fig. 2.

ond stripe of Fig. 2, in which it will be noticed that the same spectrum as before is obtained, but with another set of bands superposed or added. If the heating is continued, the first spectrum will grow weaker and the new one stronger, until at last the new one only is left, as is shown in stripe 3 of Fig. 2; after this the same heating will produce no further change.

If, however, the heat is greatly increased, another new spectrum shows itself in combination with the last, as is shown in stripe 4, and by continuing this heat the spectrum shown in stripe 5 remains alone. Analysis shows that the salt whose spectrum appears at 3 is the anhydrous ammonio-

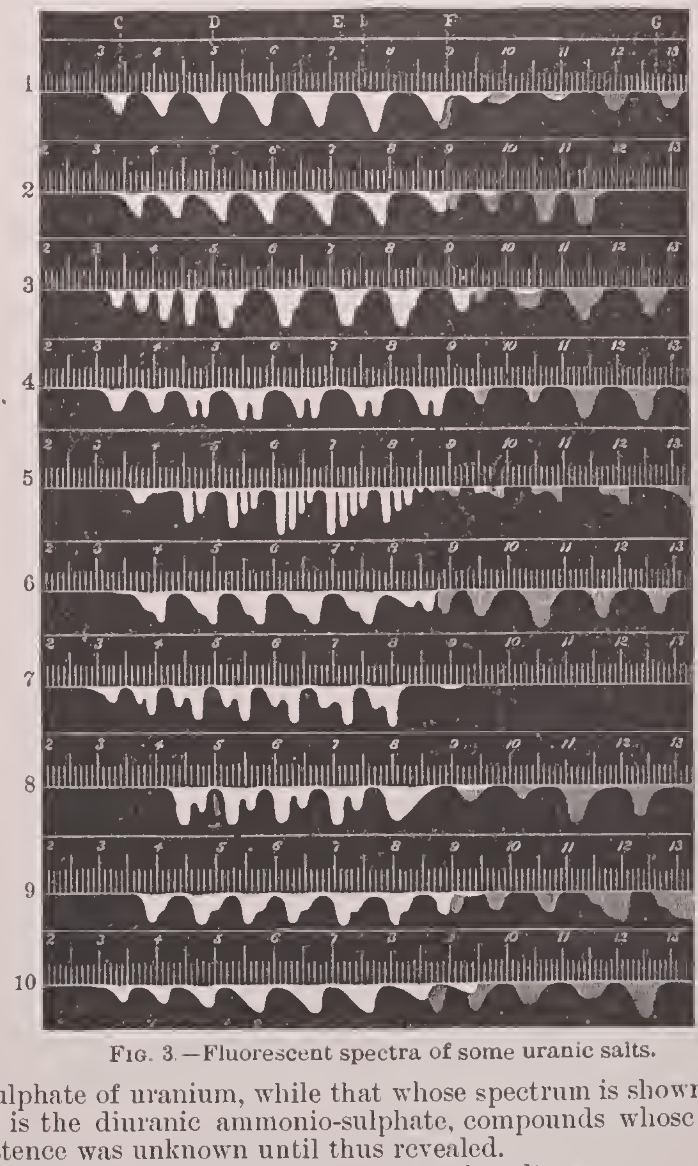

Fig. 3.—Fluorescent spectra of some uranic salts.

sulphate of uranium, while that whose spectrum is shown at 5 is the diuranic ammonio-sulphate, compounds whose existence was unknown until thus revealed.

The fluorescent spectra of the uranic salts are very various and often very beautiful. Fig. 3 is a diagram illustrating a few of them. In this diagram the location of the various bands is indicated by the position of the white spaces in reference to the Bunsen spectroscope scale and the Fraunhoffer lines indicated by their letters.

The depths of the white spaces below the lines indicate their relative brightness, or, in other words, the way in which they shade off, or terminate more or less abruptly. The salts whose spectra are indicated in this chart are the following: No. 1, nitrate of uranium; No. 2, acetate of uranium; No. 3, sodio-acetate of uranium; No. 4, oxychlorides of uranium (mixed); No. 5, potassio-oxychloride of uranium; No. 6, oxyfluoride of uranium; No. 7, bario-oxyfluoride of uranium; No. 8, phosphate of uranium (mixed hydrates); No. 9, calcio-phosphate of uranium; No. 10, ammonio-sulphate of uranium.

The shaded spaces to the right indicate absorption bands not directly concerned in the present subject.

The spectra of more than eighty such salts of uranium have been mapped and studied, and will be found in articles by the present writer in the London *Chemical News* of 1873.

In certain cases, as in that of the double acetates of uranium, there are many salts exactly alike in general constitution, one constituent being acetate of uranium in each case, and the other being the acetate of some other base, as sodium, potassium, lithium, etc. When the fluorescent spectra of these salts are studied it is found that they are all exactly alike as to the number and form of their bands, but that the entire sets of bands are shifted up or down in the spectrum in the several salts. If these salts are now tabulated according to the positions of these bands, the highest being placed first, it will be found that their order is exactly that of their molecular weights. In fact, they act precisely as though the rates of vibration due to the acetate of uranium, which is their only *fluorescent* constituent, were reduced by the "loading" effect of the other acetates in proportion to *their* molecular weights. This is precisely like what would happen if to a series of tuning-forks increasing weights were added from time to time. When a slight weight was added to each, their "pitch" would be a little lowered, and more and more so as the weights were increased.

In all fluorescent liquids and some solids the duration of the fluorescent emission after the exciting light is cut off is inappreciable, but in most solids it has a finite duration varying from a thousandth of a second in some to many minutes in others.

This persistent fluorescence is sometimes distinguished as phosphorescence, and was first systematically studied by Becquerel, and described in the works referred to earlier in this article.

In 1888 E. Wiedemann showed that this prolongation of the fluorescent action could be given to some solutions by solidifying them by combination with gelatin. *Ann. Phys. und Chem.*, new series, vol. xxxiv, p. 446.

To give anything like a complete list of all fluorescent substances would occupy much more space than can be devoted to the present subject, but it will be of interest and value to name a few of those most important in the history of the subject or by reason of their exceptional intensity.

SOLID FLUORESCENT SUBSTANCES.—*Fluor Spar* (fluoride of calcium).—Certain varieties. Fluorescence blue, moderately brilliant. Chiefly of interest because observed by Herschel and Brewster at an early period, and made the basis of the name given to this action by Stokes. *Phil. Trans.*, 1852, part ii., p. 481.

Platino-cyanide of Barium.—This salt in a certain state of hydration and aggregation has a very remarkable power of fluorescence, so that if words or figures are written or drawn on paper of an orange tint with a mixture of this salt and gum-water, and then are viewed in daylight transmitted through cobalt glass, they will shine out with a brilliant green light on the almost black ground furnished by the orange paper, illuminated by the violet-blue light.

Thallene.—A hydrocarbon obtained from the products of the destructive distillation of petroleum. (*Journal of the Franklin Institute*, Philadelphia, 1876, vol. lxxii., p. 225.) This fluoresces with an even more brilliant green light than the foregoing under like conditions.

Canary Glass.—Glass colored of a yellow tint with oxide of uranium. This fluoresces with a brilliant green tint, and is much used in Geissler tubes.

Fluorescent Solutions.—As possessing historic interest because studied by the early investigators may be mentioned:

Solutions in water of quinine acidulated with any acid except hydrochloric. Fluorescence sky-blue. Stokes, *Phil. Trans.*, 1852, ii., pp. 471 and 541.

Solutions in water (alkaline or neutral) of æsculin, from horse-chestnut bark. Violet-blue fluorescence.

Solution in alcohol of chlorophyll, the green coloring-matter of leaves. Fluorescence blood-red.

Solution in alcohol of bichloranthracene. Fluorescence purple-blue.

Solution in water or alcohol of extract of stramonium seeds. Fluorescence green.

Of more recent discovery and remarkable brilliance:

Solution in water of bisulphobichloranthracenic acid. Violet-blue fluorescence. See Perkin, London *Chem. News*, 1870, vol. xxii., p. 37.

Solution in alcohol of magdala red. Crimson fluorescence. Schiendl, *Ann. Phys. und. Chem.* (1869, vol. cxcii., p. 503); Hofmann, *Ber. d. Chem. Ges.* (vol. ii., pp. 374, 412.

Solution in water of eosin (alkaline salt of fluoresceïn). Intense grass-green fluorescence. Bayer (*Ber. d. Chem. Ges.*, 1871, vol. iv., p. 558, and 1874, vol. vii., p. 1211); Hofmann (*Ber. d. Chem. Ges.*, 1875, vol. viii., p. 62); and Bayer, same journal and volume, p. 146.

Solution in alcohol of azoresorufin. Scarlet-red fluorescence. Weselsky, *Ann. Chem. und Pharm.*, vol. clxii., p. 274.

Solution in alcohol of resorcin-blue garnet. Garnet-red fluorescence, indigo-blue by transmitted light. Brunner and Kraemer, *Ber. d. Chem. Ges.*, 1884, vol. xvii., p. 1863.

Solution in alcohol of chinolin red. Red fluorescence. Hofmann, *Ber. d. Chem. Ges.*, 1887, vol. xx., p. 4.

Iodine vapor is stated by E. Lommel to fluoresce orange-yellow, when excited by green rays about E. *Phil. Mag.*, 1883, 5th series, vol. xvi., p. 463. HENRY MORTON.

Fluoride of Aluminium and Sodium: See CRYOLITE and GLASS.

Fluoride of Calcium: See FLUOR SPAR.

Fluorine [from Mod. Lat. *fluorina*, deriv. of *fluor*, fluor spar, in which fluorine is found]: a nonmetallic element belonging to the group which includes chlorine, bromine, and iodine. It occurs abundantly in fluor spar, which is a fluoride of calcium; in cryolite (fluoride of aluminium and sodium), topaz, mica, amphibole, chondrodite, tourmaline, apatite, and numerous other minerals. It is very generally diffused, occurring in all rocks in small quantities. It is also found in almost all waters in minute quantities; in plants, especially in grasses and *Equisetaceæ*; and in animals in the bones, teeth, brain (*Horsford*), blood, urine, milk, etc. The name fluorine is derived from fluor spar, from *fluo*, to "flow," because this mineral has long been used as a flux.

As early as 1670 Schwankhardt, of Nuremberg, observed that glass could be etched by fluor spar and sulphuric acid. Scheele in 1771 referred this action to a peculiar acid liberated by the sulphuric acid. Fluorides are readily decomposed by chlorine, yielding chlorides. Fluorine is undoubtedly set free at the same time, but as it enters into combination with the material of almost every vessel that can be used to collect it, its isolation becomes a matter of great difficulty. Souyot (*Comptes Rendus*, xxii., 960) decomposed fluoride of silver by chlorine or iodine in a vessel of fluor spar, and obtained a colorless gas which did not bleach vegetable colors, but which decomposed water and attacked most metals. Frémy (*Comptes Rendus*, xxxviii., 393; xl., 966), by decomposing fused chloride of potassium by the voltaic current, obtained a gas having similar properties. He also obtained a gas which corroded glass by the action of chlorine and of oxygen, on red-hot fluor spar. H. Reinsch (*N. Jahrb. Pharm.*, xi., 1), by heating a mixture of cryolite, plumbic peroxide, and acid potassic sulphate, obtained a colorless gas consisting largely of oxygen, but containing another gas possessing a pungent odor, like that of nitrous acid, which he supposed to be fluorine. Kämmerer (*J. pr. Ch.*, lxxxv., 452), by heating iodine with fluoride of silver, obtained a colorless gas which did not attack glass, could be collected over mercury, and was rapidly absorbed by potassic hydrate. In 1886 Moissan described experiments by which he had succeeded in isolating fluorine. The method employed by him consists in passing an electric current through anhydrous hydrofluoric acid, containing a little acid potassium fluoride, HF. KF, in solution. The decomposition is effected in a vessel made of an alloy of iridium and platinum. Hydrogen is given off at the negative pole and fluorine at the positive pole.

Fluorine is a light greenish-yellow gas of a penetrating and disagreeable odor. It is the most active of all the elements at ordinary temperatures. It acts upon almost all substances. Thus it decomposes water, yielding ozone and hydrofluoric acid; it combines with hydrogen at the ordinary temperature; and it also combines with sulphur, phosphorus, iron, etc., but it does not act upon platinum. The atomic weight of fluorine is 19, its symbol F.

The detection of fluorine is effected by decomposing the supposed fluoride with sulphuric acid in a vessel of lead or platinum, and allowing the hydrofluoric acid liberated to act upon glass, which is etched or roughened by it.

Hydrofluoric Acid, HF.—When sulphuric acid is poured upon a fluoride, as, for example, fluor spar, hydrofluoric acid is given off as a colorless gas. The reaction between sulphuric acid and fluor spar is represented by the equation:

$$\underset{\text{Fluor spar, or calcium fluoride.}}{CaF_2} + H_2SO_4 = \underset{\text{Calcium sulphate.}}{CaSO_4} + \underset{\text{Hydrofluoric acid.}}{2HF.}$$

The acid is liquid below 67° F. It acts upon glass, and is used for the purpose of etching on glass. It acts upon the skin, causing swelling and violent pains. Inhaled it is extremely poisonous.

Revised by IRA REMSEN.

Fluorite: See FLUOR SPAR.

Fluor'otype [*fluor*ine + *-type*, from Gr. τύπος, stroke, mark, impression]: See PHOTOGRAPHY.

Fluor-spar, **Fluor**, or **Fluorite** [from Lat. *fluor*, flux, deriv. of *flu'ere*, flow, in allusion to its use as a flux in metallurgical operations]: a mineral composed of fluoride of calcium (F48·7 per cent., Ca51·3 per cent.). It crystallizes in the monometric system (in cubes, octahedra, etc.), and has a perfect octahedral cleavage. Its hardness is 4 (see HARDNESS), and its specific gravity 3·18. It occurs frequently very perfectly crystallized, and of beautiful and bright colors; pulverized, it becomes below a red heat brilliantly phosphorescent. It is sometimes carved into ornaments, and is used in the arts as a source of hydrofluoric acid for etching, and, as above stated, as a flux. See the article FLUORESCENCE.

Flushing [Dutch *Vlissingen*]: a strongly fortified seaport of the Netherlands; in the province of Zealand (see map of Holland and Belgium, ref. 8–C); on the island of Walcheren, at the mouth of the Western Scheldt. In connection with the ports of Rammekens and Breskens it commands the entrance of the Scheldt. Its harbor, accessible to vessels of the largest size, is one of the safest and most commodious ports of the European continent; there are extensive dockyards and a floating dock. Flushing is connected with Queenborough in England by a daily line of steamers. The principal exports are wheat, beans, fish, and cattle; the principal imports, coal from England, and coffee, tea, and tin from Java; the principal manufactures, oil and soap. Pop. (1891) 13,500.

Flushing: formerly a village; now part of the borough of Queens, New York city; Queens co., N. Y. (for location of county, see map of New York, ref. 8–K); situated at the head of Flushing Bay. It has several institutions of learning, an asylum for infants, extensive tool-works, dye-works, electric lights, gas-works, water-works, and a street railway connecting with College Point. Gardening, the nursery business, and fruit-raising are leading pursuits. Pop. (1880) 6,683; (1890) 8,463. EDITOR OF "JOURNAL."

Flustra: a genus of marine polyzoans, the species of which have the semi-common name "sea-mat."

Flute [M. Eng. *floute*, *floite*, from O. Fr. *flaüte*, *flahute* (> Fr. *flûte*), from deriv. of Lat. *flatus*, blowing]: a tubular wind instrument of very ancient origin. It is used in every part of the world, and has always had two principal forms. One of these is held straight before the performer, who blows into the end of the tube; the other is closed at one end, is held sideways, and is blown into through a lateral hole. This latter has been known as the German flute; from the former the flageolet has been derived. The German flute alone has been found worthy of orchestral and solo use. Modern flute-players easily command a compass of three octaves, beginning with  as the lowest tone. Since about 1830 the flute has undergone many changes and improvements; more than any other instrument. The bore has been altered and the fingering, number, and disposition of the keys have been entirely changed according to the system of Boehm. DUDLEY BUCK.

Flux [from Lat. *fluxus*, flow, flowing, deriv. of *flu'ere*, *fluxum*, flow]: a substance or mixture used to promote the fusion of bodies. Limestone is the usual flux for ores of iron in the blast furnace; it unites with the alumina and silica of the ore, forming a fusible slag. To flux silica and silicates, alkaline or basic fluxes are selected, as carbonate of soda or potassa, litharge, lime, or carbonate of lime; fluor spar is very effective. For lime, alumina, oxide of iron, etc., acid fluxes are selected, as borax, silica, glass, etc. Niter and litharge are both oxidizing agents and fluxes, while cyanide of potassium is a reducing agent as well as a flux; it frees metals, such as lead, from sulphur and from oxygen. *White flux* is a mixture of carbonate, nitrite, and nitrate of potassa, prepared by projecting a mixture of equal parts of niter and argol or crude cream of tartar into a hot crucible in successive small portions. It is an oxidizing flux. *Black flux* is prepared of the same materials and in the same manner as white flux, but the quantity of argol employed is double that of the niter. As this proportion of niter is not sufficient completely to oxidize the carbon of the argol, the mixture contains only carbonate of potassa and carbon. It consequently reduces metallic oxides by the union of the carbon with the oxygen. *Morveau's reducing flux* is composed of 16 parts of window-glass, 2 of calcined borax, and 1 of charcoal. *Flux for colored flames* before the blowpipe.—To enable the lithium, sodium, potassium, strontium, copper, etc., contained in minerals to color the blowpipe flame, Poole recommends a flux composed of 1 part of fluor spar and 2 parts of sulphate of lime (selenite). *Deflagrating fluxes*, for decomposing silicates, are very convenient in qualitative analysis, as they enable the student to do without the platinum crucible. For the detection of alkalies a flux composed of nitrate of baryta and charcoal is prepared. This is mixed with the finely pulverized mineral, placed on a plate of sheet iron, and fired with a match. On treating the residue with water a solution will be obtained which can be tested as usual for potassa and soda. For the detection of other bases a flux composed of carbonate of soda, nitrate of soda, and charcoal is employed; the residue, after deflagration, being treated with hydrochloric acid, evaporated to dryness to render the silica insoluble, moistened with hydrochloric acid dissolved in water, filtered, and tested for bases as usual. This flux may also be used for the decomposition of insoluble sulphates of barium and strontium. On treating the residue after deflagration with cold water, and filtering, the sulphuric acid will be found in the filtrate, and the bases on the filter as carbonates.

Fluxions [from Lat. *flu'xio*, a flowing, deriv. of *flu'ere*, *fluxum*, flow]: an old term for the differential and integral calculus, the term fluxion being applied to Sir Isaac Newton's conception of the differential or derivative which occurs in the calculus. From this point of view, a variable quantity is considered as one which is constantly growing, or being generated, as a line is generated by the motion of a point. That portion of the quantity or line which has been generated up to a certain time is called a *fluent* (deriv. of Lat. *fluere*, flow) or *genitum* (deriv. of Lat. *genere*, beget), while the rate at which it is being generated at any moment, or the infinitesimal element generated in an infinitesimal period of time, is called a *fluxion*. Thus a "genitum" corresponds to what is now called an integral, and a fluxion to a differential or derivative.

The idea of fluxions is frequently introduced in teaching beginners the calculus, and affords one of the best illustrations of its principles. But it should not be forgotten that it is only an example of an application of the calculus, and quite distinct from a differential. The modern conception of the subject, founded on the theory of limits and infinitesimals, though hard to acquire, is really simpler than the conception of a fluxion. S. NEWCOMB.

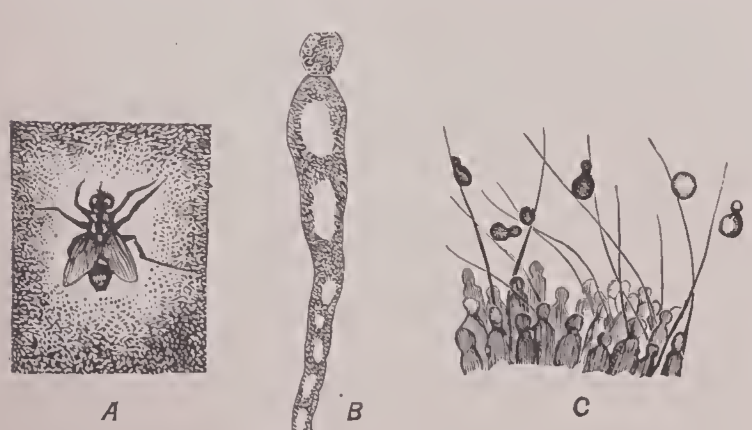
Fly [M. Eng. *flie*, *flege* < O. Eng. *flȳge*, *flēoge* : O. H. Germ. *flioga* > Germ. *Fliege*]: any one of the two-winged insects of the order DIPTERA (*q. v.*). The common house-flies (most of which belong to the species *Musca domestica*) lay their eggs in horse-manure, and hence proximity to a stable is apt to produce an abundance of these nuisances. The flesh-fly, or blow-fly, *Sarcophaga carnaria*, lays its eggs in meat of all kinds. The horse-flies belong to the genus *Tabanus*, the bot-flies to *Œstrus* and *Hippobosca*. The Hessian fly is not a true fly, but a hemipterous insect. Many species of flies are to be regarded as beneficial, as they act as scavengers and remove much noisome matter. See ENTOMOLOGY. J. S. K.

Fly-catchers: a name applied at first to birds of the genus *Muscicapa*, but now applied to a large number of American birds, none of which are of the above genus. They are assigned to the *Tyrannidæ* and other families of the order Passeres. They are distributed in many genera. These birds all have the habit of waiting until insects come near

The king of the fly-catchers.

them, when they dart upon them with wonderful quickness. The king-bird, *Tyrannus carolinensis*, is one of the best known in the U. S. The Savannah fly-catcher, *Milvulus savanna*, is found in the Southern U. S. The most common bird of the family in Europe is the so-called spotted or gray fly-catcher, which is a common summer visitant over the whole Continent and Great Britain.

Fly Fungus: a parasitic plant (*Empusa muscæ*) which attacks domestic flies and often destroys great numbers of them, especially in the autumn (Figure A). It is a plant of quite simple organization, and is apparently related to the black moulds (*Mucoraceæ*) in the order Conjugatæ of the class *Chlorophyceæ*. It is now included, along with a number of related species (forty or more), in the family *Entomophthoraceæ*. The fly fungus consists of short, tubular threads (Figure B) which grow through the tissues of the insect, and at length push through its skin, where small termi-



Fly-fungus: A, dead fly surrounded by spores; B, spore-bearing thread; C, portion of fly with protruding spore-bearing threads.

nal spores are produced by abstriction (Figure C). Just at the time when this happens the fly fastens itself securely to some object, swells up, and dies. In a short time the spores fall and surround the insect with a white halo-like powder (Figure A). Resting spores formed by conjugation were discovered by Dr. Winter, but they have rarely been seen by other observers. In some related species, as, for example, in the grasshopper fungus (*E. calopteni*), resting spores are very numerous. CHARLES E. BESSEY.

Flygare, ÉMILIE: See CARLÉN, EMILIE.

Flying [deriv. of verb *fly* < M. Eng. *flien*, *fleyen*, *flegen* < O. Eng. *flēogan*: Goth. *flaug-* in *us-flaugjan*, make fly away: O. H. Germ. *fliogan* > Mod. Germ. *fliegen* < Teuton. *fliugan*]: the motion of a living animal through the air when propelled by its own wings. Among vertebrates, most birds and all the bats possess, and the pterodactyl and some other fossil reptiles once possessed, the power of flight. It is probable that flying fishes also have a limited power of true flight, the pectoral fins serving as wings. Many insects also have the power of flying, but their wings, though functionally analogous, are not structurally homologous to those of vertebrates. In the latter the wing is the representative of the arm and hand or anterior limb of other vertebrates. The so-called flight of the flying squirrels, flying dragons, etc., is by no means a true flight. The parachutes (not wings) of these animals enable them to glide safely through the air, simply prolonging the leap of the creature, or at most joining to a parachute-action that of a sail or a kite.

The *mechanics* of flying are not yet well understood. In some birds the shape of the quills is such that at the stroke of the wing the greatest possible surface is opposed to the air; while in the *recovery*, or expansion of the wing, the edge of the quill-feather is opposed to the air. Bats are thought to fold the wing partially during the recovery, and the same may be true of some insects, and even birds. The more rapid closure of the wing also secures a greater resistance from the air during the stroke than can be offered during the expansion of the wing.

There are many varieties of flight among birds; of these among the most remarkable is the sailing motion, in which the wings are but slightly moved. There is considerable doubt as to the means by which such birds as the condor and albatross can maintain their long and almost motionless poise in the air.

Flying Buttress: See BUTTRESS.

Flying Dragon, or **Flying Lizard**: a name applied to lizards belonging to the genus *Draco* and closely allied genera of the family *Agamidæ*, in which the ribs are elongated and exserted, supporting lateral expansions of membrane which serve the animals as parachutes. The type of the group is *Draco volans* of the Indian Archipelago. The term flying dragon, in addition to its mythological application, has sometimes been applied to the extinct *Pterodactylus*.

Flying Fishes: fishes of the genus *Exocœtus* living in large schools in the open sea. They will "fly" a distance of from a few rods up to about an eighth of a mile, rarely rising more than 4 feet from the water. Their movements in the water are extremely rapid. The sole source of motive power is the action of the strong tail when in the water. No force is acquired when the fish is in the air, but when it rises from the water the movements of the tail are continued until the whole body is out of the water. When the tail is in motion the pectorals seem to be in a state of rapid vibration, but this is apparent only, and is due to the resistance of the air to the movements of the fish. While the tail is in the water the ventral fins are folded. When the action of the tail ceases the ventrals are spread and held open. They are not used as wings, but rather as parachutes. When the fish begins to fall the tail touches the water, when its motion again begins, and with it the apparent movement of the pectorals. The fish is thus able to resume its flight, which it finally finishes with a splash. When in the air it resembles a large dragon-fly. The motion is very swift—at first in a straight line, but later deflected in a curve. It has no relation to the direction of the wind. When a vessel is passing through a school of these fishes they spring up before it, flying in all directions like grasshoppers in a meadow. About thirty species of flying fishes are known, ten of them being found in the North Atlantic. The largest species, *Exocœtus californicus*, of the California flying fish, reaches a length of 18 inches; the others range from 6 inches to a foot. All are excellent food-fishes. DAVID S. JORDAN.

Flying Fox: a name sometimes given to the *Galæopithecus* (see FLYING LEMURS), but more frequently applied to the fox-bats, or large fruit-eating bats of the genus *Pteropus*.

Flying Gur'nard: See DACTYLOPTERUS.

Flying Lemurs, or **Colugos**: a name often applied to two curious insectivorous mammals, *Galæopithecus volans* and *G. philippensis*; characterized by a thin membrane extending from the fore to the hind legs, and thence to the tip of the tail. When fully extended this membrane forms so effectual a parachute that the animals can pass over distances of 200 feet, with a descent of about 50. They are nocturnal in habit, and, like bats, sleep hanging head downward. They inhabit the forests of the Malay Peninsula, Borneo, Sumatra, and the Philippine islands. See INSECTIVORA. F. A. LUCAS.

Flying-machines: machines and apparatus employed by man in the navigation of the air, and distinguished from balloons by the fact that they depend for support solely upon their own efforts, precisely as birds do. Since the article on the general subject of AËRONAUTICS (*q. v.*) was written progress of notable extent has been made in the construction of flying-machines. The basis of this advance is the work of inventors like Hargreaves and Maxim and Liliendahl, and the scientific researches of Langley and others. The inventors have established the fact of the possibility of constructing steam-engines and other forms of motor weighing from 3 to 5 or 6 lb. per horse-power, and the latter have proved the practicability of securing ample supporting power at high speeds by the action of the aëroplane alone, with no greater impelling power than is required for the forward motion of the machine. Flying has now been actually accomplished by both Maxim and Langley, and a soaring flight, without other impulsion than that given at the start by running or by drifting downward for some distance, has been effected very successfully by Liliendahl.

The question of the possibility of artificial flight by means of flying-machines has been seen to have long ago become settled affirmatively. Langley's and Maxim's experiments prove that the resistance to forward motion with well-shaped forms is insignificant. The former has shown conclusively that ample supporting power at high speeds may be obtained with aëroplanes, and that, within what are regarded as practical limits, the power demanded for impulsion is lower at the higher than at the lower speeds. It has been well settled that the power demanded, as a maximum, is about 1 horse-power for 25 lb. weight, and it is known that birds, within these limits, can usually carry 50 per cent. of their own weight as load. It is further shown by both Maxim and Langley that it is perfectly practicable to build steam-machinery weighing but a fraction of the limiting weight for any stated power and on a scale, in the case of Maxim's machine, of several hundred horse-power. Hargreaves has made fourteen model flying-machines which actually fly, and over distances of several hundred yards. Maxim, July 31, 1894, flew about 100 yards, and was stopped by the springing of his guide-arms. Langley's machine flew 900 feet, Dec. 13, 1894. Liliendahl's soaring flight has attained 1,500 feet.

Liliendahl's apparatus is simply a set of wings and a tail fitted to the person, and manipulated in such manner as to take advantage of the supporting power of the atmosphere acting on aëroplanes, while retaining, for considerable distances, an initially imparted velocity.

Maxim's machine consists of a framework of seamless steel tubes of varying sizes, connected with a square frame of white cloth, 50 feet by 50 feet at the top, and all starting from and neatly connected with an inclined wooden platform, built of narrow strips of wood—very strong, but very light. The platform measures 8 feet wide by 40 feet long. The large cloth frame is the aëroplane. There is also an aëroplane above the platform and ten additional side aëroplanes or wings, five on either side, and yet another, which surmounts the entire structure. The area of the main aëroplane is 2,874 sq. feet; of the small one, 126 feet; and of the bottom of the car or platform, 140 feet. With the rudders and wings added the total area is about 6,000 sq. feet.

Rudders and wings, like all the other aëroplanes, are made of a specially woven cotton-cloth, so fine in texture that it is impossible to blow through it, and mounted on a strong but extremely light framework of hollow steel tubes. All these aëroplanes are inclined at the angle which gives the most support, combined with the least resistance, to forward motion.

The screws are 17 ft. 11 in. in length, 5 feet wide at the ends, and 22 inches at the waist. They are made of American yellow pine, covered with canvas, and are painted a pale blue, the paint having been sandpapered to perfect smoothness, and in order to reduce the skin fraction to a point at which it becomes negligible. There are two compound steam-engines, weighing, with their steam-generator, approximately 1,960 lb., and capable of developing 300 horse-power. A compound engine has been constructed, the high-pressure cylinders of which are 5 inches in diameter, with a 12-inch stroke. The low pressure is 8 inches in diameter, with a 12-inch stroke. The piston speed is 800 feet per minute.

The boiler is inclosed in a house 8 feet long, 8 feet wide at the base, and 6 feet high. The sides of this house are made of asbestos-cloth, and the frame and top of thin iron. There are 7,600 naphtha gas-burners, which can be instantly ignited or extinguished, or increased from a tiny glimmer to full flame. The boiler has 600 tubes which are 8 feet long, and 200 tubes which are 4 ft. 10 in. long. These tubes are $\frac{1}{2}$ inch external diameter, and $\frac{1}{2}$ mm. or $\frac{1}{50}$ inch in thickness. They are curved and joined to a steam-drum 10 inches in diameter and 8 feet long, where the water and steam are separated, the water again passing through the boiler and the steam passing to the engine. There are also some 300 or 400 smaller tubes constituting a feed-water heater. In order to prevent the tubes from being injured by the great heat of the fire, a forced circulation is employed. The boiler is designed for a pressure of 410 lb. to the square inch; the engine, at 325 lb., has developed 300 brake horse-power. The machine carries 600 lb. of water and 200 lb. of naphtha. The consumption of naphtha is about 1 lb. per horse-power per hour.

This machine, on July 31, 1894, rose from the earth, carrying its inventor and two assistants, and flew 300 feet or more, and, as the first instance of actual flight by man, this will undoubtedly be forever recorded among the remarkable dates of chronology. The construction of the steam-engine, of the boiler, and of the flying-machine itself, will each be reckoned as wonderful triumphs of the inventor. The speed attained on the occasion referred to above was about 50 miles an hour. The lifting power of the machine was about 5 tons. Were the machinery of the largest contemporary steamship constructed of similar proportions of weight to power, it would generate more than ten times as much power as at present—about 350,000 horse-power.

Prof. Langley's first attempt at flight was made, successfully, on the afternoon of Dec. 8, 1894. The machine is an aëroplane driven by screw propellers and impelled by a small steam-engine of marvelous lightness and power. The machine is 12 feet in length and 8 feet wide, and has two sets of wings, the forward and main pair of about double the spread of the after set. The hull of this air-ship is made largely of aluminium; it is 4 feet in length, 2 feet wide, and weighs 2 lb. The aëroplane wings are made of a very light, strong, and stiff framing, covered with thin but strong cloth.

An air-ship constructed by Count Zeppelin made several successful ascents in 1900, the most notable being at Friedrichshafen on Oct. 21, when for several hours the machine was successfully manipulated in a heavy wind.

Flying Phalan'ger [from Fr. *phalanger*, deriv. of *phalange*, phalanx, viâ Lat. from Gr. φάλαγξ]: any one of several marsupials of Australia and the neighboring islands. They are surprisingly like the flying squirrels in appearance and habits, and are, in fact, the marsupial representatives of those squirrels. The species are rather numerous. The largest, the *Petaurus flaviventer*, is 20 inches long, and its tail measures 18 inches. The smallest, *Acrobates pygmæus* is 2 inches long, and its tail is of the same length.

Flying Squid: a name given to the cephalopods of the genus *Ommastrephes*, of which there are many species known, varying in length from an inch to 4 feet. They have the power of leaping from the water, whence the name. They are preyed upon by sperm-whales, birds, and fishes, and are largely employed as bait by fishermen.

Flying Squirrel: any animal of the genus *Sciuropterus* (family *Sciuridæ*), characterized by a hairy expansion of the skin between the fore and hind limbs by which the animal is enabled to glide from tree to tree in very prolonged leaps. The tail also aids to support it in the air. The common species of the U. S. is *S. volucella*.

Flynn, EDMUND JAMES: See the Appendix.

Fly-wheel: a balance-wheel; a heavy wheel carried on the main shaft of a steam-engine, or attached to other machinery, for the purpose of securing a steady motion where the power and the load are not in precise equilibrium at all times. It insures the comparatively slow variation of speed about a mean value which is usually that proposed for the regular working of the machine. In the steam-engine the variations of energy acting on the wheel, and absorbed or given out by it, come in part from the varying effort of the steam in the cylinder, in part from the varying turning power of the piston acting on the crank and its shaft, and in part from variations of the load driven by the engine. The latter is called an external variation of load; the others are internal. In its operation the varying speed determines the energy stored in the revolving rim of the wheel, and the variations in the magnitude of this energy, $\frac{WV^2}{2g}$, measure and balance the differences between the power exerted by the engine at the given instant and the work absorbed by the load. In a cotton-mill the variations in these differences of effort and resistance are due to internal variations of effort; in a rolling-mill they are consequent upon the rapid and great variations in the resistance of the rolls.

R. H. Thurston.

Fo, or **Foh**, also **Fo-to** [Chinese < older Chinese *Bod*, from Sanskr. *Buddha*]: the Chinese equivalent of Buddha (*q. v.*). Hence Buddhism as it exists in China is sometimes called *Fohism*, and the votaries of Buddhism *Fohists*.

Focus [Lat., hearth, fireplace]: a point at which rays of light meet after deviation by a lens or mirror.

Focus of a Conic Section.—A point on the principal axis through which a double ordinate to that axis is equal to the parameter. The ellipse and hyperbola have each two foci, and the parabola has one. In all the conic sections the foci possess the remarkable property that they are the only points in the plane of the curve from which the distance to any point of the curve can be expressed rationally in terms of the abscissa of that point. The name *foci* was given to these points from the property that rays of light proceeding from one focus and reflected from the curve pass through the other focus. In the *ellipse* rays of light from one focus reflected from the curve pass directly through the other focus; in the *hyperbola* rays of light from one focus reflected from the curve take such directions that on being produced backward they will pass through the other focus; in the *parabola* a second focus on the principal axis at an indefinite distance may be supposed, in which case rays from either focus reflected by the curve will go to the other focus. In the last case rays from the second focus are parallel to the principal axis, and after reflection they go to the first focus; rays from the first focus are parallel to the principal axis after reflection. If either of these curves is revolved about its principal axis, it will generate a surface of revolution whose foci are identical with those of the generating curve. Rays of light from either focus of such a surface will be reflected from the surface in accordance with the laws already explained.

Focus of a Lens or Mirror.—The point from which rays of light proceed before being deviated by a lens or mirror is called a *radiant* point: if the rays converge before deviation they must be produced beyond the lens to meet, and this point of meeting is called a *virtual radiant*. The point at which the rays meet after deviation is called a *focus*; if the deviated rays diverge after deviation they must be produced backward to meet, and this point of meeting is called a *virtual focus*. The radiant point and focus are reciprocal; that is, if the focus be taken as a radiant, the radiant will become the focus. Any two points so related with respect to a lens or mirror are called *conjugate foci*. The *principal focus* of a lens or mirror is the focus that corresponds to rays parallel to the axis. In this case the radiant point is on the axis at an indefinite distance. Rays proceeding from the principal focus are so deviated as to be parallel to this axis. In this case the focus is on the axis at an indefinite distance. In all cases the conjugate foci are on a line through the optical center of the lens or mirror.

Fodder: See Forage.

Fœtus [Lat. *fētus*, *fœtus*, the bringing forth, offspring, fruit, connected with *fēcundus*, fruitful, *fētu'ra*, generation, *fēnus*, interest, and probably from I.-E. root *dhēi̯-*, *dhē-*, suck, suckle, repr. in *fēmina*, θῆλυς, etc.]: the name given to the young of viviparous animals during the greater part of their existence before birth. The intra-uterine life of the human product of conception is divided into three epochs: the stage of the *ovum*, of the *embryo*, and of the *fœtus*.

To the stage of the *ovum* belong the *first two weeks* of existence, including the period from the moment of conception to the formation of the rudiments of the future being. The details of this *blastodermic stage*, as it is also frequently termed, for man are largely conjectural, founded upon the observations upon the lower animals, since the youngest well-authenticated human ovum examined was already probably twelve days old.

The *embryo* stage embraces from the second to the close of the fourth week, the period of greatest developmental activity, during which the principal organs are established and the provisional division effected by transient embryonal structures, as the somites, visceral arches, etc. (see Embryology), is replaced by the permanent differentiation resulting in the definite form of the fœtus.

The transition of the embryo into the fœtus occurs gradually, and, although the demarkation is somewhat arbitrary and conventional, it may be assumed to take place when the embryo reaches a length of between 13 and 16 mm., or at about the beginning of the fifth week. Before this period the appearance of the human embryo is insufficient to distinguish it with certainty from similarly advanced embryos of other mammals; after attaining a length of 16 mm., on the contrary, the distinctly human features are so pronounced that the recognition of the embryo as that of man is no longer uncertain.

While for the accurate descriptions of the anatomist adherence to the foregoing stages is desirable, for general purposes it is unnecessary, and the term fœtus will here be employed as denoting the young animal without strict regard to its embryonal and fœtal stages. The early stages of the ovum and the fundamental embryological processes having been described in the article Embryology, a consideration of the *external characteristics* of the human fœtus will here claim attention.

In its earliest stages the human fœtus is only slightly bent. At the end of fifteen to twenty days the head comprises the expanded *brain-vesicles* and the imperfectly formed series of *visceral arches*; the heart appears as a sigmoid tube, and the widely open gut is in free communication with the large umbilical vesicle.

Very soon (by the twenty-third day) the embryo becomes markedly flexed, so that its cephalic and caudal extremities are brought into contact. The completion of the visceral arches and the appearance of limb-buds also mark this stage. Toward the end of the fourth week the head, which meanwhile has assumed conspicuous proportions, becomes less acutely bent, and shows indications of the beginning of the return to the more erect position which later follows. Coincidently with these changes the eye and the ear become more prominent, the external portions of the auditory apparatus appearing as the persistent first visceral cleft, the remaining furrows gradually disappearing.

By the fourth week the extremities, which very early appear as flattened projections, are well advanced, the separation of the upper limb into the arm, the forearm, and the hand, with an indication of the division into fingers, having been established. The upper extremity first develops, and consequently anticipates in its differentiation the lower limb; the formation of the fingers and toes is not completed until about the ninth week.

The series of visceral arches mentioned play an important *rôle* in the development of the face, since by the growth and specialization of these structures the boundaries of the nasal and oral cavities are largely formed. In man four pairs of these arches exist; the first becomes partially cleft into the upper or *maxillary* and the lower or *mandibular* division; union and fusion of the lower projections contribute the tissues from which the inferior boundary of the mouth is derived, the upper border being formed by the union of the superior divisions of the arches with a central nasal process. When the fusion of these parts is imperfect, the originally distinct processes remain separated by a fissure of greater or less extent; this defect constitutes harelip, which may be single or double according to the extent of the faulty union.

In the early embryo immediately in front of the lower visceral arches lies a conspicuous and tortuous projection, due to the underlying primitive heart; somewhat later, by the fourth week, the cardiac elevation has been completely overshadowed by the distension of abdominal walls, caused by the relatively excessive size of the fœtal liver, which at this period occupies a large portion of the entire body-cavity.

After the third month the fœtus is developmentally complete, the increase in its general bulk resulting from the growth and perfecting of the parts, which by this time have been established, and not by the addition of new structures. The rate of growth is very rapid during the third, fourth, fifth, and especially sixth months, the weight of the fœtus within this time increasing over a hundredfold. While the size and weight of the healthy fœtus are liable to considerable variation, the table given herewith represents, according to Hecker, the average weight of the fœtus:

Third month,	11 grammes.		Seventh month,	1,218 grammes.	
Fourth "	57	"	Eighth "	1,569	"
Fifth "	284	"	Ninth "	1,971	"
Sixth "	634	"			

The *nutrition* of the fœtus during the earlier weeks is carried on by the absorption of nutritive tissue-juices derived from the surrounding structures; by the end of the third month the respiration and nutrition of the fœtus are provided for by the formation of the *placenta* (see EMBRYOLOGY), by means of which the blood of the fœtus is brought into intimate relation, but not actual contact, with the maternal circulation, thus affording the opportunity for interchange and absorption.

The placenta is the organ for the purification of the blood before birth, and is connected with the body of the fœtus by means of the important *umbilical blood-vessels*, the two arteries, and the single vein. The arteries return the venous current from the fœtus to the placenta, and the umbilical vein carries the freshly oxygenated blood back to the fœtus. The renewed blood passes first to the liver, and after traversing this organ is emptied into the great *inferior caval vein*, which in time pours its blood-stream (composed of blood returned from the lower half of the body as well as from the liver) into the right auricle of the heart. Notwithstanding the large size of the liver, this organ during the later months of gestation is unable to receive the entire volume of blood returned from the placenta by the umbilical vein; in consequence, it becomes necessary to establish an additional path by which the excess of blood may reach the vena cava on its journey to the fœtal heart; relief is afforded by the formation of a new blood-channel, the *ductus venosus*, which extends between the umbilical vein and the inferior caval vein; through this canal a large part of the blood brought by the umbilical vein from the placenta is directly carried into the venous current returning from the lower half of the body.

The *fœtal circulation* is characterized by peculiarities in the course of the blood-current rendered possible by the existence of passages which disappear shortly after birth. One of these channels, the *ductus venosus*, has already been mentioned; another exists as an opening (the *foramen ovale*) in the interauricular partition of the heart through which the blood-current brought by the inferior cava and guided by the *Eustachian valve* passes directly from the right into the left auricle. Again, the limited capacity of the unexpanded fœtal lungs is unequal to the reception of the entire blood-stream carried by the pulmonary artery, a condition necessitating the establishment of an additional means of carrying off the excess; this is provided for by the *ductus arteriosus*, a short cut placed between the pulmonary artery and the descending aorta, by means of which channel most of the blood forced from the right ventricle finds passage into the descending current distributed by the aorta to the lower half of the body. Before passing into the lower limbs the blood-stream is divided, a large part entering the *hypogastric arteries* (the direct intrafœtal continuations of the *umbilical arteries*) and returning to the placenta, while the remaining smaller part supplies the lower limbs. It will be seen from the foregoing that, after leaving the liver, at no point within the circulation of the fœtus is the blood-current composed of strictly arterial blood, but that the various organs are supplied by blood more or less contaminated with that already in use.

After birth, with the cessation of the placental circulation and the establishment of pulmonic respiration, the blood-current is limited to the paths definitely followed throughout life, the temporary channels afforded by the ductus venosus, the foramen ovale, the ductus arteriosus, and the hypogastric arteries becoming obliterated, and remaining during life as atrophic structures.

The contractions of the fœtal heart are more frequent than those of the child after birth, from 135 to 145 beats per minute on the average taking place. While by no means always so, yet the heart-beats are usually more frequent when the fœtus is of the female sex. This fact has been utilized in predicting the sex of the fœtus; in about 66 per cent. of cases where the contractions number less than 135 per minute the fœtus proves to be male, while about an equal proportion prove to be female when the pulsations exceed 145 per minute.

During intra-uterine life the sustenance of the fœtus is carried on by the nutritive materials absorbed from the maternal blood; the digestive glands consequently remain imperfectly developed until called into functional activity by the ingestion of food. Secretion and excretion are carried on by the cutaneous glands and the kidneys, as evidenced by the sebaceous material covering the surface of the fœtus and the urine; the latter is first collected within the allantois, and later, together with the contents of the digestive canal, expelled into the amniotic fluid, by which the fœtus is surrounded during the later months of its sojourn within the uterus. At the time of birth the fœtus possesses an average length of from 20 to 21 inches and an average weight of about 7 lb. For the details of the processes connected with the early formation of the embryo and fœtus see EMBRYOLOGY. G. A. PIERSOL.

Foggia, fod′jăă: town of Southern Italy; capital of province of same name (see map of Italy, ref. 6-G); 75 miles by rail N. W. of Bari; the seat of a bishopric. It is a beautiful city, situated in the rich plain of Apulia, of which it is the commercial center. A celebrated fair is held here annually May 9-20. Pop. (1895) 45,700.

Fog-horn: See FOG-SIGNALS.

Fo′go: a port of entry of Newfoundland, and capital of Fogo island district; 122 miles N. W. of St. John's. Lat. of Fogo Cape, 49° 41′ N., lon. 54° W. It has important fisheries and considerable trade. Pop. 800.

Fogo, or **Fuego**, fwā′gō: one of the CAPE VERDE ISLANDS (*q. v.*); consists of a single volcanic cone rising 9,157 feet above the sea, and surrounded at the base with a steep wall of immense lava-blocks. Area, 171 sq. miles. The soil is extremely fertile, and produces grain, wine, fruits, and tobacco of the very first quality. But, besides suffering occasionally from the eruptions of the volcano, that in 1847 being very destructive, the island lacks water, and the droughts are sometimes so prolonged as to cause famine, during which thousands of the inhabitants are starved to death. Before 1834 the population numbered about 17,000, but in the three dry years it sank to 5,600, and it has risen very slowly since, becoming 16,004 in 1885.

Fogs [of Scandin. origin; cf. Dan. *fog*, drift, spray, shower, storm; Icel. *fok*, spray, drift]: clouds at the surface of the earth. They are produced by the condensation of the vapor of the atmosphere into liquid particles of extreme minuteness. De Saussure thought these particles were vesicles, and not solid globules, and that their suspension in the atmosphere was due to the rarefaction of the air within them, caused by the radiant heat absorbed from the sun. But later meteorologists do not subscribe to this hypothesis—first, because it is impossible to conceive of any operation of nature by which such hollow globules could be formed; and, secondly, the formation of the rainbow is in strict accordance with the laws of the refraction of light from solid globules. Furthermore, Plateau of Ghent has shown by a very ingenious experiment that the particles of fog do not contain air. For this purpose he filled a glass tube, closed at one end, with col l water; then gradually inverted it with such precaution that the water was sustained in the tube by the pressure of the atmosphere. Under the mouth of this tube was placed a rising column of steam or visible vapor, which was condensed by the surface of cold water with which it came in contact. The contractile power of the bubbles would in this case eject any air which might be contained in them into the column of water, where its presence would in due time be made manifest, especially by the aid of a magnifying-glass. No air was found by this experiment. The suspension of the cloud is due to the extreme fineness of the globules, and also perhaps slightly in the daytime to the higher temperature of the air which surrounds them. The rising of a fog from the surface of the earth is evidently due to the latter cause, when the source of vapor is cut off. A fog is produced when a gentle current of warm air surcharged with moisture passes over a colder surface, as is the case especially on the lower Mississippi river during the prevalence of a warm southerly wind in the early spring. At this season of the year the water of the lower river, having come from a northern latitude, is much colder than the air above it, and hence a precipitation of the vapor takes place.

A fog, however, is not produced in absolutely still air even when resting on a colder surface. In order to this effect it is necessary that two strata of air be mingled with each other, one of which, being the colder, precipitates on itself, as it were, the particles of invisible vapor of the other. This fact is illustrated by the phenomenon of dew, in which atmospheric vapor is condensed into water without producing fog. In this instance the process may be conceived as follows: An indefinitely thin stratum of air resting directly upon a surface cooled by radiation deposits its moisture, leaving it unsaturated; the vapor of the stratum immediately above it is then diffused into the first stratum; the second is then unsaturated, and diffusion takes place into this from the third stratum, and so on, without the production of a fog. If, however, the radiation takes place into a clear sky from a sloping surface of ground, the colder and consequently heavier air resting on such surface will roll down into the valley, and there, mingling with the warmer saturated air, produce a fog. A fog is also produced when a current of cold air passes over warmer water or a warm damp soil. Water evaporates at all temperatures, and in the case just mentioned the vapor as it rises is condensed into visible fog. But the density of fogs produced in this way is not usually as great as that which is generated by the other process.

The eastern coast of the U. S. is especially subject to fogs, the cause of which will be readily seen, from what has been before mentioned, when the relative position of the currents on the western side of the Atlantic Ocean is considered. First, a cold polar current coming out of Baffin's Bay is thrown by the revolution of the earth laterally against the coast of North America from Labrador to Cape Hatteras, where it passes under the Gulf Stream. Contiguous to, but outside of, this current, and moving in an opposite direction, is the great Gulf Stream, an immense body of warm water, which throughout its whole course across the Atlantic heats and saturates with vapor the air immediately over it. Now, it must be evident that whenever the wind is in such a direction as to blow this warm and saturated air across the cold surface of the polar current, mingling the heated and moist air with the colder stratum, a fog must be the result. Hence the fogs on the Banks of Newfoundland, and also along the coast of Maine, whenever the wind is in a southerly direction, especially in the warm summer months. In proceeding southerly along the coast the direction of fog-bearing wind is found to be more and more easterly. Fogs are also produced on the western coast of North America when the wind from the exterior ocean passes across the coast current which comes from the N. The production of fog is in this case more complex, since the coast current is in fact the eastern portion of the great Gulf Stream of the Pacific. The northern part of this current is warmer than the surrounding ocean, while in its southern portion its temperature is less than that of the water through which it is passing. But in either case a fog will be produced when a wind of opposite temperature blows from the exterior ocean across this current. On the same principle fogs are produced in other parts of the world; and their existence may be inferred from the relative position of the cold and warm currents of the ocean. Fogs are sometimes associated with smoke in the atmosphere; minute particles of carbon radiating heat tend to become colder than the surrounding air, and thus condense the particles of vapors around them. London and other cities of England are frequently covered with fogs of this kind. See FOG-SIGNALS.

Fog-signals: signals made in foggy weather to prevent collisions or other accidents to vessels or railway trains. Along the eastern coast of the U. S. fogs prevail almost continuously at certain periods of the year; and as the shore is exceedingly precipitous the sounding-line can not be used with any certainty, and therefore fog-signals must be resorted to. Attempts have been made in France and Great Britain to penetrate fogs by means of lights of intense character, such as those of aluminium and electricity; but that these could not be successful must be evident from the consideration of everyday experience, that a mile of cloud —or, in other words, of fog—shuts out the image of the sun. Recourse must therefore be had to sound, which, when of a powerful character, is not materially affected in its propagation by fog.

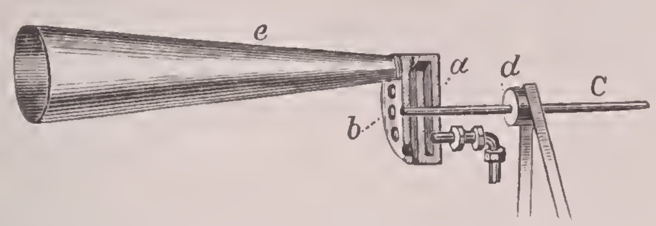
For the production of sound for this purpose bells, gongs, whistles, trumpets, and sirens have been used by the lighthouse board of the U. S. Although a powerful sound may be produced by a cannon, the shortness of its continuance and the blending of the echo with the original impulse render it less favorable to the precise determination of its direction than the prolonged sound produced by the trumpet or the whistle. Bells, even of a large size, give too feeble a sound to be distinguished across the breakers at a sufficient distance or in opposition to the wind; they are only used when a signal is required to give warning of danger at a short distance at intermediate positions. They are rung by a weight wound up at intervals, the descent of which is regulated by the vibration of a pendulum with clock escapement. In some cases an automatic apparatus actuated by the waves of the sea has been used for ringing a bell, but this device has not found favor with the U. S. lighthouse board, since every automatic instrument is liable to get out of order, and so fail to point out the direction of danger at a time when it is expected to do so. Uninterrupted action is a fundamental principle of lighthouse signals.

Gongs, although they appear to produce a powerful sound when near the ear, in reality give an impulse of too feeble a character to be heard under all circumstances at a distance.

The mechanisms which have been found to produce sound of the greatest penetrating power are those which depend upon the principle of resonance, such as the organ-pipe, the trumpet, and the whistle, in which the air itself becomes the sounding body, as well as the medium of conduction of the sound. Of this character is the ordinary locomotive whistle, in which the vibration is produced by a thin sheet of air striking against the edge of a resounding cavity called the bell. The stiffness—if the expression may be used—of the sheet of air depends upon the tension of the steam in the boiler; and in order that the vibration of this sheet may be in unison with the reverberation of the air in the resounding cavity, the sheet must be increased and diminished in length; which is effected by a screw, the turning of which increases or diminishes the distance between the narrow opening through which the sheet is emitted and the lower edge of the bell-shaped cavity. As the loud sound is produced in this instrument by the vibrations of the air in the resounding cavities, the form or material of the inclosure of the latter has little effect upon the result. Instead of the metallic cylinder, a square wooden box may be used, the orifice through which the sheet is ejected being made to correspond in form. The locomotive whistle is the simplest of the more powerful of the fog-signals employed by the lighthouse board of the U. S. It is actuated by an ordinary locomotive steam-boiler at a pressure of from 50 to 75 lb. per sq. inch. The sound is distinguished from that of locomotives and steam-vessels by the length of the blast and the interval between two soundings; and these are regulated and produced automatically by a small engine attached to the boiler, which opens and closes the valves, letting on and shutting off the steam at the proper intervals. The whistles employed are from 8 to 12 inches in diameter.

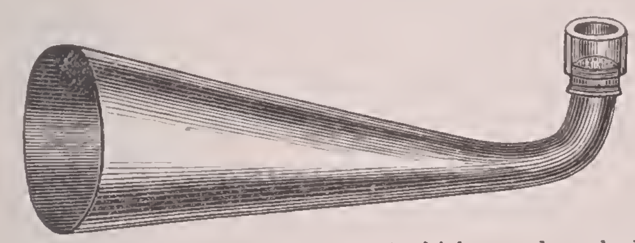
The next powerful instrument used is that called the reed or Daboll trumpet, actuated by air condensed in a reservoir by means of an Ericsson caloric (or heated-air) engine. In this instrument the trumpet itself is the resounding cavity, and the reed by its vibration produces the requisite motion of the air. The reed, consisting of a bar of iron, is, in the larger class of trumpets, 18 inches in length, 2 inches in width, and three-quarters of an inch in thickness at the fixed end, thinning gradually toward the free end. In order to gain the best effect, sound from these parts must be in unison, and for this purpose means should be provided for gradually increasing or diminishing the length of the trumpet. With a given stiffness of the reed the pressure of the air in the reservoir can not exceed a given intensity, since beyond this the reed can not recoil, and the orifice remains closed. A pressure of from 10 to 15 lb. per sq. inch is the maximum employed. This instrument is the most economical of power, giving the greatest amount of sound with a given expenditure of fuel. Its range of power, however, with a given size of trumpet is less than that of the 18-inch whistle; still it is a valuable instrument in all places where fresh water can not be obtained, since the motive-power consists of heated air, and not of vapor generated from a liquid.

Another instrument, and the most powerful of all yet employed, is the siren trumpet. The siren is the invention of Cagniard de Latour (see under ACOUSTICS, *Length of Sound-waves*), but its application as a fog-signal and the addition of the trumpet were patented by the Messrs. Brown, of New York. The sound from this instrument can be heard distinctly in still air at a distance of from 20 to 30 miles, even during the existence of a dense fog. The siren trumpet is



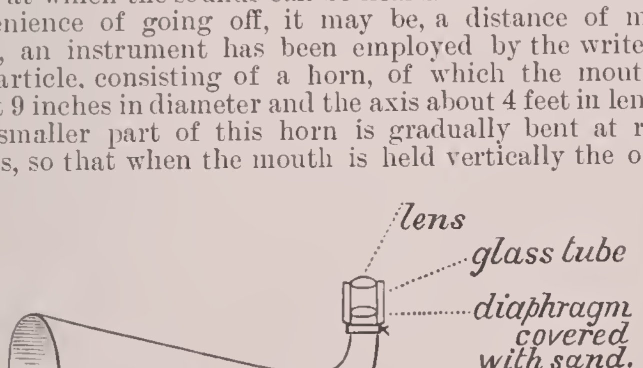
Explanation.—*a*, Steam drum, with one hole on front face; *b*, revolving plate, perforated with eight holes and supported on the shaft *c*.; *d*, a pulley, to which rapid motion is given by a band and driving-wheel; *e*, resonator or trumpet.

usually operated at a pressure of 75 lb. of steam, generated in a locomotive-boiler. It is not improbable that a better effect would be produced by using condensed air, since the space immediately around the point of origin of the sound is filled with steam, which must have an effect upon its subsequent transmission to the air. On the other hand, however, the increased complexity of machinery would probably more than neutralize any increase of effect from the change in question. By increasing the number of revolutions of the disk the pitch of the sound may be changed, and by this means the fact has been established that a medium pitch gives a sound of a greater penetrating power than one lower or higher. It is probable that the effect upon the tympanum of the ear will be in proportion to the quantity of air moved, multiplied by the square of the velocity, since at a very high pitch the amplitude of vibration must be exceedingly



Trumpet for determining the distance at which sound can be heard.

small, as well as the quantity of air put in motion, and the effect will be less. The shrill sound of the boatswain's whistle is heard more distinctly at a moderate distance, not on account of its more penetrating power, but on account of its dissimilarity to the ordinary coexisting sounds. It is impossible to judge of the penetrating power of a sound by its effect upon the ear when placed near its origin. To ascertain this it is usual for the observer to separate himself gradually from the place of origin of the different sounds of which the penetrating power is to be compared; the relative penetrating power being determined by the distance at which the sounds can be heard. To obviate the inconvenience of going off, it may be, a distance of many miles, an instrument has been employed by the writer of this article, consisting of a horn, of which the mouth is about 9 inches in diameter and the axis about 4 feet in length. The smaller part of this horn is gradually bent at right angles, so that when the mouth is held vertically the open-



ing at the smaller end is horizontal. Across this smaller end is stretched a delicate membrane on which fine sand is strewn. When the instrument is held in the hand horizontally, and the mouth is directed toward a sounding instrument, the sand, protected from the wind by a cylinder of glass, is observed to be agitated. The instrument is then carried off from the source of sound until the sand ceases to be moved. The measured distance at which the agitation ceases is taken as the relative penetrating power of the sound under examination as compared with the standard instrument, such as a reed horn or a bell. This instrument has been found by repeated comparison to give the same relative indications as those of the ear. Its degrees of sensitiveness will depend upon the relative size of the mouth and of the smaller orifice. In the more perfect form of the instrument it is so constructed as to be capable of a slight increase or diminution in length—an adjustment which is necessary in order that the horn may not be in unison with the sound to be measured, since in that case the resonance would produce an exaggerated effect in the increase of distance at which the agitation of the sand would take place. With an instrument of this kind having a small mouth a series of experiments have been made to determine the number and best form of the openings in the head of the drum and the revolving plate of the siren, without going to a distance of more than a few rods from the instrument.

In experimenting with sounds of such powerful magnitude as those produced by the instruments already described, certain peculiarities are observed which escape detection in ordinary acoustic investigations with sounds of inferior power. An important one is that of the great divergence of powerful sounds. It is well known that there is a striking analogy between the reflection of sound and that of light—that sound, like light, may be concentrated and directed in parallel lines by concave reflection; but this appears to be true only to a limited extent, and perhaps for more feeble sounds, since we have found that although the sonorous ray from a parabolic reflector, in the focus of which a powerful steam-whistle is sounded, is more powerful in the direction of the axis of the reflector than in any other at a comparatively short distance—for example, a mile or so—yet when the distance is increased to 4 or 5 miles the effect of the reflector is almost entirely lost, and the sound in the line of the axis may be heard apparently with the same intensity behind as before the reflector. This lateral divergence of the sound explains some abnormal phenomena which have been observed; for example, when a building or an elevation of ground exists between the observer and the reverberating body, the sound of the latter may be distinctly heard at a distance, but is lost on gradually approaching it in a direct line, the observer falling, as it were, into the sound shadow. This frequently happens in cases where the instrument is placed on one side of an island. At a distance it is heard almost equally well in every direction, while nearer it can only be heard on one side of the island.

Another set of phenomena which are conspicuously presented in the observation of loud sounds are those which result from the effect of the wind. It is a fact of daily observation that sounds are heard farther with the wind than against it, and that even a gentle breeze produces a remarkable effect in the way of increasing or diminishing the intensity of a given sound. The explanation of this phenomenon is by no means simple, which will be evident to one who reflects that the velocity of sound is at the rate of 700 miles an hour, while that of a wind which will nearly obliterate the perception of the sound at a given distance may be only 3 or 4 miles per hour. The only explanation of the effect of a wind on sound is that first indicated by Prof. Stokes, of Cambridge. To understand this, recall the fact that a beam of sound consists of a series of waves the length of the crests of which is at right angles to the direction of the sound. Now, although the wind may have very little effect upon the absolute velocity of these waves, it may materially affect their relative position, and consequently the direction of the sound. To render this plain, suppose the beam of sound to be represented by a series of parallel rods which in still air are perpendicular to the horizon. Next suppose a wind blowing against the sound—that is to say, toward its origin; the stratum of this wind next the earth will be the most retarded, on account of friction and other resistance; the one next above less retarded; and so on toward the upper stratum, which will have the greatest velocity. The effect of a moving river of air of this character will be to cause the perpendicular rods representing the waves of sound to lean, as it were, backward, and the sound itself to take a direction upward, passing far above the ear of an auditor placed on the surface of the earth at a distance to the windward of the origin of the sound. An opposite effect will be produced by a wind in the direction of the sound; the upper parts of the rods or waves will be inclined downward, and the sound, which in still air would pass above the ear of the observer, would in this case be thrown down upon it. In accordance with this hypothesis, it must be evident that a variety of phenomena in regard to sound must result from the slight changes in the intensity and direction of the wind. Thus a sound which may be heard at a distance of 10 miles with a slight wind against it is lost on approaching its origin, or even becomes inaudible at several intermediate points by an imperceptible increase in the velocity of the wind at the surface—a greater change perhaps taking place above. That this phenomenon can not be explained by the interposition of strata of air acoustically rendered flocculent and opaque by an admixture of invisible vapor, is evident from the fact that in a case of this kind the whistle from an approaching vessel has been continuously heard while the sound from the instrument on shore has been, as stated above, interrupted in its passage.

That a sudden change in the condition of the air by its saturation with moisture will have some effect in the propagation of feeble sounds is evident from both experiment and analogy; but this cause is entirely insufficient to produce the effects described, since they are exhibited without any apparent change in the hygrometrical condition of the atmosphere. Besides this, the fact that they depend upon the direction of the sound with reference to the wind is conclusive evidence that they are the result of the latter. In the case of a series of observations by two observers, A and B, each sounding a powerful instrument, it frequently happens that when A can distinctly hear the sound from B, the sound from A can not be heard by B. To explain this phenomenon on the principle of an acoustic opacity produced by flocculency would require a medium which would transmit sound in one direction and not in the opposite.

Fo-Hi, or **Fuh-Hi**: a half-mythical character in Chinese history generally considered to be the founder of the Chinese nation. His accession is assigned in the Chinese annals to 2852 B. C., but is placed by Dr. Legge (*Yi-King*, p. 11) in 3322 B. C. He is said to have introduced social order, music, writing, and marriage, and established a kind of mystic religion, which superseded to a great extent the ancient star-worship. He is the reputed discoverer or designer of the pah-kwa or "eight diagrams," lineal figures of three lines each (either whole or divided), each figure representing some power in nature, either active or passive. These by combination and multiplication form the sixty-four hexagrams on which is based the text of the *Yi-King*, or *Book of Changes*, one of the Five *King* or classics of the Chinese. Fo-Hi is said to have copied these diagrams from the back of a tortoise. R. L.

Föhr: an island in the North Sea, off the west coast of Schleswig, to which it belongs; area, 25 sq. miles; pop. 4,150. It is a good bathing-place; the chief industries are fishing, oystering, and fowling.

Foil [M. Eng. *foil*, leaf, from O. Fr. *foil*, *foille*, *feuille* > Fr. *feuille* < Lat. *folium*, *folia* : Gr. φύλλον]: thin sheets of metal (gold-foil, tin-foil, etc.) thicker than the leaf metal of commerce. Gold-foil is obtained by beating. It is in fact unfinished gold-leaf, and is chiefly used by dentists for stopping decayed teeth. Tin-foil is obtained by rolling the metal or by shaving a thin layer from a block of tin in an ingenious machine, which not only cuts off the foil, but rolls and stretches it at the same time. It is much adulterated with lead. Pure tin-foil is of great use in chemistry and the arts. Foils of copper and other metals are used for the backing of gems by the lapidary. The skillful use of nicely colored foils sets off and greatly heightens the effect of most precious stones.

Foils: See FENCING.

Foix, fwaă: town of France; department of Ariège; at the foot of the Pyrenees (see map of France, ref. 9–E). It was the birthplace of Gaston de Foix and the residence of the Counts of Foix, of whose ancient castle only three towers remain. The town has some trade in iron. Pop. (1891) of commune, 6,177; (1896) 6,722.

Foix, COUNTS OF: French family prominent from the eleventh century to the sixteenth. The first to assume the title was ROGER, who inherited the town of Foix and adjoining territory from his uncle, the Count of Carcassonne. D. 1064.—A more noted name is that of RAYMOND ROGER, who succeeded to the county in 1188. He was a companion of Philip Augustus in the third crusade, and one of the heroes of the siege of Acre. In the persecutions of the Albigensians he exposed himself to the charge of heresy by championing their cause against Simon de Montfort, who attempted to gain possession of the count's lands. De Montfort fell at the siege of Toulouse 1218, and Raymond became reconciled to the Church a short time before his death in 1223.—Count ROGER IV. (1241–1265) rendered homage for his estates to the King of France.—His successor, ROGER BERNARD III. (1265–1302), was a better troubadour than warrior, and stands high among the Provençal poets. He was humiliated by his enemies, and taken prisoner both by the King of France and the King of Aragon.—GASTON III., surnamed PHŒBUS, was one of the most conspicuous figures of the time. He became count in 1243, fought in the war against the English, and for this was made governor of Languedoc, but was suspected of conspiracy with Charles the Bad of Navarre, and thrown into prison 1356. He was soon released, and fought on the side of the Teutonic knights against the heathen of Prussia. On his return to France he aided in putting down the Jacquerie, and rescued the royal princesses from the rebels by his victory at Meaux. Renewing the ancient feud with the house of Armagnac, he defeated the Count of Armagnac and took possession of Béarn. He was again appointed governor of Languedoc by the king, but on the king's death the regency bestowed that dignity on the Duke of Berry. Gaston defeated him in the battle of Revel, but subsequently renounced his claims. D. in 1391. He was skilled in hunting, and has left a record of his fondness for the chase in his *Miroir de Phébus des déduicts de la chasse, etc.* (Paris, 1507), written in an involved and pompous style. In 1484 the county of Foix became merged in the kingdom of Navarre.—GASTON DE FOIX (*q. v.*), who fell in the battle of Ravenna 1512, was the descendant of a collateral branch. F. M. COLBY.

Fokien, or **Fukien**: See FUH-KIEN.

Foktchany, fok-chaa'nē, or **Fokchani**: a town of Roumania; province of Moldavia, on the Milkow (see map of Turkey, ref. 2–D). It has vineyards and an important trade with Galatz. On Aug. 1, 1789, it was the scene of the victory of the Austrians and Russians under the Prince of Coburg and Suwarrow over the Turks. Pop. 25,290.

Folc-land [O. Eng. *folc*, people + *land*, land]: a term of the Anglo-Saxon laws and institutions, used to designate lands owned by the community at large, and not by individual proprietors—that is, lands the title of which was held by the state, although the possession and usufruct might be temporarily enjoyed by private persons. When the institutions of the ancient German tribes first came within the observation of the Romans land was owned by the community, and this primitive mode of proprietorship was the basis of their tribal polity. The territory of a tribe, being divided into cantons and then into townships (marks), was allotted at regular intervals by the tribal authorities to the individual freemen; such distribution, according to Cæsar, being made annually. Kemble is of the opinion that this common or public land did not embrace all the territory belonging to a tribe, but that the notion of private, absolute proprietorship had already become familiar to the Teutonic peoples. It is certain that at the epoch of the final overthrow of the Western empire this notion was established as a part of their tribal institutions. Upon the barbarian invasions of Gaul, Spain, Italy, etc., the provincial owners were at once deprived wholly or partially of their lands. Of the territory thus seized by the conquerors, a portion was divided in unequal amounts among the warriors and heads of families, who took an absolute property or inheritance in their allotments, and who thus became, according to the nomenclature of the modern law, *allodial* proprietors. The remainder of the territory belonged to the community, and, as a more regular and firm political organization grew up, it was held under the control and at the disposal of the supreme authority—king or assembly of the people. Of this public land a part was appropriated to the uses of the government and to the support of the crown; a part was from time to time granted to allodial proprietors; while another part was bestowed upon individuals, not in absolute ownership, but as benefices to be held in consideration of fealty and services rendered, so that the beneficiaries or tenants enjoyed the usufruct only (*dominium utile*), the ultimate ownership (*dominium directum*) remaining in the state. In respect to the modes of ownership, there thus existed simultaneously among the Teutonic successors to the Western empire three varieties or species of land: (1) the public land, owned by the state and under its immediate control; (2) allodial land; (3) land held by tenure from the state or from some superior lord, to which the name *feudal* was subsequently applied. In the lapse of time, and especially during the periods of internal discord, the allodial mode of proprietorship very generally disappeared, the allodial proprietors finding it for their advantage to voluntarily change their lands into feudal benefices, and by this means to obtain for themselves as vassals, and for their estates, the protection of powerful superior lords.

The foregoing description applies in all its substantial features to the history of land tenures among the Anglo-Saxons in England. Separated at first into a number of petty states, each under the headship of a military chief whose authority in civil affairs was merely nominal, and preserving their ancient forms and modes of local administration in full vigor, they converted the land which they had seized from the Britons partly into allodial estates of inheritance granted to individual freemen, while they retained the greater part as the property of the public, and held it at the disposal of the state. As the former portion was granted to the recipients thereof by means of written charters or deeds, it collectively received the appellation "*boc-land*"; the latter, belonging to the people at large, was appropriately termed "*folc-land.*" "Folc-land" was, then, land the *title* to which was in the community as a whole, but not necessarily that which was actually *possessed* and used in common. While some of it might be suffered to remain in common—and in fact a tract of common land seems always to have been left in every Saxon township, as afterward in every Norman manor—it might also be granted by the state to separate and individual occupants. Such grants, however, could not be for a longer period than the life of the grantee; to confer an inheritance would be to change its nature from folc-land to boc-land. Those who thus obtained temporary possession and usufruct of tracts of folc-land held them subject to heavy burdens. Among these burdens resting upon the occupant were his liabilities to render military service, to contribute to the repair of roads, bridges, and fortifications, to pay various dues to the king, to furnish transportation for public messengers, to furnish provision, horses, and carriages for the king on his travels, and even to provide for the royal hawks, hounds, and horses. Tracts or parcels of folc-land might thus be held by freemen of every degree, noble or not noble, and even by the king himself. An ancient document, preserved from the time of King Alfred, shows that a nobleman owning great estates of boc-land was also possessed of a life interest in certain folc-lands, and these latter he prays the king to continue to his son after his own death.

In addition to these donations or grants, in which the recipient acquired no absolute or inheritable estate, and which did not change its nature, folc-land was the source —or, so to speak, fund—out of which gifts were made in perpetuity to the military or civil servants of the state as rewards or compensation for their services. The tract thus transferred, however, was at once severed from the mass of folc-lands, and passed into the class of boc-lands. If the grant was to a military servant—a thegn—the term "thegn-land" was applied to the portion so conveyed; if to a civil officer, the corresponding designation was "reeve-land" (gerefa-land). Indeed, Kemble supposes that all the territory in a Saxon kingdom was at first considered as folc-land, and that whatever estates of inheritance were held by private persons were derived from this original source; so that every particular case of boc-land had been at some time carved out of the soil once belonging to the people. All boc-land was held by the proprietors under the particular limitations contained in the first charter or grant and under the common burdens imposed by the law. Although there was doubtless some variation in the extent and character of the limitations prescribed to the first grantee, there was a general sameness among them all. The estates were inheritable and alienable, and, although subject to certain common services due to the crown, it is clear that these services were far less onerous than those which were required from tenants during the flourishing periods of the feudal system under the Norman kings. The gifts of the people's land to private persons which have been thus described are intended to embrace also those made to the Church, which obtained in this manner vast quantities of the public domain.

Another use to which the folc-land was put was the maintenance of the crown and the defraying of the public expenses. Income was derived from some portions of it which were granted to life-tenants upon the payment of rents, which were generally, however, products of the soil, and not money. Other portions were retained for the actual use of the crown, in all respects resembling the demesne-lands of a manor occupied, cultivated, and enjoyed by the lord thereof for his personal convenience and benefit. As the royal prerogative increased in strength, these lands came to be regarded as the private property of the king.

Folc-land, being the property of the people as a whole, could not be alienated or changed into boc-land without some act of the government. In the earliest periods of the Saxon commonwealths the "gemote" or general assembly of the nation alone possessed this power. In later times the charters or deeds ran in the name of the king, but still required the assent of his "witan" or council of advisers. As the royal powers increased, and the king came to be regarded as the representative of the state and as embodying in himself the supreme authority, the theory was suggested, and in time was adopted, that the folc-land belonged to him in his official capacity—that it was to be used for his maintenance, and employed by him at his pleasure in rewarding his servants. When this notion was universally accepted the term "folc-land" disappeared from ordinary speech and from the language of all official writings, and that of "*terra regis*" or "crown-lands" was substituted.

From the foregoing sketch it is apparent that the description of folc-land given by many legal text-writers, which makes it synonymous with "common land," or land possessed "in common" or by the common people, is altogether a mistaken one. Sir William Blackstone has fallen into a still graver error in his statement that it was land possessed by the serfs or villeins alone, and therefore belonging, together with themselves, their families, and their effects, to the lord of the soil. For an exhaustive discussion of the subject, with a citation of ancient documents and proofs, the reader is referred to the following authorities: *The Saxons in England*, by John Mitchell Kemble (vol. i., chs. ii. and xi.); *Inquiry into the Rise and Growth of the Royal Prerogative in England*, by John Allen (pp. 129–155); *The Rise and Progress of the English Commonwealth—Anglo-Saxon Period*, by Francis Palgrave (pp. 65–104); *A History of England under the Anglo-Saxon Kings*, translated from the German of Dr. J. M. Lappenberg, by Benjamin Thorpe (vol. ii., pp. 323–326); and *Constitutional History of England*, by W. Stubbs (vol. i.). JOHN NORTON POMEROY.

Földvár: See DUNA FOLDVAR.

Fo'ley, JOHN HENRY, R. A.: sculptor; b. in Dublin, May 24, 1818. His first impulse toward sculpture came from his step-grandfather, who was a sculptor in that city, and he began to study at the age of thirteen. In 1834 he went to London, and entered the Royal Academy as a student. He first exhibited in 1839. He entered in 1844 into the competition for the decoration of the palace at Westminster with statues, and as one of the successful candidates received the commission to make a statue of John Hampden, now in the House of Parliament. The statues of Selden and of Sir Charles Barry in the same building also were from his chisel. In 1856 Foley produced his bronze equestrian portrait-statue of Lord Hardinge for Calcutta; this is counted his finest work. Later he made an equestrian statue of Outram, also in bronze, which added greatly to his reputation. Foley was of a sensitive disposition, and in 1862 he took offense at the way in which his statues were placed at the Royal Academy exhibition, and never afterward would contribute to the exhibition, nor take any advantage whatever of his membership. He made the statue of the Prince Consort and the group of *Asia* for the national memorial to the prince in Hyde Park. Among his other works are statues of Oliver Goldsmith and Edmund Burke for Dublin, and a statue of Father Mathew for Cork. Foley's latest work was a statue in bronze of the Confederate general Stonewall Jackson, a commission from the State of South Carolina. Foley died in London, Aug. 27, 1874. He was buried in St. Paul's Cathedral Sept. 5.

Folger, CHARLES J., LL.D.: jurist; b. in Nantucket, Mass., Apr. 16, 1818; removed to Geneva, N. Y., with his father in 1831; graduated at Hobart College, Geneva, in 1836; admitted to the bar in 1839; judge of the Ontario court of common pleas in 1844, and also master and examiner in chancery; county judge 1851–55; New York State Senator 1861–69; assistant U. S. treasurer at New York 1869; elected associate judge of New York court of appeals 1871; chief judge Nov. 2, 1880; appointed U. S. Secretary of Treasury Nov. 14, 1881, which office he held till his death; nominated by Republican convention Sept. 20, 1882, for Governor of New York, but, because of a defection in his party, was defeated by Grover Cleveland by nearly 200,000 majority. D. Sept. 4, 1884.

Folger, Peter: colonist and writer; b. in England in 1617; removed from Norwich in 1635, and with his father settled at Martha's Vineyard, Mass.; in 1663 removed to Nantucket. His daughter Abia was Benjamin Franklin's mother. From 1673 he was clerk of the courts, and wrote *A Looking-glass for the Times, or the Former Spirit of New England Revived in this Generation* (1675). D. at Nantucket, 1690.

Foligno, fō-leen'yō (Lat. *Fulginium*): town of Central Italy; province of Umbria; 25 miles S. E. of Perugia (see map of Italy, ref. 5–E). It is the seat of a bishopric, and has celebrated manufactures of woolens and parchment. It was known in the Middle Ages as *Fulignum*, and retained its independence until 1281, when it was conquered and destroyed by the Perugians. Rebuilt, it was ruled by the Trinci family until 1439, when it was incorporated with the states of the Church. It was nearly destroyed by an earthquake in 1833. Pop. 8,753.

Folkes, Martin: antiquary; b. in London, England, Oct. 29, 1690; d. there in 1754. He was educated at Clare College, Cambridge, and distinguished himself so much by his mathematical studies that in 1713 he became a fellow of the Royal Society, and in 1741 its president. In 1733 he traveled through France and Italy, and published his *Dissertations on the Weights and Values of Ancient Coins.* His principal work is his *Table of English Gold Coins from the Eighteenth Year of King Edward III., when Gold was first coined in England, to the Present Time, with their Weights and Intrinsic Values*, which was printed in 1745 together with a similar account of the history of silver coinage in England. He contributed papers on Roman antiquities to the *Transactions* of the Royal Society and those of the Society of Antiquaries.

Folkestone: town of England; on the southeast coast of Kent; 83 miles by rail S. E. of London (see map of England, ref. 13–L). It is a favorite watering-place, and its harbor is much frequented by boats used in the mackerel and herring fisheries. Pop. (1891) 23,700.

Folk-etymology, or **Popular Etymology**: that natural and unscientific impression concerning the origin and etymological connection of words which immediately suggests itself to the popular mind without the use of reflection or of reasoning upon consciously collected materials. It is related to scientific etymology somewhat as folk-lore is related to scientific history. Its phenomena are due to an instinctive tendency of the human mind to find meaning and adaptation in the apparently perverse and meaningless material of language. They furnish therefore no guide to the correct etymology of the words concerned, but are, on the contrary, almost invariably misleading, often dangerously so; they do, however, furnish most important clews to the laws of the mind's action, as well as to the scope and relation of the factors of ordinary consciousness. The most commonly recognized cases of folk-etymology are those in which the attempt to "read meaning into" a body of sounds has resulted in a modification of the form of the word. The word has been made to conform to its supposed etymon. Thus (1) a portion of a word may be adapted to the form of an entire word, its supposed etymon; as *causeway* from *causey* (Milton), cf. French *chaussée*, Lat. *calciata* (*via*)—i. e. paved road. Here the syllable *-ey* has been conceived to represent the word *way*, and has been changed accordingly. (2) One of the elements of a compound is readapted to a distincter etymon; as *belfry* for older *berfray* viâ O. Fr. from M. H. Germ. *bercvrit*, watch-tower, in which the former part is connected with Germ. *bergen*, protect; the change of *ber-* to *bel-* is undoubtedly due to the supposed etymon *bell*. So *hangnail* for *agnail* or **angnail*, in which *ang-* represents O. Eng. *ange*, pain; Germ. *beispiel* for *beispel*; *maulwurf* for *moltwurf*, etc. (3) A word of obscure etymology may be changed so as to have a clear etymology, as *touchy* for "vulgar" *tetchy* or *techy*, a derivative of M. Eng. *teche*, *tache*, freak, habit, from O. Fr. *tache*, spot, blemish. Proper names and loan-words, which to the popular ear are generally only arbitrary accumulations of sounds, are peculiarly liable to these corruptions: thus Lat. *Proserpina* (for Gr. *Persephone*); *Agrigentum* (as if *ager* for Gr. *Akragas*); Gr. *Hierosolyma* (as if *hiero-*, sacred) and O. Norse *Iōrsalir* (i. e. horse halls) for the Heb. city-name *Jerushalem*; Mod. Gr. *Anthēna* (for *Athēnai*, Athens) as if the "city of flowers" (*anthos*); *Gotts-chalk* (Germ. *Gottschalk*); *Roths-child* (Germ. *Roth-schild*); *wiseacre* (Germ. *weissager*); not to speak of enormities like *perish* (*Paris*) *green*, *Asiatic* (*acetic*) *acid*, etc.

The false etymological connection may, however, often take place without resultant change of form. It betrays itself then either (1) by the orthography, as *island*, in which the *s* shows a false connection with *isle*; or (2) by the use of the word in its context, as when *incentive* is used as something which inflames (Lat. *incendere*) instead of as something which gives the keynote (Lat. *incinere*), cf. Milton's

Part *incentive* reed
Provide, pernicious with one touch of fire" (*P. L.*, vi., 519);

or (3) in the linguistic consciousness of the individual, as in the use of *cutler* (from Lat. *cultellus*, knife), which most speakers feel to be connected with the verb *to cut*.

Folk-land and **Boc-land**: See Folc-land.

Folk-lore [*folk*, used in the sense of the Germ. *Volk*, people + *lore* < O. Eng. *lār*: Germ. *Lehre*]: that mass of customs, beliefs, and ideas, possessing a primitive character, which is traditionally communicated from generation to generation. The word, in its stricter sense, is properly applied to the traditions of civilized countries, especially European countries and regions colonized from Europe. By an extension of this signification, however, it is now currently employed in such a manner as to include all material of a similar character, although existing among semi-civilized or uncivilized races; it is common, for example, to speak of Egyptian, Hindu, Aino, or American-Indian folk-lore. This usage seems to be justified by the following considerations: (1) The traditions of Western Europe are connected with those of other continents, and often identical with these; (2) the progress of civilization, even among tribes considered to be in a "primitive" stage of culture, is so rapid that ancestral habits and opinions are rapidly being relegated to the status of superseded notions that constitute folk-lore. Nevertheless, in order to bring the matter within the compass of a general treatment it will be necessary to have in mind, in the first instance, the folk-lore of Europe.

The name originated with W. J. Thoms, who, in writing to *The Athenæum*, Aug. 22, 1846, urging the collection of what in England were designated popular antiquities or popular literature, remarked that the latter "would be most aptly designated by a good Saxon compound 'folk-lore,' the lore of the people." He included under this head manners, customs, observances, superstitions, ballads, and proverbs. The term has not only taken root in English speech, but has become so far naturalized in the Romance languages that it is employed in new formations, as in French *folkloriste*, Italian *folklorico*. The German *Volkskunde*, or information of any kind in regard to a race, is properly a more inclusive term, but is now used as identical with folklore, *Völkerkunde* being reserved for *ethnology*.

The expansion in the meaning has been accompanied by a change in the connotation of the word *folk*. This was defined by the makers of early English dictionaries as signifying *plebs* or *vulgus*, "the common people," and this was the idea it conveyed to the authors who were first to treat of folk-lore, and who had especially in their minds the peasantry of Europe. Under the influence, however, of compounds suggested by the German *Volk*, such as folk-speech, folk-art, folk-music, folk-life, the English word also has shown a tendency to revert to its older sense, as denoting the members of a community united by ties of blood and vicinage. It is also true that the traditions of peasants and uneducated persons do not, in the main, belong to these as a class, but that the illiterate simply retain ideas which once belonged to all classes. Folk-lore is found to exist among the most intelligent as well as among the rudest part of the population; so that *folk*, in this connection, must be taken to include old-fashioned people, and even enlightened minds in so far as these are old-fashioned in their conceptions. By the folk-lore of any particular people, therefore, may be understood the customs and beliefs once proper to the whole race, and now preserved among its less highly educated and consequently more conservative elements.

The compass and character of folk-lore are perhaps best indicated by its external characteristic, namely, in that the traditions of which it consists are transmitted by word of mouth and without the intervention of writing. In oral tradition, from the necessity of the case, individual peculiarities are in a measure eliminated, and the standard is that common to the great majority of the members of the community. With the introduction of the habit of writing the influence of individual ways of thinking becomes greater, and the reading class forms an intellectual aristocracy, among whom ancestral conceptions exist as a survival. In the course of time this reading public so enlarges itself as to become coextensive with the community, which is therefore entirely brought under the influence of superior minds and of exact observations. Corresponding to this change is the substitution of written volumes for the ancient narrations. Thus it is found that with any people in which the use of reading and writing has not become general, there of necessity survives a body of traditions possessing a degree of literary merit, as well as a mass of customs handed down from remote times. With the progress of education, what is characteristic and peculiar yields to what is uniform and cosmopolitan. Isolated persons, unlettered individuals, and children, less under the control of books, preserve this lore for a longer period than others.

According to this view folk-lore, or oral tradition, is the supplement of written literature; folk-lore and literature may be represented as two provinces, which taken together include the whole field of human thought; while over both extend the intersecting circles which mark the territory claimed by different sciences, and which overlap like the various boundary-lines on an historical map.

On the other hand, it must be evident that although oral tradition plays a less important part than formerly, it still can never be entirely superseded; that every generation must have its own folk-lore or characteristic conceptions and usages, which are continually superseded by the introduction of more accurate and intelligent notions as these are formed in superior minds and gradually become universal.

Classification of the Material.—The territory of folk-lore is so extensive, its boundaries so undefined and variable, the survey of the ground so recent and incomplete, and the determination of limits so much a matter of individual preference, that no method of mapping out the field has yet received general recognition, nor perhaps can any system of classification be proposed which will not be found to involve inconsistencies, deficiencies, and cross-divisions. In taking account of the material, it will be well to consider, in the first instance, only civilized Europe and its colonies, thus adopting the narrower signification of the term as above defined. Such matter only need be comprehended as seems to possess an antiquated character, or fulfills the requirement of descending from past generations, and exhibiting the permanence of ancestral habits of thought. For this purpose three sections may be made, corresponding to the categories of action, thought, and expression, under the headings of customs, superstitions, and oral literature.

I. *Customs.*—(*a*) In the first place may be mentioned usages of a ceremonial character, relating to the popular calendar or particular days of the year, such as New Year's Day, Easter, the First of May, All Souls' Day, Christmas; days dedicated to the worship of particular saints; agricultural festivals of sowing and harvest; the celebration of national holidays, as in America the Fourth of July, Thanksgiving, etc. (*b*) *Customs of worship*, consisting of peculiar and local usages connected with established faiths, or religious observances of eccentric sects, household ritual, and individual religious practice. (*c*) *Social customs*, festival gatherings, not determined to precise times of occurrence, like "house-raisings," "bees," and the like; the ritual of secret societies; social etiquette, with its rules of introduction, salutation, leave-taking, etc.; table manners; conditions of service, and rules governing domestic relations; customs of particular families and clans. (*d*) *Customs relative to human life*, in its periods of birth, infancy, puberty, courtship, betrothal, marriage, child-bearing, death; customs of children. (*e*) *Industrial customs*, incident to special occupations, to old-fashioned methods of work, to the holding of fairs and markets, the construction and dedication of houses, launching of ships, etc. (*f*) *Customs of rights and obligations*, communal property and communal jurisdiction, the rules regulating the transaction of business and agriculture, habits of asseveration and obligation, customs of bestowing charities and expecting contributions. (*g*) *Games*, in their many subdivisions; games exhibiting the dramatization of myths and stories, representations of love-making, war, and labor; games intended to test strength and agility, of chance, skill, and wit; guessing games and puzzles; games of children and of nurses. (*h*) *Gestures*, employed to express any of the emotions, appeal, protest, ridicule, etc.

II. *Superstitions.*—Traditions included in this section might, in many cases, be also brought under that which precedes, inasmuch as a superstitious belief is usually accompanied by a custom. The various superstitions form a mass of pseudo-information, the complete examination of which would require a treatise of encyclopædic dimensions. Without any pretense of completeness, superstitions may be divided into those concerning (*a*) *Mythic beings*: fairies, dwarfs, giants, hobgoblins, familiar spirits, and other remains of ancient ethnic belief; angels, saints, and demons, belonging to Christian mythology; ghosts, or souls of the departed; fantastic and imaginary beings, creations of the popular fancy. (*b*) *Times and seasons*: lucky and unlucky days. (*c*) *Objects of nature*: the sun and moon, stars and elements, winds and tempests, ideas exhibiting mythic conceptions; mountains, rocks, and stones, animistically conceived; jewels, with the respective virtues attributed to them. (*d*) *Witchcraft and magic*, in all their varieties and with all their literature; mesmerism, clairvoyance, and the like in so far as these are dependent on traditional error. (*e*) *Divination*: the prediction of the future, whether by direct prophecy or by means of prognostics; astrology, necromancy, geomancy, chiromancy, etc.; popular signs and omens, the tokens used to determine a partner for life; weather-lore and popular meteorology; ordeals and tests; the divining-rod. (*f*) *Popular medicine*, with its history; the doctrine of signatures, belief in the curative power or magic power of human flesh and blood, imaginative methods of cure, faith-healing and mind-cure, so far as these are traditional. (*g*) *Amulets and charms*, their different sorts, descriptions, and effects. (*h*) *Personal*: superstitious beliefs belonging to particular families or individuals. (*i*) *Physiological*: popular ideas of the characteristics of persons belonging to different races, to the connection of mental traits with certain bodily marks, and the like.

III. *Popular Literature.*—A. *Poetry.*—Under this head we have to consider: (*a*) *Popular epics*, of which an example is furnished by the Finnish *Kalevala*, and by Russian popular epics. On the boundaries of folk-lore and literature lie some of the great literary epic poems. (See Epic Poetry.) (*b*) *Ballads*, or narrative songs, so called from their original use in the dance. (See Ballad Poetry.) (*c*) *Carols*, or sacred songs employed in connection with days of the Church, especially Christmas. The word carol is originally identical in meaning with ballad, and may be derived from the Middle Latin *chorea*, although said by etymological dictionaries to be of Celtic extraction. (*d*) *Songs*, especially love-songs. This species of popular literature, current in great abundance in many European countries, is partly represented in English, popular English songs having apparently perished for want of record, although some refrains are preserved. Some of the songs in Shakspeare have something of a popular character. English popular literature entirely lacks the salutations, quatrains, etc., found in Southern Europe.

B. *Prose.*—(*a*) *Sagas* or hero-tales, professing to be historical in character. Familiar examples abound in Norse literature; the heroic literature of Celtic-speaking races has been doubtfully supposed to have been solely of this nature, as exemplified in Old Irish sagas. In English this species of popular composition scarcely exists, owing, no doubt, to the absence of early collection. (*b*) *Märchen*, or fairy tales. This class of composition differs from the former by possessing a less distinctly marked pretense of historical verity, in this respect resembling modern novelettes; yet the distinction is not absolute. The *Märchen* do not belong exclusively to children; on the contrary, the tales of children are generally survivals of those meant for grown folk. (*c*) *Animal Tales.*—In the case of races still in the earlier mythic stage, a considerable part of the mythology consists of such tales; but the animal tales now current in Europe, Asia, Africa, and among the Negroes of America, like the *Märchen*, have no ritual connection. (See Beast-fables.) The passions of man are attributed to beasts, merely in order to justify a moral or turn a jest; these tales, although sometimes of much length, otherwise belong to the category of fables. (*d*) *Legends* are distinguished by their character as sacred histories, relating to a divine being, saint, or holy personage. (*e*) *Drolls*, or jests, are of a humorous nature, being generally broadly comic in their type. (*f*) *Myths.*—The term is often applied to popular narratives belonging to any of the classes named, but in a stricter sense is employed to denote tales professing to give explanations of the existing conditions of beings or things (etiological), or to those assumed to symbolize the operations of nature. (*g*) *Examples*, illustrations, anecdotes.

C. *Minor Elements of Popular Literature.*—(*a*) *Rhymes.*—The designation includes a great variety of forms, game rhymes, nursery rhymes of different sorts, place rhymes, and personal rhymes, what the French call *blason populaire*, etc. (*b*) *Riddles.*—Amusements now regarded as congeners, the conundrum, paronomasia, etc., are not very closely allied to this ancient kind of literature. (*c*) *Proverbs* and sayings. (*d*) *Phrases*, not so distinctly expressive of a general truth. (*e*) *Expressions* and words of a primitive character, when regarded from the point of view of the folk-lore which they contain.

THEORY.—According to the definitions above given, folk-lore makes part of the subject-matter of anthropology, ethnology, psychology, history, æsthetics, ethics, music, and many other sciences. For the purposes of comparative treatment it is impossible to limit examination to the folk-lore of civilized communities, but the traditions of races in a simple stage of culture must also be taken into account. It might seem that the resulting expansion of the material would make it as impossible to deal with the contents of folk-lore as with the contents of literature. There may, however, be a science or theory of folk-lore, considered with reference to its distinguishing characteristics and method of communication. Such an investigation, for which materials are only beginning to exist, might consider, besides a survey and subdivision of the field, the manner of collection of folk-lore; the genuineness of the record; its distribution and diffusion; the different stages and the development of oral tradition; the characteristics belonging to this tradition as inherited and popular; the relation of the ideas of the illiterate to the literate classes; the connection of oral and written literature; the manner in which popular belief and fancy furnish the groundwork for productions of art, and the reaction of conscious art on tradition; the connection of superstition with philosophy and poetry; and numerous similar topics. In regard to such questions, which require extended treatment, only a few remarks can here be offered.

(*a*) *The Recording of Folk-lore.*—It is now considered as essential that a popular tradition, in order to become the material of scientific consideration, should be written down exactly as repeated to the collector, without addition or adornment. Such, however, was by no means the practice of early collectors, who regarded folk-lore as mere curiosities which were interesting only when singular, and which required to be ornamented and corrected before being committed to print. For example, the early gatherers of English ballads had no hesitation in adding an introduction or conclusion to their material, or in reconstructing any irregular stanza or quaint idiom. The imperfect understanding of the true characteristics of oral tradition caused collectors of tales, even when of distinguished scientific attainments, to include pieces not really of a popular character. As these productions were highly estimated according to literary merit, the temptation was irresistible to edit the ruder stories in such manner as to give them an attractive dress, and this practice of beautifying folk-tales has continued down to the present time. To this erroneous procedure has been added, in many cases, absolute forgery; the literary conscience of the past generation scarcely considered invention in this field as anything more than a justifiable effort of ingenuity. A particularly flagrant example of this artificial production of traditions was furnished by Hersart de la Villemarqué, whose Breton collections are now known to have been in great part fictitious. Even at the present moment this method of creating folk-lore has by no means ceased, but, in part from miscomprehension and mistaken theory, in part from deliberate imagination, myths and stories which have no real existence on the lips of any folk continue to be added to the stock. Such inaccuracy renders necessary particular caution, both in the recorder and in the critic of traditional material. These remarks apply also to a great part of the information to be found in books respecting the mythology and customs of primitive races, and affect the validity of the general conclusions constantly founded on imperfect testimony and appearing in general treatises on the theory of religions, mythologies, and ethical notions.

(*b*) *Folk-lore and Anthropology.*—The popular traditions of civilized countries may be considered from either of two different points of view. The products of oral tradition may be estimated according to their value as literature, and judged according to the rules of æsthetics, or else they may be viewed especially as survivals of earlier conditions of culture, and as calculated to throw light on the progress of history and the development of intelligence. As the latter method is the more inclusive, and as a consideration of folk-lore as science is not incompatible with a just estimate of its interest as literature, the material is usually regarded as coming within the province of anthropology. With regard to the definition and limits of the latter science, no agreement exists, some investigators being disposed to limit the inclusiveness of the term to the study of man regarded as an animal, or to the review of the characters of uncivilized man, while others, apparently in the majority, take in the whole field of human action, and include those general questions which formerly were considered to form the province of philosophy. Ethnography consists in the description of the characters of a race or of the races of a certain territory; ethnology in the corresponding theoretical inquiries. The folk-lore of any given country would therefore form part of the ethnography of that country; but as it will be shown that race is a secondary question in regard to folk-lore, and as the comparative subject may be viewed from a general human point of view, it must be under general anthropology, rather than ethnology, that folk-lore should be brought.

(*c*) *The Antiquity of Folk-lore.*—The persistence of oral tradition and tenacity of the popular memory are often the subject of remark, and might be illustrated by numerous examples. Certain games are as old as history, and in some cases even the formulas with which they are played may be traced for 2,000 years. The elements of folk-tales also, or some portion of them, seem to be prehistoric in date. In recent collections of ballads in Scandinavian countries it was found that many of these had changed only in language or in reduction of compass from the forms collected in manuscript three centuries before. Some modern spells and superstitions also have been shown to be nearly identical with similar matter recorded more than a thousand years ago. Observations of this sort have led to extravagant assertions regarding the antiquity of all popular traditions. It is certain, however, that no such general principle can be established. If some traditions are ancient, others are modern. There is constantly going on a change in the fashions of popular tradition, although the alteration is much slower than in the case of literature. The question of the probable date of a usage or story can not be answered in any universal manner, but must in each separate case be a theme of inquiry.

(*d*) *Folk-lore, Race, and Language.*—The questions which have been most eagerly debated, and on which most difference of opinion continues to exist, are those which affect the diffusion and distribution of folk-lore. To Jacob and William Grimm, and other students of the early part of the century, tradition, descent, and linguistic form were parallel. The doctrine of these scholars was that the mythology of each particular race expressed the special way of considering nature proper to that branch of the human family, and that this information was traditionally handed down unmingled as a sacred treasure to descendants; this inherited stock of knowledge, though affected by the influences of time, survived in the oral tradition of the later age; thus folk-lore, as the remainder of what was especially national, indicated the true way of feeling proper to a folk, and thus collection and study went hand in hand with patriotic feeling. After comparative philology had established the kinship of Indo-European tongues and undertaken to reconstruct the civilization of the original stock, by means of linguistic comparisons, the principle continued to be held that community of popular tradition was proof of common descent. This view, expressed in the phrase "Aryan origins," played a great part in the speculations of Max Müller and other writers. In this method of research, however, ethnology and archæology had not been consulted. The results of recent investigation have been to cast into uncertainty results which were supposed to be secure; the original habitat of the Aryan race, formerly established in Asia, has been variously fixed in Southern Europe and North Africa; the physiological characteristics of the peoples in question have been shown to be so mixed that at the present time no certain opinion can be maintained regarding their original racial characters. Corresponding to this debate, comparisons of the material of folk-lore have shown that race is a very secondary element in tradition, and that language itself is no certain guide. Thus the Basques of Europe appear entirely to lack any characteristic folk-lore; Finns have adopted many traditions from their Swedish neighbors: Bretons have altogether forgotten the legends and sagas, which in the Middle Ages must presumably still have existed, in favor of notions imported from more cultivated France. It has been established that Europe and Asia, from Ireland to Japan, form an area of communication throughout which has been diffused a folk-lore in some respects corresponding. Similar conclusions are indicated in regard to other continents—Africa, Australia, and America. It appears, therefore, that the influence of one race on another depends chiefly on contiguity, and that such intercommunication is not solely a product of civilization, but has existed from the most remote times. Although promoted by alliance of religious belief and sympathy of trade relations, this process of diffusion goes on even between races which cordially hate each other, and which are at war with each other. The tendency of modern inquiry, therefore, is to reverse the older way of thinking, and to regard race and language as secondary factors in determining the prevalence of popular traditions. This remark, however, applies only to the story, or to the outline of the narrative; in the decoration and linguistic form the character of the race appears; the story is so reconstructed as to become illustrative of the ideas and customs of the region, and in this manner may be no less valuable for ethnological purposes than if it had in the first instance been the reflection of the habits of the tribe which recites it. Such, at least, seems to be the conclusion to which comparative investigation is tending. This conclusion, however, is not matter of universal assent. Some writers, especially in Great Britain, insist that folk-lore may prove serviceable in tracking out remote ethnic relationships, while others have hitherto been inclined to explain resemblances in belief and practice as independent inventions, indicating not counteraction, but only the natural products of corresponding stages of culture. It must be said, however, that the observable relation does not admit of the indefinite extension of this theory. On the other hand, it must be allowed that general parallelisms prove nothing in regard to interchange; and such seems at present to be the character of the parallelism of American and Asiatic tradition; while it appears certain that there has been some effect of Asiatic influence on the ideas of American aborigines, it is not established that this connection is other than secondary and relatively unimportant. See F. Boas, *Dissemination of Tales among the Natives of North America*, *Journal of American Folk-Lore* (1891).

(*e*) *Oral and Written Composition.*—A series of difficult questions, to which it is only necessary to allude, arise as to the relations of these two sorts of composition. It has been doubted whether the inventors and repeaters of popular traditions use conscious art in the same manner as do writers with the pen, or whether these productions arose with deliberate invention by the process of repetition from lip to lip. It has also been held that some part, at least of folk-narratives, are based on literary antecedents. On the other hand, it is urged that many of the great productions of genius are based on popular imagination, the author employing and reconstructing traditions contained in the folk-lore of his land. The whole theory of the relation between the written literatures of advanced civilizations and the literary creations of races not in the habit of recording their knowledge is a subject which can not be dealt with in a satisfactory manner until there exist fuller and more accurate collections of the myths, tales, and songs of uncivilized races than those which have hitherto been at the disposal of the student.

BIBLIOGRAPHY.—All that can be done here is to note a few works of a general character, leaving the bibliographic information proper to each division to appear in its proper place.

(*a*) Question-books or *questionnaires*: *The Handbook of Folklore*, edited by G. L. Gomme (London, 1890); *Questionnaire de Folklore*, publié par la Société du Folklore Wallon (Liège, 1891); P. Sébillot, *Essai de Questionnaire* (Paris, 1889); A. Gittée, *Vraagboek tot het Zamelen van vlaamsche Folklore of Volkskunde* (Ghent, 1888); *Topics for Collection of Folk-Lore*, F. D. Bergen and W. W. Newell (*Journal of American Folk-Lore*, 1890).

(*b*) Journals: *Folk-Lore* (London, established in 1890), continuing the *Folk-Lore Record* (1878), and the *Folk-Lore Journal* (1883), all published by the Folk-Lore Society; *Revue des Traditions Populaires* (Paris, 1886); *Journal of American Folk-Lore* (Boston, 1888); *Zeitschrift des Vereins für Volkskunde* (Berlin, 1890); *Ethnologische Mitteilungen aus Ungarn* (Budapest, 1889), published by the Gesellschaft für die Völkerkunde Ungarns, and continuing the work of the *Journal of the Gypsy Folk-Lore Society* (London, 1889–92). Among other periodicals are to be especially named the following: *Mélusine* (ed. A. Gaidoz, Paris, 1877); *Wallonia* (ed. O. Colson and others, Liège, 1893); *Am Ur-Quell* (ed. F. S. Krauss, Vienna, 1890); *Archivio per lo Studio delle Tradizioni Popolari* (ed. G. Pitrè, Palermo, 1882); *Český Lid* (ed. L. Niederle, Prague, 1892); *Wisla* (ed. J. Karlowicz, Warsaw, 1887); *Zhivaya Starina* (ed. J. Lamanski, St. Petersburg, 1890); *Indian Antiquary* (Bombay, 1892); American anthropological journals are: *The American Anthropologist* (Washington); and *The American Antiquarian and Oriental Journal* (Good Hope, Ill.).

(*c*) General works: There is no general introduction to the study of folk-lore. The beginner will find a series of suggestive papers in *The International Folk-Lore Congress, Papers and Transactions* (London, 1892). For the relation between folk-lore, ethnic custom, and mythology, see W. Mannhardt, *Die Korndämonen* (Berlin, 1868); *Wald- und Feldculte* (Berlin, 1876); *Mythologische Forschungen* (Berlin, 1888); J. G. Frazer, *The Golden Bough, a Study in Comparative Religion* (London, 1890); A. Lang, *Custom and Myth* (London, 1884) and *Myth, Ritual, and Religion* (London, 1887); G. L. Gomme, *Folk-Lore Relics of Early Village Life* (London, 1888) and *Ethnology in Folk-Lore* (London, 1892).

For ballads the student may refer to the work of F. J. Child, *The English and Scottish Popular Ballads* (Boston, 1882–93); for tales, to E. Cosquin, *Contes populaires de Lorraine comparés*, etc. (2 vols., Paris, 1885); T. F. Crane's *Italian Popular Tales*, with notes (Boston, 1885); W. A. Clouston, *Popular Tales and Fictions, their Migrations and Transformations* (2 vols., Edinburgh, 1887); J. Jacobs, *Æsopus* (2 vols., London, 1889); E. Sidney Hartland, *The Science of Fairy Tales* (London, 1891).

For popular festivals and the calendar, see W. Hone, *The Every-Day Book* (London, 1826); *The Table Book* (1827); *The Year Book* (1829, and several times reprinted); R. Chambers, *Book of Days* (Edinburgh, 1863).

(*d*) English collections: J. Brand, *Popular Antiquities of Great Britain*, arranged by H. Ellis (2 vols., London, 1813), with additions by W. Carew Hazlitt (3 vols., London, 1870); C. S. Burne, *Shropshire Folk-Lore* (London, 1886); R. Chambers, *Popular Rhymes of Scotland*; W. Gregor, *Notes on the Folk-Lore on the Northeast of Scotland* (London, 1881); J. O. Halliwell-Phillips, *Popular Rhymes and Nursery Tales* (London, 1849); J. Harland and T. Wilkinson, *Lancashire Folk-Lore* (London, 1867); W. Henderson, *Notes on the Folk-Lore of the Northern Counties of England and the Borders* (London, 1866); R. Hunt, *Popular Romances of the West of England, or the Drolls, Traditions, and Superstitions of Old Cornwall* (London, 1865; 2d ed. 1878); J. Napier, *Folk-Lore, or Superstitious Beliefs in the West of Scotland* (Paisley, 1879). The Irish literature is inadequate; as examples, in addition to collections of ballads and tales, may be mentioned Lady Wilde, *Ancient Legends, Mystical Charms, and Superstitions of Ireland* (2 vols., Boston, 1867); J. Mooney, *The Funeral Customs of Ireland*, in *Proceedings* of the American Philosophical Society (1888). For American aboriginal folk-lore, see INDIANS. See also GAMES, EXEMPLA-BOOKS, LEGENDS, MYTHOLOGY, and SONGS.

W. W. NEWELL.

Folk-tales: the title given to narratives of whatever description which are orally current, not having been composed with the pen, but communicated by way of recitation and repeated by word of mouth. From this method of transmission it results that the compositions in question reflect the average intelligence rather than that of a superior literary class; furthermore, that they possess, for the most part, a considerable antiquity, and represent the conceptions, not of recent civilization, but of a much earlier period. The different classes of these tales have been enumerated in classifying the material of FOLK-LORE (*q. v.*). See also *The Dissemination of Tales among the Natives of North America*, by F. Boas.

W. W. N.

Fol'len, CHARLES THEODORE CHRISTIAN, Ph. D., LL. D.: writer, reformer, and liberal preacher; b. at Romrod, in Hesse-Darmstadt, Sept. 4, 1796; educated at Giessen. His patriotic sympathies soon got him into trouble. He was several times arrested, and after fleeing from Giessen he went to Switzerland. He was appointed Professor of Latin and History in the cantonal school at Chur (Coire); but being a liberal in theology as well as in politics, his lectures gave offense to the Calvinistic ministers; so that, finding his position uncomfortable, he resigned it and left. Next he lectured on law and metaphysics at Basel, but his reputation went with him; the allied powers demanded his surrender, and again he fled, this time through Paris to Havre, whence he embarked for the U. S., where, thanks to influential friends—La Fayette among them—he found welcome. A few months after he landed, in the autumn of 1825, he was made tutor of German at Harvard College. Three years later, having in the meanwhile studied divinity with Dr. Channing, and been admitted to the Unitarian ministry, he was appointed Professor of Ecclesiastical History and Ethics in the Cambridge Divinity School; in 1830 the professorship of German Language and Literature was conferred on him. In the five years he held it he did much to make that department attractive. For a short time (1836–37) he was pastor of the First Unitarian church in New York, following Rev. William Ware. His freedom of speech about slavery cut short his ministry there, and in 1839 he accepted a call to East Lexington, Mass., where he had hardly established himself when he was lost in the steamer Lexington, which was burned on Long Island Sound, Jan. 13, 1840. His writings, with memoir, were published in five volumes at Boston in 1841.

Follen, Eliza Lee: wife of Charles Theodore Christian Follen; daughter of Samuel Cabot; b. in Boston, Aug. 15, 1787. She, like her husband, whom she married in 1828, was an earnest abolitionist from first to last, and a diligent writer. Her *Selections from Fénelon*, *Well-spent Hours*, and *Married Life*, exerted wholesome influence in their time. The memoir of her husband was from her pen. *The Child's Friend* was under her editorship from 1843 to 1850. D. in Brookline, Mass., Jan. 26, 1860.

Folly Island: an island of South Carolina; in Charleston co.; extends S. W. from Lighthouse Inlet to Stone river, having Folly Island river on the northwest and the ocean on the southeast. It is in part heavily timbered, and was the scene of important operations during the civil war.

Folsom, George, LL. D.: antiquary; b. in Kennebunk, Me., May 23, 1802; graduated at Harvard College in 1822, and studied law. In 1830 he published a *History of Saco and Biddeford, Me.*; in 1837 removed to New York and became a member and librarian of the New York Historical Society; in 1841 edited a volume of its *Collections*; afterward translated the *Dispatches of Hernando Cortés*; in 1843 published the *Political Condition of Mexico*; in 1858 *Documents Relating to the Early History of Maine*. He was a member of the New York State Senate in 1844–48, and *chargé d'affaires* to the Netherlands 1850–54. Mr. Folsom was president of the American Ethnological Society. D. in Rome, Italy, Mar. 27, 1869.

Folsom, Joseph L.: soldier; b. in Meredith, N. H., May 19, 1817; graduate of the U. S. Military Academy, and brevet second lieutenant of infantry July 1, 1840; served in Florida against the Indians, and on the Northern frontier 1840–44; transferred to the quartermaster's department, with rank of captain, Sept. 1, 1846, and served in California during the war with Mexico. He was among the first to appreciate the discovery of gold in California, and communicate the information officially to his Government. He was identified with the early history and development of San Francisco, where he became a large property-owner. Folsom City, on the American river, near the locality where gold was discovered, is named in his honor. D. at San José, Cal., July 19, 1855.

Folsom, Nathaniel: soldier; b. at Exeter, N. H., in 1726; commanded a company at Fort Edward in 1755, and aided in the capture of Baron Dieskau. Commanded a regiment of militia before the Revolution, and as brigadier-general of the New Hampshire forces served in the siege of Boston until July, 1775. Was a member of the Continental Congress 1774–75 and 1777–80; councilor in 1778; and president of the convention which framed the constitution of New Hampshire in 1783. D. at Exeter, May, 26, 1790.

Folsom, Nathaniel Smith: clergyman; b. at Portsmouth, N. H., Mar. 12, 1806; graduated at Dartmouth College 1828, and at Andover (Mass.) Theological Seminary in 1831; ordained at Bradford, Mass., 1831; was missionary in Liberty co., Ga., in 1831–32; was professor in Lane Seminary and in Western Reserve College from 1833 to 1836; was pastor of the Congregational church at Francestown, N. H., from Oct. 12, 1836, to Aug. 21, 1838; then of a church at Providence, R. I., 1838–40; of a Unitarian church at Haverhill, Mass., 1840–46; edited *The Christian Register* 1846–48 at Charlestown, Mass.; and was Professor of Literature and Biblical Interpretation at Meadville Theological School, Pennsylvania, from 1848 to 1861. He took up his residence in Boston in 1875. He published an address on temperance (1839), and an *Interpretation of the Prophecies of Daniel* (1842), but his most important work was a *Translation of the Four Gospels* (revised edition 1885). D. Nov. 10, 1890.

Folwell, William Watts, LL. D.: b. at Romulus, Seneca co., N. Y., Feb. 14, 1833; graduated at Hobart College 1857; was teacher in Ovid Academy two years, then became adjunct Professor of Mathematics in Hobart College; in 1860 and 1861 studied philology in Berlin and traveled extensively in Europe; in Jan., 1862, was commissioned first lieutenant in the U. S. Engineers, with which command he served through all the campaigns of the Army of the Potomac till the close of the civil war, attaining the actual rank of major of engineers and the brevet rank of lieutenant-colonel U. S. Vols. After some years spent in business he became in 1869 Professor of Mathematics in Kenyon College, Gambier, O., and later in the same year was elected president of the University of Minnesota, and afterward Professor of Political Economy there and librarian. He has published *Public Instruction in Minnesota*, in the *Transactions* of the National Educational Association (1875), and *Lectures on Political Economy*.

Folz, or **Folcz**, Hans: poet; b. at Worms in 1478; became a resident of Nuremberg and a Protestant; was by profession a barber. He was one of the most noteworthy of the German mastersingers, and besides mastersong wrote dramatic Shrovetide pieces and rhyming tales. His lyrics are often spirited, graceful, and of high moral tone and much literary merit; but his other writings are often marked by needless coarseness and a roughly vigorous style of humor.

Fomentation [viâ Fr. from Lat. *fomenta'tio*, deriv. of *fomenta're*, foment, apply warm lotions, deriv. of *fomentum*, **fovimentum*, foment, warm lotion, deriv. of *fove're*, warm, keep warm]: in therapeutics, the application of hot epithems, wet or dry (wet fomentation, dry fomentation), to diseased parts. Fomentations act chiefly by the heat and moisture they convey to the surface treated, but they are sometimes medicated. Fomentation is usually a safe, and often an effective, means of treating many diseases.

Fomites, fom'ĭ-tēez [Lat., plur. of *fomes*, kindling-wood, tinder, deriv. of *fove're*, to warm]: in sanitary science, objects, such as clothing, furniture, bedding, wall-paper, etc., by which the infection of certain diseases is retained, and by which disease may be propagated.

Fonblanque, fōn̄'blaȧnk', Albany William: journalist; b. in London, England, in 1797; the son of John de Grenier Fonblanque (1759–1837), a famous equity lawyer, and a brother of John Samuel Martin Fonblanque (1787–1865), an able writer on law reform. Mr. Fonblanque was (1820–46) editor of *The Examiner*, and was distinguished for literary abilities and for his useful labors as a publicist. He was (1846–72) chief of the statistical department of the Board of Trade, and comptroller of the corn returns. D. in London, Oct. 14, 1872. His *England under Seven Administrations* (1837) is a valuable collection of articles from *The Examiner*. See *Life and Labors of Albany Fonblanque*, by his nephew, Edward Barrington de Fonblanque, 1874.

Fonda: village and railway junction; capital of Montgomery co., N. Y. (for location of county, see map of New York, ref. 4–I); on the Mohawk river; 42 miles N. W. of Albany. It has knitting-mills and manufactures of flour and carriages. Principal business, farming and dairying. Pop. (1880) 944; (1890) 1,190; (1900) 1,145.

Fond du Lac: city and railway center; capital of Fond du Lac co., Wis. (for location of county, see map of Wisconsin, ref. 6–E); on Lake Winnebago, at the mouth of Fond du Lac river; 148 miles from Chicago, 63 from Milwaukee, 65 from Green Bay, and 43 from Sheboygan, thus enjoying the advantages of four competing lake-ports. The city is well built, and is delightfully situated on a plain surrounded by hills and groves. It has a public library, several public gardens for out-door amusements, manufactures of lumber, agricultural machinery, cars, paper, etc., and an important trade in grain, lumber, and pork. Water is supplied by the Holly system from artesian wells, the mineral properties of which have made them famous. Pop. (1880) 13,094; (1890) 12,024; (1900) 15,110. EDITOR OF "REPORTER."

Fonseca, fōn-sā'kaă, BAY OF (also called GULF OF CONCHAGUA): an inlet of the Pacific Ocean; in the southwest coast of Central America; between Salvador on the W., Honduras on the N. E., and Nicaragua on the S. E. The mouth is 22 miles wide between two opposing points, and is divided by islands into four channels, all of which admit large vessels; within the bay broadens to 44 miles from N. W. to S. E. by 19 miles from N. E. to S. W. It contains several islands, and there are a number of good ports on the coast, the bay itself forming a large and secure harbor. The tides average over 10 feet. The volcano of Coseguina occupies the point on the southern side of the entrance to the bay.

HERBERT H. SMITH.

Fonseca, JUAN RODRIGUEZ, de: Spanish ecclesiastic and administrator; b. in Toro, near Seville, 1451. He was successively Archdeacon of Seville, Bishop of Badajoz, Palencia, and Conde, Archbishop of Rosario in Italy, and finally Bishop of Burgos, besides being head chaplain of Queen Isabella and afterward of King Ferdinand. In 1493 he was appointed to superintend preparations for the second voyage of Columbus, and thereafter he had chief control of all matters relating to the New World until the death of Ferdinand in 1516; he directed the Casa de Contratación, or Council of Seville, and was the first head of the COUNCIL OF THE INDIES (*q. v.*), organized in 1511. Columbus quarreled with him almost from the first, and Fonseca's influence was constantly exerted against him and his family; he also schemed against Cortés, and opposed the reforms of Las Casas. Probably his malignity has been exaggerated by Irving and others, but it is certain that he did much harm. Under Ximines he was disgraced, but regained his influence some years later, and was predominant in the Indian council until his death, which occurred at Burgos, Nov. 4, 1524.

HERBERT H. SMITH.

Fonseca, MANUEL DEODORO, da: Brazilian soldier and politician; b. in the province of Alagoas, Aug. 5, 1827; entered the army as a cadet in 1843; subsequently studied in the military school, and graduated in 1849 with the rank of sub-lieutenant of artillery. In the Paraguayan war, 1868–70, he served as colonel; later he was military commandant of various provinces, and attained the rank of major-general. During this period he was a conservative, and personally attached to the Emperor Dom Pedro II.; but in 1887 he and other military leaders opposed certain acts of the Government, and were punished for insubordination. The malcontents eventually brought about a mutiny, deposed and banished the emperor (Nov. 15, 1889), proclaimed a republic, and made Fonseca chief of the provisional government. The republic was recognized by the U. S., and later by France, Great Britain, and other European countries. A constituent assembly met on Jan. 20, 1891; the constitution proposed by Fonseca and his colleagues was adopted, and Fonseca was elected president for four years with the military title of marshal (Feb. 24, 1891). On the meeting of the first legislative congress (June 15, 1891) opposition to the Government took a serious form, and revolts broke out in various places. President Fonseca finally dissolved the congress (Nov. 4, 1891), and proclaimed a state of siege; but disorders continued, and the state of Rio Grande do Sul virtually seceded. Fonseca was accused of arbitrary acts, and on Nov. 23 was forced to resign, the vice-president, Peixoto, taking his place. He remained at Rio de Janeiro, where he died Aug. 23, 1892. HERBERT H. SMITH.

Fonseca, PEDRO, da, D. D.: "the Portuguese Aristotle"; b. at Costizada in 1528; became a Jesuit in 1548; held professorships at Coimbra and Evora; resided at Rome 1572–79; was the instructor of Molina; wrote commentaries on Aristotle (4 vols., 1572–1602); *Institutiones Dialecticæ* (1564); and a treatise on foreknowledge and free will (1588). D. at Lisbon, Nov. 4, 1599.

Font [M. Eng. *font, fant* < O. Eng. *fant*, from Mediæv. Lat. *fons, fontis*, font < Lat. *fons*, spring, fountain]: a cistern or vessel used in churches to contain the baptismal water. It is usually of stone, frequently porphyry, or other rich marbles. It was permitted by the Council of Lerida (A. D. 524), that if the priest could not procure a stone font he might provide himself with a *vas conveniens ad baptizandi officium* of any material (Labbe, *Concil. IV.*, 1615), which was not to be used for ordinary purposes, but reserved for the sacrament alone (Leo IV., *de Cura Pastoral.*; Labbe, *Concil. VIII.*, 37). In the Eastern Church the font was usually of metal or wood, and seldom or never possessed any special beauty or adornment (Neale, *Eastern Church*, i., 214).

The proper place for the font was at the entrance of the church building, symbolizing baptism as the "door" of the Church. The usual form was octagonal, with a mystical reference to the eighth day as the day of our Lord's resurrection, and of regeneration by the Spirit (cf. Ambros, *Epist.* 20, 44, quoted in Smith and Cheetham's *Dict. Christ. Antiq.*, i., 680). The font is frequently fashioned with much taste and skill. The most detailed description of a baptismal font is that given in the life of St. Sylvester, in the *Bibl. Pap.* of the pseudo-Anastasius (sec. 37); vide Smith and Cheetham, *Dict. Christ. Antiq.* This font is said to have been presented by Constantine the Great to the Church of the Lateran. The cistern is stated to have been made of porphyry, overlaid within and without with silver. In the middle of the font were two pillars of porphyry supporting a golden dish, in which was the Paschal lamp. A golden lamb and seven silver stags (cf. Psalm xlii. 2) poured out water, and on either side of the lamb were silver statues of Christ and John the Baptizer. The oldest fonts existing date from the eleventh century, but, though full information on the subject is lacking, it is evident that the font has undergone various changes of form as the rite of baptism changed. It is believed that the use of "standing fonts" began with the practice of infant baptism, and the substitution of aspersion for immersion in the sacrament, perhaps in the Middle Ages. In the old baptisteries—often buildings entirely separated from the church proper, and used exclusively for the performance of baptism—the font was often a large basin approached by descending steps, indicating that in those days baptism was most generally administered by immersion. At the time of the Reformation the fonts were generally much larger than those made now; they were, indeed, made so large that an infant could be baptized in them by immersion, as is shown by a glass picture from that time. The name *font* is often incorrectly applied to the stoup, stock, or *bénitier*, a vessel containing holy water and placed near the entrance of Roman Catholic churches. See Simpson, *Series of Ancient Baptismal Fonts*, and Paley, *Ancient Fonts*.

Revised by WILLIAM STEVENS PERRY.

Fontaine, fōṅ'tān', PIERRE FRANÇOIS LOUIS: architect; b. at Pontoise, France, Sept. 20, 1762; practiced during the whole period from the first republic to the second empire, mostly in partnership with his fellow-pupil, Percier. Among his works may be mentioned extensive alterations of the court and staircases of the old Louvre; plans for uniting the Tuileries to the Louvre; the Arc de Triomphe du Carrousel (1807); the Chapelle Expiatoire for Louis XVIII. (1815–20); the Chapelle St. Ferdinand, memorial to Duke of Orleans (1843); besides several literary works, especially *Choix des plus célèbres maisons de plaisance de Rome* (1809–24) and *Recueil de Décorations Intérieures* (1812); officer of the Legion of Honor in 1814, commander 1832; and for many years president of the Conseil des Bâtiments Civils. His work, especially in furniture and decoration, displays great refinement of taste. D. in Paris, Oct. 10, 1853. A. D. F. HAMLIN.

Fontainebleau, fōṅ'tān-blō': town of France; department of Seine-et-Marne; 35 miles S. E. of Paris (see map of France, ref. 3–F). Its palace, built in the twelfth century and enlarged and embellished in each succeeding century, is one of the most magnificent buildings in France. The forest which surrounds it, and which is wholly laid out as a landscape-garden, comprises 64 sq. miles, and the roofing of the palace covers no less than 14 acres. The present structure was begun by Francis I., who employed Leonardo da Vinci, Andrea del Sarto, and Benvenuto Cellini to complete and execute his plans. By Henry IV. the building was much enlarged. He added the Diana Gallery, the Court of the Princes, and the Galerie des Cerfs. The later Bourbons disliked the place, and suffered it to be neglected, but it was again restored with great magnificence by Napoleon I., who spent 6,000,000 francs for the purpose. Some of the most pathetic incidents in his life occurred here. The first of the five great courts still bears the name in popular parlance of the Court of Adieux, as it was there Napoleon bade farewell to the Old Guard. The town is neat and well built. It has some trade in wine, grapes, garden-produce, etc., and some manufactures of porcelain and earthenware. Pop. (1896) 14,078.

Fontana, fon-taa'naă, DOMENICO: Italian architect; b. at Como in 1543; studied architecture at Rome. Cardinal Montalto, afterward Sixtus V., commissioned him to build a chapel in Santa Maria Maggiore for him, but the expense being above his means the chapel was not finished till the cardinal became pope and Fontana was appointed pontifical architect. The difficulty of raising the obelisk on the piazza of St. Peter was solved by Fontana, who received high honors as well as liberal pay. After this Fontana was commissioned to raise three other obelisks—that of the mausoleum of Augustus, which was placed on the piazza of Santa Maria Maggiore; another before the basilica of St. John Lateran; the other on the piazza before Santa Maria del Popolo. He then added a portico of travertine to the façade of St. John Lateran, and built a splendid palace of three stories for the pope, and began the Vatican library finished under Clement VIII. Fontana also continued the pontifical palace of the Quirinal, and transported from the baths of Diocletian the two colossal groups of demigods with horses which stand before it. He fell into disgrace while constructing a bridge in the quarter of the city called Borghetti, having been accused of misappropriating money confided to him for this purpose. The pope, judging him to be guilty, dismissed him. Count Miranda, Viceroy of Naples, then offered him the post of architect and first engineer to the King of the Two Sicilies, and Fontana went to Naples about the year 1592 with his wife. There he constructed several canals, protecting the province of the Terra di Lavoro from inundations, and the royal palace, which is marred by the additions of later architects. He made designs for the port of Naples and a pier. He was greater as engineer than as architect. D. at Naples in 1607. W. J. STILLMAN.

Fontana, GIOVANNI: architect; elder brother of Domenico Fontana, and his assistant in several enterprises; was especially successful as a hydraulic engineer and designer of fountains. D. 1614.—CARLO, perhaps related to Giovanni, b. 1634; d. 1714; assisted Bernini in several works; designed the Palazzo Torlonia and many other works, none of first-rate importance. A. D. F. HAMLIN.

Fontanel' [from Fr. *fontanelle*, fontanel, dimin. of *fontaine*, fountain]: the soft palpitating spot upon the head of a young infant; so called because its throbbing was likened to the welling up of a fountain. The fontanels are usually from four to six in number, but only one or two are easily detected in most cases. The great fontanel is at the crossing of the coronal and sagittal sutures. It is generally closed by the development of the neighboring bones within two years after birth. The smaller posterior or bregmatic fontanel is at the junction of the sagittal with the lambdoidal suture, and closes in a few months after birth. There are also two sphenoidal and two mastoidal or Gasserian fontanels, but they are very small, and generally close soon after birth. The two principal fontanels are of great importance in midwifery, as they enable the skillful practitioner to determine the position of the fœtus in head presentations.

FONTANEL is also a small issue or artificial ulcer made by the surgeon for its derivative effect. A common dried pea, a lump of beeswax, or other hard mass is kept in a small cut under the skin, causing a flow of pus. The fontanel, though a valuable therapeutic means, is not much employed.

Fontanel'la, FRANCESCO: Italian educator and author; b. at Venice, June 28, 1768; became a priest, and was for a time Professor of Grammar in Venice, and afterward Professor of Latin Eloquence at Udine, but his principal employment was proof-reading. He was author of Greek and Hebrew grammars and lexicons, and of several learned philological treatises. D. at Venice, Mar. 22, 1827.

Fontanes, fon'taan', LOUIS, Marquis de: poet and politician; b. at Niort, France, Mar. 6, 1757; went to Paris in 1777 and in the following year published *La Fôret de Navarre*. This was followed by several other poetical works of merit, among which may be mentioned a translation of Pope's *Essay on Man* (1783), *La Chartreuse de Paris*, *Le Jour des Morts dans une Campagne*, the latter a poem in the style of Gray's *Elegy*, and *L'Épitre sur l'Édit en faveur de non-Catholiques*, which was crowned by the Academy in 1789. In the early period of the Revolution he edited the *Modérateur*, and opposed the growing spirit of anarchy. Having retired to Lyons after the death of the king he dared to present to the convention an eloquent appeal on behalf of the city, for which he was proscribed, but he escaped by flight. He remained in hiding till after the fall of Robespierre, when he once more became prominent in Paris, but an article in the *Mémorial*, of which he was an associate editor, displeased the Government, and he was again obliged to flee. He found a refuge in London, where he became a close friend of Chateaubriand, also an exile. Returning after the *coup d'état* of 1799 (18th and 19th Brumaire), he was reinstated as a member of the Institute; became a member of the legislative body, of which he was chosen president in 1804; was appointed grand master of the University of Paris in 1808, became a senator in 1810 and was raised to the peerage. During the Hundred Days he was passive, and on the second restoration he was on as good terms with the Bourbon Government as he had been with that of Napoleon. He was nominated a member of the privy council in 1815, and two years later received from the king the title of marquis. D. at Paris, Mar. 17, 1821.
F. M. COLBY.

Fon'te Avella'na, Order of: a monastic order established in 1001 at Fonte Avellana, near Faenza, Italy, by Ludolf, Bishop of Iguvium. In 1570 it was united to the Camaldulians. St. Peter Damian was its most famous member.

Fontenay-le-Comte, fōn'te-nā'le-kōnt': town of France; department of Vendée; on the Vendée (see map of France, ref. 6–D). It has great linen manufactures and tanneries. On May 16, 1793, it was the scene of the victory of the republican army under Chabot over the Vendeans. Pop. (1896) 10,096.

Fontenelle, fon'te-nel', BERNARD LE BOVIER, de: author; a nephew of Corneille; b. at Rouen, France, Feb. 11, 1657; admitted to the French Academy in 1691, and to the Academy of Sciences in 1697, of which he was perpetual secretary from 1699 to 1741. His *Dialogues of the Dead* was published in 1683, *Discourse on the Plurality of Worlds* in 1686, and *Essay on the Geometry of the Infinite* in 1727. Wrote also *History of Oracles*, and in forty years composed eulogies on about seventy members of the French Academy of Sciences. D. at Paris, Jan. 9, 1757.

Fontenoy, fōn'te-nwaă'; village of Belgium; province of Hainaut; 5 miles S. E. of Tournay (see map of Holland and Belgium, ref. 11–B). Here was fought, May 11, 1745, the famous battle between the French under Marshal Saxe and the allied English, Dutch, and Austrians under the Duke of Cumberland, in which the French won a great victory. Pop. 800.

Fontevrault, fōn'te-vrō': town of France; department of Maine-et-Loire; 10 miles S. E. of Saumur (see map of France, ref. 5–D). In its church are the tombs of Henry II. and Richard I. of England. The church, now a prison, is nearly all that remains of the ancient abbey of Fontevrault, once the mother-house of the monastic order of Fontevrault, founded 1100, and broken up at the Revolution. Pop. (1896) 2,853.

Fonvielle, fōn'vi-el', WILFRID, de: aëronaut and popular scientific writer; b. in Paris, France, in 1828; was a teacher of mathematics, then a journalist, and finally aëronaut. During the siege of Paris he escaped from the city in a balloon. Among his works are *L'homme fossile* (1865); *Les merveilles du monde invisible* (1866); *Éclairs et tonnerres* (1867; translated into English by T. L. Phipson under the title of *Thunder and Lightning*); *L'Astronomie moderne* (1868); *La conquête du pôle nord* (1877); *Les saltimbanques de la science* (1884). Accounts of his balloon ascensions were published in 1871, and translated into English under the title of *Travels in the Air*. He has written several political and polemical pamphlets; thus in 1879 he published *Comment se font les miracles en dehors de l'Église*, in which he reviews the claims of spiritualist mediums from a common-sense standpoint.

Food [M. Eng. *fode* < O. Eng. *fōda* < Teuton. *fōd-* < Indo-Europ. *pă(t)-*; cf. Lat. *pasco*, feed, *pā'bulum*, food, Gr. πατεῖσθαι, to eat]: a substance which supports the functions and powers of the body—one by which the body may live, act, and grow; aliment. It is not one which simply satisfies or arrests appetite, for a nauseous smell or a mental shock will do that; nor one simply which gives a sense of satisfaction at the stomach and removes craving for food, like the lump of clay which is swallowed by savages in the absence of food; yet food does both. Neither is it a substance which controls and regulates the functions, for that is the special duty of a medicine; and yet it so far governs that it increases the activity of some or all of them. With want of food there is a natural subsidence of vital action, accompanied by craving for food and appetite or relish for it, while after food has been eaten the action of the heart, lungs, and other organs is increased, heat is generated more freely, appetite is arrested, and a sense of satisfaction is felt. After an interval of three or four hours appetite and a sense of want of food return, and the process of renewal must be repeated.

Food must be identical with the elements of our bodies, or be capable of transformation into them, supplying the want caused by waste and the material required for growth. It must also be adapted to the needs of the infant as well as those of man at all ages and in various conditions of season, climate, modes of life, and exertion. Its nature must be such that it can be digested within a proper period, lest the body starve while food is within it; but this is commonly assisted by the process of cooking, which by softening the food shortens the term subsequently required for digestion. Thus a piece of the bark of a tree may contain the elements of food, but in a form most difficult of digestion. When in periods of great privation bark has been eaten it has been first broken up into the smallest pieces, immersed and then boiled in water to soften the fiber and to cause the starch-cells to burst. Or again, in infants the digestive powers are feeble, so that they require foodstuffs of the most digestible nature, such as milk, pap, corn-starch, bread, etc. Idiosyncrasy is another factor; articles of food which are easily digested by most people are digested with difficulty by others.

Classification.—As foods have two chief duties to perform—to maintain the heat of the body and supply material for growth and repair—they were formerly classed as *heat-generators* and *flesh-formers.* Included among the former were the starches, sugars, oils, etc., and among the latter the albuminous substances, such as meat, fish, the white of egg, etc. These classes were also called respectively *non-nitrogenous* and *nitrogenous*—the former not containing nitrogen in their molecules. The advance of knowledge teaches that the non-nitrogenous substances also serve for repair and growth of the body, consequently the division into heat-generators and flesh-formers is not logical.

Foodstuffs are usually divided primarily into the inorganic and organic, the former including the various mineral substances—water, oxygen, etc.—found so commonly diffused throughout nature; the latter those which are derived directly from plant or animal life. Organic substances are subdivided into the non-nitrogenous and nitrogenous as above.

Foods will be considered in this article under the two general heads of solids and fluids, the former being divided into three classes, according to their source—viz., mineral, vegetable, and animal.

I. Solid Foods.

A. *Mineral Food.*—The bones, nearly every soft tissue, and the blood require mineral matters combined with acids, and foods supply them in about the following proportion: Common salt, or chloride of sodium, is found in water and in many animal and vegetable substances, and it is usual to eat from one-quarter to one-half an ounce daily with food. Potash is supplied by lemons, oranges, grapes, pineapples, strawberries, mulberries, tamarinds, apples, and nearly all fruits, as well as by potatoes, cauliflowers, cabbages, cucumbers, artichokes, asparagus, rhubarb, and nearly all garden vegetables. Sulphur is contained in albumen (as the white of eggs), fibrin, and casein in proportions of 3½ to 7 parts in 1,000. Iron enters into the composition of most vegetable foods, as potatoes, carrots, cucumbers, peas, cabbages, and mustard, and into many animal substances, as milk and flesh. Aluminium exists in carrots, and silica, or flint, in potatoes, wheat, rice, and numerous vegetable structures. Phosphorus, when combined with a base, as lime, magnesia, soda, potash, etc., is found in nearly all vegetable and animal foods. Thus there are in blood 0·14; barley, rice, and oats, 0·22 to 1·32; milk, 0·56; wheat, 0·8 to 2·0; potatoes, 2·5; casein, 13·2; and in bones, 27 to 72 per cent. It is also found in fibrin, albumin, the brain, and numerous other structures of the bodies of animals.

From this statement it follows that while the need of the body for mineral matter may be supplied in very different quantities, a mixture of foods is the most fitting. But of all classes those which contain fresh vegetable juices appear to be the most important, for without them the nutrition of the body can not be long maintained.

B. *Vegetable Foods.*—The lowest classes of vegetables which supply man with food are the lichens, fungi, mosses, and seaweeds. Lichens and mosses are ordinary articles of food in the northern regions, as in Lapland and Greenland, and supply food to man and beast for several months in the year. Iceland moss (*Cetraria islandica*) has long been appreciated in more southern climates for its mucilaginous quality, and is eaten alone, as an infusion in hot water, or made into various compounds, as Iceland moss cocoa or as a preparation similar to corn-starch. It is deficient in flavor, and requires the addition of sugar and a condiment, but it produces a more valuable infusion than linseed tea. Reindeer moss (*Cladonia rangeferina*) has similar qualities, but is inferior as a nutriment, since while the former yields about 30 per cent. and the latter has only about 1 per cent. of starch, the potato usually contains about 18·0 or 19·0 per cent. of starch. It is inferior in that respect to Iceland moss. Irish or carrageen moss (*Chondrus crispus*), a seaweed, is not equal in nutritive value to Iceland moss, but is a well-known article of food or physic. Seaweeds have long been in use as food in Scotland and the more northern islands of Europe, particularly when other vegetable food is scarce. They have also been used in periods of abundance by a few persons, so that laver (*Porphyra laciniata* and *vulgaris*) is eaten with roast meat at the most luxurious tables. There are many edible seaweeds, but as all have a bitter flavor, which soda only partially removes, they are not likely to be generally used as food. They, however, rank very high in nutritive value, for they are said to contain 10 to 15 per cent. of nitrogenous and 60 to 70 per cent. of carbonaceous matter, and therefore merit the attention of countries having a wide seaboard and a poor population.

Mushrooms (*Fungi*) constitute a large class of vegetables, many of which have most attractive colors, and not a few very repellent odors. Some varieties are edible; others are poisonous. The chief variety used is the common edible mushroom of small size (*Agaricus campestris*). In chemical composition this class of vegetables ranks somewhat high, but they are very light in structure, and from the bulk required at a meal could not become a necessary article of food. They are generally luxuries, or when made into ketchup may be called condiments. Truffles, whether white or black (*Rhizophagon album* and *Tuber cibarium*), grow about a foot in depth under ground, to the size of a potato, and are more fashionable than useful as a food.

Succulent Vegetables.—This very large class of foods is eaten chiefly for their juices and starch, and are prized according to the abundance of these elements and their flavor.

The potato (*Solanum tuberosum*) occupies the first place in temperate climates, on account of the large quantity of starch which it contains, and its agreeable flavor. It is a native of North and South America, but has become acclimatized in all except very hot and very cold climates. It contains only about 2·1 per cent. of nitrogenous matters and salts, and is therefore not fitted to be a sole article of food. The greater the specific gravity the larger is the quantity of starch which it contains; so that with a specific gravity of 1·123 there is 24·14 per cent. of starch, while with a specific gravity of 1·090 the starch is only two-thirds of that quantity, or 16·38 per cent. The sweet potato (*Batatas edulis*) and the yucca are eaten largely in America. The yam (*Dioscorea alata, batatas*, or *sativa*) is a common food in China and many other countries, and contains a quantity of starch scarcely less than that of the common potato, but is not equal to the latter in flavor. There are many edible tubers bearing starch growing in South America, and also a few in North America, as the prairie turnip (*Apios tuberosa*), which contains a larger proportion of edible matter than the common potato. The artichoke (*Cynara scolymus*) is valued for its flavor, as well as for its nutritive qualities. The *Helianthus tuberosus*, or Jerusalem artichoke, has edible and quite nutritious tubers, which are, however, rarely used as human food.

The fruit of the breadfruit-tree (*Artocarpus incisa*) and of the plantain (*Musa paradisiaca*) may be regarded either as culinary vegetables or fruits, but from the quantity of nutritive material which they afford they belong rather to the former. The breadfruit is always cooked by baking in an earthen oven or on heated stones, and then resembles wheaten bread.

The carrot (*Daucus carota*), parsnip (*Pastinaca*), beet (*Beta vulgaris*), turnip (*Brassica*), vegetable marrow, and pumpkin (*Cucurbita*) occupy a position between potatoes and ordinary green vegetables, since they contain a larger quantity of starch and sugar, and are therefore more nutritious, than the latter. They are nearly equal in nitrogenous elements—viz., about 1·3 per cent.—but in reference to sugar they vary as follows: turnips, 2·1 per cent.; parsnips, 5·8; carrots, 6·1; and beets, 10·5. Swedish turnips contain more carbonaceous matter (starch and sugar) than the white variety, but the flavor is harsher, though in the U. S. the more delicate varieties are highly prized.

All the well-known succulent vegetables, as spinach, turnip-tops, cabbage (*Brassica*), broccoli, cauliflower, sea-kale, tomatoes, nettles, lettuce, dandelion, endive, chicory, may be regarded as nearly alike in nutritive value, while they vary extremely in flavor, and are chiefly valuable for their fresh juices. They should be well cooked, for if eaten in large quantity they do not readily digest. No part of a dietary is more valuable than the abundant supply of such substances, but when eaten raw or in salad it should be in moderation. Cucumbers (*Cucumis*) are regarded apart from this class, since they are always eaten raw, but are difficult of digestion, and have very little nutritive value. Rhubarb (*Rheum*) has the character of a fruit rather than a vegetable, and has juices that are very valuable. Wild lettuce (*Lactuca sativa*) is poisonous, while when cultivated it is both harmless and agreeable.

Fruits may now be considered, since they are more like succulent vegetables than any other productions in the composition of their juices and their uses in the animal economy. It is needless to cite them by name, as they are well and widely known, and it would be impossible to refer to more than a very small proportion of them. No products are so universal and none so agreeable. All agree in having a larger proportion of sugar and vegetable acids and salts than occurs in ordinary vegetables, and flavors of infinite variety and delicacy. Some, as the date, are so valuable as to be a chief support of life, but the characteristic of the class is to afford agreeable and refreshing rather than nutritious elements. It is, however, worthy of note that in these qualities the choice fruits of the gardens and hothouses of Europe and the U. S. far excel those of the products of Eastern climates, while the chemist has produced substances which closely imitate the flavor of all the most appreciated fruits. The following table contains the percentage, quantities of water, sugar, and free acid in ordinary fruits:

FRUITS.	Water.	Sugar.	Free acid.
Grapes, generally	79·8	13·8	....
Klaubegen, ripe	....	10·59	....
White Austrian	....	13·78	....
Red Asmannshäuser, ripe	....	17·28	....

Currants, white	83·4	7·12	2·53
" red	85·2	6·44	1·84

Seeds.—The seeds of plants have so much in common that they may be treated under one head, notwithstanding their infinite variety of flavor and diversity of production. The most highly nitrogenized seeds are peas, beans, lentils, and numerous other products of pod-bearing plants, called pulses, or dahls and grain in India, and frijoles in Mexico. White potatoes contain about 2 per cent. of nitrogenous matter, peas have 23 and lentils 25 per cent., and are the most highly nitrogenized natural foods known to mankind. They are also rich in starch, for peas contain 55 per cent. of that substance. Whole nations are largely indebted to these foods for their highest nourishment, and it seems as if the nitrogenous vegetable food were more suitable to the body in hot climates than meat. The 4 oz. of dahls which each inhabitant of a large part of India eats daily is to the rice accompanying it that which buttermilk is to the potato in Ireland; and it is scarcely possible to overestimate its value. The flavor is, however, somewhat harsh as compared with that of fine wheaten flour, and with the luxurious habits of the age the latter, although affording less nutriment, is preferred. The most agreeable member of this class in Europe is the haricot bean, which is in almost daily use in France, and is served alone or with meat and sauce. All such foods require to be well cooked by boiling, and the skins should be rejected. They are deficient in fat, and consequently demand an addition of that food. When eaten too abundantly and constantly they are liable to produce skin-disease and indigestion. The least nutritious seed in nitrogenous matters in extensive use is rice, for it contains but 6·3 per cent., and the next is millet, with 9 per cent.; yet these substances supply the chief food of more than half of the inhabitants of the world. At the same time they supply a proportionally greater amount of starch—viz., rice 79·1, and millet 74 per cent., as against 55·4 per cent. in peas. Experience has shown that whatever may be the use of nitrogen, it is most abundant in food used in cold climates, while starch is the reverse. As a part of the dietary they are agreeable and valuable. Ground rice can not alone be made into a loaf, but small cakes and biscuits are prepared with it. Parched rice made into *sulpawn* is in common use in the East.

The seeds which supply staple vegetable foods occupy a position between these and peas, and have a close similarity in their nutritive qualities—viz., wheat, maize, and oats, which possess 11 to 12 per cent. of nitrogenous and 75 to 80 per cent. of carbonaceous matter. They differ in flavor, so that both maize and oats are said to be rough, while wheat has a softer and perhaps sweeter flavor, and although wheat has the preference wherever it is grown, each kind of corn has its advocates. Regarded simply as nutritive foods, one may be substituted for the other.

Bread which is made from wheat may have all or any part of the husk or bran of the grain in it. If there be much it is called brown-bread, and as the flinty covering of the bran is indigestible, it is very apt to cause purging, and is the rich rather than the poor man's food. White flour has lost some of the nitrogen of the bran, but it is more digestible and therefore more useful, and probably the most nutritious kind is that known as seconds or households. Fourteen pounds of fine white flour should make 19½ to 20 lb. of bread. Passover cakes are made from the finest and purest flour. Oatmeal is rarely obtained entirely devoid of the hard and indigestible skin, to which also it owes its high percentage of nitrogen; but when the whole grain has been decorticated it is known as groats. Maize is the only grain under consideration which is eaten whole in its unripe condition and when full of milky juices, but whole ripe wheat is steeped in water to make frumenty, and both the oat grain and the skin of the oatmeal are used to make foods in Wales and Scotland under the name of *sowens* and *sacan* or *slymru*. Very valuable preparations for infants' food and puddings are made from them, as corn flour, hominy, and semolina.

The nutritive qualities of all these grains vary with climate and season, so that moderately hot and dry climates and seasons produce the best wheat, and the highlands better oats than the lowlands. The *tortilla* is a cake prepared in Mexico and South America with ground maize, while johnny-cake and corn bread are commonly made in the U. S. from the same grain.

Rye and barley, although inferior grains, are largely eaten by the poorer inhabitants of Northern and Central Europe. The proportion of nitrogenous matter is only from 7 to 8 per cent., and therefore but little exceeding that of rice and millet, while the carbonaceous is 78 to 80 per cent. An improved food is made by a mixture of rye and wheat called *maslin*, which is in use in Northumberland and North Yorkshire, and it is not unusual to add a little rye meal to wheat meal in making bran bread, with a view not to increasing the nutritive value of the latter, but to keep the bread moist. The Norwegian *flödegröd*, or cream porridge, is made by boiling barley meal in cream, during which process it is stirred with a *grödstick* twisted between the palms of the hands.

The following table shows the percentage composition of the chief representatives of this class of seeds and foods:

SEEDS, ETC.	Water.	Nitrogenous.	NON-NITROGENOUS, INCLUDING			Salts.
			Sugar.	Starch.	Fat.	
Maize	14	11·0	0·4	64·7	8·1	1·7
Millet	13	9·0	74		2·6	2·3
Rice	13	6·3	0·4	79·1	0·7	0·5
Oat meal	15	12·6	5·4	58·4	5·6	3·0
Wheaten flour, seconds	15	10·8	4·2	66·3	2·0	1·7
Wheat bread	37	8·1	3·6	47·4	1·6	2·3
Barley meal	15	6·3	4·9	69·4	2·4	2·0
Rye meal	15	8·0	3·7	69·5	2·0	1·8

Nuts.—There are numerous seeds which are regarded as fruits from their agreeable flavor and unfitness to be eaten as standard articles of food, such as the cocoanut (*Cocos nucifera*), Brazilian nut (*Bertholletia excelsa*), ground-nut (*Arachis hypogœa*), walnut (*Juglans*), chestnut (*Castanea*), and almonds (*Amygdalus communis* and *amara*), constituting a very large class, and found in almost every part of the world except the extreme north and south. They are rich in albuminous, saccharine, and fatty elements, and supply a much larger quantity of nutriment than the ordinary cereals. The cocoanut is doubtless the most valuable nut in hot countries, both as yielding fluid and solid food, besides oil and fat for commercial purposes; while the edible chestnut is the most useful in temperate climates, and supplies a larger proportion of starch and smaller proportion of fat than the cocoanut. The nutritive value of these products has not yet been sufficiently appreciated, but as a rule they are very indigestible.

Starchy Foods.—Foods which are composed almost exclusively of starch are artificial, for they must be prepared by man from natural foods. Such are sago, tapioca, arrowroot, cassava meal, and manioc. None are absolutely destitute of nitrogen, but the quantity is so small that it may be practically discarded in calculations. Sago is obtained from several palms by beating and washing the pith, while all the others are extracted from roots or tubers. Arrowroot is prepared from the *Maranta arundinacea*, or even the potato, and the others from the *Jatropha* and other euphorbiaceous plants, which contain poisonous juices until expelled by heat. The process is the same in all—viz., to beat the root and wash and dry the fecula. The size and color of the grains depend upon the mode of preparation. All are practically equal in nutritive value, but Bermuda arrowroot is generally preferred in the market. These foods may be readily distinguished from each other by the microscope, which shows the figure and size of the starch-cells. As all are really starches, their respective values depend upon flavor and cheapness, and not upon their relative usefulness in the system. All alike require to be sufficiently cooked, so as to burst the cells and to thicken the fluid in which they are macerated, and for the use of young infants must be given with milk and other nitrogenous food.

Sugar is found in almost every kind of vegetable foods, but particularly in fruits, where it is called fruit or grape sugar; in the sugar-cane (*Saccharum officinarum*) and Chinese sugar-grass (*Sorghum saccharatum*), where it is known as cane-sugar; and in milk, as milk-sugar. The composition of sugars varies only in the elements of water, and that of cane is $C_{12}H_{22}O_{11}$; but all are not equal in sweetening properties. The quantities per cent. found in certain foods are as follows: Raw sugar, 95; treacle, 77; buttermilk, 6·4; carrots, 6·1; parsnips, 5·8; oat meal, 5·4; skim milk, 5·4; new milk, 5·2; barley meal, 4·9; wheat flour, 4·2; rye meal, 3·7; wheaten bread, 3·6; potatoes, 3·2; turnips, 3·1; peas, 2·0; Indian meal and rice, 0·4. See SUGAR.

Honey is not the product of the bee, as many believe, but is simply collected by that useful insect from flowers, and has a flavor varying with its source. In Turkey and other countries that procured from certain plants is poisonous, and other kinds are very unwholesome.

Manna as ordinarily obtained is derived from the juices of the manna ash, growing in Southern Europe. It is also found as a deposit upon the trees and ground under certain conditions of weather and climate, when it is in grains as small as a coriander-seed, and if not carefully picked will be mixed with other substances. Its peculiar substance is called *mannite*.

C. *Animal Foods.*—All kinds of flesh have their essential properties in common, and for ordinary dietetic purposes are interchangeable; but as lean corresponds with lean and fat with fat, the true distinction is the proportion of one to the other: thus there is the largest proportion of fat in the pig, and a greater proportion in sheep than oxen as ordinarily fed and when ready for the butcher. The same quantity of food produces a larger quantity of fat in one than in the other: thus with 100 lb. of nitrogenous food the pig produces 13·5 lb. of fat, the sheep 4·2 lb., and oxen 4·1 lb., while the same quantity of carbonaceous material produces 18·5 lb., 9·4 lb., and 7·2 lb. in the three classes.

The flesh of all animals consists of bundles of extremely fine tubes which contain the muscular substance. The better the breed and feeding the richer are the flavor and fat, while the older the animal the tougher are the fibers or tubes and the tissue which connects them. Each class of animals has its own special characters, but the quantity of meat depends upon these two conditions. This is true of the nitrogenous part of an animal, but the fat, which is carbonaceous, is nitrogenous only to the extent of the fine nitrogenous tissue in which it is contained. Beef has always been regarded as the kind of flesh which gives the best nutriment to the eater, while mutton and poultry are softer in texture and more delicate in flavor. The flesh of wild animals approaches to, if it does not excel, beef in nutritious qualities, but it is almost always harder, and requires more cooking to separate its fibers. The rich flavor of wild game is nearly lost with domestication. Pork and veal have always justly been regarded as less digestible than beef.

The juices of flesh are obtained when making beef-tea. The meat is cut into small portions which are placed in a bottle, and the bottle allowed to stand in warm water, the juice being drawn off from time to time as it collects. It contains considerable of the salts which were present in the flesh and some albuminous matter. Liebig's and similar extracts of meat are valuable as nervine stimulants and meat flavorers, but are not a rich nutrient in the ordinary sense of the word, and should not be depended upon to serve as foods without admixture of other nutritious substances.

The flesh of fish contains more phosphorus, and differs little from that of animals in chemical composition, but much in texture and flavor, and the nearest approach is found in salmon and sturgeon. The proportion of fat and oil to flesh is in some kinds greater than that of quadrupeds, for the eel contains 50 per cent., herring 30 per cent., and a salmon in fine condition 10 to 20 per cent. Whitefish usually contains less than red-blooded fish, but some of the former, as the cod, lay up a large store of oil in the liver. Fish is rich in phosphorus. On the whole, fish is excellent food, but not equal to flesh, nor sufficient to maintain full health and strength. Leprosy is found chiefly in fish-eating and poverty-stricken populations. The roe of fish is a luxury, and contains both albuminous and fatty matters, and when obtained from the sturgeon and some other fish, and prepared, is called *caviare*. It is eaten raw in Sweden and Russia as an appetizer before dinner. The gelatinous parts of fish, as the head and fins, are also much prized, but unless eaten in great quantity do not suffice for a meal. When fish, as herring, is cheap, it is the cheapest of all animal foods in the market in proportion to the nutriment contained in it, but its price is subject to great variation. Oysters are readily digested and are of great nutritive value, while lobsters and similar shellfish are too indigestible to be eaten by some persons with impunity.

Eggs consist chiefly of albumen, but the yolk contains oil, and there are also sulphur and other elements which have a certain nutritive value. They are not fitted to supplant flesh, but rank next to fish. All have the same nutritive value in proportion to their size, but some are repelling in flavor, as those of fish-eating birds, while others are delicious, as those of well-bred and well-fed barnyard fowls. Those of the plover are among the most delicate in flavor. It is not desirable that they should be boiled hard, unless to be grated down, but they may be boiled, as in puddings, when well divided into the semi-liquid state. The highly nutritious quality of an egg may be appreciated from the following percentage analysis, and but few know that it contains so large a proportion of fat as is shown in the following statement: thus dry matter, 30; dry fat, 11·0; carbon, 17·52, or carbon and nitrogen reckoned as carbon, 20·56; mineral matter, 1·4; nitrogen, 2·0; besides water.

Gelatin is a valuable food, notwithstanding the erroneous inferences which have long been drawn from the report of the French gelatin commission, and in composition is nearly identical with albumen. Isinglass is the best form of it, but in China certain birds' nests, with which soup is made, have the preference. It is, however, usually obtained from the bones, skins, and hoofs of animals.

Casein is obtained principally from milk, but exists largely in pease and almonds, and has the same nutritive character as albumen and gelatin. As ordinarily found in cheese, it is mixed with a proportion of fat (butter), and by drying, as well as by decomposition, acquires a flavor very different from that of fresh curd. While the latter may be eaten with impunity, the former is digested with difficulty and requires careful mastication. Skim-milk cheese contains a larger proportion of nitrogenous and a less proportion of carbonaceous matter, as shown in the following percentage analysis:

DESCRIPTION.	Water.	Nitrogenous.	Fat.	Salts.
New-milk cheese, very good.	36	28·4	51·1	4·5
Skim-milk cheese........	44	44·8	6·3	4·9

The proportion of fat varies much in the best kinds of cheese, as from 18·7 in Neuchâtel to 32·3 in Roquefort, while in an ordinary Cheshire cheese it is 26 per cent. The chemical composition of all these elementary substances, and also of flesh if perfectly freed from fat, is almost identical, and may be illustrated by that of albumen, which is C., 53·4; H., 7·0; O., 22·1; and N., 15·7. Hence the nitrogenous element is somewhat more than one-sixth, and the carbonaceous more than one-half of the dried substance.

Offal.—The offal of animals is the head, feet, liver, lungs, and heart, while the blood and bowels may be added to the list for dietetic purposes. The heart consists of muscular fiber or flesh, having, however, a firmer texture, is not so easily masticated, and is much inferior to other flesh as food. The lungs and liver consist largely of albuminous, and the head and feet of gelatinous matter, and while not equal to flesh are very good foods, and might be eaten by the poor more largely than at present with advantage. Tripe is prepared chiefly from the stomach of the ox, and contains much fat as well as albuminous and gelatinous substances. Its flavor is delicate, and it is quickly digested. Blood is less valuable as a food than any of the foregoing, but as it contains all the elements under discussion, besides iron and other valuable mineral matters, it should be eaten. When heated to 212° F. it loses any diseased taint that it might have acquired. The nutritive elements in liver and tripe may be ascertained from the following percentage analysis, and compared with a similar one on vegetable foods already given:

SUBSTANCE.	Water.	Nitrogenous.	Fat.	Salts.
Ox liver....................	74	18·9	4·1	3·0
Tripe......................	68	13·2	16·4	2·4

The time required for the digestion of these animal substances was investigated by Dr. Beaumont, with the following results: pigs' feet and tripe, 1 hour; whipped eggs, salmon trout, and venison steak, 1½ hours; ox liver and dried codfish, 2 hours; roasted eggs, 2¼ hours; turkey, gelatin, goose, sucking pig, and lamb, 2½ hours; fricasseed chicken and boiled beef, 2¾ hours; roasted beef and boiled mutton, 3 hours; roasted mutton, 3¼ hours; stewed oysters, cheese, hard-boiled or fried eggs, 3½ hours; fried beef, boiled and roasted fowls, roasted ducks, 4 hours; and pork, 5¼ hours. Similar investigations have since been conducted by Smith, Richet, and others.

Fats.—The richest hydrocarbonaceous food is fat. The relative composition of fat, starch, and sugar, is shown in the following table:

SUBSTANCE.	Carbon.	Hydrogen.	Oxygen.
Fat........................	77	12	11
Starch.....................	44	6	50
Sugar......................	42	6·5	51·5

It is customary to reckon fat as equal to one and three-fourths times its weight of starch. All fats have nearly the same composition when freed from water and the tissues in which they are contained, so that one may be substituted for another; but they differ in flavor and the temperature at which they liquefy. So also oils remaining liquid at ordinary temperatures may be eaten instead of solid fats. The fats of meat, butter, lard, and dripping are the fats in most general use, and in their natural state the last contains the greatest proportion of the hydrocarbons, since it has the least proportion of water. The fat of meat is selected simply for its flavor, but butter varies with its manufacture, since it may contain ½ oz. to 3 oz. of water, and ½ oz. to 2 oz. of salt in the pound. Its flavor is due largely to the food of the animal—as, for example, turnips—and the nature of the animal, for it has a much stronger flavor when produced from the goat or the buffalo than from the cow. A clarified butter called *ghee* is used in India, but is by no means as agreeable as our butter. It is prepared from milk (not cream) by first adding *dhye*, or sour milk, and afterward hot water, and by churning. In a few days it becomes rancid, and is again clarified, and then kept for use in closed pots. Fat of every kind becomes rancid, unless subjected to some preserving process. Thus fine sugar is used in condensed milk, salt is added to butter and lard or rubbed into pork or other meat fat. The quantity which is consumed by an adult daily is probably 2 to 4 oz. in temperate regions, but in cold climates as many pounds may be eaten.

There are no animal oils which are avowedly used as food in temperate climates, but in the far north whale oil or seal oil is taken either with or without the solid mass which constitutes the blubber. Lard oils and other animal oils are used largely to adulterate vegetable oils, and fish oils are used as medicines. Vegetable oils are, however, in great request in all temperate and hot climates, and are derived from the seeds of many plants, and particularly from the pulpy pericarp of the olive, and are a much more agreeable and convenient food than butter. The finest salad oil, expressed from the olive berry without heat, and the oil of cucumbers are deliciously mild in flavor, and good food. No separated vegetable fat is ordinarily used as food in temperate climates, but both fat and oil are eaten largely in certain seeds, as the Brazilian nut (*Bertholletia excelsa*), the cocoanut (*Cocos nucifera*), and almonds (*Amygdalus*). Fats and oils derived from various seeds are much more commonly used in India and other hot countries than in Europe and America.

Condiments.—Condiments are rather adjuncts to food or appetizers than food, although vegetable substances used therein are nutritious. This term includes pickles and sauces, which are almost innumerable, besides pepper, mustard, and vinegar, alone or in combination with other substances. The luxurious habits of the day lead to a free use of these substances, but he who would retain a natural taste for food and a good digestion should either eschew them or use them in their milder forms and in great moderation.

II. Fluid Foods.

Milk is the type of nutritious fluids, since it contains all the elements of nitrogenous and carbonaceous foods in a fluid form. It is therefore adapted to every condition of man, but particularly to such as require the immediate use of food, as in infancy and when there is not time for prolonged digestion. It contains casein and albumen as its chief nitrogenous elements, and sugar and fat as its carbonaceous, besides salts of the most valuable kinds. The proportion of each varies in different animals and with age, food, and climate, while certain special flavors, due to peculiar fatty acids, mark each kind. With so much variety it is impossible to give more than a general analysis, but even that has at least a comparative value, as in the following table:

MILKS.	Sp. gr. +1,000.	Water.	Solids.	Nitrogenous compounds.	Sugar.	Fat.	Salts.
Goat......	33·53	84·49	15·61	3·51	3·69	5·68	0·61
Sheep....	40·98	83·23	16·77	6·97	3·94	5·13	0·71
Mare.....	33·74	90·43	9·57	3·33	3·27	2·43	0·52
Ass.......	34·57	89·0	10·99	3·56	5·05	1·85	0·54
Woman...	32·67	88·9	10·92	3·92	4·36	2·66	0·13
Cow......	33·28	86·4	13·59	5·52	3·8	3·61	0·66

The salts in milk are small in quantity, but of the utmost value in nutrition, and consist of the following in 100 parts: potash, 23·46; soda, 6·96; lime, 17·34; magnesia, 2·20; chloride of potassium, 14·18; chloride of sodium, 4·74; phosphoric acid, 28·40.

Human milk is the standard of comparison for the food of infants, and varies in quality with health, food, production, and anxiety, but a mixture of two-thirds of ordinary cow's milk with one-third of water and half an ounce of milk-sugar or cane-sugar in a pint is a tolerable approximation. Ass's milk is sometimes substituted, and equal parts of it and cow's milk fairly represent human milk. For adults the milk of the cow, goat, and sheep is preferable. Skimmed milk has lost nearly all its fat or butter, but is used to a large extent as a food in certain chronic diseases. The addition of half an ounce of suet in a pint makes it equal to new milk. Buttermilk differs little from skimmed milk, except that it has become sour by the transformation of sugar into acid, and it is in constant use as a food in Ireland, Wales, and many other countries. Whey is much less valuable, since it has lost both the fat and the casein, but it offers an agreeable drink in warm weather, and the useful salts of milk. It is, however, never absolutely destitute of fat and casein, and has some nutritive value from its milk-sugar. Preserved milk may be made from either new or skimmed milk, or with a part only of the cream removed. It may be simply condensed, so that four parts become one, in which state it will remain good from one to four weeks, or it may be preserved so as to remain undecomposed for many months by the addition of refined sugar and an alkali, and by evaporation. A one-pound tin contains 3 to 4 oz. of sugar, and as sugar is destitute of nitrogen, the proportion of nitrogen in the milk is thus reduced. The proportion of nitrogen to carbon in natural milk is about 1 to 12, which is little more than in bread, while in sugar-preserved milk it is about 1 to 20.

Tea, Coffee, Cocoa, Chocolate.—These substances, from which so many beverages are made, have elements in common by which a sort of unity is given to the whole—viz., the chemically identical compounds called *theine* in tea and *caffeine* in coffee; while the *theobromine* of cacao and chocolate, though by no means of the same composition, is believed to have analogous effects upon the animal economy. The quantity is too small to be regarded simply as a nutrient, but it is believed to exert a peculiar action on the nervous system. See TEA.

Tea should always be prepared with water which has just begun to boil, and before the air is expelled, and the water should be soft, or be softened by the addition of a pinch of carbonate of soda. It has a powerful action on the respiratory system by which that function is greatly increased, and also over the nervous system, by both of which wakefulness is very commonly produced. It should be taken with the meal, rather than alone or when fasting. It is especially fitted for warm weather, when there is a desire to cool the body, for it produces perspiration. Europeans and the people of the U. S. drink a much stronger infusion than the Chinese, but do not do so with impunity, for it is apt to produce nervous and mental excitement and indigestion, and is not unfrequently followed by a reaction in which the spirits and vital powers are depressed.

In preparing coffee for the table it should be freshly ground and placed in cold water, which should be brought to the boiling-point and then served. Hot new milk or cream may be added to it. Its actions are like those of tea, but it is more apt to cause wakefulness.

Chicory has an analogous action to coffee, but in greatly inferior degree. It is prepared from the root of the well-known vegetable after it has been roasted with fat, dried to a brown color, and ground into powder. See COFFEE.

Chocolate and cocoa are produced from the seed of the *Cacao theobroma*, the pods of the ground-nut *Arachis hypogæa*, the cacao-shrub of Zanzibar, and other plants. The nuts are coarsely broken and called cacao-nuts, after which they are carefully ground under a considerable pressure and with wheels having a very smooth surface, so as to be reduced to an impalpable powder. Sugar is usually added in preparing chocolate, but not so generally to produce cocoa. The peculiar principle which they possess is called *theobromine*, but the flavor depends upon volatile oils and fat, which constitute 34 to 37 per cent. of the whole.

Alcohols.—The limits of this article do not allow more than a general sketch of these important substances. Ordinary or ethylic alcohol is the product of the fermentation of saccharine substances, whether they be malt, grain, potato, beet-root, sugar, or molasses, and comes over, mixed with other compounds, in distillation. The portions which distill early in the process are the finest and purest, and are used for the manufacture of the finest essences and spirits, while the latter are mixed with an increasing quantity of fusel oil, until at length they are fit only for the manufacture of varnish. Alcohol is an artificial and not a natural product, and in the process referred to is mixed with a proportion of water, but it is possible by a further process to remove the water, when the remaining fluid is called absolute alcohol (specific gravity 0·793). It is never sold in this form for use as food, but is mixed with water, and when about equal quantities of water and absolute alcohol are added together, *proof spirit* is produced, with a specific gravity of 0·920. When spirits of various kinds are manufactured they are prepared of various strengths, but usually brandy is imported at 1° or 2°; whisky at proof, or 10° over proof; rum at 25° to 35° over proof; and gin at 17° under proof, which means that if a number of gallons of water equal to the degrees over proof were added, the result would be proof spirit. The retailer often lowers the quantity of the spirit by adding water, so that he may sell the same spirit at 10° to 30° under proof.

Many deny that alcohol is a food, asserting that the fluid is not decomposed and transformed, but leaves the body in the same or an analogous condition to that in which it entered, while others dispute the inference, because the alcohol administered in any one experiment has in no case been all recovered in the excretions. But alcohol is only one of the elements in this class of fluids, and does not therefore give a uniform character to them all. The essential oils in brandy and other spirits, which are developed in the manufacture or produced by time, give approved flavors, and rum contains a large quantity of sugar. Alcohol when taken in moderate amounts is almost immediately changed within the system, and the final products of its decomposition are rapidly eliminated, but when ingested in excessive quantities the early derivative products remain in the tissues for a period of one or two days. The addition of juniper berries to hollands and gin stimulates the kidneys, and thus early tends to carry off the alcohol and its derivatives, but if habitually indulged in may go beyond the necessities of the case and bring on kidney disease. Wines produced from the grape only obtain the alcohol which they possess from the fermentation of the sugar in the juice of the grape, and if the fermentation be complete, no sugar remains. Sugar bears a proportion to the other elements of the juice, and as the quantity of alcohol produced is a measure of the sugar, it is also a measure of all the elements, and therefore, as is the alcohol in natural wine, so is the value of the grape-juice. Thus the wines of comparatively cold climates, as the Rhine and north of France, do not yield more than 9 to 16 per cent. of alcohol, while those of hotter climates and volcanic soils, as Greece, yield 26 or 27 per cent. The latter therefore are fuller in body than the former, and so far should be more valuable as food.

The salts in wine are valuable as food, as, for example, the tartrates and malates of potash, which give a tartness (but not from a free acid) to natural wines, and are deposited with age, or more rapidly when gypsum (sulphate of lime) is added, which sets free the vegetable acids. When the wine is red the coloring-matter and tannin are deposited with them and form a crust; but in old white wines the tartar may be seen as a whitish powder, moving as the bottle is turned up. The chief advantage of such wines (apart from alcohol), when comparatively new, lies in these salts, but when older in the essential oils and ethers.

There is a flavor and a bouquet connected with each kind of wine which gives pleasure to the consumer, and introduces it into the class of luxuries. Such as are in general favor command prices far beyond their value as food, and indeed beyond any value besides that of rarity. Their choice qualities are due partly to growth, for one plot of ground may produce flavors far superior to that of an adjoining vineyard; partly to selection of the ripest grapes and care in the manufacture; partly to the process of maturation, which can not be determined beforehand; and partly to the age of the wine, and hence skill and capital are largely required to produce a luxurious if not a dietetic wine. The production of this class of wine is most rapidly extending, and now embraces the central parts of Europe, Italy, Greece, Hungary, large districts in the U. S., Australia, and the Cape of Good Hope; but hilly or mountainous ranges, with a warm soil and sunny skies, without extremes of heat and cold, are the most suitable, and the limits may be indefinitely extended.

Fortified wines (and therefore adulterated) are those to which alcohol is added which was not produced from the grapes under manipulation, and which are commonly of inferior quality. Such are port, sherry, and madeira, which are rather weak ardent spirits or liquors than wines. The strength of these wines is from 38 to 42 per cent. of alcohol, and the objects of the manufacturers are to gratify a taste for strong liquors and to preserve the wine. They are prepared for particular markets, and not for home consumption, so that such port and sherry as are sent to Great Britain are not consumed in the countries of their production. The alcoholic strength of champagnes varies very much, but seldom exceeds 20 per cent.

True champagne and other effervescing wines are prepared from ordinary grapes, but the juice is chosen with great care as to its flavor, bouquet, and sugar, and such a combination is made as will produce the quality of champagne which the manufacturer desires. It is fermented in large vats or in smaller casks, after which it is drawn off, fined, and placed in underground cellars. Here it is frequently racked and fined until the following April, when it is bottled, and for three weeks again ferments freely. It is then kept under watch for two, three, or four years, during which time it is at first turbid, but afterward deposits a substance which by proper inclination of the bottle is left upon the cork; and the latter being skillfully removed, allows the deposit to escape. In this state the wine is matured, and called *vin brut*; and if the quality of the grape was fine and the subsequent treatment successful, the wine is very dry and has the flavor of the grape. Rhine and Moselle wines are prepared in this state for the market with great success, but it is much more common to add a sweet compound of the finest sugar-candy, champagne, and old cognac or other liquors, by which the required sweetness and alcoholic strength are produced. The quantity of this liqueur is usually from 2 to 6 per cent., but it varies with the natural richness of the juice of the grape converted into champagne. The effervescence is creamy rather than frothy, and rises in bubbles for hours rather than discharges the gas at once, and the bouquet and aroma are perfect. The Muscadine, Lemel, and Frontignac grapes have special odors which remain in the champagne, and some of the ripest bunches are allowed to hang in the cask. Red grapes naturally give a slight tinge to the wine, but pink champagne is artificially colored with cochineal. It is said that a bitter principle is added to certain kinds to modify the sweetness. There are certain wines, as Frontignac, Cyprus, and Tokay, produced from grapes which are allowed to dry upon the vine, and thus become raisins. The flavor readily proves this fact, and as the resulting wine is never perfectly fermented, it is rich and luscious, and contains much sugar. From the foregoing observations it will be seen how readily fictitious wines may be made. See PRESERVATION OF FOOD.

Revised by EDWARD T. REICHERT.

Fool, or **Court Jester**: See LICENSED FOOL.

Fools, Festival of (transl. of Lat. *Festum Stultorum*, or *Festum Fatuorum*): a mediæval Christian merry-making of fantastic and childish character, which fell especially upon Holy Innocents' Day (Dec. 28), but had more or less to do with the whole period between Christmas and Epiphany (Jan. 6). Exercises were held in the principal church edifice of the place; a mock pope, archbishop, or bishop was chosen; and all the most sacred rites of Christianity were travestied. The wild license which reigned resembled that of the old Roman *Saturnalia*. The leading performers were of the lower clerical orders, especially the subdeacons; hence another name for the festival, *Festum Hypodiaconorum*, with some reference to St. Stephen, who is commemorated on Dec. 26. The aim professed was to interest young and ignorant people in the story of the Advent, but profaneness soon got the better of piety in the matter. This festival, which is first mentioned by the Parisian ritualist, John Beleth, in the latter half of the twelfth century, originated apparently in France, and was more popular there than anywhere else, though observed also in Spain, in Germany, and in England. In spite of repeated condemnations by prelates and councils, it survived the Protestant Reformation, one instance of its observance being reported as late even as 1644.

Fools' Parsley: a poisonous umbelliferous plant (the *Æthusa cynapium*), so called because its leaves slightly resemble in appearance those of some varieties of parsley, so that people who have by mistake gathered it have been seriously poisoned by it. It is a native of Europe, naturalized in the U. S. It may be distinguished by its acrid taste and fetid smell; its general umbels have no involucre; its minor umbels a partial involucre of three leaves; in both respects quite unlike parsley. It is an acronarcotic, causing numbness, faintness, and dimness of vision. Give as an antidote a thorough emetic, followed by wine or other gentle stimulant.

Foot [M. Eng. *foot*, *fot* < O. Eng. *fōt* : Icel. *fōtr* : Goth. *fōtus* : O. H. Germ. *fuoz* > Mod. Germ. *Fuss* < Teut. *fōt* < Indo-Eur. *pōd*, *pŏd-*, *pĕd* > Gr. πούς, ποδός, foot : Lat. *pes* : *pedis*, foot]: in anatomy, the terminal part of man or an animal.

Foot of Mammals.—The foot (*pes*) in mammals, and in some other vertebrates in distinction from the hand (*manus*), is the last member or terminal segment of the pelvic girdle, or lower limb. The fore limbs are more generally used for the support, and the hind limbs for the propulsion of the body. Hence, "the manus is commonly shorter and broader than the pes" (*Prof. Owen*), and but few animals use the foot (hind) for prehension or defense, save in flight. The exception to the rule that the hand is smaller than the foot is seen in the mole, or in the seal and walrus, which are deficient in the hind foot.

The foot is divided into three portions: (1) a group of more or less rounded bones called the tarsus or instep; (2) a row of long bones placed side by side in front of the tarsus—the metatarsus; (3) the phalanges of the digits, or the toes. The complete tarsus consists of seven bones—the astragalus, calcaneum, navicular, internal, middle, and outer cuneiform, and the cuboid. The chief variations in number are from six to eight. The general arrangement of these bones is in two rows—the proximal, or those articulating with the bones of the leg, and the distal row, those joining the metatarsus. The bones of the metatarsus usually correspond in number with the digits, and at their proximal ends the first, second, and third bones are supported respectively by the three cuneiform bones of the tarsus; the cuboid supporting the fourth and fifth. Upon each joint between the metatarsus and the toes are often found a pair of sesamoid bones, for the mechanical advantage of the tendon gliding over them. These are best seen in the mole and tiger. The digits never, except in abnormal instances, exceed five in number on each foot in any existing vertebrate animal above the rank of fishes, and in the class *Mammalia*, except the Cetacea, the number of phalanges is limited to two in the first digit, and to three in each of the other digits in both fore and hind feet (*Prof. R. Owen*). The hallux or great toe, though in man very strong, and one of the largest digits, is in many mammals entirely wanting, rudimentary, or inconsiderable in length. In many climbing animals it is considerably developed and has prehensile characteristics. This is well shown in the gorilla and orang. The other digits vary in number from one to five, as is illustrated respectively in the horse and the elephant (Fig. 2).

FIG. 1.—Fore foot of the mole. Hind foot.

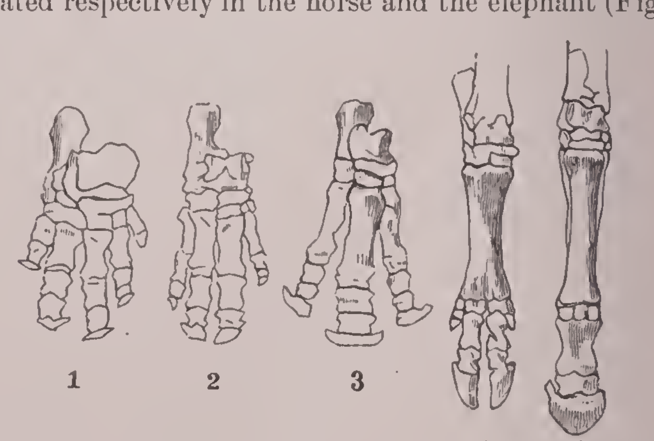

FIG. 2.—Simplification of the digits (after Owen): 1, foot of the elephant; 2, foot of the hippopotamus; 3, foot of the rhinoceros; 4, foot of the deer; 5, foot of the horse.

This modification of the digits is accounted for by their diminution and simplification in a definite order. Thus in a four-toed animal the great toe is wanting, as in the hippopotamus; in a three-toed animal the outer or smaller digit and the hallux—seen in the rhinoceros; in a two-toed animal, such as the cow or deer, both of those already mentioned and the second digit; and in the one-toed animal, such as the horse, only the third digit remains. That this is the order of disappearance is known by the absence of the corresponding metatarsal bone, each one of which has its definite attachment to one or more of the tarsal bones.

FIG. 3.—A side view of the bones of the human foot.

The Human Foot.—The human foot illustrates the general points of osteology already described, and at the same time is specially modified for its uses peculiar to man, the upright animal. And, as it might properly be stated, the foot is merely a hand modified for a base of structure to support the body. It is always larger than the hand, mainly in length and thickness; is also narrower, and of an ovoidal figure, the long axis reaching from before backward. The longest transverse diameter of the foot is the anterior one, in order to place on a broader base the support to the body, which is carried before the center of the body in walking. The solid parts of the

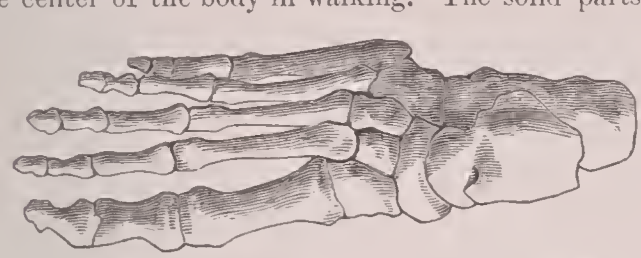

FIG. 4.—Skeleton of the human foot (original).

foot are more firm than the corresponding parts of the hand, and the movable parts of the foot less movable than those of the hand, in order to make the foot as perfect an organ as possible to give support and the surest and most facile locomotion of the body (Fig. 4).

The foot is constructed of two arches (Fig. 5), one from front to rear and another from side to side. The anteroposterior arch has for its points of support the heel and forward ends of the metatarsals, and the lateral the cuboid on the outside and the inner cuneiform on the inside. The segments of these arches, however, are not inflexible, but are made to yield among themselves, each a little, by the interposed cartilages. There is also a special arrangement, known as the Y-shaped calcaneo-scaphoid ligament, holding the keystone of the arch, which by its elasticity aids much in securing the beautiful spring of the body in motion. And as this ligament is attached to the heel-bone, it is called by the Germans the spring-bone.

One modification of the typical foot of mammals to the special structure of man is the angle of the plane of the foot

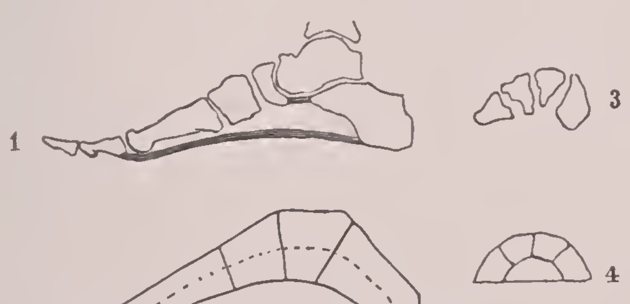

FIG. 5.—1, A view of the natural position of the bones forming the front arch of the foot; 2, a diagram of the same; 3, view of the bones of the side arch of the foot; 4, a diagram of the same. (1, 2, original; 3, 4, after Holden.)

and the leg. In the horse the angle averages 12°, while in man it is 90°. The design of this variation is to give as secure a leverage as possible to the muscles which must keep the weight of the body securely supported so far above the point of support, about two-thirds of the weight of the body being above the hips. Another peculiarity of the human foot is the great projection and horizontal direction of the heel, or, as some one has said, "ex calce hominem." In all animals it is the largest of the tarsal bones, as it is the lever for moving the foot; but in animals which assume the semi-erect attitude there is found either a greater development of this bone or larger development of the muscles of the "calf." Hence the small "calf" of the Negro is attributed by anatomists to the larger heel-bone, the smaller muscles being compensated by a longer lever at which to apply the power (Fig. 6).

The articulation of the great toe with the inner cuneiform bone is another special modification of the foot as pointing only to the erect position of the body. In the semi-erect apes, the gorilla especially, this joint is marked by a considerable degree of mobility, and the foot resembles a hand. (See Fig. 7.) But in man's foot the great toe is limited in its motions to simple flexion and extension; it lies parallel to the other toes, and is superior in strength, muscular and bony, to any of the other toes. In fact, each foot is to be viewed as a triangular pedestal of the body, supported respectively at the three angles of the great toe, heel, and little toe; so that the greatest muscular power is found furnished to each of these portions of the foot.

FIG. 6. — Illustrating the attachment of the muscles of the calf (1) of the human leg to the os calcis (2). (Original.)

The superior length of the great toe is a characteristic of the human foot; for while the second digit projects farther forward than does either of the other toes when the foot is viewed as a whole, yet the great toe itself alone, if compared with any other of the rows of phalanges, obtains the longest measure.

Although the foot, when compared with the hand in structure adapted to delicate operations, is very far inferior to it, yet it is astonishing what remarkable work can be accomplished by it when the hands are wanting. Thus instances frequently occur of persons who carve, write, and paint in a remarkable manner with their toes instead of fingers; so that the phrase "pes altera manus" is often not far from the truth.

Probably no organ in the body has been more abused by the fashion of its dress than has the foot. From time im-

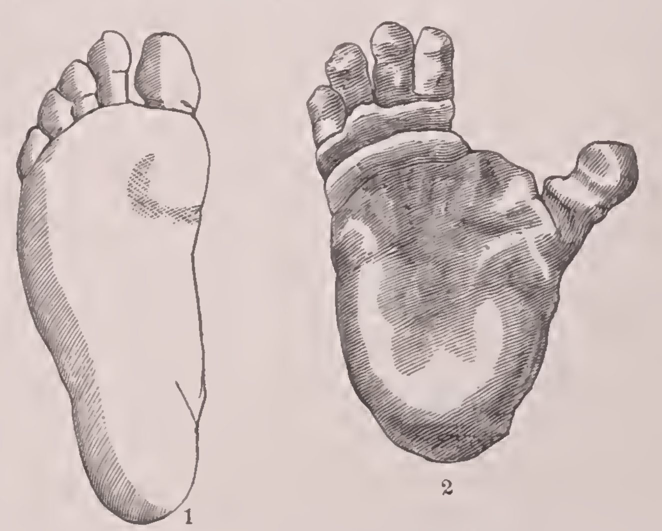

FIG. 7.—The plantar surfaces of the human and gorilla foot compared: 1, the human foot; 2, the foot of the gorilla (after Owen).

memorial, and by almost the entire human race, it has been squeezed into an unyielding case of hard leather, never so large as the foot itself when resting on the ground, and with a high appendage called the heel, from whence have come corns, bunions, *et id omne genus* of similar accessories of civilization. EDWARD HITCHCOCK.

Foot: the unit of lineal measure in common use in the U. S. and in Great Britain. All the nations of Europe and their colonies or dependencies employ, or have employed, a unit of length having in each language a name of the same significance as *foot* in English. This identity of name indicates similarity of origin, which was therefore unquestionably the length of the human foot. No two peoples, however, have agreed in the value assigned to their foot-measures. No two provinces, and hardly any two considerable towns even, have had the same foot. Nor have any of these measures corresponded very nearly with the presumed prototype; nearly every one of them being greater, and many of them much greater, than the average length of the foot of an adult man. In the volume of *Investigations in the Military and Anthropological Statistics of American Soldiers*, by Dr. B. A. Gould, published in 1869 among the memoirs of the U. S. Sanitary Commission, are given measurements of nearly 16,000 individual men, volunteers for the army, of various races and nationalities, 11,000 being white and the rest colored. The mean length of the foot was found for no nationality to exceed $10\frac{24}{100}$ inches, and for none to fall short of $9\frac{89}{100}$; the mean value for the total being $10\frac{058}{1000}$, or about one-twentieth of an inch above 10 inches. It is probable that the foot-measures in use in the later centuries have been in general entirely arbitrary. The account commonly given of the adjustment of the British standard yard in the year 1101 from the arm of the king, Henry I., is probably a true one; and the British foot is simply one-third of the British yard. But it was doubtless otherwise in the earlier ages. The ancient Greeks first used this measure, and their Olympic foot was said to have been determined by the length of the foot of Hercules. This, according to the best authorities, was about equivalent to $12\frac{14}{100}$ English inches. But there were among them other foot-measures materially differing from this. Thus the Macedonian foot was $14\frac{08}{100}$ inches; the Pythian, $9\frac{72}{100}$ inches; and the Sicilian, $8\frac{75}{100}$ inches. In more recent times the diversity has been almost endless. In Italy the foot was, not long ago, $11\frac{62}{100}$ inches in Rome, $13\frac{68}{100}$ in Milan, and $23\frac{22}{100}$ inches in Lucca. In France it was $9\frac{76}{100}$ inches in Avignon, $9\frac{79}{100}$ inches in Aix-en-Provence, $10\frac{57}{100}$ inches in Rouen, $14\frac{05}{100}$ inches in Bordeaux, while the *pied du roi* of Paris was $12\frac{79}{100}$ inches. In Switzerland it was $10\frac{52}{100}$ inches in Neuchâtel, $11\frac{33}{100}$ inches in Rostock, $11\frac{99}{100}$ inches in Basel, and $19\frac{21}{100}$ inches in Geneva. In the Spanish peninsula it was $10\frac{12}{100}$ inches in Aragon and $10\frac{96}{100}$ in Castile. In Germany it was $9\frac{25}{100}$ in Wesel, $10\frac{89}{100}$ inches in Bavaria, $10\frac{998}{1000}$ inches in Heidelberg, $11\frac{45}{100}$ inches in Göttingen, and $13\frac{12}{100}$ inches in Carlsruhe. And in the Netherlands it was $10\frac{86}{100}$ inches in Brussels and $11\frac{28}{100}$ in Liège. Alexander's *Dictionary of Weights and Measures* (Baltimore, 1850) gives more than 100 foot-measures, all differing from each other. In Barnard's *Metric System* (p. 354, Supplement) may be found a table containing no fewer than 292, all different. The confusion resulting from this great diversity was intolerable. The inconvenience caused by it in business transactions prepared the public mind of Europe early in the nineteenth century to receive with favor the new system of metrology called the metric, first definitely adopted in France in the year 1799. The foot has therefore ceased to be the legal unit of length throughout Europe except in Great Britain and Russia, and the meter has generally taken its place. The Russian unit of length, the *sagene*, was fixed by Peter the Great, after his sojourn in England in 1698, at exactly 7 British feet. The foot of the U. S. is identical with that of Great Britain, from which it is copied. In both countries the legal standard is properly the yard of 36 inches. The copy of the British standard, by which the U. S. standards were long adjusted, is a brass bar prepared by the celebrated Troughton, of London, to the order of Prof. F. R. Hassler, the first chief of the U. S. Coast Survey, and superintendent of the bureau of weights and measures at Washington. It is 82 inches in length, and the 36 inches between the twenty-seventh and the sixty-third divisions were taken as the prototype yard of the U. S. A copy of the British prototype, officially certified, has been substituted for the Troughton bar, and the standards furnished the several States are now carefully adjusted by this.

Foot: in music, a name or measure denoting the pitch of stops in an organ. In organ music, directions are often given for the use of 4-foot, 8-foot, or 16-foot stops. The meaning is this: the lowest note on the keyboard (C C) is assumed as the standard for such designations. Now, to produce the sound C C, an open pipe 8 feet long is required; its octave *above* will be given by a pipe 4 feet long; the double octave, 2 feet, and so on; and for the intermediate notes the pipes are properly graduated in length. A set of pipes of this description is therefore called "an *8-foot stop*" (as the *open diapason*, *dulciano*, *trumpet*, and several others). Such stops give the ordinary, standard, or concert *pitch*. If another range of pipes be added, sounding an *octave lower*, they will be of double length, and it will be called "a 16-foot stop" (as the *double diapason*, or *bourdon*). On the other hand, the *principal* is an octave *higher* than the open diapason; consequently, its pipes are only half as long, and it is called "a 4-foot stop." The *fifteenth*, in like manner, being tuned an octave above the principal, is "a 2-foot stop," its lowest pipe being that of length. In a large organ there are many stops belonging to each of these classes, the largest pipe of a 32-foot stop sounding C C C C. Revised by DUDLEY BUCK.

Foot, SOLOMON: lawyer and U. S. Senator; b. at Cornwall, Vt., Nov. 19, 1802; graduated at Middlebury College, Vt., in 1826; was principal of Castleton Seminary in 1826 and 1828; tutor in Vermont University in 1827; Professor of Natural Philosophy in the Academy of Medicine at Castleton, Vt., 1828–31; was admitted to the bar in 1831, and settled at Rutland, Vt. In 1833, 1836–38, and in 1847 was in the Vermont Legislature, and Speaker of its house for his last three terms. Was M. C. 1843–47, and U. S. Senator from 1850 to his death, at Washington, D. C., Mar. 28, 1866. Mr. Foot was for some years president *pro tempore* of the U. S. Senate; was a Whig in politics.

Foota Jallon: See FUTA JALLON.

Football: an athletic game of very ancient origin, believed by some to have been introduced into Great Britain by the Romans. From a rude pastime it has been developed into a scientific game, and has undergone considerable modification since the middle of the nineteenth century. There are two ways of playing football: one according to a code of rules adopted by the Football Association of England, formed in 1863, and the other according to rules long in force at Rugby School. The Rugby game has been changed and still further elaborated by the colleges of the U. S., among which it is very popular. Football surpasses every other game in its demand for a high combination of physical, mental, and moral qualities. The *American Rugby*, as the game played in the U. S. is called, requires a rectangular field 330 by 160 feet, the boundaries being plainly marked with white lines, as are also cross lines at intervals of 5 yards. Goal-posts, 20 feet high and 18 ft. 6 in. apart, with a cross-bar 10 feet from the ground, are erected at the middle of each end. The ball is about 12 inches long, elliptical in form, and made of inflated rubber protected by a covering of leather. Upon each side are eleven men who play offensively so long as in possession of the ball, losing it to their opponents only on penalty for illegal play, or by fumbling, or on failure to advance the ball 5 yards on four tries by running, or by kicking it. Points can be scored in three ways. Touching the ball down behind the opponent's goal line counts four points. This gives the privilege of a "place" kick for goal from a point in the field straight out from the touch down. Five points can be scored by a "drop" kick of goal from the field, and two more from a "safety" touch down. Two halves of forty-five minutes, with a rest of ten minutes between them, constitute full playing time. The players on each side are arranged in two distinct sets, the forwards and the backs, each set having highly specified duties. The forward line consists of the center, who usually puts the ball in play by snapping it back between his feet; a guard on each side, with duties indicated by the name; a tackle next to each guard, who in defensive play breaks through the opposing line to seize the player having the ball; and two end men freer in action. Immediately back of the center is the quarter-back, who receives the ball and places it in the hands of a third man before an advance can be made. Behind the quarter-back are two half-backs and a full-back, who do most of the running with the ball. A secret signal indicates to every player the projected play. Each year develops systematic play, by movements of surprise and stategy, by preconcerted interference in behalf of the runner, and by skillful blocking on the defensive side.

English Rugby is played with fifteen men on a side. It is slower and less scientific, but not so rough.

Association football is primarily a kicking game, the ball being advanced in that way, and by "heading," "breasting," and "kneeing" it. Five forwards, three half-backs, two full-backs, and a goal-tender play on each side. Goals are made by propelling the ball between two posts 8 feet apart and beneath a cross-bar 8 feet from the ground.

A. ALONZO STAGG.

Foote, ANDREW HULL: rear-admiral U. S. navy; b. at New Haven, Conn., Sept. 12, 1806; entered the navy as a midshipman Dec. 4, 1822; became a lieutenant in 1830, a commander in 1852, a captain in 1861, a rear-admiral in 1863. In the fall of 1861, the civil war being in progress, he was appointed to the command of the Western flotilla, then in course of construction for the purpose of opening the navigation of the Mississippi river. On Feb. 6, 1862, Foote took Fort Henry after a most obstinate fight; on the 14th of the same month engaged Fort Donelson, for an hour and a half, with four ironclads and two wooden gunboats, and so demoralized its garrison as to insure an easy victory over it by the army on the following morning; and on Apr. 7, after many a hard-fought action with its numerous batteries, received the surrender of Island No. 10, considered by the Confederates, next to Vicksburg, their most important stronghold on the Mississippi. Unfortunately, however, the flag-officer had received a severe wound at Fort Donelson, which from neglect had become so serious as to endanger his life, and he was forced to resign his command to another and return to his home. On June 16, 1862, he received the thanks of Congress and was made a rear-admiral, and on the 22d of that month was appointed chief of the bureau of equipment and recruiting. On June 4, 1863, he was ordered to relieve Rear-Admiral Dupont off Charleston, and on his way to his command was taken ill at New York, where he died on the 26th of the same month. He published *Africa and the American Flag* (1854). See his *Life* by James M. Hoppin (New York, 1874).

Foote, ARTHUR: composer; b. at Salem, Mass., Mar. 5, 1853. He received his musical education at home, studying composition at Harvard College under Prof. John K. Paine, and the piano and organ under B. J. Lang, of Boston. He has composed considerably, and has taken a place among the best of the composers of the U. S. His works include a cantata, *Hiawatha*, for baritone solo, male chorus, and orchestra: a trio for piano, violin, and 'cello; a string quartet; a suite for string orchestra, performed in 1887 at the London Symphony concerts; an overture, *In the Mountains*, produced Feb., 1887, by the Boston Symphony Orchestra, and other works of similar character.

D. E. HERVEY.

Foote, HENRY STUART: U. S. Senator; b. in Fauquier co., Va., Sept. 20, 1800; graduated at Washington College, Virginia, in 1819; was licensed to practice law in 1822; removed to Tuscumbia, Ala., in 1824; edited a Democratic paper, and in 1826 established himself at Jackson, Miss. He was presidential elector in 1844, and in 1847 was elected U. S. Senator, which position he held until 1852. He was elected Governor of Mississippi over Jefferson Davis in that year. In 1854 removed to California; in 1858 settled at Vicksburg, Miss., and at the Southern convention at Knoxville, Tenn., in May, 1859, spoke against disunion; was a member, however, of the Confederate Congress. He published *Texas and the Texans* (2 vols., Philadelphia, 1841); *The War of the Rebellion, or Scylla and Charybdis* (New York, 1866); *Bench and Bar of the Southwest* (St. Louis, 1876); and *Personal Reminiscences*. D. at Nashville, Tenn., May 19, 1880.

Foote, MARY (*Hallock*): artist and novelist; b. in Milton, N. Y., Nov. 19, 1847. She was married in 1876 to Arthur D. Foote, a mining engineer, and has since resided in California, Colorado, and Idaho, illustrating Western life and scenery by her drawings and her novels, among which are *The Led-Horse Claim* (1883) and *John Bodewin's Testimony* (1886). Poems by other writers have been illustrated by her, including Longfellow's *Skeleton in Armor* and *Hanging of the Crane*.

H. A. B.

Foote, SAMUEL: actor, wit, and dramatist; "the English Aristophanes"; b. at Truro in 1720; studied at Worcester College, Oxford (whence he was expelled for indiscretions), and at the Middle Temple, but indulged in gaming and other excesses until his considerable fortune was expended; and in 1744 he made his appearance as Othello at the Haymarket, but his success was small until he began to play in pieces written by himself; and his best characters were ludicrous imitations of living public men. From 1747 to 1767 he conducted the Little Haymarket theater without license, no one daring to enforce the law against him for fear of his terrible mimicry. He wrote at least twenty-seven plays of small literary merit, of which twenty or more have been printed. His humor was of the broadest and noisiest kind, and his jests were often practical ones, not without a large element of brutality. An accident which led to the loss of a leg was followed by paralysis, and the last years of his life were passed in great physical and mental distress. D. at Dover, Oct. 21, 1777.

Foote, SAMUEL AUGUSTUS, LL. D.: U. S. Senator; b. at Cheshire, Conn., Nov. 8, 1780; graduated at Yale College in 1797, and practiced law in Cheshire; was representative in Congress from Connecticut in 1819, 1823, and 1833; Speaker of the Connecticut Assembly in 1825–26, and Senator in Congress from 1827 to 1833. In 1834 was Governor of Connecticut, and in 1844 presidential elector. Senator Foote offered in the U. S. Senate the resolutions upon which the great debate occurred between Hayne, of South Carolina, and Webster, of Massachusetts. (See FOOTE'S RESOLUTION.) D. Sept. 16, 1846.

Foote, WILLIAM HENRY, D. D.: preacher and author; b. at Colchester, Conn., Dec. 20, 1794; graduated at Yale in 1816; taught at Falmouth and Winchester, Va.; studied in Princeton (N. J.) Theological Seminary; was licensed by the presbytery of Winchester Oct., 1819; preached in Virginia, and was in 1824 ordained pastor of the Presbyterian church at Romney; was agent of the central board of missions; prepared *Sketches in North Carolina* (1 vol., 1846) and *Sketches, Biographical and Historical, of the Presbyterian Church in Virginia* (2 vols., 1850–55). Was also agent for Hampden-Sidney College in Virginia, and Confederate chaplain at Petersburg, Va., during its siege, 1864–65. D. at Romney, Va., Nov. 28, 1869. *The Huguenots, or Reformed French Church*, was published after his death.

Foote's Resolution: a resolution introduced in the U. S. Senate Dec. 29, 1829, by Senator Samuel A. Foote, of Connecticut, instructing the committee on public lands to inquire into the expediency of limiting the sales of the public lands for a period to those which had already been offered for sale. The resolution was interpreted by Senators of the West as indicating a disposition on the part of Eastern Senators to check Western growth by limiting land sales. The Senators from the South joined with those of the West. In January Robert Y. Hayne, of South Carolina, declared that the East was inspired by the still further motive of desiring to limit the public revenue in order that the Government might be still further "centralized." Daniel Webster in his first reply to Hayne claimed that the growth of the Western States was chiefly due to the ordinance of 1787, which, as he declared, was drawn and introduced by Nathan Dane, of Massachusetts. Hayne declared that Dane was a member of the HARTFORD CONVENTION (*q. v.*), and made the fact a basis for the charge that the Eastern States favored a loose construction of the Constitution which tended to a centralized form of government. This brought out the second reply of Daniel Webster, in which, with remarkable cogency and eloquence, he not only expounded his own views of the nature of the government, but also those which he understood to be held by Hayne and his supporters. In the course of Webster's speech Hayne interrupted him by declaring that the right of nullification was not merely "a right of revolution, but a right of constitutional resistance." This assertion gave Webster the opportunity of replying at length to the new doctrine of nullification, and his speech is universally regarded as the most powerful presentation of the "national" theory of the government that had ever been offered. The effect of Webster's speech was so great that Calhoun in the following December resigned the vice-presidency in order that he might resume his old place in the Senate, and there meet his old antagonist. The great question involved in this discussion was nothing less than the constitutional right of secession. While Webster convinced the North that no such right existed, Hayne and Calhoun were equally successful in urging the opposite doctrine upon the South. As these doctrines, so fundamentally antagonistic, were held with perhaps equal earnestness and honesty, it was impossible to prevent collision whenever a dividing question of sufficient importance should present itself. The influence of the debate on Foote's resolution was to consolidate the North and the South in their respective opinions, and thus prepare the way for the civil war of 1861. See NULLIFICATION and SECESSION.

C. K. ADAMS.

Foot-rot: a disease of sheep which is rare in the U. S. Sometimes, when sheep from rocky pastures are taken to the English fen-country to fatten, the hoof grows too rapidly for its new conditions, and when it has become long it may become cracked and broken, or in part separated from the fleshy part of the foot. Sand and grass may lodge on the raw surface and lead to active inflammation. The cure is in removal of the foreign matter, clipping of the hoof, and the application of stimulants and caustics, with removal to a dry pasture.

Foppa, VINCENZO; painter; b. at Brescia, Italy, in 1400. He established a school of painting at Milan about the year 1445, which flourished up to the time of Leonardo da Vinci. Foppa was a great colorist and a proficient in perspective, being one of the first to introduce bold foreshortening in his compositions. His works are to be seen at the Brera Gallery in Milan. The painting of the Chapel of Peter Martyr

in Sant' Eustorgio, one of the most exquisite pieces of decoration of the fifteenth century, is also by him. D. in 1492.
W. J. S.

Forage [M. Eng. *forage*, from O. Fr. *fourage* (> Fr. *fourrage*), deriv. of *forrer*, forage, deriv. of *forre*, fodder, straw (> Fr. *feurre*), from Mediæv. Lat. *fo'drum*, from a Teuton. word; cf. O. N. *fōdr* : Eng. *fodder* : O. H. Germ. *fuolar* > Mod. Germ. *Fuller*. See FOOD]: food or fodder, food for animals. (See HAY.) The word is also used as a verb, when it means to collect supplies generally for both man and beast, from an enemy by force, from friends by impressment, but giving to friends receipts, to be paid ultimately.

Forage may be roughly divided into concentrated and coarse fodders. The more common concentrated foods are found in the cereal grains, the by-products of their manufacture into human food, and the ground cake left after extracting the oil from certain seeds as linseed, cotton seed, rape, colza, etc. The coarse fodders are found in the various grasses, the straws of the various grains, the stover of maize, and certain other plants, notably several members of the *Leguminosæ* (the clovers, alfalfa, pease, beans, etc.). A plant to be useful as forage must not only possess substances suitable for animal nutrition in a form readily assimilable, but must be palatable to the animal, free from acrid or poisonous qualities, and capable of easy cultivation and preservation. Coarse forage is usually preserved in the form of hay—i. e. sufficiently dried to prevent fermentation and decomposition, but a method of preservation in the green state (see ENSILAGE) furnishes a variety of available coarse fodders.

The daily ration of forage in the army of the U. S. is for each horse 14 lb. of hay and 12 lb. of grain, either oats, corn, or barley. For a mule the daily ration is 14 lb. of hay and 9 lb. of grain. The blades of Indian corn are used for forage in the absence of hay. The consumption of forage in a large and active army is enormous. Its weight, owing to the number of animals employed in military operations, is about four and a half times as great as that of the subsistence supplies for the same army. There were issued from the dépôt at Washington during the war of 1861–65 4,500,000 bush. of corn, 29,000,000 bush. of oats, and 490,000 tons of hay. Partial reports of the quartermaster-general show issues of forage during the war as follows:

22,816,271 bush. of corn, costing......	$29,879,314
78,663,799 bush. of oats..............	76,362,026
1,518,621 tons of hay, costing........	48,595,872
Total.........................	$154,837,212

The weight of these supplies in pounds was—

Corn............................	1,277,711,176
Oats............................	2,517,241,568
Hay............................	3,037,242,000

making a total of 6,832,194,744 lb.—numbers difficult to realize, but interesting as showing the magnitude of the operations necessary to provide and distribute these few items of the expenses of war. Revised by H. H. WING.

Foraker, JOSEPH BENSON: statesman; b. near Rainsborough, Highland co., O., July 5, 1846; at the age of sixteen enlisted as the first private in Company A, Eighty-ninth Ohio Infantry; his promotion was rapid, and at the battle of Mission Ridge he commanded his company. He was mustered out June 18, 1865, a captain, before he had completed his twentieth year. In 1869 he graduated at Cornell University, and afterward became one of its trustees; commenced practicing law in Cincinnati, O., in 1869; in 1878 became chief supervisor of elections for the southern district of Ohio; in 1879 he was elected to the superior court bench for five years; in 1883 he was nominated for Governor of Ohio by the Republican party, but was defeated by George Hoadly; in 1885 Judge Foraker was again nominated for Governor, and was elected; re-elected in 1887. He is one of the prominent leaders of the Republican party, and in 1896 was elected U. S. Senator to succeed Calvin S. Brice.

Fora'men (plural **Foram'ina**) [Lat., opening, deriv. of *fora're*, pierce, bore: Germ. *bohren*, bore: Eng. bore: Gr. φαράω, plow]: in anatomy, denotes in general any natural opening through a substance; more particularly an opening through a bone. It is especially applied to the bony passages through which the nerves and blood-vessels enter and leave the skull and spinal canal.

Foraminif'era [Lat. *fora'men*, *fora'minis* + *fer're*, bear]: a sub-class of Protozoa belonging to the Rhizopoda, and better named Reticularia. Most of the species are marine, and they are characterized by their ability to send out processes of protoplasm (pseudopodia) in the shape of fine threads, which unite together to form a network, whence the name Reticularia. A few species are naked, but most form a protective shell, often of a very complicated pattern, with either one or two large terminal openings or with numerous small pores for the protrusion of the pseudopodia. They were formerly regarded as organisms without a nucleus, but they are now known to possess one. The shell may be formed of carbonate of lime, of a horny-like matter, or of particles of sand cemented together. The shape and character of the shells are used in classification. In some it is simple, but in others it becomes very complicated by the budding of the protoplasm, the separate chambers thus formed being connected together. Many families and genera of recent forms have been described.

As fossils the Foraminifera hold an important position, as their shells build up vast beds of rock. Examples may be cited in the chalk cliffs of England, the nummulitic limestone of Egypt, and the Silurian beds of Russia. As fossils they occur in the lowest fossiliferous rocks (the celebrated *Eozoön* is probably not of organic origin), and a formation of chalk is taking place at the bottom of the ocean of to-day in the so-called globigerina ooze, which occurs at great depths. J. S. KINGSLEY.

Forbach, fōr'baakh: town of Lorraine, Germany; 12 miles N. W. of Saargemünd (see map of German Empire, ref. 6–C). It has coal mines and important manufactures. Near here (Aug. 6, 1870) the French under Frossard were badly beaten by the Germans under Prince Frederick Charles. Pop. (1890) 9,575.

Forbes, ARCHIBALD: war correspondent; b. in Morayshire, Scotland, in 1838; studied at the University of Aberdeen; served for several years in the Royal Dragoons; after 1870 he was war correspondent of the London *Daily News*; he accompanied the German army from beginning to the end of the Franco-German war; witnessed the close of the Commune; visited India during the famine of 1874; saw the Carlist war in Spain, the war in Servia 1876, the Russo-Turkish campaign in 1887, etc. Author of *Drawn from Life*, a military novel; *My Experiences of the War between France and Germany*; *Glimpses through the Cannon Smoke* (1880); *Soldiering and Scribbling* (1882); *Life of Chinese Gordon* (1884); *Life of the Emperor William of Germany* (1889); and *Havelock* (1890). D. in London, Mar. 29, 1900.

Forbes, EDWARD, F. R. S.: naturalist; b. in the Isle of Man, Feb. 12, 1815; began the study of medicine at Edinburgh in 1830; founded the Botanical Society of Edinburgh in 1836; visited Paris and the Mediterranean in 1837; was naturalist of the expedition to Lycia in 1841; Professor of Botany at King's College, London, in 1842; F. L. S. in 1843; assistant secretary to the Zoölogical Society in 1844; F. R. S. in 1845; Professor of Natural History at the School of Mines in 1852, and in the same year president of the Geological Society; Professor of Natural History at Edinburgh 1853. D. Nov. 18, 1854. Published *History of British Starfishes* in 1841, and, with Hanley, *History of British Mollusca* in 1853, besides other important works, including a great number of valuable papers upon zoölogical, botanical, and literary subjects. See *Memoir* by Dr. George Wilson and Archibald Geikie (London, 1861).

Forbes, JAMES DAVID, D. C. L., F. R. S.: physicist; b. at Colinton, near Edinburgh, Apr. 20, 1809; was Professor of Natural Philosophy in the University of Edinburgh in 1833; published *Travels in the Alps* in 1843; made discoveries in the laws of glacial motion, and in the phenomena of radiant light and heat in relation to polarization; and received the Rumford medal and that of the Royal Society of London. In 1860 became principal of the United Colleges in the University of St. Andrews. *Norway and the Glaciers Visited in 1851* was published in 1853; *A Tour of Mont Blanc and Monte Rosa* in 1855. He published many valuable papers, mostly upon questions in physics. *The Sixth Dissertation*, prefixed to the *Encyclopædia Britannica*, was his production. D. at Clifton, England, Dec. 31, 1868.

Forbes, JOHN: soldier; b. at Petincrief, Fifeshire, Scotland, 1710; became a physician, but gave up the profession to enter the army, and became lieutenant-colonel in the Scots Greys in 1745. After service in the German war was, Dec. 28, 1757, made brigadier-general in North America, and was adjutant-general in the expedition against Louisburg.

He commanded the expedition against Fort Duquesne, Pa., in Nov., 1758, and after it was abandoned by the French took possession and renamed the place Fort Pitt (now Pittsburg) in compliment to the English Prime Minister. D. in Philadelphia, Pa., Mar. 11, 1759.

Forbes, Sir JOHN, M. D., F. R. S.: physician and medical writer; b. in Banffshire, Scotland, Oct. 18, 1787; entered Marischal College in 1805, and was in the navy as assistant surgeon in 1807; received his M. D. degree in Edinburgh in 1817; practiced at Penzance and Chichester, England, and settled in London in 1840; became physician extraordinary to the Prince Consort the same year, and soon after to Queen Victoria; knighted in 1853; translated the works of Auenbrugger and Laennec on auscultation and percussion (1824); was an editor of the *Cyclopædia of Practical Medicine* (1833–35); published *Manual of Select Medical Bibliography* in 1835; and afterward edited the *British and Foreign Medical Review*. *Physician's Holiday, or a Month in Switzerland in 1848*, was published in 1849; *Memoranda made in Ireland*, in 1852; and *Nature and Art in the Cure of Disease*, in 1857. D. in London, Nov. 13, 1861.

Forbes, JOHN, LL. D., D. D.: a scholar of the Church of Scotland; b. in Boharm parish, Morayshire and Banffshire, Scotland, July 5, 1802. He was educated at Marischal and King's Colleges, Aberdeen, also studying at Göttingen and in Italy and Paris. After teaching for some years he was head master of John Watson's institution, Edinburgh, 1840–50, and of Donaldson's Hospital 1850–70, and Professor of Oriental Languages in the University of Aberdeen 1870–87. He published *Symmetrical Structure of Scripture* (1854); *Analytical Commentary on Romans* (1868); *Predestination and Free Will Reconciled* (1879); *Studies on the Book of Psalms* (1888); *The Servant of the Lord in Isaiah* (1890); *Universal Salvation* (1892). WILLIS J. BEECHER.

Forbes, JOHN COLIN, R. C. A.: artist; b. in Toronto, Canada, Jan. 23, 1846; entirely self-taught in art until the production of his first work. Subsequently studied for two years at the Royal Academy in London, England, and on the Continent, and upon his return to Canada painted *Foundering of the Hibernia*, *The Canon in the Royal Gorge*, *The Mount of the Holy Cross*, *The Glacier of the Selkirk*, *The Lily*, etc. He has painted portraits of the Rt. Hon. William E. Gladstone, presented by the Liberals of Canada to the National Liberal Club of London, England, Sir John A. Macdonald, Marquis of Dufferin, Lady Helen Blackwood, Sir Charles Tupper, Bart., and others. NEIL MACDONALD.

Forbes, JOHN MURRAY, D. D.: clergyman; b. May 5, 1807; graduated at Columbia College in 1827, and at the General Theological Seminary of the Protestant Episcopal Church in 1830; was for a short time assistant Professor of Ancient Languages in Trinity College, Hartford; ordained in 1830; in 1834 became rector of St. Luke's church, New York, and temporarily Professor of Pastoral Theology and Pulpit Eloquence in the General Theological Seminary. In 1844 and 1847 he represented the diocese of New York, as one of her clerical delegates, in the General Convention of the Church. In 1849 he entered the Church of Rome, and became shortly after pastor of St. Ann's Roman Catholic church in New York. In 1852 he was appointed by the Rt. Rev. Bishop of South Carolina his theologian in the plenary council of the Roman Church, held that year in the city of Baltimore, and in 1854 acted as theologian to the Rt. Rev. Bishop of Boston in the provincial council held in New York. He received the degree of S. T. D. by Vatican decree of Pope Pius IX. In 1859 Dr. Forbes returned to the Protestant Episcopal Church, in 1862 was restored to the exercise of his ministry, and in 1869 was appointed dean and permanent executive officer of the General Theological Seminary of the Protestant Episcopal Church in the U. S.—an office held by him until 1872. D. in 1885.

Forbes, STANHOPE A.: genre-painter; b. in England; contemporary. Pupil of Bonnat, Paris; associate Royal Academy, London; first-class medal, Paris Exposition, 1889. His pictures are remarkably good in drawing, and show great truth of observation in the treatment of effects of light in interiors. One of his best works is *The Village Harmonic* (1888), belonging to the corporation of Birmingham, England. Studio in London. W. A. C.

Forbidden Fruit: a name given in different countries to fruits which, according to tradition, represent the fruit of which Adam and Eve ate at the time of man's fall in Eden. One of these is a sort of thick-skinned orange (*Citrus aurantium*, var. *Paradisi*), which bears marks which are likened to tooth-marks. The skin is the part eaten; the pulp is very sour, but the skin is soft and pleasant to the taste. Another kind is a small shaddock (*Citrus decumanus*). Still another is the poisonous fruit of *Tabernæmontana dichotoma* of Ceylon, a tree of the order *Apocynaceæ*. This fruit appears as if bitten; hence the tradition.

Forcade-Laroquette, fōr'kaad'laa'rō'ket', JEAN LOUIS VICTOR ADOLPHE, de, LL. D.: b. in Paris, Apr. 8, 1820; a half-brother of Marshal Saint-Arnaud; became an advocate in 1841, and received the doctorate in 1846; became master of requests in 1852; director-general of forests 1857; director-general of customs revenues and indirect contributions, and councilor of state; minister of finance 1860–61; vice-president of the council of state 1863; minister of agriculture, public works, and commerce 1867; was one of the chief promoters of the Havre marine international exposition; minister of the interior 1868; was distinguished for parliamentary eloquence, and was an imperialist of liberal views. D. Aug. 15, 1874.

Force [O. Fr. *force*: Ital. *forza*: Span. *forza*, *fuerza* < Lat. **fortia*, deriv. of *fortis*, strong]: any action between material bodies by which they change, or tend to change, each other's condition. Every change of condition of a material body implies motion of some kind, either, first, of the mass (molar), or, secondly, of its component particles (molecular). Our earliest idea of force is derived from the resistance of matter to the touch. Matter itself becomes known at the same time; and as we perceive it to have extension, we acquire simultaneously the idea of space. Matter is whatever occupies space. Nothing is known of force except as a cause producing, or tending to produce, motion or change of motion in matter. Force, therefore, is the efficient cause of all physical phenomena, including not only those commonly called mechanical, but also those attendant on heat, light, electricity, and chemical action. Mechanical forces are such as produce their effects upon masses of measurable magnitude directly. They are distinguished as dynamical (producing actual motion; see DYNAMICS) and statical (held in check by opposing forces; see STATICS). Statical forces may be compared with each other by means of the efforts or pressures they exert, which may be measured by a spring balance or by opposing them to known forces through an intervening lever. But as static forces produce motion if opposed by resistances less than themselves, such forces may also be measured by their relative power to generate motion when all resistance is removed. A heavy body resting upon a support exerts a pressure which is due to the force of gravity acting statically. If the support be removed, the body falls. We have the means of ascertaining experimentally the velocity imparted by gravity to a falling body in a unit of time; and this furnishes us with a natural standard for measuring other forces. Observation again shows that the pressure exerted by a mass in consequence of gravity is proportioned to the mass. It shows, however, also, that every mass of matter, whether small or great, falls, if unsupported, with the same velocity. By experiments made with Atwood's machine, and in other ways, it is found that if the force which acts upon the same mass is increased or diminished, the velocity generated is also increased or diminished proportionally. It may therefore be said, briefly, that forces are proportional to the masses moved and to the velocities generated at the same time—in other words, that force is as the product of velocity into mass. This product is called moment. Putting, then, f for force, p for pressure, m for mass, and v for velocity, the result is $f \propto p$, and $f \propto mv$. Moment as well as pressure may accordingly be taken as the measure of static force; but in this expression v represents what is called a *virtual* and not a real velocity, being that which the mass m would take on if the system were to be set in motion.

When a force acting continuously produces motion or overcomes a resistance through space, it is said to do work. If the resistance is simply the inertia of a constant mass, the work done will consist in accelerating velocity. If the resistance is external (as of friction opposing motion on a horizontal plane), the work done will consist in transferring the mass from one point to another in space. In either case the measure of the work will be the force acting or the resistance opposing, multiplied by the distance passed over. For external resistances, as of friction just mentioned, this is self-evident. For the resistance of inertia it may be shown to be true by considering the case of gravity. The increments of velocity imparted by gravity in successive equal instants of time to a body falling from rest are equal; but the minute spaces passed over in these successive instants, being proportional to the successive actual velocities, form an arithmetical series. (See FALLING BODIES.) The sum of this series gives the total space fallen, which is $\frac{1}{2}vt$. Now, mg being the measure of the static force of gravity, $\frac{1}{2}mgvt$ represents the work of gravity in putting a body into motion with the velocity v. And as $gt = v$, we obtain finally for work (W), $W = \frac{1}{2}mv^2$. Any other constant force, as f, greater or less than gravity, will generate the velocity v in a time proportionally less or greater; but the work done will in all cases be the same, and will be independent of both force and time. For, as $ft = v$, and as v is, by hypothesis, constant, ft is constant also, and $W = \frac{1}{2}mfvt$ is invariable, whatever be the value of f. In like manner, the work which may be done by the moving mass in overcoming resistance to its motion is equally independent of time, while the space through which it may move in expending the force accumulated in it will be inversely as the resistance it encounters. Thus a heavy ball rolling over smooth ice, being but slightly retarded by friction, will roll very far, but a hammer or bullet suddenly arrested will exert an enormous and even destructive pressure.

We thus see that the power of a moving mass to do work is proportioned to the square of the velocity of motion, while the power of a simple pressure to hold in check an opposing pressure is proportioned to the virtual velocity only. For distinction, the product mv^2 is called the *vis viva*, the living force, or the kinetic energy, and mv the moment. By *energy* is meant the capacity of a body to do work. This may depend on its position or condition, and is then called *potential energy*. The body is doing no work, but may be made to do work by some change in one or both the respects mentioned. A clock-weight wound up, the mechanism being at rest, is an example of energy of position. Gunpowder is an example of energy of condition. *Actual* energy is that exercised by a moving mass, and is equivalent to living force. A pendulum at the end of its swing possesses only potential energy, and in the middle of the swing only actual energy.

Thus far we have confined ourselves to the relations of force and energy in mechanics. We now proceed to consider them in their wider significations. The forces of nature which are characteristically different from each other may be stated as follows: 1, gravitation; 2, molecular force; 3, chemical affinity; 4, heat and light; 5, electricity; 6, vital force. Gravitation, which is the attraction between bodies at a distance, is proportional directly to the product of the two masses, and inversely to the square of the distance between them. Molecular force is the attraction between the particles of bodies, and is manifested in solids and liquids by their cohesion and elasticity, and in liquids additionally in capillarity and osmose. Chemical affinity resembles the force last named in acting at insensible distances, but differs in being manifested only between unlike substances. Heat is supposed to be a mode of vibratory motion actuating the molecules of every material substance. Elevation of temperature is explained as an increase in the energy of the vibrations and an enlargement of their amplitude, whereby the volume of the combined mass is expanded, and ultimately the cohesion and even the affinities of its molecules are overcome. These vibrations are supposed to be propagated from body to body by undulations in an exceedingly rare medium filling all space, called ether. When these undulations fall within certain definitely assigned limits as to length, they have power to affect the retina of the eye, and thus give rise to the phenomena of light. Electricity is a very energetic force, the physical theory of which is still unsettled. It produces, according to circumstances, attractions and repulsions between masses and between molecules. Magnetism is but a form of electrical action. Vital force is more obscure as to its manner of action than any other; and it is even denied by many physicists and physiologists that any such distinctive force exists, all the phenomena ascribed to it being attributed to electricity, chemical affinity, and heat. There is no doubt, however, that there exists in the nervous centers of living animals a certain power which can cause contraction of the muscles of the body by exciting the proper nerves. The velocity with which this message is transmitted is by no means great, not exceeding 20 or 30 meters per second. When a whale is struck by a harpoon, such is the size of the animal that quite an interval elapses before the brain can be informed of the fact and can put the muscles of the tail in operation; so that before this effect is produced the whalers have time to retreat.

Having thus classified forces, we may still further distinguish the kinds of energy dependent on them as follows: Kinetic energy exists in the four forms, A, of bodies in motion; B, of radiant heat and light; C, of electricity in motion; and D, of absorbed heat. Potential energy may be, E, position of the body in regard to gravity or other force acting at a distance; F, molecular separation; G, chemical separation; and H, electrical separation. In the first four of these forms work is obtained directly from the motion of the body or its molecules; in the second four it is derived from an alteration of its condition.

Whenever energy in one form disappears, it reappears in another, and this property is known as the transmutation of energy or the correlation of forces. (See ENERGY.) For example, the energy of a moving body suddenly arrested in its motion is converted into heat; the energy of an electric current may be transformed, in an electro-dynamic engine, into kinetic energy or into potential energy of chemical affinity in electrolysis. In general, such transformations are not from one form of energy into a single other form only. The moving body arrested expends some part of its energy in molecular separation (fracture of the opposing body), some part in giving motion to the fragments, and the rest in heat. The energy of the electric current is distributed between mechanical motion, heat, and chemical separation. But if in every such case we could collect and reunite all these fractions of distributed energy, we should find their sum just equal to that which has disappeared; and this leads us to one of the grandest generalizations of modern times, the doctrine of the persistence of force, or the conservation of energy, expressed in the proposition that energy, like matter, is indestructible, so that, however its form may change, its total quantity is forever constant.

With the demonstration of this doctrine a fatal blow has been given to an illusion which from the earliest times has exercised a singular fascination over many ingenious minds—the belief in the possibility of a perpetual motion. By this was meant, not the eternal persistence of motion in a body which encounters no resistance whatever—for in this sense the doctrine of the conservation of force is also a doctrine of perpetual motion—but the delivery at one part of a mechanical contrivance of a greater amount of kinetic energy than that which is applied at another to set the contrivance in operation. See PERPETUAL MOTION.

Measure of Forces.—In order to compare quantities of any kind it is necessary that we have some definitely fixed units of measure. By the aid of such units the relative magnitudes of quantities of the same kind are expressible in abstract numbers. And when quantities of different kinds are in the relation of dependent variables, the laws which connect them may be expressed by comparing the abstract numbers which denote their relations of magnitude among themselves. For this purpose it is necessary to take as a starting-point some state of the related quantities of which the conditions are definitely known. Take, for instance, the law of pressure and volume in gases, commonly called the law of Mariotte. If the elasticity of air compressed in a cylinder by a force of 20 lb. to the sq. inch maintains the piston at the height of 4 feet, 40 lb. to the sq. inch will reduce this height to 2 feet. We have here a variety of units, and the numbers are unnecessarily large. It would be simpler to say that if under a pressure of 1 (unit of force) the air compressed occupies 2 units of volume, then a pressure of 2 units of force will reduce it to 1 unit of volume. It is therefore desirable that, in order to compare with facility the relations of quantities of different kinds, the units shall be so chosen as to have the simplest possible relations between each other.

The centimeter, gramme, and second have been recommended by the British Association for the Advancement of Science as fundamental units on which to establish other unit measures of quantity and energy for physical purposes, called, therefore, derived units. These fundamentals are sometimes referred to as the "B. A. units" or the "C. G. S. units" (centimeter, gramme, second).

Since, when bodies move uniformly, $s = vt$, the unit of velocity will be naturally that found by making s and t equal to the fundamental units C and S; that is, it will be that velocity which will carry a body 1 cm. in 1 second. In the same way, if a be put for acceleration, $v = at$; and putting v and t each unity, a is the force required to generate a velocity of 1 cm. in 1 second. The unit of mass is deduced from the two forms above given for expressing statically the force of gravity—viz., $mg = w$. This gives $m = w \div g = w \div 981$ cm., this last expressing nearly the accelerative force of gravity. If $w = 1$ gramme, m is a little over a milligramme. As all the derivative denominations of this system are decimal multiples of the unit, the introduction of an incommensurable divisor, as in this case, is an incongruity to be regretted, but it is unavoidable. Since g, however, varies in different latitudes (though only slightly), it is advisable to employ, as has been proposed by Sir William Thomson, the value of g at Paris, which is 980·87 cm. Hence putting $m = 1$ and $w = 1$, the unit of mass is 1 gramme divided by 980·87. The unit of force $f = ma$ is found by making $m = 1$ and $a = 1$, when $f =$ the force required to produce in the mass of 1 gramme the unit of acceleration, which, as above, is 1 cm. in 1 second. But the mass of 1 gramme is, as we have seen, the weight of 1 gramme divided by 980·87. Hence the unit of force, compared with gravity, is $\frac{1}{981}$ part as great, or, expressed as weight, is slightly over a milligramme. This unit of force is called a DYNE (*q. v.*). The unit of work, $W = fs$, is found by making f and $s =$ unity, and is therefore 1 dyne acting through the space of 1 cm. This is called an *erg*. The higher denominations in this system are formed by decimal multiplication; and inasmuch as, in consequence of their minuteness, the quantities which we deal with every day exceed them a thousand or a million times, a short mode of writing and naming these multiples has been adopted; thus: a gramme being 981 dynes and a kilogramme 981,000 dynes, a mass of 1,000,000 dynes would not greatly exceed a kilogramme. And 1,000,000 dynes is written 1×10^6 dynes, or *one dyne-six*. So the circumference of the earth, being 4,000,000,000 cm., is written 4×10^9 cm., and is read *four centimeter-nines*. If division is to be expressed, the ordinal numbers are used. Thus 1 milligramme $= \frac{1}{1000}$ gramme is written 1×10^{-3} gramme, and read *one gramme-third*. This system of units has not been generally accepted as yet in the scientific world. Still less has it been introduced into the arts of industry. For the units now generally employed in the U. S. and in other countries for computing the force of engines, water-powers, or animals, or calculating the work performed by any one of these motive-powers, see UNITS.

Passing from mechanical to physical units, the most important of all, whether in its scientific or its industrial relations, is the unit of heat, which is the amount of heat necessary to raise the temperature of 1 kilog. of water one degree centigrade. The number of units of work necessary to generate this amount of heat is called the *mechanical equivalent of heat*. Much careful labor has been expended in the attempt to determine this important constant (see HEAT). The value commonly received is 423 kilogrammeters, or 423 kilog. raised 1 meter high. The corresponding value for British units and the Fahrenheit thermometer is 772 foot-pounds, or 772 lb. raised 1 foot high. The derived unit of heat on the B. A. system would be the amount necessary to raise the temperature of 1 gramme of water through one degree centigrade. The mechanical equivalent of this would be 42,300 grammes raised 1 centimeter, or 42,300 gramme-centimeters, or centigrammeters; which, in ergs, would amount to 41,491,000, or 41 erg-sixes + 491 erg-threes. For electrical units, see ELECTRICITY.

Sources of Energy.—The immediate sources of energy in our planet are numerous, embracing, as sources of kinetic energy, the radiation of the sun, the motion of air and water, and the muscular force of animals; and, as sources of potential energy, water accumulated above the general level in lakes and rivers or lifted by the tides, unequal distribution of temperature on the earth, wood, coal, native sulphur, and other combustible minerals, and food as the source of kinetic muscular force. All these, however, except the tides and some unimportant cases under the head of combustibles, are originally derived from the great source first named—viz., the solar radiation. The internal heat of the earth, sometimes exhibited in volcanic action, is a source of energy practically unavailable; but its gradual decline, causing contraction of the interior mass, permits the energy of gravitation occasionally from being potential to become active, and to manifest itself in earthquakes. Tidal action requires some explanation. To an observer on the moon the tidal wave, if visible, would appear as a mass of water nearly at rest, under which the earth is revolving like a car-wheel under the brake. The energy therefore is derived from the motion of the earth, and since this energy is continually converted by friction into other forms, there is a constant drain upon its source; or, in other words, it is continually making the earth turn more and more slowly. This effect is of course exceedingly slight, but it is supposed to account for the astronomical phenomenon known as the secular acceleration of the moon's mean motion, the moon appearing to move faster since the earth moves more slowly. The ultimate result will be that the time of revolution of the earth around its axis will at length equal the time of revolution of the moon around the earth, or the latter will always turn its same face toward the moon. Now, if the moon ever contained a liquid like our ocean, a similar effect would be produced on it, only in a much more marked manner, owing to the larger size of the earth. The necessary result would be that which has actually occurred—that the times of revolution of the moon around its axis and around the earth would be equal.

Although in a system of bodies in communication with surrounding objects the total amount of energy is always constant, yet all of it is not available to do work. For instance, if two bodies, one warmer than the other, are thus isolated, the heat passes from the first to the second, and is thus able to do work; as soon, however, as they both attain the same temperature the available energy is exhausted, and although their actual temperature may be very high, they have no power of doing work until brought in contact with some cooled body. This available energy is known as the *entropy* of the system. In any actual case a considerable portion of the energy of a body is lost by being converted into a form from which we can not reconvert it into work. Thus a heated body when used as a source of energy begins at once to lose its heat by radiation, by heating the surrounding air, and by conduction through its support, the energy being here converted into heat but little above that of surrounding bodies, and therefore not readily convertible into work. A similar loss takes place with an electrified body, since there is no perfect non-conductor of electricity. In the case of motion we can not avoid the resistance of the air or of friction; and often some surrounding bodies being set in vibration, a portion of the energy is converted into sound. The effect of all this is slightly to warm the various bodies moved, and thus again the energy is brought into a form from which it can not easily be brought back. This is what is known as the dissipation of energy.

The grandest application of these laws is in astronomy to the determination of the source of energy in the solar system. We have already seen that the effect of a liquid on a satellite is to act as a brake to alter the time of rotation, until it is finally rendered the same as the time of revolution in the orbit, so that the same face shall always be turned toward the primary. The planets would also be affected in the same way, both by their satellites and by the sun itself; and although the problem becomes one of great complication, probably the final result would be the conversion of nearly all the kinetic energy of rotation into heat, which would eventually radiate into space. The far greater energy derived from the sun is also rapidly passing off into space. The total amount received by the earth, great as it is, is almost infinitesimal compared with the amount radiated into space, and thus lost. This energy is estimated at the surface of the sun to be equivalent to 7,000 horse-power for each square foot of surface. This amount of energy is so great that if the sun were a mass of burning coal, it would be wholly consumed in 5,000 years, and in 5,000 years more would have cooled down 9,000° C. Since geology proves that for hundreds of thousands of years the temperature of the earth has been about the same as at present, evidently chemical combination is not sufficient to account for this vast fund of energy. The nebular hypothesis assumes that the matter of the solar system was originally distributed through space, and the planets and sun formed by its condensation. Here there would be an enormous source of energy, since the potential energy due to the distance of the particles would by the force of gravitation become kinetic in their approach to each other. On making the calculation, however, the energy thus set free proves to be as much too great as the other was too small; and this theory also must be rejected. The view now held with regard to the source of the sun's heat is that it is due simply to its contraction. The mass of the sun is so great that on the most unfavorable supposition the heat set free by the diminution of potential energy due to its contraction would supply the present loss for 7,000 years before the whole mass would have altered its temperature by one degree centigrade. Still, enormous as this supply is, it must eventually be exhausted, and then, by the dissipation of energy, be finally converted into radiant heat and diffused through space. The final result, therefore, would be that all bodies would assume the same temperature; there would be no further source of energy; physical phenomena would cease, and the physical universe would be dead. Such, at least, is the present view of this stupendous question. E. C. PICKERING.

Force, PETER: historian and journalist; b. at Passaic Falls, N. J., Nov. 26, 1790. In 1820 he commenced the publication, in Washington, of *The National Calendar*, a volume of national statistics, which he published annually until 1836. He also published (1823–30) a political newspaper, *The National Journal*, which was, during President J. Q. Adams's administration, the official organ. By desire of the Government he undertook in 1833 the preparation of a documentary history of the American colonies, a labor to which he devoted thirty years, during which time nine folio volumes were published, entitled *American Archives*. While thus engaged he accumulated a valuable library relating to early American history, consisting of books, documents, manuscripts, maps, etc., which were purchased by the U. S. in 1877 for the Congressional Library. D. at Washington, D. C., Jan. 23, 1868.

Force Bill, The: the name popularly applied to the bill introduced in the U. S. Congress Mar. 15, 1890, providing for the Federal control of elections. It passed in the House July 2, went to the Senate, and, after a bitter struggle, was forced aside without a decisive vote on Jan. 17, 1891. The Democrats who opposed it made the bill an important issue in the congressional and presidential campaign of 1892.

Forcellini, fōr-chel-lee'nēē, EGIDIO: Latin lexicographer; b. at Féner, near Feltre, in the Venetian territory, Aug. 26, 1688. The poverty of his parents deprived him of early advantages, but having entered the seminary of Padua, he by his marked abilities and devotion attracted the notice of Facciolati, then director, who soon engaged his aid in carrying out his own designs for improving the Latin dictionaries then in use. In 1705, under the direction of his teacher, Forcellini began the revision of the book called *Calepinus* (see FACCIOLATI), and finished it at the end of 1718. Facciolati meantime had conceived the plan of a complete dictionary of the Latin language, which should comprise all the words of existing authors, as well as those found in inscriptions and on medals. The execution of this great work devolved entirely upon Forcellini, and to him this credit belongs, though he enjoyed throughout the whole period the counsel and supervision of his old teacher. A brief memorandum by Forcellini states that he began the task at the end of 1718, and worked three and a half years on the letter A. In 1724 he was called away to be Professor of Rhetoric and director of the seminary at Ceneda, and was obliged to suspend work on the dictionary till his recall to Padua in 1731. From this time he labored for eleven years without interruption, for the next eleven, with more or less hindrance, till the completion in 1753; two years were given to revision, and eight years to the transcription, which was finished Nov. 13, 1761. D. at Padua, Apr. 4, 1768, one year before Facciolati, and three years before the publication of the work that had occupied nearly forty years of his life. The title-page sets forth fairly the relation of the two editors: *Totius Latinitatis Lexicon Consilio et cura Jacobi Facciolati opera et studio Ægidii Forcellini alumni Sem. Patav. lucubratum.* The work, after lying ten years, was published in 4 vols. folio, under the care of Cognolati, who wrote the preface. A new edition appeared in 1805, and a third, revised with additions by Furlanetto, Padua, 1823–31, 4 vols. 4to. The newest edition by De Vit, with Onomasticon, 1858 ff. An edition with the Italian explanations translated into English was issued by G. Bailey, London, 1828, 2 vols. 4to. See J. B. Ferrari, *Life of Forcellini*, (Padua, 1792). Revised by ALFRED GUDEMAN.

Forceps [from Lat. *forceps* for **formiceps*; *formus*, warm + *ca'pere*, take]: in surgery, an instrument for seizing, and often for removing, bodies which can not conveniently be seized by the hand. Forceps are of many forms. Special kinds are used for special purposes, as for drawing teeth, for cleansing sores, for seizing a bleeding artery, for extracting bullets, for assisting in the birth of the fœtus, and for many other uses.

Forchhammer, fōrkh'haā-mer, JOHAN GEORG: geologist; b. at Husum, Schleswig, July 26, 1794; became a distinguished geologist, mineralogist, and chemist; was the associate of Oersted, and long held the chair of Geology at Copenhagen; author of works on the geology of Denmark (1835), of Scandinavia (1843), and a manual of chemistry (1834–35). D. at Copenhagen, Dec. 13, 1865.

Forchhammer, PAUL WILHELM: Greek archæologist and mythologist; b. at Husum, Schleswig, Oct. 23, 1803; privat docent in Kiel 1828; professor extraordinary in 1836; professor ordinarius in 1843. His writings are chiefly the result of his extensive travels through Greece, and pertain particularly to topography and Greek mythology. In the treatment of the latter subject he persistently advocated throughout his long life a purely symbolical interpretation of Hellenic myths and legends, regarding them as the anthropomorphized embodiments of aquatic phenomena. This theory, which has justly not been received except in some minor details, is brought out with great learning and remarkable ingenuity in all his publications, of which only a few can be mentioned: *Achill* (1853); *Daduchos* (1875); *Wanderings of Io* (1880); *Erklärung der Ilias*, on the basis of the topographical features of the plain of Troy (1884); *Mykenæ* (1881); *Hellenika*, vol. i. (no more published); *On Aristotle's Poetics*, etc. D. at Kiel, Jan. 9, 1894.

Forcible Entry and Detainer: in law, a forcible entry consists in an unlawful entry upon lands or tenements, accompanied by the exercise of force or by the use of such threats and menaces as overawe those rightfully in possession, and prevent their resistance. Forcible detainer consists in wrongfully keeping possession of lands or tenements by force and threats, whether the original entry was forcible or peaceable. Entry and detainer are usually included in the same act. The remedy for a forcible entry and detainer is twofold, the law affording both a criminal and a civil remedy. The common-law remedy is criminal in its nature, while the statutes afford a civil remedy. The sole object of the civil action is the recovery of the possession which has been invaded, the judgment being that the plaintiff have restitution of the premises of which he has been unlawfully deprived. The civil and criminal remedies can not both be pursued in the same proceeding.

From the time of the Norman Conqueror until the statute of 5 Rich. II., c. 8, the common law of England permitted one having a right of entry to enter with force and arms, and to retain his entry by force when his entry was lawful. But experience showing this to be prejudicial to the public peace, as it enabled the powerful to tyrannize over their less fortunate neighbors, it was deemed proper to restrain by severe laws all persons from themselves taking possession by force, and the statute referred to was enacted. This statute has been followed in England by others of like import, and similar statutes have been enacted in the U. S. These statutes generally declare that "no entry shall be made upon lands except in cases where entry is given by law, and that in such cases it shall be made only in a peaceable manner, not with strong hand, nor with multitude of people." In most of the States jurisdiction over the action is conferred upon the justices of the peace. They have no jurisdiction, however, in cases where the title to real property is in question. But the limitation of the jurisdiction of justices of the peace to actions where the amount in dispute does not exceed a certain amount does not deprive them of jurisdiction in actions of forcible entry and detainer.

1. In order to maintain the action, the complainant must show that he was in the actual and peaceable possession of the premises at the time of the ouster complained of. The action does not involve the right to possession, but only the fact of possession.

2. The person who may bring the action is the person who was deprived of the possession. A landlord can not bring the action while his tenant is in possession, but the action should be brought by the tenant. In some States, however, the statute gives the landlord the right to maintain the action against his tenant.

3. The person against whom the action may be brought is the person who is in possession at the time of the commencement of the action. It may be maintained against the representatives of the disseizor, and against those in possession under him.

When entry is made by one who seeks to justify his act by a plea of ownership, as by a landlord against a tenant holding over after his term, it is generally held that the ten-

ant can not bring a private action for the offense, although the landlord is punishable for the violation of the peace.
HENRY WADE ROGERS.

Forcing: among gardeners, properly the production of any fruit or flower out of its proper season by the judicious use of hot or cold frames, glass houses, stimulating ammoniacal fertilizers, and other like appliances. The term can not be extended to the growing, by similar means, of exotic, and especially tropical, fruits or plants in an uncongenial climate. The system pursued in the orchard-house is not, properly speaking, forcing. It is simply the production of another climate, the imitation of the climate in which the plant naturally grows, the furnishing of the necessary conditions for the life of the plant. Fruit-trees, especially cherry-trees, are often forced, in the true meaning of the word. Very diminutive trees may be seen richly loaded with fruit. The Chinese and Japanese are great masters in the art of forcing. Certain varieties of fruit-trees are by gardeners considered as particularly suitable for forcing.

Forcite: See EXPLOSIVES.

Ford, JOHN: English dramatist; b. at Ilsington, Devonshire, in 1586; entered the Middle Temple, London, Nov. 16, 1602, and appears to have followed the legal profession with some success. He produced, alone or in conjunction with other dramatists, a dozen or more plays, of which only nine are extant, including the two powerful but morbid tragedies, *The Broken Heart* and *'Tis Pity She's a Whore.* D. about 1640.

Ford, LEWIS DE SAUSSURE, M. D., LL. D.: physician; b. in Morristown, N. J., Dec. 30, 1801: graduated from the College of Physicians and Surgeons of New York City in 1822; in 1832 assisted in organizing the Medical College of Georgia, at Augusta, an institution in which he held the professorships of Chemistry and Practice of Medicine. He was twice mayor of Augusta; received the degree of LL. D. from the University of Georgia in 1868. He contributed valuable essays on paroxysmal fevers, from 1836 to 1845, to *The Southern Medical and Surgical Journal.* D. in Augusta, Ga., Aug. 21, 1883. C. H. THURBER.

Ford, WORTHINGTON CHAUNCEY: statistician; b. in Brooklyn, N. Y., Feb. 16, 1858; educated at Columbia College; served on the editorial staff of the *New York Herald*; chief of the U. S. bureau of statistics from 1893 till 1898; author of *Wells's Natural Philosophy* (1879); *The Standard Silver Dollar* (1884); *American Citizen's Manual* (1882); *Letters of Joseph Jones* (1889); *Writings of Washington* (14 vols., 1889–92); *Spurious Letters of Washington* (1889); *Washington as an Employer and Importer of Labor* (1889); *The United States and Spain in 1790* (1890); *General Heath's Orderly Book* (1890); *Washington Wills* (1891); *Letters of William Lee* (3 vols., 1891); *Correspondence and Journals of Samuel B. Webb* (2 vols., 1892). C. H. THURBER.

Foreclosure: See MORTGAGE.

Forefathers' Day: the anniversary of the landing of the Pilgrims at Plymouth, Mass., in 1620. The event occurred on Monday, Dec. 11, *old style*. The day was first publicly and formally commemorated in 1769, when seven gentlemen of Plymouth, on Dec. 18, formed the Old Colony Club to celebrate "the landing of our worthy ancestors in this place." Eleven days were erroneously added to the recorded date, in order to accommodate the event to the Gregorian style, hence the date Dec. 22 came to be generally accepted. The Gregorian calendar was not adopted in England until 1752, when it was necessary to add eleven days to *old style* in order to correct the error. But in 1620 the addition of ten days only was necessary to correct the error, the same that had been provided for in 1582 by Pope Gregory when the Gregorian calendar was substituted for the Julian. It follows that the date of landing, *new style*, was Dec. 21 instead of Dec. 22, which is usually celebrated. The Old Colony Club disbanded in 1773, but the town of Plymouth voted to keep up the celebration, the usual form being a church service and anniversary service. From 1780 to 1794 exercises were suspended. In 1819 the Pilgrim Society was formed. The formation of the New England Society of the city of New York, May 6, 1805, "to commemorate the landing of the Pilgrim Fathers on Plymouth Rock, to promote friendship, charity, and mutual assistance, and for literary purposes," seems to mark the beginning of the observance of Forefathers' Day outside of New England. The annual meetings of this society on Dec. 22 (Forefathers' Night) have acquired wide fame. Numerous New England societies have been formed in all parts of the U. S., so that the celebration of the day is likely to become national.
C. K. ADAMS.

Foreign Attachment: a process of attachment by which the property of a foreign or absent debtor in the hands of third persons, or debts due him from them, may be levied upon for the discharge of his indebtedness to a suing creditor. This form of procedure has existed in England from a very remote period, but only in a few of the larger cities, as London, Liverpool, etc., and owes its origin to immemorial usage in these particular localities, but does not constitute a part of the general common law. In these cities it still subsists in its ancient form, but a process of a similar nature has been established to operate uniformly throughout the realm, which is known as garnishment. This statutory proceeding, however, is applicable not only with reference to foreign but also to domestic debtors; and since it gives a right to seize upon their effects and credits only after the recovery of judgment, it is less beneficial than the special system of foreign attachment. In a number of the U. S. a process similar to foreign attachment has been adopted by statute, providing for a levy upon the property of absent, non-resident, and absconding debtors, but its extent of application is not always the same. Garnishment, which is known in some parts of the country as the "trustee process," may commence with the suit, and includes both foreign and domestic attachment, and is the term generally used to designate the case where a debtor's property or credits may be attached in the possession of third persons. The statutes of the respective States must be consulted. See GARNISHMENT. Revised by H. W. ROGERS.

Foreign Corporations: See the Appendix.

Foreign Judgments: the judgments of a foreign tribunal. As no state is under any obligation to enforce laws which are not of its own creation, the effect to be given to foreign judgments must depend entirely upon the comity of nations in their mutual relations with one another. But the general voluntary acceptance among the states of Christendom of the doctrines of international law has also extended to the recognition of the validity of such judgments when rendered by tribunals having jurisdiction of the cause determined, and when the proceedings were characterized by no fatal irregularity or fraud. Due inquiry may be instituted in regard to the authority of the foreign court and the conduct of the suit, in order to ascertain whether any oppression was exerted or injustice done; but if no error appears the decree is sustained. This practice operates as a great preventive of vexatious and protracted litigation, by which defendants might otherwise be persecuted and the courts burdened, while it nevertheless tends to secure the administration of full and exact justice.

In all cases when it is desired to introduce into any court the proof of a foreign judgment in order that it may be inquired into or enforced, it must be proved and authenticated as a matter of fact. This may be done either by an exemplification of a copy of the judgment under the great seal of a state, or by a copy sworn to as correct by a witness who has compared it with the original, or by the certificate of an officer properly authorized by law to give a copy; which certificate must itself be properly authenticated. When the tribunal rendering the judgment is one whose acts are recognized by the law of nations, such as a court of admiralty, etc., an exemplification under the seal of the court will be sufficient.

The several States of the U. S. are, as regards the proceedings of the State tribunals, regarded as foreign to one another, and judgments rendered in each are accordingly, on general principles of law, sustainable in the others as foreign judgments. But as these States are subordinate to one general government, the effect to be given in one to the judicial acts of another has not been left to depend simply upon interstate comity. In the U. S. Constitution is contained a provision that "full faith and credit shall be given in each State to the public acts, records, and judicial proceedings of every other State, and that Congress may prescribe the manner in which such acts, records, and proceedings shall be proved, and the effect thereof." In pursuance of this authority the following enactment has been passed by Congress, establishing a mode of proof which is, however, not exclusive of any which the State itself may see fit to adopt. "The records and judicial proceedings of the courts of any State shall be proved or admitted in any other court within the U. S. by the attestation of the clerk and the seal of the court annexed, if there be a seal, together with the certificate of the judge, chief justice, or presiding magistrate, as the case may be, that the said attestation is in due form. And the said records and judicial proceedings, authenticated as aforesaid, shall have such faith and credit given to them in every court within the U. S., as they have by law or usage in the courts of the State from whence such records are or shall be taken." If a judgment, therefore, would be conclusive in the State in which it was rendered, it is conclusive in every other State. It is not, however, put upon the same footing in all respects as a domestic judgment. No execution can issue upon it without a new suit in the courts of the State where it is sought to be enforced. It is moreover established that the above statute does not prevent an investigation into the jurisdiction of the court in which the judgment was rendered, or an inquiry as to the point whether it was obtained by fraud.

Some special remarks should be made as to judgments affecting the status of a person or thing, commonly called judgment *in rem*. An illustration of such a judgment as to a thing is a proceeding in a prize court to ascertain the title to a ship; of such a judgment as to a person, a divorce from the marriage contract. The peculiarity of such a judgment is that of its own force it establishes the fact which it announces. A judgment in a prize court that a ship is a U. S. ship makes it a U. S. ship everywhere, even though the court may have proceeded on an erroneous principle of law. In this respect such a judgment differs widely from one between persons (*in personam*), as that requires an act of the executive power to carry it into effect.

As to the effect of a decree of divorce, there is a diversity of opinion. The English courts hold that no foreign court can dissolve an English marriage in such a sense that its decree will be recognized in England. In the U. S. a divorce granted in any State between parties who are domiciled there will be recognized in every other State, if the court had jurisdiction over the parties and there is no fraud. The same rule prevails if the plaintiff be domiciled in a State, and the other party makes due appearance either in person or by attorney to defend the action. For this purpose it is held that a married woman may acquire a different domicile from that of her husband. But if a person residing in one State goes into another and obtains a divorce without the presence of the other party, the decree will not in general be respected in the State of the latter's domicile, because the court has no jurisdiction over the absent defendant. See DIVORCE, MARRIED WOMEN, etc.

Foreknowledge: in theology, God's absolute knowledge or OMNISCIENCE (*q. v.*) from eternity—his knowledge conceived of, as in advance of, before, the thing known. All human knowledge is, strictly speaking, simultaneous with the object it contemplates, or, in a looser sense, may be subsequent to it. In the doctrine of PREDESTINATION (*q. v.*) foreknowledge is regarded in its relation to the salvation of men. It is admitted by all thorough theologians that the foreknowledge of God is *dialectically* distinct from his foreordination or eternal purpose, but as to the question whether or how an absolute (that is, an infallible) foreknowledge (which is conceded by both sides) can be consistent with a conditional foreordination, they answer differently. It is also admitted on both sides that there is no interval of time between the foreknowledge and the foreordination of God; both are alike eternal. The question is, which is properly put first in the system, in the order of nature and of logic? Out of the different answers to these questions have arisen, in large part, the conflicts between ARMINIANISM (*q. v.*) and CALVINISM (*q. v.*). The Calvinists make foreknowledge subsequent to and dependent on foreordination; the Arminians invert the relation, and make the purpose or ordination of God dependent upon what he foreknows. In one system the two are distinct, but not separable; in the other they are separable as well as distinct.

Forel, FRANÇOIS A.: See the Appendix.

Foreland, North and **South**: two promontories of England, on the east coast of Kent, 16 miles apart. They consist of chalk-cliffs 200 feet high, on which are lighthouses to warn the ships from the Downs and Goodwin Sands, which extend along the coast between them. Lat. of North Foreland, 51° 22′ N., lon. 1° 27′ E.; lat. of South Foreland, 51° 8′ N., lon. 1° 22′ E.

Forensic Medicine: See JURISPRUDENCE, MEDICAL.

Foreordination: ordination or decree in advance, the eternal appointment of all ends, and of all men to those ends, by God. When predestination, as some of the Fathers and some of the Calvinistic divines have used the term, covers all the acts of God's will, it is synonymous with foreordination. When predestination is confined to the purpose of God in regard to salvation, foreordination is related to predestination as a whole to a part. See FOREKNOWLEDGE.

Forerius, fō-ree′ri-ŭs, or **Foreiro**, fō-rā′i-rō, FRANCISCUS: b. of noble stock at Lisbon in 1523; entered the Dominican order 1539; studied at Paris, and acquired a brilliant reputation as a linguist, theologian, preacher, and writer; became instructor of the Prince Antonio and preacher to the King of Portugal; was prominent in the Council of Trent 1561–64; was one of the committee which revised the missal and breviary and prepared the Tridentine catechism; became confessor to Cardinal Borromeo; and in 1588 provincial of the Dominicans of Portugal. His chief work is a translation into Latin of Isaiah, with a commentary (1563). D. at Almeida, Jan. 10, 1587.

Foreshortening: in drawing, painting, and engraving, the representation of objects as if turned endwise or partly endwise to the spectator, the whole length being expressed or represented by means of the drawing.

Forestalling: a common-law offense which consisted in buying or contracting for any merchandise or victuals on their way to market with the intent to sell them again at an increased price, or in dissuading persons from bringing their goods or provisions to market, or in persuading them to enhance the price when there. Any device, practice, or conspiracy to enhance the market price of merchandise is a forestalling of the market. The law against forestalling was repealed in 1773, but it retained its penal character at common law till 1844, when it was abrogated by statute 7 and 8 Vict., c. 24. In the U. S. forestalling the market usually takes the form of "trusts" or "corners," being an attempt to enhance the price by monopolizing an article of trade or by regulating the supply. Whether such agreements are criminal or not in the U. S., they are clearly illegal, and an agreement in pursuance of such an object is certainly void. HENRY WADE ROGERS.

Forest Fly: a name given to those insects of the family *Hippoboscidæ*, order *Diptera*, which have well-developed wings. This family includes many of the ticks. All are parasitic. The larvæ are hatched in the oviduct, and turn to pupæ just before birth. The *Hippobosca equina* is a European horse-fly.

Forest Grove: town; Washington co., Or. (for location of county, see map of Oregon, ref. 1–B); on the Southern Pacific Railway; 24 miles W. of Portland. It is the seat of Pacific University and Tualatin Academy (Congregational), and has a canning-factory and grain elevators. Pop. (1880) 547; (1890) 668; (1900) 1,096.

Fores′ti, ELEUTARIO FELICE, LL. D.: patriot and scholar; b. at Conselice, near Ferrara, Italy, about 1793; graduated at the University of Bologna; practiced law at Ferrara; was prætor of Crespino in 1816; was arrested Jan. 7, 1819, as one of the Carbonari, and imprisoned at Spielberg until Aug., 1836, when he was permitted to go to the U. S. Was Professor of Italian in Columbia College, New York, and a teacher for more than twenty years. He was appointed in 1858 as U. S. consul at Genoa, and died in that city Sept. 14 of that year. Published *Chrestomazia Italiana* (1846), and edited an edition of Ollendorff's Italian grammar (New York, 1846).

Forest Laws: laws preventing injury to the soil or trees of a forest or to the game sheltered within its limits. A forest, under the ancient English law, was a tract of woody country in which the sovereign enjoyed an exclusive right to hunt game. Forests were not necessarily inclosed, but they were under the special protection of certain courts termed "forest courts," and a particular system of laws was established to prevent any violation of the king's rights. Both these courts and laws have now fallen into complete desuetude.

Foreston, Ill.: See FORRESTON.

Forestry: that branch of arboriculture which concerns itself with the growing and management of trees in masses, called forests. It is the art of systematically utilizing, reproducing, and improving in productive efficiency natural forests, or of establishing and managing new forests, wherever it is in the interest of man to do so. Forestry stands in the same relation to wood crops as agriculture to field crops, and involves the application of thought and knowledge to attain certain results and accomplish certain ends. The forest is not a mere collection of individual trees, but represents a complete organism with special conditions of existence, special properties, special relationships and functions as a whole. Hence forestry does not deal, except incidentally, with single trees like orcharding, or groups of trees like landscape gardening; it deals with masses. Forestry as a science studies the phenomena of the vegetation in the natural forest; forestry as an art applies itself to utilizing this vegetation without impairing or destroying its physiological functions and its continuance.

Objects.—The objects of the forest in the economy of man are twofold, and forestry keeps both in view. Its first object is to furnish by its wood and other products useful and indispensable materials without which human development and civilization would have been greatly impeded, if not impossible. The readiness with which wood was to be obtained from the natural forests, the ease with which it could be shaped, its adaptation to so many varied uses, its special properties combining strength and elasticity in endless variety, according to the species of tree, lastly the facility with which it can be reproduced, have given it and will always insure for it a most important place among the raw materials at command of man. It is pertinent for the intelligent forester—that is, he who proposes to apply art in the production of this material—to know the qualities as well as the uses of his crop, for his ultimate object is not to grow trees, but to produce material of given quality and fit for given uses. The wide range of application of which wood is capable can only be indicated in this article. While almost any kind of wood will serve for fuel, for charcoal in iron-smelting quality begins to demand consideration. The building of houses, railroads, bridges, trestles, ships, and boats calls for special qualities. Housefinishing and decorative woodwork depend on others; other qualities, again, are needed for carriage-building, tool-handles, and millwork; others for veneering, carving, turnery, bent work, small woodenware and furniture, and the greatest nicety of selection is required for musical instruments. Wood fit for shingle, basket, and box making may not be fit for cooperage. Not only do such minor manufactures as matches, toothpicks, skewers, shoe-pegs, pencils, excelsior, etc., require consideration of the quality of the material, but even for the making of paper pulp not all kinds of trees may be used. Besides the wood itself a number of extractive materials are derived from the forest, the use of which influences the practices of the forester. The bark and wood of some trees, like oaks, chestnut, hemlock, acacias, yield valuable tanning material; others furnish naval stores, as rosin, tar, and, by distillation, turpentine, creosote, wood-alcohol, gas, vanillin, wintergreen, birch oil, etc. Again, wood-ashes act as a valuable fertilizer; brushwood has been successfully prepared for cattle feed; textile fabrics, dyes, ink, edible fruits, birch wine, maple sugar, etc., are yielded by the forest—so that one must readily admit that the richest of natural resources of man, capable of supplying all his wants, is stored in the forest wealth, which therefore calls for especial attention on his part.

The second object of the forest is to furnish a certain condition of soil cover for the influence which such cover has upon climate (see CLIMATE) and upon water conditions. This object has been only vaguely felt, until in more recent times experimental proof has been brought of the relations of forests to meteorological phenomena and to waterflow.

That these influences must be in the first place of limited extent and of a local nature stands to reason, but by accumulation of many smaller local effects of properly disposed forest-areas it is conceivable that the character of climate and waterflow over a larger section of country would be influenced. The relative position of the forest, its extent and its density, besides its composition and height, are important factors in determining its influences on the surroundings. It is therefore improper to speak of them in general; they can only be discussed with reference to the factors named. The forest influence upon soil and water conditions is more or less important, according to the topography and geologic formations. It consists in holding the soil upon steep slopes, preventing erosion in hill lands underlaid with impenetrable subsoils, the formation of shifting sands checking the rapid, superficial flow of waters and the formation of destructive torrents with the consequent sanding over of fertile valley lands, the filling up of rivers with *débris*, and the increased danger of floods. The forest cover excluding sun and wind checks evaporation, and thereby renders more water available in the soil, the crowns, underbrush, moss-cover, and litter or forest floor prevent the mechanical action of the rain-drops in compacting the soil, facilitating thereby percolation and the formation and constant flow of springs, except where geologic formations (limestones without cleavage, etc.) prevent or impede such subterranean drainage. Altogether, the action of the well-kept forest in this direction is to regulate and equalize the run-off, serving as a storage basin to prevent or at least reduce excessive floods and droughts. For proof of these influences not only the desolation of once fertile regions of Mediterranean countries, but especially the experience of modern France, may be cited, where also, by reforestation of denuded and eroded mountain-slopes, a correction of the unstable soil and water conditions has been effected. The effect of a timber belt as windbreak, in reducing the velocity and thereby the evaporative power of the wind for some distance beyond, is well established, and of importance to the growing of crops in wind-swept prairies. The forest influence upon meteorological conditions, temperature, humidity, and rainfall is a mass effect; i. e. it is dependent upon the amount of soil area shaded and upon the density of the shade by which a difference of temperature (lowering) and of humidity (increasing) of the air within and above the forest is effected as against the air over the open field. To become effective there must be air columns of considerable amount affected to an appreciable degree, and since the differences of conditions can be communicated to the open field only by air currents, the location of the forest toward the prevailing currents is also of moment in exercising an influence.

Forest Policy.—Both of the objects which the forest is to serve must enter into the consideration of the forester as well as of the nation at large, and must influence the policy which legislators and administrators of public interests should pursue with reference to the forest cover. Every civilized nation, and even some of the nations which are wont to be considered lower in the scale of civilization, like the Japanese and Korean, have sooner or later recognized that besides the private interest in forest property there exists a far-reaching, more or less direct or indirect public interest in the existence and condition of the forest cover, which necessitates special governmental consideration and policy. The guiding principles of such a policy should be (1) that as far as production of material is concerned the widest latitude should be left to private enterprise, only aiding such enterprise by furnishing correct statistical information regarding supply and demand, and furnishing educational facilities; (2) that adequate protection by law be extended to forest property, and such ready means of enforcing the law be provided as the difficulty of protecting it against damage requires; (3) that wherever damage would result to neighboring property by improper methods of management the state shall interfere in behalf of the threatened adjoiners; (4) that where reforestation of denuded areas is desirable for public reasons the state should either aid private or communal enterprise, or else undertake reforestation as a work of internal improvement; (5) that where permanency of forest cover for climatic or hydrologic reasons is necessary, and private interest, either for a lack of profitableness or otherwise, can not be expected to engage in a conservative management of the same, the state should own and manage the forest.

In addition, since forest growth can be supported on the poorer soils, the relegation of the forest to these, giving up the richer portions to agricultural use, is a proper economic policy, while to produce upon the smallest area by means of wood crops the largest returns is the financial policy of the forester.

Forestry Technique.—Forestry as an individual pursuit, like all such pursuits, is based upon technical as well as economic considerations, and consequently there are two distinct or separate directions in which forest management must develop, namely, forest production or sylviculture, and forest economy or forest organization. Sylviculture concerns itself with the technical manipulations by which the greatest quantity and best quality of crop are produced, while forest economy provides for the systematic organization or running of the business of forest production and for its best financial results, acting as the economic regulator of the productive technique.

There is greater need for such a systematic *organization* in forest management than in other pursuits, because a long time elapses between the sowing and the reaping, and because, since the crop may be utilized at various stages of development, it becomes a matter of considerable study when it is most profitable to take it. In a comprehensive forest management, it is also difficult to determine how much is to be left as working capital or stock, and how much of the growth is to be considered as interest or accumulated accretion to be harvested. If, furthermore, it is desired to make the revenue as nearly as possible equal, or to harvest equal amounts of material from year to year, a further complication arises. In Europe this side of the science has been very thoroughly elaborated, a considerable amount of mathematics being applied in this elaboration. The matter can be dismissed here with a simple enumeration of some of the problems that require solution in the four subdivisions in which this part of the science is generally presented; namely: (1) forest surveying; (2) forest valuation; (3) forest regulation; (4) forest administration.
