PLATES AND FULL-PAGE ILLUSTRATIONS.

PECULIAR PHONETIC SYMBOLS

USED IN THE WRITING OR TRANSLITERATION OF THE DIFFERENT LANGUAGES.

ā, ē, etc.: long vowels; in the Scandinavian languages the accent (*á*, *é*, etc.) is used to denote length.

ą: a nasalized *a*; so used in the transliteration of the Iranian languages.

å: labialized guttural *a* in Swedish.

æ: open *a* of Eng. *hat*, used chiefly in O. Eng.

aí: used in Gothic to denote *e* (open), in distinction from *ái*, the true diphthong.

aú: used in Gothic to denote *o* (open), in distinction from *áu*, the true diphthong.

bh: in Sanskrit a voiced labial aspirate (cf. *ch*).

ƀ: voiced bilabial (or labio-dental?) spirant, used in discussions of Teutonic dialects.

ç: voiceless palatal sibilant, similar to Eng. *sh*, used especially in transliteration of Sanskrit.

č: frequently used, e. g. in Slavonic languages, to denote the sound of Eng. *ch* in *cheek*.

c: voiceless palatal explosive, commonly used in transliteration of Sanskrit and the Iranian languages.

ch: as used in the transliteration of Sanskrit, a voiceless palatal aspirate, an aspirate being an explosive with excess of breath; as used in German grammar, the symbol for a voiceless palatal or guttural spirant.

dh: voiced dental aspirate (cf. *ch*) in Sanskrit.

ḍ: voiced cerebral explosive, so used in transliteration of Sanskrit.

ḍh: voiced cerebral aspirate (cf. *ch*) in Sanskrit.

đ: voiced dental (interdental) spirant, equivalent to Eng. *th* in *then*; so used in the Teutonic and Iranian languages and in phonetic writing.

ë: a short open *e*, used in Teutonic grammar, particularly in writing O. H. G.

ə: the short indefinite or "obscure" vowel of Eng. *gardener*; used in the reconstruction of Indo-Eur. forms, and in transliterating the Iranian languages.

gh: in Sanskrit a voiced guttural aspirate (cf. *ch*).

g: voiced velar (back-guttural) explosive, used most frequently in Indo-Eur. reconstructions.

ʒ: voiced guttural (or palatal) spirant, equivalent to Mod. Greek *γ*, and used in transliteration of Iranian languages and O. Eng.

ḥ: a voiceless breathing, the Sanskrit *visarga*.

ƕ: a labialized *h*, similar to *wh* in Eng. *what*; used in transliteration of Gothic and the Iranian languages.

ḫ: voiceless guttural (or palatal) spirant, equivalent to German *ch*, and used in transliteration of the Iranian languages.

i̯: the semi-vowel *y*, or consonant form of *i*; used in phonetic writing and reconstructions of Indo-Eur. forms.

j: in the transliteration of Sanskrit and the Iranian languages a voiced palatal explosive; in the Teutonic languages a semi-vowel (= *y*), for which in Indo-Eur. reconstructions *i* is generally used.

jh: in Sanskrit a voiced palatal aspirate (cf. *ch*).

kh: in Sanskrit a voiceless guttural aspirate (cf. *ch*).

ł: the guttural ("thick" or "deep") of the Slavonic and some of the Scandinavian languages.

ḷ: vowel *l*; used in transliterating Sanskrit, in reconstructing Indo-Eur. forms, and in other phonetic writing.

n̥: nasal vowel; used in reconstruction of Indo-Eur. forms and in phonetic writing.

ṇ: in Sanskrit the cerebral nasal.

ṅ: in Sanskrit the guttural nasal (see following).

ŋ: the guttural nasal, equivalent to Eng. *n* in *longer*; used in transliteration of Iranian languages.

ñ: palatal nasal, similar to *gn* in Fr. *regner*; used in transliterating Sanskrit and in phonetic writing.

ö: palatalized *o*; used in German and in phonetic writing.

ǫ: short open *o* in Scandinavian.

ø: short palatalized *o* (ö) in Scandinavian.

ph: in Sanskrit, voiceless labial aspirate (cf. *ch*).

ꝗ: voiceless velar (back-guttural) explosive; used in reconstructions of Indo-Eur. forms and in other phonetic writing.

ṛ: vowel *r*; used in transliterating Sanskrit, in reconstructions of Indo-Eur. forms, and in other phonetic writing.

š: voiceless cerebral sibilant, equivalent to Eng. *sh*; used in transliterating the Iranian languages and in phonetic writing.

ṣ: voiceless cerebral spirant; used in transliterating Sanskrit.

th: in Sanskrit a voiceless dental aspirate (cf. *ch*).

ṭh: in Sanskrit a voiceless cerebral aspirate (cf. *ch*).

ṭ: in Sanskrit a voiceless cerebral explosive.

ț: a form of dental spirant used in transliterating the Iranian languages (represented in Justi's transliteration by ṭ).

þ: voiceless dental (interdental) spirant, equivalent to Eng. *th* in *thin*; used in Teutonic dialects and in phonetic writing.

u̯: consonant form of *u*; used in phonetic writing.

ž: voiced cerebral sibilant, equivalent to *s* in Eng. *pleasure*, and to *j* in Fr. *jardin*; used in Iranian, Slavonic, and in phonetic writing.

ʒ: a symbol frequently used in the writing of O. H. G. to indicate a voiced dental sibilant (Eng. *z*), in distinction from *z* as sign of the affricata (*ts*).

EXPLANATION OF THE SIGNS AND ABBREVIATIONS USED IN THE ETYMOLOGIES.

>, yielding by descent, i. e. under the operation of phonetic law.

<, descended from.

=, borrowed without change from.

: , cognate with.

+, a sign joining the constituent elements of a compound.

*, a sign appended to a word the existence of which is *inferred.*

ablat.	ablative
accus.	accusative
adjec.	adjective
adv.	adverb
cf.	compare
conjunc.	conjunction
deriv. of	derivative of
dimin.	diminutive
fem.	feminine
genit.	genitive

Teuton.	Teutonic

KEY TO THE PRONUNCIATION.

---

aa...... as *a* in *father*, and in the second syllable of *armada*.

ăa...... same, but less prolonged, as in the initial syllable of *armada*, *Arditi*, etc.

a....... as final *a* in *armada*, *peninsula*, etc.

ă....... as *a* in *fat*, and *i* in French *fin*.

ay or ā.. as *ay* in *nay*, or as *a* in *fate*.

ay̆ or *ā*.. same, but less prolonged.

ã....... as *a* in *welfare*.

aw...... as *a* in *fall*, *all*.

ee...... as in *meet*, or as *i* in *machine*.

ĕe...... same, but less prolonged, as final *i* in *Arditi*.

e....... as in *men*, *pet*.

e....... obscure *e*, as in *Bigelow*, and final *e* in *Heine*.

ė....... as in *her*, and *eu* in French *-eur*.

i....... as in *it*, *sin*.

ī....... as in *five*, *swine*.

ī....... same, but less prolonged.

ō....... as in *mole*, *sober*.

ō....... same, but less prolonged, as in *sobriety*.

o....... as in *on*, *not*, *pot*.

oo...... as in *fool*, or as *u* in *rule*.

o͝o...... as in *book*, or as *u* in *put*, *pull*.

OI...... as in *noise*, and *oy* in *boy*, or as *eu* in German *Beust*.

ow...... as in *now*, and as *au* in German *haus*.

ö....... as in *Göthe*, and as *eu* in French *neuf*, *Chintreuil*.

ŭ....... as in *but*, *hub*.

ŭ....... obscure *o*, as final *o* in *Compton*.

ü....... as in German *süd*, and as *u* in French *Buzançais*, *vu*.

y or *l*.... see *l* or y.

yu....... as *u* in *mule*.

y̆u....... same, but less prolonged, as in *singular*.

ch....... as in German *ich*.

g........ as in *get*, *give* (never as in gist, congest).

hw...... as *wh* in *which*.

*k*h....... as *ch* in German *nacht*, *g* in German *tag*, *ch* in Scotch *loch*, and *j* in Spanish *Badajos*, etc.

ṅ....... nasal *n*, as in French *fin*, *Bourbon*, and nasal *m*, as in French *nom*, Portuguese *Sam*.

ñ or n-y.. Spanish *ñ*, as in *cañon*, *piñon*, French and Italian *gn*, etc., as in *Boulogne*.

l or y.... French *l*, liquid or mouillé, as (-i)ll- in French *Baudrillart*, and (-i)*l* in *Chintreuil*.

th....... as in *thin*.

th....... as in *though*, *them*, *mother*.

v....... as *w* in German *zwei*, and *b* in Spanish *Cordoba*.

sh....... as in *shine*.

zh....... as *s* in pleasure, and *j* in French *jour*.

All other letters are used with their ordinary English values.

NOTE.

The values of most of the signs used in the above Key are plainly shown by the examples given. But those of ö, ü, ch, *k*h, ñ, and *v*, which have no equivalents in English, can not be sufficiently indicated without a brief explanation, which is here given.

ö. The sound represented by this symbol is approximately that of -u- in *hurt* or -e- in *her*, but is materially different from either. It is properly pronounced with the tongue in the position it has when ā is uttered and with the lips in the position assumed in uttering ō.

ü. This vowel is produced with the lips rounded as in uttering oo and with the tongue in the position required in uttering ee, into which sound it is most naturally corrupted.

ch and *k*h. These are both rough breathings or spirants made with considerable force, ch being made between the flat of the tongue and the hard palate, and *k*h between the tongue and the soft palate. ch approaches in sound to English sh, but is less sibilant and is made further back in the mouth; *k*h is a guttural and has a hawking sound.

l or y. These are both used to represent the sound of French l mouillé, in (-i)ll- and (-i)l, which resembles English -y- in *lawyer*. Final *l*, that is, (-i)l, may be approximated by starting to pronounce lawyer and stopping abruptly with the -y-.

ñ or n-y. The consonants represented by ñ (Spanish ñ, French and Italian gn, etc.) are practically equivalent to English -ni- or -ny- in bunion, bunyon, onion, etc., and, except when final, are represented by n-y. Final ñ, as French -gn(e), may be produced by omitting the sound of -on in the pronunciation of *onion*.

v. This may be pronounced by attempting to utter English v with the use of the lips alone.

See Preface (vol. i., p. xli.) and the article Pronunciation of Foreign Names.

THE

UNIVERSAL CYCLOPÆDIA.

Eiffel, ef'fel, GUSTAVE: civil engineer; b. at Dijon, France, Dec. 15, 1832; after graduating at the École centrale in 1855, attached to the administration of the Western Railway of France; from 1858 devoted himself to metallic constructions. In that year he superintended the construction of the bridge of Bordeaux, the foundations of which were cylinders sunk by means of compressed air—a method which had but recently been applied to that purpose. In 1867 he made the calculations for the metallic arches of the Machinery Gallery of the Exposition building of that year, and tested his results by experiments upon the arches themselves. In 1868 he constructed two of the high viaducts between Commentry and Gannat. He has applied methods peculiar to himself in the erection of girder bridges, of which he has built a large number. He constructed the large iron arched bridge of the Douro in Portugal, and that of the Garabit in Central France, both of which were erected without false works. He also constructed the principal façade of the Exposition of 1878 (Grande Galerie and Dômes). He invented a portable bridge, for which he received the prize Elphège-Baude. The revolving dome of the observatory of Nice, which was also designed by him, can be turned by a single person, although it weighs 100 tons. One of his greatest works is the EIFFEL TOWER (*q. v.*) of the Exposition of 1889, on the completion of which he was made an officer of the Legion of Honor. He has written papers upon the arches of the Machinery Gallery of 1867, and upon the Douro and Garabit viaducts, and a discussion of the Eiffel tower.

WILLIAM RICH HUTTON.

Eiffel Tower: a tower erected on the grounds of the French International Exposition in 1889. It is 300 meters, or 984 feet, in height, of light structure and graceful form. Visitors are carried to the upper platform by elevators. Meteorological observations are carried on at the top, affording very important results.

Ei'kon Basil'ike, or **I'con Basil'ice** (Gr. εἰκὼν βασιλική, likeness of the king): a book descriptive of the sufferings of King Charles I. of England, and professing to be an autobiography. It was published in 1649 immediately after the execution of the king, and became very popular. Some historians believe that it was composed by Bishop Gauden (1605–62), who about 1660 laid claim to the sole authorship. In his *History of Oliver Cromwell and the English Commonwealth*, Guizot characterizes it as "a constant mingling of blind royal pride and sincere Christian humility; heart-impulses struggling against habits of obstinate and haughty self-consciousness; invincible, though somewhat inert, devotion to his faith, his honor, and his rank; and all these sentiments are expressed in a monotonous language which, though often emphatic, is always grave, tranquil, and even unctuous, full of serenity and sadness. It is not surprising that such a work should have profoundly affected all royalist hearts."

Eilenburg, ī'len-boor*k*h: town of Prussian Saxony; on an island in the river Mulde; 27 miles E. N. E. of Merseburg (see map of German Empire, ref. 4–F). It has an old castle and two bridges; also manufactures of calico, woolen yarn, brandy, chemicals, starch, and tobacco. Pop. (1890) 12,477.

Eilethyia: ancient city of Egypt, whose modern name is El Kâb; on the right bank of the Nile, near Edfu; contains curious and interesting ruins, the most important of which are the rock-tombs excavated in a hill. Some of these date from the thirteenth dynasty, and throw much light upon the every-day life of the people. The tomb of Aahmes, the captain of the Egyptian flotilla, bears an inscription which records his services to the monarchs of the eighteenth dynasty in the Shepherd wars, and mentions the fort of Suben (Lucina or Eilethyia, the goddess of the city), the ruins of which are still standing. Small temples dedicated to Ra, a Ptolemaic temple dedicated to Lucina, and an ancient temple dedicated to the local deities, are also to be found there, together with the tomb of Pahir, decorated with rich and elaborate paintings.

Eimeo: one of the Society islands. See the Appendix.

Einbeck: town of Hanover, Germany. See the Appendix.

Einhard: See EGINHARD.

Einsiedeln, īn'sēē-deln: town of Switzerland; in the canton of Schwytz; about 24 miles S. S. E. of Zurich (see map of Switzerland, ref. 4–G). Here is a famous Benedictine abbey, containing a black image of the Virgin Mary, which is visited annually by about 20,000 pilgrims. An abbey was built here in the ninth century, but the present edifice was erected about the year 1720. It contains a large library, and in connection with it are a priests' seminary, a gymnasium, a lyceum, etc. The town contains a great number of inns. Large numbers of prayer-books, sacred images, and rosaries are made here. Zwingli the Reformer was curate of Einsiedeln in 1516. Pop. (1888) 8,512.

Eisenach, ī'zen-aă*k*h: town of Saxe-Weimar, Germany; finely situated amid wooded hills on the river Hörsel and on the railway from Leipzig to Cassel; about 48 miles W. of Weimar (see map of German Empire, ref. 5–F). It is well built, with wide and clean streets, is inclosed by walls, and has a handsome ducal palace, now used as a court-house, several churches, and a school of design. Here are manufactures of cotton and woolen fabrics, art pottery, leather, carpets, soap, white lead, etc. In close proximity to this town is the Castle of Wartburg, formerly a residence of the landgraves of Thuringia, and memorable as the place of refuge in which Luther remained secreted ten months (1521–22), having been carried thither for safety by his friend, the Elector of Saxony. The castle has been restored since 1851. Pop. (1890) 21,399.

Eisenberg, ī'zen-bārch, town of Saxe-Altenburg, Germany, near the Saale; 26 miles E. of Weimar (see map of German Empire, ref. 5–F). It has a castle, an observatory, and a town-house; also manufactures of porcelain and woolen stuffs. Pop. (1890) 7,349.

Eisenburg, ī'zen-boor*k*h (Hun. *Vas*): county of South-western Hungary; bounded N. by Oedenburg, E. by Veszprem, S. by Zala, and W. by Styria. Area, 1,945 sq. miles. The soil is very fertile. The chief products are grain, tobacco, flax, wine, and fruit. Pop. (1890) 389,854.

Eisenerz: a town of Styria, Austria. See the Appendix.

Eisenstadt: market-town of Hungary. See the Appendix.

Eisleben, īs′lā-ben: town of Prussian Saxony; about 20 miles W. of Halle, with which it is connected by a railway (see map of German Empire, ref. 4–F). It is divided into the old and the new town, the former of which is inclosed by walls. It has an old castle and a gymnasium, also manufactures of potash and tobacco. Copper and silver are mined in the vicinity. Martin Luther was born here in 1483, and died here in 1546. The house in which he was born was partially consumed by fire in 1689, but has been restored. In the Church of St. Andrew are preserved his cap, cloak, and other relics. A bronze statue of the great Reformer was erected in 1883. Pop. (1890) 23,903.

Eisteddfod, ā-steth′vōd: a congress of Welsh bards and musicians for promoting the cultivation of the national poetry and music, and secondarily of maintaining the traditions and customs of the country. Its origin is very ancient, probably dating from a time long previous to the Christian era, but the first meeting of which there is any record was held on the Conway in North Wales in the sixth century. The term Eisteddfod, however, was probably not applied to these sessions till early in the twelfth century, when such an assembly was called at Caerwys, in Flintshire, and attended by all the bards of Wales and some from England and Scotland. Here and at other royal seats the congresses were held for a long time every three years, and being under the patronage of the princes were generally occasions of magnificent display. Poetical and musical contests were the chief features of these gatherings. Degrees and prizes were conferred upon the successful competitors, who were thereby raised to a position of high honor and admitted to the halls of the Welsh princes and nobles. Edward I. sanctioned these bardic congresses by his statute of Rhuddlan, and they occurred in the reigns of Edward III., Henry VI., Henry VIII., and Elizabeth, often under the royal permission or patronage. There was an important one held at Bewper Castle, Glamorgan, in 1681, but from that time till 1819 little is heard of them. At the latter date the reawakening of the Welsh national spirit gave them a new impulse, and they have since then been held annually and attended by large numbers. A Gorsedd is held at the conclusion of each Eisteddfod, and the degrees conferred and the place of the next festival announced. F. M. Colby.

Eitelberger von Edelberg, ī′tel-bărch-er-fōn-ā′del-bărch, Rudolf: art-historian; b. at Olmütz, Austria, Apr. 14, 1817; became in 1852 Professor of Art History at the University of Vienna, and contributed much to the improvement of Austrian industry and art. He wrote, among other works, *Die Reform des Kunstunterrichts* (1848); *Mittelalterliche Kunstdenkmale des Oesterreichischen Kaiserstaats* (2 vols., 1858–60); and *Quellenschriften zur Geschichte der Kunst des Mittelalters und der Renaissance* (1871). D. in Vienna, Apr. 18, 1885.

Ejectment [from Lat. *eji′cere*, *ejec′tum*, cast out; *e*, out, + *ja′cere*, cast]: in law, a *mixed* action, as it is resorted to in order to recover the possession of land, and damages for the wrongful withholding of it, though the damages are nominal. Originally, it was a "possessory" action—that is, adapted to the recovery of the possession of land. By a series of fictions it finally came to be a convenient means of testing the title. The substance of the fiction was a supposition that a lease for a certain number of years had been made to a tenant, John Doe, who had entered into possession, and had then been ejected by a person supposed to represent the party to be ultimately made defendant. This person was termed "a casual ejector," and was usually represented as Richard Roe. An action was then brought substantially under the following title: "Doe, as tenant of Edwards (claiming the land), against Roe." A written notice was thereupon sent in the name of Roe by Edwards's attorney to the opposing claimant (Archer), who is the party in possession. By this notice Archer was advised to defend the action, otherwise Roe would allow judgment to be taken against him and the possession would be lost. Archer, on making application to be made defendant, was allowed to defend upon condition that he would admit the validity of the fictitious portion of these proceedings; so that the matter was narrowed down to a trial of the merits of the case. The action was now deemed really to be between Edwards and Archer, though Doe still remained plaintiff on the records of the court. It is a well-settled rule in this action that the plaintiff can only recover upon a *legal* title, as distinguished from a title in a court of equity. He can succeed only upon the validity of his own title, and not upon the weakness of that of his adversary. He must also have, in legal phrase, a "right of entry." Where that does not exist another form of action must be adopted. There was one serious practical inconvenience following this method of procedure. There was no limit in law to the number of successive actions of ejectment that could be brought by a plaintiff, although he had been worsted. He had only to substitute another fictitious tenant in the place of Doe, and all the proceedings might be gone through with again. The only check upon repeated actions of this kind was a resort to a court of equity for an injunction to prevent harassing, and perhaps exhausting, litigation. The fictitious portion of the proceeding was abolished in England by the Common-Law Procedure Act of 1852, and the action placed upon satisfactory grounds. The same result had been accomplished as early as 1830 in New York.

Should the plaintiff succeed in his action, he has also an independent cause of action for the loss of profits sustained by reason of the defendant's wrongful possession. This is known as an action of trespass for *mesne* (intermediate) profits. In some of the U. S.—e. g. New York—this cause of action may be united with the action of ejectment. The recovery would, by the statute of limitations, commonly be limited to the mesne profits for the last six years.
T. W. Dwight.

Ekaterinburg, ā-kăă-tā-reen-boorg′: fortified town (founded in 1722); government of Perm, Russia; 160 miles S. E. of Perm (see map of Russia, ref. 6–I). It has straight broad streets, many churches, manufactures of metals, and government mints, and is the principal city of the mining district in the Ural Mountains. Pop. (1897) 43,052.

Ekaterinodar′, or **Jekaterinodar**: the chief town of the Kuban territory, Southern Russia; on railway, and on the right bank of the Kuban river; in lat. 45° 3′ N., lon. 38° 30′ E.; 555 miles N. W. of Tiflis (see map of Russia, ref. 11–E). It is on a swampy site, subject to overflow, and the houses are wooden structures. It was founded in 1792, in the reign of Catherine II., and is now the seat of the hetman of the Chernomonan Cossacks. It has an active though local trade, and one of the government horticultural institutions is established in the vicinity. Pop. (1871) 17,622; (1897) 65,697.
M. W. H.

Ekaterinoslaf′: a government of Southwestern Russia; bounded N. by Kharkof and Poltawa, E. by the country of the Cossacks of the Don, S. by Tauria and the Sea of Azof, and W. by Kherson. Area, 26,148 sq. miles. It is traversed by the Dnieper, the Samara, and the Waltschija, and consists almost entirely of large steppes. The soil is fertile. Pop. (1897) 2,112,651.

Ekaterinoslaf: city of Russia; capital of the government of same name; situated on the Dnieper, 115 miles S. W. of Kharkof (see map of Russia, ref. 10–D). It was founded in 1784 by Prince Potemkin, and named after the Empress Catherine II., in whose honor a monument has been built. It has a large cloth factory, and many other manufactures. Pop. (1888) 46,876; (1897) 121,216.

Ek′ron: one of the royal cities of the ancient Philistines, and the seat of an oracle of Beelzebub; in Judea; about 25 miles W. by N. from Jerusalem. Its site is identified with the modern *Akir*, or *Akree*. Although no longer powerful, it was a large village in the time of the crusades, but now consists of about fifty mud huts.

Elæagna′ceæ [deriv. of Lat. *elœag′nus* = Gr. ἐλαίαγνος, a Bœotian marsh-plant]: a family of exogenous plants (trees or shrubs), natives of Europe, North America, and other parts of the northern hemisphere, being rare south of the equator. They have entire leprous or scurvy leaves, a superior ovary, and apetalous flowers. Several species indigenous in Persia and Nepaul bear edible berries. This order also comprises the *Shepherdia argentea*, or buffalo berry, which grows near the upper Missouri river, and bears a pleasant acid fruit; this and the *Shepherdia canadensis* and the *Elæagnus argentea* (silver berry of the Northwest) are the only known North American species. The oleaster (*Elæagnus angustifolia*) is a native of the Levant and Southern Europe. This tree is often planted in shrubberies for the sake of its fragrant yellow flowers and its silvery white foliage. It attains a height of nearly 20 feet.

Elæagnus: a genus of the family Elæagnaceæ (*q. v.*).

Elæ′is [from Gr. ἔλαιον, olive oil, ἐλαία, olive-tree]: a genus of trees of the family *Palmaceæ*. The *Elæis guineensis*, or oil-palm, a native of Western Africa, produces the palm oil which is extensively used in the manufacture of candles and soap. This tree abounds in the tropical parts of Africa, and bears a very large quantity of fruit, from the outer fleshy rind or coating of which the oil is obtained by boiling in water. This oil is made into soap more readily than any other known oil. A still further supply of oil can be obtained by treatment of the boiled fruit. This is called palm-nut oil. This species and others of the genus have been naturalized to some extent in tropical America, where they are cultivated for their oil. They also yield a pleasant alcoholic drink.

Elæococ'ca [from Gr. ἐλαία, olive-tree + κόκκος, berry]: a genus of plants of the family *Euphorbiaceæ*. Useful oil is obtained from the seeds of several species. A tree called *Elæococca verrucosa* is cultivated in Mauritius and Japan for its oil, which is used for burning. One or more species in China yield drying oils, used in that country for preparing varnishes and paints. These oils have acrid properties.

Elæoden'dron [from Gr. ἔλαιον, olive oil + δένδρον, tree]: a genus of trees belonging to the family *Celastraceæ*. *Elæodendron croceum*, commonly called saffron-wood, grows near the Cape of Good Hope, where it is prized for building and cabinet-work. *Elæodendron glaucum*, found in Southern India, is called the Ceylon tea-tree. Some of the species yield a fixed oil like oil of olives.

Elagab'alus, or **Heliogab'alus**, Marcus Aurelius Antoninus: a Roman emperor; b. in Syria in 204 A. D. His original name was Varius Avitus Bassianus, but on being appointed a priest of the sun-god, whom the Syrians called Elagabal, he assumed that name. Caracalla was assassinated Apr. 8, 217 A. D., and Macrinus was proclaimed emperor Apr. 11, 217. Elagabalus was proclaimed emperor by the army in Syria May 16, 218. A battle was fought between Macrinus and Elagabalus June 8, 218, and Macrinus was put to death some days afterward. Then followed a reign marked by such excesses of self-indulgence and cruelty as to make him the type of all the vices that characterized the corrupt society of the later empire. Altars were erected in Rome to the sun-god, whom he continued to worship with licentious rites. He was assassinated by his soldiers Mar. 11, 222 A. D., and succeeded by Alexander Severus.

Ela'in: same as Olein (*q. v.*).

E'lam: the name given in the Bible and in the cuneiform inscriptions to that part of the ancient Persian empire called Susiana and Cissia by the Greeks; the Elymais of the Greeks appears to have been only that part of Susiana next the Persian Gulf. Shushan or Susa was its chief city. The ancient inhabitants, like the modern, were chiefly nomadic. The northern part is mountainous, the southern flat, the gulf coast marshy and unproductive.

E'land [Dutch *eland*, elk, borrowed from Germ. *Elend*, *Elen* (*Elenthier*), itself a loan-word from Lith. *élnis*, elk; cf. Gr. ἔλαφος, stag]: an African antelope (*Oreas canna*), the largest of the family. It is about the size of a horse, meas-

Eland.

uring 5 feet high at the shoulder, with two horns, nearly straight, about a foot and a half long and turned backward. In form it somewhat resembles the ox, being much less slender in the body and limbs than other antelopes, and having an enormous dewlap. The eland is usually in good condition, and being from its size and fatness a poor runner, is captured with comparative ease by mounted hunters. It is gregarious in habit, and was formerly extremely abundant in Southern Africa, but owing to the demand for its flesh and hide, the one being remarkably good for the table, while the other makes excellent leather, this fine animal has sadly diminished in numbers, and in many localities is quite exterminated. Although the eland can be readily domesticated, it is an unprofitable animal to raise for market.

F. A. Lucas.

Ela'net: any bird of the genus *Elanus*. It is of the kite kind, but differs from them in having the claws, except that of the middle toe, rounded, and the tarsi partly covered with feathers. The black-shouldered hawk (*Elanus glaucus*) is found in the U. S., and *Elanus melanopterus* is a native of Africa and India, and is found in Europe and even in Australia. The elanet is a bold and active little bird, feeding mostly on insects, but often capturing snakes, and more rarely mice and birds.

E'laps [from Gr. ἔλλοψ, ἔλοψ; originally the name of a harmless serpent]: a genus of venomous snakes found in tropical and sub-tropical America. The snakes of this genus are mostly under 3 feet in length, with a small head and tapering tail, and are beautifully marked with rings of red, black, and yellow. The bite of the larger species is dangerous, and even the smaller species should be handled with care, since, in spite of assertions to the contrary, it is certain that some of them can inflict a painful, lingering wound. This is true of the bead snake or coral snake (*Elaps fulvius*) of the Southern U. S., a snake not uncommon in Florida, and said to be often dug up in sweet-potato fields. Two other species also occur in the U. S., *Elaps distans* and *E. euryxanthus*.

F. A. Lucas.

El Araish [i. e. the garden of enjoyment], called **Carache**, or **Larache**: a fortified town of Morocco; province of Aygar; at the mouth of the Luccos, which forms an excellent but shallow harbor; lat. 36° 13′ N., lon. 6° 9′ W.; 15 leagues S. W. of Tangier (see map of Africa, ref. 1–B). The surroundings are covered with olive groves and rich pomegranate and orange orchards, but are not healthful. The town has a fine old mosque and market-place. It exports corn, cork, wool, and beans. Pop. 5,000.

El Arish (anc. *Rhinocolura*): a walled town of Egypt; on the confines of Palestine, near the Wady el Arish. It is situated on an eminence half a mile from the Mediterranean, in lat 31° 6′ N., lon. 33° 56′ E.; 195 miles N. E. of Cairo and about 30 miles S. W. of Gaza. It has a few remains of the Roman period. The ancient *Rhinocolura* is said to have been founded by King Actisanes of Æthiopia as a penal colony, and the convicts sent thither had their noses cut off. Before the rise of Alexandria this town was a great emporium of the Red Sea trade. The Wady el Arish is supposed to be the "river of Egypt" mentioned in the Bible. It drains the central part of the peninsula of Sinai, and empties into the Mediterranean near El Arish; hence the name.

Elasmobran'chiates [from Gr. ἐλασμός, ἔλασμα, metal beaten into thin plates (deriv. of ἐλαύνειν, drive, beat) + βράγχια, gills]: the class of vertebrates containing the sharks, rays, and chimæras; intermediate between the true fishes and the Marsipobranchiates. They may be briefly defined as lyriferous vertebrates, destitute of membrane or dermal bones, and with the branchial chambers separate from each other.

Geographical Distribution.—The class, which appears to have been a predominant one, and of which the members formerly outnumbered those of the true fishes, is on the wane, and contains not many more than 300 species. These are quite generally distributed, and have the following systematic relations: Of the *Squali* nearly 150 species are known; of the *Raiæ* about 165 have been described; and of the *Holocephali* but 4 or 5 species are inhabitants of the waters of the present epoch. The class, as a whole, is developed in the greatest perfection in the tropical and warm oceans, but representatives extend toward both poles, and some are found in the high polar regions. Many of the *Squali* are animals of great activity, and endowed with the power and will for extensive wandering, and are met with in mid-ocean; the species, therefore, sometimes have a great range; for example, the typical sharks of the family *Galeo-*

rhinidæ, in some respects the highest and most wide-ranging of the class. To this family belong several of the most common species of the eastern American coasts. Equally wide-ranging, and perhaps still more admirably adapted for a wandering life, and even more formidable in their armature, are the *Lamnidæ*, which include the mackerel sharks and the formidable man-eater (*Carcharodon carcharias*, etc.). The families of more limited distribution are the *Scylliidæ*, which are chiefly represented along the shores of the Old World and Australia; the *Pristiophoridæ*, which are peculiar to the oceans of China, Japan, and the neighboring seas; and the *Heterodontidæ*, which are confined to the Pacific. The representatives of the order *Raiæ* are distributed in an analogous manner. The most widely diffused of the types is the family of *Raiidæ*; all the others are more limited in their range, at least toward the northward and southward, and are, on the whole, less represented by species and by individuals in the regions where they occur at all. The *Chimæridæ* of the present epoch are rather cold-water types; and of the generic or super-generic types one (*Chimæra*) is represented by species of the northern seas, and another (*Callorhynchus*) by species in southern waters. The oceans are the stations for which all the members of the class are most fitted; but although, on the whole, they are essentially marine types, nevertheless some are found at times, and a few permanently, in fresh waters. THEODORE GILL.

Elastic Curve: in mechanics, defined by James Bernoulli as the figure which would be assumed by a thin horizontal elastic plate if one end were fixed and the other loaded with a weight. The curve assumed by a plate or beam when resting upon two supports and loaded with weights is also an elastic curve, provided that the weight be not so great as to impair the elastic properties of the material. These curves belong to the class known as cubic and quartic parabolas, the cubic ones being for single loads and the quartics for uniform loads. See FLEXURE.

MANSFIELD MERRIMAN.

Elasticity [from Gr. ἐλατικός (as if *ἐλαστικός), driving, ἐλατήρ, driver, deriv. of ἐλαύνειν, drive]: the property possessed by certain bodies of recovering their original form and size after the external force is withdrawn by which they have been compressed. Matter is believed to be composed of molecules or small particles, acted upon by attractive and repulsive forces, and from the combined action of these forces result the various forms and properties of matter. According to this view, molecules are not in contact, but at an infinitesimal distance from each other, which, however, may be increased or diminished. When the body is at rest the opposite forces which any of its molecules exercise on each other are in equilibrium. If the distance between the molecules be increased within the limits of the action of the forces, both forces are diminished; and if the distance is lessened, both are increased, but not in the same proportion. Solid bodies are imperfectly elastic, and do not entirely recover their form when the disturbing force is removed; but there seems to be no limit to the elasticity of gases. The phenomena of elastic bodies are—1. That a perfectly elastic body exerts the same force in restoring itself as that with which it was compressed; 2. The force of elastic bodies is exerted equally in all directions, but the effect takes place chiefly on the side where the resistance is least; 3. When a solid elastic body is made to vibrate by a sudden stroke, the vibrations are made in equal times to whatever part of the body the stroke may be communicated. No theory of elasticity founded on any assumed hypothesis as to the molecular constitution of matter has as yet been found satisfactory when applied to solids. In this case, therefore, the theory of elasticity is best investigated without resorting to any such hypotheses.

Elastic Limit: the limit to which a body can be strained and yet recover its original shape when the strain is removed. A strain carried beyond this causes permanent deformation. See FATIGUE OF MATERIALS.

Elastic Tissue: a form of fibrous tissue, sometimes called **Yellow Fibrous Tissue**, which may be drawn out to twice its original length, to which it returns when released. It is found in the membranes which connect the cartilaginous rings of the trachea and various other structures of the animal body requiring elasticity. In the human body perhaps the most remarkable example of the elastic tissue is seen in the *ligamenta subflava*, or intervertebral ligaments. Almost all other ligaments are unyielding and inelastic, but these are extremely elastic. Their action is to help restore the spinal column to its vertical position when it has been deflected by muscular action. In some of the lower animals the *ligamentum nuchæ*, the great ligament of the nape of the neck, is highly elastic, and serves to maintain the proper equilibrium between the muscles that erect and those that depress the head, as when the animal is grazing.

El′ater [Gr. ἐλατήρ, driver, deriv. of ἐλαύνειν, drive]: a Linnæan genus of coleopterous insects, now the type of a very large and distinct family of the serricorn Coleoptera, called *Elateridæ*. They have a narrow, elongated body, and are distinguished by the presence of a strong spine projecting from the posterior margin of the prosternum, and a groove or socket fitted for the reception of the spine. If they fall on their back, they recover their feet by a violent muscular effort, which throws them into the air with a jerk and a clicking sound. Hence they are called click-beetles, snap-bugs, etc. This movement is the rebound caused by the sudden disengagement of the spine from its socket. The wireworms of the U. S. are larvæ of the *Elateridæ*, and are very destructive to growing crops. The elaters feed on flowers, leaves, and other soft parts of plants. The firefly of tropical America is the *Elater* or *Pyrophorus noctilucus*, and it has been discovered that the larvæ of at least one North American species of *Melanactes* are luminous.

Elate′rium [Gr. ἐλατήριον (sc. φάρμακον, medicine), cathartic, driving, deriv. of ἐλαύνειν, drive]: a drug obtained from the *Ecbalium elaterium*, or wild cucumber, called also squirting cucumber. It is an annual belonging to the family *Cucurbitaceæ*, with a trailing stem, heart-shaped leaves, lobed and toothed, yellow flowers, axillary; fruit grayish green, about $1\frac{1}{2}$ inches long, covered with soft prickles. The fruit in parting from its stalk expels the seeds, along with a mucus, through the opening in which the stalk was inserted. Elaterium is contained in the thick green mucus surrounding the seeds. It is a powerful hydrogogue cathartic, dangerous when used in excess, and is very irritating to the eyes and skin. The active principle called elaterin is obtained from it. Elaterium is sometimes used in dropsy.

E′lath (Heb. *Eloth*, trees; Lat. *Æla′na* or *Ela′na*): a town several times mentioned in the Bible; situated at the foot of the valley El Ghor in Idumæa, and at the head of the Elanitic arm of the Red Sea (now known as the Gulf of Akabah); near lat. 29° 30′ N., lon. 30° E.; 10 miles E. of Petra. It was conquered by King David, and under Solomon became an important commercial emporium. It continued to be a seaport of importance under the Romans. It was twice taken by the crusaders (1116 and 1182 A. D.), but after their time fell into decay. It stood on or near the spot now occupied by the fortress of Akabah, which is held by a small garrison of Egyptian troops.

El′ba (Fr. *Elbe*; anc. *Il′va* and *Ætha′lia*; Gr. Αἰθαλία): an island of Italy; in the Mediterranean Sea, between Corsica and Tuscany; from the latter it is separated by a channel 6 miles wide. It is about 18 miles long, and varies in width from $2\frac{1}{4}$ to 10 miles; area, 87 sq. miles. The coasts are bold and deeply indented by several gulfs which form good harbors. The surface is mountainous, and the highest point has an altitude of about 3,500 feet. The island has no manufactures; among its agricultural products are wine, wheat, olives, and various fruits. Excellent iron ore is found here, which on account of the lack of fuel is not smelted, but shipped directly to the opposite coast of the mainland. The sardine and tunny fisheries are of some importance. The climate is mild and equable, and the whole island salubrious with the exception of a few spots on the coasts. Pop. 23,000. Capital, Porto-Ferraio. By the Treaty of Paris this island was designated as the residence of Napoleon I., who removed to it May 4, 1814, and escaped Feb. 26, 1815.

Elbe (anc. *Al′bis*; Bohemian, *La′be*; Dutch, *El′ve*): an important river of Germany; rises in the northeastern part of Bohemia, among the mountains called Riesengebirge. One of its sources is about 4,500 feet above the level of the sea. It flows generally in a northwestern direction, drains the northern part of Bohemia, intersects Saxony and Prussia, and enters the German Ocean near Cuxhaven; at this point the tide rises about 10 feet. It drains an area of over 55,000 sq. miles. Its total length is about 725 miles. This river is several miles wide at every point between its mouth and Altona, a distance of nearly 70 miles. Its principal affluents are the Havel, the Moldau, the Saale, and the Eger. The chief towns on its banks are Dresden, Magdeburg, Hamburg, and Altona. Between Dresden and Aussig it flows between high rocky banks like natural battlements, and presents very picturesque scenery. Vessels drawing 14 feet of water can ascend at all times to Hamburg. Small steamboats navigate the Elbe between Hamburg and Magdeburg, and between Meissen and the mouth of the Moldau. Navigation was formerly restricted by tolls and taxes, but was made free in 1870.

El Beni: province of Bolivia. See BENI.

Elberfeld, el'ber-felt: an important manufacturing town of Rhenish Prussia; on the Wupper; 16 miles E. of Düsseldorf, with which it is connected by a railway (see map of German Empire, ref. 4–C). It is irregular in plan, and is several miles long. The newer streets are well paved. Barmen, a rich and prosperous town, is contiguous to the eastern part of Elberfeld, which has a normal school, an asylum for the deaf and dumb, a museum, a public library, and extensive manufactures of silk stuffs, velvets, cotton fabrics, merinos, ribbons, and tapes. Elberfeld has about 70 dyeing establishments, 10 bleaching-grounds, and several print-works. It is famous for the dyeing of Turkey red, and this dye is said to be imparted here at a cheaper rate and with more firmness of color than at any other town in Europe. Pop. (1900) 156,937.

Elberton: town; capital of Elbert co., Ga. (for location of county, see map of Georgia, ref. 2–I); situated on the Ga., Car. and N. railway; 100 miles E. by N. of Atlanta. It is the terminus of the Elberton Air Line railway, and has 3 churches, a college, a public library, very extensive granite quarries, a cotton-factory, 3 fertilizer-factories, cottonseed-oil mill, etc. Cotton is the chief agricultural product. Pop. (1880) 927; (1890) 1,572; (1900) 3,834.
EDITOR OF "STAR."

Elbeuf, el'böf', or **Elbœuf**: town of France; department of Seine-Inférieure; beautifully situated on the left bank of the Seine, 12 miles above Rouen and 75 miles N. W. of Paris (see map of France, ref. 3–E). Several of the newer and finer streets converge to a spacious open area called Champ de Foire. It has eight artesian wells and six public fountains. Among the finest edifices are the churches of St. Étienne and St. Jean Baptiste. Steamers ply daily between this place and Paris and Havre. It has important manufactures of fine flannels, billiard-table covers, habit cloths, checkered stuffs, woolen fabrics, chemicals, machinery, etc. Pop. (1896) 20,542.

El'bing (Lat. *Elbinga*): fortified town and river-port of Prussia; on the navigable river Elbing; 5 miles from its entrance into the Frische Haff, and about 40 miles E. S. E. of Dantzic (see map of German Empire, ref. 2–J). It has a gymnasium founded in 1536, a normal school, an asylum for the deaf and dumb, and a large public library; also manufactures of cotton and linen fabrics, sailcloth, soap, tobacco, leather, etc., iron-foundries, dye-works, print-works, and sugar-refineries. The town originated in the beginning of the thirteenth century, when German colonists from Lübeck and Bremen settled around a fortress which the Teutonic knights had built, in the midst of the Slavic population. It rendered homage to the Kings of Poland in the fifteenth century, but was gained by Albert of Brandenburg in 1525, and finally passed to Prussia in 1772. Pop. (1890) 41,578.

El Bostan: See ALBISTAN.

Elbruz: the loftiest range and summit in the Caucasus, between the Black and Caspian Seas. Mt. Elbruz is situated in lat. 43° 20′ N., lon. 60° E.; its altitude is 18,570 English feet.

Elburz: a range of high mountains in the northern part of Persia; forming the connecting chain between the Anti-Taurus and the Kuen-Lun. The Elburz extends nearly parallel with the south shore of the Caspian Sea, and forms the southern boundary of the basin of that sea. The highest point of this range is the volcanic peak of Demavend, which rises about 18,600 feet above the level of the sea.

Elces'aites, or **Elkesaites** [from *Elxai* or *Elkasai*, the name of their founder or of a book containing their doctrines]: a sect of Essenian Ebionites, or of Jewish Christians who in the second century mingled Judaism and Christianity in their doctrines, adding to them certain pagan or Gnostic views and magical practices. This sect appears to have originated in the early part of the second century, and probably lasted till the fourth century. They claimed to be in possession of a book which had fallen down from heaven to them, or at least been specially revealed to them by the Son of God. The book, which was a coarse mixture of Christian, Judaistic, and pagan elements, was widely circulated and highly esteemed. The fragments are given in Hilgenfeld, *N. T. extra canonem receptum*.

El'che (anc. *Il'ici* or *Il'lice*): town of Spain; province of Alicante; about 6 miles from the sea and 15 miles S. W. of the city of Alicante (see map of Spain, ref. 18–I). It is situated on both sides of a steep ravine, which is crossed by a handsome bridge. It has an Oriental aspect, being built in the Moorish style and surrounded by large groves of date-palms. Among the remarkable edifices are an old castle, and a church which has a majestic dome and a famous organ. There are manufactures of cotton and linen stuffs, brandy, wine, cigars, and soap. Large quantities of dates are exported. Pop. (1887) 23,854.

Elchingen, el'ching-*en*: village of Bavaria; on the left bank of the Danube; 8 miles N. E. of Ulm (see map of German Empire, ref. 7–E). Here the French marshal Ney defeated the Austrians on Oct. 14, 1805. Pop. 500.

El'cho, FRANCIS WEMYSS CHARTERIS DOUGLAS, Lord: statesman; eldest son of Francis Wemyss Charteris Douglas, Earl of Wemyss; b. in Edinburgh, Scotland, Aug. 4, 1818; educated at Oxford. He became a Conservative member of Parliament in 1841, and was a Lord of the Treasury from 1852–55. He took a prominent part in the formation of the National Rifle Association in 1860. In 1866 he opposed the Reform bill of Russell and Gladstone, and was connected with the party called "Adullamites." He represented Haddingtonshire in Parliament from 1847 until he succeeded his father as ninth earl in 1883; author of *Letters on Military Organization* (1871).

Eldad Ben Malchi, also called **Ha-Dani**, or **The Dan'ite**: a Jewish traveler of the ninth century of the Christian era; a native either of Southern Arabia or of Media, who about 860 undertook extensive journeys in order to visit his Jewish brethren in Asia and Africa, and among his many other adventures at one time fell into the hands of cannibals. Ransomed by a countryman of his, he was able to continue his voyages, and visited both China and Spain. The work which bears his name is written in Hebrew and consists of six books, but it seems to be only an abbreviation, and not the original form of the narrative. It was first printed in Constantinople in 1518, then at Venice in 1540 and 1605, and often afterward. There exists a Latin translation of it by Genebrard, *Eldad Danius de Judæis clausis eorumque in Œthiopia imperio* (Paris, 1563); there is also a German translation. The most complete text and translation are found in Dr. Jellinck, *Bet-Ha-Midrasch* (Leipzig, 1853–55). One of the most curious passages in the whole work is the account of the Levites, who, according to the author, were miraculously guided into the land of Havila, and were there protected from their enemies by the mystic river Sabbation, which is calm but covered with dense fog on the Sabbath, and impassable on other days.
Revised by C. H. TOY.

El Dakkel (anc. *Oasis Minor*): the third of the five Egyptian or Libyan oases; situated in lat. 29° 10′ N. It is well watered and has warm springs. It produces dates, olives, etc., and in ancient times yielded much wheat.

Elder: a shrubby plant belonging to the genus *Sambucus* and family *Caprifoliaceæ*. The common elder (*Sambucus canadensis*) of North America grows from 5 to 10 feet high. Another American species is the red-berried elder (*Sambucus racemosa*), which is found in rocky woods and among mountains. It is found in some parts of Europe, and is prized as an ornamental shrub. The common elder (*Sambucus nigra*) is indigenous to Europe and parts of Asia and Northern Africa. It sometimes attains the size of a small tree, having pinnate leaves, terminal cymes of creamy white flowers, and small black berries, three-seeded. The dwarf elder or danewort (*Sambucus ebulus*) is seen occasionally in Great Britain. It was formerly believed to have sprung from the blood of Danes killed in the Anglo-Saxon wars. The flowers of the elder are used in medicine, and elder-flower water, employed in perfumery, is distilled from them. Wine is also made from the berries.

Elder [O. Eng. *eldra* : O. H. G. *altiro*, Mod. Germ. *älter* : O. N. *eldre* : Goth. *alþiza*, compar. of Teuton. *alđoz* > Eng. *old*]: a term used to translate Heb. *zaken*, Gr. πρεσβύτερος, etc., words originally indicative of age, but acquiring in time a secondary official sense. Each Hebrew town had its senate of elders, who administered justice. (Deut. xix. 12.) Commonly, each synagogue had also its board of elders, although in smaller towns there was often but a single rabbi. The early Christian Church is believed by many to have borrowed its eldership from the Jewish synagogue. In the New Testament elder and bishop are thought by many Christians to be identical, but opinion on this point is by no means uniform. But at least as early as the second century (in the Ignatian *Epistles*) we find the three orders of bishops, presbyters (or elders), and deacons. Presbyterians have both "teaching" and "ruling" (or lay) elders, but whether this distinction existed in the apostolic age is still a mooted question. See PRESBYTER.

Eldon, JOHN SCOTT, Earl of: Lord Chancellor of England; b. at Newcastle, June 4, 1751. He was educated at Oxford, where he gained in 1771 a prize of £20 for an English prose essay. In 1772 he contracted a clandestine marriage with a lady named Elizabeth Surtees, and by this act forfeited a fellowship which he had obtained in the college. He studied law in the Middle Temple, was called to the bar in 1776, inherited £3,000 from his father in that year, and began to practice in the northern circuit. After four years of moderate success, he gained great distinction, and rose rapidly to fame and affluence. He became in 1783 a member of Parliament, in which he supported Mr. Pitt, and showed himself an able debater. He was appointed solicitor-general in 1788, and attorney-general in 1793. During the excitement of the French revolution he prosecuted Horne Tooke and others who were accused of treason, but they were defended by Erskine and acquitted. In 1799 he became chief justice of the court of common pleas, was created Baron Eldon, and entered the House of Peers. On the formation of a new ministry by Mr. Addington in 1801, Lord Eldon was appointed Lord Chancellor. He continued to fill that high office under several successive administrations for a period of twenty-six years, except an interval of nearly a year in 1806–07. His reputation as a judge was very high, but as a statesman his merit was not great. D. Jan. 13, 1838. His brother William was an eminent judge, and bore the title of Lord Stowell. See Twiss, *The Public and Private Life of Lord Eldon* (3 vols., 1844); Lord Campbell, *Lives of the Lord Chancellors.*

Eldo'ra: town; capital of Hardin co., Ia. (for location, see map of Iowa, ref. 4–H); situated on the Iowa river and the Chi., Ia. and Dak. and Ia. Central R. Rs., about 66 miles N. N. E. of Des Moines. It has eight churches, a state reform school, a flouring-mill, planing-mill, potteries, large brick and tile works, electric lights, etc., and is a shipping-point for coal, live stock, and grain. Pop. (1880) 1,584; (1890) 1,577; (1900) 2,233. EDITOR OF "HERALD."

El Dorado, el-dō-raa'do (Sp., the gilded): the fabled king of an equally fabulous Indian city, long supposed to exist somewhere in the northern part of South America. In its most definite form the story described a lake in which was an island with a city marvelously rich in gold, silver, and precious stones. The chief or "king" of the city was daily or periodically anointed with thick oil, in which gold-dust was stuck until he appeared to be covered with the metal. This king was "El Dorado" of the Spaniards, and the name has been erroneously transferred in common language to the supposed city or region which he governed.

This widespread delusion was probably the result of various causes which we can only conjecture at this day. It is quite possible that vague reports of Cuzco and other Andean cities passed from tribe to tribe of the Indians, and were recounted by them to the Spaniards. Or we may explain the numerous stories of golden cities as bits of aboriginal folk-lore, come down from more ancient times, just as the child's tale of a pot of gold under the rainbow is a legacy of the Middle Ages It is even possible that El Dorado may have been a real personage whose wealth was magnified by time and distance. It is said that the Indians about the sacred lake of Guatavita, in the Bogotá highlands, celebrated a strange yearly sacrifice. "On the appointed day the chief smeared his body with balsam and then rolled in gold-dust. Thus gilded and resplendent, he entered a canoe, surrounded by his nobles, while an immense multitude of people with music and songs crowded the shores of the lake. Having reached the center, the chief deposited his offerings of gold, emeralds, and other precious things, and then jumped in himself to bathe" (Acosta, *Descubrimiento y Conquista de la Nueva Granada*, p. 199). But it is not averred that the Spaniards ever witnessed this ceremony, and the story itself may be but a form of the El Dorado myth.

The sixteenth century was a very credulous period, and the cupidity of the Spaniards eagerly grasped at stories of golden cities and rich kings. Tales imperfectly understood were embellished to suit their imagination; and, above all, they constantly asked leading questions, which savages almost invariably answer in the affirmative. No doubt, also, the Indians often concocted stories of distant mines and towns, hoping that their unwelcome guests would go in search of them; or, seeing how the Spaniards loved gold, they invented stories to please them. In 1492 Columbus heard, or thought he heard, of rich mines and cities back from the coasts of Cuba and Hispaniola, and in 1502 he named Costa Rica and Castilla del Oro from similar reports. At Darien Balboa heard of the rich temple of Dabaiba, vaguely located somewhere about the head of the Atrato; the temple, it was said, was lined with gold, and slaves were sacrificed there. In 1512 he led an expedition in search of it; there were others in 1515 and later, and it was long a tempting bait. Some of the explorers found tombs, rich in golden ornaments, but no temple. In 1530 Alfinger marched into the mountains of Venezuela searching for a golden city, and he and most of his men perished. In 1531 Diego de Ordaz explored the Orinoco with a similar object; one of his officers, Martinez, afterward claimed that he had actually been in the golden city, which he called Manoa: and he, it is said, was the first to apply the name El Dorado to the gilded king. It was natural enough that lying reports like this of Martinez should grow up around the story, all the more so that they were readily believed. For a time the mountains of New Granada were the favored region of El Dorado. In 1537 Quesada, marching from Santa Marta, reached the plateau of Bogotá and the country of the Chibchas; soon after he was joined there by Federmann, who had come from Venezuela, and Benalcazar from Quito, all chasing the same golden phantom. The spoil of the Chibchas only whetted their appetites: when it was known that El Dorado could not be found in the highlands, his city was located farther and farther toward the center of the continent, in the great forests of the Orinoco and Amazon. These wilds are almost unknown at the present day, but in the sixteenth century they were traversed again and again by bands of Spanish adventurers. The early knowledge of the Orinoco and Amazon, with their tributaries, was almost entirely due to these expeditions. In 1541 Philip von Huten, starting from Coro, passed clear across the Orinoco basin, and actually reached the country of the Omaguas, near the Amazon, a journey that seems nearly incredible. He failed to conquer the Omaguas, and probably for no better reason they became for a time the guardians of El Dorado. Pedro de Ursua started from Bogotá to find a "golden city of the sun," and his expedition founded the town of Pampluna. In 1560 the same leader was appointed "governor of Omagua and El Dorado," and he started to find his domain by way of the Huallaga and Amazon. Ursua was murdered by Lope de Aguirre, who finally descended the Amazon and reached Venezuela after one of the maddest piratical cruises ever recorded. By this time the myth had taken many new forms. On the southwestern tributaries of the Amazon there were the fabled districts of Enim and Paytiti, said to have been founded by Incas who had fled from Peru, and to have surpassed ancient Cuzco in splendor; these were the objects of numerous expeditions, and even in the eighteenth century they were universally supposed to be realities. North of the Amazon the supposed town of El Dorado was shifted eastward until it reached Guiana. There the Englishman Raleigh searched for it in 1595, believing that he had located this much-desired city in a lake called Parima. Raleigh's expedition led indirectly to the modern colony of British Guiana; and the Lake Parima remained on English maps until Schomburgk's explorations conclusively proved that it was a pond and swamp. The emerald mountain of Espirito Santo, and the Martyrios gold mine, long sought for in Western Brazil, recall the El Dorado myth; while far southward in the Argentine plains, the city of Cesar, with silver walls and houses, was another alluring phantom. It was said to have been founded by shipwrecked Spanish mariners, and even late in the eighteenth century expeditions were sent to search for it.

El Dorado: city (founded in 1867); capital of Butler co., Kan. (for location, see map of Kansas, ref. 7–H); on Walnut river and Atch., Top. and S. F. and Missouri Pacific R. Rs., 30 miles E. N. E. of Wichita. It has good schools, a carriage-factory, woolen-mill, iron-foundry, extensive magnesian limestone quarries, new-process flour-mills, machine-shop, water-works, gas and electric lights. Pop. (1880) 1,411; (1890) 3,339; (1900) 3,466.

EDITOR OF "WALNUT VALLEY TIMES."

Eldred: borough and railway junction; McKean co., Pa. (for location of county, see map of Pennsylvania, ref. 2–D); situated on Allegheny river, 20 miles east of Bradford, Pa.; in a coal-mining region. Pop. (1880) 1,165; (1890) 1,050; (1900) 963.

E′lea, or **Ve′lia**: an ancient Greek city of Southern Italy; in Lucania, on the Mediterranean Sea. It was the native place of Parmenides and Zeno. See ELEATIC SCHOOL.

Eleanor of Guienne: Queen of France, and subsequently Queen of England; b. about 1122. She was the daughter and heiress of the last Duke of Aquitaine, and was married in 1137 to Louis VII. of France, with whom she went to the Holy Land in 1147. She was divorced from Louis in 1152, and was soon married to Henry II. of England. It appears that she instigated her sons to rebel against their father (Henry II.), who imprisoned her for fifteen years. She acted as regent while her son, Richard I., conducted a crusade to Palestine. D. in 1203. Despite her wayward character she did much to further poetry and art. She surrounded herself with troubadours and *trouvères*, and many of them have sung her praises. Her daughter, Marie of Champagne, also had the same tastes and interests, and her court at Troyes was at one time the poetic center of France. Revised by A. R. MARSH.

Eleatic School: a group of Greek philosophers, the first of whom was Xenophanes of Elea, who flourished about 530 B. C. While the Ionic school gave its attention to outward nature, and investigated the laws which regulate its progress, the Eleatic philosophers directed their speculations to the idea of Being in itself, which they conceived to be the only object of real knowledge. They regarded as vain and illusory the world of change and succession, which they designated τὸ γιγνόμενον (that which becomes or happens, as by accident). Time, space, and motion they considered as phantasms, caused by the deceiving senses, and incapable of scientific explanation. They distinguished between the pure reason, the correlative of being, and opinion or common understanding, which judges according to the impressions of sense. Parmenides and Zeno were the most celebrated disciples of Xenophanes; the former was the author of an epic poem on the Eleatic and Ionic systems. See PHILOSOPHY, HISTORY OF; Zeller's *Pre-Socratine Philosophy*, vol. i.; *The Fragments of Parmenides* (*Jour Spec. Phil.*, vol. iv.).

Elecampane [corruption of Med. Lat. *e′nula* (Class. Lat. *inula*), *campa′na*; *i′nula*, a plant name, *campa′na*, of the fields]: a plant of the genus *Inula* and family *Compositæ*. The common elecampane (*Inula helenium*) is indigenous to Middle and Southern Europe, and has become naturalized in various parts of the U. S. The root somewhat resembles camphor in taste, and has sudorific and diuretic properties. It contains the principles *helenin*, or elecampane camphor, and *inulin*, which is allied to starch.

Election [from Lat. *electio*, choosing, deriv. of *eli′gere*, select]: in law, the choice of two alternatives; sometimes the right to make such choice. The law frequently imposes upon a party the duty to choose between two inconsistent or alternative rights or claims. This obligation may present itself in all branches of the law, and often occurs as a rule of practice. In a court of law, as distinguished from equity, there may be a case of election where a contract is to be performed in the alternative, as where an insurance company stipulates that in case of loss of a building by fire it may either pay its value or rebuild. In such a case, should the company elect to rebuild, its election would be irrevocable. It may also happen that a creditor will have a right, from the circumstances of the case, to elect one of two persons as his debtor. A case of this kind occurs in the law of agency, when an agent purchases goods on credit for an undisclosed principal; the seller, on subsequently discovering the principal, may elect to regard the sale as having been made to him or to the agent, as he may see fit. An instance of election in the case of real estate is that of dower in land which the husband exchanged for other land. The widow has her choice to take dower in either parcel, but she can not take it in both.

In courts of equity the doctrine of election assumes great importance. The case may occur where alternative benefits may be presented to a person by a will or other legal instrument, or more generally he may be required to choose between a gift made to him and something to which he is already entitled. The duty to choose in such a case is not a positive rule of law, but a matter of equity practice, and is not imperative when this artificial doctrine is not known to be a legal rule by the party to whom the gift is made. The fact of election must be shown by some positive act; and if a party who ought to elect holds two estates under inconsistent titles, there is no evidence of an election having been made. A person under a duty to elect between the retention of his own property and the gift of another, may retain his own without forfeiting the gift, but must make due compensation. Thus if a testator devises an owner of property land of his own, and then assumes to dispose of the property of the devisee, and the latter elects to retain his own property, he does not forfeit the devise, but is required to make compensation to the testator's estate equivalent in amount to the property retained by him. Election in procedure may take place in the choice of remedies; as where an owner has been wrongfully deprived of a chattel, he may elect to sue for its value or for the chattel itself. A court will in some cases require a party to an action to elect as between inconsistent allegations as to the cause of action. T. W. DWIGHT.

Election: in politics, the choice of public officers by those persons who possess the right of suffrage, as distinguished from appointment, which is such choice made by superior officers. Popular elections were held in ancient times, as, for example, in the Roman *comitia* and the Athenian popular assemblies; but soon after the establishment of the Roman empire elections, outside the Christian Church, became obsolete. Elections reappear in mediæval Europe in the choice of representative burgesses, who stood for the third estate. Certain monarchs, as the German emperors and the Kings of Poland, were also elected to their place, but not as popular representatives. In no other European country did the election of representatives become so important in the Middle Ages as in England; and the representative systems of other nations have been chiefly imitations of, and in some cases improvements upon, the English system. Elections are called *direct* when officers are chosen by a direct vote of their constituency; *indirect*, when electors are chosen for the purpose of designating the persons who shall exercise official powers.

With regard to the officers voted for, political elections in the U. S. are distinguished into *local* or *municipal elections*, at which officers for some particular town or locality are chosen; *general* or *State elections*, at which officers for the whole of a commonwealth are elected (the most important of which are the gubernatorial and presidential elections for filling the places of Governor and President); and *congressional* or *legislative elections*, at which members of Congress or Legislatures are voted for. Vacancies in offices are sometimes filled, and the acceptance or rejection of particular laws is decided by *special* or *supplementary elections*. All questions relating to political elections must be fully provided for in the election laws of the State. The great interests frequently at stake at elections naturally give rise to *election frauds*, which have assumed in some countries, and in particular in some parts of the U. S., the most alarming dimensions. In view of them attempts have been made to improve, as much as possible, the existing election laws. Special attention has been given for that purpose to stringent registration laws, requiring every voter to register his name some time before the day of election, in order to enable the authorities to verify his claim to taking part in the election. The *inspectors of elections*, whether appointed or elected, are generally taken from the different political parties which engage in the contest. The excitement which often prevails at political elections sometimes leads to *election riots*. These are of frequent occurrence in England, Ireland, and Greece, but they are almost unknown in France and Germany. As in most cases the instigators and leaders of election riots in the U. S. act under the influence of intoxicating liquors, many States have provided by law that on election days liquor-stores must be closed. When the defeated party believes or claims that the declared majority owes its success to election frauds, the elections are likely to be contested. At elections to legislative assemblies such assemblies ordinarily decide finally on the claims of rival candidates; but in some cases the decision rests with the courts. If a presidential election is contested in a republic, there is danger of civil war, of which, in particular, the republics of South and Central America furnish many examples. The U. S., which, on the whole, have been free from the sad experiences of the South and Central American republics, had in 1873 a conspicuous instance of a contested gubernatorial election and its disastrous consequences in Louisiana, where for several months two rival governors claimed each to be the lawful executive of the State, and tried to enforce his claim, until on May 22, 1873, the President of the U. S. interfered by a proclamation in favor of one. The most serious case of a disputed national election was the memorable Hayes and Tilden contest of 1876, which was decided in favor of the former by an electoral commission composed of five Senators, five Representatives, and five associate judges of the Supreme Court. (See PRESIDENTIAL ELECTORAL COMMISSION.) For information as to presidential elections in the U. S., see Stanwood, *A History of Presidential Elections* (4th ed. 1892). See BALLOT REFORM, NOMINATION, PLÉBISCITE, REPRESENTATIVE SYSTEM, SUFFRAGE, and VOTE.

Election, in theology: See CALVINISM.

Elector [Lat. *elec'tor*, chooser, deriv. of *eli'gere*, select; *e*, out from + *le'gere*, choose]: a title of those German princes who had the right or privilege of electing the Emperor of Germany. There were originally (1256 A. D.) seven—namely, the Electors of Cologne, Mentz, Treves, Bohemia, Brandenburg, Saxony, and the Elector Palatine. The first three were Archbishops of Cologne, Mentz, and Treves. The electors had several important privileges, and a very peculiar position in the empire. They usually chose the heir or near relative of the preceding emperor. As the electoral dignity of the Palatine had been transferred to the Dukes of Bavaria, an eighth electorate was established by the peace of Westphalia in 1648 for the Palatine, which ceased in 1777, when the house of Bavaria became extinct. In 1692 the electorate or dignity of elector was conferred on the Dukes of Brunswick-Lüneburg, who were afterward styled Electors of Hanover. The electors were entitled to all royal dignities and honors except the title of majesty. On the dissolution of the Holy Roman Empire in 1806, the office became obsolete, but the title was retained by the rulers of Hesse-Cassel till 1866, when that state was united to Prussia. The term elector is also applied to each of those persons who, under the Constitution of the U. S., are chosen to elect the President. See ELECTORS.

Electoral College: See CONSTITUTION OF THE U. S., Art. XII., and ELECTORS.

Electoral Commission: See PRESIDENTIAL ELECTORAL COMMISSION.

Electoral Crown, or **Cap**: a crown worn by the electors of the German empire. It was surmounted by two golden demicircles, ornamented with pearls and a golden orb and cross at the top.

Electors: in the political system of the U. S., the persons who are chosen by the people of the several States to elect the President and Vice-President. Each State chooses a number of electors equal to the whole number of members it sends to both houses of Congress. No Senator or Representative, or person holding an office of profit or trust under the U. S., can be appointed an elector. The electors must be chosen on the same day in all the States—that is, on the Tuesday next after the first Monday in November. The Constitution ordains (Amendment XII.) that the electors shall meet in their respective States and vote by ballot for President and Vice-President, one of whom at least shall not be an inhabitant of the same State with themselves; and they shall make distinct lists of all persons voted for as President, etc., and of the number of votes for each; which lists they shall sign and certify, and transmit sealed to the seat of government of the U. S., directed to the president of the Senate. The electors of all the States constitute the electoral college. A majority of the whole number of electoral votes is necessary to elect the President and Vice-President. In 1896 the whole number of electors was 447. By the Act of 1792 the date of meeting was the first Wednesday in December, but this was changed by the Act of 1887, which ordains "that the electors of each State shall meet and give their vote on the second Monday in January next following their appointment" at such place as the State Legislature may direct. The electoral votes are opened and counted on the second Wednesday of February by both houses of Congress, which meet in the chamber of the Representatives. If no candidate has a majority of all the votes, the House of Representatives has a right to choose either of the three persons having the highest number of votes. It was supposed by the framers of the Constitution that the electors would exercise a free discretion and choose the best man for the offices, but the position has lost its importance from the fact that the elector is obliged by usage to vote for the candidate of his party.

Electra (in Gr. Ἠλέκτρα): a daughter of Agamemnon, King of Mycenæ; sister of Orestes, and wife of Pylades. She was sometimes called Laodice. Her story is the subject of dramas written by Æschylus, Euripides, Sophocles, and Racine. The most perfect of the ancient tragedies of "Electra" is that of Sophocles; in this she stimulates her brother Orestes (whose life she has saved from the violence of her father's murderers) to avenge the death of that parent. This he does, with the aid of Apollo. Five other persons of this name are mentioned in the Greek mythology.

Electrical Fishes: fishes having the power of giving sensible shocks of electricity. At least fifty marine animals of very diverse character are known to have this power. Among the best known are several species of *Torpedo* and *Narcine* (of the ray family), one of which is occasionally found on the Atlantic coast of the U. S. The *Electrophorus electricus*, a fresh-water eel of South America, sometimes 6 feet long, has the power of overcoming men, and even horses, by its tremendous shocks. Two species of *Malapterurus* of the African rivers are also electric. Faraday observes that the *Electrophorus* may produce a shock equal to that of fifteen Leyden jars, containing in all 3,500 sq. inches, charged to the highest degree. The force is that due to ordinary static electricity, and readily affords a spark. The *Torpedo* and the electric eel have electric organs intimately connected with the nervous system, consisting of a series of highly vascular cells or hollow prisms containing a watery fluid. Other electrical fishes have a less definite apparatus for this function. It is not known that this remarkable power is of any service to these fishes, except in self-protection.

Electrical Machines: machines for the electrostatic generation of differences of potential, that is to say, for electrification by friction or by electrostatic induction. In frictional machines the body rubbed is a revolving glass plate (in early forms a cylinder or ball rubbed by the hand), passing between rubbers of soft leather to which a dressing of sodium amalgam has been applied (Fig. 1).

In the process of electrification, equal and opposite charges are always generated. In frictional machines the glass plate and the metal parts which gather charge therefrom (combs and prime conductors) become positively, the rubber negatively, electrified. The latter is usually connected metallically to the earth. In a dry atmosphere under such circumstances the prime conductor soon begins

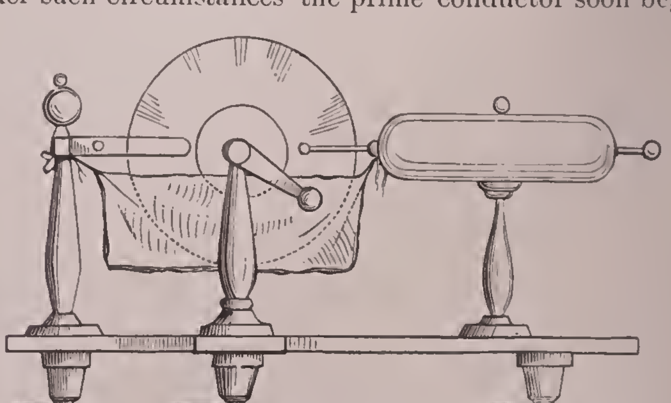

FIG. 1.

to show signs of strong electrification, and after a few rapid revolutions of the plate sparks may be drawn.

In all such machines, however, even under the most favorable conditions, a scarcely appreciable portion of the work done appears in form of electrical energy, the remainder being wasted as heat. For this and for other reasons friction-machines have gone almost entirely out of use, being replaced by a class of machines which produce electrification by electrostatic induction. There are many forms of such apparatus, the best known being the "influence-machines" of Holtz, Toepler and Wimshurst, and the various forms of replenisher devised by Lord Kelvin (Sir William Thomson).

The simplest of all electrical machines of this class is the electrophorus (Fig. 2), which consists of a plate of vulcanite or of some other substance easily electrified by friction, and a metal disk with an insulating handle. When the disk is placed upon the vulcanite surface which has been previously excited by rubbing with fur, it makes contact in three points of support only. All other portions of the metallic surface are in the immediate neighborhood of the charged body. Electrostatic induction brings about a difference of potential between the upper and lower faces of the disk, and when the former has been connected for a moment with the earth and insulated again and the disk removed, it comes away heavily charged. The charge thus obtained is always opposite in character to that residing upon the vulcanite plate (i. e. positive). The source of electrification is the work which must be done to overcome the attractive forces between the oppositely charged faces of the vulcanite and the metal. The quantity of electricity residing upon the former is in no way drawn upon, and the process may be repeated again and again, without exhausting the original charge.

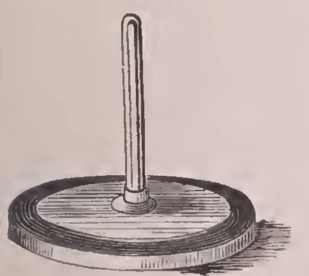

FIG. 2.

This series of operations is known as the electrophorus cycle, and it is of interest, not only because the instrument affords a most convenient method of obtaining small quantities of electricity, but also because it is a cycle, upon the automatic repetition of which all influence-machines and replenishers depend for their action.

The cycle consists of the following steps: 1, a conductor is brought into the neighborhood of a body previously charged; 2, electrostatic induction having brought about difference of potential in the conductor, the repelled charge is carried off by momentary metallic contact with the earth (or sometimes with the opposite pole of the machine); 3, the conductor is removed from the immediate neighborhood of the inducing charge; 4, the charge thus isolated is utilized, or, in the case of most influence-machines, is transferred to a storage reservoir (Leyden jar).

Of the machines based upon the electrophorus process, one of the earliest was that of Holtz (Berlin, 1865).

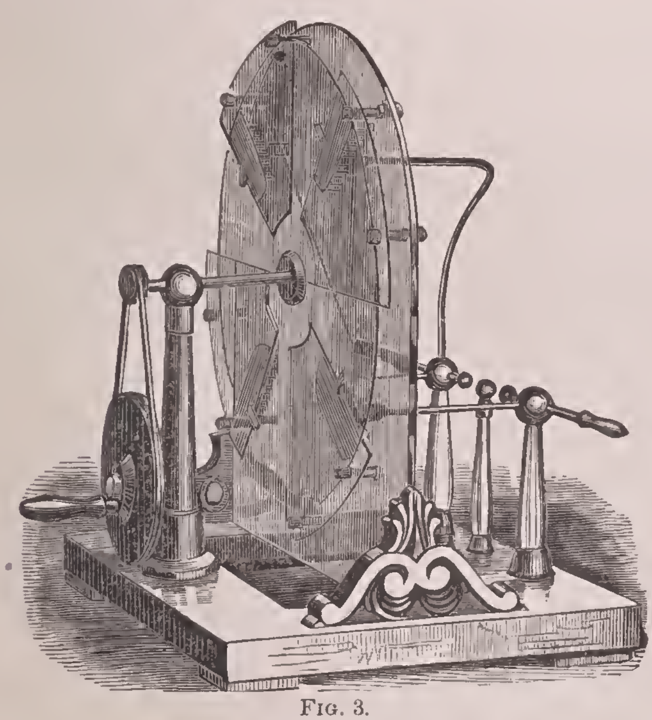

FIG. 3.

The Holtz machine may be selected as a type of the class of instruments to which it belongs. One modification is shown in Fig. 3; the essential parts in the diagram, Fig. 4. A disk of glass ($g\ g'$) is driven upon an axle ($a\ a'$). A stationary glass plate ($n\ n'$) is mounted parallel to the revolving disk and as near to it as possible. Upon the back of the former, and diametrically opposed to one another, are two, or sometimes four, sectors of papers ($s\ s'$). Opposite these, but on the other side of the revolving plate, are the collecting combs ($c\ c'$), which are in metallic connection with the terminals of the machine ($b\ b'$). Each paper sector corresponds to the inducing-plate of an electrophorus.

To bring the machine into action one of the paper sectors s is given a charge of electricity by contact with a piece of vulcanite or glass previously excited by friction. (See ELECTRICITY.) It then acts inductively upon the metallic

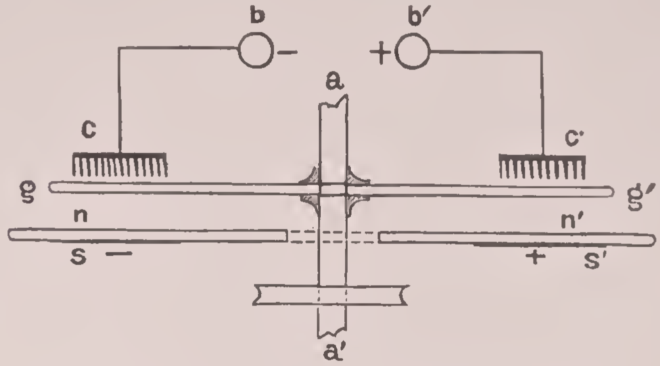

FIG. 4.—The essential parts of the Holtz machine.

comb and terminal, also upon the portions of the revolving disk lying between. The outer face of the latter receives a positive charge from the comb, the inner face gets a similar charge by the inductive action of the sector. In the course of revolution these charged surfaces are brought into the neighborhood of the other sector and comb. Near each sector is a window cut in the fixed plate of the machine, through which a piece of stiff paper from the sector protrudes, terminating in a point which is nearly or quite in contact with the revolving disk. By electrostatic action between the charged faces of the disk and the sector s' on the one side, the paper strip acting as a carrier of electricity, also between the disk and the comb c' on the other, both sectors and comb become positively charged. The disk in turn receives from these negative electricity enough to more than neutralize it, and returns to its original position between the sector and the comb, s and c, carrying a negative charge. Electrostatic induction at this point increases the negative charge of the former, and there is a continuous rise of positive electrification in one sector and terminal of the machine, and of negative electrification in the other, until the differences of potential are such as to produce rapid and brilliant spark-discharges between the knobs $b\ b'$.

The number of modifications of this cycle in the various influence-machines and replenishers is very great; but by none of the more recent devices have more striking and beautiful results been obtained than with the machine of Holtz.

Some description of the effects obtained is to be found in the article ELECTRIC DISCHARGE (*q. v.*).

The difference of potential produced by means of influence-machines is very great (50,000 to 200,000 volts). It has been reached artificially by only one other device, the induction coil. (See INDUCTION COIL.) As compared with machines for the development of electrical energy of moderate tension (dynamo-machines, etc.), friction-machines and influence-machines are of exceedingly low economy. Several attempts have been made to estimate the output of the latter class, and it seems to be well established that under ordinary conditions of working less than one part in fifty thousand of the work expended becomes available in electrical form. (Rossetti, *Nuovo Cimento* (2) 12, 1874.) Influence-machines have played a very important part in the study of electricity, and the literature of the subject is an extensive one. The following are references to some of the most important papers: Volta, *Collezione delle Opere*, 1, p. 118. Töpler, *Ann. der Physik*, 125, p. 469; 127, p. 117. Holtz, *Ann. der Physik*, 126, p. 157; 127, p. 320; 130, p. 287; 156, p. 627. Bertin, *Ann. de Chimie et de Physique*, (4) 13, p. 191. Poggendorff, *Ann. der Physik*, 139, p. 158; 141, p. 161; 154, p. 643. Rossetti, *Nuovo Cimento*, (2) 11, p. 5; (2) 12, p. 89; (2) 14, p. 5. Kohlrausch, *Ann. der Physik*, 135, p. 120. Bouty, *Journal de Physique*, 4, p. 135. The reader is also referred to the following treatises: Mascart, *Traité de l'Électricité* (vol. ii.); Riess, *Die Reibungselektricität*; and Wiedemann, *Elektricität* (vol. ii., pp. 196–244).

E. L. NICHOLS.

Electric Arc: the layer of an incandescent vapor between terminals, not quite in contact, in an electric circuit. The arc is the path of the current between such terminals. Its temperature, which is higher than that attainable by any other artificial means, is maintained by reason of the resistance which the arc offers to the passage of the current. At ordinary temperatures gases are of almost infinite electrical resistance. To establish an arc between two points, therefore, it is necessary to heat the intervening air to a degree at which it is capable of carrying the current. This can be done in some cases by the application of a flame, but the usual method is to bring the terminals together for an instant. Current then flows, and at the point of contact where the resistance is high much heat is generated, the points glow, and the air-film between reaches a temperature such as to make it a conductor. The terminals may now be separated without extinguishing the arc. If, however, neither of these methods is followed, but the difference of potential between the two points is increased to a very high value, the insulating power of the intervening medium will be overcome, and a discharge will take place. With most of the devices by means of which sufficient potential differences can be reached (the induction-coil, influence-machine, etc.) the result is simply a spark which differs from the arc in being of short duration (rarely more than $\frac{1}{40000}$ of a second). After the passage of the spark, the medium, being mobile, will re-establish itself, and no further discharge will occur until the potential difference has risen again to its former high value. The term "electric arc" is applied to the permanent air-path established for the current by one of the previous methods.

The surfaces between the terminals and the arc offer greater resistance to the current than does the arc itself. These then are the regions of the highest temperature. If the terminals are of metal, however refractory, it is at once fused and rapidly volatilized. Almost the only material capable of withstanding the heat developed is carbon in graphitic form, and even this, under the action of the arc, is slowly disintegrated and oxidized, and it is necessary to keep the points at the required proximity either by gravity or by a mechanical device. When an arc is maintained in a continuous-current circuit, the contact resistance at the positive terminal is greater than at the negative. The former, therefore, is always hotter. Both carbons, however, are rendered vividly incandescent, and it is to the light which they emit that the system of illumination known as "arc-lighting" owes its brilliancy. See Electric Lighting.

According to Rossetti, the temperature of the hottest part of the positive carbon of the arc-lamp is 3,900° C., that of the negative carbon 2,450° C. Owing to this difference, also to the electrolytic action of the current, the two terminals are attacked in a different manner, and each assumes a characteristic form. The positive is consumed the more rapidly, in general about twice as fast as in the negative carbon.

Fig. 1 is from a photograph of the arc, made by the writer. Owing to the high actinic value of its rays the arc appears in the photograph relatively brighter than to the eye, but the illustration brings out several of the points already mentioned, viz., the greater brightness of the upper, or positive, carbon, the difference in the shape of the two, and the fact that the incandescent carbons are more important as a source of light than the arc itself. It will be seen that the positive pencil is eaten away at the end, forming a cavity (technically known as the crater), which is the brightest region of all; also that the lower carbon is pointed, with a little crest or nipple. This is formed in great part of carbon which has been detached from the positive pencil, transferred through the arc by the current and deposited there.

In order that an arc may be maintained across an appreciable air-gap, a difference of potential of about twenty-two volts must exist between the terminals. As the voltage rises, the maximum length of arc increases until at fifty volts it is perhaps as much as a centimeter.

Arc-lamps in commercial practice are maintained at a voltage of approximately the latter value.

The resistance of the electric arc varies with the current flowing, but it seems surprisingly small when we consider the materials of which it is composed. With ten ampères flowing and fifty volts between terminals, the resistance (by Ohm's law) is only five ohms. Of this a considerable and nearly constant factor is the "contact-resistance" between the terminals and the intervening gas. It follows that the resistance of the arc is not directly proportional to the distance between the carbons, but is expressed by a formula of the following sort:

$$R_a = r_c + lr_s.$$

Where R_a is the total resistance between the terminals, r_c is the contact resistance, l is the length of the arc, and r_s a quantity which expresses the resistance of the gas layer per unit length.

The electric arc acts like any conductor carrying current. When placed in the magnetic field, for instance, it tends to move at right angles to the lines of force. Since the medium is a mobile one, this tendency is indicated by marked displacement of the arc (as in the well-known experiment of the repulsion of the arc by means of the horseshoe magnet).

In an alternating-current circuit many of the phenomena of the arc differ from those just described. The terminals

Fig. 1.—The electric arc (direct-current circuit).

tend to assume the same shape, they are equally bright, and they are consumed at nearly the same rate. In such circuits the current passes through zero at every alternation, and the arc is extinguished at every reversal; but it is re-established as the current rises, before the air-gap has had an opportunity to cool. The familiar humming of the alternating arc is due to this reignition at each alternation. The fact of the extinction of the arc has been established by photographing it upon a rapidly moving plate.

Fig. 2.—The alternate current arc, photographed on a moving plate (showing the periodic extinction of the arc).

Fig. 2 is from such a photograph, made by Mr. J. C. McMynn (*Trans. Am. Inst. E. E.*, 1891).

The trace of the image of the arc is not continuous, but consists of alternate light and dark spaces, which correspond in time to the period of reversal. The continuous traces above and below the image of the arc are due to the incandescent tips of the upper and lower carbons.

The materials present in the arc depend upon the character of the terminals and of the intervening medium. The arc-spectrum always shows bright lines, which are traceable to the vapors of whatever metals chance to be present. Between carbon points are obtained, besides the lines characteristic of carbon compounds, the sodium lines and lines due to iron and to various other metals.

Aside from its value in artificial illumination, the arc is of importance in metallurgy and in various processes where very high temperatures are essential. For some description of its application, see Electric Light, Electric Welding; also Electricity and Electric Discharge.

E. L. Nichols.

Electric Blowpipe: (1) a device in which the electric arc between carbon pencils is powerfully deflected by means of an electric magnet and given the form of a blowpipe flame. The arc was used in this way by Werdermann for the fusion of especially refractory minerals, etc. (2) The term "electrical blowpipe" was applied by some of the older writers on electricity to the familiar experiment upon electrical convection, in which the current of air from a point attached to the prime conductor or to any highly charged body was made to deflect a candle flame, giving the latter somewhat the appearance of the flame of an ordinary blowpipe. E. L. NICHOLS.

Electric Clocks: clocks in which (1) electricity is the motive power which propels the machinery; or (2) power is obtained from weights or springs, and electricity is used for controlling or regulating the motion.

In some electric clocks there is an electro-magnet, which attracts a soft iron keeper whenever a current passes through it. The keeper gives motion to the clock-hands by an extremely simple arrangement of levers and wheels. The current is made and interrupted by the vibrations of a standard clock, which may serve to give time to any number of secondary electric clocks, even if they are at a great distance from each other.

Bain's clock has a soft, hollow electro-magnet for a pendulum, swinging between the like poles of two permanent magnets, the current in the pendulum being broken and reversed in every swing, so that it is forcibly repelled from each magnet.

Electric clocks are capable of running a long time without attention, but when moved by electricity alone are not very regular in their motion, owing to slight irregularities in the electric currents; but when electricity is used as a regulating power, it is capable of rendering important services in making ordinary clocks do accurate work. For example, an astronomical clock of great precision is connected in the proper manner by telegraph wires with a great number of common clocks, in such a way that signals are sent at given intervals. Now, suppose that any one of the common clocks has gained or lost a small interval of time between two signals, the electric current is made to retard or accelerate the motion just enough to correct the work, and to impart to all the common clocks the precision of the astronomical clock. In some cases the hands of the controlled clocks, whether fast or slow, are set right at frequent intervals by the direct mechanical action of an electro-magnet moved by an electric impulse from the standard clock.

Electric Column: See DRY PILE.

Electric Discharge: a phenomenon which takes place whenever the dielectric separating two conductors, between which difference of potential exists, breaks down. The result is in general an electric spark due to the heat developed along the path over which equalization of potential occurs. When the conditions are such that a considerable potential difference continues to be maintained after the breaking down of the dielectric, the discharge is termed an arc. (See ELECTRIC ARC.) More commonly, however, a flow of extremely brief duration occurs, occupying, as a rule, but a few millionths of a second.

The medium through which a spark passes may be a solid, a liquid, or a gas. In the first case its path is generally marked by mechanical rupture of the material. In the case of fluids, however, although decomposition takes place (probably by dissociation due to the very high temperatures), the dielectric tends to re-establish itself, so that another spark can not pass until the potential-difference necessary to pierce the fluid has again been reached. It is to this fact that oils, etc., owe their superiority as high-tension insulators.

The spark discharge has as its essential features (1) short duration; (2) a definite path; (3) the production of temperatures along the path sufficient to render gases incandescent and to volatilize metals; (4) a detonation of high pitch, the intensity of the sound depending upon the quantity of electricity discharged.

The color of the spark depends upon the chemical constituents of its path. In air it has a decidedly purple tint, characteristic of incandescent nitrogen; the presence of water vapor and of the vapor of mercury tend to modify the color of the spark in air, rendering it more nearly white. In the presence of vapors of the various metals the color of the spark depends upon the nature of the bright line spectrum of the metal—e. g. sodium (yellow), copper (green), zinc (bluish), etc.

Pressure has marked influence upon the character of the discharge. As the pressure of a gas or vapor through which sparks are passing falls, the discharge is seen to lose its definiteness, the path becomes ill defined, and the brilliancy diminishes.

At low pressures the discharge is no longer a spark, but a continuous or prolonged light, often called by the older writers the barometric light. It takes on a new form, and undergoes a series of most striking and beautiful modifications. Many of these discharges *in vacuo* can be observed by means of a good air-pump and an induction-coil, or even with the aid of the Torricellian vacuum in the top of a barometer tube. Some of the more striking phenomena of electrical discharges in pressures, lying between a few hundredths and a few hundred-thousandths of an atmosphere, are exhibited in the sealed vacuum tubes devised by Geissler, of Bonn. (See GEISSLER TUBES.) Other and still more wonderful results have been obtained at lower pressures, extending to the hundred-millionth of an atmosphere, by Crookes. The radiant heat of these discharges has been measured by the BOLOMETER (*q. v.*).

The duration of the electric spark is measured by means of a revolving mirror. At all ordinary rates of rotation the image of the discharge suffers no widening due to the change of plane of the mirror. At high speeds, however, measurable dilation of the image is obtained, and it is found that within the interval of the life of a single spark we have to do, under certain conditions, such as the discharge of a condenser, with the rather complicated phenomenon known as the oscillatory discharge. This consists of a series of discharges following one another with almost inconceivable rapidity. It has been shown that it is accompanied by a number of *reversals of charge* in the condenser, each one involving a smaller potential-difference than the preceding. The rate of oscillation depends upon the *capacity* of the circuit, the *number* of oscillations that occur before equilibrium is established, upon the *resistance* through which the discharge takes place.

Fig. 1 is from a photograph of the oscillatory discharge by Prof. C. V. Boys (see *Philosophical Magazine* (5), 30, p. 248).

The path of a spark between two points is always that which offers the least resistance. It is, however, rarely a straight line. In air, except when special precautions have been taken to remove all dust particles, the course of the spark is always a broken line. Around good insulators, such as glass, resin, or vulcanite, the discharge will follow long and devious paths through media offering less resistance. Since in general there is one path of less resistance than all others, simultaneous sparks over different paths do not occur. The path of least resistance changes from moment to moment, however, and the impression on the retina of the observer lasts for a considerable part of a second. The effect, therefore, when discharges follow one another rapidly between the terminals of the Holtz machine or induction coil, is that of a bundle of simultaneous sparks.

In Fig. 2 is reproduced a photograph of the poles of a large influence-machine between which sparks were passing. The exposure lasted half a second, during which time eleven successive discharges occurred.

Under certain conditions the discharge through air at ordinary pressures, instead of taking the form of a spark, simulates the discharge *in vacuo*. It becomes almost noiseless, the path is ill defined, the color is a faint bluish or purple, scarcely visible in a well-lighted room. This is the *brush discharge*. The effect to the eye is that *of continuity*, as in the vacuum discharge, instead of the abruptly interrupted character of the spark. Analysis by the method of the revolving mirror, however, indicates that both the brush in air and the discharge *in vacuo* are really made up of well-defined, abrupt discharges of short duration and small intensity, these following each other so rapidly that by persistence of vision they give the effect of continuity.

The phenomena connected with the electric discharge are very numerous and complicated. They have been studied at great length, but many points are still doubtful. The differences in appearance, for instance, between the positive and the negative terminals of a vacuum tube, or in the case of the brush discharge the reason why an insulated zinc or magnesium plate negatively electrified loses charge under the influence of light, while the same plate positively charged is uninfluenced by radiation; why, in the case of the spark, the negative terminal is *hotter*, while in that of the continuous-current arc it is *cooler* than the positive—these and a multitude of other questions are in great measure undetermined. The details of the work already done in this interesting domain of experimental physics are scattered throughout the scientific journals and transactions. Excellent summaries are to be found in such works as Riess's *Reibungs-elektricität*, and in the fourth volume of Wiedemann's treatise, *Die Lehre von der Elektricität.*

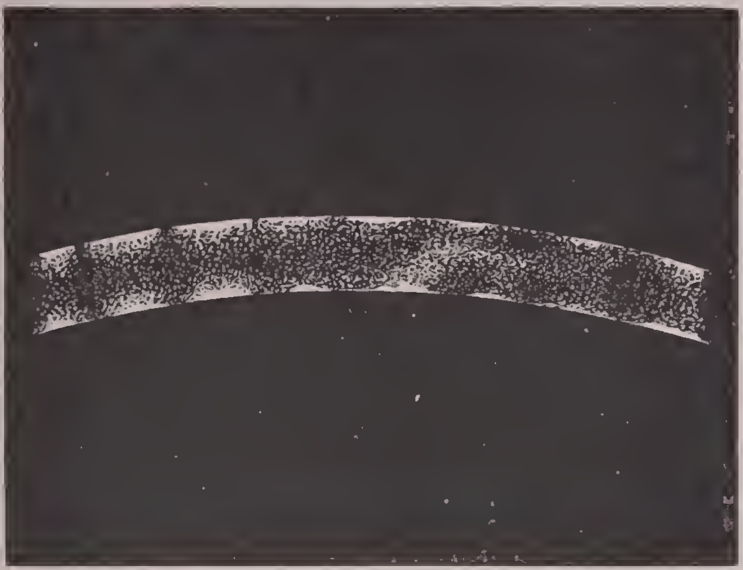

FIG. 1.—The oscillatory discharge (after a photograph by Prof. Boys).

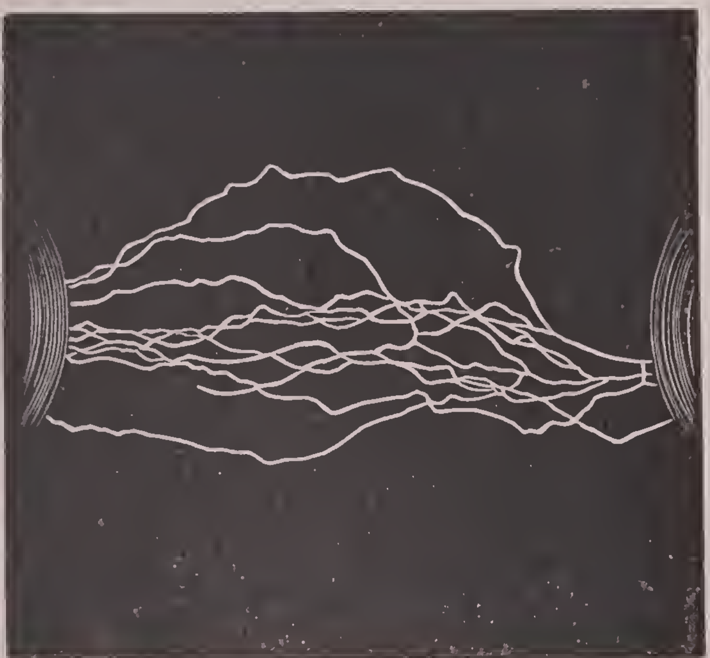

FIG. 2.—Group of sparks passing between the poles of a Holtz machine during half a second (from a photograph).

Electrical discharges occurring in nature are treated in the article LIGHTNING (*q. v.*). For explanation of various terms used in this article, see CAPACITY, CONDENSER, CONDUCTOR, DIELECTRIC, ELECTRICITY, SPECTRUM, and VACUUM.
E. L. NICHOLS.

Electric Eel: See ELECTRICAL FISHES and GYMNOTI.

Electric Furnace: an apparatus in which very high temperatures are attained by surrounding the electric arc, or sometimes a group of arcs, in parallel with carbon, lime, or other refractory substance. The material within which the arc is imbedded should be a poor conductor of heat and of electricity; it should be extremely refractory, and it should be a reducing agent. In some forms of furnace a carbon pot is used, into which is inserted a heavy carbon pencil or a bunch of pencils, the bottom of the pot forming one terminal. The material to be fused is placed between the end of the pencil and the bottom of the pot, surrounded with suitable fluxing material. Another form consists of two groups of pencils dipping diagonally into a furnace box, one group serving as positive, the other as negative terminals. The temperatures produced suffice to reduce the most refractory ores, such as the oxides of aluminium and magnesium. A furnace of small size, consisting of two slender pencils inserted into a cylinder of lime, has been used for the reduction of the rare metals, erbium, yttrium, etc.
E. L. NICHOLS.

Electricity [from Lat. *elec'trum* = Gr. ἤλεκτρον, amber]: the cause of an important class of phenomena, the science of which may be said to have its origin in the experiments of William Gilbert, of Colchester, physician to Queen Elizabeth (1540–1603). The isolated fact, generally ascribed to Thales, that amber when rubbed attracts other bodies was known to the Syrians and Persians at an early day, as well as to the Greeks; but, aside from the statement of Theophrastus that the fabulous mineral lykurion shared with amber the property in question, scarcely an addition seems to have been made to this branch of knowledge for 2,000 years.

Gilbert studied the phenomenon of amber-rubbing systematically, and made out a long list of substances which he found capable of being excited by friction. He was the first to propose the term "electric" by which to distinguish the forces thus brought into play from those due to magnetism. From his time on, the students of electricity rapidly increased. In the seventeenth century there were among its votaries such men as Newton, Boyle, von Guericke, and Hawksbee; in the eighteenth, Du Faye, Symmers, Nollet, and Franklin. Modern electricity began, however, with Cavendish, toward the end of the eighteenth century. His more precise investigations, followed by those of Davy, Oersted, Ohm, Ampère, Faraday, Weber, Henry, and their disciples, made possible the work of the great school of electricians of which Maxwell, von Helmholtz, and Kelvin are the leaders, as well as the important industrial achievements of the closing years of the nineteenth century.

The nomenclature in vogue in electricity is strangely at variance with the present opinions concerning the nature of the phenomena with which the science deals. It is a survival of the time when the two-fluid theory of Du Faye and Symmer and the one-fluid theory of Franklin were the two conflicting "modern views of electricity." We still speak of the separation of the electricities; of the positive (or negative) electricity flowing off to earth, when a body electrified by induction is connected metallicly with the ground. We speak of current, of the direction of the current, of flow and rate of flow. The term *charge* originally conveyed the idea of filling a body with the electric fluid, and *discharge* referred to the supposed escape of that fluid. Terms indicative of the existence of the electric fluid are still used, but it is merely for convenience, and with recognition on the part of every well-informed student that the nomenclature is an artificial one. Electricity, from the standpoint of the present day, is a science which deals with certain transformations of energy. It is the purpose of this article to describe some of the more important of these transformations, and to point out their relation to the phenomena with which other parts of the science of physics have to do. In the course of the discussion it will be necessary to deal primarily with a process called electrification, and indirectly with a large number of important and interesting phenomena which result therefrom.

Electrification is a process which involves the expenditure of energy, the nature of the work done always being such as to bring about a certain *difference of condition* (difference of potential) between neighboring bodies or between parts of the same body. It is not easy to determine precisely in what this difference of condition consists, but there is an analogy between electrification and other physical processes, in which potential energy is produced, which may in some degree aid in the understanding of the nature of the case. The processes in question are those in which difference of temperature is created or difference of level in liquids, or in which a spring is stretched or a chemical compound is broken up. In all such cases there is a tendency for the difference of potential to be equalized. In the equalization, energy in one form or another is always developed, giving rise to the innumerable phenomena which it is the province of the science of physics to describe. When the difference of potential produced manifests itself in certain ways it is classified as electrical, and the process by means of which the potential difference has been produced is called electrification.

Difference of electrical potential may be produced by friction, by induction, by chemical action, by application of heat, by the movement of a conductor in the magnetic field (or by variation in the strength of the magnetic field in which conductors lie), and in other ways. These will be considered in turn, and in connection with each the more important phenomena which characterize the re-establishment of equilibrium will be touched upon. It will be seen that the effects produced by these various methods are not related merely, but are identical; and that the result brought about by electrification is entirely independent of the method employed to produce it.

Electrification by Friction.—Whenever two bodies differing in chemical constitution or in physical structure are rubbed together, difference of potential is produced. One of them is then said to be positively, the other negatively, electrified. The indications of electrification are: (*a*) the attraction of bodies thus oppositely charged for one another; (*b*) the mutual repulsion of bodies similarly charged, or between different parts of the same body, in so far as these have freedom of motion. A typical case is that of glass rubbed with silk. Bodies repelled by glass thus excited are by common agreement said to be positively electrified; those which, like the silk under the above conditions, are attracted by glass, are said to be negatively electrified. The terms vitreous (+) and resinous (—) are also in vogue in describing electrification, the resins, when rubbed with fur or flannel, showing electrification opposite to that of glass.

This phenomenon of electrification by friction is a perfectly general one, and it is found that all known substances can be arranged in a series, such that each member when rubbed with any of those which follow it in the list will be positively excited, and when rubbed with those which precede it will develop a negative charge.

The following list is that given by Faraday in his *Experimental Researches* (article 2,141):

+	
Cat (or bear) skin,	Linen,
Flannel,	White silk,
Ivory,	The hand,
Goose-quill,	Wood,
Rock-crystal,	Shellac,
Flint-glass,	Metals (iron, copper, brass, tin, silver, or platinum).
Cotton.	Sulphur.
	—

Many such lists have been made out, but they do not agree with one another, because mere surface changes will sometimes transfer a substance from one part of the series to another. Thus polished glass and ground glass behave very differently, the one being positive, the other negative, when rubbed with such a material as leather.

Conductors and Insulators.—When by friction, or by any of the processes just mentioned, one portion of a body is brought into a different electrical condition from neighboring portions, the rapidity with which equalization occurs depends upon the character of the substance. In metals complete equilibrium is established almost instantly. Such bodies are said to be good conductors of electricity. Others, where difference of potential equalizes itself very slowly, are poor conductors. Very poor conductors are called insulators. To this class belong certain solids, such as dry glass, nearly all resins and vegetable gums, silk, and pre-eminently quartz; also oils, hydrocarbons, and many other liquids, and at ordinary temperatures the gases. There is no sharp line of division between conductors and non-conductors, but the difference between metals and non-metals in this respect is very great.

The crust of the earth, save in exceptional localities, is a conductor, and differences of potential between neighboring parts are quickly equalized. Under the usual conditions of experiment, bodies which are to be electrified are of necessity in material connection with the earth. If there is metallic contact with the latter by means of a rod or wire, and if the body in question is a conductor, the difference of potential between the earth and the body will disappear at once. Conductors of electricity therefore can be made to manifest electrification as a result of friction only when they are insulated—i. e. when the matter which connects them with the earth is not a good conductor. A body which is itself an insulator, however, may be in metallic connection with the earth at one point, and a high degree of electrification may be produced on its surface not contiguous thereto. The very quality which constitutes it an insulator involves slowness of equalization of potential between its parts. The following are some of the more important phenomena occurring in the case of an insulated conductor which is subjected to electrification:

(1) Electrification of any portion of the surface immediately distributes itself over the entire surface of the conducting body.

(2) Electrification shows itself on the surface only.

(3) Electrification shows itself equally on all points of the surface of a conducting sphere. Where, however, the radius of curvature of the surface varies from point to point, electrification is most marked in regions of shortest radius. For example, if the charged body be egg-shaped, it will appear most strongly electrified at the apex.

This principle extended to extreme cases leads to some very interesting results. If, for instance, the radius of curvature at any point is zero (as at the apex of a perfect cone), electrification would then show itself only at the point, and all other portions of the surface would remain unaffected in spite of every effort to electrify them. An approach to this state of affairs is frequently met with in practice.

Another case of interest is that in which the radius of curvature becomes negative, and the surface concave instead of convex.

Within such cavities the show of electrification is always less than on those portions of the surface which are convex, diminishing as the cavity deepens, until in extreme cases, as on the inside of a metal cup, or, better yet, of a metal bottle, it becomes inappreciable. When, finally, the opening is entirely closed over, the electrification within becomes zero.

That electrification shows itself only on the surface of bodies can be shown in a variety of ways.

If the leaves of a delicate gold-leaf ELECTROSCOPE (*q. v.*) be connected with the interior of a hollow sphere, no divergence of the leaves will show itself, however strongly the surface be electrified. Faraday, in an experiment which has become famous, further demonstrated the absence of electric disturbance within a metallic body by carrying an electroscope into a large box, 12 feet each way, which had been highly charged. The instrument showed no indication of electrification, even when connected with the inner wall, although from without 4-inch sparks could be drawn from the tinfoil with which the box was covered.

That electrification shows itself on the outer surface where the radius of curvature is positive, and not on re-entrant portions, is strikingly indicated by the following apparatus:

A flattened ring (Fig. 1) is mounted upon an insulated foot. Inside and out are suspended gilded pith-balls which hang in contact with the surface of the ring. When the ring is electrified the outer balls, sharing the electrification of the surface, are strongly repelled, but those within the ring show no sign of disturbance.

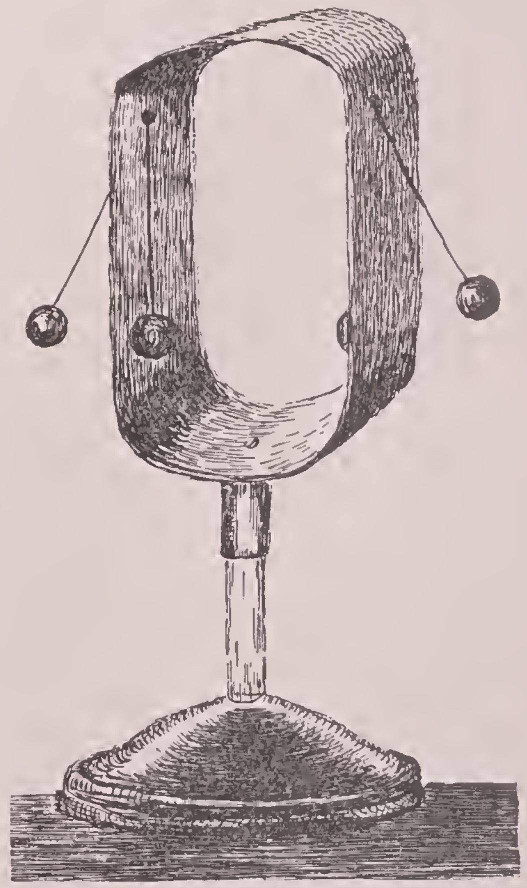

FIG. 1.

The phenomena resulting from the electrification of an insulated body are by no means confined to its own surface. It has already been seen that such a body repels others similarly electrified and attracts those of opposite charge. The forces it is capable of exerting show themselves in another and very important way. It is found that in the neighborhood of such a charged body all other bodies suffer a difference of potential between their parts. Those portions lying nearer to the body in question, which in this case is called the *inducing body*, become electrified in the opposite sense from it. Those portions lying at the greatest distance from the inducing body acquire a charge similar to its own. It is usual to describe this phenomenon by saying that the body in question has been subjected to *electrostatic induction*.

The condition of the body thus influenced is as follows: It carries upon its surface two equal and opposite electrifications. The difference of potential tends toward equalization, but it is kept up by the continued action of the inducing body. If the latter be removed, or if its electrification disappear, instant equalization within the body carrying the induced charges will take place (if it be a good conductor). In the case of a poor conductor the return to the neutral condition will be more gradual. In both cases, however, the restoration of equilibrium will be accompanied by the development of energy in some form.

For a long time these effects were regarded as cases of action at a distance. It is now generally accepted that the action takes place through a universal medium filling all space and permeating all matter; and that the medium possesses properties such as to establish its identity with the luminiferous ether. See LIGHT.

It is usual to express the above condition of affairs by saying that every electrified body possesses a field of force of which it forms a center. Particles of matter within this field tend to move toward or away from a body, according to the manner in which they may be electrified. The paths which they tend to follow are called *lines of force.*

The simplest case is that of a field in which there are only two bodies, a and b, at a distance, d, from one another. The force of their mutual attraction or repulsion is expressed by the equation

$$f = \frac{q_a q_b}{d^2},$$

where q_a and q_b are factors which express the electrical condition of the two bodies. They are called the *quantities of electricity* with which a and b respectively are charged—a name which has come down from a time when there was thought to be an electric fluid.

Considering electrification as a process by means of which a difference of potential is produced, q_a and q_b may still be used, defined as the amount of work done upon the bodies a and b to electrify them.

It is of importance to note that the equation for the force between two electrified bodies is precisely analogous to that which expresses the law of gravitation between any two particles of matter in space, and also to the formula for the attraction or repulsion between two magnetic poles, viz.,

$$f_g = \frac{M_1 M_2}{d^2}, \text{ and } f_m = \frac{m_1 m_2}{d^2},$$

where f_g and f_m are the forces in question, and $M_1 M_2$ the masses or $m_1 m_2$ the strength of the poles respectively.

All three are examples of what are known as central forces, and act inversely as the square of the distance.

Since every material particle in the neighborhood of an electrified body suffers electrical disturbance (insulated bodies having difference of potential between their parts, bodies in metallic connection with the earth coming to a different potential from the latter), and since the production of these changes involves the expenditure of energy which is restored in one form and another whenever the potential differences cease, it follows that the electrification of a body always implies work done, the quantity of which depends upon the amount and the arrangement of matter in the neighborhood.

Whenever a field of force is established within which there is matter to be acted upon inductively, a temporary storage of electrical energy takes place, and in certain cases the amount stored is very large. Apparatus designed for thus storing definite quantities of electrical energy is called a *condenser.*

A condenser generally consists of two or more parallel walls or coatings of conducting material, separated from each other by a layer of some insulating substance called the dielectric. A familiar form of condenser is the Leyden jar. See CONDENSER.

Electrification by Induction.—Electrostatic induction affords the most convenient and effective means of bringing about differences of potential, and it is in the equalization of such differences that many of the most striking phenomena of electricity occur. In the early days of the science, bodies were electrified chiefly by friction. A sphere of glass maintained in rapid rotation and excited by contact with the dry hands of the experimenter (Fig. 2) constituted the celebrated electrical machine of Hawksbee. Later a cylinder was substituted for the revolving sphere, and later still a revolving disk of plate glass, rubbed with leather. About the year 1865 Toepler, and independently Holtz, introduced machines based upon the principle of electrification by induction.

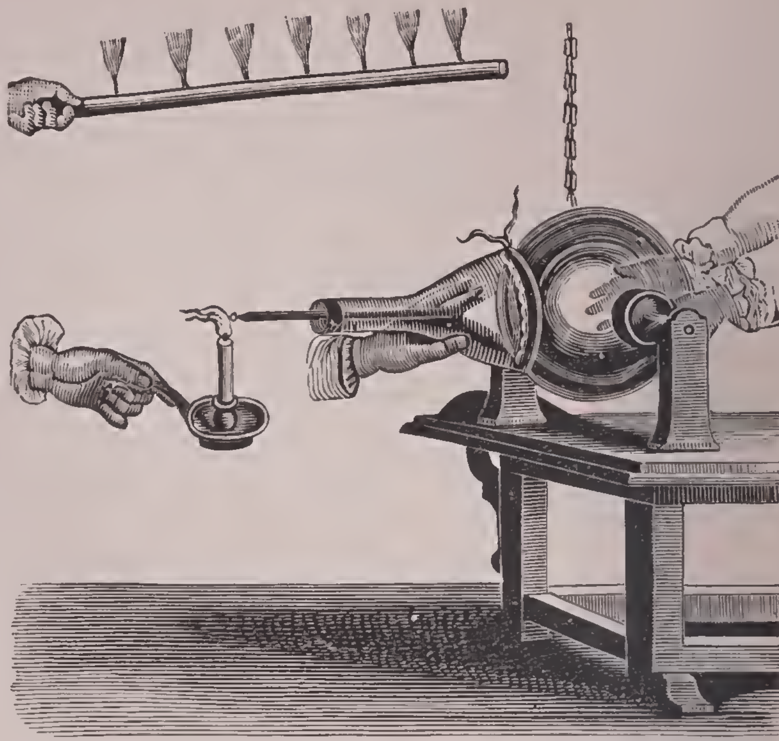

FIG. 2.—Facsimile of an old copper-plate engraving, showing Hawksbee's machine (from the Abbé Nollet's *Lettres sur l'électricité*, Paris, 1764).

Stated in the most general way the process in all such machines consists of the following cycle of operations:

(1) A conductor of electricity is brought very near to some body previously electrified.

(2) The former is connected metallically with the earth.

(3) The earth connection is severed.

If at this point the inducing body and the conductor be separated, the latter will be found to be charged (i. e. to be electrified, and at a different potential from the earth). The sign (±) of its charge will be opposite to that of the inducing body.

This cycle of operations may be gone through with over and over again without depreciation of the inducing charge. The source of the electrical energy developed each time is the work necessary to separate the two bodies of unlike electrification (inducing and induced) from one another.

The simplest form of apparatus by which electrification by induction can be carried on is the well-known electrophorus. The replenisher of Lord Kelvin and the influence-machines of Holtz, Toepler, Wimshurst, etc., are to be regarded simply as devices for the continuous and automatic performance of the electrophorus cycle (just described). See ELECTRICAL MACHINES.

Experiments showing the development of energy during the discharge of electrified bodies are much more numerous than those indicating the expenditure of work in producing electrification. The latter is a gradual, cumulative process, and in the case of most machines the amount of energy converted into heat is so much greater than that which takes electrical form that it is difficult to distinguish the latter. In influence-machines of the Holtz type, for example, the amount of power used when a high difference of potential is maintained between the terminals of the machine is not much greater than for small differences. Determinations of electrical output in terms of the energy applied show a scarcely appreciable efficiency. It is nevertheless frequently possible to detect fluctuations in the speed of such a machine when driven by a small water-motor or other source of power of inadequate regulation, the power necessary to produce rotation rising steadily before each spark and dropping to a small value at the moment of discharge.

Whenever electrical discharge takes place, there is, however, immediate and complete reconversion of the energy of electrification into other forms. The transformation into energy of motion, for instance, may be made to manifest itself in a variety of ways. The experiment of the electrical *tourniquet* is a familiar illustration.

A body (Fig. 3), charged by connection with one of the terminals of a Holtz machine, carries a pair of revolving arms with points.

At each point the degree of electrification is very great, and the atmosphere in the neighborhood is acted upon inductively. It is attracted, then, after electrification is repelled. The result is a convection current of air which moves away from the point in the direction of its axis. A candle held

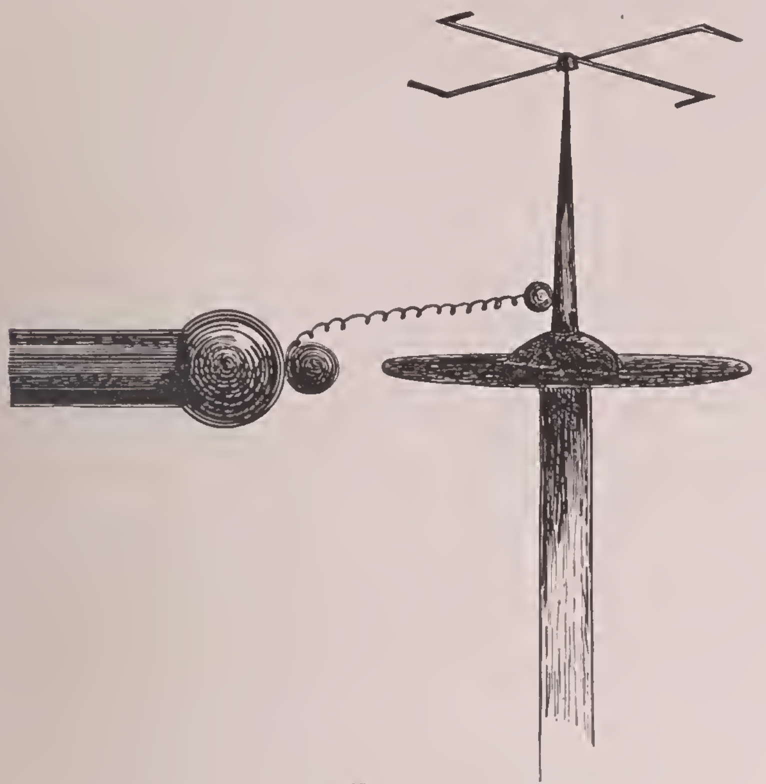

FIG. 3.

before the point will show by the distortion of its flame how powerful this convection current is. The reaction, like the reaction in Barker's mill, tends to thrust the point backward, and motion of rotation results.

A still more striking experiment, showing the conversion of electrical energy into motion, is that of the *reversibility* of the Holtz machine.

If two such machines be taken and their terminals connected by means of a line of wire, as in Fig. 4, and if machine

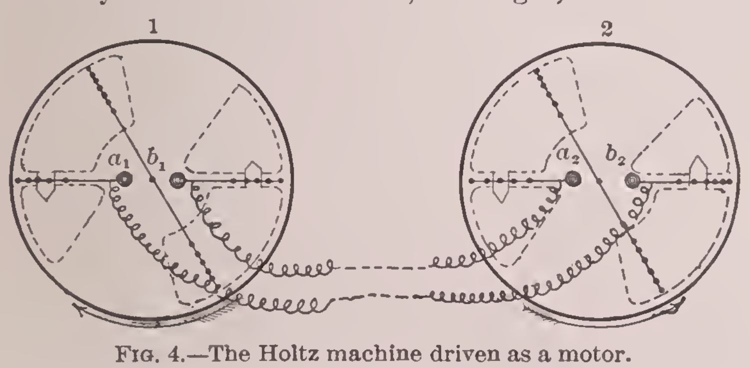

FIG. 4.—The Holtz machine driven as a motor.

1, duly excited, be driven, producing potential differences between its terminals a_1 b_1, which are in metallic connection with the terminals a_2 b_2 of machine 2, the latter will be driven as a motor. The movable plate of machine 2 will travel in the opposite direction from that in which it would be driven when the machine is to be used as a generator. This reversibility of the influence-machine was discovered by Holtz at an early stage of his experiments, and was described by him in 1867.

Voltaic Electricity.—By the means of producing electrification just discussed, i. e. friction and electrostatic induction, great differences of electric potential are produced, resulting in the many brilliant phenomena usually classified under the head of "static electricity."

The invention of the voltaic pile in 1800 opened a new field for research. Volta's experiments, originally intended to throw light upon the discovery of Galvani, which already had attracted the widest interest among physiologists and physicists, were found to lead to so many new phenomena that the discussion of the source of nervous excitation in the frog's leg (of Galvani's experiment) soon became of secondary importance. Physiological effects were the first looked for, but in the hands of Banks, to whom (as president of the Royal Society of London) Volta early communicated his discovery, and of Carlyle, electrolysis within the voltaic cell and by means of it was discovered, together with such phenomena as the production of sparks between the terminals of the pile and the action of the same upon the gold-leaf electrometer. Thus almost immediately the connection between voltaic electricity and electrification by friction was made manifest.

Stated in its most general form, the fundamental discovery of Volta, upon which one of the most important branches of electrical science has its basis, is as follows:

Whenever two conductors of electricity which are capable of acting upon one another chemically are in contact, a difference of potential is set up between them. The usual combination consists of two unlike metals placed in a liquid which conducts electricity and is capable of attacking one of them. Such a device is a *voltaic cell*; a collection of such cells constitutes a BATTERY (*q. v.*). That a difference of potential exists between the metals of a voltaic cell can be determined by connecting them respectively to the quadrants of an electrometer of fair sensitiveness. It will then be found that metals may be classified into two groups: copper, platinum, gold, etc., on the one hand, showing a decided positive (vitreous) electrification when used in a cell in which a member of the other group, zinc, iron, magnesium (and nearly all easily oxidized metals), forms the other terminal. When the first-named terminal is connected with the earth the other shows a correspondingly great negative (resinous) charge.

Electrification by the voltaic method is distinguished by the following characteristics:

(1) It owes its origin to chemical action between the parts of the cell, the energy necessary to bring about the difference of potential and to maintain it being the result of degenerative chemical reactions which lower the potential energy of the system.

(2) With given metals and a given solution separating them, the potential difference is a definite one, both as to direction and amount, being entirely independent of the size and shape of the cell.

(3) The difference of potential between the terminals of a cell can not be reduced to zero by connecting them metallicly. As in the case of two bodies previously charged by friction or induction, continual *tendency* toward equalization of condition manifests itself, but this tendency is overcome by continued chemical reaction within the cell, the reaction being of such a character as to re-establish the potential difference. There results the phenomenon known as the *electric current*, which for convenience is spoken of as flowing from the positive terminal of copper, platinum, or carbon (in accordance with previous conventions established in the study of electrification by friction) through the outer connecting circuit to the other terminal (zinc).

The energy developed in the outer circuit of a voltaic battery may be made to take useful forms—heat, motion of masses, chemical activity, etc. It may be used to establish fields of force—a process which involves the expenditure of energy—or in the production of radiation, and in many other ways. Thus the discovery of the voltaic pile underlies the first really important attempts to utilize electrical energy.

The electrometer, as has already been indicated, serves to show the relation of voltaic electricity to the "static" forms previously known, but it is to another and almost infinitely more sensitive instrument, the GALVANOMETER (*q. v.*), that knowledge of the voltaic current is chiefly due. The *quadrant electrometer* is sensitive to a hundredth of a volt, perhaps; *galvanometers* have been constructed by means of which differences of potential of less than a millionth of a volt can be measured, or currents down to the hundred-thousand-millionth of an ampère.

The laws governing the development of energy in the electric circuit have been very fully studied and precise quantitive relations have been established. The most important of these are Faraday's law of the chemical action of the current, Joule's law of the heating effect of the current, and the laws of electro-magnetic induction. These last govern (1) the production of *motion* by the agency of the electric current, with transformation of energy from the electric to the kinetic form; (2) the production of *current* by the movement of a conductor through a magnetic field, with transformation of kinetic energy into electrical form; (3) the establishment and modification of magnetic fields of force, by which means electrical energy is transferred from one system of conductors to another through space, or into motion, or *vice versa.*

Faraday's laws of electrolysis deal with phenomena occurring when an electric current traverses any liquid (not an element) which is capable of transmitting it.

Under the above conditions the liquid is decomposed. The acid radical contained in it always appears at the terminal whence the current enters the liquid; the metallic component of the liquid always appears at the terminal toward which the current is flowing. Faraday investigated this subject and expressed his results in two laws, which may be stated as follows:

(1) *The chemical action per unit of time in an electrolytic cell is directly proportional to the strength of the current flowing through it.*

(2) *If the same amount of current flows through a series of cells containing various electrolytes, the weight of the materials set free* (called by Faraday the "ions") *in each will be proportional to the chemical equivalent of the substances* (which may be elements or radical groups).

The amount of any ion liberated by the passage of a coulomb of electricity (i. e. by one ampère of current in one second of time) is called its *electro-chemical equivalent.*

The following is a table of the electro-chemical equivalents of some of the more important elements:

Elements (in the order of their atomic weights).	Electro-chemical equivalents (milligrammes per ampère).
Hydrogen	0·01038
Oxygen	0·08283
Sodium	0·2387
Chlorine	0·3671
Potassium	0·4051
Iron (from ferric salts)	0·1934
Iron (from ferrous salts)	0·2900
Nickel	0·3042
Copper (from cupric salts)	0·3279
Copper (from cuprous salts)	0·6558
Zinc	0·3367
Bromine	0·8279
Silver	1·1180
Tin (from stannic salts)	0·3046
Tin (from stannous salts)	0·6093
Iodine	1·3134
Gold	0·6789
Mercury (from mercuric salts)	1·037
Mercury (from mercurous salts)	2·074
Lead	1·071

Of the above, oxygen, chlorine, bromine, and iodine were termed *anions* by Faraday, the others *kations.* The terminal at which the former class, which includes the acid radicals, is set free is called the *anode*; that at which the metallic elements appear is the *kathode.* The current travels through the electrolyte from anode to kathode, and metals therefore may be considered as moving with the current to the point of deposition, while the acid group travels against it.

Familiar examples of the electrolysis of metals are found in the plating of copper, nickel, silver, gold, etc. Where the deposited metal takes crystalline form, very striking

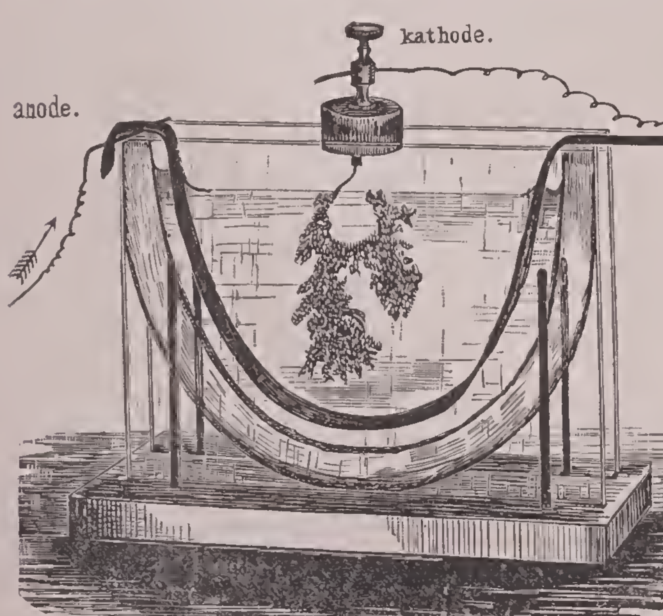

Fig. 5.—The "lead tree."

effects are produced, as in the case of the "lead tree," Fig. 5.

The phenomenon of electrolysis is well brought out in the following experiment:

In a V-shaped tube (Fig. 6) is placed a solution of neutral sulphate of sodium. The platinum terminals *p n* introduce the electric current to the cell and conduct it away. The solution is previously stained purple by the action of litmus. When current passes through from *p* to *n* the following reactions occur, viz.:

$$Na_2SO_4 + mH_2O = SO_4 + mH_2O + 2Na = O + H_2SO_4 + (m-2)H_2O + 2NaHO + 2H.$$

Here we have two sets of chemical changes: (1) Those due to electrolysis, viz., SO_4 set free at the positive pole, 2Na at the negative. (2) Secondary reactions purely chemical. Free SO_4 forms H_2SO_4, setting free O. 2Na at the other pole forms the hydrate 2NaHO, and two parts of hydrogen are liberated. The free acid shows itself by the reddening of the litmus solution in the regions surrounding the posi-

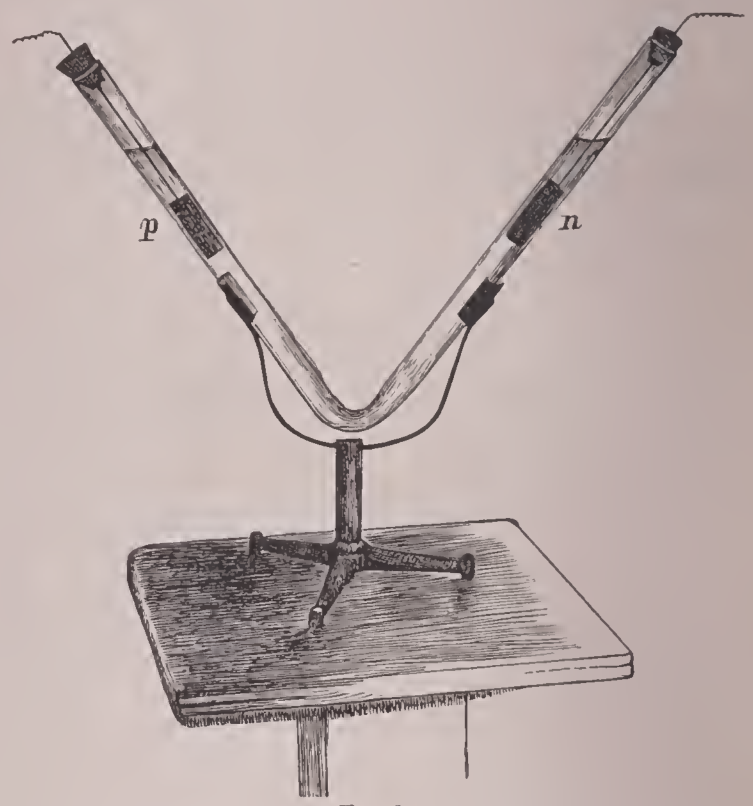

Fig. 6.

tive electrode; sodium hydrate by its alkalinity turns the solution blue in its neighborhood. Oxygen and hydrogen are given off as gases at their respective terminals, and may be collected and tested.

If, after electrolysis has proceeded for some time, the cell is taken out of circuit and the poles connected to the terminals of a galvanometer, that instrument will indicate the passage of current in the direction opposed to that in which the electrolyzing current has been flowing. This current will continue as long as there is a difference between the liquids in the two arms of the cell. The current in electrolysis has broken up a neutral, inactive compound, Na_2SO_4, producing two chemically different and very active substances, H_2SO_4 and NaHO. The separation of these, then, has been accomplished by the expenditure of energy now stored in the cell. Difference of potential will exist between them, and so, by contact, between the platinum poles. Flow of current in direction opposite to that which charged the cell tends to *recombine* the acid and alkali of the two arms of the tube; and it is their recombination that creates the current which the cell has become capable of generating. Such a cell, after the passage of the charging current, is a form of *storage* battery or Accumulator (*q. v.*), giving current as long as the difference between the solutions surrounding the platinum terminals continues.

Voltametry.—It having been established by many critical and precise investigations that the first law of Faraday is rigorously true, it follows that the quantity of electricity transmitted in a circuit (i. e. the integral of the current or product of the average current and the time) may be measured by electrolysis. Any instrument for such purpose is called a Voltameter (*q. v.*).

The electrolyte selected for voltametry must contain as one of its ions a substance insoluble in the liquid, chemically stable and easily collected and weighed. In practice but few materials are used; viz., oxygen and hydrogen (from decomposition of water), silver, copper, and zinc. Silver and copper voltameters are used where precision is desired, since they can be made to give results accordant, within $\frac{1}{10}$ per cent. Zinc has been found to be the best metal for commercial measurements extending over considerable intervals of time. It is used in chemical meters for indicating the energy used in electric lighting of buildings, etc.

Thermal Relations of the Current.—It has already been shown that the electric current is the result of the tendency toward equalization in a circuit, two points in which (for example, the poles of a voltaic cell) are maintained at different potentials.

The current depends upon the resistance of the circuit in such manner that

$$I = \frac{E}{R}$$

where I is the current strength, R the resistance of the circuit, E is the *electromotive force*, a term by means of which is expressed the *tendency* to equalization due to potential differences in the circuit.

This formula is an algebraic statement of the fundamental relation existing in all circuits possessing a constant electromotive force. It is known as *Ohm's law*, from the German physicist of that name, author of a memoir, now classical, upon the mathematical theory of the voltaic circuit (Berlin, 1827.)

Whatever the character of the path traversed by the voltaic current may be, a transformation of energy into the form of heat takes place. During the years in which the doctrine of the conservation of energy was in process of development, this transformation was studied with great care. Joule, to whom the doctrine owed in great part its experimental footing, showed the energy developed in any part of the circuit to be proportional to I^2 and to R. Joule's law stated mathematically is $HJ = I^2Rt$; whence from Ohm's law the corresponding form $HJ = IEt$. In these equations t is the time, H is the heat in calories, and J is "Joule's equivalent," the ratio of the calorie, as a measure of heat expended, to the erg as a measure of work.

Now, since

$$1 \text{ calorie} = 4{\cdot}175 \times 10^7 \text{ ergs, we have}$$

$$\frac{0{\cdot}24 I^2Rt}{10^7} = H \text{ (in calories, nearly),}$$

where R and I are in absolute measure. If current and resistance are measured in the well-known practical units Ampere (*q. v.*) and Ohm (*q. v.*), the inconvenient factor 10^7 disappears; for

$$1 \text{ ampere} = \tfrac{1}{10} \text{ C. G. S. unit of current:}$$
$$1 \text{ ohm} = 10^9 \text{ " " " units of resistance.}$$

The product I^2R (or IE) in practical units is called a *watt*. It measures the energy expended per second in a circuit of one ohm, through which an ampère of current is forced to flow; and when that energy is transformed into heat, it measures the latter in terms easily converted into heat units. The approximate relation of the watt to the calorie and to the erg is as follows:

$$1 \text{ watt} = 0{\cdot}24 \text{ calories per second (nearly);}$$
$$\text{"} \quad = 10^7 \text{ ergs} \quad \text{"} \quad \text{"}$$

Its relation to the horse-power is as follows:

$$1 \text{ horse-power} = 746 \text{ watts (approx.).}$$

It is so simple a matter to measure current and electromotive force, and by their product to express the work done in any electric circuit, that the watt and its multiple the *kilowatt* (1,000 watts) have come into nearly universal use wherever the relations of *electricity* and *power* are to be dealt with.

From the laws of Ohm and Joule many important electrical relations follow. Some of the most obvious are:

(1) In a circuit with fixed electromotive force the current depends solely upon the resistance, and may be controlled and varied through any range by varying the latter. Fluctuations of electromotive force introduce additional factors into the relationship, and instead of Ohm's law there is a law which takes into consideration the *capacity* of the circuit and its *self-induction*. These quantities depend upon the arrangement of the parts of the circuit with reference to each other and to surrounding objects. The nature and rate of fluctuation in the electromotive force are also of influence. The general expression for the energy in the case of fluctuating electromotive force is

$$EIdt = I^2Rdt + LI\frac{dI}{dt}dt + \frac{Idt \int Idt}{C},$$

a differential equation which indicates the fact that the energy of the circuit, EIdt, is expended in three ways. One portion, I^2Rdt, goes to the production of heat in accordance with Joule's law. Another portion, $LI\frac{dI}{dt}dt$, is spent in the building up and in ever-recurring modification of the field of force due to the current. The remainder, $\frac{Idt \int Idt}{C}$, is expended electrostatically, viz., in charging whatever portions of the circuit are (by virtue of their action as a condenser) capable of storing energy in that manner.

Whenever the electromotive force of the circuit becomes constant, the factors of self-induction and capacity disappear, and the equation assumes the familiar form of Ohm's law, $I = \frac{E}{R}$. For full discussions of interesting cases arising under conditions of rapidly changing electromotive force, see Fleming, *The Alternating Current Transformer*; also Bedell and Crehore, *Alternating Currents Analytically and Graphically Treated*, etc.

(2) In a circuit to which Ohm's law does apply, resistance being constant, current will always be directly proportional to the electromotive force. Where the circuit is supplied from a voltaic battery, the electromotive force may be changed, simply by varying the number of cells. If a battery be arranged in series, the positive pole of one cell to the negative of the next, there results the potential rising step-wise from cell to cell, as indicated in Fig. 7.

The total potential - difference upon which the electromotive force of the circuit depends is proportional to the number of cells A, B, C, D, E. It is the sum of the electromotive forces due to these individually.

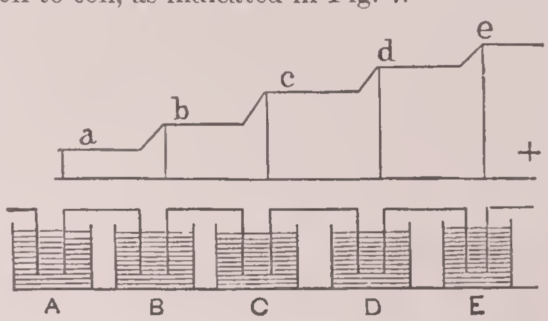

Fig. 7.—Diagram showing the rise of potential-difference in a battery arranged in series.

(3) Circuits in which continuous currents are flowing owe their condition to one or more *generators*, which may be voltaic cells, dynamos, or other sources. Between the terminals of these exist differences of potential. The complete circuit consists of two portions—that within the generator (inner circuit), and that which forms the path along which equalization of potential is taking place (outer circuit). The resistance of both of these must be taken into account

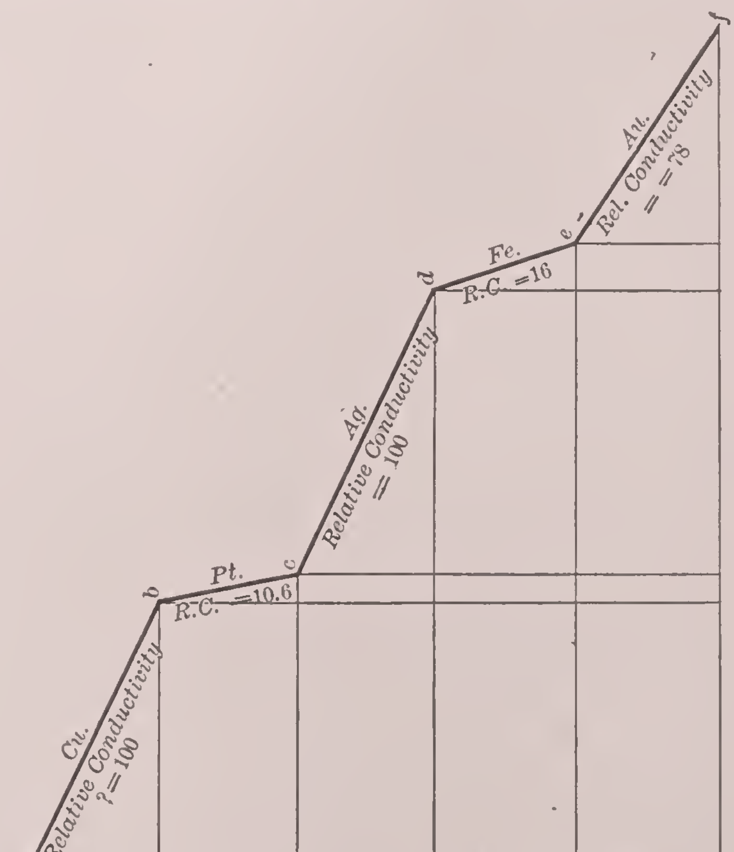

Fig. 8.—Fall of potential.

in calculating current by Ohm's law. Throughout the outer circuit there is continuous fall of potential from the positive pole of the generator to its negative pole. The rate of fall for each portion of the circuit depends upon the resistance per unit of length of the conductor traversed by the current. Through regions of high resistance the fall of potential is rapid; through good conductors of large cross-section it may be inappreciable.

In the accompanying diagram (Fig. 8) a circuit between two points is represented. The total difference of potential between a and f is 100 volts, maintained, say, by a storage battery of fifty cells. This is indicated by the vertical distance between a and b. The fall of potential from a to the successive points b c d e f is represented likewise by vertical distance, the rate of fall by the gradient of the line which connects them.

Abscissas in the diagram represent *lengths* of the various conductors used in the circuit.

The circuit contains:

(1) 20 ohms of copper wire (between			a	and	b)
(2) "	platinum "	"	b	"	f
(3) "	silver "	"	c	"	d
(4) "	iron "	"	d	"	e
(5) "	gold "	"	e	"	f

The cross-sections of these wires are all the same, and their lengths respectively indicate the relative conductivity of the metal. The fall of potential through each piece will be the same, since the resistances are the same, and by Joule's law the amount of heat developed in each (I^2R) per second will be the same. If all other resistances beyond a and f be supposed to be negligible, the current by Ohm's law will be one ampère, the energy developed in each section will be 20 watts, or 4·8 calories per second. In wires of equal diameter the radiating surface will be proportional to the length. The good conductors, copper, silver, and gold, being long and of relatively large surface, will remain cool while carrying current sufficient to raise the temperature of the platinum and iron to points high above the surrounding atmosphere. The difference may be brought out in a striking manner by sending a heavy current through a composite circuit of the kind under discussion. It will be found that the platinum becomes white hot and the iron red hot, while the copper and silver are still barely warm to the touch. This is an illustration of the physical principle made use of in lighting by incandescence (see articles ELECTRIC LIGHTING, ELECTRIC ARC, and GLOW-LAMP); also in heating by electricity.

Resistance, which is one of the factors which enters the equation for Ohm's law, is the reciprocal of *conductivity*, is directly proportional to the length of the conductor, and inversely proportional to its cross-section. Resistance in the diagram (Fig. 8) is measured by the fall of potential through a unit length of the conductor in question, i. e. by the gradient of the lines joining the successive points, a b c, etc. As there is a direct and constant relation between the resistance of a conductor and the heat evolved by the passage of a current, it is evidently possible by using conductors of equal length and equal cross-section to compare the resistances of different substances in terms of heat-units. One of the most ingenious and widely used devices for comparing electrical resistances is that which is known as Wheatstone's bridge, introduced by Sir Charles Wheatstone, and described in the article WHEATSTONE'S BRIDGE (*q. v.*).

Electricity from Heat (thermo-electricity).—The direct production of difference of potential in a metallic circuit by application of heat is perhaps a less important phenomenon than that of the transformation of electrical energy into heat (discussed under heading JOULE'S LAW). It has, however, numerous interesting applications. Whenever two metals are arranged so as to form a closed circuit and the surfaces of contact differ in temperature, a voltaic current will flow through the circuit. The electromotive force, generally very small, depends upon the difference of temperature of the junctions, although rarely in direct proportion to that difference, excepting through small ranges. The electromotive force varies greatly with the nature of the metals in the circuit. For each temperature it is possible to arrange a list of substances so that, when any two of them are made into a thermo element, current will flow through the hot junction from the metal which is first in the series into the other. Such a list is called the thermo-electric series for that temperature. By measurement of the electromotive forces generated by a difference of one degree (centigrade) in the case of the union of each member of the series with some selected metal, the relation of each to all the other members of the list may be expressed quantitatively, and the performance of any given couple may be indicated. The following is such a table:

Thermo-electro series and E. M. F. in volts between each member and the metal lead, when a difference of one degree (centigrade) exists between junctions. (The average temperature of the two junctions is 20° C.)

Bismuth $+ 89\cdot \times 10^{-6}$ volts.	Silver $- 3\cdot0 \times 10^{-6}$ volts.
Cobalt $+ 22\cdot \times 10^{-6}$ "	Zinc $- 3\cdot7 \times 10^{-6}$ "
Mercury $+ 0\cdot418 \times 10^{-6}$ "	Copper $- 3\cdot8 \times 10^{-6}$ "
Lead $+ 0\cdot0 \times 10^{-6}$ "	Iron (soft) $- 17\cdot5 \times 10^{-6}$ "
Tin $- 0\cdot1 \times 10^{-6}$ "	Antimony $- 2\cdot8 \times 10^{-6}$ to $26\cdot4 \times 10^{-6}$ volts.
Platinum $- 0\cdot9 \times 10^{-6}$ "	Tellurium $- 502\cdot \times 10^{-6}$ "
Gold $- 1\cdot2 \times 10^{-6}$ "	Selenium $- 807\cdot \times 10^{-6}$ "

Compiled for other temperatures or ranges of temperatures, other values would be obtained, and certain members, notably iron, would have other positions in the series. This is due to the fact that the electromotive forces are never simply proportional to temperature differences. In nearly all cases, indeed, the current generated in the circuit containing a thermo element will reach a maximum at some definite temperature difference, falling off again as the difference between the junctions increases, and finally being reversed in direction. This phenomenon, in the case of an iron-copper element, is shown graphically by means of the curve, Fig. 9.

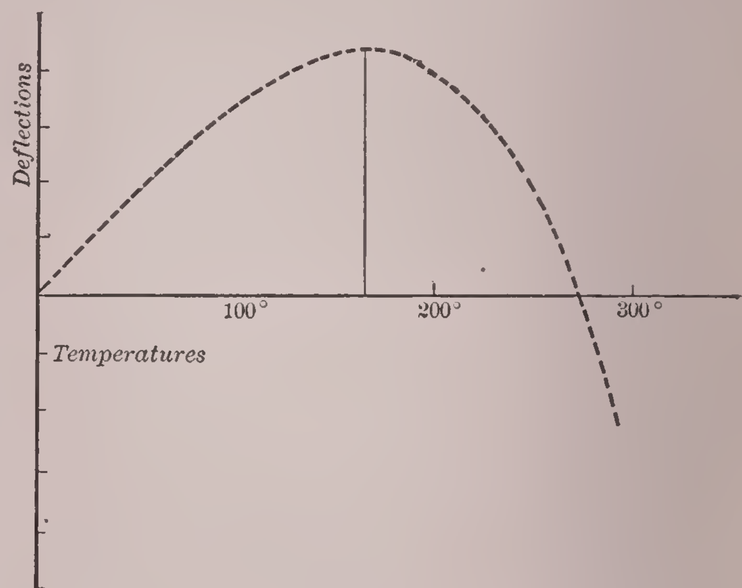

FIG. 9.

One junction of such an element being kept at 0° centigrade (32° Fahrenheit), the other is heated slowly, and the deflection of a galvanometer with which the element is in circuit is followed. Starting from zero, the deflection rises at first in direct proportion to the rise of temperature, then more slowly. It reaches maximum at 169° centigrade (336·2° Fahrenheit) and zero again at 270° centigrade (518° Fahrenheit), after which it continues indefinitely in the negative direction.

Thermo-currents afford a most convenient and delicate means of measuring temperatures. The method is employed especially in cases where the temperatures to be measured are in localities inaccessible to direct observation by means of ordinary thermometers; as for example, in the study of subterranean or deep-sea temperatures, or of the fluctuations occurring within the cylinder wall of a steam-engine, or where the temperatures lie beyond the range of the mercury thermometer, as in the measurement of the heat of furnaces, or of the extreme cold obtained by the liquefaction of oxygen, etc.

Another and even more interesting field is in heat measurements of such character that ordinary thermometers are of insufficient delicacy, as in the exploration of the spectrum. The materials used in thermo elements for heat measurements depend upon the temperatures to be studied. To determine flame temperatures, metals of the platinum group would be selected; where great delicacy is desired the metals at the ends of the thermo-electric series are combined, notably antimony and bismuth; where greater sensitiveness than can be obtained with a single element is necessary, or higher potential-difference is desired, several elements are united to form a THERMOPILE (*q. v.*). When a current is sent through a thermo element from any other source, it is found that, aside from any heating effects coming under Joule's law, difference of temperature between the junctions is brought about, such as to produce a current opposed to that to which the heat is due. For instance, if a bar of bismuth be introduced into a circuit of copper through which a current flows, the junction at which the current passes from the copper to the bismuth will be heated, while the other junction will be cooled. This phenomenon is called, from its discoverer, the *Peltier effect.*

Considered as a generator of the electric current, the thermopile is a machine of low efficiency, the proportion of heat energy transformed to that lost by conduction and correction being very small. By means of certain forms of the apparatus, however (which are described in the article THERMOPILE), very considerable currents may be obtained; and the cheapness of the source of energy, as compared with that available in voltaic cells, sometimes more than compensates for the low efficiency of the method by which it is transformed.

Electro-magnetic Induction.—The fundamental fact in considering the magnetic relations of the electric current is the formation of a field of force surrounding every conductor through which such currents flow. The field exerts forces upon other conductors carrying current and upon magnetic poles. Magnets in the field tend to set themselves parallel to the lines of force, the poles tending to move along the lines, but in opposite directions. These forces are identical as to size, and form a couple which sets the axis of the magnet into the direction of the lines. Conductors bearing current tend to move at right angles to the lines of force, being acted upon because of their own lines, in accordance with a principle to be stated later. The classical observation of the action of an electric circuit upon magnets is that of Oersted (1819), which has been formulated by Ampère in the following manner: "If the observer imagine himself in the circuit, swimming with the current and facing the magnetic needle, the north-seeking pole of the latter will always be deflected to his left hand."

The presence of the field of force around a conductor may be shown by means of iron filings, following the meth-

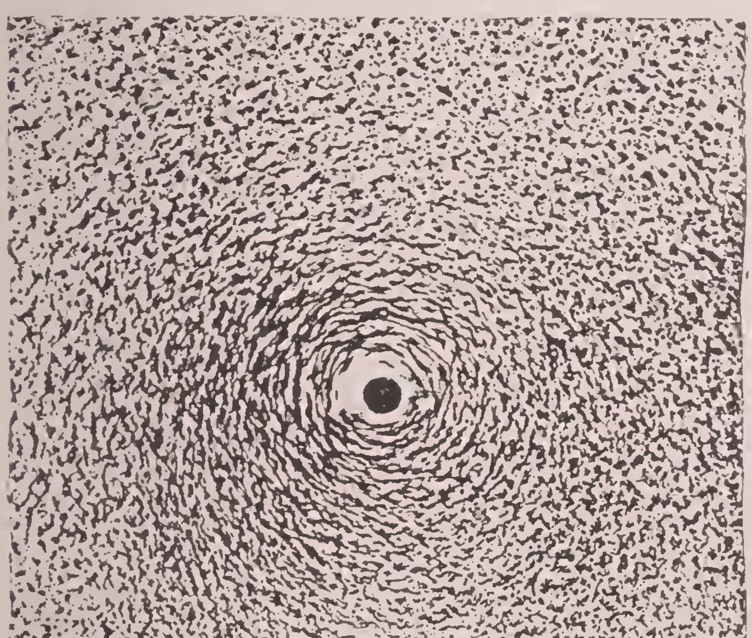

FIG. 10.

od commonly used in the study of magnetic fields. The lines of force are closed curves surrounding the conductor. In the case of a straight wire situated in a medium of uniform permeability, they are concentric circles, the planes of which are at right angles to the axis of the wire (Fig. 10). Lack of homogeneity in the medium will distort the lines, but they always remain closed curves. Fig. 11 shows the distortion of the field by the introduction of a piece of iron into the neighborhood of the conductor.

Fig. 12 shows the character of the field around a wire carrying a current, when the conductor is in the axis of a nearly complete ring of soft iron. It will be noticed that the lines of force are everywhere diverted from their normal position as concentric circles around the wire, and that they tend to pass through the iron rather than through the surrounding medium. Figs. 10, 11, and 12 are directly from photographs of the magnetic field, made by a modification of the ingenious method described by Houston and independently by Thwing in 1892.

It is interesting to compare the electro-magnetic field surrounding a cylindrical conductor carrying current with

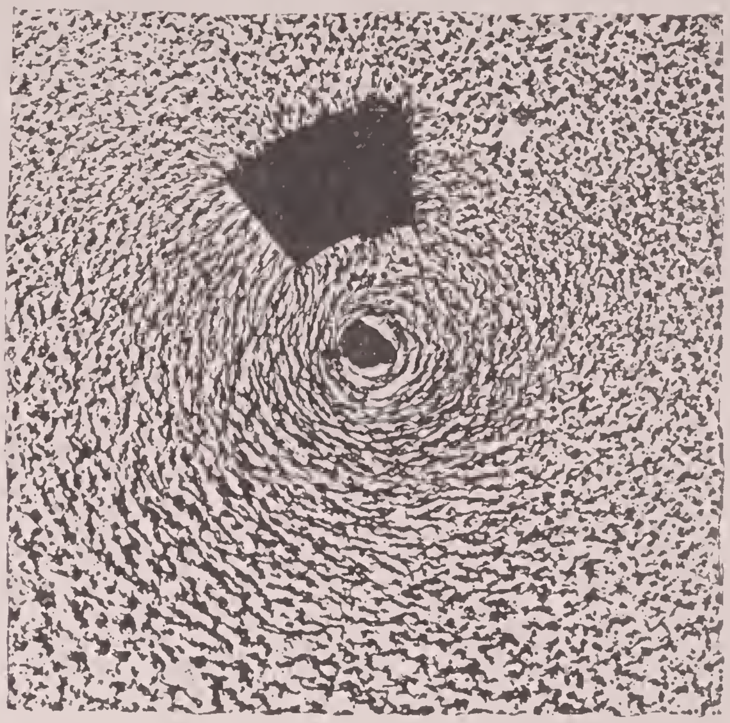

FIG. 11.

the electrostatic field of a cylinder charged to high potential. The lines of force in the latter case are radial. In the electrostatic field electrified particles tend to move along the lines of force, either away from or toward the body to which the field is due. In the electro-magnetic field, magnet poles tend to move along the closed lines of force as just stated, but conductors move at right angles to the lines in directions determined by the direction in which the current is flowing.

All cases of the movement of conductors in the magnetic field, as well as of the movements of magnets near other magnets or near voltaic circuits, may be dealt with by taking advantage of the following assumed properties of lines of force:

(1) Lines of force in the same direction repel each other, and *vice versa.* (2) The direction in which a north-seeking

FIG. 12.

pole is urged along a line of force is taken as the positive direction. From Ampère's rule for the deflection of the needle and the above, it follows that to an observer looking along a wire in the direction of the current lines of force have the clockwise direction, and in a wire carrying current toward the observer the direction of the lines is counter-clockwise (Fig. 13).

From the repellent and attractive forces between lines, it follows that the conductors *a* and *b*, carrying current in the same direction, will be drawn together, while *b* and *c* will be repelled.

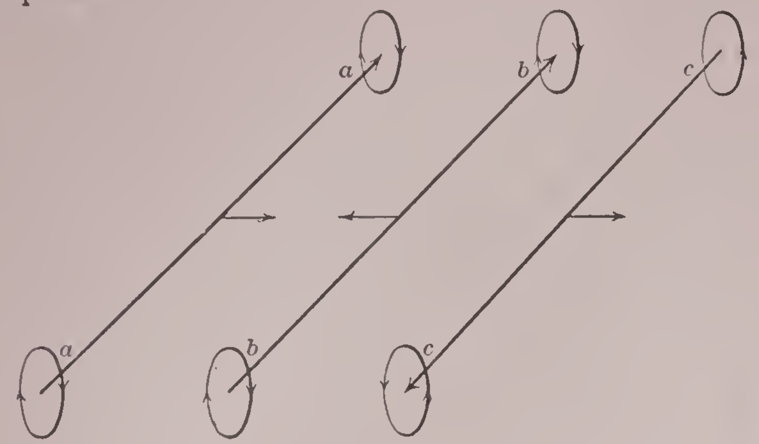

Fig. 13.

This *mutual action of currents* was observed by Ampère, who stated his results thus:

Ampère's Rule.—(1) Currents in parallel circuits attract each other when flowing in the same direction, and repel when flowing in opposite directions.

(2) Circuits making any angle with one another tend to become parallel with the current flowing in the same direction through them.

It is usual to attribute these forces between circuits, and the analogous effects which occur when wires carrying current are brought near to magnets or when one magnet is in proximity to another, to the mutual action of the two fields of force. The effect is entirely independent of the source of the fields, and the movement which will tend to be produced may be predicted whenever the directions of the two systems of lines of force are known.

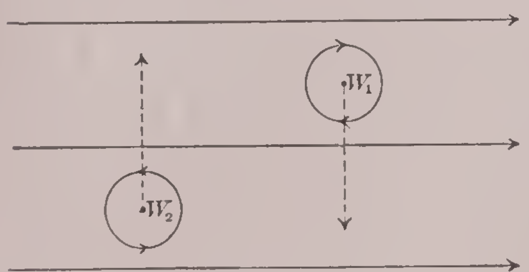

Fig. 14.

Thus a wire (w_1, Fig. 14) normal to the paper and carrying current away from the observer, in the uniform field of force represented by the long, parallel arrows, will tend to move downward. Wire (w_2) carrying current toward the observer will travel upward. Upon this reaction is based one of the most important of electrical devices—the motor. See Electric Motor.

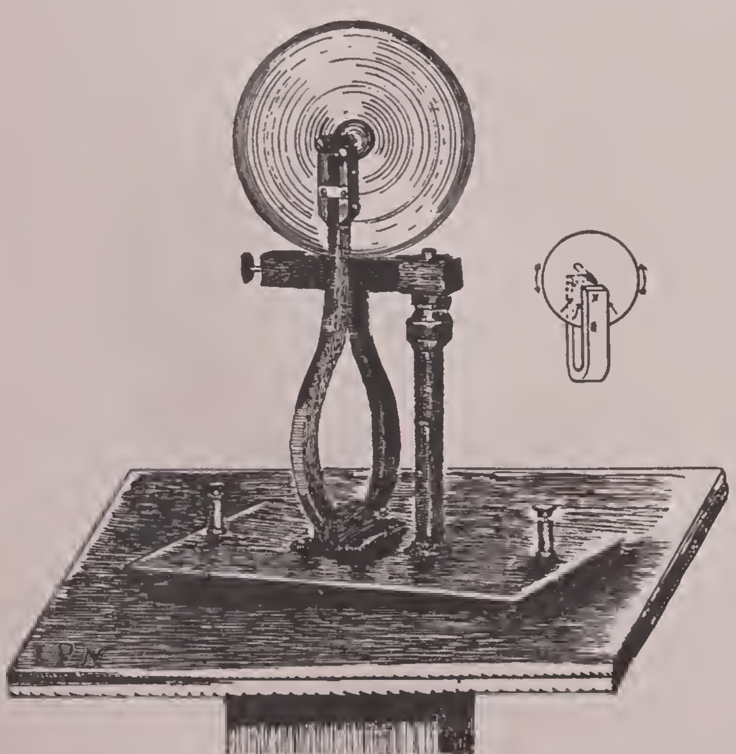

Fig. 15.

Faraday's disk motor is an application of the principle in an exceedingly simple and instructive form.

Between the poles of a horseshoe magnet (Fig. 15) is mounted a thin disk of copper, its axis parallel to the lines of force, so that the sector vertically below the axis is in the field. At its lowest point the periphery of the disk dips into a trough of mercury. If current be sent through the disk, entering through the mercury and leaving by way of the axle, the lines of flow will be vertical and at right angles to the magnetic field, which will act upon that portion of the copper which carries current, driving it out of the field in the direction indicated by the arrow. The result is a rapid rotation of the disk, the direction of which depends upon the direction in which current passes through it and the polarity of the magnet.

Even the earth's field exerts such action upon every conductor which carries current. The effect is shown in a striking manner by the apparatus shown in Fig. 16.

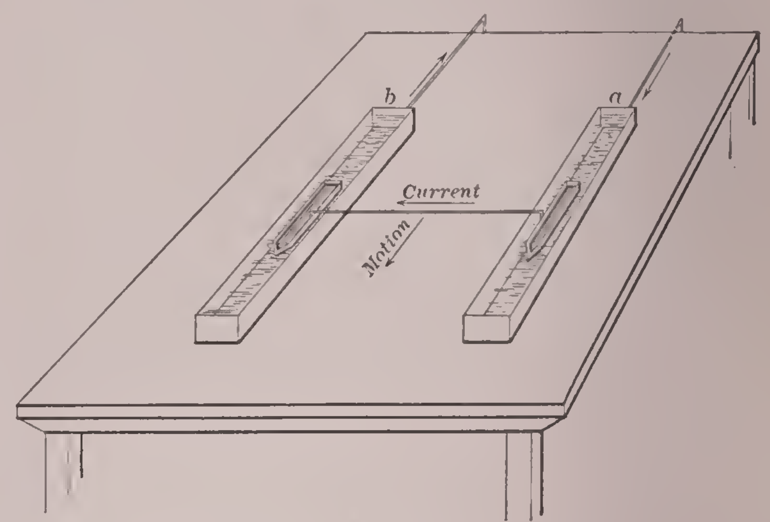

Fig. 16.

Two parallel troughs of copper are filled with a conducting liquid, preferably an acidulated solution of copper sulphate. Two boat-shaped copper vessels are joined by a rod of the same metal, forming a sort of catamaran. This double boat is allowed to float in the two troughs as indicated in the diagram. Current introduced at *a* will flow by means of the connecting bar to the other trough, finding exit, and returning to the battery at *b*. By the action of the earth's magnetic field upon the connecting bar the boats will be driven from end to end of the trough at considerable speed.

The application of the general principle to this case may be seen by reference to Fig. 17, in which *w* is the conductor between the boats seen in cross-section, the current flowing from the observer. The vertical component of the earth's magnetism *v v*, acting upon the lines of force surrounding the wire, tends to drive the latter in the direction of the dotted arrow *a*.

Thus far the case of straight wires has been considered. Conductors are frequently arranged so as to form a cylindrical coil (helix or solenoid). When current traverses such a coil, the lines of force unite to form a single set. They enter the coil at the end in which the current viewed from without axially travels clockwise, and issue from the other end. Such a coil, hung from its center, its axis horizontal and free to rotate about a vertical suspension, will set itself axially in the magnetic meridian when current is sent through it. To an observer looking northward toward the south-pointing end of the coil the current then flows clockwise.

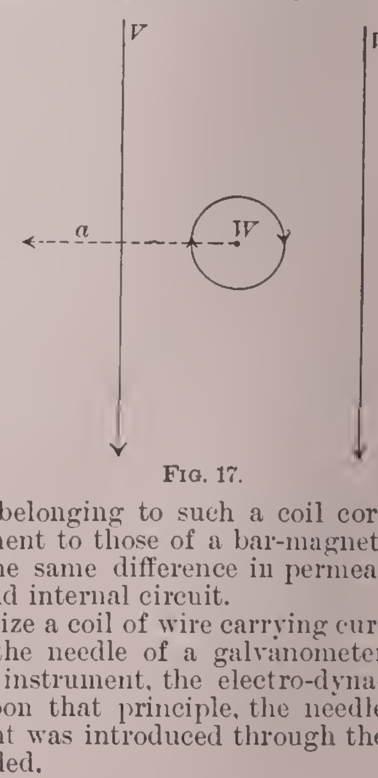

Fig. 17.

The system of lines of force belonging to such a coil correspond precisely in arrangement to those of a bar-magnet, excepting that there is not the same difference in permeability between the external and internal circuit.

It is, indeed, possible to utilize a coil of wire carrying current instead of a magnet for the needle of a galvanometer (*q. v.*). Weber's well-known instrument, the electro-dynamometer, was constructed upon that principle, the needle being a coil into which current was introduced through the wires by which it was suspended.

By introducing a core of iron into the coil, the carrying capacity for lines may be increased many fold, with relative increase of the outer magnetic field. Such an arrangement, indeed, constitutes an electro-magnet. The performance of the electro-magnet is further discussed in MAGNETISM OF IRON (*q. v.*). It is sufficient to note here that the function of the iron core is simply to *increase the magnetic conductivity of the region within the coil*, and that a helix without iron is as truly a magnet as a bar which has been previously magnetized (permanent magnet), or as one in which the polarity is maintained by the action of a coil surrounding it (electro-magnet).

The movement of an electric conductor through the magnetic field, like most phenomena involving transformation of energy, is reversible.

The reversed process may be stated in general terms as follows: Whenever a conducting body is moved in a magnetic field in such a direction as to cut lines of force, there is set up within the moving body a current of such direction as will oppose the motion. Since parallel lines of force in the same direction repel each other, the current induced by any movement of the conductor must create lines of force around the latter, which (on the side toward which the movement takes place) are *parallel to those of the field and in the same direction.* In Fig. 18, v_1 and v_2 are the velocities both as to direction and magnitude, with which the wires w_1 and w_2 are moved through the field. The induced current in w_2 due to this motion will flow toward the observer; in w_1 it will flow away from him. Where the direction of the movement is not normal to the lines of force, the component of the velocity, which is at right angles to the lines, is to be considered.

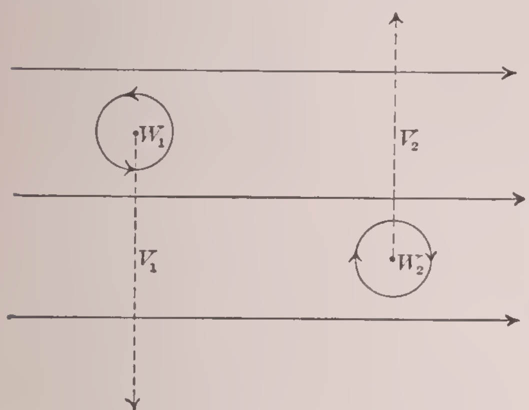

FIG. 18.

The movement of bodies in a magnetic field produces primarily difference of potential between their parts, and consequently electromotive forces and current. The induced electromotive force is proportional to the number of lines cut by the conductor in a unit of time, i. e. to the normal velocity-component, to the strength of the field, and in uniform fields to the length of the conductor measured at right angles to the lines.

Currents thus produced are *induction currents.* They last only during the motion which induces them, and depend upon that motion for their direction and magnitude in the manner stated above.

The DYNAMO-ELECTRIC MACHINE (*q. v.*) is a device for utilizing the principles just laid down for the purpose of generating current. It depends upon the movement of conductors through strong magnetic fields after methods which are discussed at some length in the article just cited. One of the simplest forms of dynamo is the Faraday disk (Fig. 15). When a *current* is sent through the disk it becomes a *motor*, as has been noted already. When *driven through the field*, on the other hand, there will be difference of potential between periphery and axle, and when these are connected metallicly current will flow through the outer circuit. The direction of this current, which will be of such direction as to oppose the motion of the disk, may be deduced from the principles already enunciated.

The great economical importance of the dynamo-machine lies in the fact that it enables the engineer to transform energy of motion directly into electrical form, instead of being obliged to utilize energy derived from the chemical reactions between the expensive materials of the voltaic cell.

It is shown in the article ELECTRIC LIGHTING (*q. v.*) that the development of that great industry depended upon the perfection of the dynamo, and the same thing may be said of every application of electricity involving the use of any considerable power.

The method of cutting lines of force which is used in the dynamo consists in the rapid revolution of a coil or set of coils of wire (the armature) between the poles of a magnet. At first permanent magnets were used. Machines with such magnets are classed as magneto-generators. Fig. 19 shows a well-known early type. Later, electro-magnets were introduced on account of the much stronger field obtainable. The current to excite the electro-magnet in early forms was derived from some external source, then from the dynamo itself. An intermediate type, shown in Fig. 20, carried a small magneto-generator upon the yoke to magnetize the coils of the large machine. This form of dynamo was therefore "separately excited" at first and then became "self-exciting." It was found in practice that nearly all dynamos carried sufficient residual magnetism in their magnet cores to render them self-exciting from the moment of starting. Extraneous means of magnetizing the fields of dynamos therefore fell into disuse.

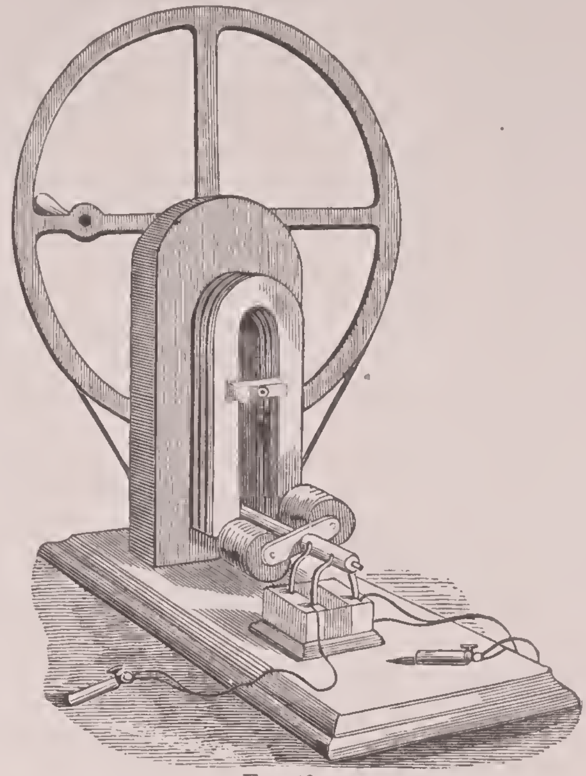

FIG. 19.

To induce currents in a conductor in the magnetic field it is not necessary to move the conductor. Analogous effects may be obtained by causing the field itself to fluctuate in strength or to suffer any rearrangement of its lines. The following is a typical case: Within a coil of wire, and having the same axis, is a second coil. If the inner coil be brought into circuit with a battery, current will flow through it giving rise to lines of force, which in surrounding it will embrace the outer coil also. The effect upon the latter is the same as if it had suddenly been brought from a distance into a field previously formed. There is a very rapid cutting of the lines of force by the outer coil, which induces current during the brief period necessary to the establishment of the field. The entire phenomenon is over in a small fraction of a second of time, the precise interval depending upon the conditions of the circuit. Fig. 21a is from a photographic record of what takes place when current is suddenly sent into a coil of 70 ohms resistance, the impressed electromotive force being 15 volts. During the period of time covered by this curve, between *a* and *b* there will be induced current flowing in the secondary (outer) coil. Its time curve (*c d*, Fig. 21a), however, will not be like that of the primary. It will reach a maximum at the instant when the *rate of change* in the primary is greatest, i. e. when the establishment of the field was taking place most rapidly.

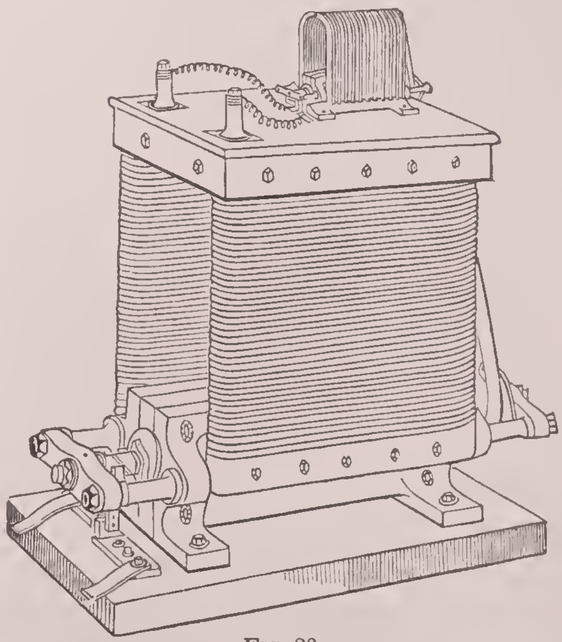

FIG. 20.

The direction of the induced current may be derived from the consideration that the establishment of the field is equivalent to movement into the field, i. e. into the neighborhood of the primary coil, so that the *induced* current which

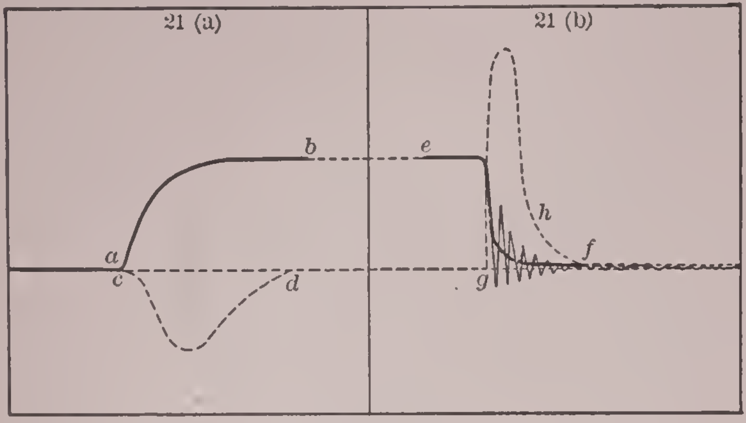

Fig. 21.

opposes the motion must be in a direction opposite to that in the primary. The law may be stated thus:

In neighboring wires the introduction of current into one produces an opposite induced current in the others, the duration of which corresponds to the interval required to completely establish the field of force due to the primary current.

The instant that the primary current has reached its normal value all induction ceases. Let the current be stopped, however, by breaking circuit, and a disappearance of the field of force follows, which is equivalent to the removal of the secondary circuit to a distance, and which induces a current to oppose such motion.

In general, therefore, *in neighboring wires, one of which carries current, the effect of breaking circuit is to induce current in the others, the direction of which is the same as that of the primary, and the duration of which is the interval necessary for the complete disappearance of the field of force due to the primary current.*

The duration of these induced currents is a question involving the resistance, self-induction, and capacity of the two circuits; also the character of the medium within which the field must be established or destroyed. The complete discussion lies quite beyond the scope of this article; it may, however, be noted as of some practical import that the rise of the primary current is in general less rapid than its decadence, and that therefore the induced current rises to a higher value, and is of shorter duration in the latter case. For example, the photographic record of the dying away of the current in the 70-ohm coil, already referred to, when circuit was suddenly broken, is shown in Fig. 21b (curve *e*, *f*) and the induced current by the dotted curve (*g*. *h*.).

These photographic traces (*a b* and *e f*) were obtained by the movement of a mirror attached to the plate of a telephone receiver, according to the ingenious method devised by Dr. Fröhlich, of Berlin (1890–91).

The oscillations shown in the curve *e*. *f*. are the natural vibrations of the telephone plate upon being suddenly released from tension. The heavy curve intersecting them represents the curve of current. The phenomena arising when a voltaic circuit is opened or closed are not always of the simple character shown in these two diagrams. It is found, for instance, that when the capacity of the circuit bears certain relations to the resistance and self-induction, the rise of current or its decadence will be *oscillatory*, with corresponding oscillations of induced current in the secondary circuit.

Electro-magnetic induction is a phenomenon involving the transformation of energy. The mere establishment of an electro-magnetic field of force, like the creation of an electrostatic field, involves the expenditure and storage of energy, to be utilized when the field disappears again. Every movement of a conductor through a field meets with resistance, the surmounting of which requires the expenditure of energy equivalent to that which is represented by the induced current. The induced currents, for example, which circulate in a block of metal driven rapidly through the magnetic field are transformed into heat under Joule's law. If the Faraday disk (Fig. 15) be driven between the poles of a powerful magnet, it will soon rise in temperature above the boiling-point of water. A strip of copper mounted to oscillate between the poles of such a magnet (see Fig. 22) will swing freely so long as the magnet is not in circuit, but when the field is established, powerful eddy currents are set

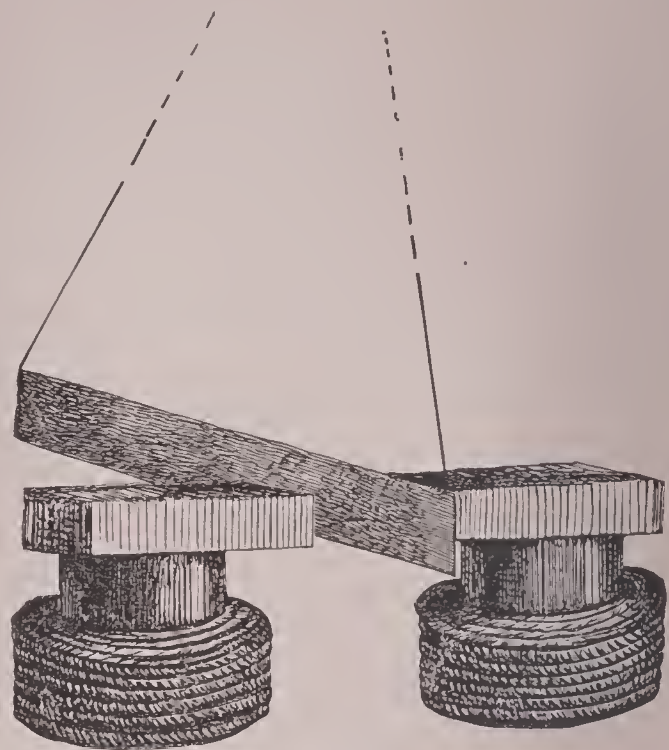

Fig. 22.

up within the copper, resisting its motion. Whatever be its amplitude of vibration, the strip will be brought to rest within the period of a single oscillation. The experiment is a most striking one, the motion of the pendulum being checked as if by passing through some viscous medium. These eddy currents, or Foucault currents (after their discoverer), are a serious source of loss in many forms of electrical machinery. They can be guarded against in a great measure by lamination of those parts of the machine which cut lines of force.

The induction coil (Ruhmkorff coil, spark coil) is a form of apparatus for the utilization of the induction effects produced by making and breaking circuit. It consists of a primary and a secondary coil, one within the other, the common axis of the two being occupied by a core of iron

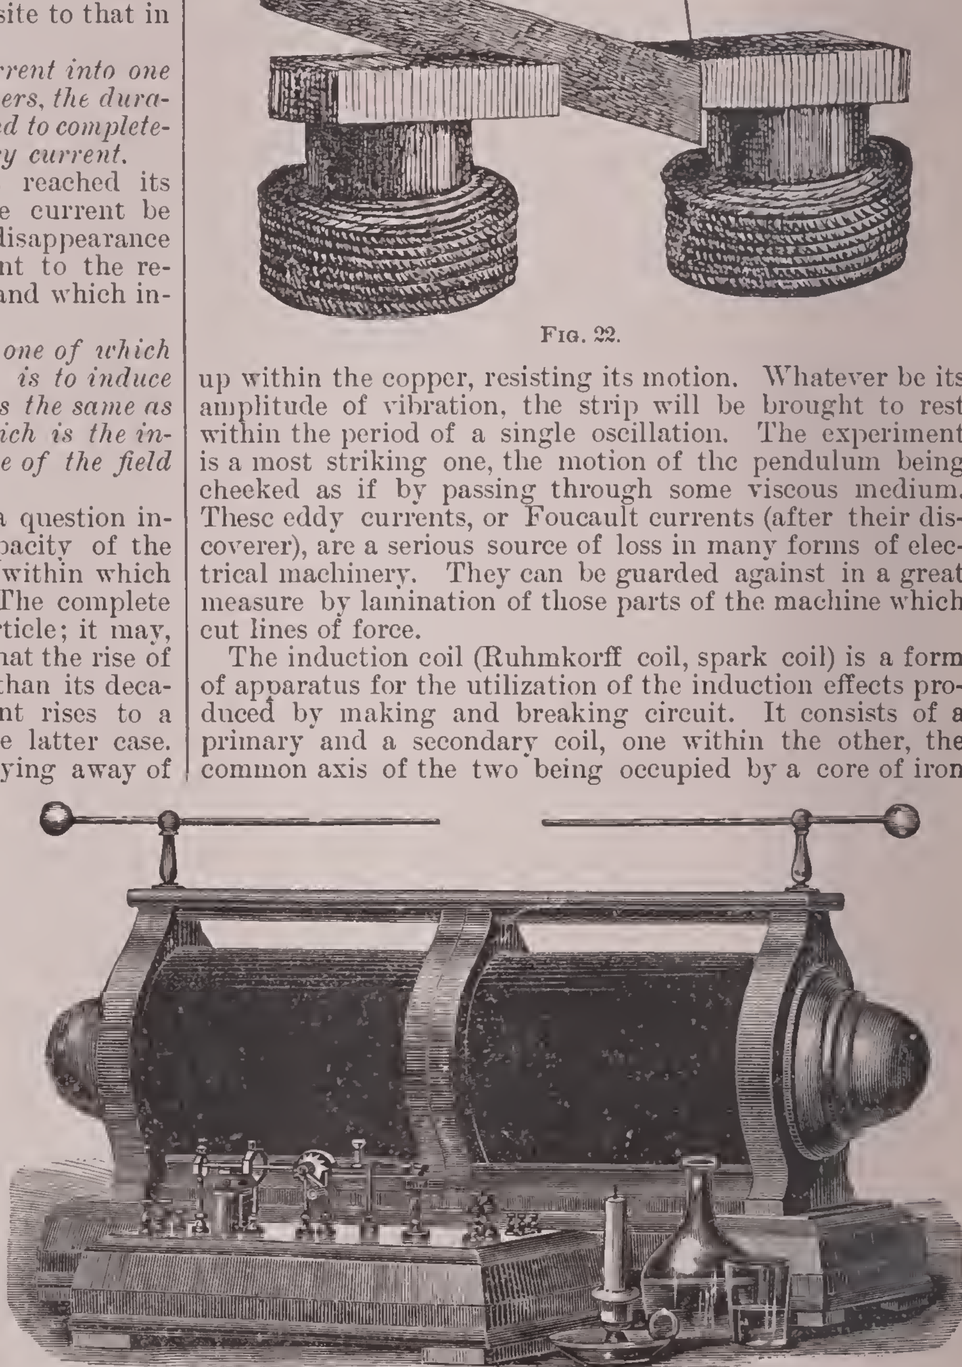

Fig. 23.

wires. Since the ordinary use to which the induction coil is put is to obtain spark discharges similar to those obtained from the Holtz machine and devices of that character, the primary usually consists of a few turns of *heavy wire*, the secondary coil of very many turns of *fine wire*. The details of construction of such coils, and some account of their performance, are given under Induction Coil (*q. v*).

The currents obtained by induction, either in the movement of conductors in the magnetic field, as in the case of the dynamo, or by making or breaking circuit, as in the Ruhmkorff coil, are identical with voltaic currents, being capable of producing electrolysis, of developing heat in accordance with Joule's law, and of magnetic action. Where the potential rises to values giving disruptive discharge, on the other hand, all the phenomena usually identified with electrification by friction or by electrostatic induction occur.

Induction currents arising from the presence of undulating or alternating currents in the primary coil have found extensive application. The telephone transmitter (see TELEPHONE), the MICROPHONE (*q. v.*), and the system of telegraphy to and from moving trains are examples in which undulatory currents, often of very intricate character, are transmitted from one coil to another by induction. The TRANSFORMER (*q. v.*; see also ALTERNATE CURRENTS) is an induction coil for the transfer of the alternate current from one circuit to another, and thence, often at greatly changed tension, to a distance. A notable illustration of its use was that of the transmission of power by means of transformers from Lauffen, on the Neckar, to Frankfort, during the Electrical Exposition of 1891.

Some of the most interesting phenomena connected with electro-magnetic induction are those which take place when the medium within which the field of force is set up is iron. These are considered under MAGNETISM OF IRON (*q. v.*).

Other phenomena, also of the utmost interest in their bearing upon our conception of the nature of electricity and its relation to other branches of physics, particularly to light and the science of radiation, are treated in the article LIGHT, THE ELECTRO-MAGNETIC THEORY OF (*q. v.*).

For further information upon the topics contained in the present article, the reader is referred to such treatises as Wiedemann, *Elektricität*; Riess, *Die Riebungselektricität*; Frölich, *Handbuch der Electricität und Magnetismus*; Larden, *Electricity*; Thomson, *Lessons in Electricity and Magnetism*; also to the standard treatises on physics.

For the mathematical theory of electricity, the works of Maxwell, Thomson, Boltzmann, Hertz, and Poincaré should be consulted.

In electrotechnics, Thomson's *Dynamo-electric Machinery*; Dredge, *Electric Illumination*; Kittler, *Handbuch der Elektrotechnik*; Fleming, *The Alternate-current Transformer*; Ewing, *Magnetism of Iron and other Metals*; also the pages of such journals as *La Lumière Électrique*, the *Electrician*, *Electrical Review*, and *Electrical Engineer*, of London; the *Electrical Engineer* and the *Electrical World*, of New York, are among the most valuable sources of information.

Finally, the transactions of the great scientific academies and technical societies afford the student of electricity means of consulting original sources, as do also the pages of the various physical journals and the reports of international electrical exhibitions. E. L. NICHOLS.

Electricity, Animal: that developed by living animals, such as the torpedo and electric eel. The shock given by a fully grown electric eel is said to be sufficiently powerful to cause death; it is certainly sufficient to knock a man down. Electric currents are claimed by some, and denied by others, to be generated in muscular and nervous tissue, and elaborate experiments have been devised to prove that the electrical action shown by muscle is not a natural attribute of the muscle itself, but due to change produced by injury to the fibers. F. A. LUCAS.

Electric Lighting: a system of artificial illumination in which the source of light is rendered incandescent by the agency of the electric current.

Historical.—Although the beginnings of electric lighting are to be found in certain lecture-room experiments of the very early years of the nineteenth century (in the case of the arc-light as early as 1802), its rise and development as an industrial element and as an important factor in civilization is a matter of the last quarter of that period. From the day when Sir Humphry Davy exhibited his electric light (a magnificent 4-inch arc fed by 2,000 cells of battery) in 1821, the splendor of this source of illumination was recognized. Faraday may have assisted in this experiment of his master, Davy, whom he was soon to succeed as director of the Royal Institution, but although he spent a long life in furthering the science of electricity, he died an old man before the electric arc had come to be a street light in London.

The practical development of electric lighting on a large scale began with the introduction of the dynamo, which machine, in turn, owed its early development almost solely to the desire for cheap and reliable means of generating current for the production of light.

There are three periods into which the history of the rise of this great industry naturally divides itself:

(*a*) From the beginning of the nineteenth century to 1867, during which the only source of current for electric lighting was the voltaic battery, and during which, consequently, the electric light was to be seen only in a few of the better equipped laboratories. (*b*) From 1867 (in which year Werner Siemens and Wheatstone announced respectively the principle of series-wound and shunt-wound self-excited dynamos, and Ladd and Wilde perfected their machines for electric light) to 1879–80. During this period the Siemens and Gramme types of dynamo were developed and perfected, and the electric arc-light began to make its appearance, although still in a tentative way, in the great cities. Toward the end of this period (1877) the Jablochkoff candle was introduced into Paris and London upon a commercial scale. (*c*) The third period, from 1879–80 onward, has been that of the general commercial introduction and development of electric lighting. It began with the perfection of the glow-lamp and the invention of the "open coil" machines of Brush and of Thomson and Houston, which, by virtue of their excellent regulation, greatly hastened the introduction of arc-lighting.

How rapid the growth of electric lighting has been may be gathered from the following statistics:

In 1877 the industrial electric lighting of the world consisted of 300 or 400 Jablochkoff candles in operation in Paris and London, with a few insignificant plants elsewhere. Ten years later there were, in the U. S. alone, 140,000 arc-lights in the "all-night" service of street-lighting, etc., and 650,000 glow-lamps (Martin, *Electrical World*, vol. ix., p. 50).

There were in thirteen principal cities of Germany in that year 3,280 arc-lamps and 50,000 glow-lamps. The same cities, however, contained 1,221,882 gas-flames; so that electric lighting still formed but 4 per cent. of the total of artificial illumination.

In the U. S. a year later there were 102,000 arc-lights and 1,700,000 glow-lamps. In 1889 225,000 and 3,000,000 respectively; and at the present time it is almost impossible to estimate the numbers.

The two great systems of electric lighting, by arc-lights and by glow-lamps, have thus grown up side by side, each without encroaching upon the domain of the other. The arc-lamp is used as a means of lighting streets and large spaces under roof, such as railway stations, markets, warehouses, and wharves. The incandescent lamp finds its proper field in detailed lighting, as in lighting the apartments of hotels and private houses, in lighting steamships and railway trains, and in nearly all "indoor illumination."

The arc-light has as its essential features (*a*) two pencils of graphitic carbon, generally placed in line with one another with common axis; (*b*) a mechanism for maintaining them in a constant position, with the tips nearly, though not quite, in contact, viz., with an air-space of from 1 to 5 mm. The pencils and the intervening air-space form part of an electric circuit through which there flows, as a rule, from 5 to 10 ampères of current, and in certain special cases much more.

The possibility of maintaining a current through such an air-space depends upon the fact that gases, although possessed of insulating power when cold, become conductors of electricity when sufficiently heated. In order to render the resisting medium, air, incandescent, the carbon points are brought into contact. A current then flows, heat is generated at the imperfect junction of the carbons, which, together with the intervening air-film, attain a high temperature. The pencils may then be withdrawn to a distance of several millimeters without extinguishing the arc.

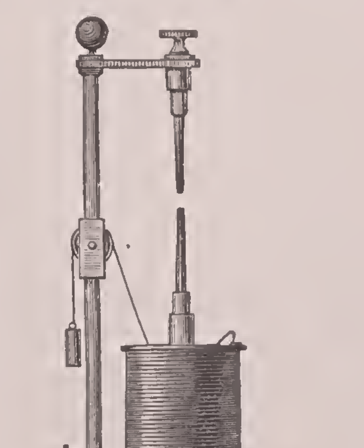

FIG. 1.—Archereau's regulator.

An arc-lamp, to be successful, must contain some device for establishing the arc in this way, and then for maintaining a proper distance between the carbons automatically. The approach of the carbons is performed either by clockwork or by the action of gravity upon the upper carbon, the lower pencil being fixed. The regulator lamps of Duboscq, Foucault, Siemens, and others belong to the former, nearly all lamps in ordinary commercial service to the latter class. As soon as contact between the carbon tips has been made the pencils are drawn apart, either by the clockwork train, driven by a spring but started and stopped electrically, or by a clutch operated directly by an electro-magnet. This play of the carbons, in which they approach each other at every diminution of the current and separate whenever the current increases again, constitutes the regulation of the lamp.

Innumerable devices for performing these operations have been resorted to, most of them based upon the principles just touched upon. One of the earliest of arc-lamps, Archereau's regulator, is shown in Fig. 1. In this lamp the lower carbon is movable, being balanced by a weight which acts over a pulley. When the current passes through the solenoid, the lower carbon-holder, which is partly of iron, is drawn down into the core of the coil until the resistance of the arc reduces the current to the extent necessary to bring about equilibrium between the magnetic forces and gravity. Figs. 2 and 3 show other early forms of the arc-lamp. They illustrate the two types

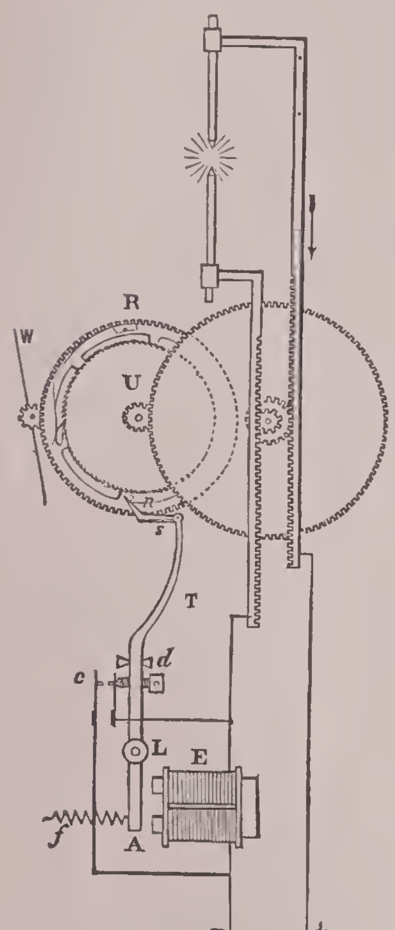

Fig. 2.—The Siemens or Häfner-Alteneck regulator.

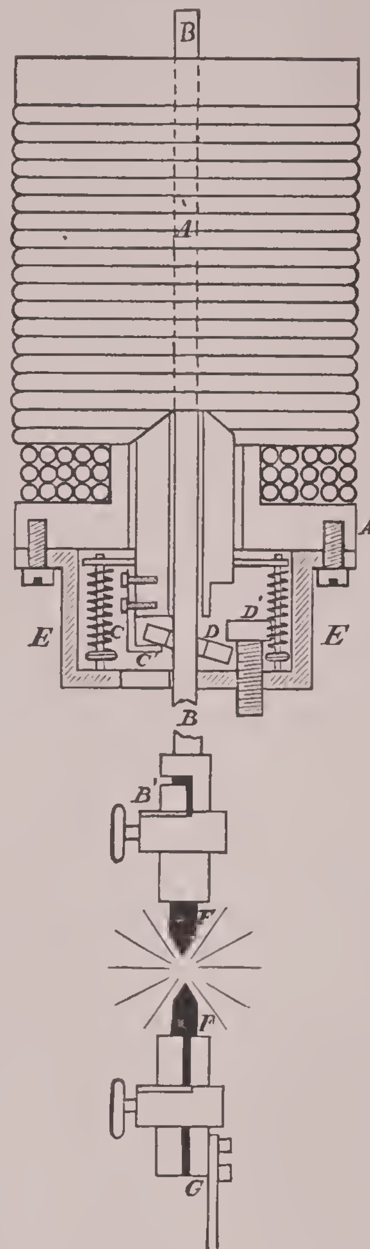

Fig. 3.—The Brush regulator (an early form).

most frequently met with in modern practice. In the Siemens regulator (Fig. 2) the electro-magnet E, which is in circuit with the arc, attracts the anchor A, moving the gang of toothed wheels in such direction as to slightly separate the carbons. By means of the contact device, *c d*, which throws the magnet out of circuit, this movement of the anchor is repeated over and over again until a balance is obtained. Fig. 3 shows one of the older forms of the Brush lamp, of which many modern commercial lamps are modifications. The lower carbon-holder is fixed. The upper one, B B, plays freely within the iron cylinder C, which in turn forms the movable core of the large solenoid A. The clutch consists of a flat brass collar, D, which surrounds the carbon-holder. When no current is flowing, C drops to the bottom of the box E E, and the ring assumes a horizontal position, releasing the carbon, which falls until contact occurs between F and F. The circuit thus completed, the core rises within the coil, D is thrown into an oblique position, clutching the carbon-rod B and lifting the pencil out of contact. The arc once established, the upper carbon is held in its proper position magnetically, every fluctuation of current being followed by a slight readjustment of its position, tending toward the maintenance of equilibrium.

In the case of an arc-lamp fed with direct current, it is found that the positive carbon is much hotter than the negative; also that it is consumed more rapidly. Roughly speaking, the rate of consumption is as two to one, but this ratio, which is by no means fixed, depends upon the voltage of the arc, the amount of current flowing, and the quality of the pencils. The shape of the two pencils is also characteristic, the upper or positive terminal being flattened or even indented, forming a "crater," while the lower carbon is pointed, and there is a tendency for the carbon particles transferred through the arc by the current to build a nipple in the axis of the pencil. These features are shown in Fig. 4.

Fig. 4.

The crater is the surface of highest incandescence in the arc-lamp. Consequently the illumination will be a maximum in those regions surrounding the lamp from which its surface is visible (viz., obliquely below the lamp and at an angle between 40° and 60° from the horizontal plane). Fig. 5 is a diagram indicating the vertical distribution of light from a direct current arc-lamp.

The length of the radius vector gives the candle-power emanating in the direction selected. The form of the curve of illumination will vary in different cases with the length of the arc, the diameter of the carbons, and the amount of energy developed in the lamp. The diagram may be regarded as typical for the case of an ordinary commercial lamp with carbons half an inch in diameter, a potential-difference of 50 volts and 10 ampères of current flowing through the lamp.

In the case of arc-lamps fed with alternating currents the conditions are altogether different from those which exist where the direct current is employed. The distribution of light above and below the horizontal plane is more nearly equal, and the difference in form of the two carbons is less marked. The illumination at any given instant is by no means uniform, but the distribution shifts so rapidly as to defy close measurement.

The candle-power of arc-lights, in general, has been greatly overrated. For example, according to the system in vogue up to 1890, and used to some extent even after that year, lamps were rated at 2,000 "nominal candle-power," the "mean spherical" illuminating power of which was from 250 to 400 candles, and whose brightness in the direction of

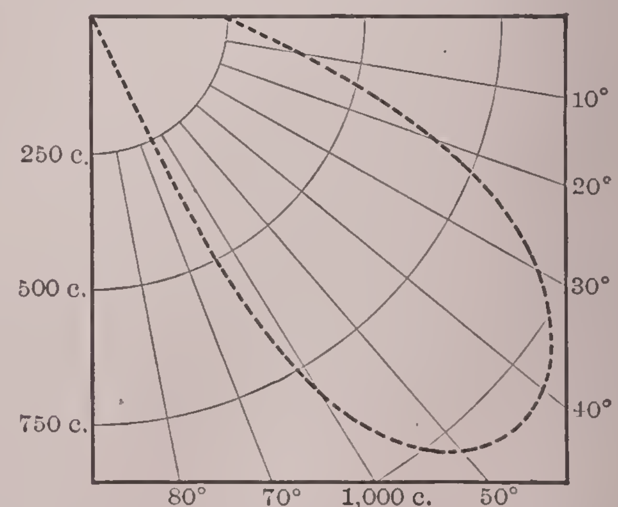

Fig. 5.—Curve of the distribution of light on one side of a direct-current arc-lamp.

the maximum was from 1,000 to 1,500 candles. Fig. 5 is taken from measurements upon such a lamp, the mean spherical candle-power of which is but 491 candles. The maximum radius of the curve, which indicates the intensity of the light in the direction of greatest brightness, corresponds to 1,056 candles.

The candle-power of the average arc-light when viewed in the direction of greatest brightness is found to be about five times the intensity in a horizontal plane. The average "mean spherical candle-power" is about 35 per cent. of the maximum.

For special purposes, such as search-light illumination at sea and the illumination of large areas from a single point, lamps of great candle-power are employed. The increased power is obtained by sending very heavy currents through large pencils. Wherever practicable, however, a better effect is obtained by the subdivision of the light into many lesser units. Many attempts have been made to state the candle-power of the arc-lamp in terms of the current flowing, or of the voltage, or of the electrical energy expended in overcoming the resistance of the arc. The factors which go to determine the brightness, however, are numerous, and some of them, such as the hardness and structure of the carbons, difficult to define and control. M. Palaz (*La Lumière Électrique*, t. 37, p. 420, 1890) finds that the intensity of arc-lamps, measured in the direction of the maximum brightness, may be expressed very nearly by means of the formula

$$I_m = 20i + 0{\cdot}4i^2,$$

where I_m is the illuminating power in carcels and i is the current in ampères. To reduce to candle-power, the result must be multiplied by 9·5 (the ratio of the British candle to the carcel).

Tischendoerfer has tabulated results of measurements of the candle-power of the arc under varying currents, as follows:

2 ampères	25 candles*	12 ampères	1,900 candles
3 "	165 "	14 "	2,425 "
4 "	300 "	16 "	3,000 "
5 "	456 "	18 "	3,625 "
6 "	625 "	20 "	4,300 "
8 "	1,000 "	40 "	13,800 "
10 "	1,425 "	50 "	20,424 "

The quality of the light from the arc-lamp is very different from that of most other sources. The hottest portion perhaps of the radiating center is the arc itself. This is simply a mass of incandescent vapor. Its spectrum is a bright-line spectrum with its energy massed in regions ly-

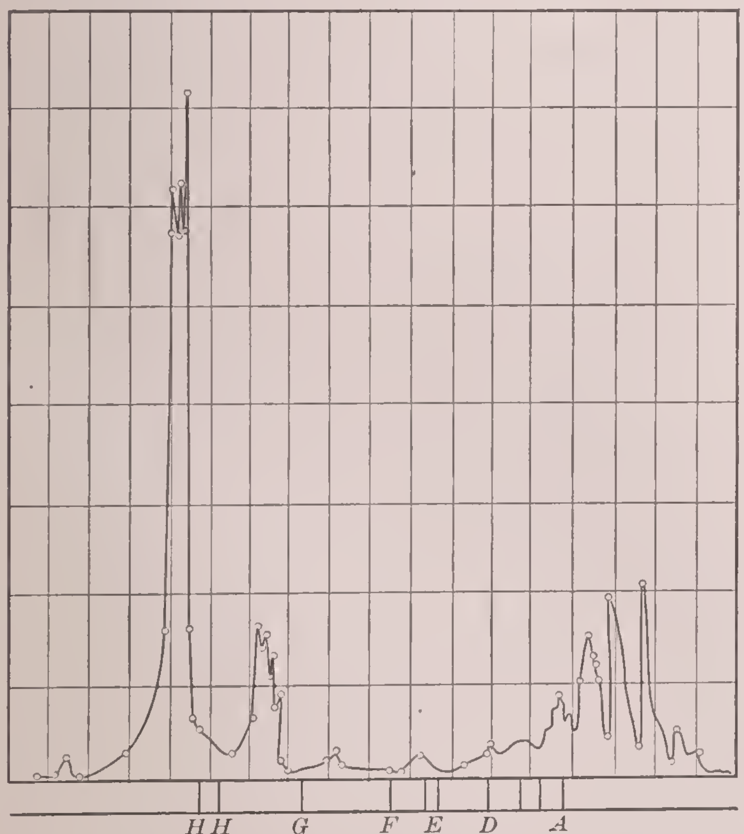

Fig. 6.

ing, for the most part, outside of the visible spectrum. Fig. 6 shows the distribution of the arc-spectrum (according to Prof. B. W. Snow, *Annalen der Physik*, 1892).

The maxima lying beyond wave-length ·8μ are of no interest from the photometric point of view, but the two crests near ·4μ are of great importance. It is to these, which represent complicated groups of violet bands, due to carbon, that the arc-light owes its characteristic bluish color, also its great power of affecting the photographic plate. The light of the arc-lamp, however, is chiefly due to the crater and to the contiguous regions on the two pencils. These afford radiating surface at all stages of incandescence down to the red heat. The radiation from all of these surface elements goes to form the "continuous spectrum" of the electric arc, which, when mingled with the rays of the bright-line spectrum, makes up the *arc-light*.

* Measured in the direction of maximum brightness.

The electric arc-light, as a source of artificial illumination, is surpassed in whiteness and brilliancy by the magnesium light alone.

To counteract the too great contrast of light and shade due to the extreme concentration of the are-light, shades of porcelain and milk-glass, etc., are frequently necessary. These give the desired diffusion, but at the expense of from 40 to 60 per cent. of the light.

Electric lighting by incandescence, while a more recent, has become a more important industry than arc-lighting. Only about 3 per cent. of the artificial illumination in cities is devoted to lighting streets and public places. Nearly all other illumination is of a kind to which the glow-lamp (better known in the U. S. as the "incandescent lamp," and to some extent in Great Britain as the "incandescence lamp") is much better adapted than is the arc-light.

Since its introduction about 1879, after a long period of experimental development in the hands of Lane-Fox, Swan, Edison, Maxim, Weston, and many other inventors, the glow-lamp has undergone minor modifications of construction, but in its essential features it consists of a filament of carbon in an exhausted bulb. The filament, in the absence of oxygen, may be brought to a white heat without combustion. Since the resistance of the form of carbon used in such lamps is high, great heat results from the passage of the voltaic current. In the absence of a surrounding medium, cooling by convection currents does not occur, and dissipation of energy takes place by radiation. Of this radiant energy a certain small proportion is light-giving.

The number of substances capable of carrying current, and refractory enough to remain in the solid form at the temperatures necessary to the production of the desirable light, is small.

The metals of the platinum group were first tried, but lamps in which they formed the incandescent material were very short-lived. The carbon filament alone has been found reasonably permanent under the conditions to which it must be subjected. Carbon has the further advantage of cheapness, and it has high radiating capacity.

The skeleton upon which lamp filaments are formed is generally a strip of fibrous material containing carbon, from which all the more volatile components have been expelled by heating to a bright cherry red under conditions which prevent oxidation. Silk and cotton threads, hairs, strips cut from the bamboo and from similar plants, using the close-grained portions lying next beneath the siliceous coating of the stem, loops stamped from paper by means of a die, and a variety of other materials have been utilized.

Of these, the skeleton in a few cases—notably that obtained from the bamboo—is suitable for light-giving purposes without further manipulation; as a rule, however, it is built up by the deposition of the silvery gray form of carbon which is derived by the decomposition of the hydrocarbons at high temperatures.

To obtain this deposit the filament is surrounded with the hydrocarbon vapor, and brought to a white heat by the application of the current. The vapor is thus decomposed, and the entire surface of the filament is covered with a layer of the residual carbon. This treatment is continued until the filament has acquired the desired cross-section and conductivity. Such filaments are technically known as "treated carbons," in contradistinction to those which have not been through this building-up process. After being thus prepared the filament is mounted in a glass bulb, and the air is exhausted by the aid of a mercurial pump (as the Geissler or the Sprengel pump, for which see PNEUMATICS). See VACUUM. Further description of the construction of the lamp is given in the article LAMPS (electric).

The quality of the light obtained from incandescent lamps is that which a carbon surface would radiate at the temperature at which the filament is maintained. Since that temperature does not differ greatly (although in general it is somewhat higher) from that of gas and petroleum lamp-flames, and since the radiating material is the same (carbon in solid form), the quality of the light of the glow-lamp is similar to that of the above-mentioned flames.

The light of the glow-lamp, however, is due to a carbon surface all at one temperature, which temperature varies with the electrical energy expended in the lamp, while that of gas and petroleum flames is made up of radiation from a great number of separate carbon particles, the temperature of which depends upon their position within the flame. The mean temperature of the flame, on the other hand, is always nearly constant.

In spite of this slight difference of condition, it is possible to find a temperature at which an incandescent lamp will give light, the distribution of energy of which throughout the visible spectrum will agree approximately with that of an ordinary naked "bat's-wing" gas flame. Five lamps tested for the purpose in 1891 (Mr. J. C. Shedd observer) were found to reach the condition of incandescence most nearly corresponding to that of the gas flame (at 15·1 candle-power), the energy expended then being 4·3 watts per candle (average). This was at a somewhat lower temperature than that at which the lamps were intended to be used, viz., 16 candles.

At lower temperatures than the above the light of the glow-lamp differs from that of gas in being relatively richer in the red, and at still higher temperatures in being richer in the blue.

Distribution of light from the glow-lamp is a question of the cross-section of the filament. Filaments of circular

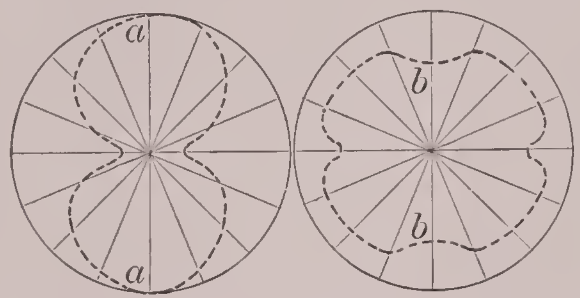

Fig. 7.—Diagram showing the distribution of light in the case of glow-lamps with filaments of rectangular cross-section.

cross-section give almost uniform distribution in the horizontal plane. Filaments are, as a rule, rectangular in cross-section. These are placed with the longest diameter in the plane of the filament, or at right angles to that plane. The result is that different amounts of radiating surface are exposed, according to the direction from which the lamp is viewed. Curves a and b, Fig. 7, show the results of candle-power measurements upon lamps of these two types.

The electric maintenance of arc and incandescent lamps is carried out upon entirely distinct systems. Arc-lamps are placed in series (Fig. 8), the same current traversing all that are in circuit. Glow-lamps are arranged in multiple (Fig. 9). The condition to be met in dynamo machines for arc-lighting is complete and automatic regulation for constant current through wide ranges of external resistance. The dynamo for incandescent lighting, on the other hand, must possess complete power of regulation for con-

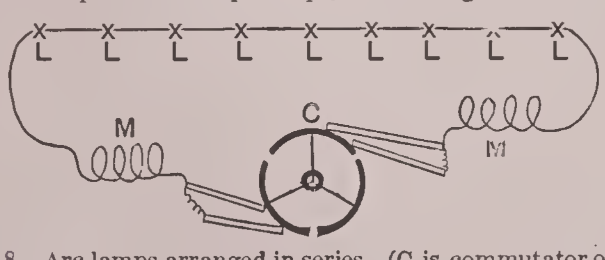

Fig. 8.—Arc-lamps arranged in series. (C is commutator of dynamo; M, M, the field magnets; L, L . . ., the lamps.)

stant potential. The means by which these requirements are met is described in the article Dynamo-electric Machine (*q. v.*). The desirability of furnishing both arc and glow lamps from the same circuit has led to many attempts to operate arc-lamps on constant-potential circuits and incandescent lamps in series. It has been found possible to do both, but the conditions are such as to lead to a separation of the two types wherever practicable.

In arc-lighting the number of lamps which can be fed by a single machine is limited to about sixty. The difference of potential at the terminals of the dynamo, about fifty volts for each lamp in circuit, reaches a value at this limit, beyond which it is not found possible to maintain the insulation of the machine. In incandescent lighting the number of lamps which can be supplied from a given center is limited only by the cost of the copper conductors necessary to carry the current. Since the potential-difference is independent of the number of lamps, the amount of current must increase in direct proportion to that number, and with it the weight of copper used.

Thus far this article has dealt with electric lights maintained on direct-current circuit. It is equally practicable,

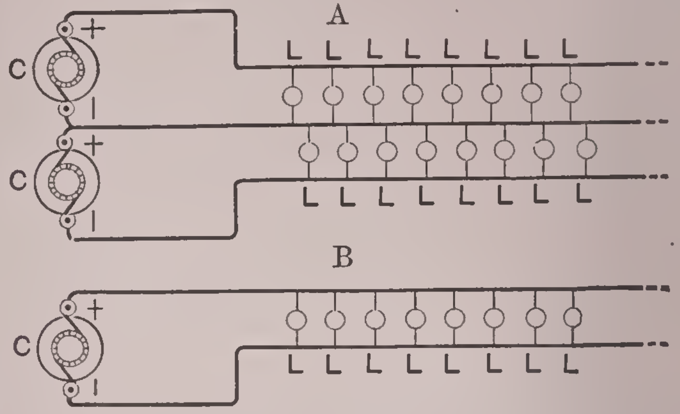

Fig. 9.—Arrangement of glow-lamps in multiple: A. three-wire system; B, two-wire system. (C, C, C, commutator of dynamo; L, L . . ., lamps.)

and under many circumstances more advantageous, to use alternating currents.

In the earliest days of arc-lighting alternate-current generators were employed, and the delicacy of regulation possible in alternate-current dynamos, without loss of efficiency, has led to a return to the older practice. For incandescent lighting also, wherever it is necessary to transmit to considerable distances, the alternate current permits the carrying of large amounts of energy over small wires. This is accomplished by the use of the Transformer (*q. v.*; see also Alternate Currents and Dynamo-electric Machine), a device by means of which the current and voltage in a circuit may be raised and lowered almost at will, their product which

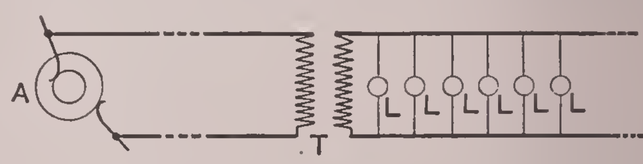

Fig. 10.—The arrangement of glow-lamps in an alternating-current circuit: A is the armature of the alternator; T is the transformer; L, L, L . . ., arc-lamps.

represents the energy remaining constant. Fig. 10 shows the arrangement of a circuit for transmission of energy to glow-lamps at a distance by means of an alternate-current generator and transformers.

The economy of the electric light is a question involving many factors. One does not have to deal, as in light production by direct combustion, simply with the consumption of fuel by oxidation. In the arc-lamp, nevertheless, the carbon pencils undergo continual disintegration, and have to be renewed daily at an appreciable cost. Even the glow-lamp, although incandescence takes place in the absence of oxygen, is subject to more or less rapid depreciation during service, and the renewal of degenerated lamps is an item of expense to the consumer. The life of the incandescent lamp diminishes as the temperature at which it is maintained rises. The amount of light per unit of energy expended, on the other hand, increases very rapidly with the temperature. The relationship between life and the degree of incandescence has been carefully studied by John W. Howell (*Transactions Am. Institute of Elec. Engineers*, vol. v., p. 239). The curve in Fig. 11 gives graphically the results which he has obtained from the life study of a very large number of lamps.

Abscissas in this diagram represent the degrees of incandescence (indirectly the temperature of the filament), expressed in terms of the number of watts expended in the lamps to produce a candle-power of light. Now, the cost of light to the consumer is made up of two factors—viz., the cost of developing the necessary amount of energy in the lamps, and that of renewing the broken lamps upon his circuit. He may, for instance, pay 50 cents apiece for lamps, and 3, 5, 10. or even 20 cents per kilowatt (one horse-power is equal to 0·7459 kilowatts) per hour; or the price of lamps may be 20, 30, or 40 cents, with power at any one of the above rates. Whatever may be the relative cost of power and of lamp renewal, the sum of these two factors can be so proportioned as to always be at a minimum. Mr. Howell has investigated this relationship, and found that the minimum total cost always occurs when lamp renewals make up 15 per cent. of the total cost of operation. It is interesting and important to note the way in which the efficiency of glow-lamps rises with the degree of incandescence. If such a lamp is taken and brought successively to 5, 10, 15, 20, etc., candles, and in each case the energy expended within the lamp is noted, it is found that as the candle-power rises the energy necessary to produce one candle-power of light falls off. If the results thus obtained are plotted graphically a curve similar to that shown in Fig. 12 is always obtained, by inspection of which it is found that a lamp requiring 15 watts per candle, in order to produce 2 candle-power of light, required but 3 watts per candle when the intensity was increased to 21 candles.

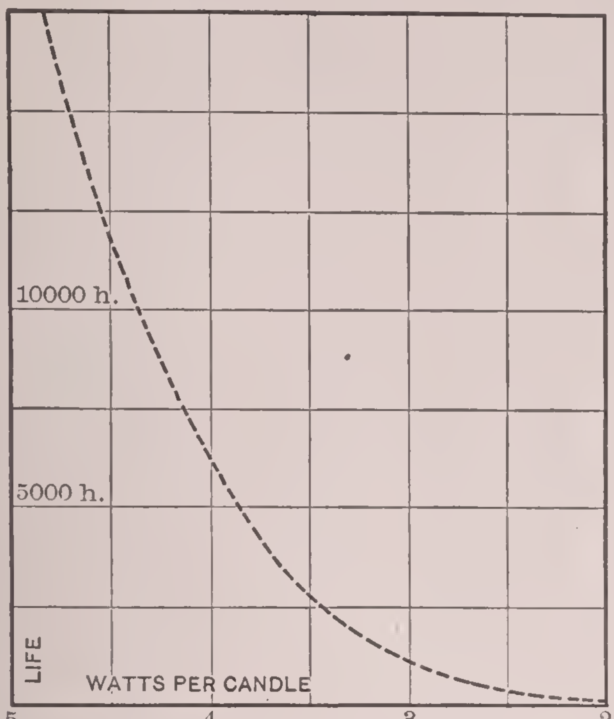

FIG. 11.—Curve showing lives of equally good lamps burned at different efficiencies (Howell).

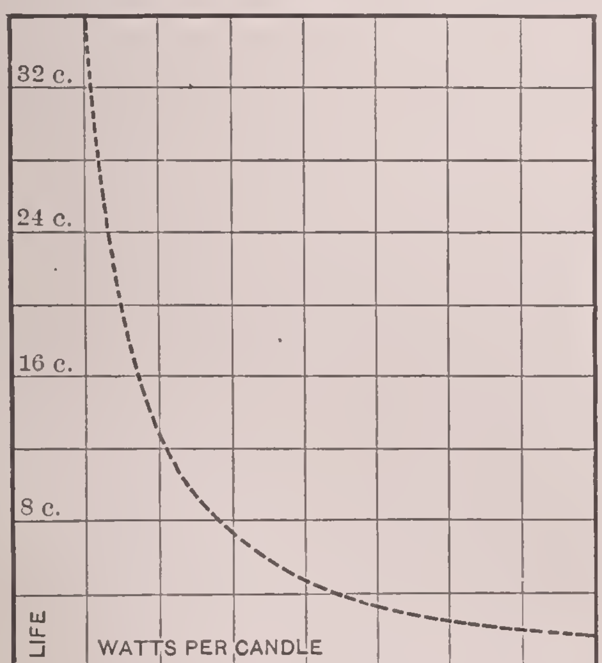

FIG. 12.—Curve showing the relation between candle-power and efficiency in the glow-lamp.

The discussion of the economy of the electric light involves more than the question of the electrical energy expended within the lamp and the amount of light produced. To define the performance of arc and glow lamps, considered as machines for illumination, the total amount of work done must be taken into account and its relation to the available light-giving radiation expressed in units of energy. In the case of light produced by direct combustion of fuel, as in the candle and oil flames, the problem reduces itself to a consideration of the total energy of combustion and the mechanical equivalent of luminous radiation.

Estimates of the energy dissipated in various sources of light have frequently been made. F. Fischer (*Bericht über die Electrische Ausstellung in Wien*, 1883, p. 461) found the following results with the usual older forms of illuminant:

TABLE SHOWING PRODUCTS OF COMBUSTION AND THE AMOUNTS OF HEAT DEVELOPED IN THE PRODUCTION OF 100 CANDLE-POWER OF LIGHT (FOR ONE HOUR).

ILLUMINANTS.	H_2O (Kg.).	CO_2 (cubic meters).	Heat (greater calories).
Gas (argand burner)	0·86	0·46	4,860

Rapeseed oil (student lamp)	0·85	1·00	6,800
Wax candle	0·88	1·18	7,960
Stearin candle	1·04	1·30	8,940
Tallow candle	1·05	1·45	9,700

In comparison with these values the heat emitted by the arc and glow lamps is insignificant.

A glow-lamp maintained at 3·1 watts per candle generates 266 calories per hour per 100 candle-power of light. An arc-lamp under good conditions emits only 86 calories of heat per hour for each 100 candles (mean spherical), or 29 calories for each 100 candles, measured in the direction of maximum illumination.

The heating effect of electric lights, as compared with wax candles, is therefore about 3 per cent. for glow-lamps and less than 1 per cent. for arc-lamps, with the additional advantage of freedom from the products of combustion.

A comparison of glow-lamps and gas, made in the Royal theater in Munich (see v. Pettenhofer, *Bericht über die Elektrische Ausstellung in Wien*, 1883, p. 463), showed that in the empty auditorium gas raised the temperature of the air in the upper gallery about 16·5° F., glow-lamps about 1·5° (9·2° C. and 0·83° C.). Even when the theater was occupied the difference was as much as 11° F. (6° C.).

With gas the amount of carbonic acid gas in the gallery, with the auditorium empty, rose in one hour from ·0004 to ·0020.

The amount of heat generated in electric lamps and in various flames affords no measure of the relative efficiencies of the systems of illumination. When fuel is burned to produce light the total expenditure, excluding such extraneous items as the cost of conveying the combustible to the point of consumption and the expense of refining and preparing fuels (as oils and gas) from cruder forms, is represented in the energy of combustion of the flame. In the case of the electric light the losses in boiler-room, in the steam-engine and dynamos, and the loss in electrical transmission from the generator to the lamp, must be added to the heat losses in the lamp itself.

Study of the character of the rays emitted by artificial illuminants shows that gas flames, etc., radiate between 98 and 99 per cent. of waves too long to be of service in lighting; also that the glow-lamp sends out 95 per cent. of such rays and the arc-lamp 90 per cent. The radiant efficiencies of these sources are then 1 per cent. to 2 per cent., 5 per cent. and 10 per cent. respectively.

Of the heat of combustion of flames, on the one hand, about 15 per cent. to 20 per cent. is dissipated by radiation, so that the total efficiency of these sources can not be greater than ·003. Of the total energy represented in the coal used to produce electric lights, on the other hand, not more than 10 per cent. reaches the lamp; so that the *maximum total efficiency* of these may be placed at ·005 and ·010 respectively. In the case of many installations for electric lighting, where the conditions of highest economy of transformation have not been observed, much lower values for the total economy would be found.

Direct determinations of the energy of the rays which go to make up a candle-power of light afford an excellent means of checking the above-mentioned estimates. It is found, for example, that a candle-power represents about ·216 calories per hour. Applying this value to the case of a wax candle, in which energy is dissipated (according to Fischer) at the rate of 79·6 calories per hour, the total efficiency of this source is

$$\frac{\text{light-giving energy}}{\text{total energy}} = \frac{\cdot 216}{79\cdot 6} = \cdot 0027,$$

a value in good agreement with that obtained by the former method.

Regarded as a light-making device, the efficiency of the arc and glow lamps is not very much higher than that of the sources of artificial light which they have in a great measure superseded.

The question of actual relative cost of production is a most complicated one, involving the cost of power, of attendance, of interest upon the money invested, as well as the price of copper and of machinery. The adoption of electric lights is more frequently based upon other considerations than upon mere cheapness of production. Sanitary or æsthetic conditions often prevail, or the adaptability of the light to the circumstances under which it is to be used. The applications of the electric light are almost innumerable. In some cases, it is true, where much was expected, unforeseen difficulties have led to the return to the older illuminants. This is the case in *coast lighting*, for which purpose the brilliancy of the arc-light seemed to indicate it as the most desirable of sources. The experiments of Tyndall in the service of the Trinity House, 1876–77, showed, however, that in thick weather the shorter wave-lengths of the spectrum, which are especially prominent in the arc-light, are wholly absorbed by the atmosphere; so that the fluctuations both in quantity and quality, with changes of weather, rendered the electric arc the very worst of lights for lighthouse purposes. In many other situations, as in lighting mines, steamships at sea, in submarine work, etc., the electric light possesses advantages such that the question of cost becomes unimportant. In these and in innumerable other services where it is not in the same sense indispensable, it has come to be regarded as an essential feature of modern equipment. Many details concerning the electric light may be found in the following special treatises:

Dredge, *Electric Illumination*; Maier, *Arc and Glow Lamps*; Hedges, *Continental Electric-light Stations*; Desmond, *Electricity for Engineers*; also in the admirable summaries published from time to time by MM. Palaz, Richard, and others in *La Lumière Électrique* (Paris); also in the reports of the commissions of the electrical exhibitions of Philadelphia, Paris, Munich, Vienna, Antwerp, Frankfort, etc. E. L. NICHOLS.

Electric Meters: appliances for the measurement of the energy developed in an electric circuit. These are of three kinds: (*a*) clockwork recorders, (*b*) chemical meters, (*c*) motor-meters. In the first a known fraction of the current to be measured passes through a galvanometer which records by means of a stylus upon a chronograph sheet driven by clockwork. Large first cost and the difficulties of maintaining clockwork devices in continued use have kept this class of meters out of general use. Chemical meters are zinc voltameters, the plates of which are weighed from time to time. Motor-meters are electric motors, the speed of which is recorded by a dial device like that of the gas-meter. See METERS and WATTMETERS. E. L. N.

Electric Motor: a machine for the conversion of electrical energy into the form of mechanical power. The first motor of any real importance was constructed by Jacobi in 1838. This motor, like all its predecessors, depended for its action on the attraction and repulsion of electro-magnets. Its efficiency was very low, chiefly because of the large amounts of energy that had to be expended in producing magnetization in magnetic circuits, completed only through large air-gaps. The iron masses or electro-magnets, which are set in motion by the action on them of stationary electro-magnets, are called armatures. A great advance was made by the invention of the Siemens shuttle armature in 1855. This machine is the highest development of the old ideas of the electric motor—the repulsion and attraction of electro-

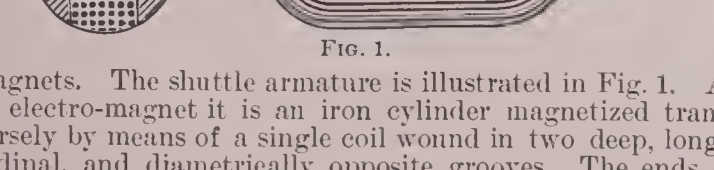

FIG. 1.

magnets. The shuttle armature is illustrated in Fig. 1. As an electro-magnet it is an iron cylinder magnetized transversely by means of a single coil wound in two deep, longitudinal, and diametrically opposite grooves. The ends of the coil are connected to opposite halves of a metallic ring, insulated and mounted on the shaft, forming a two-part commutator. Electric connection through the armature coil is made by means of brushes resting on the commutator, as shown in Fig. 2. Fig. 2 shows the form of the stationary magnet and the arrangement of the armature with respect to it. The poles present the surface of a cylinder in diameter slightly larger than that of the armature. It is seen that the function of the two-part commutator is to reverse the current in the armature at the proper instant for continuing the rotation through the action of electro-magnetic repulsion or attraction. By the adoption of this form of moving and stationary electro-magnets the magnetic effects were enormously increased, owing to the fact that the magnetic circuit is made up almost entirely of iron. The electro-dynamic effects and the efficiency of the electric motor were increased in proportion. Owing to numerous causes, the efficiency and output for a given size of machine were, however, still hopelessly low.

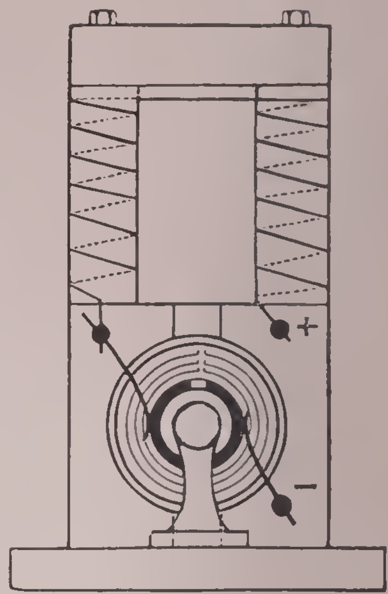

FIG. 2.

Chief among these causes were the Foucault current losses in the core and the energy wasted, and the trouble encountered in reversing the current suddenly through the large number of turns in the armature coil.

The great and effective advance of the electric motor was made shortly after the introduction of the Gramme dynamos in 1871. It was found that these dynamos would work equally well as motors, and with this discovery came a clearer understanding of the nature of electro-magnetic induction, which may be briefly stated as follows:

A conductor carrying a current and moving across the lines of force in a magnetic field takes up or gives out mechanical energy in amount equal to the product of the current through the conductor into the electromotive force developed in it by its motion through the magnetic field. The mechanical energy is given up to the conductor when the electromotive force generated in it is positive with respect to the current, and is given up by it when the electromotive force is negative. It is this knowledge that has enabled an improvement in electric motors to be made each time that an improvement has been made in electric generators. It follows from the absolute reversibility of the electro-magnetic induction of electric currents that good electric generators make good electric motors. It does not necessarily follow, however, that a good dynamo operated under one set of conditions will make an equally good motor when operated relatively under entirely different conditions.

Electric machinery for motor practice is required to operate almost universally under different conditions from that of the generator as to speed, load, and speed regulation. Where it is required to meet conditions different from those that are met by the dynamo, it must be different in design and construction. These special requirements have enlisted the attention of some of the ablest engineers of the world since the introduction of the dynamos with the Gramme and Häfner-Alteneck armatures.

The great use of the electric motor is for the transmission and distribution of power. The electric motor and the ease with which electric energy may be transmitted without serious loss to great distances make possible the commercial use of many waste powers. Served with current from neighboring electric-light stations, it is a ready and economical power in small and large units in cities. The application of the electric motor to railway propulsion forms now a great industry by itself.

There are two great classes of electric motors, direct current and alternate current. The simple law that a dynamo acts as a motor when a current from an external source is passed through its armature in a sign opposite to the electromotive force it develops extends to direct current, alternate current, and all forms of motor alike. In any motor, as in the dynamo, there are two distinct organizations of parts, the field and the armature. The field is generally established by current from the source supplying the motor. The current is allowed to pass through the armature, which sets up a rotation due to the force exerted by the action of the field on the armature. Now the motion of the armature conductors through the field produces in them an electromotive force precisely the same as though they were driven by mechanical means instead of by electro-magnetic. The electromotive force is negative with respect to the current in the armature, and is therefore called counterelectromotive force. The product of the counterelectromotive force into the current in the armature is the number of watts transformed into mechanical power. In the actual motor not all of the power thus developed is given off at the pulley of the motor; a small portion of it is expended in friction of the journals, brushes, and in losses in the armature core. Since there are two great methods for distributing electrical energy, one by constant difference of potential and variable current and the other by constant current and variable difference of potential, there are likewise two classes of motors for transforming these two great forms of electrical energy into mechanical energy. In direct-current working series motors are used exclusively on constant-current circuits, and on constant-pressure circuits both shunt and series motors are used; where constant speed is desired, as is generally the case in stationary work, the shunt motor is employed, and for speeds varying through wide ranges the series motor has been found to give the best results. A shunt motor operated as indicated in the diagram of Fig. 3 has its field excited at all times with a constant number of ampère-turns. This is so because the terminals of the field coils, whose resistance is constant, are connected to the supply main on which is maintained a constant pressure. In starting up such a motor the field is first connected to the supply mains, and then the armature through a variable resistance. The armature, on the admission of a current through it in the presence of the strong field already produced, experiences a powerful torque or tendency to rotate. As it comes up to speed the resistance is gradually cut out, and when all is cut out the armature attains the full normal speed for which it has been designed. This speed is that at which the armature produces an electromotive force almost equal and opposite to that of the supply mains; it is plain that if the armature should go fast enough to develop an electromotive force equal and opposite to that of the mains, the difference of electromotive forces would be zero, and there would be no electromotive force remaining to set up a current through the armature, which therefore would slow down slightly to a point at which this difference would be great enough to set up a current that would maintain the rotation of the armature. Since the resistance of the armature is small, the amount that it needs to slow down in order to permit even a very large current to be set up through it is but slight, generally not more than from 2 to 5 per cent. When very close speed regulation is desired, shunt-machines are given a differential winding. A few heavy turns of wire are placed on the field, and through these the armature current passes in such a direction as to exert magnetomotive force in an opposite direction to the shunt or fine wire winding. These turns are so adjusted in number that by the action of the armature current through them they weaken the field of the motor. As a consequence, the armature must run at the same speed that it did at no load in order to produce an electromotive force that is a small amount less than that of the line. This amount is equal to the fall of potential through the armature caused by the current. These principles are expressed more exactly by the aid of the following symbols and formulæ:

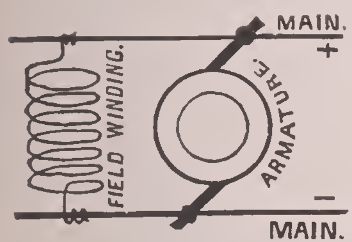

Fig. 3.

Let E be the electromotive force of the mains,
Let E be the counterelectromotive force of the motor,
Let e be the fall of potential caused by the current through the armature, or the electromotive force that sets up the current through the armature,
Let C be the current through the armature,
Let c be the current through the field,
Let R be the resistance of the armature,
Let n be the revolutions per minute of the motor armature at no load,

Whence $\mathrm{E} = E + \mathrm{e}$, $\mathrm{e} = \mathrm{CR}$, $\mathrm{C} = \dfrac{\mathrm{E}-E}{\mathrm{R}}$, $\dfrac{E\mathrm{n}}{\mathrm{E}}$ = revolutions per minute at full load,

$$\frac{\mathrm{n} - \frac{E\mathrm{n}}{\mathrm{E}}}{\mathrm{n}} = \text{per cent. variation of speed}, = \frac{\mathrm{E} - E}{\mathrm{E}} = \frac{\mathrm{e}}{\mathrm{E}}.$$

Whence the ratio of the fall of potential produced by the current through the armature to the pressure of the supply mains is the drop of the speed in a shunt motor. For example, a 10 H.-P. motor runs at a speed of 1,000 revolutions per minute on a 110-volt circuit. The current that will produce 10 electrical H.-P. at 110 volts is

$$\frac{10 \times 746}{110} = 68 \text{ ampères.}$$

The resistance of the armature, $\mathrm{R} = {\cdot}068$ ohms,

$$\mathrm{CR} = 68 \times {\cdot}068 = 4{\cdot}6 \text{ volts} = \mathrm{e}$$

$\dfrac{\mathrm{e}}{\mathrm{E}} = \dfrac{4{\cdot}6}{110} = {\cdot}042$, or 4·2 per cent. change of speed in going from no load to full load. In practice plain shunt-machines operated as motors give even better regulation than indicated by these theoretical considerations. This is due to the fact that the magnetizing effect of the current in the armature conductors is to increase the reluctance of the magnetic circuit of the field, thereby diminishing the magnetization through the armature slightly as the current in the armature comes up to its full value. The effect of this diminution of magnetization is to aid in diminishing the counterelectromotive force, so that to produce the required $\mathrm{E} - E$ to let the necessary current through the armature at full load the speed of the armature needs to fall off less than it would if these armature reactions were absent. It is not an uncommon thing, therefore, to find a shunt motor that gives a constant speed at all loads.

Series motors operated from constant-pressure circuits are usually regulated by hand. These motors are used where a great effort to produce rotation or torque is required, and where the speed must be varied by the operator at will. This is accomplished by inserting a variable resistance in series with the field winding and the armature of the motor on starting up. The most powerful fields are used, and the armature contains as many conductors as possible. Thus at low speeds the torque or starting effort is made a maximum. For higher speeds the resistance in circuit with the motor is all cut out, and for the highest speeds the field is weakened by cutting out some of the field turns, thus weakening the field, and making the motor run at a higher speed in order to maintain the counterelectromotive force. Power is often transmitted by means of constant-current generators, circuits, and motors. This system is confined entirely to stationary work. Since the current in this system, through the motor, is constant, the counterelectromotive force of the motor must vary with the load. This variation of counterelectromotive force in the motor is accomplished practically by two methods, precisely the same as in constant-current generators, viz., by shifting the brushes and by changing the magnetization through the armature by varying a resistance connected in parallel with the field. Either one of these operations is accomplished automatically by means of ball-governors attached rigidly to the motor-shaft, which act much as the automatic governors on modern high-speed engines.

Any alternate-current dynamo will operate as a motor from an alternate-current circuit that possesses the same periodicity. The alternator to be operated as a dynamo must first have its field excited by means of a direct current, and the speed of the armature brought up to its normal value, so that it will produce an electromotive force almost equal and opposite to that of the supply mains; the periodicity must also be the same, when the machine may be connected to the circuit and will operate as a motor. Alternators thus operated are called synchronous motors. The difficulty of starting them limits their use. They are used in the U. S. for transmitting water-power to distances as great as 10 miles or more, for operating stamp-mills, etc., in mining districts. Tesla, Dobrowolski, and others have devised special systems for the generation of alternate-current energy in such a form as to enable the practical operation of alternate-current motors that should be self-starting. The current used in these systems is known as the "Drehstrom," or "current that produces rotation." By means of this method during the summer of 1890 100 H.-P., developed by waterfall at Lauffen, Germany, was transmitted to Frankfort, a distance of 100 miles, with a total loss of power of but 25 per cent. At Lauffen an Drehstrom generator produced the necessary current at a moderate electromotive force, which was then transformed to a small current at 20,000 volts. At this enormous pressure the energy of 100 H.-P. could be transmitted the distance of 100 miles with a copper wire a quarter of an inch in diameter, and at a loss of but 5 per cent. At Frankfort a "step-down" transformation took place through transformers similar to those used at Lauffen; from these the current, once more at ordinary voltage and correspondingly increased strength, was delivered to an Orehstrom motor that developed 75 H.-P. in return for the 100 H.-P. given up to the dynamo by the turbines at Lauffen. HARRIS J. RYAN.

Electric Railways: those railways on which electricity is the motive power. The first step toward the application of the electric motor to railway propulsion was made by Thomas Davenport, of Brandon, Vt. He constructed in 1835 a model electric car operated on a circular track. The car motor was of the pole-attracting type, and was operated by means of batteries carried on the car. In Apr., 1851, Prof. Page, of the Smithsonian Institution, operated a 16-H.-P. locomotive that derived electric current from 100 large Grove cells carried with it. This locomotive attained a speed of 19 miles an hour, and was run on the Baltimore and Washington Railway. The motor was likewise of the pole-attracting type. The experiments of Page demonstrated the entire possibility of railway propulsion by means of electricity, but with primary batteries the cost was prohibitive. The next decided advance came with the commercial introduction of the Gramme and Siemens dynamos, which provided at once an economical means for the production of electrical energy and an efficient motor when the operation of these dynamos was reversed. From 1872 to 1887 experiments were made in Europe and in the U. S. with varying success. Among the promoters of these enterprises were Fontain and Breget, Siemens and Halske, Gramme and Egger, of Europe, and George F. Green, Edison, Stephen D. Field, J. C. Henry, Daft, Van Depole, Short, and Sprague, of the U. S. Through the efforts of these men a dozen or more experimental roads were operated, and while they were not all successful, each one constituted a great practical lesson.

Numerous forms and methods of mounting the motor were tried. Methods of every kind were used for generating and conducting the current to the motors. The direct supply of electrical energy in the form of constant current or constant potential from the generators to the motors was made by sliding or rolling contact through the rails insulated from each other and from the earth; through a third rail insulated and mounted at the center of the track in a slotted conduit, or just above the ground, using the track as a return; or through a conductor mounted on insulated supports overhead, with the track and the earth as a return for the current. Storage batteries were used by charging them at the generating stations, and then loading them on the cars to supply the motors with current, thus avoiding the need of running conductors along the road.

Out of all these practical trials, attempts, and experiments there was developed the system of electric street-railway propulsion that is now being used in most of the cities in the U. S., and has been introduced in Europe. In 1887 Frank J. Sprague undertook to equip the Union Passenger Railway, of Richmond, Va., operating twenty cars, for electric traction. The work was completed and the road went into operation with electric motive-power early in 1888. This, therefore, was the first road to be equipped in a real engineering spirit and determination: consequently the results of all previous attempts and experiments were care-

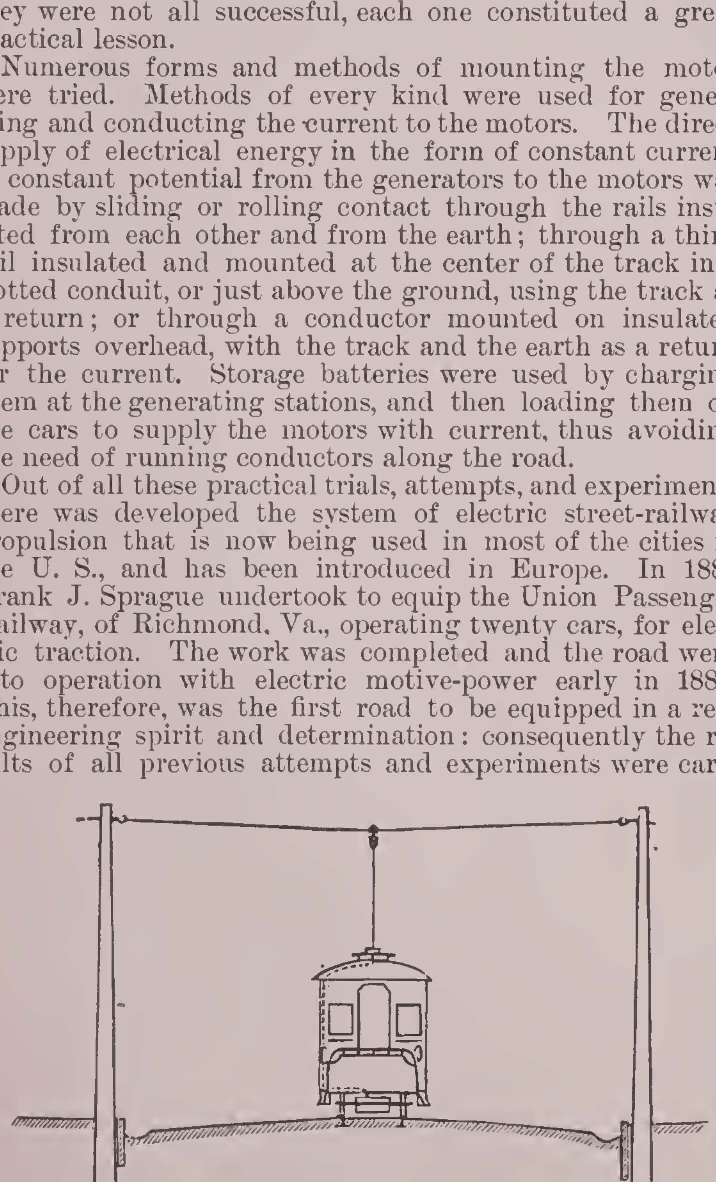

FIG. 1.

fully looked into, and the methods that were found to be best and most practicable were adopted. The final outcome was the adoption of the single overhead trolley system, using the earth and the rails as a return. The success of the Richmond road invited public confidence to such an extent that a lapse of five years sufficed to bring about the almost universal use of electric propulsion for street railways.

In modern practice the current is supplied at a constant potential of 500 volts from the dynamos in the generating station to the car motors direct by means of a bare copper wire, called the trolley-wire, suspended in the air over the center of each car-track. Fig. 1 gives one a good idea of the manner in which the trolley-wire is suspended in the streets and the method adopted for taking the current from it to the motors on the car-trucks, from which it is returned to the power-house through the wheels, track, and earth. The trolley-wire is suspended by means of cross wires attached to poles erected at the curbs in the streets. These cross wires are insulated from the trolley-wire except where it is electrically joined to the feed-wires. The feed-wires provide all extra conducting capacity needed for keeping up the full supply of current in all parts of the trolley-line. They are given a weather-proof insulation and mounted on glass insulators carried on the poles, or they are given a su-

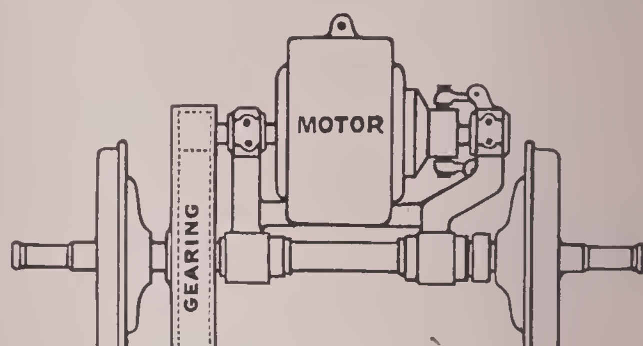

FIG. 2.

perior insulation, covered with lead, and placed in conduits underground; to these the trolley-line is joined electrically at intervals. The current is taken from the trolley-line to the moving car through the trolley and trolley-pole that are carried by the car. The trolley-pole has a pivot attachment to the top of the car, and by means of springs presses the trolley uniformly against the trolley-wire. The trolley and pole being metallic, the current is led through them to the top of the car, and thence through metallic conductors to the motors below. It is necessary, on account of its weight, to give the motor flexible suspension on the car-trucks, in order to lessen the wear on the tracks and the tendency to damage the insulation of the wires on the fields and armatures of the motors, due to the excessive shocks that would otherwise be experienced. This is accomplished by pivoting one end of the motor to the car-axle, and suspending the other with springs from the truck-frame. The power of the motor is transmitted from the armature to the axle by means of spur-gearing usually boxed in and flooded with solid oil. The method of mounting and connecting the

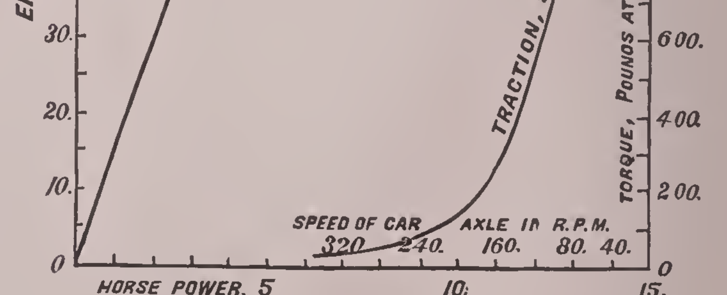

FIG. 3.

motor is illustrated in Fig. 2. Series motors are used, and for driving a 16-foot car in ordinary practice two 15 H.-P. motors, one on each axle, are used. The speed of the motors is regulated by changing the electrical pressure applied at the brushes of the armature, and by varying the magnetization through the armature. The change of electrical pressure through the armature is accomplished by means of a variable resistance in series with the motor, while the magnetization through the armature is varied by cutting in or out of circuit turns in the field winding. In some motors the two operations are made simultaneous by so winding the field coils that they will properly furnish the necessary resistance in the field circuit. Fig. 3 gives a diagram showing the relation between the efficiency and H.-P. and the speed and H.-P. for a 500-volt 15-H.-P. motor connected to the car with a single set of gears.

A prominent engineer gives the following data for good electric street-railway practice:

"There should be installed in generating capacity for power-plant 20 to 25 H.-P. per car operated, which will give reserve power.

"The cost of generating power is from three to five cents per car mile.

"A car uses, under average conditions, 1 H.-P. per car mile per hour. That is, a car operating at a speed of 5 miles, 5 H.-P.; at 8 miles, 8 H.-P.

"Cars are generally equipped with two 15-H.-P. motors.

"The attainable speed with electric motors is limited only by conditions of roadbed and local requirements; 130 miles an hour have been attained experimentally.

"Electric traction means rapid transit and increase of traffic of from 40 to 200 per cent., and moderate reduction in operating expenses per car mile."

As yet there has been no commercial application of the electric motor in which the locomotive on the overland railways of the U. S. has been displaced. Experiments, however, have been made in which higher speeds have been attained than will probably ever be made with the steam locomotive, so that it is highly probable that the highest railway speeds in the future will be obtained commercially by means of the electric motor.

In conclusion, the following facts are of interest in connection with the development of electric railways: "By Jan. 1, 1888, there were in operation in the U. S. and in Canada 13 electric roads, operating 95 motor-cars over 48 miles of track." (*The Electric Railway*, p. 350, by Crosby and Bell.) In 1892 there were "in operation or under contract more than 450 roads, equipped with nearly 6,000 cars and over 10,000 motors, and with over 3,000 miles of track. There is made a daily mileage of not less than 700,000 miles, over a billion of passengers are carried annually, and at least $75,000,000 have been invested in this industry." (F. J. Sprague's *Inaugural Address, Proceedings of the American Institute of Electrical Engineers*, 1892, vol. ix., p. 230).

Electric Telegraph: See TELEGRAPH.

Electric Welding: a process of welding metals in which advantage is taken of the heat generated by the electric current. The chief advantage of electric welding over older methods consists in the complete localization of the heat. Either continuous or alternating currents may be used, but it is a simpler matter to generate the enormous currents necessary to the welding process by means of alternating current apparatus. A dynamo of the customary

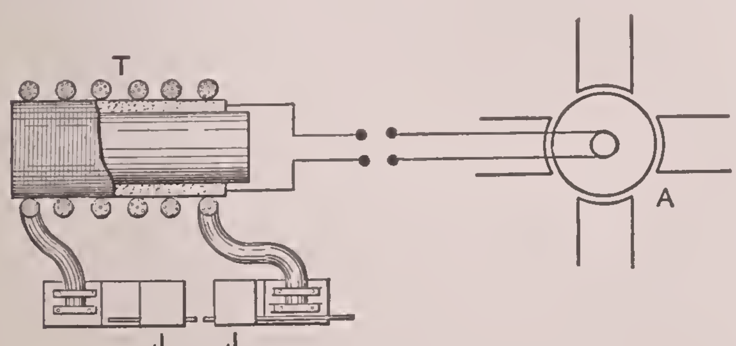

FIG. 1.

form (A, Fig. 1) is used in a circuit with a "step down" transformer, T, which reduces the voltage to very small values with corresponding increase of the current. The quantity of current will frequently, for short intervals of time, rise to thousands of ampères. A coil of variable self-induction, technically known as a "choking coil" or "dimmer," is placed in the circuit. It affords a very complete device for regulation.

When two pieces of metal are to be joined they are firmly clamped within the jaws of the welding-machine (J J). These are insulated from one another, and they form the terminals of the secondary circuit of the transformer. The pieces are then brought into imperfect contact and current begins to flow, developing heat in the only portion of the circuit which offers high resistance, i. e. at the junction of the metals. This region is brought into incandescence and to fusion so promptly that but little heat is dissipated by conduction, even in the case of where massive bars are being welded. The joint is made good by end pressure applied at the proper instant, for which purpose the jaws of the welding-machine are further thrust together. The re-

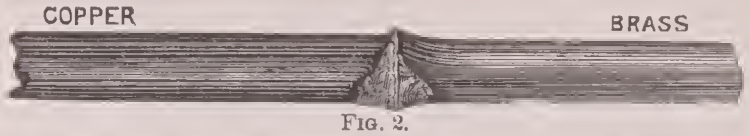

FIG. 2.

FIG. 3.

FIGS. 2 and 3.—Electrically welded joints between brass and copper rods. In Fig. 3 the metal is cut away to show the character of the junction.

sult is a slight enlargement of the joint. Figs. 2 and 3 show the form of junction produced between brass and copper by electric welding.

Electric welding has been introduced into a considerable number of manufacturing operations, even where the welding involves the heating of large masses of metal. Well-known instances are the welding of pipes, of steel rails, and of heavy projectiles and guns.

Electro-ballistics: See the Appendix.

Electrocution [a barbarous newspaper coinage which has come into common use]: infliction of capital punishment by the shock of an electric current, as enacted by the Legislature of the State of New York (Chap. 489), approved by the Governor June 4, 1888, and amended by Chap. 16 of the laws of 1892. A number of persons have suffered the death penalty in this manner, the first of whom was one Kemmler, a murderer, at Auburn, Aug. 6, 1890.

The apparatus used in the Kemmler execution, as described by Dr. C. F. MacDonald in his official report, consisted of a stationary engine, an alternating-current dynamo and exciter, a voltmeter with extra resistance coil, calibrated for a range of from 30 to 2,000 volts, an ammeter for alternating currents from 0·10 to 3 ampères, a Wheatstone-bridge rheostat, bell-signals, and necessary switches, a "death-chair" with adjustable head-rest, binding-straps, and two adjustable electrodes. The dynamo was an alternating-current dynamo intended to supply 750 incandescent lamps of sixteen candle-power each, and capable of generating, as shown by careful tests made several months prior to the execution, a maximum electromotive pressure of 2,376 volts, the commercial and mean voltage being 1,680 and 1,512 respectively, the speed of the dynamo being 1,900 revolutions, and of the exciter 2,700. The chair, a square-framed oaken one, with a high slightly sloping back and broad arms, was fastened to the floor, the feet of the chair being properly insulated. Attached to the back of the chair above the head-rest was a sliding arrangement shaped like a figure 4, the base or horizontal arm of which projected forward, and from which was suspended the head electrode, so as to rest on the vertex of top of the head, against which it was firmly held by means of a spiral spring. The spinal or body electrode was attached to the lower part of the back of the chair, and projected forward horizontally on a level with the sacrum. The electrodes each consisted of a bell-shaped rubber cup, about 4 inches in diameter, the part corresponding to the handle of the bell being of wood, through the long axis of which the wire passed into the bell terminating in a metallic disk about 3 inches in diameter, and faced with a layer of sponge. The lower electrode was also provided with a sliding arrangement and spiral spring to hold it in place, while a broad strap fastened to the back of the chair, and passed round the lower part of the prisoner's abdomen, rendered the contact secure. The head was firmly secured by means of conjoined broad leather bands, which encircled the forehead and chin, concealing the eyes and upper portion of face, and were fastened to the back of the almost perpendicular head-rest, while the chest, arms, and legs were secured by broad straps attached to corresponding portions of the chair. The wire attached to the head electrode descended from the ceiling, and that of the lower one passed along the floor to the chair, being protected by a strip of wood. The dynamo and engine were located in one of the prison shops, several hundred feet from the execution room; the voltmeter, ammeter, switch-board, etc., were located in a room adjoining the execution-room, which contained the death-chair, electrodes, and connecting wires.

Communication between the meter-room and dynamo-room was by means of electric signals. The apparatus used in all the subsequent executions at Sing Sing and Auburn was substantially a duplicate of that described, except as regards the location of the measuring instruments, switch-board, etc., and the form and points of application of the electrodes.

In the execution of Kemmler the voltmeter, ammeter, and switch-board, etc., were not in the execution chamber; hence there is no official record of the electromotive pressure and current-strength at the time of making and during the continuance of the first contact. But reasoning from cases of accidental death and experiments on some of the lower animals, and also from the subsequent electrocutions, it must have been at least 1,500 volts. The ampèrage also was not recorded in this case. An account of the execution of Kemmler will give a very correct idea of all subsequent executions by electricity, except in regard to some matters of detail in the points and length of time of contact of the electrical current. After Kemmler was seated in the chair and properly strapped and the electrodes moistened, all of which time occupied about three minutes, the warden signaled the assistant in charge of the switch in the next room to turn the lever which closed the circuit and sent the deadly current through the prisoner's body. The moment the contact was made the body was thrown into a state of extreme muscular rigidity. Every muscle of the body seemed to be in a state of tonic spasm. Synchronously with the onset of rigidity, motion, sensation, and consciousness were apparently absolutely suspended, and remained so while the contact was maintained. At the end of seventeen seconds the prisoner was pronounced dead, and the contact immediately broken. When the electrical contact was broken the rigidity noted was succeeded by complete muscular relaxation; at the same time superficial discolorations appeared on the face. The body remained limp and motionless for about half a minute, when there occurred a series of slight spasmodic movements of the chest, accompanied by the expulsion of a small amount of mucus from the mouth.

There were no evidences of return of consciousness or of sensation, but in view of the possibility that life was not wholly extinct, and in order to take no risk, the current was ordered to be reapplied, which was done about two minutes after the first contact was broken. The sudden muscular rigidity noted on the first contact was observed, and continued until the contact was again broken, when the same state of complete muscular relaxation again set in. The second current lasted about seventy seconds, and toward the end was accompanied by a small volume of smoke issuing from the points of contact, due to scorching of the sponges on the electrodes. There was also some desiccation of the already dead body under the electrodes.

After this contact there was no radial pulse or heart-action, and the corneas were depressed and flaccid. The sudden and painless character of the death of the criminal was demonstrated. In point of fact the criminal was absolutely dead at the time of breaking the first current. The movements referred to have been noticed in some of the subsequent executions, and also in animals experimentally killed by electricity, and afford no evidence of conscious suffering.

These movements were very slight in comparison with those usually found after decapitation and hanging, which have sometimes been noted an hour after the execution, whereas in subsequent executions by electricity no reflex muscular action was found three minutes after the last contact was broken.

No doubt there were certain minor defects in the arrangement and operation of the apparatus used in the Kemmler execution, but notwithstanding these defects unconsciousness was instantaneous and death painless. This was clearly demonstrated in subsequent executions, four of which were witnessed by the writer. The object to be attained in the infliction of the death penalty, so far as the individual is concerned, is sudden and painless death. One celebrated electrical expert recommended the passing of the electrical current through the hands instead of vertex of skull and legs, as then the current would have a more direct paralyzing effect on the heart. In the case of McElvaine (Feb. 8, 1892) this was shown to be erroneous and not practical. It has been shown by physiologists and medical electricians that the arrest of the heart's action can be as readily effected by destroying or paralyzing the brain center, which presides over the heart's action. It has been conceded by all the medical and electrical experts present during these executions that by including the brain directly in the circuit the action of the heart would probably be quickly arrested, while at the same time all the vital centers, including that of consciousness, would be paralyzed. The brain itself is very susceptible to the influence of electricity, as is shown sometimes to an alarming extent by the passage of mild currents into it through the skull. The nerve tissues also contain an excess of saline moisture, and hence are among the best of conductors, while the amount of organic matter in live bone also renders it a fairly good conductor.

In all the executions following Kemmler's one electrode was applied so as to cover the forehead and temples, and the other to the calf of the leg, this one being the larger. The point of contact of the body electrode is not one of great importance. It may be applied to the hand, foot, or any other part. The electrodes were kept thoroughly moistened by a continuous flow from two suspended fountain syringes containing salt water. The preparations of the prisoners from the time they entered the execution-room to the closure of the circuit which rendered them unconscious varied from about four minutes in Kemmler's case to one minute and nine seconds in Tice's case (May 17, 1892). The electromotive pressure in the executions succeeding Kemmler's, as shown by the voltmeter taken by Prof. Landry, varied from 1,458 to 1,716 volts, while the ammeter showed a variation in current of from two to seven ampères. In each instance the prisoner walked deliberately to the chair, and quietly submitted to the application of the straps and electrodes. There was nothing unduly repulsive in the executions. About the only objective phenomena observed were instantaneous and complete tonic rigidity of the muscular system on closure of the circuit and marked muscular relaxation as soon as the contact was broken. The length and number of contacts varied from two contacts of seventeen and seventy-two seconds respectively in Kemmler's case to four contacts of nine seconds each in Tice's case. There were chest movements and possibly heart-beat after first contact in Kemmler's case; in Jugiro's (three contacts of fifteen seconds each, July 7, 1891), slight radial flutter; in Tice's case, none after breaking the last circuit. The length of time which elapsed from the time the condemned person entered the room until he was absolutely dead varied from about eight minutes in Kemmler's case to two minutes and forty-nine seconds in Tice's case. Executions by hanging usually required from fifteen to thirty minutes, and frequently the heart has been found beating thirty minutes after the fall of the drop. Additional time is consumed in adjusting the rope and cap and in pinioning, and frequently the victim is simply strangled.

In the opinion of C. F. MacDonald, M. D., there are abundant reasons for believing that conscious life is destroyed so rapidly by electricity that the application of the current could be repeated several times within the interval that is known to elapse between the receipt of an injury or a peripheral sensory impression and its conscious perception by the brain through the medium of the sensory nerves. In other words, the electrical current would travel from the point of contact to the brain many times faster than sensory impressions or nerve currents would—the rate of velocity of the latter being, roughly speaking, only about 155 feet per second, while electricity travels at the rate of millions of feet per second. Thus it will be readily seen that an electrical current of lethal energy coming in contact with the body so as to include the brain in the circuit would reach the latter and produce unconsciousness long before any sensory impression at the point of contact could be conveyed to and appreciated by that organ through the process of nerve-conduction, which, as has been shown, requires a distinctly appreciable period of time—the rate of transmission of painful sensations being even slower than that of ordinary tactile impressions.

This was shown very clearly by a series of experiments in instantaneous photography made by Prof. Muybridge. A careful *post-mortem* examination was held on each of the persons thus executed, but nothing, either macroscopic or microscopic, was found to show the passage through the body of the electrical current, except perhaps a slight desiccation of the skin at the points of contact of the electrodes.

Experience so far has demonstrated that the only reasonable objection to the use of electricity in carrying out a death sentence, at least so far as the individual is concerned, as compared with other modes of capital punishment, lies in the fact that the application of a current generates heat at the points of contact, and if sufficiently prolonged is attended with vesication of the skin at those points. This occurs, if at all, toward the end of the contact and long after conscious life is extinct; hence the objection is only a sentimental one. As compared with hanging, in which death is often produced by strangulation, with every indication of conscious suffering for some time on the part of the victim, electric shock is preferable both as regards the suddenness with which death is effected and the expedition with which all the preliminary details may be arranged.

R. T. Irvine.

Elec'trodes [formed from *electro-*, used as meaning electricity (from Gr. ἤλεκτρον, amber) + Gr. ὁδός, way; cf. *anode* (ἄνοδος), positive pole, *kathode* (κάθοδος), negative pole]: the surfaces by which electricity passes into and out of different media; especially the poles of the voltaic battery or pile. The so-called positive electrode is the anode, and the negative the kathode.

Electro-dynamic Engine: See Dynamo-electric Machine.

Electro-dynamics: the science which treats of the phenomena of electric currents. See Electricity.

Electro-horticulture: a term applied by C. W. Siemens, of England, about 1883, to the cultivation of plants by the aid of the electric light, and revived in 1891 by L. H. Bailey, of Cornell University, who in his experiments has found that some plants, notably lettuce, are greatly assisted by the electric light, while others are injured.

Electro-etching: See *Glyphography* under Stereotyping.

Electrol'ysis [from *electricity* and the Gr. λύω, to set free]: the decomposition of chemical compounds by the action of the voltaic current. When the electric current flows through any liquid not a chemical element, decomposition of the latter occurs, and the acid radical is separated from the metallic element with which it had been in combination. The two components into which the electrolyte (as the liquid which suffers decomposition is termed) is separated do not appear together at any one point. The acid radical shows itself only at the electrode through which the current enters the electrolytic cell, the metal only at the other electrode. At no intervening point within the liquid can any trace of either component in nascent state be discovered, nor does the electrolyte show any change of condition or properties, excepting at the surfaces of the electrodes, to indicate that it is under electrolytic action.

Electrolysis differs from chemical dissociation by heat or by other agencies in another respect—it occurs at all ordinary temperatures. Faraday, to whom we owe much of our knowledge of electrolysis, formulated the laws of electrolytic action in terms which have needed no modification. He originated many names still in use in the literature of the subject. Of these the most important are: *anode*, the electrode through which the current *enters* the cell; *kathode*, the electrode through which the current *leaves* the cell; *ion*, an element resulting from electrolysis; *anion*, the ion deposited upon the anode; *kathion*, the ion deposited upon the kathode.

Faraday's laws of electrolysis were stated by him as follows: 1. The amount of chemical action per second is directly proportional to the current strength. 2. If the same or equal currents pass through several electrolytic cells the weight of the ions set free at the several electrodes will be in the proportion of the chemical equivalents of the ions.

The amount of an ion deposited by the unit current in a unit of time is termed the *electro-chemical equivalent*. The amount of electrolysis due to the passage of a Coulomb (*q. v.*) of electricity is thus a definite quantity. For a table of electro-chemical equivalents, see article Electricity. The precise nature of the electrolytic process is not known. The best-known hypothesis is that of Grotthuss (*Physicalische-chemische Forschungen*, 1820), but this together with other and later views is to be regarded as artificial. Electrolytic processes have found extended application in analytical chemistry and in the industrial arts. They afford means of measuring current-strength also (voltametry), and make possible the storage of energy utilized in secondary batteries. See Accumulator.

For a very complete summary of facts and theories relating to electrolysis, see Wiedemann, *Elektricität*, vol. ii.

Electromagnetic Induction: See Induction, Electromagnetic.

Electro-magnetism: See Electricity.

Electro-metallurgy: See Electrotype.

Electrometer [formed from *electro-*, used as meaning electricity (Gr. ἤλεκτρον, amber) + Gr. μέτρον, measure]: an instrument for the measurement of differences of potential by means of electrostatic forces. Potential galvanometers and voltmeters, which are also employed for the determination of potential differences, depend for their action upon the electromagnetic effect of the current; these, therefore, are not to be classed as electrometers.

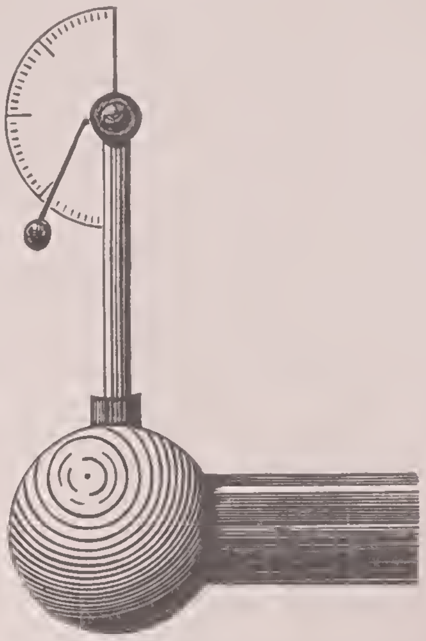

Fig. 1.

Electrometers may be conveniently divided into three classes: (1) modifications of the electroscope, (2) absolute electrometers, (3) quadrant electrometers.

To the first class belongs Henley's electrometer (Fig. 1) which is simply a pith-ball electroscope, provided with a vertical scale for reading the deflection of the ball. It is a rough instrument, and of use only as an indicator of the approximate condition of heavily charged conductors. Peltier's electrometer (Fig. 2) and the Coulomb balance may also be regarded as developments of certain forms of electroscope.

In Peltier's instrument the deflection of a pivoted rod was read upon a circular scale; in the Coulomb balance the electrical forces were measured by means of the torsion of the suspension fiber. Both instruments have been superseded by the more accurate and convenient quadrant electrometer.

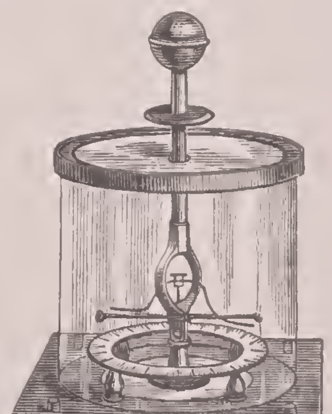

Fig. 2.

Absolute electrometers depend upon the principle that the force between an area S of an electrified plane conductor at potential V, and a parallel plane conductor (b b) at potential O, is

$$F = \frac{V^2 S}{8 \pi d^2},$$

where d is the distance between the two planes (see Fig. 3). This law holds only when d is small compared with the surfaces of the two planes, and the area S is situated at a considerable distance from the edge of the plane in which it lies.

Lord Kelvin (Sir William Thomson), to whom in great part the perfection of the absolute electrometer is due, meets these conditions by the device known as the guard ring. The area S is cut out from the remainder of the plane and is pivoted with the freedom of movement at right angles to the plane (Fig. 4).

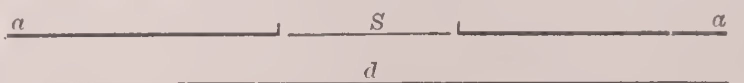

Fig. 3.

The remainder of the plane is fixed and serves as the guard ring. The parallel plane is moved by means of a micrometer screw, thus varying the distance d, until the force F between the attracted disk and the parallel plane is sufficient to bring the former to a selected position (the zero of the index). The difference of potential between the planes is thus measured.

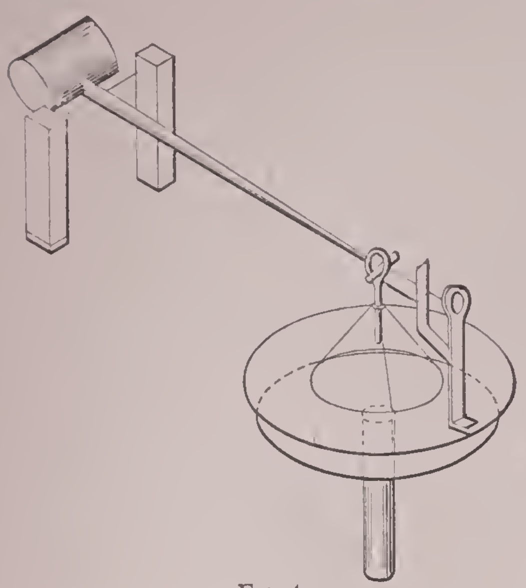

FIG. 4.

A far more sensitive instrument is the quadrant electrometer, one of the simplest forms of which is shown in Fig. 5. The essential parts are the needle, which is simply a strip of metal, and the quadrants. The former is very light and thin, mounted in a flat cylindrical box (Fig. 6), or sometimes above a divided disk, as in Fig. 5. The box is cut into quadrants which are separated from one another by an air-space sufficient to give complete insulation. Each quadrant is mounted upon a glass post. The needle, swinging in the center of the box, touches none of the quadrants. The suspension is usually bifilar, although in some forms of the instrument the torsion of a single suspension fiber is substituted. The normal position of the needle with reference to the quadrants is shown in Fig. 6. The quadrants are connected pairwise by wires diagonally across, 1 with 3 and 2 with 4.

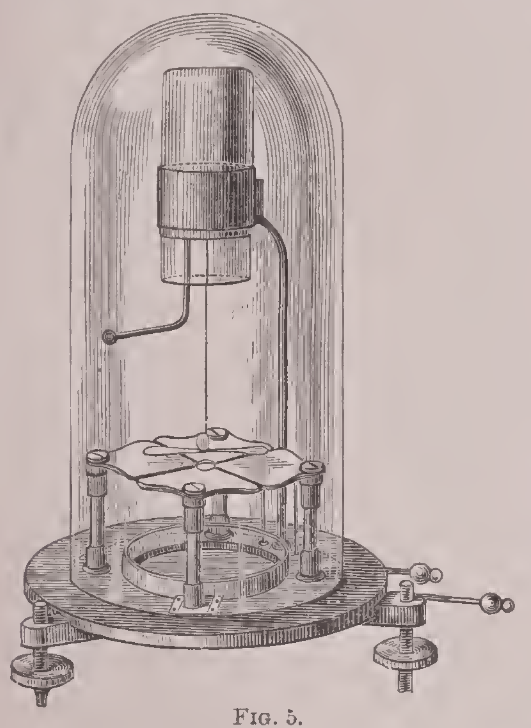

FIG. 5.

The quadrant electrometer may be used in four ways:

(1) The needle is given a large constant charge and the quadrant pairs are brought to the potentials, the difference of which is to be measured. The deflection of the needle is then determined by the method of the mirror and scale.

The following is the law of the instrument thus used:

$$\text{Sin } d = \frac{c}{C}(V_1 - V_2)V_n,$$

where d is the deflection; $\frac{c}{C}$ is a constant depending upon the dimensions and adjustment of the quadrants and needle and upon the bifilar suspension; V_1 and V_2 are the potentials of the quadrant pairs; and V_n is the potential of the needle.

To hold the needle at the high potential necessary to great sensitiveness Lord Kelvin (in the Thomson electrometers) mounted the needle and quadrants upon a Leyden jar, the inner coating of which consisted of strong sulphuric acid. The needle was connected with the inner coating by means of a fine platinum wire which dipped into the acid, and thus always shared the electrification of the jar. For the extremely ingenious devices by means of which the charge of the needle is replenished and gauged, and the sensitiveness of the instrument is varied, the reader is referred to the monograph *On Electrometers* (Thomson's *Papers on Electrostatics and Magnetism*), or to *Encyclopædia Britannica* viii., p. 117, or to Gray's *Absolute Measurements in Electricity and Magnetism*, vol. i.

(2) In the second method of using the electrometer the quadrant pairs are given a large potential-difference and the body, the potential of which is to be measured, is connected with the needle. The same formula applies.

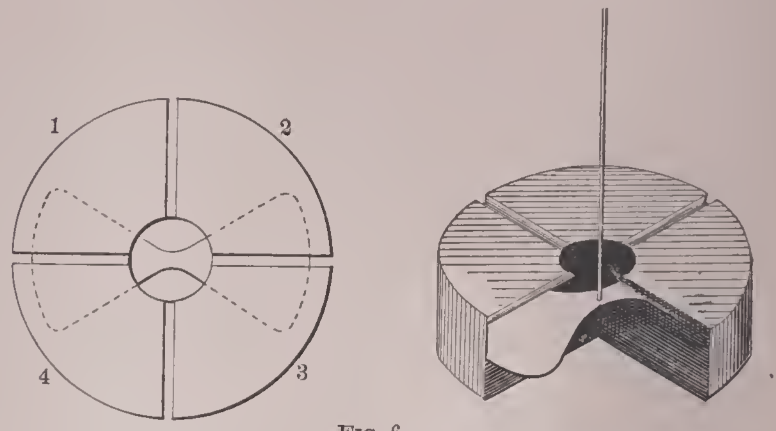

FIG. 6.

(3) In the third method the needle is connected to one quadrant pair. The formula then becomes:

$$\text{Sin } d = \frac{c}{2C}(V_1 - V_2)^2,$$

where $V_1 - V_2$ is the difference of potential between the quadrant pairs.

(4) In the fourth method the quadrant pair which is not connected with the needle is brought to zero potential (earth). The formula becomes:

$$\text{Sin } d = \frac{c}{2C}V^2.$$

Methods 2 and 3 are of small sensitiveness, but they have the advantage of being applicable to the measurement of alternating potential differences.

Valuable modifications of the Thomson electrometer have been made by Kirchhoff, Mascart, Carpentier, Ryan, and others, and an entirely different principle has been introduced by Lippmann in his "capillary electrometer." In this instrument advantage is taken of the movement of a mercury column in a small tube (owing to changes of the surface tension when electrified), and it is found possible to measure very minute differences of potential (·0001 volts). See ELECTRICITY, ELECTROSCOPE, etc. E. L. NICHOLS.

Electroph'orus [from *electro-* (Gr. ἤλεκτρον, amber), used as meaning electricity, + Gr. -φορος, bearing, deriv. of φέρειν, to bear]: the simplest form of apparatus for the continued production of electricity by electrostatic induction. It consists of a disk of vulcanite, sulphur, or of some resinous composition, and a metallic disk of smaller diameter with an insulated handle. The resinous surface having been electrified by friction, the metallic disk is placed upon it. The latter is then momentarily connected with the earth to allow of the escape of the negative charge, which, having been generated by the inductive action of the resinously electrified surface below, is repelled and escapes to the ground. The metallic disk then possesses a positive charge, which may be removed by withdrawing the disk from its resinous bed, and may be utilized in charging Leyden jars, etc. Since in this cycle of operations, which is known as the electrophorus cycle, and which is performed automatically in influence machines, accumulators, and replenishers, the original charge is not depleted, the performance may be repeated as often as is desired without recharging the resinous plate. The source of the electrical energy thus developed lies in the work which must be done in removing the positively charged disk from the neighborhood of the negatively electrified plate upon which it has been lying during the first portion of the cycle. See ELECTRICITY.

E. L. NICHOLS.

Electro-plating: the covering of the surface of articles formed of the cheaper metals with gold, silver, platinum, nickel, copper, or other costly metals by means of the electric current, on the same principle as that which is employed in electrotyping. German silver is one of the best substances to receive an electro-plate, though copper and its alloys are excellent. If iron, zinc, or pewter were to be used, they were formerly first plated with copper, but improvements render that unnecessary. All articles to be plated are most carefully cleaned and scoured. They are then dipped in a solution of nitrate of mercury, and receive therefrom a thin film of mercury, which causes the plate to adhere firmly. The bath of silver, gold, or platinum contains 100 parts of water, 10 of potassium cyanide, and 1 of the cyanide of the precious metal to be employed. The articles to be plated are suspended in this bath, and treated as described in the article ELECTROTYPE (*q. v.*). After removal, they are brushed and burnished. The above account is necessarily very general, for though the principle is simple, there are in practice many details which require careful attention in order to secure success. This process is of great importance in the arts, one of its applications being the operation of nickel-plating. There is much literature on electro-plating. See Urquhart's *Electro-plating* (London), Hiorns's *Metal-coloring and Bronzing* (London), and Brunor's *Practical Electro-plater* (New York, 1893).

Electroscope [from *electro-*, electricity (Gr. ἤλεκτρον, amber) + Gr. -σκοπός, observing]: an instrument for indicating electrification. The forces between charged bodies are either repellent or attractive, and both are made use of in the electroscope. The form generally employed is shown in Fig. 1. It consists of a pair of gold leaves attached to the lower end of a vertical metallic rod. For protection the leaves are mounted within a metal box with glass windows. The rod which terminates without in a ball or disk is carefully insulated from the case by means of a layer of shellac or glass. When a charged body is brought near to the disk or knob, the latter, together with the gold leaves, is acted upon inductively, and the leaves diverge. Used in this way the electroscope indicates electrification, but does not show the character of the discharge. If the leaves be given a permanent charge, the instrument will indicate the *sign* as well as the *relative degree* of excitation of any charged body brought near. Bodies of similar electrification to the electroscope will then increase the dilation of the leaves; those with the charge of opposite sign will draw the leaves together. This form of electroscope was first described by Bennet (1787).

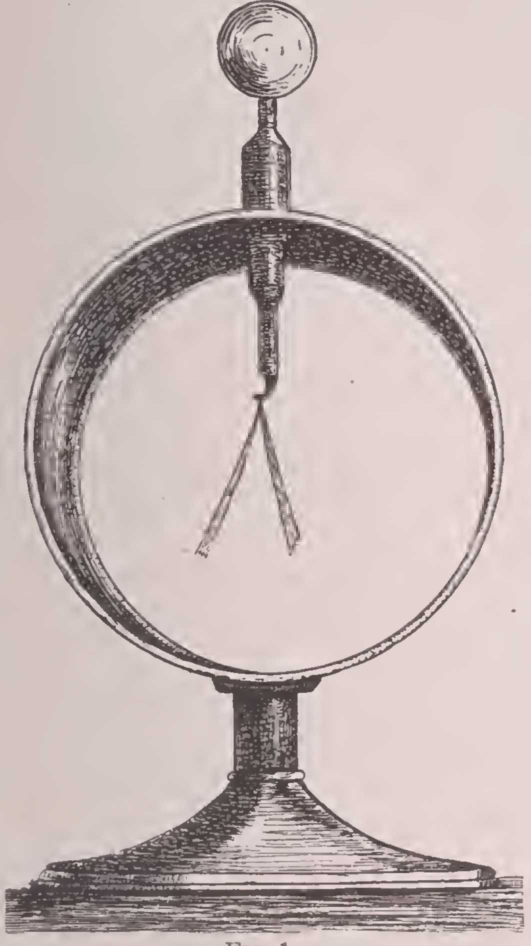

FIG. 1.

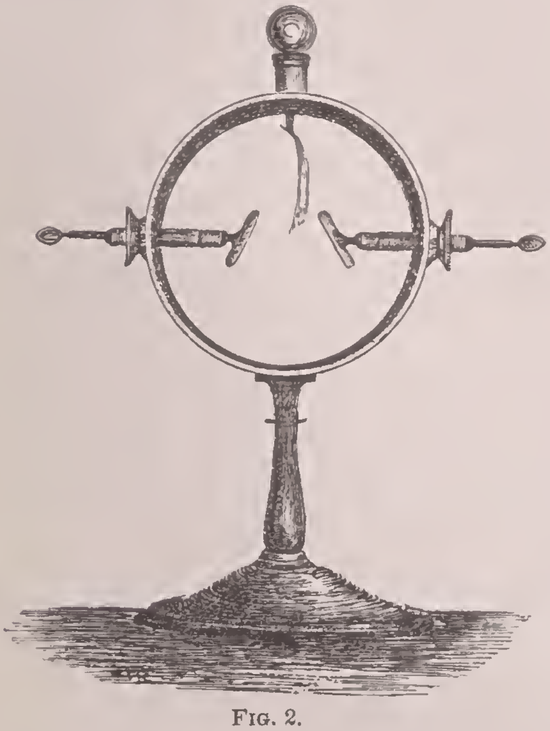

FIG. 2.

Another type of electroscope (Fig. 2) contains but one strip of gold leaf, which hangs vertically between two terminals of polished metal. These are inserted through the opposite sides of the electroscope-case, from which they are insulated. These terminals are brought to a considerable potential-difference by connecting them with the poles of a battery of many cells, usually of a voltaic dry-pile. If the gold leaf is not electrified, and if it is situated midway between the terminals, it will be acted upon by equal and opposite forces, and although in nearly unstable equilibrium it will maintain its position. The presence of even a minute charge upon the gold leaf (which may be imparted either by induction or by contact from without) will subject it to attractive forces on one side and forces of repulsion on the other, and it will be drawn toward the terminal, the electrification of which is opposed to its own.

The electroscope just described was first used by Bohnenberger (1819), who maintained the charge of the terminals by means of a dry pile. In the hands of Hankel, who substituted a hundred cells of water battery for the dry pile, and observed the deflections of the gold leaf through a reading microscope (see Wiedemann's *Elektricität*, i., p. 162; also *Annalen der Physik*, 84, p. 28), the Bohnenberger electroscope was rendered capable of accurate quantitative indications. Hankel's modification should therefore be classed as an electrometer.

In cases where considerable charges are to be studied much less sensitive devices may be made to serve as electroscopes. A pith ball hung by a silken thread, a rod of vulcanite or of sealing-wax suspended in a stirrup, even a lath balanced upon a point, may be used. See ELECTRICITY and ELECTROMETER. E. L. NICHOLS.

Electrotype [formed from *electro-* (Gr. ἤλεκτρον, amber), used as meaning electricity, + *type*, from Gr. τύπος, image, figure]: the cast of an object procured by the gradual deposition of a metal from a solution by means of a current of electricity. When two pieces of clean platinum are put into a solution of sulphate of copper, no change takes place. But if an electric current is transmitted through the solution by means of these platinum plates, copper is at once precipitated upon the plate which forms the kathode, the anode remaining clean. If the current be reversed, the copper will be transferred from the platinum plate on which it had been deposited to the clean plate. By thus reversing the direction of the current the copper may be sent backward and forward, being always deposited upon the negative pole, or that surface by which the electric current leaves the electrolyte or solution that is undergoing decomposition. By continuing the electric currents, and keeping up the strength of the solution by adding fresh portions of the salt of copper, the metallic film on the kathode may be made of any required thickness, and afterward peeled off the platinum surface. The texture of the copper deposited varies with the battery-power employed and with the strength and temperature of the solution, and may be hard, brittle, and crystalline, or tough and malleable, according to the management of the operator. A current of low intensity, a moderately strong solution of sulphate of copper acidulated with sulphuric acid, and a temperature not below 60°, are the most favorable circumstances for obtaining the best deposit of copper. When the negative pole or kathode is irregular (like a coin or medal), instead of being a plane surface of platinum, an exact impression of the device may be taken off on the precipitated copper. Gold and other metals may be substituted for copper by proper management, or if the precipitated metal be left upon the surface on which it is thrown down, gilding, silvering, etc., may be done extensively and with fine effect. This art is called electro-plating. Proficiency in electrotyping or the galvano-plastic art requires but little apparatus, and involves no great expense. A medal may be either copied directly, and an inverted impression obtained from which a second electrotype can be taken, or a cast of the metal may be first made in stearin or plaster. In the latter operation, which is the most generally used, the mould, if of plaster, must be first soaked in oil, tallow, or melted spermaceti, so as to render it impervious to water. It must then be made a conductor of the current, and this is done by thoroughly brushing black lead over the surface which is to be reproduced. In case the medal itself is used, in order to prevent the deposition of copper which would take place upon the edges and upon the reverse of the medal, those parts should be covered with sealing-wax, varnish, or shellac. The introduction of this valuable art has been ascribed to different persons. Daniell is said to have been the first to notice the deposition of metallic copper by electricity while working with his battery; Jacobi, of St. Petersburg, first published in 1839 a practical application of this fact, which publication called out announcements from Spencer and Jordan, two Englishmen, who were both working independently at the same object as Jacobi. Messrs. Elkington, of Birmingham, soon after applied the process to the gilding and plating of goods on a large scale. Electrotyping has to some extent superseded the old stereotype process for making plates for printers' use, especially for the reproduction of engravings and where large numbers are to be printed. For a summary of the various processes used by printers in the departments of stereotyping and electrotyping, see STEREOTYPING.

Electrum [Lat. = Gr. ἤλεκτρον, amber]: a natural alloy of gold and silver, in the proportion of two of gold and one of silver. It is found in Siberia, Norway, and California, and occurs in tabular crystals or imperfect cubes of a silver-white color.

Electuary [from Late Lat. *electua'rium* (also *electa'rium*), a deriv. from a corrupted form of Gr. ἐκλεικτόν, cf. ἔκλειγμα, derivatives of ἐκλείχειν, lick up. The word appears in Ital. *lattovaro* (under the influence of *latte*) and in Germ. as *Latwerge*]: in pharmacy, a variety of confection thinner than a conserve, and composed of powdered drugs mingled with honey, sirup, glycerin, or other vehicle. Electuaries are not now recognized in the U. S. and British pharmacopœias.

Elegiac Distich: a couplet consisting of a dactylic HEXAMETER and a PENTAMETER (*qq. v.*). The second verse repeats the movement of the hexameter, as if reconsidering it. Hence its reflective, emotional character. Schiller's famous distich is translated by Coleridge thus:

In the hexameter rises the fountain's silvery column;
In the pentameter aye falling in melody back.

The elegiac distich was the first step toward the STROPHE (*q. v.*), and was used in the elegy (ἐλεγεῖον), the poetry of subjective reflection. As to the inventor, the ancients did not agree. There are extant elegies, or fragments of them, by some fifty poets, from Callinus (730 B. C.) down; but the period specially marked by elegiac composition closes not long after Theognis (540 B. C.), of whom we have about 1,400 verses. This form of poetry was much used in epigrams, epitaphs, etc. The chief Roman elegists are Catullus, Propertius, Tibullus, and Ovid. MILTON W. HUMPHREYS.

Elegy [viâ Lat. *elegi'a*, from Gr. τὰ ἐλεγεῖα, an elegiac poem, a lament, collec. plur. of ἐλεγεῖον]: the name given by the ancient Greeks and Romans to poems of various kinds, being applied to the martial lyrics of Tyrtæus, the aphorisms of Theognis and Solon, the melancholy effusions of Mimnermus, and the erotic poems of Ovid, Catullus, and Tibullus. In modern times the name is applied chiefly to poetical compositions of a melancholy character, such as Gray's *Elegy Written in a Country Churchyard.*

Element [from Lat. *elementum*, a constituent or fundamental part: the word possibly originated in the names of the letters, *l, m, n.* i. e. *el-em-en-tum*, and was afterward felt to be a noun with the common suffix *-mentum*; cf. Eng. *a b c's*, pron. *ābeeseez'*, or it may be connected with Skr. *ánimaṅ-*, smallest piece]: a term used in various senses; a first principle; a rudiment; a constituent part of a compound; sometimes the proper state or sphere of a person or an animal. In the plural, the first principles or rules of a science or art; also the bread and wine in the Eucharist. Ancient philosophers applied this term to fire, air, earth, and water, each of which, in their several systems, was supposed to be the first principle of all things. The elements of the alchemists were sulphur, mercury, and salt. As a modern scientific term, *element* signifies a simple substance, or one which chemists have not yet decomposed.

ELEMENTS: in astronomy, the data required to compute the place of a planet, satellite, or comet; numerical quantities, etc., employed in the construction of tables exhibiting the motions of the moon and planets. They comprise the least mean distances of the planets from the sun, the eccentricity of their orbits, their mean motions, their masses, etc.

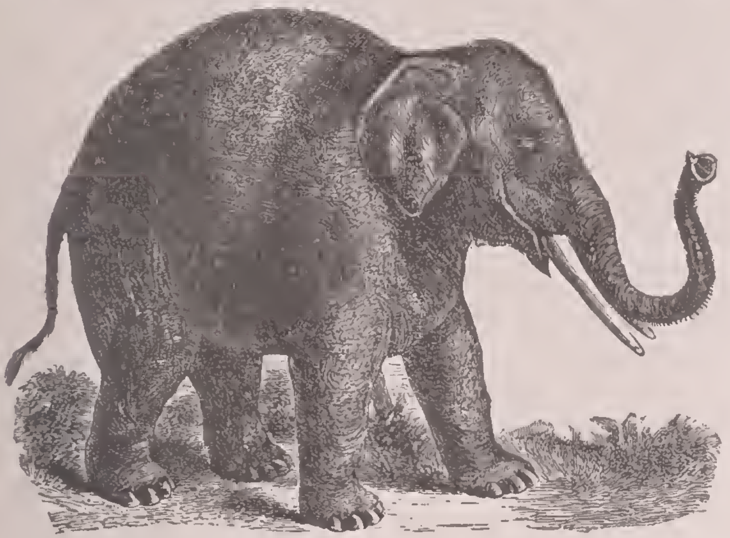
ELEMENTS, CHEMICAL: See CHEMISTRY.

Elements, New Chemical: See the Appendix.

Elemi [cf. Fr. *élémi*, Span. *elemi*, Ital. *elemi*; the word is of Eastern origin]: a fragrant resinous substance procured from several species of trees of the natural order *Amyridaceæ*. It exudes from incisions made in the bark, is at first soft, but becomes hard and brittle. It is generally pale yellow, semi-transparent, and soluble in alcohol, except a residue called *elemin*. It is obtained from the *Icica icicariba*, which grows in Brazil; from *Elaphrium elemiferum*, of Mexico; and from *Canarium commune*, of Manilla. Elemi is used in the preparation of ointments and plasters.

Elephant [from Lat. *elephantus*, or *elephas*, from Gr. ἐλέφας, -αντος; origin obscure]: the common name of the members of the sub-family *Elephantinæ*, a group of thick-skinned mammals of the order *Proboscidea*, distinguished among living mammals by the possession of a long trunk, or proboscis, forming a prolongation of the nose. The head is large and rounded, and, owing to the shortness of the neck, seems to be set directly on the shoulders. The limbs are straight and massive, the ears large, flattened, and in repose carried along the side of the neck; the dark wrinkled skin is nearly naked, being sparsely sprinkled with black hairs, while the end of the tail bears a tuft of coarse whalebone-like hairs. The dentition is remarkable. There are but two incisors; these, which are in the upper jaw, are the successors of two small milk incisors, and grow throughout life as two pointed, slightly curved tusks. In many of the Asiatic elephants, however, the tusks are poorly developed. The tusks consist of that fine-grained, elastic modification of dentine termed ivory.

The grinders are formed of vertical, transverse plates of enamel, arranged in compressed U-shaped folds, imbedded in dentine, and having the hollow of the U filled with cement. During the life of an elephant there are altogether six molars on each side of each jaw, but, owing to the peculiar mode of their succession, not more than one entire tooth and part of another is in place and in use at any one time. The teeth are not developed one below the other, as in mammals generally, but one behind the other, the tooth in use moving slowly forward in the jaw, being replaced by the one which forms at its back. The lower jaw is very heavy, and is loosely articulated with the cranium, being, as it were, suspended by the large masticatory muscles. While the upper bones of the legs are unusually long, the bones of the feet are small and imbedded in a mass of tough spongy tissue, which forms an elastic pad and renders the step of these huge beasts springy and noiseless. The bones of the forearm are crossed one over the other, and there is no round ligament (*ligamentum teres*) running from the center of the thigh bone to its socket. The head of the elephant is large, but this is not due to the size of the brain, this being comparatively small, but to the necessity for providing surface for the attachment of the muscles which form the trunk, and for those which sustain the weight and leverage of the trunk and tusks. A large portion of the skull is formed of bony air-cells which give great increase in bulk, with but slight additional weight, and these constitute so large a proportion of the cranium that a ball may—and frequently does—pass entirely through the head without causing death. The most striking feature of the elephant is the trunk, which, formed of thousands of interlacing muscles and capable of the most varied movements, compensates for the shortness of the neck and enables the animal to reach objects far above his head or lying on the ground at his feet. With it he conveys food to his mouth, or drinks by drawing up water in the nostrils and discharging it into his mouth, a peculiar valve-like arrangement preventing the water from reaching above a certain point in the proboscis. The trunk of the Asiatic elephant is provided with a little finger-like projection, but the African species has none. In the case of the African species, which furnishes the bulk of the ivory of commerce, the tusks, although weapons of defense, bid fair to be the cause of its extermination, from 75,000 to 100,000 animals being killed annually. As the animal grows but slowly, and as Africa is being yearly rendered more and more accessible, the end can not be very far off. Tusks have been obtained 9 or 10 feet in length, and 150 lb. in weight, but such are rare, the average weight of tusks from Africa now brought to market being about 30 lb., that of tusks from India much less. Elephants are polygamous, and usually associate in small herds, although formerly the African species was found in great numbers. The period of gestation is twenty-one months, and the female brings forth but one young at a birth, the baby elephant being about 3 feet high and from 150 to 200 lb. in weight. The rate of growth is slow, an elephant requiring from twenty to thirty years to attain its full stature and full weight, this latter varying from 6,000 to 9,000 lb. Its food is strictly vegetable, consisting of the twigs and leaves of trees, shoots of young bamboo, grass, and aquatic plants. There are but two species of existing elephants, the Asiatic and the African, these being the sole survivors of a race that once ranged over the greater portion of the earth and whose fossil remains bear testimony to former abundance. The Asiatic elephant (*Elephas indicus*), the species most commonly seen, is distinguished from its African relative by a greater



Asiatic elephant (*Elephas indicus*).

number of enamel plates in the grinders, the flatness of the forehead, smaller size of the ears, a greater number of folds in the trunk, and by having four nails on the hind foot instead of three. The Asiatic elephant reaches an extreme height of 10 ft. 6 in., or possibly 11 feet, but 8 ft. 6 in. is above the average. The females are but little less in size than the males, but have smaller tusks often not showing at all. It inhabits the forest lands of India, Burma, the Malay Peninsula, Cochin China, Ceylon, Sumatra, and Borneo. The Bornean elephants are believed to be the descendants of some presented by the old East India Company to the Sultan of Sulu, and by him turned loose in Borneo.

The African elephant (*Elephas* or *Loxodon africanus*) is found in nearly all the wooded regions of Africa S. of the Sahara. The males attain a maximum height of 12 feet, but the females are usually decidedly smaller than the males. While the Asiatic elephant has been tamed by man since time immemorial, it has never been domesticated, it being easier to capture and subjugate wild elephants than to breed them in captivity. Elephants formerly played a prominent part in the wars and state ceremonials of East Indian potentates, and are to-day used by them in hunting tigers and other game, and to swell the pomp and circumstance of their state. They are used in the British Indian forestry department, and in the East Indian army for the transportation of artillery and military stores. The cost of maintaining an elephant is considerable, for, in addition to the large amount of food consumed, each animal requires five or six attendants and two or three buffaloes and a pony to bring in fodder from the forest. In the teak forests the elephants drag and pile up the hewn timber, laying the heavy beams as regularly and as skillfully as men. Elephants are captured by being driven into a strongly built inclosure, where they are secured and fastened to trees by the aid of tame elephants, and left until subjugated by fatigue and hunger. The capture or killing of wild elephants is prohibited by law throughout India, and in Ceylon there is also an export duty placed upon them.

Since the days of Hannibal, when the Carthaginians employed elephants in their wars with Rome, no African race has had the ability to capture and train these huge beasts, although the African elephant in captivity seems to be quite as intelligent as its relative of India.

Extinct elephants are described under MAMMOTH and MASTODON (*qq. v.*), but it may be said that the fossil species seem to have varied quite as much in size as their modern representatives, and that while their tusks were larger they do not appear to have exceeded in bulk the largest representatives of the living species. F. A. LUCAS.

Elephan'ta: an island of British India; in the harbor of Bombay, 7 miles from that city. It is 6 miles in circumference, and contains several remarkable ancient cave-temples excavated out of the native rock, and adorned with numerous sculptured figures of the Hindu mythology. The largest of these cave-temples is about 133 feet long, and is supported by twenty-six pillars. A gigantic stone figure of an elephant formerly stood on the shore, and from this the island received its name.

Elephant Bay: an inlet of the Atlantic; in Benguela, Africa; lat. 13° 14′ S., lon. 12° 33′ E. It affords good anchorage, but no fresh water.

Elephant-beetle: a name popularly applied to various lamellicorn beetles of the genera *Goliathus*, *Megasoma*, and *Dynastes*, either on account of their great size or from their long snout-like projections of the head. F. A. L.

Elephant-fish: a name applied to the southern chimæra (*Callorhynchus antarcticus*) on account of the curious prolongation of the snout, which suggests a proboscis and is somewhat prehensile. It is found in the Southern Pacific, especially in the vicinity of the Cape of Good Hope, and is occasionally eaten. F. A. L.

Elephanti'asis [Gr. ἐλεφαντίασις, a cutaneous disease, so called from the resemblance of the diseased skin to the elephant's hide]: the disease anciently known as *elephantiasis Arabum*, the elephantiasis of the Arabians, so called to distinguish it from the *elephantiasis Græcorum*, the elephantiasis of the Greeks, which was probably identical with leprosy. Elephantiasis is rare in Europe and North America, though not unknown in either. It is endemic in the Levant and the East and West Indies, whence it is often called *Barbados leg*. The foot and leg, or sometimes other parts, become greatly enlarged and enormously increased in density and hardness, the skin assuming a remarkable roughness and usually a darkness of hue. It is sometimes caused by a small animal organism, the *Filaria sanguinis hominis*, which, in its adult state, infects the lymphatic vessels or glands, especially in the groin, and by obstructing the flow of lymph finally leads to the swelling of the limb. The prognosis is usually grave, very few cases recovering, though many cases remain completely stationary after the disease is once established. In fatal cases suppuration and erysipelas are the active symptoms. The treatment is thus far unsatisfactory. The use of iron, iodine, and quinia, with bandaging, is recommended. Revised by W. PEPPER.

Elephan'tiné: an island of the river Nile; on the boundary between Egypt and Nubia; opposite Assouan (the ancient *Syene*). It is a mile long, and is partly occupied by gardens and houses interspersed among ruins of ancient temples erected by the Pharaohs. Among its monuments is the Nilometer mentioned by Strabo, and designed to record the height of the inundations of the Nile. It was long an independent city, with its own kings, and gave to Egypt the fifth dynasty; its modern inhabitants are all Nubians. See EGYPT, ANCIENT.

Elephant Seal, or **Sea-Elephant**: the name applied to the two largest members of the hair-seal family (*Phocidæ*), partly on account of their great size, but more from the fact that the adult males have a short proboscis. The male southern elephant seal (*Macrorhinus leoninus*) is, when fully grown, about 16 feet in extreme length, or 20 feet from tip of nose to end of outstretched hind flippers. The color is gray, with a blackish or olive cast, darkest above. The head is large, external ears absent. There are five nails on the fore foot, none on the large webbed hind feet, which, as in the other hair seals, are the chief organs of propulsion. The females are but one-half or one-third the bulk of the males. The food of the animal is mainly cuttlefishes. The southern elephant seal is most abundant at Kerguelen, Heard, and Macquarie islands in the southern seas, where they have long been hunted for their oil. Their numbers have been greatly lessened, and the profit of a sea-elephant voyage is now uncertain. The northern elephant seal (*Macrorhinus angustirostris*), which very closely resembles that of the south, was once abundant on the coast of Lower California, but has been probably exterminated. F. A. L.

Elephant's Foot: a plant (*Testudinaria elephantipes*) sometimes called Hottentots' bread. It belongs to the family *Dioscoriaceæ*, having a large, fleshy root-stock, abruptly truncated at the end. This root-stock is eaten by the Hottentots. It is covered with a soft, rough bark, from which springs a climbing stem, bearing the leaves and flowers. The same name is also given to a genus of the family *Compositæ*, the *Elephantopus*, of which a few species are found in the U. S.

Elephant-shrew: a name applied to various members of the family *Macroscelidæ*, on account of their elongate noses. This group of insectivorous mammals is peculiar to Africa, and its members are distinguished by their long hind feet and jumping abilities. In habits and appearance they some-

Elephant-shrew (*Macroscelides typicus*).

what resemble the jumping-mice of North America, and are sometimes locally termed elephant-mice. F. A. L.

Elets: a town of Russia; government of Orel; on the Sosna; 220 miles S. S. E. of Moscow (see map of Russia, ref. 8–E). It has many factories, and a large trade in leather, grain, and flour. Pop. (1897) 37,455.

Eleusi'ne: a genus of grasses (*Gramineæ*), comprising several species which are natives of India and other warm climates, and are cultivated for food. *Eleusine coracana* is extensively cultivated for its large farinaceous grain (called korakan or dagussa) in India, China, Japan, and throughout Africa. The *Eleusine indica* is naturalized about dooryards, etc., in the U. S.

Eleusin'ia, or **Eleusinian Mysteries**: an annual festival celebrated in ancient Greece in honor of Demeter (Ceres) and Persephone (Proserpine). The worship of Demeter originally took place at Eleusis only, but after the conquest of that city by the Athenians feasts were celebrated in her honor in various Grecian cities. The origin of these mysteries is uncertain, but the popular tradition was that Demeter herself, while searching for her daughter Persephone, came to Attica, where she taught the inhabitants the use of corn and instituted the mysteries. The festival consisted of the greater and the lesser mysteries. The lesser feast was held in the spring at Agræ, on the Ilissus, and was only a preparation for the real or greater mysteries. The latter took place in October. On the first day, called ἀγυρμός (the assembling), the mystæ—i. e. those who had been initiated in the lesser Eleusinia—assembled at Athens. On the second they walked to the sea in procession and were purified. The third day appears to have been a day of fasting, and, according to some authorities, sacrifices of fish and cakes of barley from the Rarian plain were offered. On the fourth day the procession of the sacred basket (κάλαθος κάθοδος) took place. This basket contained pomegranates and poppy-seeds, and was drawn on a cart by oxen, and followed by women bearing mystic cases. The fifth day appears to have been known as the torch-day, and probably symbolized the search of Demeter for Persephone. The mystæ walked with torches to the temple of Demeter at Eleusis, where they seem to have remained all night. The sixth day, called Iakchos, from a son of Demeter, was the most solemn of all. A decorated statue of Iakchos was carried from Athens to Eleusis, where the votaries again passed the night and were initiated into the last mysteries. Under an awful oath of secrecy they were admitted into the inner sanctuary, where they were allowed to see the sacred things, after which they were called *epoptæ*—i. e. watchers. On the seventh day they returned to Athens with jests and music, resting at the bridge over the Cephisus, where they ridiculed all who passed. The eighth day is supposed to have been added to the original number, so that those might be initiated who had been unable to attend on the sixth day. On the ninth and last day two vessels filled with wine or water were emptied—one toward the east, the other toward the west—by the priests, who at the same time uttered some mystical words. Besides these ceremonies there were several others, of which the Eleusinian games, supposed to have taken place on the seventh day, and to have been the most ancient in Greece, were the chief. The Emperor Theodosius suppressed the festival. Nothing certain is known respecting the doctrines revealed to the initiated, but they are supposed to have contained comforting assurances with regard to a future state. Distinctions of class were abolished at the Eleusinia, and with this view Lycurgus forbade any woman to ride in the procession in a chariot, under penalty of a heavy fine. See Hermann, *Lehrbuch der gottesdienstlichen Altertümer der Griechen*; Förster, *Der Raut und die Rückkehr der Persephone*; Haggenmacher, *Die Eleusinischen Mysterien*; Grote, *History of Greece*, part i., chap. i.

Eleu'sis (in Gr. Ἐλευσίς, or Ἐλευσίν): an ancient and celebrated city of Greece; situated in Attica, near the northern shore of the Gulf of Salamis; about 12 miles N. W. of Athens. It was the chief seat of the worship of Demeter (Ceres), who had here a large temple, and whose mystic rites, called ELEUSINIA (*q. v.*), were performed annually with great pomp. The site of Eleusis was near the modern village of Levsina. See Wordsworth, *Greece* (1853).

Eleu'thera: one of the BAHAMA ISLANDS (*q. v.*).

Eleuthe'ria [from Gr. ἐλεύθερος, free]: a national festival of the ancient Greeks, instituted in 479 B. C. to commemorate their deliverance from the Persian armies which had invaded Greece. It was celebrated annually at Platæa in the early part of autumn.

Elevation [from Lat. *eleva'tio*; *ē*, out + *leva're*, lighten, raise]: the act of raising to a higher level or place; the act of exalting in rank; altitude; height above the surface; sometimes exaltation of mind or style; a hill or elevated ground. In engineering and architecture, a geometrical representation of a building or other object, as if projected (see GEOMETRY, DESCRIPTIVE) upon a vertical plane by perpendicular lines drawn through its defining lines or points. It is generally a projection of the exterior, therein differing from a *section* which shows the interior, or a part, as if cut through.

ELEVATION in astronomy is the angular height or the altitude of a celestial object above the horizon, measured by the arc of a vertical circle passing through it and the zenith. Thus the elevation of the pole denotes the arc of the meridian intercepted between the pole and the horizon, and is always equal to the latitude of the observer. The greatest elevation of a star occurs when that star is on the meridian.

ELEVATION in gunnery is the inclination of the axis of the cannon or gun above the object aimed at, in order to counteract the effect which the force of gravity causes. It varies with the range.

Elevation of the Host (in Lat. *eleva'tio hos'tiæ*): in the Roman Catholic ritual of the mass, the lifting up of the elements after consecration for the adoration of the people. It forms one of the most solemn and impressive features of the whole Roman Catholic liturgy.

Elevators, or **Lifts**: machines for lifting passengers or freight, consisting essentially of a car which is raised by ropes or is pushed up by a ram from below, power being applied to the ropes or ram, the car being maintained in lateral position by rails of wood or metal, upon which it moves. The term is usually applied to machines of which the vehicles move in a vertical direction. Elevators of crude form have been known and used since the earliest times, being propelled by man, animal, and water power, but have been applied extensively to buildings only since about the year 1850.

Elevators are classified as hand, power or belt, steam, hydraulic, and electric elevators. *Hand elevators*, as the name implies, are worked by hand-power. *Power elevators* are those in which the ropes supporting the car are wound upon drums, revolved by gearing and pulleys driven by belts, and are applied to factories where power is distributed by shafting. *Steam elevators* are those in which the ropes are wound on drums revolved by steam-engines, the engines forming part of the machine, and are used principally in mines, blast furnaces, and warehouses.

Hydraulic elevators are of two principal forms, the ram type much used in Europe, and the suspended type. The ram elevator, which was first used extensively by M. Léon Edoux, of Paris, France, consists of a cylinder, usually sunk in the earth, containing a ram, on top of which is placed the cage. When water pressure is admitted to the cylinder, the ram is forced upward, pushing the car above it; when the pressure is relieved, the car and plunger descend by their own weight. In the suspended type the cables are carried over sheaves at the top of the building, and thence down and around alternately fixed and movable sheaves, the movable sheaves being attached by rods to a piston moving in the cylinder, the arrangement being simply the reverse of a tackle. When water-pressure is admitted to the cylinder, the fixed and movable sheaves are forced apart, taking up on the cables and lifting the car. When the pressure is relieved, the car descends by its unbalanced weight, drawing the sheaves together. The cylinder is usually placed in a vertical position, but is sometimes placed horizontally. In towns possessing high-pressure water-service, the cylinders are connected directly with the water-mains, the water being discharged after use into the sewers. In some instances elevators are operated directly from artesian wells. In towns where the city water-pressure is insufficient, pressure is obtained by pumping water into storage tanks on top of the building; and where the height is insufficient, additional head is obtained by using closed tanks partially filled with compressed air. Where water is specially pumped, it may be used over again indefinitely, the only loss being by leakage and evaporation. *Electric elevators* are essentially the same in construction as steam elevators, electric motors being substituted for the engines and winding the cables on drums in the same manner.

The movement of an elevator is controlled from the car by means of an operating rope connecting with the motive machinery, the control being effected in power elevators by a belt shifter, and in steam and hydraulic by a valve which reverses the direction of the steam or water, or cuts them off entirely. In electric elevators the current is reversed or cut off by a switch. The operating rope is usually moved directly by hand, but is sometimes moved indirectly through the medium of a lever or hand wheel.

Safety devices are applied to elevators to prevent overrunning the limits of travel, falling in case of rupture of the cables, or descending at dangerous speed.

Overrunning is prevented by stop balls on the operating rope, which are operated by the car itself in the event of neglect of the conductor. The winding drums of steam and electric elevators, and the pistons of hydraulic elevators, also automatically close the operating valve when the proper length of travel has been completed. Falling is prevented by grips which act upon the strips guiding the car, and which are thrown into action by springs or levers, actuated by the breaking of one or more of the cables. Descending at dangerous speed is prevented by ball governors, placed at top of the shaft or on the car, so adjusted as to operate the safety-grips whenever the car attains an undue velocity. A great variety of safety-grips are in use; those most employed consist of wedges which squeeze the guide strips, or toothed dogs which cut into the strips, the guide strips being made of wood.

Among the most notable elevators are the steam elevator in the Washington monument, at Washington, D. C., which has a travel of 500 feet; the hydraulic elevators in the Eiffel Tower, having a travel of 420 feet, and lifting 50 persons at a speed of 400 feet per minute; and the three Otis hydraulic elevators in the terminal station of the North Hudson County Railway Company, at Weehawken, N. J., having a travel of 148 feet each, capable of lifting 140 persons at a speed of 300 feet per minute.

THOMAS E. BROWN, Jr.

Elf: [O. Eng. *ælf* : Germ. *Alp*, ghost, sprite; cf. *Alpdrücken*, nightmare; the word is probably closely connected with the Skr. *ṛbhú-*, a name applied to three deities or genii of artistic handiwork in Vedic mythology]: one of a class of imaginary beings who figured prominently in the mythology of Northwestern Europe, Germany in particular; as good or bad elves their exploits gave rise to a great number of marvelous tales. Fairies take the place of elves in Celtic legends, and are in general represented as beneficent.

Elgin, ĕl'gin: a royal burgh of Scotland; capital of County Moray or Elginshire; on the river Lossie; 5 miles from the sea and 118 miles N. of Edinburgh, with which it is connected by a railway (see map of Scotland, ref. 6–H). It is beautifully situated in a fertile valley, and has ten churches, a hospital, and an institution for the education of orphans, endowed with £70,000 by Gen. Andrew Anderson. Elgin has the ruins of a cathedral founded in 1224, the most extensive and beautiful of ancient Scottish remains; also the ruins of a castle which was the residence of the Earls of Moray. Pop. (1891) 7,799.

Elgin, ĕl'jin: city and railway center; Kane co., Ill. (for location of county, see map of Illinois, ref. 2–F); situated on Fox river, and on the Ch., Mil. and St. P., Ch. and N. W., and E., J. and E. railways; 36 miles W. by N. from Chicago. It has an excellent academy, fine schools, the Northern Insane Asylum, which cost $750,000, great water-power, and more than forty manufacturing concerns; among them the National watch-factory, one of the largest in the world, employing 3,200 skilled operators, and large milk-condensing factories. Elgin is also one of the great dairy centers of the U. S. Pop. (1880) 8,787; (1890) 17,823; (1900) 22,433.

EDITOR OF "COURIER."

Elgin, ĕl'gin, JAMES BRUCE, Eighth Earl of: statesman; b. in London, July 20, 1811; educated at Oxford; in 1841 succeeded his father, Thomas Bruce, in the earldom, which was a Scottish peerage, and did not admit him into the House of Lords. As governor of Jamaica he improved the condition of the Negroes who had been emancipated during the administration of his predecessor, Lord Metcalfe, at the same time earning the respect and confidence of the planters. His administration of the office of Governor-General of Canada, to which he was appointed in 1846, was even more successful. He followed the policy marked out by his uncle, Lord Durham, the friend of Canadian self-government, holding the position of a mediator between parties governed in accordance with constitutional principles. He was created a peer of the United Kingdom in 1849, and in 1854 was offered a seat in the cabinet as Chancellor of the Duchy of Lancaster, which he declined. He was sent on a mission to China in 1857, and negotiated the treaty of Tientsin (1858), guaranteeing protection to Christians, permitting the residence of foreign ambassadors, opening the country to travelers with passports, and granting important commercial privileges. He afterward went to Japan, where he negotiated the treaty of Yedo. In 1859 he was Postmaster-General, and in 1861 was appointed Governor-General of India, where his administration was marked by a faithful adherence to Canning's policy in conciliating the feudatories of the British Government. D. at Dhurmsala, India, Nov. 20, 1863, and was succeeded in the earldom by his son Victor Alexander Bruce (b. 1849), who was appointed Viceroy of India in Oct., 1893. See Walrond, *Letters and Journals of Lord Elgin* (1872), and *The Friend of India* (1862–63).

Elgin, THOMAS BRUCE, Seventh Earl of: diplomat; b. in Scotland, July 20, 1766. He obtained the rank of general in the army, and was sent as envoy extraordinary to Berlin in 1795. In 1799 he was appointed ambassador to Constantinople. He expended a large sum of money (about £74,000) in the removal of statues, bas-reliefs, and other remains of ancient art from the Parthenon and Acropolis of Athens to England. See ELGIN MARBLES. D. Nov. 14, 1841.

Elgin Marbles: a collection of Greek sculptures in the British Museum, London. These were taken to England from Greece by Thomas Bruce, seventh Earl of Elgin, who was British ambassador at Constantinople from 1799 to 1803. He obtained a firman from the Turkish Government allowing him to put up scaffolding around the Parthenon at Athens, to make casts and drawings, and even to remove sculptured or inscribed stones. Under this permit he stripped the Parthenon of many of the metopes of the outer frieze (that of the entablature), all the pediment sculptures that were in fair condition, and the greater part of the cella frieze in low relief. The temple had been shattered by an explosion a century before (see ACROPOLIS and PARTHENON), but the two ends were comparatively little injured until Lord Elgin's workmen wrenched the blocks of marble apart. The result is that the building is now almost entirely in ruins, and while a few slabs of the inner frieze and a number of the metopes remain in the building, all the pediment-sculptures, the best of the metopes, and by far the larger part of the cella frieze form part of the Elgin marbles.

The Elgin marbles were partly exhibited in London by their owner, and were purchased by the nation in 1816 at a price less than half as great as their cost to him. They are arranged in the Elgin room in the British Museum. The slabs of the cella frieze are let into the wall and covered with glass to preserve them from the injurious effects of the London atmosphere. The statues and groups from the pediments are arranged on tables. Fifteen metopes are let into one of the walls, casts of others are shown, but no more of the originals are in the collection.

A full account of the removal, transportation, and purchase is to be found in Michaelis's *Ancient Marbles in Great Britain*, Ellis's *Elgin Marbles*, and Edwards's *Lives of the Founders of the British Museum*. The more important sculptures are described and figured in Michaelis's *Der Parthenon*, and many of them also in works on Greek sculpture, for which see SCULPTURE. RUSSELL STURGIS.

Elginshire, called also **Moray**: a county of Scotland; bounded N. by the German Ocean, E. by Banffshire, S. by Inverness, and W. by Nairn. Area, 482 sq. miles. The climate is mild and dry, and the soil open, sandy, and gravelly; very fertile in the northern part. The chief agricultural products are wheat, oats, and other kinds of grain; the county was formerly called the granary of Scotland. The chief articles of export are cattle, salmon, grain, and timber. Together with Nairnshire, it sends one member to Parliament. Chief town, Elgin. Pop. (1901) 44,757.

Elgon, Mt.: See the Appendix.

Eli (Sept. 'Ηλί): high priest at the temple of Shiloh when the ark of the covenant was in the tabernacle at that place (1 Sam. i. 3, 9), and civil judge of Israel for at least twenty years. In his old age his sons, Hophni and Phinehas, whom he had invested with authority, profaned the sanctuary and received from him only a feeble rebuke. In consequence judgments were pronounced against his house by Samuel, who, as a child, had ministered to the Lord before Eli. Several years after this Israel was defeated in battle by the Philistines, Hophni and Phinehas were slain, and the ark of God, which they had taken to the field, was captured (1 Sam. iv.). A messenger from the army brought the fatal news to the aged high priest, who, on hearing that the ark was taken, fell from his seat and died.

Elia: See LAMB, CHARLES.

Elias, *ā*-lee'ăăs, DOMINGO: Peruvian statesman; b. in Ica, 1805; educated in Europe. He was a prominent agriculturist and statesman, acting president for a short time in 1844, and was otherwise prominent in Peruvian politics. D. at Lima in 1867.

Eli'as Levi'ta: a Jewish rabbi; b. at Neustadt, near Nuremberg, Feb. 8, 1472. He taught Hebrew at Rome and Venice, was distinguished as a grammarian, and published numerous works, among which are a *Hebrew Grammar*, a *Chaldaic, Talmudic, and Rabbinical Lexicon*, and *Massorah*, containing critical notes on the text of the Bible. Among his pupils were Sebastian Münster (who translated several of his works into Latin), Fr. Buxtorf, Cardinal Egidio, of Viterbo (in whose house he lived for many years, and whom he aided in unraveling the enigmas of the Cabala), Dr. Eck, and others. He was neither a deep nor an original spirit, but he was learned and sound. He remained a Jew, although so much with Christians. He first popularized the views that the canon of the Old Testament was formed by Ezra and the great synagogue, and in the face of the current Jewish theory denied that the Hebrew vowel-points were earlier than the Talmudists. D. in Venice in 1549.

Élie de Beaumont, *ā*'lee'de-bō'mōṅ', JEAN BAPTISTE ARMAND LOUIS LÉONCE: geologist; b. at Canon, Calvados, France, Sept. 25, 1798. He was educated in the Polytechnic School, and became Professor of Geology in the College of France in 1832, chief engineer of mines in 1833, and a member of the Institute in 1835. Among his works are *Carte géologique de la France* (2d ed. 1855), and *Notices sur les systèmes des montagnes* (1852), in which he gave his theories on the elevation of mountain-ranges. He succeeded Arago as perpetual secretary of the Academy of Sciences in 1853. D. in Canon, Sept. 21, 1874.

Elijah [Heb. *'Elijahu*, for whom Jehovah is God; Gr. 'Ηλίας]: a Hebrew prophet concerning whose ancestry the Scriptures are silent. The chief events in his life, as related in the first and second books of Kings, were his prediction of the great drouth which afflicted Israel; the confounding and destruction of the priests of Baal; his persecution by Jezebel; his prediction of the violent deaths of Ahab, Jezebel, and their son Ahaziah; his appointment of Elisha to succeed him in the prophetic office; and his own translation in a chariot of fire.

E'lim [Heb., stout trees]: the second station mentioned in the march of the Israelites after crossing the Red Sea (Ex. xv. 27). It has been identified with Ghurundel, about halfway between Suez and Sinai.

Elio, ā'lēĕ-ō, FRANCISCO JAVIER: general; b. at Pamplona, Spain, Mar. 4, 1767; entered the army in 1785. In 1805 he was sent to the Rio de la Plata with re-enforcements against the English; was appointed commandant-general of the Banda Oriental; forced the English to give up Montevideo (Sept. 9, 1807), and was made governor of that city; returned to Spain in 1810, and was appointed viceroy of Buenos Ayres; but he was opposed by the junta and people. (For events of the period, see URUGUAY.) Gen. Elio returned to Spain in 1811, and as commander of the Spanish troops in Catalonia and Valencia won brilliant victories over the French in 1812–13. He was made governor and captain-general of Murcia and Valencia soon after the restoration of Ferdinand VII.; in 1820 he was imprisoned by the revolutionists; accused of instigating an armed attempt to liberate himself, he was condemned by a court martial, and executed at Valencia, Sept. 4, 1822.

HERBERT H. SMITH.

Eliot, ANDREW, D. D.: b. in Boston, Mass., Dec. 28, 1718; a descendant of Andrew Elliott, of Somersetshire, England, who settled at Beverly, Mass., about 1683. He graduated at Harvard in 1737, and became associate pastor of the New North church, Boston, Mass., in 1742, and sole pastor in 1750. He took an active interest in the conversion of the Indians, and in defending the Congregational polity against the attacks of the Episcopalians. In 1773 he declined an election to the presidency of Harvard College. D. in Boston, Sept. 13, 1778.

Eliot, CHARLES WILLIAM, LL. D.: president of Harvard University; b. in Boston, Mass., Mar. 20, 1834; educated at Boston Public Latin School; A. B., Harvard, 1853; tutor in mathematics at Harvard 1854–58; assistant Professor of Mathematics and Chemistry 1858–61; of Chemistry 1861–63; Professor of Chemistry in the Massachusetts Institute of Technology 1865–69; president of Harvard since 1869; author (with F. H. Storer) of *Manual of Inorganic Chemistry* (1866); *Manual of Qualitative Chemical Analysis* (1869). President Eliot's chief writings since his election to the presidency of Harvard have been his annual reports; these have ranked among the most valuable contributions to the literature of higher education. His influence has been widely felt, and has strongly promoted progress in university methods and management. C. H. T.

Eliot, GEORGE: *pseudonym* of Mary Ann (or Marian) Evans, an English novelist: b. at Arbury farm, in Warwickshire, England, Nov. 22, 1819. She remained under the parental roof, first at Griff, on the same estate, afterward at Coventry, until 1849. Her father, a man of considerable business ability, was agent of the estate on which Arbury farm was situated, and afterward also of Lord Aylesford, Lord Lifford, and others. His children were well educated and strictly trained, but Mary Ann very early exhibited great independence of character, and in 1841 abandoned the beliefs in which she had been reared, choosing a spiritual path of her own. In 1846 she published anonymously a translation of Strauss's *Life of Jesus*, which in 1854 was followed by a translation of Feuerbach's *Essence of Christianity*. After the death of her father, in 1849, she resided for one year at Geneva, and then settled in London as assistant editor of the *Westminster Review*, to which she contributed a great number of remarkable articles. She enjoyed the intimate friendship of all the most advanced thinkers of her day, and in 1854 she formed a union with GEORGE HENRY LEWES (*q. v.*), which was somewhat embarrassing, as Mr. Lewes, who had separated from Mrs. Lewes, but was not divorced from her, was unable to make Miss Evans his lawful wife. Otherwise the union was a happy one, and it was Mr. Lewes who first gave her the idea of attempting a work of fiction. In 1858 *Scenes of Clerical Life* appeared, and was immediately recognized as the product of a great and original power. It was followed by *Adam Bede* (1859), which was a still greater success, and by *The Mill on the Floss* (1860); *Silas Marner* (1861); *Romola* (1863); *Felix Holt* (1866); *Middlemarch* (1871–72); *Daniel Deronda* (1878); *The Impressions of Theophrastus Such* (1879). She published, also, a drama, *The Spanish Gypsy* (1868), and the poems *Agatha*, *The Legend of Jubal*, and *Armgart* (1869). After the death of Mr. Lewes, in 1878, she married John Walter Cross, who published an elaborate and very interesting biography of her, *George Eliot's Life as Related in her Letters and Journals* (1885–86). She died at Cheyne Walk, Chelsea, Dec. 22, 1880.

Eliot, JOHN: "the apostle to the Indians"; b. in England; baptized at Widford, Hertfordshire, Aug. 5, 1604. He was educated at Cambridge, removed to Boston, Mass., in 1631, and in 1632 began his connection with the church at Roxbury which he held at his death. He acquired the language of the Indians, and from 1646 he devoted himself to improving their condition and converting them to Christianity. He traveled extensively among them, enduring great privations and passing through many dangers. He succeeded in acquiring great influence over them, and many of them embraced the Christian faith. He translated the Bible into the Indian tongue (1661–63), published an Indian grammar (1666), and a number of other works, mostly relating to his missionary labors. D. in Roxbury, Mass., May 21, 1690. See his *Life* by Convers Francis (Boston, 1836).

Eliot, Sir John: statesman; b. at Port Eliot, Cornwall, England, Apr. 20, 1592; traveled abroad in his youth and met Villiers, afterward Duke of Buckingham, whose friendship and patronage procured his official advancement. Entering the Parliament of 1624 the devoted adherent of the duke, he supported with zeal his warlike policy toward Spain, but being a staunch upholder of parliamentary privilege against royal encroachment he was soon driven into opposition by the duke's haughty assertion of the king's prerogatives and became as bitter in his antagonism as he had been zealous in his partisanship. He pressed with force and ability the proceedings that ended in Buckingham's impeachment, and at the trial (1626) he displayed his exceptional gifts as an orator in a masterly speech, denouncing the minister. For this he was imprisoned in the Tower (May 11–19).

For the next few years Eliot was the central figure of the opposition to arbitrary government, and the persistent advocate of the principle of ministerial responsibility. Too radical for the other leaders, who deprecated the passion that he showed, he nevertheless found them following his policy in the end. In the Parliament of 1628 he denounced the king's arbitrary taxation, and was instrumental in carrying through the famous petition of right. In 1629, when the king ordered the House to adjourn and the indignation of the members broke out in a scene of wild disorder, it was Eliot who held the Speaker in his chair, while with locked doors and amid noisy summoning from without the Commons passed his resolutions vindicating parliamentary rights. "None have gone about to break parliaments," said he on this occasion, "but in the end parliaments have broken them." Eliot's boldness again cost him his liberty. With eight others he was thrown into the Tower (Mar. 4, 1629), and his steadfast refusal to acknowledge himself in the wrong caused his detention there till his death, Nov. 27, 1632. Among his writings are *The Monarchy of Man* (1879); *An Apology for Socrates* (1881); and *Negotium Posterorum* (1881). F. M. Colby.

Eliot, Samuel, LL. D.: historian; b. in Boston, Mass., Dec. 22, 1821; graduated at Harvard in 1839. Having visited Rome and traveled in Europe, he projected a *History of Liberty*, a part of which he published in 1849, two volumes, entitled *The Liberty of Rome*. *The Early Christians* (2 vols., 1858) is the second part of the same work. Among his other writings is a *Manual of United States History from 1492 to 1850* (1856). He was president of Trinity College, Hartford, in 1860–64; lecturer at Harvard College 1870–73; superintendent of Boston public schools 1878–80; became a member of the Boston school committee in 1885; and was connected with various charitable institutions. D. Sept. 14, 1898.

E'lis (in Gr. Ἦλις; Fr. *Élide*): a small state of ancient Greece in the northwestern part of the Peloponnesus; bounded N. by Achaia, E. by Arcadia, S. by Messenia, and W. by the Ionian Sea. It is intersected by the rivers Alpheus (now Rouphia) and Peneus (Gastuni). The surface is diversified by hills and fertile plains and valleys. Elis was divided into three districts—Hollow Elis, Pisatis, and Triphylia. The chief towns were Elis, Cyllene, Pylos, and Olympia. The Olympic games, the greatest national festival of the Greeks, were celebrated at Olympia. Elis forms with Achaia a nomarchy of the modern kingdom of Greece; area, 1,901 sq. miles; pop. (1896) 236,251.

Elis: city of ancient Greece; the capital of the state of the same name; situated on the river Peneus, about 10 miles from its mouth. It is mentioned as a town of the Epeii by Homer (*Iliad*, ii.). Its acropolis was on a hill nearly 500 feet high. The city contained several fine temples, a theater, and the largest gymnasium in Greece. All the athletes who contended at the Olympic games were required to undergo one month's previous training in this gymnasium. When Pausanias visited Elis (about 175 A. D.) it was one of the most splendid and populous cities of Greece. The site is occupied by the modern Paléopoli or Kaloscopi.

Elisæ'us (in Armenian *Egishe*): Armenian historian and theologian of the fifth century; educated by Sahab and Mesrob; entered the service of the Armenian prince Vartan, and was his private secretary during the rebellion against the Persians; was afterward elected bishop of the Amadunians, and was present at the great national synod of Ardashad in 450. His principal work is a history of the Persian persecution, when Yzdegerd II. actually attempted to extinguish Christianity in Armenia, *The History of Vartan and the Battle of the Armenians*. He narrates these events as an eyewitness, and all official sources of information were at his disposal. The book was first printed in Constantinople (1764); the best edition of it is that of Venice (1852). It was translated into English by C. F. Neumann (London, 1830). Elisæus also wrote commentaries on various books of the Old Testament, sermons, etc., of which a collected edition appeared in Venice (1838). D. in 480.

Eli'sha: a Hebrew prophet, called to the prophetic office by Elijah, receiving his mantle when he was taken up into heaven; was recognized by the other prophets as their spiritual head, and enjoyed great respect from the people of Israel throughout his whole life. His history is told in the second book of Kings, and his death is commonly fixed at 840 B. C.

Eli'sors [O. Fr. *elisour*, deriv. of *elire* (Mod. Fr. *élire*) < Lat. *eli'gere*, choose]: in law, persons (two in number) named by the court to return a jury when the sheriff and coroners are incompetent. Against their return no challenge can be taken to the array of jurors, though there may be a challenge to individual jurors or to the polls.

Elizabeth: city and railway center; capital of Union co., N. J. (for location, see map of New Jersey, ref. 3–D); situated on Staten Island Sound and on Elizabeth river, 14 miles from New York. It has many churches, among them one which cost $500,000 (R. C.), an orphan asylum, an extensive establishment for making sewing-machines, ship-yards, pump-factory, oil-refineries, a large brick-yard, several foundries, etc. The census of the U. S. for 1890 shows 187 manufacturing establishments, with a capital of $7,770,703, giving employment to 6,532 persons, at an annual wage of $3,703,-731. The cost of materials was $4,490,353; the value of product $10,446,864. Elizabeth contains the residences of many New York business men, has several parks, and is surrounded by a rich farming country. Elizabethtown, as it was originally called, was settled in 1665, and was the capital of New Jersey until 1790. Pop. (1880) 28,229; (1890) 37,764; (1900) 52,130. Editor of "Leader."

Elizabeth: borough; Allegheny co., Pa. (for location of county, see map of Pennsylvania, ref. 5–B); situated on railway and on the Monongahela river, 22 miles S. E. of Pittsburg. It is an important shipping-point for coal, and is also engaged in boat-building and agriculture. Pop. (1880) 1,810; (1890) 1,804; (1900) 1,866.

Elizabeth: Queen of England, and the last sovereign of the house of Tudor; b. at Greenwich, Sept. 7, 1533. She was a daughter of Henry VIII. and Anne Boleyn. Her childhood was passed in comparative retirement, and she was educated by persons who favored the Reformed religion. She learned the Latin, Greek, French, and Italian languages of the famous Roger Ascham. In 1554 she was confined in the Tower by order of Queen Mary, who believed her to be implicated in Wyatt's rebellion, and regarded her with jealousy because she was the favorite of the Protestant party. Elizabeth narrowly escaped death, for some of the bishops and courtiers advised Mary to order her execution. After she had passed several months in the Tower, she was removed to Woodstock, and appeased Mary by professing to be a Roman Catholic.

On the death of Queen Mary (Nov. 17, 1558) Elizabeth ascended the throne, and the majority of the people rejoiced at her accession. She appointed William Cecil Secretary of State, and Nicholas Bacon keeper of the great seal. She retained several Roman Catholics in her privy council, but she refused to hear mass in the royal chapel. The Protestants were the majority in the Parliament which met in 1559, abolished the mass, adopted the Thirty-nine Articles as the religion of the state, and recognized the queen as the head of the Church. She declined an offer of marriage made to her by Philip II. of Spain. Her foreign policy was pacific. She waged no war for conquest, but to promote the stability of her throne she aided the Protestant insurgents in Scotland, France, and the Netherlands with money and troops. In 1563 the Parliament, anxious that she should have an heir, entreated her to marry, but she returned an evasive answer, and would neither accept the hand of any of her suitors nor decide in favor of any claimant of the throne. Among her suitors were the French Duke of Anjou, the Archduke Charles of Austria, and Robert Dudley, Earl of Leicester, who was for many years her chief favorite. William Cecil, Lord Burleigh, was her Prime Minister and most trusted adviser during the greater part of her reign, the prosperity of which was largely due to his prudence and influence.

Mary Queen of Scots, fleeing from her rebellious subjects, took refuge in England in 1568, and was detained as a prisoner by Elizabeth. The latter regarded Mary as a dangerous rival, because the English Catholics wished to raise her to the throne of England, and formed several plots and conspiracies for that object. (See MARY STUART.) Mary was beheaded Feb. 8, 1587. Philip II. of Spain had long meditated a hostile enterprise against Queen Elizabeth, who had offended him by aiding his revolted Dutch subjects and by persecuting the English Catholics. For the invasion of England he fitted out the Invincible Armada, which consisted of about 130 vessels, with over 19,000 soldiers, and sailed in May, 1588. A violent storm dispersed the Spanish ships, many of which were wrecked, and the rest were encountered by the English fleet, mostly consisting of small but excellently equipped vessels, under Admiral Howard, and thoroughly beaten, Aug. 8, 1588. The disastrous failure of this expedition did not terminate hostilities between England and Spain. An English fleet took Cadiz in 1596. After the Earl of Leicester died (1588) the Earl of Essex was the queen's favorite courtier. The Puritans were severely persecuted in the latter part of her reign. She died Mar. 24, 1603, and was succeeded by James VI. of Scotland, who became James I. of England. Her reign was one of the most prosperous and glorious in English history. The Elizabethan age was almost unequaled in literature, and was illustrated by the genius of Shakspeare, Spenser, Bacon, Sidney, and Raleigh.

AUTHORITIES.—Froude, *History of England* (vols. vii. to xii.); Green, *History of the English People*; Camden, *History of Queen Elizabeth* (1625); Dr. Thomas Birch, *Memoirs of the Reign of Queen Elizabeth* (1754); also Motley, *The Rise of the Dutch Republic* and *History of the United Netherlands.* Revised by C. K. ADAMS.

Elizabeth, SAINT, of Hungary: a daughter of Andrew II., King of Hungary; b. at Presburg in 1207. She became in 1221 the wife of Louis, landgrave of Thuringia, who died in 1227 at Otranto, on a crusade to the Holy Land. His eldest brother Henry seized his possessions, and banished his widow and children. The knights of Thuringia restored her son Herman to the throne, and Elizabeth received as a dower the city of Marburg, where she retired with her daughters, and spent the remainder of her life in what became one continued penance. D. Nov. 19, 1231. Says Mrs. Jameson, "Of all the glorified—victims must I call them, or martyrs?—of that terrible but poetical fanaticism of the thirteenth century, she was one of the most remarkable; and of the sacred legends of the Middle Ages hers is one of the most interesting and most instructive." See Charles de Montalembert, *Vie de S. Elizabeth de Hongrie* (1836), which has been translated into English; also Charles Kingsley's *Saint's Tragedy*.

Eliz'abethan Architecture: a term applied to the style which prevailed in England after the decline of the Gothic, mainly during the reigns of Elizabeth and James I. It resulted from the introduction of Renaissance or classic forms from Germany and Holland during the reigns of Henry VIII. and Elizabeth; and, while it retained the mullioned and traceried windows and bays, the hood-mouldings and parapets of the preceding Tudor style, it employed many classic details and a somewhat monotonous style of surface-carving derived from Holland and Germany. It appears chiefly in domestic architecture, and was succeeded by the Jacobean, in which the Gothic details wholly disappeared.
A. D. F. HAMLIN.

Elizabeth, Cape: See CAPE ELIZABETH.

Elizabeth City: town; capital of Pasquotank co., N. C. (for location of county, see map of North Carolina, ref. 2–J); situated on railway and on the Pasquotank river, 46 miles S. of Norfolk, Va. It is the center of an agricultural district producing chiefly grain and cotton, and has Creecy Park, a State normal school, steam grist-mills and saw-mills, a cotton-factory, shingle-factories, and planing-mill; also a fine harbor, safe and sufficiently deep for large vessels. Pop. (1880) 2,315; (1890) 3,251; (1900) 6,348.
EDITOR "ECONOMIST AND FALCON."

Elizabethgrad, or **Jelissawetgrad**: town of Russia; government of Kherson; 160 miles N. E. of Odessa (see map of Russia, ref. 9–C). It has an important trade and is a great market for horses. Pop. (1897) 61,841.

Elizabethine Nuns: a congregation of monastic women in the Roman Catholic Church, belonging to the third order of St. Francis. The name Elizabethines was at first applied to voluntary associations of women who imitated the zeal of St. Elizabeth of Hungary, without taking monastic vows or retiring from the world. But from the tradition that St. Elizabeth belonged to the third order of St. Francis, the name is sometimes given to Franciscan nuns. It is probable, however, that the Franciscan nuns of the third order were not established till 1395.

Elizabeth Islands: a group of sixteen small islands belonging to Dukes co., Mass., lying between Vineyard Sound and Buzzard's Bay. Since 1864 they have constituted the township of Gosnold. The largest of the islands in the order of their size are Naushon, Nashawena, Pasque, Cuttyhunk, Nonamesset, Uncatena, and Penikese. Cuttyhunk was the seat of Bartholomew Gosnold's first colony in "Virginia," founded in 1602, but abandoned the same year on account of troubles of the colonists with each other and with the Indians. The islands are a favorite resort for fishing and yachting, and were formerly much more thickly inhabited. Pop. (1880) 152; (1890) 135; (1900) 164.

Elizabeth Petrov'na: Empress of Russia; b. in Dec. 1709; daughter of Peter the Great and Catherine I. She was dissolute in morals, and appears to have been unambitious, as she made little effort to obtain the throne. Ivan, an infant, was proclaimed emperor in 1740, but the French surgeon Lestocq and other partisans of Elizabeth conspired against Ivan with success, and she became empress in 1741. As an ally of Austria and France she waged war against Frederick the Great in the Seven Years' war. Her army gained a victory at Kunersdorf, and entered Berlin in 1760. She had several children by Count Rasumovski, who was first her servant, subsequently her chamberlain, and was at length secretly married to her. D. Jan. 5, 1762, and was succeeded by her nephew, Peter III.

Elizabeth Stuart: Queen of Bohemia; daughter of James I. of England; b. in the palace of Falkland, Scotland, Aug. 19, 1596. She was married in 1613 to Frederick V., elector palatine, who was chosen King of Bohemia in 1619 by the Protestant party. She is said to have been beautiful, and is considered a heroine. Her husband was defeated in battle in 1620, and she passed the remainder of her life in exile and adversity. She was the mother of thirteen children, including the famous Prince Rupert. D. in England, Feb. 13, 1662. George I. of England was her grandson. See her *Life* in Mrs. Everett Green's *Lives of the Princesses of England* (1851).

Elizabeth'pol, or **Jelissawetpol'**: a government of Transcaucasia, Asiatic Russia; bounded N. by Tiflis, E. by Baku, S. by Persia, and W. by Erivan; area, 17,038 sq. miles. The government consists in the west of high mountains, while the east is more level. It is drained by the Kur and numerous other small streams. Chief town, Elizabethpol. Pop. (1897) 888,954.

Elizabethpol: city; capital of the government of the same name; 90 miles S. E. of Tiflis (see map of Russia, ref. 12–G). It has a number of churches, mosques, and fruit-gardens. Silkworms are raised here. Pop. (1897) 33,022.

Elizabethtown: city and railway junction; capital of Hardin co., Ky. (for location of county, see map of Kentucky, ref. 3–F); 42 miles S. by W. from Louisville. It has various manufactures, and is an agricultural center. Pop. (1880) 2,526; (1890) 2,260; (1900) 1,861.

Elizabethtown: borough; Lancaster co., Pa. (for location of county, see map of Pennsylvania, ref. 6–H); situated on railway, 18 miles W. N. W. of Lancaster and 18 miles E. S. E. of Harrisburg. It has a farming-implement manufactory, a machine-shop, and a flouring-mill. Pop. (1880) 980; (1890) 1,218; (1900) 1,473.

Elk [O. Eng. *elch*, *eolh*, though $k < ch$ remains unexplained: M. H. Germ. *elch* < O. H. Germ. *elaho*; the word has been displaced in Mod. Germ. by *Elen*, *Elenthier*, a Baltic loan-word, cf. Lith. *élnis*]: the popular name of a species of deer (*Alces machlis*) found in the northern parts of Europe, Asia, and North America. It is one of the largest animals of the deer family or *Cervidæ*, is about 6 feet high, and

Elk or moose.

sometimes weighs 1,200 lb. It has a short, compact body raised on long stilt-like legs, a short, thick neck, and a large, narrow head nearly 2 feet long. The neck is covered with a short thick mane. The antlers of the full-grown elk are flattened, displaying a broad blade with numerous snags on each horn. The tail is only 4 or 5 inches long. The color of its hair is brownish black. Elks can run with great speed. They frequent marshy districts and swampy forests, feeding on lichens, leaves, and branches of trees. Their flesh is esteemed for food.

The true American elk, commonly called the moose, is found from Maine westward to British Columbia. It is much hunted for its flesh and skin in winter, when the frozen crust of the snow, not strong enough to bear the animal's weight, seriously impedes its progress, its great speed at other times making its capture difficult. When brought to bay, a blow with its fore foot or horns is a serious matter for the huntsman. It is the largest known animal of the deer family now existing.

The beast generally known in North America as the elk is the wapiti (*Cervus canadensis*), an animal nearly as large as the moose, once found as far east as Pennsylvania but now restricted to the northwest. It goes in large herds, and is hunted for its flesh, and especially for its skin, which is highly prized. Several other large species of deer (as in Ceylon) or of antelope (as in South Africa) are known locally as elks. The true elks have a broad hairy muzzle, with a bald spot between the nostrils, horns large and palmated, with no basal snag; true deer have a basal snag, and more or less rounded horns; the muzzle is bare and moist. See DEER. Revised by F. A. LUCAS.

El Khargeh, el-kaar'ge: a town of Upper Egypt, capital of the Great Oasis; lat. 25° 28′ N., lon. 30° 40′ E. Here are ruins, chiefly Macedonian and Roman, including a temple, and an ancient necropolis. El Khargeh is also the name of the Great Oasis itself, which is 80 miles long and 10 miles broad, and was anciently still larger. It abounds in acacia and doum-palm trees, and has warm and cold springs and a stream of water; rice is here cultivated. See OASES, LIBYAN.

Elkhart: city and railway center; Elkhart co., Ind. (for location of county, see map of Indiana, ref. 2–E); situated at the confluence of the St. Joseph and Elkhart rivers, 100 miles E. of Chicago. It has fine churches and schools, locomotive repair-shops of the L. S. and M. S. Railway, carriage-factories, paper-mills, starch-mills, manufactories of printing-presses and musical instruments, water-works, electric lights, electric street railway, etc. It is chiefly a manufacturing town, and has several building and loan associations. Pop. (1880) 6,953; (1890) 11,360; (1900) 15,184.

EDITOR OF "REVIEW."

Elkhorn: a river of Nebraska; rises in the northeastern part of the State, flows nearly southeastward through the counties of Madison, Stanton, Cuming, Dodge, and Douglas, and enters the Platte in the western part of Sarpy County. Length estimated at 250 miles.

Elkhorn: village; capital of Walworth co., Wis. (for location, see map of Wisconsin, ref. 7–E); on Chi., Milwaukee and St. Paul R. R., 65 miles N. W. from Chicago, Ill., and 45 miles S. W. from Milwaukee. It has a fine Union school building, a beautiful park, comprising 6 acres of large oak-trees, and manufactures of butter and cheese, wagons, carriages, wood-saws, brick and tile, treadpowers, windmills, etc. It is situated in one of the richest farming districts in the State. Pop. (1880) 1,122; (1890) 1,447; (1900) 1,731.

EDITOR OF "INDEPENDENT."

Elkin, WILLIAM LEWIS: astronomer; b. in New Orleans, La., Apr. 29, 1855; took the degree of Ph. D. in astronomy under Winnecke at the University of Strassburg in 1881; soon after went to the Cape of Good Hope, where he was for a time the coadjutor of Dr. David Gill at the Royal Observatory. Returning to the U. S. he became astronomer at the observatory of Yale College, where he has since devoted himself to work of the highest precision with the heliometer. His principal subjects of research have been the parallaxes of the fixed stars and of the sun, the satellites of Jupiter and Saturn and the Pleiades. S. NEWCOMB.

Elk, Irish: a large, extinct deer, *Megaceros giganteus*, whose remains are found in the Pleistocene of Northwestern Europe, and are particularly abundant and well preserved in the peat-bogs of Ireland. It attained a height of 6 feet at the withers. The antlers, which stand at right angles to the cranium, are flattened and palmate; they are usually about 6 or 7 feet from tip to tip, but specimens 11 feet across are known. Although popularly termed elk, this extinct deer is the sole representative of a distinct division of the deer family, and has no near living allies. F. A. L.

Elk Lake: See the Appendix.

Elk River: a river of West Virginia; flows nearly westward through Braxton and Clay Counties, and enters the Great Kanawha at Charleston. Length, nearly 150 miles.

Elk River: village; capital of Sherburne co., Minn. (for location of county, see map of Minnesota, ref. 8–E); on the Mississippi river, and the Great Northern and N. Pacific R. Rs., 38 miles N. W. of St. Paul; in a farming region. It has a brick schoolhouse and manufactories. Pop. (1900) 831.

Elkton: town; capital of Todd co., Ky. (for location of county, see map of Kentucky, ref. 5–E); on the Louisville and Nashville Railroad; 20 miles E. S. E. of Hopkinsville. It is in an agricultural and tobacco-growing region, and has several churches, public schools, and two weekly newspapers. Pop. (1880) 874; (1890) 1,158; (1900) 1,123.

Ell [O. Eng. *eln*: O. Norse *oln*: O. H. Germ. *elina*, Mod. Germ. *Elle*: Goth. *aleina*, with fundamental meaning forearm; cf. Lat. *ulna*, Gr. *ὠλένη*, Skr. *aratni-*, elbow]: a measure of length adopted from the length of a man's forearm. The English ell is 3 ft. 9 in., and the Flemish is equal to 27 inches, or three-quarters of a yard.

Ellagic Acid [Fr. *ellagique*, by transposition of *galle*, gall-nut]: a constituent of certain animal concretions, as the bezoar-stones of the antelope; also produced by the decomposition of gallic acid.

Ellenborough, EDWARD LAW, Lord: lawyer; b. in Cumberland, England, Nov. 16, 1750. He was engaged in 1785 as the leading counsel for the defense in the trial of Warren Hastings, for whom he pleaded with success. Though he began his political career as a Whig, he was, like many others, driven into the Tory ranks by the fears which the French Revolution excited. He became attorney-general in 1801, and lord chief justice of the king's bench in 1802. In the same year he was created Baron Ellenborough. D. Dec. 13, 1818.

Ellenborough, EDWARD LAW, Earl of: statesman; son of Baron Ellenborough; b. Sept. 8, 1790, and succeeded his father as baron in 1818. He was Lord Privy Seal in 1828–29, and gained distinction as an orator in the House of Lords. In 1841 he was appointed Governor-General of India, where his brilliant but rash administration provoked the severest criticism. He was recalled in 1844 by the East India Company, and then received the title of earl and viscount. He was First Lord of the Admiralty in 1846 for a short time in the cabinet of Peel. On the formation of a new Tory ministry in Feb., 1858, he became president of the board of control. One of his dispatches, censuring Viscount Canning for his conduct in India, offended the public, and he had to resign in 1858. In 1852 he had outlined a home constitution for the Government of India, and when the transference of authority to the crown followed under Lord Stanley's presidency, Ellenborough's plan was carried out in all essential points. D. at Southam Hall, near Cheltenham, Dec. 22, 1871.

By his death the earldom became extinct, and the barony reverted to his nephew.

Ellensburgh: city; capital of Kittitas co., Wash. (for location of county, see map of Washington, ref. 5–F); situated on Yakima river and on the Northern Pacific Railroad, 135 miles E. S. E. of Seattle. It has six churches, State normal school and fine public schools, and is chiefly engaged in agriculture, stock-raising, and mining. Pop. (1890) 2,768; (1900) 1,737. EDITOR OF "CAPITAL."

Ellenville: village; Ulster co., N. Y. (for location of county, see map of New York, ref. 7–J); on railway and on the Delaware and Hudson Canal; 100 miles N. N. W. of New York city. It is situated in a beautiful and fertile valley at the foot of the Shawangunk Mountains, and is a favorite summer resort. It is the seat of Ulster Seminary, and has an academy and graded public schools, many handsome public and private buildings, a glass-manufactory, cutlery-works, stoneware pottery, bluestone quarries, manufactories of leather and boats, excellent water-works, and electric lights. Immense quantities of huckleberries are shipped from this point. Pop. (1880) 2,750; (1890) 2,881; (1900) 2,879. EDITOR OF "JOURNAL."

Ellery, WILLIAM: patriot; b. at Newport, R. I., Dec. 22, 1727. He was a merchant in his youth, and began to practice law in 1770 at Newport. Having gained a high reputation for integrity and wisdom, he was chosen a delegate from Rhode Island to the national Congress of 1776, in which he signed the Declaration of Independence. He was re-elected, and remained in Congress until 1785. In that year he actively supported Rufus King in his attempt to secure the abolition of slavery. In 1790 he was appointed collector of Newport, a position which he held till his death. He supported the Federal party. D. at Newport, Feb. 15, 1820.

Ellet, CHARLES: engineer; b. at Penn's Manor, in Bucks co., Pa., Jan. 1, 1810; devoted himself to mathematical and engineering pursuits, and became an assistant engineer on the Chesapeake and Ohio Canal. He then visited Europe, and after a course at the Polytechnic School in Paris returned to the practice of his profession, holding successively the positions of engineer on the Utica and Schenectady Railway, on the Erie Railway, and chief engineer of the James River and Kanawha Canal. He was the author of an *Essay on the Laws of Trade*, and of other works of a similar character. He built the bridge across the Schuylkill at Fairmount, the first wire suspension bridge in the U. S. In 1845 he affirmed that a bridge might be built across the Niagara below the falls, secure and fitted for railway uses; and he was in 1847 the designing and constructing engineer of the preliminary wire suspension bridge (a light foot-bridge), intended as a service bridge for the construction of the main work. During the civil war he was commissioned to do what he could to protect the Mississippi gunboat squadron against a fleet of hostile rams understood to be coming up the river. He hastily equipped a fleet of nine river steamboats as rams, of which he was given the command. In a subsequent battle (June 6, 1862), terminating in a decisive defeat of the Confederate squadron, he received a wound, from which he died at Cairo, Ill., on June 21.

Ellice Islands: a group of small islands in the South Pacific; N. W. of Samoa and N. of Fiji; discovered in 1819. They are atolls or coral islands and contain lagoons, which in two of the group, Lakena and Olosenga or Quiros Island, are of fresh water. Nui, another of the islands, is remarkable for the fine natural fountains caused by the water from the sea gaining access to the lagoon underneath the reef. The population, which exhibits the same general traits as that of Samoa, numbers about 2,500.

Ellichpur′: a district (and city) of East Berar, British India; between the parallels 20° 51′ and 21° 46′ N., and the meridians 76° 40′ and 78° 30′ E.; along the south side of the Tapti river. Area, 2,623 sq. miles. The northern half is in the Satpura mountains; the southern is flat and intersected by streams. It has no railways. The principal agricultural products are wheat (of excellent quality), rice, pulses, oil seeds, and timber. The principal town is Ellichpur, formerly a capital of the Deccan, and a place of importance, now with little trade. Pop. of the town, 27,000; of the district, 315,000. M. W. H.

Ellicott, ANDREW: civil engineer; b. in Bucks co., Pa., Jan. 24, 1754. He founded Ellicott's Mills in Maryland, and removed to Baltimore. He was a friend of Dr. Franklin and of Washington. In 1790 he was employed by the Federal Government to survey and lay out the capital of the U. S. He was appointed surveyor-general of the U. S. in 1792, and became Professor of Mathematics and Engineering at West Point in 1812. D. at West Point, Aug. 29, 1820.

Ellicott, CHARLES JOHN, D. D.: theologian; b. at Whitwell, near Stamford, England, Apr. 25, 1819, and was educated at Cambridge, where in 1859 he was appointed Hulsean lecturer and in 1860 Hulsean Professor of Divinity. In 1861 he became Dean of Exeter, and in 1863 Bishop of Gloucester and Bristol. His commentaries on the Epistles of St. Paul, which began to appear in 1854, put him into the front rank of biblical scholars. His *Historical Lectures on the Life of our Lord Jesus Christ* (1860) were the Hulsean lectures for 1859. His first work was a *Treatise on Analytical Statics* (1842).

Ellicott City: town (incorporated in 1867); capital of Howard co., Md. (for location of county, see map of Maryland, ref. 2–E); situated on the Patapsco river and the Balt. and O. R. R., 10 miles W. of Baltimore and 31 miles N. N. E. of Washington, D. C. It has 8 churches, a college, 5 public schools, a large flouring-mill, 2 cotton-factories, 2 barrel-factories, a large paper-mill, a stone-crusher, granite quarries, electric lights, etc. Pop. (1890) 1,488; (1900) 1,331.

Ellinwood, FRANK FIELDS, D. D.: clergyman; b. in Kirkland, Oneida co., N. Y., June 20, 1826. He graduated from Hamilton College 1849, and took the theological course in Auburn (1851–52) and Princeton (1852–53) Seminaries. He was pastor in Belvidere, N. J., 1853–54, and in Rochester, N. Y., 1854–65; then was secretary of the committee of church erection for five years, and of the memorial fund committee 1870–71; in 1871 became secretary of foreign missions of the Presbyterian Church in the U. S. He published *The Great Conquest* (New York, 1876) and *Oriental Religions and Christianity* (1892). WILLIS J. BEECHER.

Elliot, ARTHUR R. D.: See the Appendix.

Elliott, CHARLES, D. D., LL. D.: clergyman; b. in Glenconway, County Donegal, Ireland, May 16, 1792; entered the ministry of the Methodist Episcopal Church. He emigrated to the U. S. in 1814, and went to Ohio in 1818, where he edited the *Western Christian Advocate* and other journals. He was a Professor of Languages at Madison College, Uniontown, Pa., 1827–31, and president of Iowa Wesleyan University 1856–60 and 1864–67; author of *A Treatise on Baptism* (1834); *Life of Bishop Roberts* (1853); *Delineation of Roman Catholicism* (2 vols., New York, 1842); *Sinfulness of American Slavery* (2 vols., Cincinnati, O., 1851); *History of the Great Secession from the Methodist Episcopal Church* (1855); *The Bible and Slavery*, etc. D. in Mt. Pleasant, Ia., Jan. 3, 1869.

Elliott, CHARLES LORING: portrait-painter; b. at Scipio, N. Y., Dec., 1812; pupil of Trumbull and of Quidor, New York; National Academician 1846. His portraits are well painted and excellent in color; he was considered by his fellow-artists the best portrait-painter of his time. His portrait of Prof. T. A. Thacher is in the Yale Art School; those of Erastus Corning and Asher B. Durand, the artist, are in the Corcoran Gallery, Washington. He painted the portrait of Matthew Vassar, at Vassar College. D. in Albany, N. Y., Aug. 25, 1868. W. A. C.

Elliott, EBENEZER: poet, called the "Corn-law Rhymer"; b. near Rotherham, Yorkshire, England, Mar. 17, 1781. He was not liberally educated, and was considered a dull boy at school. In early youth he worked in an iron-foundry, in which his father had been employed. He produced in 1798 *The Vernal Walk*, a poem. After he had worked for many years in the foundry he married and removed in 1821 to Sheffield, where he engaged in the iron-trade on his own account, and was successful. His most popular poems are *The Corn-law Rhymes*, which promoted the repeal of the corn-laws, and were much admired. He afterward wrote *The Village Patriarch* (1829); *Byron and Napoleon* (1831); *Love*, and other poems. His works are commended for their energy and the sympathy with the poor which they exhibit. D. at Great Houghton, near Barnsley, Dec. 1, 1849. See Ward's *English Poets* (2d ed. 1883).

Elliott, SAMUEL MACKENZIE: physician; b. at Inverness, Scotland, Apr. 9, 1811; studied at the Royal College of Surgeons in Glasgow, where he graduated in 1828, and in London; removed in 1833 to the U. S.; visited Cincinnati and Philadelphia, and settled finally in New York, where he acquired a great reputation as an oculist. At the outbreak of the civil war he was lieutenant-colonel of the Highland Guard, and was wounded in the first battle of Bull Run. He was subsequently commissioned to raise the Highland Brigade, and was made a brevet brigadier-general. D. at Elliottville, Staten Island, Apr. 30, 1873.

Elliott, Stephen: naturalist; b. at Beaufort, S. C., Nov. 11, 1771; graduated at Yale College in 1791; from 1812 until his death, president of the bank of the State; aided in founding the Literary and Philosophical Society of South Carolina, and the State Medical College, in which he became Professor of Natural History and Botany. He was for a time editor of the *Southern Review*. Author of *The Botany of South Carolina and Georgia* (Charleston, 1821-24). D. at Charleston, S. C., Mar. 28, 1830.

Elliott, Stephen: P. E. bishop; b. at Beaufort, S. C., Aug. 31, 1806; son of Stephen Elliott, the naturalist; graduated at Harvard College in 1824; was admitted to the bar of South Carolina and practiced from 1827 to 1833; ordained a deacon in the Protestant Episcopal Church in 1835, and became Professor of Sacred Literature in South Carolina College; ordained priest in 1836; chosen first bishop of the diocese of Georgia in 1840, and provisional Bishop of Florida in 1844; founded a seminary for young ladies at Montpelier, Ga., which was his home from 1845 to 1853. D. at Savannah, Ga., Dec. 21, 1866.

Elliott, Stephen, Jr.: brigadier-general in the Confederate army; b. at Beaufort, S. C., 1832; son of Stephen Elliott, first P. E. Bishop of Georgia. On the outbreak of the civil war he organized and equipped the battery known as the Beaufort Artillery. He commanded at Pinckney island Aug., 1862, and was promoted for gallant conduct; was in command of Fort Sumter during the protracted bombardment to which it was subjected; and in 1864 was severely wounded by the mine explosion near Petersburg, which incapacitated him from further active service for the remainder of the war. In 1865 he subscribed to the oath requiring him to support the Constitution of the U. S. and that of his own State; was a candidate for Congress. D. at Aiken, S. C., Mar. 21, 1866.

Ellipse [viâ Lat. *ellipsis*, from Gr. ἔλλειψις, defect, a falling short, deriv. of ἐλλείπειν, omit, fall short, so called by the Greek geometer Apollonius Pergæus, because the square of the ordinate "falls short of" the rectangle of the abscissa and parameter]: a hypotrochoid curve of the second order, one of the conic sections, formed by the intersection of a plane with a cone. If two fixed points be taken in a plane, and a third point be conceived to move around the two fixed points in such a way that the sum of the distances of the moving point from the fixed points shall always be the same, the moving point will describe an ellipse. The fixed points are the foci of the ellipse, and the point half way between the foci is the center. That axis of the ellipse which passes through the foci is the transverse or major axis; the axis through the center perpendicular to the transverse is the conjugate or minor axis.

If a moving circle roll along the concavity of the circumference of a fixed circle in the same plane, the radius of the former circle being half that of the latter, any given point in the plane of the rolling circle, within or without, will describe an ellipse. Various instruments for marking the ellipse have been devised on this principle.

Ellis, Alexander John, F. R. S., F. S. A.: philologist; b. at Hoxton, a suburb of London, June 14, 1814; graduated at Trinity College, Cambridge, in 1837; studied law at the Middle Temple for some time, but devoted himself finally to the study of phonetics, and published *Alphabet of Nature* (1845); *Essentials of Phonetics* (1848); *Plea for Phonetic Spelling* (1848); *Universal Writing and Printing* (1856); *Early English Pronunciation* (1869-89); *Glossic* (1870); *Practical Hints on the Quantitative Pronunciation of Latin* (1874), besides papers on various subjects. The family name, which was originally Sharpe, was changed by royal license in 1825.

Ellis, Edward Sylvester: See the Appendix.

Ellis, George: English scholar and antiquary; b. in 1745. He was a friend and correspondent of Walter Scott. Among his publications are *Specimens of the Early English Poets* (1790) and *Specimens of Early English Romances in Metre* (1805), both standard works. D. in 1815.

Ellis, George Edward, D. D., LL. D.: Unitarian minister and author; b. in Boston, Aug. 8, 1814; graduated at Harvard in 1833; pastor of the Harvard church, Charlestown, 1840-69. He wrote for Sparks's *American Biography*, and was Professor of Theology in the Divinity School at Cambridge 1857-63. Among his works are *A Half Century of the Unitarian Controversy* (Boston, 1857) and *The Puritan Age and Rule in the Colony of the Massachusetts Bay, 1629-1685* (1888). He was president of the Massachusetts Historical Society. D. in Boston, Mass., Dec. 20, 1894.

Ellis, Sir Henry: antiquary; b. in London, 1777; graduated at St. John's College, Oxford; became assistant librarian to the Bodleian at Oxford; received an appointment at the British Museum in 1800, and in 1827 was made chief librarian there. D. in London, Jan. 15, 1869. He wrote a large number of valuable works, of which the most important are *Original Letters Illustrative of English History* (1824-46): *Introduction to Domesday Book* (1833); *Elgin Marbles of the Classic Ages* (1847); and *The Townley Gallery of Sculpture* (1847).

Ellis, Henry Havelock: See the Appendix.

Ellis, Job Bicknell, M. A.: botanist; b. in Potsdam, N. Y., Jan. 21, 1829; educated at Union College. He has published many papers on the fungi of North America, and with B. M. Everhart, *North American Pyrenomycetes* (1892) and twenty-nine centuries of *North American Fungi* (1878-93), consisting of sets of 2,900 specimens. From 1885 to 1888 he was one of the editors of the *Journal of Mycology*.

Ellis, Robinson, LL. D.: classical scholar; b. at Baring, England, Sept. 5, 1834; educated at Balliol College, Oxford; elected fellow of Trinity College, Oxford, in 1858, and appointed Professor of Latin in the University College, London, in 1870. Returning to Trinity College in 1876, he has been university reader in Latin literature since 1883. He is best known as the author of an elaborate critical edition of *Catullus*, with notes (2 vols., 1889, 2d edit.), and a metrical translation; a commentary on Ovid's *Ibis* (1881); the *Fables of Avianus*, with prolegomena and critical apparatus; and of *Noctes Manilianæ* (1891). He is a frequent contributor to English philological periodicals and to the *American Journal of Philology*. Alfred Gudeman.

Ellis, Theodore Grenville: civil engineer; b. in Boston, Mass., in 1830. He began business in New England; subsequently engaged in mining surveys in Mexico; in 1861 settled in Hartford, Conn. In 1862 he accompanied the Fourteenth Connecticut Volunteer regiment to the battlefield as its adjutant, and was breveted a brigadier-general for his bravery. He was a member of the American Society of Civil Engineers, and its vice-president from 1873 to 1877. At the time of his death (Jan. 8, 1883) he had charge of the Government works on the Connecticut river.

Ellis, William: missionary; b. in London, Aug. 29, 1794; received a scanty education, and worked as a market gardener till 1814, but in that year offered himself as a missionary to the London Missionary Society, and after a profitable year of preparatory study was sent to the South Sea islands, Jan., 1816, where he remained till 1824, when the state of his wife's health obliged him to return to England. This mission, brief as it was, brought about marked improvement in the social and industrial, as well as in the religious, condition of the natives. In 1832 he was appointed foreign secretary to the London Missionary Society, and held that office for the next seven years. His wife having died in the meantime, he had married in 1837 Miss Sarah Stickney, the author of *The Women of England*, *The Poetry of Life*, *The Mothers of England*, and other popular works. After an interruption due to illness he resumed his work for the society, which sent him to Madagascar to inquire into the prospects of resuming a missionary enterprise there. Between 1853 and 1857 he visited the island three times, and he was again sent out by the society in 1863. D. June 25, 1872. His works, which are chiefly accounts of his travels and missionary labors, are both interesting and valuable. They are a *Tour through Hawaii* (1826); *Polynesian Researches* (1829); *A Vindication of South Sea Missions from the Misrepresentations of Otto von Kotzebue* (1831); *Village Lectures on Popery* (1851); *Three Visits to Madagascar* (1858); *Madagascar Revisited* (1867); and *The Martyr Church of Madagascar* (1870).

Ellis Island: a small island in New York harbor, about a mile S. W. of the city. It is owned by the Government of the U. S., and since 1892 has been used as the point of debarkation for immigrants. Castle Garden was formerly used for this purpose.

Ellora: town of Hindustan. See Elora.

Ellsworth: city (founded in 1867); capital of Ellsworth co., Kan. (for location of county, see map of Kansas, ref. 5-F); situated on Smoky Hill river and on the Union Pacific R. R.; 155 miles W. by S. of Topeka; also the terminus of a branch of the St. Louis and San Francisco Railway. It has 7 churches, a fine brick school-house, and 3 primary schools, and is the center of an extensive wheat belt and grazing section. Here are found valuable clays, gypsum, and mineral paints, and here was first discovered the immense salt-bed which underlies Central Kansas. Across the river are situated the G. A. R. reunion grounds, 160 acres, belonging to the State. Pop. (1880) 929; (1890) 1,620; (1900) 1,549. Editor of "Reporter."

Ellsworth: city and port of entry; capital of Hancock co., Me. (for location of county, see map of Maine, ref. 8-E); on railway and on the navigable Union river; 2 miles from its mouth, and 30 miles S. E. of Bangor. Several bridges cross the river here. The city has a public library, shoe-factories and many sawmills. Ship-building is carried on, and the trade in ice and lumber is important. Pop. (1880) 5,052; (1890) 4,804; (1900) 4,297.

Ellsworth, Ephraim Elmer: soldier; b. in Mechanicsville, N. Y., Apr. 23, 1837. At the outbreak of the civil war he became colonel of a zouave regiment in the Union army, and in taking possession of the city of Alexandria, opposite Washington, May 24, 1861, was shot dead by an inn-keeper from whose roof he had removed a Confederate flag.

Ellsworth, Oliver, LL. D.: chief justice; b. in Windsor, Conn., Apr. 29, 1745; son of a farmer; entered Yale College in 1762, but left in his junior year and completed his studies at the College of New Jersey, graduating with honor in 1766. He studied theology for a year, but abandoned it for the law; in 1771 was admitted to the bar of Hartford co., Conn.; in 1772 married Abigail Wolcott, member of an illustrious family of East Windsor; was appointed State attorney for Hartford County in 1775; in 1777 settled in Hartford and became the most eminent practitioner in the State. He represented Windsor in the General Assembly at the outbreak of the Revolution, and was one of the committee called the "Pay-table" that managed the military finances of the colony. In 1778 he was sent as a delegate to the Continental Congress, where he served on the marine committee and the committee of appeals. From 1780 till 1784 he was a member of the State Council. He left Congress in 1783, declining a re-election, and in 1784 became a judge of the superior court of Connecticut. In 1787 he was sent as a delegate to the convention at Philadelphia which framed the Federal Constitution, and took a leading part in its proceedings, but owing to temporary absence was not able to sign the instrument; was the most influential member of the State convention which in 1788 ratified this Constitution. In 1789 he was elected to the U. S. Senate, in which he gained distinction as a debater, as the chairman of the committee for organizing the U. S. judiciary, as a supporter of Washington's administration, and as the leader of the Federal party in the Senate. Through his influence John Jay was sent to England in 1794, and the treaty negotiated by Jay was upheld by the Senate. In 1796 President Washington appointed him chief justice of the Supreme Court of the U. S., to succeed John Jay, and his official conduct and decisions were approved by both political parties. In 1799 Judge Ellsworth was by President Adams appointed, with Gov. William Richardson Davie and William Vans Murray, envoy extraordinary to France, and aided in negotiating the treaty of Mar. 2, 1800, which terminated the strained relations between the two countries. Judge Ellsworth then resigned his office on account of ill-health, and, after a visit to England, returned to the U. S. in 1801, and in 1802 was re-elected to the State Council of Connecticut, on which he served until his death. In 1807 he declined the office of chief justice of the State. President Dwight (*Travels*) declared that after Mr. Ellsworth entered public life "no man, when Washington was not present, would be more readily acknowledged to hold the first character." He received the degree of LL. D. from Yale, Dartmouth, and the College of New Jersey. D. at Windsor, Conn., Nov. 26, 1807. See Van Santvoord, *Lives of the Chief Justices*.

Ellsworth, William Wolcott, LL. D.: jurist; son of Oliver Ellsworth, chief justice; b. at Windsor, Conn., Nov. 10, 1791; graduated at Yale College in 1810; studied law at Litchfield and at Hartford, Conn., which became his home; was admitted to the bar in 1813, and in that same year married Emily, eldest daughter of Noah Webster, the lexicographer. In 1827 he was appointed Professor of Law in Washington (Trinity) College, and held that office until his death. From 1829 till 1834 he served as a Whig in Congress, resigning to pursue his profession. While in Congress he prepared and reported a law of copyright which was adopted by the Government. From 1838 till 1842 he was Governor of Connecticut. He twice declined an election to the U. S. Senate, but in 1847 was elected judge of the superior court and of the supreme court of errors, retiring from the bench in 1861. D. at Hartford, Jan. 15, 1868.—His twin-brother, Henry Leavitt Ellsworth (1791-1858), a lawyer by profession, was from 1836 till 1848 U. S. commissioner of patents; published a number of reports on the science of agriculture, and *Digest of Patents from 1770 to 1839* (1840).

Ellwangen, el-vaang'en: an old town of Würtemberg; on the Jaxt; 45 miles E. N. E. of Stuttgart (see map of German Empire, ref. 7-E). It has a cathedral, a castle, a hospital, and a gymnasium; also tanneries and bleach-works. Pop. (1890) 4,606.

Ellwood, Thomas Crowell: author; b. in Oxfordshire, England, in Oct., 1639; a minister of the Society of Friends. His friend Isaac Penington secured for him in 1662 the position of reader to the poet Milton, who showed him the manuscript of *Paradise Lost*, and requested him to take it home and read it. On returning the manuscript, Ellwood suggested to Milton the idea of *Paradise Regained*, by asking, "What hast thou to say of Paradise found?" Among Ellwood's works are a *Sacred History* (1705); a poem called *Davideis* (1712); and an autobiography (1714), frequently reprinted (e. g. Boston, 1877, London, 1885). D. in Amersham, Mar. 1, 1713.

Elm [O. Eng. *elm*: O. H. Germ. *elm*, cognate, though with difference of ablaut, with Lat. *ulmus*, to which O. Norse *almr* exactly corresponds; Mod. Germ. *Ulme* shows direct dependence on the Latin word]: any tree of the genus *Ulmus* of the order *Ulmaceæ*, natives of Europe and North America, with alternate serrate leaves, which are oblique or unequally heart-shaped at the base. The ovary is two-celled, with a single anatropous ovule. The fruit is a one-celled membranaceous samara, winged all round. This genus comprises numerous species, five or more of which are indigenous in the U. S. The most remarkable of these is the *Ulmus americana* (white or American elm), a large ornamental tree, usually with spreading branches and drooping, pendulous boughs. It grows rapidly, often attains the height of 100 feet, and is admired as one of the most noble and beautiful of forest trees. Its favorite habitat is in moist woods where the soil is rich, and in the vicinity of rivers and creeks. The trunk sometimes ascends without branches 50 or 60 feet, and then separates into a few primary limbs, which gradually diverge and present long arched pendulous branches floating in the air. The wood of this tree is used for making hubs of wheels. Another species native of the U. S. is the slippery elm (*Ulmus fulva*), a smaller tree with a very mucilaginous inner bark, which is used in medicine as a demulcent. Among the important trees of this genus is the common English elm (*Ulmus campestris*), which grows in many parts of Europe, and is extensively planted in Great Britain. It is one of the chief ornaments of English scenery. The wood of this tree is compact, fine-grained, very durable in water, and is used for various purposes by wheelwrights, machinists, joiners, and ship-builders. It has a mucilaginous bark, which is esteemed as a medicine. The *Ulmus montana*, or wych elm, is a native of Scotland, and a tree of rapid growth, valuable for timber, which is used for the same purposes as the English elm. Europe also produces the cork-barked elm (*Ulmus suberosa*), a tall tree extensively planted in England, and named with reference to the corky ridges or wings on its branches. A valuable fine-grained wood is obtained from the *Ulmus alata*, winged elm or wahoo, which grows wild in the Southern U. S.

El Mesherif: See Berber.

Elmira: city (village of Newtown prior to 1828, chartered as a city in 1864); capital of Chemung co., N. Y.; on the Chemung river, and the Erie, the Del., Lack. and W., Auburn division of the Lehigh Valley, and the Northern

Cent. railways, with connections with the Tioga and Fall Brook lines; 264 miles by rail W. N. W. of New York city (for location, see map of New York, ref. 6–F). It is in a broad, fertile basin at the convergence of four beautiful valleys, defined by hills 600 feet high, and has an area of 4,747 acres. There are gas and electric light plants, 246 named streets and lanes, 2 large and 3 small public parks with total area of 75½ acres, and 3 lines of electric street-railway. The religious and educational institutions comprise 35 churches, 11 public schools, 3 parochial and 6 private schools, a free academy, and a convent academy. A large public library has been erected in memory of the late Prof. J. Dorman Steele, by his widow. The charitable and reformatory institutions are the Arnot-Ogden Hospital, Home for the Aged, Orphans' Home, the Anchorage (a refuge for females), an industrial school, and the State Reformatory, a model reform prison for young criminals. The city is noted for its manufactures, which include window glass, iron bridges, boilers, engines, fire steamers and trucks, woolen, silk, and cotton fabrics, shoes, and wooden products. The city also contains large railway shops, and is a coal-distributing center. There are 4 banks, 3 daily and 4 weekly newspapers, and 5 magazines. The assessed valuation in 1900 was, real, $15,704,020; personal, $1,192,278—total, $16,896,298; the bonded debt was $1,077,500; and the special franchise assessment, $719,560. The decisive battle of Newtown, in Sullivan's campaign against the Indians in 1779, was fought near the present city, and the spot is marked by a centennial monument. During the war of 1861–65 the city was a military rendezvous and the site of a prison in which many Confederates were confined. Pop. (1880) 20,541; (1890) 30,983; (1900) 35,672.

Joe H. Geer, editor of "Advertiser."

Elmira College, originally chartered as Auburn Female University in 1852, was transferred to Elmira in 1853, rechartered as Elmira Female College in 1855, and had the word "female" stricken from its title in 1890. It has an astronomical observatory, an extensive natural history museum, hall of music, and a faculty of 23 (1901): president, the Rev. A. Cameron MacKenzie, D. D.

Elmore: village; Ottawa co., O. (for location of county, see map of Ohio, ref. 1–E); on railway and on Portage river; 20 miles from Lake Erie and 16 miles S. E. of Toledo. It has 8 churches, excellent schools, a bicycle-factory, flouring-mill, stave-factories, a barrel-factory, brick and tile works, etc. Pop. (1880) 1,044; (1890) 1,198; (1900) 1,025.

Editor of "Independent."

Elo'bey Islands: a small group of islands in Corsico Bay, on the west coast of Africa, in lat. 1° N., belonging, with the neighboring mainland, to Spain. C. C. A.

Elocution [from Lat. *elocu'tio*, deriv. of *e'loqui*, *elocu'tus*, to speak out]: in its restricted sense, the impressive utterance of ideas through the voice alone; in a broader sense, the significant use of all the agents of expression employed in conveying ideas to other minds through voice, attitude, countenance, and gesture. Elocution in relation to the manner and method of the different forms of public address is generally styled delivery. A speaker's delivery has primary reference to his hearers. His discourse, whether original or not, is governed by his sincere purpose to influence the minds of his auditors by means of ideas communicated in language, and embodied in voice and gesture. Thought, arrangement, style, utterance, and action are all originated, energized, and directed by one vital principle—the earnest intention to transfer what is in his mind into the minds of his auditors. Delivery is the outward expression of the inward impression; like Wordsworth's conception of language, it is "thought incarnated." Elocution is not eloquence, it is merely the servant of eloquence; it is a means and not an end; it is the physical part of eloquence. Eloquence is living, convincing, persuasive address; but it is the delivery that gains the attention of an audience, elicits and sustains its sympathy, and often transports it with delight.

Expressive speech is chiefly applied to three departments of effort: (1) *Oratory*, with its ethical and practical ends of instruction, conviction, excitation, and persuasion; (2) *Recitation*, as in memorized public address, with its practical aim, and in dramatic representation and declamation, with their artistic ends; and (3) *Reading*, which includes all forms of delivery, from the manuscript or the printed page, as in written public address, with its practical purpose; and in the artistic interpretation of the works of great authors, with its æsthetic end, as in public dramatic readings.

Delivery, in these three connections, may be made the subject of study from three points of view—as a science, as an art, and as a critique. Delivery is not an exact science; it is a science as psychology, music, rhetoric, and æsthetics are sciences. The facts of delivery can be ascertained, studied, properly related, and classified according to their actual connections; their laws and principles can be deduced and formulated. When the facts of expression are honestly developed and systematized we may presume to speak within proper limits of a science of delivery. As a science, delivery naturally takes its place as a legitimate branch of æsthetics. The science of delivery is the science of a beautiful manner of public address. Elaborated discourse is the finest of the æsthetic arts. Its inseparable elements are the three constituent principles of beauty, viz., idea, material, and form. The idea—that is, the spiritual element—of public discourse is thought permeated with feeling and purpose. The material is sound—the human voice, and its frequent accompaniment, gesture; the form is the style of discourse, the unit of discourse being the word; in spoken discourse the form is the modulation of the voice and expressive movements of the body.

Under the first principle of æsthetics—that of the idea—it is natural to consider the end of delivery, the living intention of the speaker to transfer his thought and feeling to the minds of the audience. Thought and feeling in relation to delivery are mental states which prompt and govern the natural, outward signs of thought and emotion. These mental states are regarded as original sources of power in delivery. Good delivery is largely dependent upon clear thinking and earnest feeling. To secure the highest power in delivery, the subject matter, the idea of discourse, must be made as thoughtful as it is possible for painstaking thinking to make it. Then the speaker can speak with the power and accent of conviction. The expressive modulations of the voice, the changing rate of utterance, the varying degrees of force, are the effect of feeling in utterance. Oratorical and dramatic action, too, have their sources in the emotional rather than in the intellectual part of the mind. It is the feeling of anger and not its definition that contracts the brow, clinches the hand, and stamps the foot. The speaker's action should symbolize his emotional states rather than his intellectual.

A true theory of delivery must take note of the reciprocal influence between a speaker and his audience. Eloquence has been defined as "the joint product of the mental action of speaker and audience." The speaker is conscious of speaking directly to his hearers; he holds them in his mental grasp; he exerts a direct influence upon them. So long as a speaker maintains this consciousness of direct address to an audience he holds the attention and sympathy of his hearers. He, in turn, responds to the influence of their sympathetic attention.

Assuming the possession of clear, vigorous thought and quickened sensibility as original sources of inspiration, it is evident that the chief business of the speaker when actually confronting an audience is an affair of the soul—the *moral* part of delivery. The *character* of the speaker, his sincerity, sympathy, and uprightness, come to the front. "An orator," according to the Roman Cato, "is an upright man who understands speaking." The effective speaker is a good man aroused, with the power of communicating his enthusiasm. "The essential thing in speaking," says Emerson, "is heat, and heat comes of sincerity." But sympathy as well as sincerity must be manifested in public address. That was a true saying of a wise French preacher: "To address men well they must be loved much." Sincerity and sympathy not only enhance the power of delivery; they are also conditions of popular influence. Men refuse to surrender themselves to a speaker whom they believe to be deceiving them or indifferent to their welfare. The speaker's character gives character to his language, voice, and action.

The revelation of the mental, sympathetic, and moral elements of personality is concerned with the second constituent of delivery—the *material*. The idea of delivery regards the end of public address; the material takes account of the means and instruments employed in manifesting the substance of discourse. Delivery is now considered as an art for the purposes of teaching and discipline. Without the instruments of voice and gesture the transfer of thought and emotion can not be made. To obtain a scientific basis for a correct method of vocal culture requires acquaintance with certain facts of anatomy, physiology, and physics. The voice must be studied and exercised as a sound-producing body. Breath, as the material of tone, must be properly economized and directed. Control of the respiratory muscles must be acquired through systematic exercise in deep breathing. Any safe and effective system of vocal training must be grounded in the physiological laws of speech. The three physical properties of tone—(1) force (energy, loudness, intensity), (2) pitch, and (3) quality (*timbre*, clang-tint, character)—must be regarded as essential structural elements in a true method of vocal development.

Through the aid of the laryngoscope, and the researches of physicists like Helmholz, Czermak, Mayer, and König, a vocal technique for the formation and training of the voice need no longer be a matter of experiment and speculation. Vocal culture may proceed by a method which shall be at the same time natural, trustworthy, and scientific. The result of skillful training and persistent practice is the control of a voice which is at once powerful, resonant, sympathetic, of good compass, and that can be produced with ease and endurance.

In speech the natural effect of true vocal training would be a firm, incisive, yet easy and agreeable, enunciation; and closely allied with the utterance of language in complete discourse is a correct pronunciation, which is conformed to the standard authorities, that is, the best dictionaries of the English language. It is impossible to overestimate the value of the commonplace but fundamental virtues of enunciation and pronunciation in giving clearness and precision to speech.

Gesture, as the second instrument in revealing the *idea* and manifesting the speaker's personality, includes all significant movements of the body and limbs, and the expression of the countenance; it is the symbolical language of the emotions and passions of the soul. Hence gesture is significant action; but to be significant it should be reasonably rare. Insignificant action must be repressed; significant action must not be overdone. In teaching gesture great care should be exercised lest the instruction result in a mechanical and self-conscious style of action. The groundwork of discipline in gesture should be the use of æsthetic gymnastics of some approved method. Systematic practice in such exercises gradually corrects awkwardness, gives flexibility to the bodily movements, and a command of all the physical agents of expression. Significance in action is secured by observing the gestures which intelligent people spontaneously use when speaking under the influence of genuine feeling.

The third principle of æsthetic science, that of form, the special object of study and criticism, is the delivery of the complete discourse before an audience. The interpreting function of expressive speech, especially in the delivery of appropriated thought, is a department of literary criticism. All elaborate composition, like poetry or artistic prose, requires interpretation. The interpreting power of delivery is operative in every sentence a speaker utters. Complete oral expression implies a faculty of mental analysis of thought and language, and a power to sympathize with the purpose and feeling of an author, and with the order and movement of his ideas. Impressive utterance is often the truest revelation of an author's thought. Reading aloud increases the power of literary analysis. The interpreting power of the speaker is directly related to the receptive power of the hearer. "The best style," says Herbert Spencer, "is that which best economizes the recipient's attention." The law of mental economy is no less true of vocal than of literary style. Style in delivery involves the proper management of the voice in its method of enunciation, and in the use of both the intellectual and emotional elements of expression. The intellectual elements are emphasis, pause, and inflection; the emotional elements are force, pitch, quality, and rate of utterance. A slovenly enunciation, or a faulty use of any one of the elements of expression, dissipates and disturbs the hearer's attention; it puts an unnecessary strain upon his mental receptivity. The natural expression of clear thinking and true feeling, in the correct use of these elements, stimulates the hearer's attention, and enlarges his capacity for receiving ideas.

Style in gesture is directly related to *form*. Feeling suggests when action should be made; judgment and taste dictate the form of the gesture, and also a true economy of action with reference to frequency and significance. The mastery of the significant symbols of feeling contributes to variety in action.

The secret of an interesting and impressive style of speaking is an intelligent sympathy working through the imagination. The true method of delivery, both in public address and in artistic speech, is the natural method. True naturalness consists in observing the cardinal law of all expressive art, propriety, or the adaptation of manner to the varying form of the matter. Through the creative power of the imagination, spontaneously giving shape to all the intonations of the voice and to the significant movements of gesture, the speaker's personality is most completely manifested: "The style is the man."

In original discourse the natural method is that of good conversation, ennobled and idealized; it is a person's natural manner in earnest conversation on worthy themes raised to its highest power.

A good speaker always regards two things: one is found in the address itself, in the character of the subject matter; the other in the place, occasion, and circumstances of delivery. It is assumed that the speaker is master of the topic he is to present. Clearness and vigor of thinking, earnestness of purpose, and an active sympathetic imagination working in unison, spontaneously create the appropriate forms of utterance and action, and dispose the various elements of expression in harmonious relations. In the general management of delivery the speaker is careful to adapt his manner to the different parts of discourse. In the introduction he regards the place, occasion, and circumstances of delivery. He begins by directing eye and voice to the farthest auditors, speaking to them with the easy deliberation of pleasant conversation. His initial pitch and force take care of themselves, being instinctively and naturally determined by his dignified colloquial address to the distant auditors. Gesture is rarely needed in the introductory matter. If used, it is used sparingly, and in the colloquial and expository style. Deliberateness is the characteristic of the introduction. The discussion is conducted with an increased warmth of feeling, issuing in firm, full, resonant tones, an animated rate of utterance, and a positive expression of earnestness in countenance, attitude, and action. Variety is secured through the force and brilliancy given to the important ideas, and through fidelity to the theory of speaking in the method of impassioned conversation. Gesture is likely to be used because the feelings and imagination of the speaker are active. Energy of earnestness is the characteristic of the discussion. As the speaker enters upon the conclusion, he leads the audience to infer from his tones and manner that he is closing. Sometimes he concentrates his discussion into a brilliant climax; at other times he comes into a subdued and sympathetic relation to his audience; the force is softened, the quality is slightly aspirated, the rate is deliberate, and the pauses frequent though brief. The whole manner is persuasive. Even in the method of eloquent climax the artistic sense of the skillful speaker leads him to express a natural subsidence of emotion by delivering the few closing sentences in a slow and sympathetic manner. He returns to the mental plane of his auditors, but both speaker and audience are on a higher plane of thought and emotion than at the beginning of the discourse. The characteristic of the conclusion is impressiveness.

The artistic grouping of the parts of discourse into an organic whole imparts unity and concentration to delivery. The order, movement, and structure of discourse should be observed at the rhetorical points of transition. Transitions, or "landing-places," which mark the change from one aspect of the subject to another, should be properly indicated by changes in vocal treatment through some natural difference in force, pitch, rate, and pause. If a speaker, under the excitement of the occasion, feels that he is losing self-control in one or more elements of expression, let him take advantage of his "landing-places" to recover himself, and speak in his natural key and rate of movement. Sentences that contain an impassioned quality of thought should be delivered with appropriate energy and brilliancy, with the proper gradation of voice in approaching and in leaving the vigorous passage. Subordinate ideas are given with a force and an animation of movement consistent with a distinct enunciation and the clear communication of ideas.

Naturalness as related to the interpretation of elevated prose and to poetry deserves a passing mention. Prose, as distinct from colloquial speech, is an artistic or at least an elaborated production; therefore it must be delivered artistically—that is, under the influence of feeling and imagination. The best form of every-day speech is the basis and guide to the delivery of prose. But prose and almost all public address is ordinary speech idealized; feeling and imagination have entered into the ideas to ennoble them; the diction is choicer; the place, occasion, and circumstances of speaking are different from those of common conversation; the speaker is in a more elevated mood of mind; he receives influences from an audience which modify his ordinary feeling in private talk, and which have a tendency to magnify the ordinary elements of expression to suit them to the changed mood of the speaker and the external circumstances of delivery. Poetry, too, is carefully elaborated emotional thought, expressed in metrical form. Hence poetry must be read poetically—that is, in sympathy not only with the feeling and artistic purpose of the poet, but also with due care for the music of the phrase, delicately reminding the audience of the presence of rhyme and metrical rhythm, but always subordinating the technical elements of poetry to its inner soul and meaning.

In the public reading of the Scriptures good taste and the best usage have determined that the only instrument of expression is the voice. The reader of the Bible is not exercising the functions either of the orator, the actor, or the dramatic reader. His aim is not an æsthetic one, but an intensely practical one—to contribute to the culture of the spiritual life. He has no need of gesture, artistic attitude, or facial expression; he does not need, except for occasional emphasis, the magnetism of the eye. The reading should be vocal exegesis. He realizes his high aim of revealing the sense and spirit of the doctrine, or the narrative, or the scene he is interpreting, through the voice alone. But it is a voice charged with scholarly intelligence, with an appreciative sensibility that sympathizes with the purpose of the sacred writer, and with a chastened imagination that enters into the thought, feeling, and circumstances of the original utterance. Such an expressive reader does not assume appropriate modulations; his intelligent sympathy creates them; they have the accents of sincerity and reality.

The exposition of delivery as a science and an art naturally includes the consideration of delivery as a critique—delivery in its relations to the principles and practice of criticism. From this point of view delivery has for its object the study and exposition of the manifestations of oratorical and dramatic efforts. The inquiry into the nature, end, means, and method of public speaking furnishes the principles of delivery which can be applied to any specific instance of speaking, for the purpose of estimating its merit. Criticism is also largely a remedial art; it detects faults and suggests the proper means and methods of correcting them. Moreover, criticism is helpful as a formative influence in fashioning a natural manner of delivery. In overcoming specific defects it is often essential to insist upon the use of formulated rules and exercises which are derived from recognized principles of speech and action. But the judicious teacher always works for the preservation of the true individuality of his pupil; he aims at leaving the pupil at his best and in the full possession of all his native powers of manifesting his personality with freedom, naturalness, and self-forgetfulness. During the process of instruction the pupil is necessarily conscious of himself; the agents of expression and the objects of his self-criticism are parts and manifestations of his own mental and physical being. But the period of self-consciousness is one day passed. Self-mastery has been acquired through diligent practice in the universally recognized symbols of thought and emotion. After the symbols are mastered they are spontaneously used; the speaker's earnestness and sincerity have overcome his self-consciousness, and he speaks with the indefinable charm of self-forgetfulness. Self-consciousness may at first be inseparable from self-discipline; but before an audience the speaker must simply manifest the present *results* of culture. His attention must be given, not to the means and methods by which he conveys his ideas, but to the aim of fully and effectively communicating the subject of discourse to the minds of his audience. The control over the agents of expression and a due amount of experience in public speaking are essential conditions of attaining the elegance of ease. Delivery is an art that can be taught and learned; but in no other pursuit of culture is the truth of the familiar saying, "A little knowledge is a dangerous thing," so well exemplified. The harmony between the mental states and their embodied expression is the ripe fruitage of practice in true methods of culture. If, as has been said, "The charm of manner consists in its grace, its simplicity, and its sincerity," we must secure that charm by transforming art into a second nature, through acquiring "the art to conceal the art."

A final consideration is the importance of good health to the public speaker. The sustained physical vitality of the speaker and a proper regimen of life in regard to personal habits of sleep, diet, and exercise to promote that vitality are indispensable to the favorable mental moods, and to the animation and vivacity required in effective public address. The advantage of good health is seen especially in relation to the nervous system. Nerve-force is a physical source of power in delivery. Good health is conducive to the supply of nerve-force. Public speaking exhausts nerve-force, and the effort is often followed by a nervous reaction. The speaker in good health quickly recovers from the nervous exhaustion. Nerve-force can be economized, elicited, and developed, but no training can create it. Some speakers are called "magnetic," "electric." All true orators and great artists in dramatic and musical expression are conscious of a strange and often a bewitching power within. A subtle something animates voice, enunciation, attitude, and action, giving a sense of commanding power over the audience. Oratorical or artistic virtue goes out of them. For want of a better term we call this power magnetism. Whatever else it may be, magnetism is the union of nerve-force on the physical side with that peculiar quality of mental temperament and earnestness of nature best named as "soul." Magnetism is the life of public speaking and one great secret of its influence. A "natural speaker" without the advantages of training achieves remarkable success in oratory or the drama because of a rich endowment of magnetic force and the corresponding gift of communicating it. All effective and interesting speakers possess in varying degrees a good supply of nerve-force, though they may not be aware of its possession. A speaker in good physical condition unconsciously manifests this power. The chief physical means of eliciting and developing magnetism and of properly economizing and distributing it, is faithful, judicious, systematic physical training, and special culture in the art of delivery. In the act of public speaking the speaker must express and not repress its manifestation. The expression, however, must be consistent with self-control. There is a magnetic energy born of the mastery of strong emotion. A concentrated delivery is the expression of a soul filled with intense feeling held in restraint. It is the impressive influence of reserved power. But there must always be power to reserve; there must be the presence of an inward fire. The restraint of unimpassioned speech is simply tameness. The "temperance" that gives "smoothness" to impassioned utterance is the moral part of delivery. The speaker retains his self-possession while allowing himself to be carried away.

From this survey of the most important features of the nature and method of a true delivery it will be seen that the art of public address can be placed upon a rational basis. It is grounded on scientific principles; it is vitally associated with anatomy, physiology, psychology, physics, hygiene, and especially with æsthetics as a legitimate department of that science. The art of address strikes its roots far into the deepest and richest soil of the man himself. Delivery is nothing less than the man and the whole man speaking—communicating himself. The full and free communication of life to the rational and emotional life of his fellow-men for some beneficent purpose is the end and ideal of public speech. Effective delivery implies vitality, naturalness, and communicating power. Power must have guidance, and art gives that guidance. The natural result of patient elocutionary study and practice under judicious tuition is well directed, available, and polished power.

Convincing arguments for the utility of the practical study of delivery can be adduced from the overwhelming testimony of the greatest masters of the art of speaking, both in ancient and in modern times. The art of delivery is not one of the fine arts, but in its vital relations to effective public address and to the critical interpretation of the products of the greatest minds of the race it is a liberal art, and one that directly contributes to the development of personal power. Its dignity as an art is demonstrated in its important function of aiding men effectively to use the gifts and graces of mind and character.

J. W. CHURCHILL.

Elmwood: town; Peoria co., Ill. (for location of county, see map of Illinois, ref. 4–D); on the C., B., and Q. Railroad; 26 miles W. by N. of Peoria. The chief industries are agriculture, mining, and manufacturing. Pop. (1880) 1,504; (1890) 1,548; (1900) 1,582.

Elongation [from Lat. *elonga're*, remove to a distance]: in astronomy, the apparent angular distance of a planet from the sun. The greatest elongation of Mercury amounts to about 28° 30′, that of Venus to about 47° 48′, and that of the superior planets may have any value up to 180°.

Elo'ra, or **Ellora**: a decayed town of Hindustan, near Dowlatâbâd; lat. 20° 5′ N., lon. 75° 13′ E. (see map of N. India, ref. 9–D). Here are numerous remarkable cave-temples, which surpass in magnitude all others in India, and are adorned with statues and other sculptures. Besides the cave-temples hewn out in the slope of a rocky hill, there are vast edifices or pagodas carved out of solid granite hills, so as to form magnificent monoliths, having an exterior as well as interior architecture, richly decorated. They are among the most stupendous monuments ever raised by man. The most remarkable of these, the temple called the *Kailás*, dedicated to Siva, is about 145 feet long and 100 feet high, and is supported by four rows of pilasters with colossal elephants beneath. In the court which surrounds the Kailás temple are several obelisks, sphinxes, and colonnades. Many mythological figures are carved on the walls. The date of the construction of these temples is not known. According to Fergusson, they were executed not later than 200 B. C. See Lassen's *Indische Altertumskunde* and Fergusson's *Handbook of Architecture.*

El Paso, el-paa'so: city and railway junction; Woodford co., Ill. (for location of county, see map of Illinois, ref. 4–E); 17 miles N. of Bloomington. It has large mills, several grain-elevators, carriage-factory, and agricultural-implement works. A coal-shaft has been sunk here. Pop. (1880) 1,390; (1890) 1,353; (1900) 1,441.

El Paso: city, railway center, and port of entry; capital of El Paso co., Tex. (for location of county, see map of Texas, ref. 3–B); situated on the Rio Grande. Near it the river passes through a mountain-gap called El Paso del Norte (North Pass), which is the chief thoroughfare between Mexico and New Mexico. On the opposite bank of the Rio Grande, in Chihuahua, Mexico, is Ciudad Juarez, formerly called Paso del Norte, a village important as the starting-point of the Mexican Central Railroad, and having a custom-house, through which a large amount of goods pass in transit between the U. S. and Mexico. El Paso has numerous churches, five schools, a $200,000 federal building, smelters (including a copper plant), a refrigerator for beef and other meats, ice-factories, planing-mills, gas-works, electric lights, etc. Pop. (1880) 736; (1890) 10,338; (1900) 15,906.

EDITOR OF "TRIBUNE."

Elphinstone, Admiral: See KEITH, GEORGE KEITH-ELPHINSTONE.

Elphinstone, Hon. MOUNTSTUART: historian; b. in Scotland, 1779; a younger son of Lord Elphinstone. He entered the Bengal civil service in 1795, was sent as ambassador to the court of Cabul in 1808, and was governor of Bombay 1819–27. Bishop Heber expressed the opinion that he was "in every respect an extraordinary man," and that his Indian policy was wise and liberal. Mr. Elphinstone resigned in 1829, and returned to England. He published an *Account of Caubul* (1815; 2d ed. 1841) and a *History of India: the Hindoo and Mohammedan Periods* (2 vols., 1841; 6th ed. 1874), both of which are highly esteemed. His *Life* (1884) was written by Sir E. Colebrooke, who edited his posthumous volume *The Rise of British Power in the East* (1887). D. Nov. 20, 1859.

Elphinstone, WILLIAM: prelate and statesman; b. in Glasgow, Scotland, 1431; graduated at the University of Glasgow 1452; and afterward, taking holy orders, officiated as priest of the Church of St. Michael for four years. He became a student of civil and canon law in the University of Paris, where his reputation for learning caused his appointment to a professorship, which he held six years. Returning to Scotland, he was appointed rector of the University of Glasgow, and subsequently held the important office of official of Lothian. In 1478 he became a member of the privy council. With the Bishop of Dunkeld and the Earl of Buchan he brought about a reconciliation between James III. and Louis XI., a service that procured for him the see of Ross, which was afterward exchanged for that of Aberdeen. Having been made chancellor of the kingdom in 1484, he again distinguished himself as a diplomatist by the success of his negotiations with the English king and of his mediations between the barons and his own sovereign, now James IV. He was next intrusted with the mission to the Emperor Maximilian to arrange a marriage between James and the emperor's daughter. In this he failed, but succeeded in completely restoring friendly relations with the Dutch. From the year 1492 to his death he held the office of privy seal. It is as a patron of learning that he is best known. The foundation of the university at Aberdeen was due almost entirely to his influence, and King's College owes its erection and maintenance to his care and liberality. D. Oct. 25, 1514. He wrote a history of Scotland, a book of canons, and some biographies of Scotch saints.

F. M. COLBY.

El Rosar'io: town of Sinaloa, Mexico; 55 miles E. of Mazatlan (see map of Mexico, ref. 5–E). Here were rich gold mines, which are no longer worked. It is an entrepôt of trade between Mazatlan and the interior. Pop. 5,000.

El'sass: See ALSACE.

Elsass-Lothringen: See ALSACE-LORRAINE.

Els'heimer, ADAM: landscape-painter; called by the Italians IL TEDESCO (i. e. the German); b. at Frankfort-on-the-Main in 1574. His works are highly finished. He excelled in chiaroscuro and in faithfulness to nature. He worked mostly in Rome, and died in that city in want in 1620.

Elsinore, el-si-nōr' (Dan. *Helsingör*): an old town and seaport of the island of Seeland, Denmark; on the western shore of the Sound (here only 2½ miles wide); 24 miles N. by E. of Copenhagen. It is defended by the castle of Kronborg, which commands the Sound at its narrowest part. It has a cathedral, a custom-house, and a royal palace called Marienlist, from which is obtained a magnificent view of the Sound and of Helsingborg in Sweden. At Elsinore until 1887 dues were collected from foreign vessels navigating the Sound. It has an active trade, and some manufactures of arms, brandy, hats, etc. Here was laid the scene of Shakspeare's *Hamlet*, and a mile from the city Hamlet's grave is shown. Pop. (1890) 11,082.

El-Siwah, el-see'wăa (anc. *Ammonium*): the most northerly of the five Egyptian oases; about 440 miles W. N. W. of ancient Thebes. It is 6 miles long and 3 broad. The oasis abounds in salt and alum, which were anciently exported. Dates, pomegranates, and other fruits are produced in very large quantities. Sheep and cattle are bred in great numbers. The oasis abounds in fresh-water springs, and is in part rather marshy. The ruins of the temple of Ammon and of other ancient buildings are still in existence. Pop. about 8,000. Chief town, Kebir.

Elson, Louis Charles: journalist and musicographer; b. in Boston, Mass., Apr. 17, 1848, and educated there; in 1877 he became the assistant editor of the *Vox Humana*, and in 1879 sole editor. He has been for a number of years the music critic of the Boston *Advertiser*, and was also on the editorial staff of the Boston *Musical Herald*, and is a lecturer in the New England Conservatory of Music. He has published a *History of Music in Popular Form*, *History of German Song*, *Curiosities of Music*, and other works, and has written original words for many songs, and has translated and adapted many foreign vocal compositions.
D. E. Hervey.

El'ssler, Fanny: dancer; b. in Vienna in 1810. She performed with success in Berlin, Paris, and London. With her sister Therese, who was also a danseuse, she visited the U. S. in 1841. She retired from the stage with a large fortune in 1851. D. Nov. 28, 1884.—Her sister Therese was united in morganatic marriage with Prince Adalbert of Prussia in 1851, and was made Freifrau von Barnim by the king in the same year. D. in 1878.

Elster, Black: river of Germany; rises in Saxony, flows northwestward, and enters the Elbe 8 miles E. of Wittenberg. Length, 112 miles.

Elster, White: river of Germany; rises near the northwestern frontier of Bohemia, flows northward, and after a course of 122 miles enters the Saale 3 miles S. of Halle.

El'ton: a shallow saline lake of Russia; in the basin of the Caspian, government of Astrachan; 150 miles S. S. E. of the town of Saratof. It is 14 miles long, and has an area of 78 sq. miles. About 100,000 tons of salt are annually procured from it. In the summer it presents an appearance as if it were covered with snow.

Elton, Charles Isaac: See the Appendix.

Elutriation [from Lat. *elutria're*, cleanse]: the process of preparing earths and pigments by washing them in large quantities of water, so that the heavier particles sink to the bottom, and the finer particles, remaining longer suspended, are gradually deposited. This operation is a very important one in preparing clay for the porcelain manufacture and some ores of iron and other metals for the furnace. The apparatus used for this purpose is a vat in which grinding wheels revolve, and into which a stream of water flows, but there are many adaptations of the process.

El'vas (Sp. *Helves*, or *Yelves*): a fortified frontier city of Portugal; province of Alemtejo; about 125 miles E. of Lisbon and 12 miles W. of Badajos, Spain (see map of Spain, ref. 17–C). It stands on a steep hill, is inclosed by walls, and is said to be the strongest fortress in Portugal. It contains many antique Moorish buildings, a cathedral, several convents, a theater, an arsenal, and a college. Elvas is supplied with water by a large Moorish aqueduct with several tiers of arches rising to the height of 250 feet. Its bishop is a suffragan of the Archbishop of Evora. Elvas was captured by the Spaniards in 1580, and again in 1808 by the French. Pop. 15,000.

Elves: See Elf.

Elwood: town; Madison co., Ind. (for location of county, see map of Indiana, ref. 5–F); on the Pitts., Cin., Ch. and St. L. and Erie railways; 45 miles N. N. E. of Indianapolis. It is a shipping-point for grain and stock, and has grain-elevators, saw-mills, and manufactures of flax, lamp-chimneys, and plate-glass. Pop. (1890) 2,284; (1900) 12,950.

Ely, ee'li: city of Cambridgeshire, England; on the river Ouse; 72 miles N. N. E. of London and 16 miles N. N. E. of Cambridge (see map of England, ref. 10–K). It is situated in the fen country called the Isle of Ely. A monastery was founded here in 673, but it was destroyed by the Danes in 870 and not restored till a century later, by Bishop Ethelwold, of Winchester. Henry I. elevated Ely into a bishopric in 1107; and when the monasteries were dissolved, under Henry VIII., the conventual church was transformed into a cathedral. So far as the interior is concerned it is one of the most beautiful of English cathedrals, but its exterior is a singular mixture of various styles of architecture. The nave, which was completed in the middle of the twelfth century, is Late Norman. The Galilee, or western porch, which was created by Bishop Eustace (1198–1215), is Early English. The choir was originally Early Norman, but in the middle of the thirteenth century its Norman apse was pulled down and the church extended eastward by six more arches. The lady-chapel was begun by Bishop Hotham, who also rebuilt the Norman tower, much enlarged, in the form of an octagon, and crowned with a lofty lantern. The tower, as well as the lady-chapel, was designed by Alan of Walsingham. The total length of the whole structure from E. to W. is 525 feet; the height of the western tower is 220 feet. Another fine building is Trinity church, a handsome structure founded in 1321. Ely contains many interesting monuments. There are manufactures of oil, earthenware, and clay pipes. Pop. (1891) 8,017.

Ely, Isle of: a level, fenny tract of Cambridgeshire, England; the southern part of the Bedford Level; bounded S. by the river Ouse; area, 355 sq. miles. It was formerly in great part covered with water, but has been drained and reclaimed by numerous canals and ditches. Aquatic birds and marsh plants abound here. The soil is fertile, and produces good crops of hemp, flax, wheat, oats, etc.

Ely, Richard Theodore, Ph. D., LL. D.: political economist; b. at Ripley, N. Y., Apr. 13, 1854; educated at State Normal School, Fredonia, N. Y., and at Dartmouth and Columbia Colleges, graduating from the latter in 1876; studied in Europe 1876–79; received a degree of Ph. D., University of Heidelberg, 1879; Professor of Political Economy in Johns Hopkins University 1885–92; member of Baltimore and Maryland Tax Commissions, and secretary of American Economic Association; elected director of the School of History and Political Science, and Professor of Political Economy in the University of Wisconsin, June, 1892; author of *French and German Socialism* (1883); *Labor Movement in America* (1886); *Taxation in American States and Cities* (1888); *Problems of To-day* (1888); *Political Economy* (1889); *Social Aspects of Christianity* (1889).
C. H. Thurber.

Elyot, Sir Thomas: author and diplomatist; b. in Wiltshire, England, about 1490. The place of his education is not known, but the extent of his learning seems to prove him a university graduate. He held the office of clerk to the western assize from about 1511 to 1519, when he exchanged it for that of clerk of the king's council, a position which he held for six years and a half, as he complained, without compensation and without thanks. In 1532 he was sent on embassies to the pope and to the emperor, and while on the latter mission received instructions to cause the arrest of the Reformer Tyndale, but failed in the attempt. Though highly honored by his contemporaries for his learning, Elyot received but slight pecuniary rewards from his patrons for either his literary or official labors, and spent his life in straitened circumstances. D. at Carlton, Cambridgeshire, 1546. Of his works the most noted is *The Boke named the Gouernour* (London, 1531), which is a moral treatise on the way to fit a man for the duties of governing. Among his twelve other books are *Of the Knowledge that maketh a Wise Man* (1533); *Bibliotheca* (1538), the first Latin-English dictionary; *The Image of Governance* (1540); *Preservative against Death* (1545); *Defense for Good Women* (1545).
F. M. Colby.

Elyria: village and railway center; capital of Lorain co., O. (for location of county, see map of Ohio, ref. 2–G); beautifully situated at the confluence of the eastern and western branches of Black river; 7 miles S. of Lake Erie and 25 miles W. of Cleveland; has eight churches, a high school, a public library, a law library, an extensive automatic-screw factory, shears-factory, and other industrial establishments, gas-works, electric lights, etc. Sandstone is one of the chief exports. Pop. (1880) 4,777; (1890) 5,611; (1900) 8,791.
Editor of "Republican."

Elysée, The Palace of the: a celebrated residence in Paris, France; situated at the junction of the Rue du Faubourg St.-Honoré and the Avenue de Marigny. It was built in 1718 for the Count d'Evreux, and served successively as a residence for Madame de Pompadour, for her brother, the Marquis de Marigny, for extraordinary ambassadors, for the financier Beaujon, and for the Duchesse de Bourbon. After the Restoration it took the name of Hôtel de la présidence (Dec., 1848). It was at the Elysée that the *coup d'état* of Dec., 1851, was planned. During the Exposition Universelle of 1867 it served as a residence for visiting foreign potentates, and is now devoted to the use of the president of the republic.

Elys'ium, or The Elysian Fields (in Gr. ἠλύσιον πεδίον): in classic mythology, the place to which the souls of the virtuous were supposed to be transported after death. Elysium was variously represented as a part of Hades, as an island in the Western Ocean, or as located in mid-air. Some of the ancients imagined that the kingdom of Pluto was divided into two regions—Tartarus, in which the wicked were punished, and Elysium, the abode of the good.

Elytra: See ENTOMOLOGY.

Elze, el'tse, FRIEDRICH KARL: German Shakspeare scholar; b. at Dessau, May 22, 1821; studied at Leipzig and Berlin; taught in the Dessau gymnasium; called to the University of Halle as "ausserordentlicher" Professor of English in 1875; promoted to a full professorship in 1876. Elze's interests lay chiefly in the direction of modern English literature. He was a zealous member of the Deutsche Shakespeare-Gesellschaft and a frequent contributor to its *Jahrbuch*, which he edited 1868–79. Of his separate publications may be mentioned lives of Scott (1864); Byron (1870); and Shakspeare (1876); an edition of *Hamlet* (1857; 2d ed. 1882); *Notes on Elizabethan Dramatists* (3 vols., 1880–86; 2d ed. 1889); and *Grundriss der englischen Philologie* (1887; 2d ed. 1888). D. Jan. 21, 1889.

G. L. KITTREDGE.

El'zevir, or **Elzevier**: the name of a family of Dutch printers who lived at Amsterdam, Leyden, and other places, and were celebrated for the accuracy and beauty of their typography. They published excellent editions of many classic authors between 1583 and 1681. The first eminent printer of the family was Louis or Lodewijk, who was born at Louvain about 1540, settled in Leyden, and died about 1617, leaving five sons—Matthias, Louis, Giles (or Ægidius), Joost (or Jodocus), and Bonaventure, who were all publishers. The business was continued by Abraham, a son of Matthias, and his partner Bonaventure, who published duodecimo editions of the classics which are still highly prized for their beauty and correctness. The Greek New Testament is among their masterpieces. A press was established in Amsterdam in 1638 by Louis Elzevir (a grandson of Louis first mentioned), who published good editions of numerous authors. Several other members of the family were distinguished printers. At least 1,600 works were published by the Elzevirs.

Emanation [from Lat. *emana'tio*, an oozing out, deriv. of *emana're*; *ē*, forth + *mana're*, flow, ooze]: in the religions of India and of ancient Persia, in Neoplatonism, and in Gnosticism, a theory of ontology and of cosmogony which ascribes the origin of the universe and of all inferior beings to an outflow from the Deity. The name has also been applied to the good and evil influences which the heavenly bodies were formerly believed to send forth, and which were thought to determine the destinies of men.

Emancipation [from Lat. *emancipa'tio*, deriv. of *emancipa're*, formally release from authority or ownership: *ē*, forth + *mancipa're*, transfer, release by the formal act of the *manci'pium*, deriv. of *manceps*, one who acquires, purchaser, contractor; *man-* (*manus*), hand + *ca'pere*, take]: the act of freeing from subjection of any kind. In Roman law a son was regarded as the slave of his father, and could by a fiction of that law be freed by being sold (*mancipatus*) three times by the father. This enfranchisement was termed emancipation. Different modes of emancipation were afterward recognized by Roman jurisprudence. In countries where that law prevails the word signifies the exemption of the son from the power of the father, either by express act or implication of law. By the civil law of France, majority and emancipation are attained at twenty-one, and a minor is emancipated by marriage. The word emancipation is used in a general sense to signify the liberation of a slave, or the admission of certain classes to the enjoyment of civil rights, as CATHOLIC EMANCIPATION (*q. v.*).

Emancipation, Proclamation of: the most important document ever penned by a President of the U. S.; issued by President Lincoln, Sept. 22, 1862, as a notice to the Confederates to return to their allegiance, emancipation of the slaves being proclaimed as a result which would follow their failure so to return. The real Proclamation of Emancipation was the supplementary document of Jan. 1, 1863. This act was simply a war measure, based solely upon the President's authority as commander-in-chief of the army and navy.

PROCLAMATION OF EMANCIPATION.

I, Abraham Lincoln, President of the United States, and Commander-in-chief of the Army and Navy thereof, do hereby proclaim and declare that hereafter, as heretofore, the war will be prosecuted for the object of practically restoring the constitutional relation between the United States and the people thereof in those States in which that relation is, or may be, suspended or disturbed; that it is my purpose upon the next meeting of Congress to again recommend the adoption of a practical measure tendering pecuniary aid to the free acceptance or rejection of all the slave States, so called, the people whereof may not then be in rebellion against the United States, and which States may then have voluntarily adopted, or thereafter may voluntarily adopt, the immediate or gradual abolishment of slavery within their respective limits, and that the effort to colonize persons of African descent, with their consent, upon the continent or elsewhere, with the previously obtained consent of the government existing there, will be continued; that on the first day of January, in the year of our Lord one thousand eight hundred and sixty-three, all persons held as slaves within any State, or any designated part of a State, the people whereof shall then be in rebellion against the United States, SHALL BE THEN, THENCEFORWARD, AND FOREVER FREE; and the military and naval authority thereof will recognize and maintain the freedom of such persons, and will do no act or acts to repress such persons, or any of them, in any efforts they may make for actual freedom; that the Executive will, on the first day of January aforesaid, by proclamation, designate the States and parts of States, if any, in which the people thereof respectively shall then be in rebellion against the United States; and the fact that any State, or the people thereof, shall on that day be in good faith represented in the Congress of the United States by members chosen thereto, at elections wherein a majority of the qualified voters of such State shall have participated, shall, in the absence of strong countervailing testimony, be deemed conclusive evidence that such State and the people thereof have not been in rebellion against the United States.

That attention is hereby called to an act of Congress entitled "An act to make an additional article of war," approved March 13, 1862, and which act is in the words and figures following:

"Be it enacted by the Senate and House of Representatives of the United States of America, in Congress assembled, That hereafter the following shall be promulgated as an additional article of war for the government of the Army of the United States, and shall be observed and obeyed as such:

"ARTICLE —. All officers or persons of the military or naval service of the United States are prohibited from employing any of the forces under their respective commands for the purpose of returning fugitives from service or labor who may have escaped from any persons to whom such service or labor is claimed to be due; and any officer who shall be found guilty by a court martial of violating this article shall be dismissed from the service.

"SEC. 2. And be it further enacted, that this act shall take effect from and after its passage."

Also to the ninth and tenth sections of an act entitled "An act to suppress insurrection, to punish treason and rebellion, to seize and confiscate property of rebels, and for other purposes," approved July 17, 1862, which sections are in the words and figures following:

"SEC. 9. And be it further enacted, that all slaves of persons who shall hereafter be engaged in rebellion against the Government of the United States, or who shall in any way give aid or comfort thereto, escaping from such persons and taking refuge within the lines of the army; and all slaves captured from such persons or deserted by them, and coming under the control of the Government of the United States, and all slaves of such persons found on (or being within) any place occupied by rebel forces and afterward occupied by the forces of the United States, shall be deemed captives of war, and shall be forever free of their servitude and not again held as slaves.

"SEC. 10. And be it further enacted, that no slave escaping into any State, Territory, or the District of Columbia, from any of the States, shall be delivered up, or in any way impeded or hindered of his liberty, except for crime or some offense against the laws, unless the person claiming said fugitive shall first make oath that the person to whom the labor or service of such fugitive is alleged to be due is his lawful owner, and has not been in arms against the United States in the present rebellion, nor in any way given aid or comfort thereto; and no person engaged in the military or naval service of the United States shall, under any pretense whatever, assume to decide on the validity of the claim of any person to the service or labor of any other person, or surrender up any such person to the claimant, on pain of being dismissed from the service."

And I do hereby enjoin upon and order all persons engaged in the military and naval service of the United States to observe, obey, and enforce within their respective spheres of service the act and sections above recited.

And the Executive will, in due time, recommend that all citizens of the United States who shall have remained loyal thereto throughout the rebellion, shall (upon the restoration of the constitutional relation between the United States and their respective States and people, if the relation shall have been suspended or disturbed) be compensated for all losses by acts of the United States, including the loss of slaves.

In witness whereof, I have hereunto set my hand and caused the seal of the United States to be affixed.

Done at the city of Washington, this twenty-second day of September, in the year of our Lord one thousand eight hundred and sixty-two, and of the independence of the United States the eighty-seventh.

By the President: ABRAHAM LINCOLN.

WM. H. SEWARD, Secretary of State.

SUPPLEMENTARY PROCLAMATION.

Whereas, On the twenty-second day of September, in the year of our Lord one thousand eight hundred and sixty-two, a proclamation was issued by the President of the United States, containing among other things the following, to wit:

That on the first day of January, in the year of our Lord one thousand eight hundred and sixty-three, all persons held as slaves within any State, or any designated part of a State, the people whereof shall then be in rebellion against the United States, shall be thenceforward and forever free, and the Executive Government of the United States, including the military and naval authority thereof, will recognize and maintain the freedom of such persons, and will do no act or acts to repress such persons, or any of them, in any efforts they may make for their actual freedom:

That the Executive will, on the first day of January aforesaid, by proclamation, designate the States and parts of States, if any, in which the people thereof respectively shall then be in rebellion against the United States, and the fact that any State, or the people thereof, shall on that day be in good faith represented in the Congress of the United States by members chosen thereto at elections wherein a majority of the qualified voters of such State shall have participated, shall, in the absence of strong countervailing testimony, be deemed conclusive evidence that such State and the people thereof are not then in rebellion against the United States:

Now, therefore, I, Abraham Lincoln, President of the United States, by virtue of the power in me vested as Commander-in-chief of the Army and Navy of the United States, in time of actual armed rebellion against the authority and Government of the United States, and as a fit and necessary war measure for repressing said rebellion, do, on this first day of January, in the year of our Lord one thousand eight hundred and sixty-three, and in accordance with my purpose so to do, publicly proclaim for the full period of one hundred days from the day of the above first-mentioned order, and designate, as the States and parts of States wherein the people thereof respectively are this day in rebellion against the United States, the following, to wit: Arkansas, Texas, Louisiana, except the parishes of St. Bernard, Plaquemine, Jefferson, St. John, St. Charles, St. James, Ascension, Assumption, Terre Bonne, Lafourche, St. Mary, St. Martin, and Orleans, including the city of New Orleans, Mississippi, Alabama, Florida, Georgia, South Carolina, North Carolina, and Virginia, except the forty-eight counties designated as West Virginia, and also the counties of Berkeley, Accomac, Northampton, Elizabeth City, York, Princess Ann, and Norfolk, including the cities or Norfolk and Portsmouth, and which excepted parts are, for the present, left precisely as if this proclamation were not issued.

And by virtue of the power and for the purpose aforesaid, I do order and declare that all persons held as slaves within said designated States and parts of States are, and henceforward shall be, free; and that the Executive Government of the United States, including the military and naval authorities thereof, will recognize and maintain the freedom of said persons.

And I hereby enjoin upon the people so declared to be free to abstain from all violence, unless in necessary self-defense, and I recommend to them, that in all cases, when allowed, they labor faithfully for reasonable wages.

And I further declare and make known that such persons of suitable condition will be received into the armed service of the United States to garrison forts, positions, stations, and other places, and to man vessels of all sorts in said service.

And upon this, sincerely believed to be an act of justice, warranted by the Constitution, upon military necessity, I invoke the considerate judgment of mankind and the gracious favor of Almighty God.

In witness whereof I have hereunto set my hand and caused the seal of the United States to be affixed.

[L. S.] Done at the city of Washington, this first day of January, in the year of our Lord one thousand eight hundred and sixty-three, and of the independence of the United States of America the eighty-seventh.

By the President: ABRAHAM LINCOLN.

WILLIAM H. SEWARD, Secretary of State.

Eman'uel, surnamed THE GREAT: King of Portugal; b. in May, 1469. He succeeded John II. May 3, 1495, and married Isabella, a daughter of Ferdinand and Isabella of Castile. She died in 1498, and Emanuel married her sister Maria. His third wife, whom he married in 1519, was Eleonore, a sister of the Emperor Charles V. Emanuel promoted education, maritime enterprise, and commerce. During his prosperous reign the power and glory of Portugal were increased by the discoveries and victories of Vasco da Gama, Albuquerque, and Almeida in India and Brazil. Portugal was probably the greatest naval power of the world in his reign, which constitutes the golden age of Portuguese history. His power and renown were greater than any Portuguese monarch ever possessed, either before or since his time; but he greatly injured his country by the banishment of all Jews and the enforced conversion of their young children. D. Dec. 13, 1521.

Emarginate [from Lat. *emargina're*, remove the edge; *e*, forth + *margo*, *-inis*, edge]: (*a*) in botany, notched or indented at the apex: said of leaves. (*b*) In zoölogy, having a portion of the margin cut away, as of the border of the scapula, the tail of a mammal, or the feather of a bird.

Em'ba, or **Jemba**: river of Asia, in Turkistan or the Kirghiz territory. It flows southwestward, and enters the Caspian Sea. Length about 250 miles.

Embalming [deriv. of *embalm* < M. Eng. *enbaumen* < O. Fr. *embaumer*; *en-* + *baume* < Lat. *balsamum* = Gr. *βάλσαμον*, balsam; the *l* has been reintroduced into the spelling, though not into the pronunciation of the English word]: in general, the special preparation of a dead organism (human body, animal, or plant) to prevent ordinary decomposition or decay. The term in itself refers to the means, i. e. balms or balsams, employed by some of the ancients. As commonly used, it refers to the preservation of dead bodies for reasons connected with religious beliefs or from pride or sentiments of affection. On the other hand, for scientific purposes, as in museums of anatomy and zoölogy, although the process for rendering dead bodies permanent may be the same, it is usually designated *preservation* rather than embalming. *Petrifaction*, in which the form is left intact although the animal or vegetable substance has been replaced molecule by molecule by some mineral, does not properly come under the head of embalming or preservation as here used. It is a preservation of form and not of substance, while embalming aims to preserve both form and substance; furthermore petrifaction has not been successfully accomplished by art.

The cause of decay has been attributed to a supposed tendency of complex organic substances to break up spontaneously into simpler ones; but the profound physiological and chemical study of the nineteenth century has shown that these substances, having been built up by the life processes, remain stable until by the life processes they are again reduced to simpler substances with liberation of energy for the purposes of mental or physical action. After death the so-called organized or living ferments (various micro-organisms, especially putrefactive bacteria), which abound in all moist and warm or temperate climates, make use of this complex matter for their subsistence and multiplication. This furnishes the key to all methods of embalming or preservation—that is, some means must be employed to prevent the living ferments from acting upon the dead body. The means which are available and do not in themselves profoundly alter the tissues are (1) cold; (2) the displacement of the water in the body by some gum or resin; (3) drying; (4) saturation of the tissues by antiseptics. The durability of the dead body will then depend directly upon the time during which the conditions antagonistic to the living ferments can be maintained. That cold may preserve indefinitely is shown by the well-known case of the extinct hairy mammoth found in the melting ice of Northern Siberia, the flesh of which was so fresh that it was eaten by dogs and wolves. Insects in amber show how complete and permanent the preservation may be when the water of the organism is replaced by a resinous substance; and every large museum of natural history contains specimens of great antiquity in which the preservation is due to complete drying, or to a combination of drying and antiseptics, or to the use of antiseptics alone.

In the historical consideration of embalming the mind naturally turns to ancient Egypt on account of the extent to which embalming was carried in that country and the large number of bodies, or mummies as they are called, which remain practically as they were deposited in the catacombs thousands of years ago. It is thought that with the Egyptians the custom was largely due to a profound belief in the immortality of the soul, which would in some of its stages need the body again for perfect development.

Embalming as it was practiced in Egypt is sometimes said to be a lost art. In the sense that it is no longer practiced, this is true; but the way in which it was done is quite well known from the descriptions of Herodotus (484 B. C.) and Diodorus Siculus (44 B. C.), as well as by examinations of the mummies themselves, the last source of information being the most satisfactory in many respects, as it verifies both authors and gives much additional information. The process consisted in its simplest form of desiccation, with little or no wrappings or a light smearing with pitch. In the more elaborate methods, aromatics and the antiseptics found in their natron beds were used in addition to the drying. In the application of the natron (a mixture of sodium sulphate and chloride and potassium nitrate) a strong brine was made in which the body was soaked, sometimes as long as seventy days. In many but not in all cases of the best embalming the abdominal viscera were removed, and in part preserved separately or after preservation returned either to the outside or the inside of the body. The brain was in many cases broken up and removed by a curved metal rod inserted into the skull through the nostrils. In many cases the hair was clipped, but in others, especially women, it was left in tresses or arranged on the head as is still the custom. After the pickling process the cavities of the body were often partly filled with aromatics, cedar-wood dust, and dry earth, and in some cases parts of the body were gilded, especially the nails, and artificial eyes were inserted. The body was then wrapped in strips of linen cloth of varying degrees of fineness, and finally it was desiccated. Sometimes the desiccation preceded the wrapping, as shown by the charred condition of the mummy, in other cases part of the wrapping at least preceded the drying, as indicated by the charred condition of the wrappings next the body; both the circumstances just given show that artificial heat was used. Finally the wrapped and dried mummy was placed in one or more cases or coffins and then in the perfectly dry catacombs. Instead of the salting process just described, some of the mummies were embalmed by soaking or probably heating them in pitch, the pitch displacing the water and furnishing also a protective covering. These mummies are black and heavy and the features scarcely recognizable, while those previously described are brown in color, light, and although very greatly shrunken still retain some resemblance to the individual. If one considers for a moment the principles given above on which the preservation of the body depends, it will be seen that all the conditions were fulfilled by the Egyptian method, viz., the use of antiseptics, desiccation, mechanical protection by the wrappings and coffins, and finally the dry catacombs.

The Peruvian mummies were apparently simply desiccated by exposure to the dry cool air of the Andes, by covering them with dry sand, or by burial in calcareous earth. In such regions of continuous sunshine and dryness, septic organisms are almost wholly absent from the air; meat dries without becoming tainted, and wounds heal without the complications known and feared in a less pure atmosphere. For permanence in such situations, mechanical protection is all that is needed, and certainly some of the mummies of Peru retain the features of the individual in a condition as perfect as most of the elaborately preserved mummies of Egypt. There is, however, a certain weirdness in the appearance of the Peruvian mummies, due to their sitting posture.

In modern times the desire to preserve the distinguished dead, or those especially beloved, as well as the need of preserving the bodies of animals and of men for scientific purposes, has made constant demand for some means for temporary or permanent preservation, and as the knowledge of the causes or conditions under which putrefaction takes place have been determined with greater certainty, so much the more perfect have been the results obtained, because all the organs are left intact and much of the natural fullness of the body is preserved. The best examples are those saturated with and preserved in some antiseptic liquid like alcohol. Such bodies are as permanent as the vessels and the liquids that contain them. If they receive proper care there seems to be no end to their permanence, as may be seen by specimens in the great museums of the world. There are also great numbers of specimens first saturated with some antiseptic, like alcohol, mercuric chloride, zinc chloride, arsenic or some of the essential oils, or by a combination of two or more of the above, then dried and varnished. Such dry specimens have shown less tendency to deteriorate in the museums of moist climates like that of England than the Egyptian mummies. For the most permanent and perfect preservation, the method of nature in imbedding insects in amber must be imitated. This is done on a great scale in every biological laboratory in the world. The water of the specimen is displaced by alcohol or carbolic acid, etc., and then more or less indirectly by the use of turpentine, oil of cloves, etc.; the object is filled with Canada balsam, dammar, shellac, etc., and inclosed in the same. With a large body, like that of a man, the process would be somewhat expensive and require considerable time; but the time and expense would be far less than that attributed to the best Egyptian embalming (seventy days' time; cost, $1,000 to $1,500), while the results would be far superior. A body prepared in this way would require only mechanical protection to render it indestructible.

Most of the embalming of human bodies at the present day is not for the purpose of rendering them permanent, but to preserve them in their natural color and fullness until arrangements can be made for a funeral or during the time necessary for transportation in case of death away from home. The permanence depends on the thoroughness with which the body is saturated with the antiseptics, and the permanence of the antiseptics themselves. As ordinarily accomplished the body, except the eyes, which become greatly sunken unless specially preserved, retains its natural appearance for weeks or months if sealed in an air-tight coffin, to prevent evaporation and shrinkage. A body thus embalmed, if it were slowly dried, would retain far greater naturalness than most of the Egyptian mummies possess.

The method for temporarily embalming the dead is very simple. As it is necessary to saturate all the tissues with the antiseptic, a solution is made and injected slowly into the arteries (method of Ruysch and William Hunter). A vein is opened to allow the blood to escape and to aid in determining when the system is filled. The injection is usually continued till the embalming liquid runs out of the vein. It is usually better to inject part of the required amount and then the remainder after several hours. After the arterial injection the thorax is filled through a hollow needle passed through the body wall, and by the same means any gas or liquid in the abdomen or any of its organs is drawn off and the abdominal cavity filled with the antiseptic. The withdrawal of gas and the injection of the liquid into the abdomen may need to be repeated. For an adult from 2 to 4 quarts of embalming liquid usually suffices. Very soon after the arterial and other injections all odor of decomposition will disappear, for the antiseptics will destroy the putrefactive ferments, and thus cut off the possibility of their further action. If the body is to be kept for a considerable time, all but the face, neck, and hands are wrapped or bandaged with strips of cloth saturated with the antiseptic. To prevent the sinking of the eyelids, thin shells of wax (" eye caps ") are put under the lids.

The substances used for temporary embalmment are mercuric chloride (introduced by Chaussier about 1800), arsenic (introduced by Tranchina, of Naples, 1835), zinc chloride (introduced by Sucquet, about 1840). In the published formulæ of embalming fluids two or more of the above are usually employed. Sodium chloride or common salt is also an ingredient, and instead of water alone as a solvent, glycerin and alcohol are used; carbolic, salicylic, and benzoic acid and one or more of the essential oils are also frequently present. The solutions usually contain from 8 per cent. to 10 per cent. of the antiseptics.

Embalming has grown to great dimensions in the U. S., and is not left to physicians, but has become a prominent feature of the undertaking business, even in country villages. Large establishments have grown up to meet the demand for proper instruments and material, and there has been founded a so-called "college of embalming" to train undertakers in the art. Undertakers, as a rule, employ proprietary embalming liquids, the composition of which they know only in part or not at all. The half-dozen of these liquids analyzed were found to conform very closely to the formulæ published by scientific men, the efficient agents being mercuric chloride, arsenic, and zinc chloride.

Lessley, *Embalming* (Toledo, Ohio, 1884); S. Laskowski, *Embaumement* (Geneva, Basel, and Lyons, 1886).

In the Index Catalogue of the library of the surgeon-general's office, at Washington, over 100 titles of books and papers relating to embalming are given under the headings Embalming and Mummies. SIMON HENRY GAGE.

Embankment: a mound of earth for a pier or quay, for defense against the sea or streams, or for carrying a roadway. In building embankments the slopes should be of a permanent nature, and the weight of the bank should not be so great as to force out the foot. The materials should be placed according to that angle at which they would begin to move if left to themselves. Gravel or hard stone may be laid at 34°, while clay is liable to slip if the materials are dressed to an angle of more than 26°. If required to resist the pressure of water on one side, the slope toward the water had better be 34°, and that toward the land 26°. The tendency of the subsoil of an embankment to be compressed under the load brought upon it may be resisted by filling the core with light materials and by widening the base. The best way to counteract this tendency is to isolate the foundation by driving piles.

Care should be taken to free the seating of an embankment from any water that may filter through it. Covering the slopes with turf is a useful precaution, but this can not be done when the bank is formed of gravel.

Among the greatest embankments of modern times are one of 1,750,000 cubic yards on the Ulm and Augsburg Railway in Germany, and the Oberhäuser embankment of 2,500,000 cubic yards on the Augsburg and Lindau line in the same country.

Embargo [Span. deriv. of *embargar*, arrest, impede; cf. Fr. *embarrasser*, Ital. *imbarrare*, all derivatives of the unexplained Romance root *barr-*]: a restraint or prohibition imposed by the government of a country on merchant-vessels or other vessels to prevent their leaving its ports. Embargoes are usually imposed in time of war, or when war is believed to be impending. They may sometimes prohibit the arrival as well as the departure of vessels. Embargoes are of two kinds, civil and hostile. An embargo being a stoppage or prevention of a vessel's quitting a port, there may be occasions where such a measure can be adopted in order to prevent war by keeping the vessels of a country safe from collision with the rules of belligerent powers. In this case the complete non-intercourse does not generally begin until vessels, especially of foreign powers, have liberty to leave the ports, laden or in ballast. This is civil embargo. Embargo was once thought to be an unexceptionable measure, but it is not much in use, and apparently will go out of use, for it puts obstacles in the way of commerce which all friendly states feel and must complain of. The *hostile* embargo here contemplated is a detention of the vessels of a particular nation which may happen to be in the ports of the injured country. These are detained by way of offset for a wrong done by the other country, in the hope that this attachment of the property of its subjects may lead to a peaceful settlement and prevent actual war. If war should ensue, this detention may be followed by confiscation. In Dec., 1807, the Congress of the U. S., at the request of President Jefferson, laid an embargo as an offset or retaliation against the British orders in council. This embargo was repealed by Congress in Feb., 1809. Revised by T. S. WOOLSEY.

Embassador: See AMBASSADOR and DIPLOMATIC AGENTS.

Embassy [or *ambassy*, viâ O. Fr. *ambassée*, from a deriv. of Lat. *ambactus*, servant, retainer, a word of Celtic origin, also introduced into Gothic as *andbahts*, servant. See AMBASSADOR]: a diplomatic mission; the function of an ambassador. In a technical or limited application, embassy signifies a mission presided over by an ambassador; that is, a diplomatic agent of the highest rank. The term is sometimes applied to a company of persons sent on a mission, including one or more envoys, secretaries, etc. The practical difference between these two kinds of diplomatic missions is absolutely nothing, but the difference in appearance and external trappings is very great, as an ambassador actually represents his sovereign, and must be treated accordingly, while the envoy is only a commissioner. See AMBASSADOR, ENVOY, and INTERNATIONAL LAW.

Ember Week [*ember* < O. Eng. *ymbren*, is probably a corruption of latter part of Lat. *quatuor tempora*, four seasons, pronounced as *quat'tempra*, *quatembra*, cf. Germ. *Quatember*, Dan. *kvatember*. It is commonly explained as O. Eng. *ymb*, around + *ryne*, course]: in the calendars of the Anglican and Roman Catholic churches, (1) the week after the first Sunday in Lent; (2) the week after Whitsunday; (3) that after Sept. 14 (Exaltation of the Cross); (4) that after Dec. 13. The Wednesday, Friday, and Saturday of these weeks are ember days, fasts for imploring the Divine blessing on the fruits of the earth and upon the ordinations which are performed at these times. The fasts are purely Western, and probably Roman in origin, although they may not date, as they are said to do, from Pope Calixtus I. The times were fixed by Gregory VII. in the eleventh century, and confirmed by the Council of Placentia (1095).

Embezzlement [Anglo-Fr. *enbesiler*, fraudulently destroy, O. Fr. *besiler*, lay waste, ravage; origin obscure]: in criminal law, the act of fraudulently appropriating to one's own use property held under some fiduciary relation, such as that of clerk or servant. It is not to be confounded with larceny. The definition of this offense is rigid, so that this branch of the criminal law is entangled with perplexing distinctions. Larceny is defined to be "the felonious taking and carrying away the personal property of another." The word "taking," as here employed, has been closely interpreted by the courts, and generally considered not to include the case of property held in trust, particularly where it came into possession of the trustee without first having passed into the possession of the real owner. There must have been a taking equivalent to a trespass. It became a maxim that without a trespass there could be no theft or larceny. So refined a distinction as the following has been maintained: Should a clerk or servant authorized to sell goods actually sell them, and, having received the price, convert the money to his own use, there is no larceny, because the master never had the *possession of the money*, and so the clerk could not be said to have "taken" it from him. On the other hand, if the clerk had put the money received on the sale into the master's money-drawer, and had afterward fraudulently abstracted it, he would have committed larceny, for the act of depositing the money in the drawer would have placed it *constructively* in the master's possession. The moral quality of the two acts is substantially the same, yet by the common law the one is a crime and the other is a simple breach of trust, for which the servant is responsible in a mere action for damages.

This imperfection in the law led many years ago to a statute in England, which created a new form of crime called embezzlement. The early English statutes included only the case of misappropriation by clerks or servants of individuals or private corporations. This form of legislation was copied in the U. S. There is now in England a much more comprehensive scheme. (See 24 and 25 Vict., c. 96.) The present act not only includes the former cases, but embraces a great variety of cases of breach of trust, such as that by factors, brokers, agents, trustees of charitable societies, officers of cities, and public servants generally. The range of each enactment of this kind is very comprehensive, including not only positive wrongs, but all forms of willful or fraudulent neglect of duty. It is by no means necessary under this legislation that the officer should appropriate the funds of a city to his own use. It is enough if he fraudulently appropriates or permits them to be appropriated to *any other use* than that to which they rightfully belong. The punishment is severe. The crime is made a felony, punishable by not more than fourteen nor less than three years of penal servitude, or else by imprisonment at hard labor for a fixed period. In the civil law embezzlement is recognized as a wrong, subjecting him who commits it to an action for damages or other proceeding by way of reparation. A salvor may forfeit his share of salvage, compensation by embezzlement; the forfeited share accrues, not to the other members of his class, but to the owner of the property saved. T. W. DWIGHT.

Embiotoc'idæ [deriv. of *Embiotoca*, the typical genus, from Gr. ἔμβιος, living + τόκος, offspring]: a remarkable family of fishes limited to the Northern Pacific Ocean, and especially represented on the shores of the U. S., and distinguished by their viviparity. It belongs to the order *Teleocephali* and sub-order *Acanthopteri*. The body is compressed and oblong; the scales are cycloid and of moderate size, and cover the entire trunk as well as head; on the back they form a sheath of from one to three rows wide at the base of the dorsal fin; this sheath diminishes backward to the end of the fin, and is separated from the back by a well-defined groove; the lateral line is continuous, and parallel with the back; the head is compressed and moderate; the nostrils double; the eyes lateral; the mouth has a moderate or slight lateral cleft; the lips simple, and more or less developed; the teeth are present on the jaws, but absent from the palate; the branchial apertures are ample, and continuous below; branchiostegal rays five or six on each side; the dorsal fin is oblong, and modified in two ways, severally characteristic of distinct sub-families; the anal fin is oblong, and armed in front with three slender spines; the anterior portion of the anal fin is developed in a peculiar way as a conduit for the milt and eggs; the pectoral fins are produced and more or less angulated, and the rays branched; the ventrals are inserted behind the bases of the pectorals, and each has a spine and five branched rays; the vertebral column has an increased number of vertebræ; the lower pharyngeal bones are confluent together; the stomach is simple, and pyloric cæca are absent. The family exhibits two distinct modifications of structure; in one (*Embiotocinæ*) the dorsal has its spinous portion rather less developed than the soft, and only composed of from nine to eleven spines. In the other (*Hysterocarpinæ*) the dorsal has the spinous portion much longer than the soft, and sustained by about fifteen or more spines. (1) The *Embiotocinæ* are by far the most numerous in forms, and the species are marine. By American naturalists fourteen genera are admitted—viz., *Ditrema*, *Hypsurus*, *Phanerodon*, *Embiotoca*, *Tæniotoca*, *Damalichthys*, *Rhacochilus*, *Amphistichus*, *Holconotus*, *Cymatogaster*, *Hypocritichthys*, *Hyperprosopon*, *Brachyistius*, and *Abeona*. (2) The *Hysterocarpinæ* are, as far as known, represented by but one species (*Hysterocarpus traskii*), which is peculiar to the fresh waters of the Sacramento river. All the species are viviparous, and the young are developed in small number in special uterine sacs. Some of the species are among the most common of the Californian fishes, and are brought to the markets in large numbers; they are known to the inhabitants by the name of perch, although they have no relation whatever with the perches properly so called of Europe and the Eastern U. S. On the whole, they are mostly nearly related to the *Labridæ* and *Gerridæ*, but their differential characters are very positive. THEODORE GILL.

Embla: in Scandinavian mythology, the first woman on earth. Usually explained as derived from *alm*, German *Ulme*, English elm.

Emblazonry: See HERALDRY.

Emblem [from Lat. *emble'ma*, mosaic work, inlaid work, ornament = Gr. ἔμβλημα, insertion; ἐν, in + βαλεῖν, throw]: a figurative representation which by the power of association suggests to the mind some idea not expressed to the eye; a symbol; a type; thus a balance is an emblem of justice. In bibliography, the book of emblems is a book containing a series of plates or pictures of emblematic subjects, with explanations, as the poems of Jacob Cats.

Emblements [O. Fr. *emblaement*, deriv. of *emblaer*, sow with grain: Ital. *imbiadare*: O. Fr. *blef* > Mod. Fr. *blé*, wheat < Lat. *abla'tum*, what is carried from the field, grain]: the growing crops of cereal grains and vegetables produced annually, not spontaneously, but by labor and industry. By the common law a tenant for life, or other tenant, whose estate depends on an uncertain event, is entitled to the emblements, although his lease may terminate before harvest-time. If a tenant for life die, his personal representatives may after his death claim the products of his labor. But if a term be brought to a close by the voluntary act of the tenant, he is not entitled to the emblements. Revised by F. STURGES ALLEN.

Em'blica officina'lis [for etymology of *emblica* cf. Pers. *āmleh*, Skr. *āmalaka*, the name of this tree]: a species of trees of the natural order *Euphorbiaceæ*; a native of India and the Malay Archipelago. It produces a small round fruit, which is very acid, has medicinal properties, and is used to make pickles. The wood is hard and valuable. The bark is used for tanning and for dyeing cotton black.

Embolism [from Gr. ἐμβολισμός, intercalation; ἐν, in + βαλεῖν, throw]: in the calendar, an intercalation of a day, as Feb. 29 in leap-year, or of a lunar month, as in the Greek and Hebrew calendars.

EMBOLISM, in pathology, is the presence of any foreign substance (*embolus*), being usually a portion of a clot of blood in the circulating blood. Emboli frequently come from the heart, where blood clots are common and the blood is much agitated. Embolism in the brain is a recognized cause of apoplexy. An extensive embolism of the lungs may lead to sudden death; a smaller one may lead to local pneumonia, abscess, pyæmia, or gangrene. When air enters the veins through wounds or other paths, it circulates as an embolus and has frequently caused sudden death. Embolism, though frequently fatal, is sometimes followed by recovery. The best treatment is the frequent administration of concentrated food and stimulants, keeping the patient in fresh air, and allaying irritation by opiates. Revised by WILLIAM PEPPER.

Embolite: a chloro-bromide of silver, found in the silver ores of Mexico and Chili.

Embossing [from deriv. of O. Fr. *boce* > Mod. Fr. *bosse*, boil, swelling: Ital. *bozza*: Span. *bocha*; borrowed from Teutonic; cf. M. H. Germ *butze*, lump]: the raising of parts of a surface in relief above the other parts, usually for ornamental purposes. The term is usually limited to the beating up of thin plates or sheets of metal, or the molding of leather, moistened paper, or the like, rather than to relief cut in marble or stone or cast in plaster or sulphur. It is also applied to embroidery in which the pattern is raised above the surface of the stuff. See CHASING, RELIEF, and REPOUSSÉ. RUSSELL STURGIS.

Embracery [from O. Fr. *embraser*, set on fire]: in law, the offense of endeavoring to corrupt or bribe a jury or to influence a jury by any corrupt motive. This offense is punishable by fine and imprisonment.

Embrasure [deriv. of *embraser*, *ébraser*, to splay, chamfer]: in fortification, an opening made in the parapet of a fortified place or the breastwork of a battery through which the guns are pointed. The embrasures are usually made about 2 feet wide at the interior extremity or neck, and half as thick as the parapet at the exterior crest. The sole or lower surface is at the height of about 2½ feet above the platform on which the carriage of the gun is placed. The object of such embrasures is to shield as much as possible the interior of the place, and yet leave space for the free action of the gun.

Embroidery [from O. Fr. *embroder*, deriv. of a subst. appearing in Ital. *bordo*, Fr. *bord*, border, hem, outer edge, a loan-word from Teutonic; cf. O. H. Germ. *bort*]: needle-work upon textile material, leather, or the like, with which are sometimes combined applied pieces of colored material, feathers, jewels, or even pieces of looking-glass. The object of embroidery is usually decoration, but names and initials are often worked upon articles of clothing, etc., for convenience, and heraldic bearings and other devices, whose purpose is only in a secondary sense decorative, have often been embroidered. In the nineteenth century embroidery has been much in use at times for women's garments, and at others almost wholly abandoned, except that done with linen thread on undergarments, which has never gone out of fashion altogether. The colored embroidery which has been used the most commonly and for the greatest length of time during the nineteenth century is that of India shawls, called Kashmir shawls, and often, erroneously, camels'-hair shawls. Apart from these, women of European race sometimes use embroidery in color on gowns or other outer garments of silk or other unwashable material, sometimes embroidery in crewels on cotton or linen, and sometimes white embroidery on white; but none of these fashions is lasting. At times it is considered elegant to have curtains embroidered, and even hangings for walls are occasionally decorated in this way. When such decoration is in fashion, besides the costly hand-embroidery, there is produced machine-made embroidery, which always has the fault of being mechanical in look, hard and formal. (See MACHINE WORK and DECORATIVE ART.) On the other hand, some attempt has been made to work with the needle decorative pictures of great richness, the subjects selected being those which allow of a somewhat close rendering of natural forms by needle-work. Thus on a blue silk ground, golden-yellow wheat ears below and flying bees above give an impression of summer, while the effect of the soft floss-silk upon the hard and smooth ground is exceedingly decorative. This work is also applied to women's garments, but not commonly; indeed it requires protection from wear, and often needs to be framed and glazed like a water-color drawing.

The decorative art of the past is very rich in the branch of embroidery, and Oriental nations kept the ancient traditions in force and continued to produce splendid work until the influence of European commerce destroyed or greatly injured and degraded those arts in the course of the nineteenth century. In antiquity the great simplicity of the dress of European nations caused embroidery to be less in use, but with the early Middle Ages it became a common adornment of costly dress throughout Europe. It is to be observed also that where the state of the industrial arts is low, embroidery is apt to develop more rapidly than weaving. Rich textile fabrics come only with some advance in general civilization. In this way it happens that the European Middle Ages are the time of the most general use of embroidery of many kinds. The dress of laymen and ecclesiastics and the decoration of church and domestic interiors called for it continually. England was especially the home of elaborate pictorial needle-work in the twelfth and thirteenth centuries.

Some few of the special kinds of embroidery may be mentioned here. *Couching* is the laying down of threads, as of gold or silver or floss silk, side by side upon the surface to be adorned, and holding them fast there by stitches of finer and stronger thread which may not show at all. The larger and softer thread is not dragged through the material of the ground. *Appliqué embroidery* is that which is done by cutting out pieces of cloth, velvet, or other materials, sewing these pieces fast to the ground, and working the edges with stitches. Such patches of stuff may be cut to resemble leaves or flowers, and stitches on their face may express veins or shading. *Cut-cloth embroidery* is a variety of this, or merely another name for it. *Chain-stitch embroidery* is named from the stitch, in which a loop of thread is left on the surface of the stuff to be adorned, and the needle takes the thread through that loop before making another; this is the most generally used of all kinds of work, and is the very essence of the pictorial embroidery of the Middle Ages, English work being especially noted for the fineness of the chain-stitch, by means of which faces and hands, even of small size, were delicately rendered. *Crewel work* is done with worsted thread, usually on cotton or linen. For the various thread embroideries, cut-work, etc., see LACE.

RUSSELL STURGIS.

Embryol'ogy [from Gr. ἔμβρυον, a young animal, fœtus + λόγος, discourse]; the history of the development of the young animal before birth. Embryology proper includes the description of all the changes, both anatomical and physiological, which take place in the body of the imperfect young, within either the uterus or the egg, in all classes of animals. The present article, however, will be devoted more especially to the embryology of the Vertebrata, or those animals having a spinal column, since the general plan of development is the same throughout this class, and is particularly important as illustrating the development of the embryo in the human species.

In all cases the development of the young animal begins from an *ovum*, or egg. The ova exist originally in the interior of the body of the female parent, where they are produced in certain organs contained in the cavity of the abdomen, termed *ovaries*. The ovaries, containing ova, are thus characteristic of the female organization, and form an essential part of its original structure. The ova, after being produced within the ovaries, at a certain period arrive at maturity, and are spontaneously discharged. If fecundated at this time by the influence of the male, they develop into embryos; if not, they lose their vitality after a short period and perish. Thus the formation of the embryo depends upon the union and fusion of two sexual elements—namely, the ovum produced by the female, and the fecundating element or spermatozoön contributed by the male.

In some kinds of animals, such as birds, batrachians, and most of the reptiles and fishes, the egg is first discharged from the body of the female, and the development of the embryo takes place within it subsequently, the young animal being at last hatched from the egg externally; such animals are called *oviparous*, or egg-laying animals. In other instances, as in some fishes and reptiles, all the true quadrupeds, and the human species, the ova are retained within the body of the female while the development of the embryo is going on; so that at last the fully formed embryo is produced alive; such animals are called *viviparous*, because they produce living young, instead of laying eggs like the former. Nevertheless, the process is essentially the same in both cases, and differs only in the duration in which the ovum is retained within the body of the female parent.

The ovum is a typical cell, and in its simplest form consists of a globular mass of albuminous matter mixed with oleaginous granules, and invested by a transparent, colorless, homogeneous membrane. The oleo-albuminous mass is termed the *vitellus*, or yolk, while the investing layer is called the *vitelline membrane*.

Within the vitellus lies a delicate transparent sac, the *germinal vesicle*, which corresponds to the nucleus of the cell, and is of great importance for the subsequent changes necessary for the preparation of the ovum for the reception of the male fecundating element. A second still smaller body, the *germinal spot*, occupies the germinal vesicle, and represents the nucleolus of the egg-cell.

In the human species and in mammals generally the ovum, as above described, forms a little sphere about $\frac{1}{120}$ of an inch in diameter. It is therefore nearly invisible to the naked eye, and requires examination by the microscope in order to distinguish its characters.

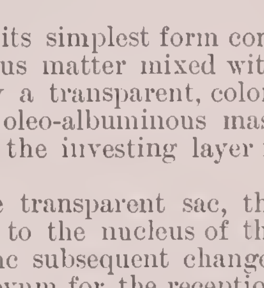

FIG. 1.—Ovum of the rabbit, from the ovary, magnified 90 diameters: *a*, vitellus; *b*, vitelline membrane; *c*, germinal vesicle; *d*, germinal spot.

Since the impregnated mammalian ovum is retained within the body of the female during the development of the embryo, and abundantly supplied with nourishment from the parent organism, such ova are provided with a very small quantity of nutritive material. In the oviparous classes, on the contrary, where the development of the embryo takes place outside the body of the parent, the egg is larger in size and more complicated in structure, and contains a store of nutritious material, as well as certain additional protective envelopes. In the common fowl, for example, the vitellus or yolk, which is the only part of the egg produced in the ovary, is nearly an inch in diameter, and contains a great abundance of oleaginous as well as albuminous material. After its discharge from the ovary, and during its downward passage through the generative canal, the size of the egg is still further increased by the deposit around the yolk of a layer of pure albumen, secreted by the lining membrane of the canal, and forming the so-called "white of egg." In the lower portion of the generative passage there are added to the outside of the albumen two fibrous membranes, called the "shell-membranes"; and lastly the calcareous shell, formed of a consolidated layer of the lime salts. These fibrous and calcareous envelopes serve to protect the embryo, while the albumen and the yolk supply it with the requisite nourishment during its formation in the egg.

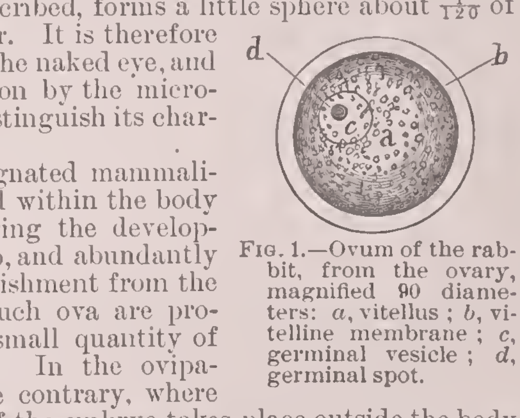

FIG. 2.—*a*, yolk; *b*, vitelline membrane; *c*, albumen; *d*, shell-membranes; *e*, egg-shell.

While the formation of the embryo follows the union of the male and female sexual elements, yet before the female cell is capable of becoming impregnated certain preparatory changes, collectively known as the *maturation of the ovum*, are necessary. These phenomena take place while the egg is still within the ovary, and consist essentially of a repeated very *unequal division* of the germinal vesicle or nucleus, resulting in the

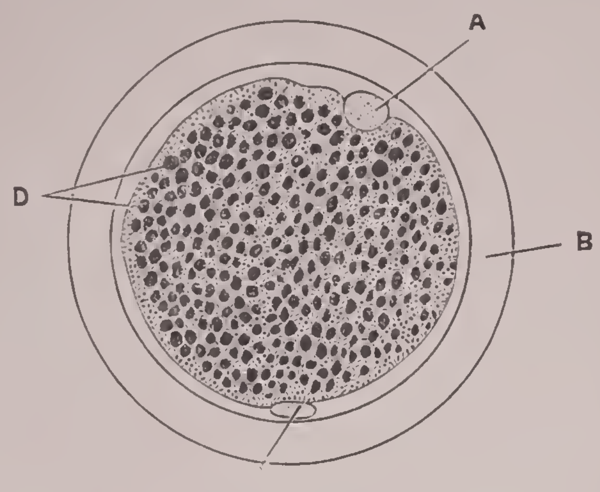

FIG. 3.—Unimpregnated ovum of cat: A and C, polar bodies; B, external membrane or zona pellucida; D, vitellus (after Bonnet).

expulsion from the ovum of two minute particles, the *polar bodies*, whose significance is still uncertain. The original germinal vesicle is replaced by a new body known as the *female pronucleus*; after the extrusion of the polar bodies and the appearance of the pronucleus, the ovum is ready for the reception of the male element. Maturation takes place in every completely developed ovum, irrespective of the possibility of future impregnation.

Conception or fertilization of the ovum follows the union of the ripe egg with the spermatozoön under favorable con-

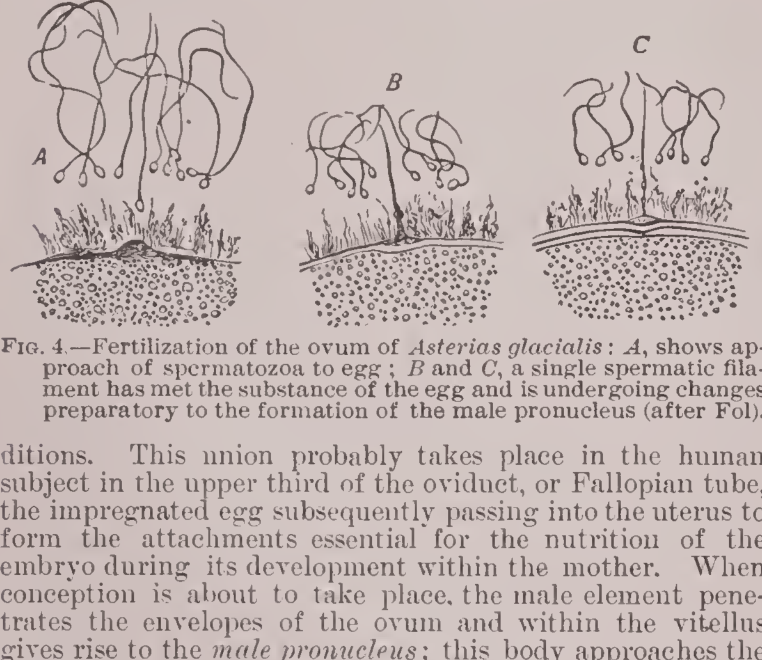

FIG. 4.—Fertilization of the ovum of *Asterias glacialis*: *A*, shows approach of spermatozoa to egg; *B* and *C*, a single spermatic filament has met the substance of the egg and is undergoing changes preparatory to the formation of the male pronucleus (after Fol).

ditions. This union probably takes place in the human subject in the upper third of the oviduct, or Fallopian tube, the impregnated egg subsequently passing into the uterus to form the attachments essential for the nutrition of the embryo during its development within the mother. When conception is about to take place, the male element penetrates the envelopes of the ovum and within the vitellus gives rise to the *male pronucleus*; this body approaches the previously formed *female pronucleus*, the two finally fusing to produce a new structure, the *segmentation nucleus*, the immediate element in which the formation of the future embryo begins. The new being therefore originates from a

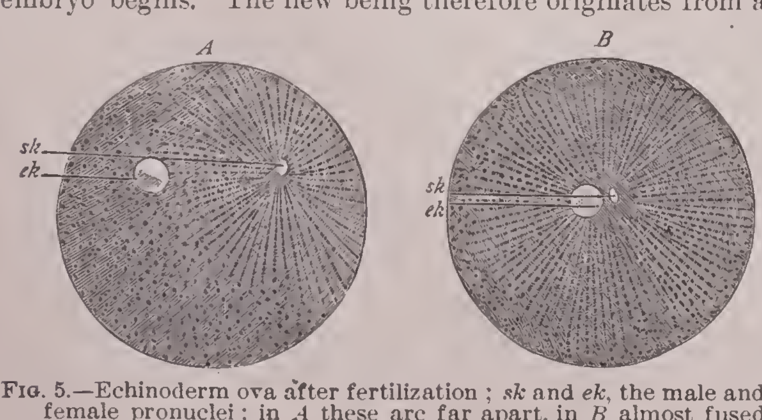

FIG. 5.—Echinoderm ova after fertilization; *sk* and *ek*, the male and female pronuclei; in *A* these are far apart, in *B* almost fused (after O. Hertwig).

cell which results from the fusion of the sexual elements of *both parents*, and which contains the potentialities contributed by both father and mother. In the history of conception, as now understood, is found the explanation of the striking transmission to the offspring of the characteristics of both parents which often seems so remarkable.

In all instances, without exception, the first indication of the commencing formation of the embryo in the ovum is

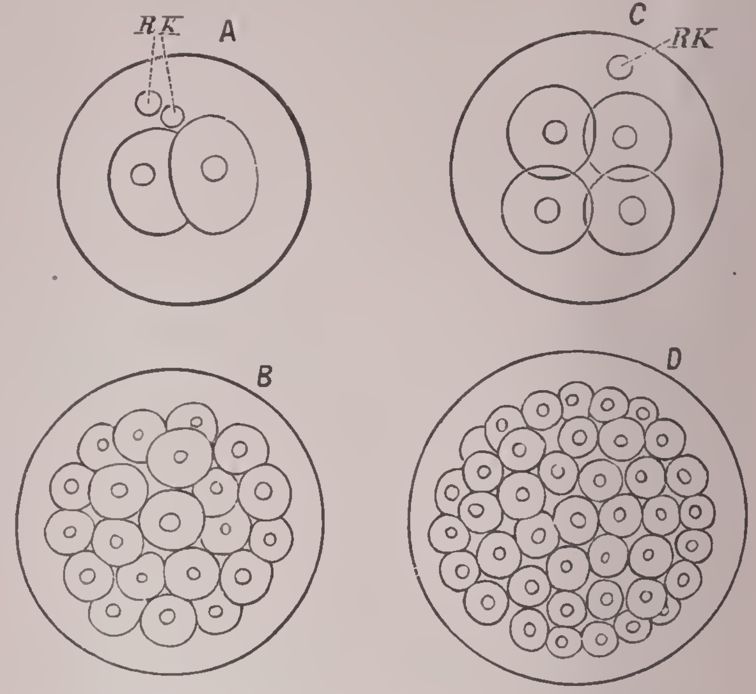

FIG. 6.—Diagram of segmentation of mammalian ovum: *A* and *C*, first and second stages of division; *B*, later stage; *D*, stage of the mulberry-mass; *R K*, polar bodies (after Bonnet).

the establishment of *segmentation*, whereby the original cell becomes divided by repeated cleavage into innumerable smaller elements from which are derived the various tissues and the organs of the new being. This process consists in the separation of the *segmentation nucleus* into two smaller nuclei, the division being accompanied by a corresponding constriction and separation of the cell-body or the vitellus into *segmentation spheres* by the appearance of a furrow running around the vitellus like an equator, which gradually deepens until it has completely separated the two hemispheres from each other. At the same time, or a little later, a second furrow, placed at right angles to the first, runs around the vitellus in another direction; and thus the two secondary globules are divided into four. By a repetition of this process the original cell, which had the form of a simple sphere, becomes converted into an aggregation of *segmentation spheres*, which from its external appearance is known as the *morula*, or mulberry mass.

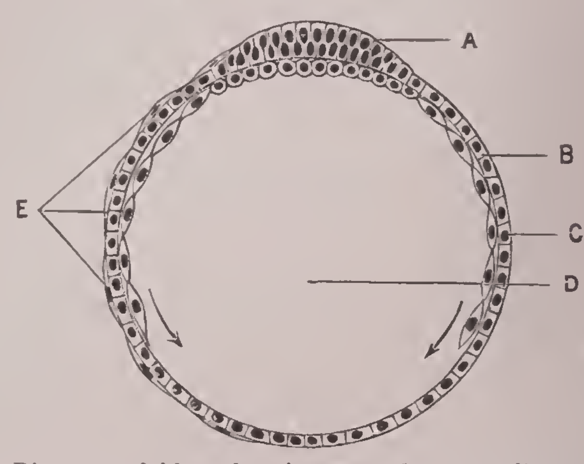

Fig. 7.—Diagram of blastodermic stage of mammalian ovum: A, thickening of primary ectoderm; B, constituting the embryonic area; C, entoderm; D, segmentation cavity; E, remains of cuticular layer of Rauber's cells (after Bonnet).

The *complete* and practically *equal segmentation* of the mammalian ovum results in the production of a hollow sphere, the *blastodermic vesicle*, which in its early stage is composed of two cell-layers, a complete external, and an incomplete inner stratum. Within a limited field known as the *germinal area* the elements composing these layers undergo proliferation, which process results in a marked thickening of the blastoderm. Coincident with these changes a third stratum of cells appears between the outer and the inner layers; these now constitute the cardinal embryonal formative tracts, the *ectoderm*, the *entoderm*, and the *mesoderm*. From the establishment of these *germinal layers* the future history of the embryo consists essentially in the unequal growth and the specialization of these three blastodermic layers.

Viewed from the surface, the *embryonic area* early exhibits an opaque periphery and a clearer central field, the

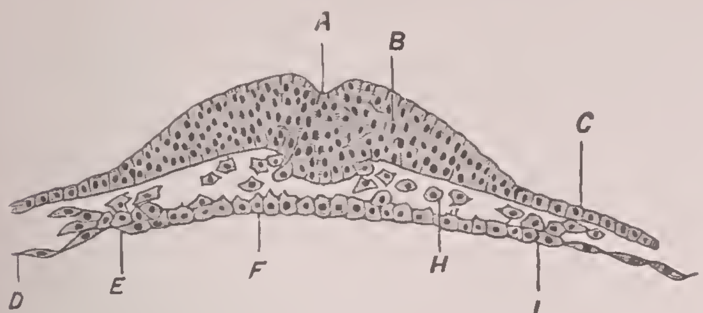

Fig. 8.—Transverse section of embryonic area: *A*, primitive groove in center of area of thickened ectoderm (*B*) which passes on either side into ordinary ectoderm (*C*); *F*, entoderm, that lying between *E* and *I* is devoted to forming lining of intestinal tube, that beyond (*D*) covers vitellus; *H*, mesoderm just appearing (after Bonnet).

area pellucida; likewise, from the caudal pole of the embryonic area there grows forward an opaque centrally situated rod, the *primitive streak*; this is a transient structure which does not form part of the embryo, but which is only the forerunner of the earliest trace of the embryo proper.

Very soon after the formation of the primitive streak the appearance of two diverging V-like folds, which embrace the anterior extremity of the primitive streak, marks the first step in the production of the future animal. These ridges are the *medullary folds*, and the included longitudinal furrow is the *medullary groove*; some time later a rod of cells appears at the bottom of the latter, and is known as the *notochord*, a structure of great importance as defining the position of the future vertebral column, and consequently the *axis* about which the fundamental structures of the embryo are grouped. The medullary folds eventually unite over the medullary groove along the dorsal line, the inclosed canal thus formed being the primitive *neural tube*, which develops into the important cerebro-spinal nervous tract. On either side of the neural tube the tissue of the embryo undergoes cleavage into minute quadrangular segments known as

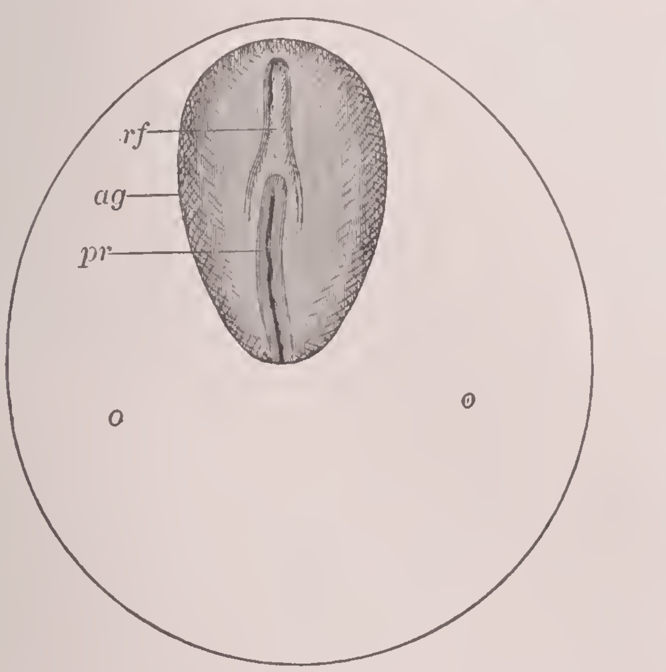

Fig. 9.—Embryonic area of the ovum of a rabbit at the seventh day: *ag*, embryonic area; *o*, *o*, region of the blastodermic vesicle immediately surrounding the embryonic area; *pr*, primitive streak; *rf*, medullary groove (after Kölliker).

the *somites*; these do not accurately correspond with the future vertebræ, but are transient structures, expressive of the earliest manifestation of the law of cleavage into segments characterizing vertebrated animals. With the establishment of these fundamental embryonic structures—the medullary folds, the notochord, and the somites—the formation of the embryo may be considered to be well under way.

While these changes, visible from the exterior, are progressing, important modifications of the blastodermic layers take place within the embryo; one of the most important of these is the cleavage of the great mesodermic tract into two sheets, a *parietal* and a *visceral* layer, which adhere respectively to the ectoderm and to the entoderm. The space included between these two layers of the mesoderm is the primitive *body-cavity*, from which are derived the important spaces containing the abdominal organs, the lungs, and the heart.

The two layers of tissue thus formed by the ectoderm and the parietal sheet of the mesoderm on the one hand, and by the entoderm and the visceral layer of the mesoderm on the other, are actively engaged in forming folds from which the protecting membranes and the body-walls and the walls of the digestive tube and its glandular appendages are respectively produced.

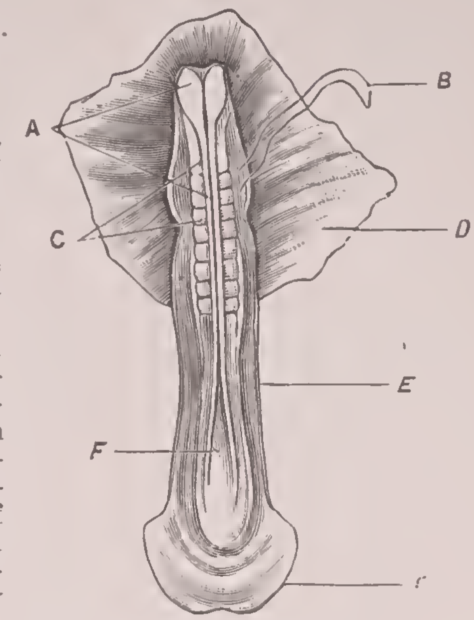

Fig. 10.—Sheep embryo of sixteen days seen from the dorsal surface: *A*, neural plates which inclose the nervous tube; *C*, primary segments or somites; *B*, *E*, portions of amnion; *D*, portions of umbilical vesicle; *F*, allantois (after Bonnet).

These are the general features of the development of the embryo in all vertebrated animals. There are other details which relate to the special growth of particular parts, and to the so-called metamorphoses or transformations which take place in particular species; these are nothing more than the successive appearance and disappearance of particular organs, which are adapted to the life of the animal at different stages of growth. Thus in the young tadpole, when first hatched from the egg, the mouth is a round orifice provided with a suctorial apparatus and adapted for feeding on vegetable matters; respiration is entirely aquatic, and is performed by means of gills; there are no limbs, but voluntary movement is accomplished by a large and muscular tail, the animal living altogether under the surface of the water. Afterward the mouth enlarges into a wide transverse opening, adapted for the seizure of living prey; the gills disappear and lungs are developed, while the mode of respiration changes from aquatic to aërial; and finally, anterior and posterior legs grow from the corresponding parts of the body, becoming powerful organs for both swimming and leaping, while the tail ceases to grow, becomes atrophied, and disappears. Thus the tadpole gradually acquires the organs and the appearance of a perfect frog. This change, in the case of the tadpole, is called a

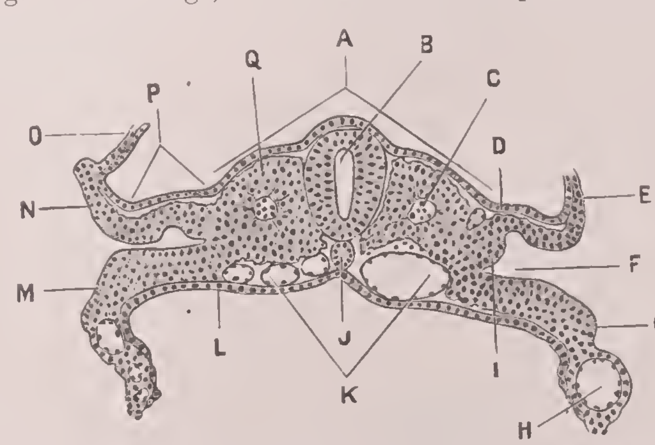

Fig. 11.—Transverse section of sheep embryo of about eighteen days: A, P, axial and parietal embryonic zones; B, neural canal; C, cavity of somites; D, ectoderm passing into amnion (O); E, G, parietal and visceral layers of mesoderm; F, primary body-cavity; H, umbilical vein; I, middle plate; J, notochord; K, primitive aortæ; L, entoderm; M, N, intestinal and abdominal plates forming by their union respectively the wall of the primary gut and of the body-cavity (after Bonnet).

"transformation," because it happens after the young animal has escaped from the egg; but equally important changes take place in the embryo of the higher animals while they are still retained within the egg or in the uterus of the female parent.

Besides the essential and general features of embryonic development detailed above, there are, in all the higher classes, certain secondary or accessory organs developed during embryonic life which will require a further description.

The first of these is known as the *umbilical vesicle.* In the process of development, as already described, the abdominal walls, growing together upon the median line, inclose directly the whole of the vitelline cavity, which subsequently, of course, becomes the cavity of the intestine. But in many of the fishes and reptiles, and in all birds and mammals, the abdominal walls approach each other before they have embraced the whole of the vitellus, so that the vitelline cavity is thus separated, by a kind of constriction, into two parts. The internal part, which is fully embraced by the abdominal walls, is, as before mentioned, the cavity of the intestine; but the external part, which is left by this constriction outside the abdomen, is the umbilical vesicle. This name is given to it because it is really a vesicle, containing some of the remains of the vitellus, and because it still communicates with the cavity of the intestine through the umbilicus or navel. This communication is at first short and wide; but as development proceeds, the umbilical vesicle gradually retreats farther from the abdomen, while the passage of communication becomes converted into a comparatively long and narrow canal. In many mammals and in the human species this canal is partially obliterated at an early period, so that the umbilical vesicle then forms an isolated cavity or sac, connected with the abdomen only by a slender solid pedicle. In the earlier stages blood-vessels run out along this pedicle, and ramify upon the surface of the umbilical vesicle.

Another important accessory organ of the embryo is the *amnion.* This is a delicate and transparent membrane, which turns up from the edges of the body walls over the back of the embryo, and thus envelops it in a secondary cavity called the "sac of the amnion"; the albuminous protective liquid which it contains, and in which the embryo is bathed, is called the "amniotic fluid." The amnion is accordingly an extension of the outer layer of the blastodermic membrane, and is continuous with the integument of the embryo at the umbilical orifice. In other words, the external layer of the blastodermic membrane in these cases develops into two different parts; that which immediately invests the body of the embryo is its integument, while that which turns backward at the edges of the abdominal opening is the amnion, a protective organ of embryonic life. The amnion at first closely embraces the body of the embryo, but afterward it expands more rapidly with the increase of the amniotic fluid, so that the young animal may move freely within its cavity when the muscular system begins to exhibit signs of activity.

The third accessory embryonic organ is the *allantois*, so called from the Greek ἀλλᾶς, ἀλλᾶντος, a "sausage," because of its elongated cylindrical form in some cases. The allantois is an outgrowth from the hind-gut or lower part of the intestine. It shows itself where typically developed, but not in the human embryo, as a small bud or diverticulum, shaped somewhat like the finger of a glove, which protrudes from the abdominal opening in front, and then rapidly expands in every direction until it has entirely enveloped the embryo, as well as the amnion, in a second exterior covering. Later its walls are exceedingly vascular; by the time the allantois has become completely formed, the external surface of the embryonic mass forms a continuous vascular membrane, in which the blood-vessels of the embryo ramify in great abundance.

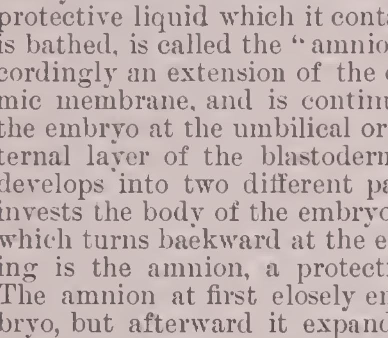

FIG. 12.—Embryo of a chick on the seventh day of incubation: *a*, body of the embryo; *b*, amnion; *c*, a portion of the umbilical vesicle; *d*, commencing growth of the allantois.

This anatomical feature will serve to indicate the usefulness and the function of the allantois. It is the organ of nourishment and respiration for the embryo. In the fowl's egg the allantois, which is placed immediately underneath the calcareous shell and shell-membranes, is very active during the latter half of the period of incubation. It absorbs oxygen from the external air through the porous egg-shell, and exhales carbonic acid, thus serving to renovate and arterialize the blood as the lungs will do in the young chick after being hatched. In mammals the allantois is still more important. The ovum in these animals being of minute size, without any abundant store of nutritious material, and being retained, after fecundation, within the body of the female parent, the young embryo is entirely dependent upon the maternal system both for respiration and nourishment. The vascular allantois here, enveloping the embryo, comes in contact with the vascular lining membrane of the uterus, and thus the blood-vessels of the embryo constantly absorb from the blood-vessels of the mother the substances requisite for its nourishment and growth. In many kinds of animals the allantois even contracts a more or less intimate adhesion with the lining membrane of the uterus at particular spots, resulting in the formation of the *placenta*, where the process of absorption and transudation is carried on with greater rapidity.

In the human species the allantois commences its growth in the same manner as in the inferior animals, but very soon exhibits certain modifications in its subsequent development. In man the allantois never exists as a free sac, but grows out largely as a solid structure which early participates in the formation of a continuous vascular envelope, the *chorion.*

The human chorion at an early period becomes shaggy or velvety by the growth of a multitude of minute filamentous projections or *villi* upon its outer surface. These projections become branched and divided, forming so many tufted filaments, which greatly favor absorption. Soon after the first month, however, the villi cease their growth over about three-quarters of the surface of the chorion, which parts thus become smooth and bald; while over the remaining quarter they grow more rapidly than before, be-

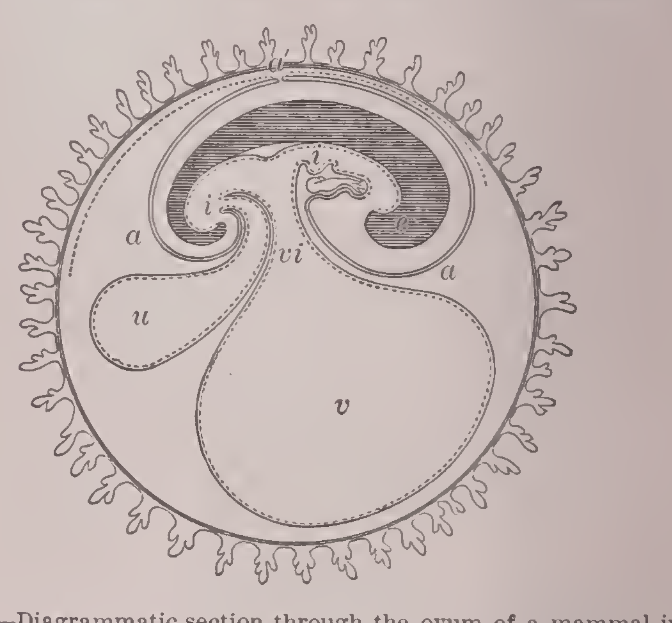

Fig. 13.—Diagrammatic section through the ovum of a mammal in the long axis of the embryo: *e*, the cranio-vertebral axis; *i i*, the cephalic and caudal portions of the primitive alimentary canal; *a*, the amnion; *a'*, the point of reflection into the false amnion; *v*, yolk-sac, communicating with the middle part of the intestine by *vi*, the vitello-intestinal duct; *u*, the allantois. The ovum is surrounded externally by the villous chorion.

coming excessively developed both in numbers and in ramification and vascularity, so that the chorion here becomes converted into a thickened and spongy mass, penetrated everywhere with an abundance of looped and ramifying blood-vessels. The union of this portion of the chorion with the maternal tissues of the uterine walls when fully developed forms a distinct organ, the *placenta.* The placenta, accordingly, is the special organ of nourishment for the embryo. It has become well developed and easily distinguishable from the remaining portions of the chorion by the end of the third month of embryonic life.

The amnion and the chorion, although termed "membranes" and "appendages," are in reality connected with the body of the embryo. The placenta includes also a portion of the tissues of the mother; for at the same time that the chorion is becoming excessively shaggy and vascular at the spot at which is afterward to be the placenta, the lining membrane of the uterus also assumes, at the corresponding point, a similar increased development. In both cases the blood-vessels preponderate over the remaining tissues, the existing maternal vascular channels especially becoming enormously enlarged and intimately united with the fœtal constituents of the placenta—the vascular villi of the chorion. Thus the placenta, when fully formed, is a double organ, containing both embryonic and maternal vessels, presenting an extensive vascular surface for reciprocal absorption and exudation. At no time is there an actual communication between the lumen of the two sets of vessels, the nutritive interchanges taking place through the interposed thin vascular walls.

Certain conditions result in the production of multiple births, of which twins are the most common example. The average ratio of twin births, taken from the statistics of the civilized world, is about one in every hundred. In Bohemia twins occur once in every sixty births; in Prussia they occur once in every eighty-eight; in France, once in every hundred; and in New York, once in every 120. Triplets occur once in 7,910, and quadruplets only once in 371,126 births. About a dozen well-authenticated cases of the birth of five children at one time are recorded in medical literature, and even a single, apparently trustworthy, case of the birth of six—two girls and four boys—has been recorded in Italy. The reputed births in excess of this number are apocryphal. Extended observations regarding twins show that in one-third of the cases both children were boys; in not quite one-third both were girls; and in the remaining third both sexes were represented. The occurrence of twins depends upon the simultaneous development of two germs; these are usually contained within two distinct ova, liberated from the ovary at the same time, but in a little over 10 per cent. of the cases studied the two germs are contained within the same ovum, which is then spoken of as "double-germed." Twins derived from a single ovum are always of the same sex.

In the formation of their attachments to the maternal structures, as already above described in connection with the placenta, the nutritive areas of the two children become very closely associated, often to the degree of direct communication between their circulations within the placentæ. When such close relations have been established, marked inequality in the vigor of the developing beings may seriously affect the weaker fœtus in consequence of the appropriation of an undue share of the sources of nutrition by its stronger brother. Triplets, likewise, may originate from three distinct ova, or from two ova, one of which was double-germed; as rare possibilities, in both twins and triplets, the division of a germ primarily single may be assumed.

The phenomena attending the menstrual epochs mark the periodic changes taking place within the uterine cavity in the preparation of the mucous membrane for the reception of the ovum should impregnation occur; in such event, the egg passes from the oviduct into the uterus, the recesses of whose soft velvety lining offer especially favorable situations for the retention and growth of the developing ovum. In addition to its important contribution to the placenta, the thickened uterine mucous membrane, known as the *decidua*, very early, long before the placenta is formed, becomes elevated around the arrested ovum, which is soon completely inclosed within a special sac formed by the extension of the uterine lining, the *decidua reflexa*.

When the development of the embryo is completed the muscular walls of the uterus contract, the membranes are ruptured, and the fœtus is expelled; subsequently the placenta or afterbirth is separated from its attachments and cast from the uterine cavity, having ceased to be an available nutritive organ. After birth the act of respiration and the absorption of nourishment are accomplished in the infant independently by the aid of internal organs (the lungs and the digestive tract), thus replacing the means of nourishment which during embryonic life were supplied by the placenta from the blood of the mother.

Revised by G. A. PIERSOL.

Embryology (in plants): Every plant, however simple or complex it may be, develops from a single (egg) cell. In simple plants the successive changes from the first cell to the adult organism are few, and the embryological history is brief, but, with the increasing complexity of the full-grown plant, the history of its development is much prolonged. Thus in the Protophytes, the reproductive cell, always asexual, merely divides into two cells, and after a period of growth these divide again, and so on. The cells so produced may separate from one another at once, as in *Chroococcaceæ*, or they may remain more or less firmly attached in a filament, as in *Nostoc*, *Oscillaria*, etc. (Fig. 1).

Many Phycophytes have an equally simple developmental history. In those in which the mature plant-body is a plane, or a mass of cells, there is first the formation of a filament, which gives rise to a plane or mass by the division, in two or more directions, of an end cell and its daughter cells (Fig. 2). The egg-cell here is one produced by a sexual process, but a similar development takes place in many cases from asexually produced cells.

The lower Carpophytes are simple rows of cells whose development is similar to that of the filamentous Protophytes and Phycophytes. In fact this is the case with most of the fungi, whose simple plant-bodies develop from the single spore, practically as in the case of the filamentous algæ. It must be borne in mind that in the case of an ordinary fungus what is popularly called the plant is in fact the "fruit," while the proper plant-body consists of slender branching filaments with little or no coherence. Thus a toadstool is the relatively large "fruit" of a mass of white filaments which grow in decaying organic matter. In the Red Seaweeds the spore soon elongates and subdivides, giving rise to a simple structure which eventually becomes more complex.

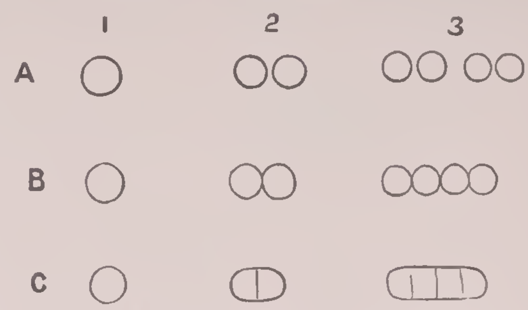

FIG. 1.—Diagrammatic representations of young stages of Protophytes: A, the cells all soon separating; B, the cells slightly cohering; C, the cells permanently cohering (1, the first cell; 2, after first division; 3, after second division).

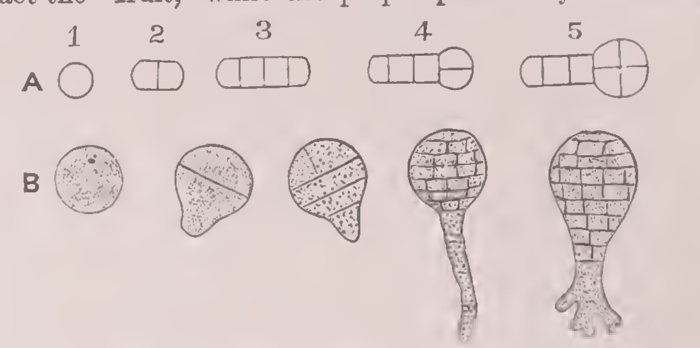

FIG. 2.—A, an ideal development of a young Phycophyte; B, actual development of a young Rockweed (*Fucus vesiculosus*).

In the nearly related Stoneworts (*Charophyceæ*) when the spore germinates it produces first a slender row of cells, the pro-embryo, which after a considerable growth produces at its apex a cluster of rudimentary leaves. Above this the structure approaches that of the mature plant. Among the Mosses we find a considerably prolonged embryonic life preceding the sexual generation. The spore upon germinating gives rise to a branching filamentous growth, known as the protonema, but in reality the young state of the moss plant. After a time leafy branches arise upon these threads (Fig. 4).

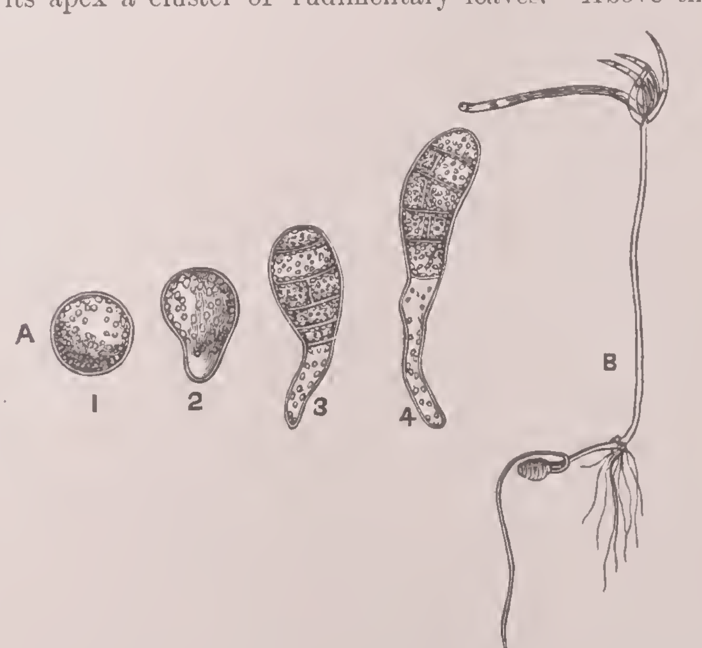

FIG. 3.—A, development of a young Red Seaweed (*Polysiphonia*) from an asexually produced cell (1); B, young Stonewort (*Chara*) developed from asexually produced cell (egg-cell).

The asexual generation develops from the fertilized egg-cell much more directly, but still there is a distinct embryonic stage, consisting of an elongated mass of growing cells (Fig. 4). This eventually develops into the stalked sporocarp with its complex structure.

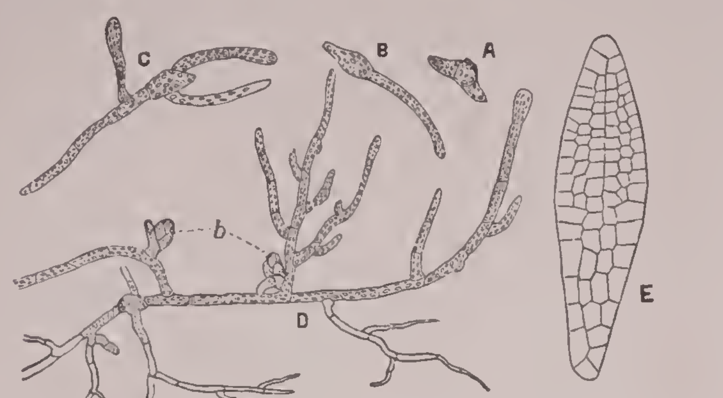

FIG. 4.—A, a spore of a moss (*Funaria hygrometrica*) beginning to germinate; B and C, germination further advanced; D, protonema with two buds (at *b*), from which leafy shoots will grow; E, embryo of asexual plant of the same moss.

In the Fernworts upon the germination of the spore a succession of embryonic stages is passed before the sexual plant attains its adult form (Fig. 5, A). The asexual plant develops quickly from the fertilized egg-cell by a series of divisions which give rise to a rounded embryo (Fig. 5, B) consisting of eight cells, from one of which develops the stem, from another the cotyledon, from still another the root, while one produces a temporary structure, the foot (an organ of suction which remains in the archegone). In the Gymnosperms the sexual generation is still a mass of tissue of considerable size, but as compared with the prothallium of ferns or the oöphore of Bryophytes it must be regarded as embryonic. It develops from the macrospore (embryo-sac) by continued subdivision, resulting in an ovoid

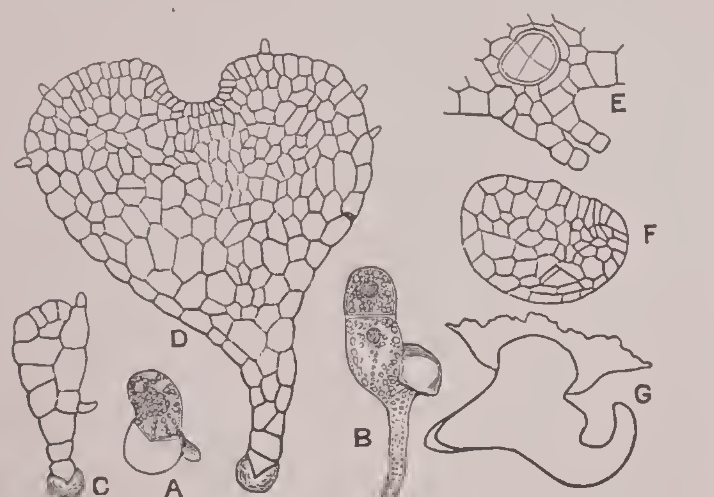

FIG. 5.—A to D, development of the sexual plant of the ferns from an asexually produced spore; E to G, development of the asexual plant from the egg-cell.

mass of parenchymatous cells (Fig. 6). The asexual generation in the Pines develops from the fertilized egg-cell (oöspore) by the subdivision of the latter, resulting in the formation of several long, tortuous filaments, the free ends of which give rise to cell-masses, one of which increases in size, becomes cylindrical, and eventually produces a whorl of leaves (the cotyledons) at one end and the primary root at the other. After the young plant is free from the seed-coats its successive nodes produce more perfectly formed leaves, while the structure of the stem becomes more complex.

In Angiosperms the sexual generation (oöphore) is still more rudimentary than in Gymnosperms, and it undergoes this interesting modification, that its development is actually delayed until after the egg-cell is fertilized, when the two generations, oöphore and sporophore, develop simultaneously. Before this the oöphore is represented by little more than the egg-cell (oösphere), but after the fertilization of the latter the macrospore (embryo-sac) develops a mass of tissue similar to that in the Gymnosperms, and which persists in some seeds, as endosperm.

The asexual generation (sporophore) develops from the fertilized egg-cell by a series of subdivisions, resulting in the production first of a row of more or less elongated cells, the so-called "suspensor." The cell at the free end of the suspensor ultimately subdivides again and again, and eventually forms a short stem, with one or two rudimentary leaves

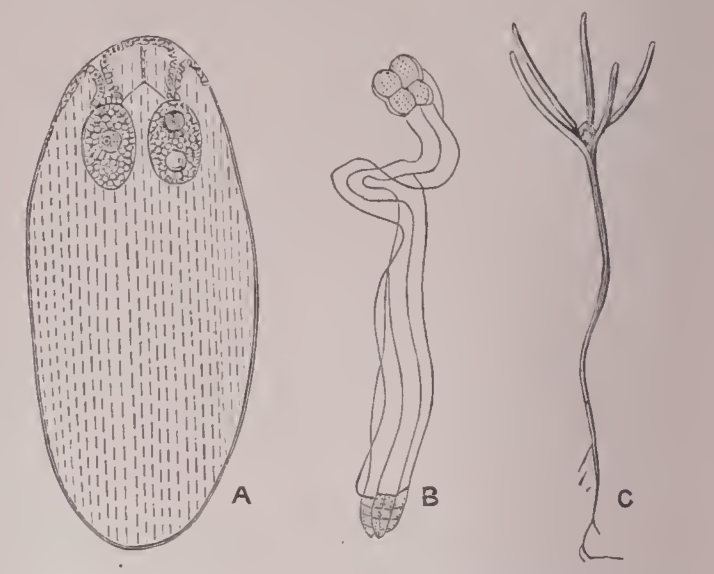

FIG. 6.—A, the sexual plant (prothallium) in the ovule of a pine, bearing the young egg-cells at its summit; B, very young stage of the asexual generation of the pine; C, the same, much later, after its escape from the seed.

(the cotyledons). The suspensor cells make no further growth, but the embryo proper may grow less or more, according to the plant under consideration. In all cases the embryo is surrounded and nourished by the endosperm (oöphore, or prothallium). Where this nourishment of the embryo is prolonged, the embryo is large, and the endosperm is correspondingly small, or it may have entirely disappeared. We have thus the technical distinction of seeds with endosperm (albuminous), and without endosperm (exalbuminous). See ENDOSPERM.

The young plant upon emerging from the seed in germination has root, stem, and leaves, but these are yet of much simpler structure than in the adult plant. This is well seen in the leaves which appear successively upon the stem, the earlier ones differing much from the later. In compound-leaved plants the earlier leaves are simple, and even the first compound leaves are smaller and simpler than those which follow.

This brief sketch of plant embryology is all that can be given here. It will serve to show that in all plants the beginning is a single cell, and that the development of the

FIG. 7.—Stages in the development of a Dicotyledon (*Orobus angustifolius*): A, fertilized egg-cell in the summit of the embryo-sac; B, egg-cell divided once; C D E, further division; F, embryo in embryo-sac; G H I K M, subsequent stages; J, young embryo of *O. aureus*; L, young embryo of pea (all highly magnified).

individual is from the simple to the complex. All plants travel a greater or less distance over what appears to be the same road; some (the higher plants) go farther, others (the lower plants) go a shorter distance.

CHARLES E. BESSEY.

Embury, Philip: the "founder of American Methodism"; b. at Ballygaran, Ireland, Sept. 21, 1729. He became a member and "local preacher" of Wesley's society at Court-Mattress in 1758. In 1760 he emigrated to New York. At the suggestion of his cousin, Barbara Heck, he began to preach there in 1766 in his own house, mostly to his own countrymen. Later he preached in an old rigging-loft, and at last (1768) erected a chapel on the site of the present "Old John Street church." Embury, who was a carpenter, worked on it himself. He built its pulpit, and on Oct. 30, 1768, preached from it the dedicatory sermon of the humble structure—the first Methodist chapel of the New World. Embury settled in Camden, Washington co., N. Y., in 1769, where also he founded his denomination, and where it grew into the prosperous Troy Conference. D. at Camden in Aug., 1775. In 1866 his remains were removed to Cambridge, N. Y., where in 1873 a monument to his memory was unveiled.

Emden: seaport-town of Hanover, Prussia; on the north shore of the Dollart, near the mouth of the Ems, about 70 miles W. N. W. of Bremen (see map of German Empire, ref. 3–D). It is intersected by several canals, which are crossed by about thirty bridges. It is well built, and contains a handsome town-hall, an exchange, a custom-house, a gymnasium, a school of navigation, and an asylum for deaf and dumb. Here are manufactures of linen fabrics, hosiery, hats, sail-cloth, starch, soap, etc. The port of Emden has shallow harbors, outer and inner, but the roadstead is deep enough for large ships. Pop. (1890) 13,695.

Emerald [O. Fr. *esmeraude* < Lat. *smaragdus* = Gr. *σμάραγδος*]: a green precious stone, really a variety of Beryl (*q. v.*), owing its exquisite color to the presence of a small amount of oxide of chromium. The crystals are six-sided prisms, usually with flat terminations. The value depends chiefly upon the depth of color; a fine gem has been sold for $12,500, coming next in price to the diamond, and often old and poorly cut stones when recut gain decidedly in beauty and value. The largest emeralds are found at Takowaja, in the Urals; one in the cabinet of the Imperial Mining School at St. Petersburg weighs 6¾ lb. troy. Most of the modern emeralds come from Muzo in the United States of Colombia, but they are also found in other localities in South America, in the Orient, and in the Henbach valley, near Salzburg. The mines at Mt. Zaborah, in Upper Egypt, where the ancients obtained many emeralds, were rediscovered in 1818 by M. Cailliand. These emeralds were used in trade with the Persians, who in turn gave lapis lazuli. Vegetable Creek, New South Wales, has yielded beautiful specimens, and in the U. S. handsome crystals of light color up to 8 inches in length, only partly transparent, have been found in Alexander co., N. C. The Romans used to polish emeralds on the six faces of the natural prism, without reshaping them, and these are known as *prime emeralds*. The gem was well known and greatly esteemed among the ancients. Oriental emerald is a green variety of sapphire, or Corundum (*q. v.*). Emerald copper is a name for diopside, a phosphate of copper, as emerald nickel is for zaratite, a hydrated carbonate of nickel. Both are beautiful minerals, but are not used as gems. George F. Kunz.

Emerald Bird of Paradise: the best known and most elegant of the birds of paradise; a native of the Aru islands, W. of New Guinea (Papua), where it is killed in great numbers for its beautiful plumage, which brings a high price in the market. It receives its systematic name, *Paradisea apoda* or the "footless" bird of paradise, from the old fable that the bird of paradise has no feet, but always flies without resting.

Emerald bird of paradise.

The skins with the plumage are used in the East for ornamenting turbans, and in Europe and America for adorning ladies' head-dress. Several thousands are annually imported into Europe, chiefly by way of Batavia. The back part of the neck is of a pale-gold color, the throat and fore part of the richest changeable golden green, the breast a deep purplish brown, the body and tail a fine chestnut. The female lacks the long floating flank plumes of the male, and is generally less highly colored and smaller than the male.

Emerald Green: See Schweinfurth Green.

Emersion [from Lat. *emer'gere*, emerge]: in astronomy, the reappearance of the sun, moon, planet, or star from behind the celestial body by which it was hidden in an eclipse or occultation. The phenomena of immersion and emersion, especially of Jupiter's first satellite, are useful in determining the longitude of places.

Emerson: town of Canada: on the boundary-line between Minnesota and Manitoba; 66 miles S. of Winnipeg; the terminus of the Emerson Branch of the Canadian Pacific Railway (see map of Canada, ref. 9–H). Pop. 1,500.

Emerson, Alfred, A. M., Ph. D.: archæologist; b. at Greencastle, Pa., Feb. 25, 1859; educated in Germany and at Johns Hopkins University. Since 1891 he has been associate Professor of Classical Archæology, Cornell University, and contributing editor of the *American Journal of Archæology*. He has published *Dissertatio de Hercule Homerico* (Munich, 1881) and several monographs.

Emerson, Ralph Waldo, LL. D.: poet and essayist; b. in Boston, Mass., May 25, 1803; fourth in the order of birth of the eight children of Rev. William Emerson and Ruth (Haskins) Emerson. He had a minister for an ancestor in every one of eight generations back, either on the paternal or maternal side. He was fitted for college at the public schools of Boston, and graduated at Harvard College in 1821. He was not among the very highest scholars of his class, but in his junior year won a Bowdoin prize for a dissertation on the *Character of Socrates*, and another in his senior year for an essay on *The Present State of Ethical Philosophy*. He also won a Boylston prize for declamation, and he was class poet. For five years after leaving college he taught school, chiefly in Boston, where he assisted his elder brother, William, in conducting a successful school for girls. In 1826 he was "approbated to preach," though his name does not appear among the graduates of the Harvard Theological School. In Mar., 1829, he was ordained as colleague to Rev. Henry Ware of the Second Unitarian church in Boston. In 1832 he resigned his pastoral charge, having announced in a sermon his unwillingness longer to administer the rite of the Lord's Supper. In Dec., 1832, he sailed for Europe, remaining absent nearly a year, and during his visit made the acquaintance of Carlyle. Two years later a correspondence sprang up between them, and continued until Carlyle's death. Soon after returning he began his career as a lecturer before the Boston Mechanics' Institute, his subject being *Water*. He gave also three other lectures—two on *Italy* and one on the *Relation of Man to the Globe*. In 1834 he gave in Boston a series of biographical lectures on Michael Angelo, Milton, Luther, George Fox, and Edmund Burke, the first two of which were published in the *North American Review*. After that time he gave many courses of lectures in Boston, and became one of the best-known lecturers throughout the U. S. It is said that he lectured for forty successive seasons before the Salem (Mass.) Lyceum. He also made repeated lecturing tours in the Western States, and even lectured in California and in Great Britain.

In 1835 Mr. Emerson took up his residence in Concord, Mass., and published in the following year a thin volume called *Nature*. It marked a new era in American thought—was received with sharp criticism from many quarters, and with corresponding enthusiasm by a small circle of admirers. It took twelve years to sell 500 copies. This was followed by several orations before literary societies on such themes as *The Method of Nature*, *Man Thinking*, and *Literary Ethics*. More important even than these was his remarkable *Address before the Senior Class at Divinity College, Cambridge*, delivered July 15, 1838. From these various addresses and publications may be dated the intellectual movement then vaguely stigmatized as *Transcendentalism*. This was a reaction against formalism and tradition, and brought together a variety of minds, some profoundly mystical, others full of projects for action. It led to some excesses and affectations, but was on the whole a valuable impulse toward many good things. The four volumes of *The Dial* contain a lasting memorial of that important seed-time of thought.

Mr. Emerson's *Essays* were collected and published in two volumes in 1841 and 1844, and his *Poems* in 1846. His miscellaneous addresses remained uncollected till 1849, in the U. S., though they had been reprinted collectively in England in 1844. Visiting the mother country in 1847, Mr. Emerson found awaiting him a large circle of admirers, whose allegiance he always retained. In 1850 he published *Representative Men*, given previously as a course of lectures in Boston. In 1852 he took part in preparing the memoirs of Margaret Fuller Ossoli. His *English Traits* appeared in 1856, *The Conduct of Life* in 1860, and *May-Day and other Poems*, and *Society and Solitude* in 1869.

Though Mr. Emerson is often assigned to the class of metaphysicians or "philosophers," yet the actual traits of his intellect clearly rank him rather among poets or literary men. All his methods were literary rather than scientific, although he won some of his warmest admirers among scientific men, as in the case of Prof. Tyndall. His statements are sometimes subtle, sometimes profound, sometimes noble and heroic, but scarcely ever systematic. He rested in his intuitions, rarely attempted even the rudiments of method, but constantly recognized, in his own words, "the opposite negations between which, as with cords, our being is swung."

In viewing Mr. Emerson simply as a literary artist, the reader must still complain of this tantalizing fragmentariness, this disregard of all the unities, this structural defect. Even in his poems his genius is like an æolian harp that now gives, now willfully withholds, its music; while some of his essays seem merely accidental collections of loose leaves from a note-book. Yet as one makes this criticism, one is shamed into silence by remembering many a passage of prose and verse so majestic in thought and rhythm, of quality so rare and utterance so delicious, as to form a permanent addition to the highest literature of the human race.

Mr. Emerson wrote in 1844 that all the books read in the U. S. were European, that "we are sent to a feudal school to learn democracy"; and demanded that his fellow-countrymen should advance out of all hearing of others' censures, out of all regrets of their own, into a new and more excellent social state. More than any previous literary man, he set the example of ignoring European traditions, methods, and literary properties wherever these could be better superseded by home products. He drew his habitual illustrations from the society and manners of the U. S., and was more ready to write of the pine woods and the humble-bee than of the nightingale and asphodel. It seems hardly credible that this should have been ridiculed by the critics as "a foolish affectation of the familiar"; but the fact of the ridicule shows the need of the innovation. If that state of things has now passed by, and if the literature of the U. S. is no longer provincial, it is to Mr. Emerson that it is most indebted.

It is well known that his position on religious questions was that of a philosophical radical, and that he became entirely detached from the church organizations of the time. He took this position, once for all, in a sentence which attracted much attention in his *Divinity Hall Address*: "The assumption that the age of inspiration is past, that the Bible is closed, the fear of degrading the character of Jesus by representing him as a man, indicate with sufficient clearness the falsehood of our theology." His precise attitude as to the conception of a Deity and the belief in personal immortality might be harder to define. He declares eloquently, however, in one of his orations, that "there is a sublime and friendly Destiny by which the human race is guided—the race never dying, the individual never spared—to results affecting masses and ages."

Though Mr. Emerson was, like Goethe, a prophet of Self-Culture, he never held himself aloof, like Goethe, from the immediate public agitations of his time, but always practically recognized the truth of his own formula, "To-day is a king in disguise." He always lent his voice in behalf of any momentous public interest. He was always frankly identified with the anti-slavery movement, and, though averse to extemporaneous speech, and ill at ease in that form of service, he often took part in the meetings of the abolitionists. In 1844 he gave an elaborate and remarkable address on the anniversary of emancipation in the British West Indies. He signed, with his wife, the call for the first National Woman's Rights Convention in 1850. He was a vice-president of the Free Religious Association, and several times addressed its conventions. He was also an overseer of Harvard University, and received from that institution the degree of doctor of laws in 1866. He was a member of the American Academy of Arts and Sciences, of the American Philosophical Society, and of the Massachusetts Historical Society.

Mr. Emerson was twice married—in 1829, to Ellen Louisa Tucker, of Concord, N. H., who died in 1831; and in 1835, to Lidian Jackson, of Plymouth. He had three children, two daughters and one son. The son, Edward Waldo, graduated at Harvard College in 1866, and afterward pursued the study of medicine. Ralph Waldo Emerson died at Concord, Apr. 27, 1882. See his authorized *Life* by J. Elliot Cabot (2 vols., 1887); also biographies by O. W. Holmes, George W. Cooke, Richard Garnett, and Alexander Ireland; Conway's *Emerson Abroad and at Home*; *The Genius and Character of Emerson*, edited by F. B. Sanborn; E. B. Emerson, *Emerson in Concord*; D. G. Haskins, *Emerson's Maternal Ancestors*; *Correspondence between Carlyle and Emerson*, edited by C. E. Norton. T. W. HIGGINSON.

Emerton, EPHRAIM: professor of history; b. Feb. 18, 1851, at Salem, Mass.; educated at the public schools, and graduated at Harvard College in 1871. He spent two years in journalism and the study of law, and was in Europe 1873–76, spending two years at the universities of Berlin and Leipzig, from the latter of which he received (1876) the degree Ph. D. In 1876 he became instructor in History at Harvard, and in 1882 received the appointment of Professor of Ecclesiastical History. He has published *Synopsis of the History of Continental Europe*; *The Study of Church History*; *Sir William Temple und die triplealliance vom jahre 1668*; *The Practical Method in Higher Historical Instruction* (in *Methods of Teaching History*, ed. by G. Stanley Hall, 2d ed. 1885); *An Introduction to the Study of Mediæval History* (1888–93).

Emery [from Fr. *émeri* < O. Fr. *esmeril* < Lat. **smiri'lis*, from Gr. σμῖρις, σμῆρις, a polishing powder]: one of the hardest minerals known, ranking next to the diamond in its power of cutting or abrading hard substances. It is a variety of the species corundum or sapphire, of a dark reddish-brown, black, or gray color, and consists of nearly pure alumina and oxide of iron. Sapphire contains $97\frac{1}{2}$ per cent. of alumina, and corundum about 92 per cent. The percentage in emery ranges from 60 to 78, with 25 to 35 per cent. of oxide of iron, and a few per cent. of silica and of water. Emery is found in large masses, and much resembles fine-grained iron ore, for which it has often been mistaken. It is obtained chiefly from Asia Minor and the island of Naxos in the Grecian Archipelago. The chief supply of foreign emery in the U. S. comes from Turkey, about 70 miles from the port of Smyrna, where it costs about $22 per ton. It has also been found at Chester, Mass., where it was at one time mined. A better quality of stone, properly called corundum, but serving the same economic purposes as emery, has been found in Georgia and the Carolinas, and an important industry has sprung up in Rabun co., Ga., and Macon co., N. C. The production in 1890 was 1,970 tons, valued at $89,395. In the same year imports of crude rock amounted to 3,867 tons, valued at $97,939, and crushed rock to 534,968 pounds, valued at $20,382.

Emery is scarcely inferior to the sapphire or ruby in hardness, and it will not only cut the hardest steel or chilled castings, but will wear away quartz, agate, topaz, and other gems, being for the last-named purpose the chief reliance of the lapidary. It was used by the ancients for cutting gems. Dioscorides mentions it under the name of *smyris* as the stone with which engraved gems are polished; and there is even a rabbinical tradition which indicates that the "smyris" was used for gem-engraving in the time of Moses. How far it was known and used in prehistoric times must be left to conjecture, but the many neatly cut and polished stone implements and ornaments indicate the use of a material not less hard than emery. Theophrastus mentions whetstones made of the mineral used to engrave gems, and mentions Armenia as furnishing the best kind. Naxian whetstones are also mentioned by ancient authors, and Pliny speaks of polishing marble statues and *filing down* gems. The backs of antique intagli have deep furrows upon them, indicating that they were *filed* into shape by rubbing with an emery-stone. It is thus probable that the massive emery was extensively used as a tool, and that it was employed for the sculpture of hard rocks, not only by the Romans, but by the ancient Egyptians.

It is now used in the arts in a pulverized form, being obtained in grains or in powders of various degrees of fineness by crushing and sifting or by elutriation. The lumps, as they come from the mine, are broken in a breaker or under stamps, and the fragments are sifted through sieves or wire-cloth having from sixty to ninety wires to the inch, by which the grades of the emery are determined. Thus a sieve of sixty wires to the inch gives a No. 60 grade. The numbers range as high as 120, or "flour emery." These higher numbers are obtained by washing, or by collecting the fine dust which floats in the air of the crushing-rooms and settles on the beams and shelves.

There is considerable difference in the effective abrasive power of commercial emery from different localities. It varies according to the composition, the state of aggregation, and the purity. The better qualities of crystalline corundum are believed to be superior to emery in abrasive powers, and powdered sapphire to be superior to corundum, although the experiments which are cited in support of this view are by no means as complete and conclusive as they should be.

The methods of application are various. Lapidaries sprinkle it with water or oil on their lead-wheels. Mixed with glue or other adhesive substances, it is spread in a thin layer upon wood, leather, paper, or cloth, or it is molded into solid blocks or wheels. It is in the latter form, known as "solid emery-wheels," that the mineral has the widest application and its greatest utility.

Emery-wheels.—Solid wheels, consisting of a mixture of powdered emery with shellac, or other substances of similar character, fused and rolled upon a stick, appear to have originated with the lapidaries of India. Small wheels of a few inches only in diameter have been in common use for many years, especially by dentists for shaping hard porcelain teeth, but they are now made by improved methods from 1 to 36 inches in diameter, and from ¼ of an inch to 4 inches in thickness. When carefully mounted upon a mandrel and run at a high speed, the abrading power of such wheels is wonderful. They will instantly take the teeth off the hardest file and reduce it to a plane, smooth surface, or will cut away parts of chilled castings that a file will not touch. Such wheels are shaping-tools of the first order, as far exceeding files in efficacy as the emery exceeds steel in hardness, and as the velocity of a wheel exceeds the velocity of a file upon the work. A file in the hands of an expert workman moves, say, 60 feet in a minute, but the proper velocity of an emery-wheel at its cutting surface is 5,500 feet in a minute. Corundum is also used for wheels.

The rapidity of abrasion depends not only on the velocity of movement, but upon the size of the grains of emery. For very heavy work, such as taking the rough edges off castings, very coarse emery is used, while the finer sorts are made into wheels for fine grinding and surface-work on brass or steel. The following table shows approximately the cuts of emery as compared with files. The numbers represent the standard grades of emery:

8–10	represents	the cut	of a	wood rasp.
16–20	"	"	"	rough file.
24–30	"	"	"	middle-cut file.
36–40	"	"	"	bastard file.
46–60	"	"	"	second-cut file.
70–80	"	"	"	smooth file.
90–100	"	"	"	superfine file.
120-flour emery		"	"	dead-smooth file.

In using emery-wheels care must be taken to maintain the proper speed, and not to press the work too strongly against the surface. If too much pressure is used, the wheels will not cut so fast, and are liable to wear away unequally and to get out of true. A rest should always be used to support the work and prevent it from vibrating upon the wheel. The bearings should be kept in good order and well lubricated.

Good emery-wheels are uniform in texture. The material with which the emery is combined must have great cohesive strength to resist the tendency of the wheels to fly asunder when revolving at high speed, and to retain the grains of emery firmly, and yet wear away evenly, leaving the cutting angles exposed, and not glaze or "gum up." It must not soften or melt under the heat generated by the friction in cutting the work, and must be free from noxious qualities. As such wheels are run at high velocities, they require to be very carefully and exactly hung, and to be kept perfectly true, so as to prevent vibrations. They should not "wedge" upon the mandrel, or even fit it closely, for expansion by heat might burst the wheel, and the flanges at the side should not be too strongly screwed up. A wheel 36 inches in diameter may have 600 revolutions per minute, and one of 12 inches 1,800 revolutions. Although the emery is extremely hard, diamonds will cut the wheels, and this gem in its crude or rough form is used as a tool to turn them true or to cut their faces into desired form. See CORUNDUM.

Emery, STEPHEN A.: See the Appendix.

Emetic [from Gr. ἐμετικός, causing vomiting, deriv. of ἐμέειν, vomit]: a medicine capable of causing the stomach to contract and discharge its contents through the œsophagus. Emetics are of two classes: (1) those which directly irritate the stomach and produce emesis, and (2) those which act on the nerve-centers with like result. Of the former, mustard and alum are examples; of the latter, ipecac and tartar emetic. Emetics are useful to remove irritating food or poisons from the stomach, to cause dislodgement of foreign bodies or croupous membrane from the air-passages, and as a revulsant. The mechanical emetics are always safer than those acting on the nervous system.

WILLIAM PEPPER.

Emeu: See EMU.

Emigration [from Lat. *emigra'tio*, deriv. of *emigra're*, *e*, out + *migra're*, migrate]: the transference of permanent abode from one country to another. Removal into a country is specifically designated as *immigration*; it of course presupposes emigration. See CRUSADES, EXODUS, and MIGRATION.

Whatever view is taken of the origin of mankind, it is evident that the earth must have been almost wholly peopled by numerous emigrations. The story of the wanderings of tribes and races constitutes the chief part of the traditions of the nations of antiquity. A complete record of emigration would amount to a synopsis of the early history of almost every considerable nation of ancient and modern times. The movements of the Aryan and Semitic races took place on a large scale, leaving everywhere their traces in languages, customs, and religions. Among the first of recorded emigrations, though of doubtful date, was that led by the Hyksos or Shepherd Kings, proceeding from Arabia or Phœnicia, and gradually overrunning Egypt, then a seat of civilization. In the book of Exodus there is an account of the emigration of the children of Israel, given with great fullness of detail. One of the earliest of the long series of incursions of the uncivilized tribes of Asia was the great invasion of Cimmerians and Scythians (650 B. C.), which even threatened Egypt, but was turned back by Cyaxares, the founder of the kingdom of the Medes.

The Greeks, boasting their own origin from the sacred soil of Hellas, were pre-eminent among the ancients for encouraging systematic emigration. They planted their colonies far and wide along the Central Sea, and founded great cities not only throughout the Grecian Archipelago, but in Sicily, Italy, and Asia Minor, and even on Gallic shores, on the Iberian Peninsula, and on the African coast. The Romans, accepting mythical traditions as eagerly as the Greeks, found their own origin in an emigration from ruined Troy. But the policy of Rome, unlike that of Greece, fostered no rival colonies, and the emigrations which marked the rise of her power were principally the flight or transportation into slavery of the inhabitants of cities and provinces that yielded to her sway. The forced emigration of the slaves and captives of conquests reaches vast proportions in ancient annals. It was, however, after the empire of Rome had reached its culmination that the great movement of barbarian nations began, which is without parallel in the history of emigrations. A brief sketch of this movement, which continued through several centuries, can merely give prominent dates and names. The multitudes of those barbarian hosts can not be estimated; they have furnished the poet with his most appropriate comparison for the countless legions which issued from the nether abyss at Satan's command.

The southward emigration of the Goths from Gothland, or Northern Sweden, began A. D. 200; their first pressure in the empire was felt on the N. of the Euxine, and they soon crossed the Danube. By the middle of the century they had overwhelmed Greece. Meanwhile the Franks and Alemanni moved down in vast hordes from Western Europe, the former crossing the Rhine and the latter pouring through the Rhætian Alps. These incursions were checked by the victories of Claudian, Aurelian, and Probus (270–282), but the Goths established themselves during the following century on the borders of the Euxine, and spread through Thrace toward Italy. Between 376 and 410 was the climax of the movement of Northern races. The Huns, a nation of Tartar origin, coming down from the Ural Mountains and the table-lands of Siberia under Balamir, established an empire at the expense of the Goths, whom they drove out of the countries N. of the Danube; the latter, soon afterward marshaled under Alaric, after ravaging Greece, descended upon Rome, effecting its capture A. D. 410. During the same period the Vandals from between the Elbe and the Vistula, with the Sueves and Burgundians of kindred origin, and the Alans from the Caucasus, swept through Italy, and, thence withdrawing, through Southern France into Spain; the Burgundians alone stopping in the valleys of the Vosges, the rest, pressed by the Goths who followed them, finally reaching Andalusia. In 429 Moorish tribes from the base of Mt. Atlas were ravaging Northern Africa; in 439 the Vandals and Alans from Spain, under Genseric, following in the path of the Moors, extended the kingdom of the Vandals over the southern shore of the Mediterranean, and then crossing into Italy, captured and sacked Rome in 455. During the rise of the Vandal kingdom the Huns under Attila (435–450) swept down on the western provinces, and made an irruption into Gaul, but being defeated at Châlons in 451 they afterward withdrew to the E. of the Carpathian range. After Attila's death (453) the bulk of the remaining Huns retired to the shores of the Volga. During the same period the Saxons from between the Baltic and the Elbe, with the Angles to the N. of them, and the Jutes of Jutland, became dissatisfied with their homes, and in 449 descended on the coasts of Great Britain, establishing themselves on the island.

Before the year 470 the Slavi had overrun what are now Prussia, Poland, and Russia; about the middle of the sixth century this Slavic territory—and in fact the whole region from Franconia to the Caucasus, from Moscow to the Danube—was taken possession of by the Avars, a Tartar tribe. They unsuccessfully besieged Constantinople. Thenceforward, and indeed until the thirteenth century, the Byzantine empire was a bulwark against the Asiatic races, and prevented their penetrating Europe except by paths N. of the Euxine or S. of the Mediterranean. Starting from Arabian deserts in 632, the tide of Saracenic invasion rolled over the Levant and Northern Africa, entering Spain in 711, and was checked on the Loire by Charles Martel in 732. The Saracens spread from the Indus to the Atlantic, from the Pyrenees to the African desert, from the Caspian to the Red Sea. They invaded Sicily in 826, and held that island 265 years. The date of their conquest of India is 1004. Within the century when Europe was saved from the sword of the Saracen by the valor of Charles Martel, the victories of Charlemagne and his lieutenants (791–798) dislodged the Avars, and they withdrew to the eastward The Bulgarians, partly of Tartar extraction, entered on a portion of the deserted territory. The Magyars, a Finnish tribe from the Ural, about the year 855 united with the vanquished Avars, and spread in camps of 1,000,000 men over the Dacian plain. A century later Otho defeated their descendants, and they afterward settled on the Danube.

The Danish vikings in 852 effected a permanent settlement in Russia, but not till 980 did they become affiliated with the native Russians and Sarmatians. The incursions of Danes on the British coasts began early in the ninth century; in 1016 Canute's kingdom included Denmark, Norway, and England. The Danish and Norwegian vikings that were afterward called Normans ravaged the French coasts during this period, and settled in great numbers in Normandy in 912; they effected the conquest of England in 1066, and by 1072 had overrun Sicily and Southern Italy.

From the ninth to the eleventh century the Tartars ravaged China. In 1050 the Uzzi and Cumani, of Tartar extraction, overran all Southern Russia; they kept possession for 170 years. From 1216 to 1250 the Mongols under Genghis Khan, starting from the frontiers of China, created an empire, at a cost of 14,000,000 men slain by the sword, that extended from the Pacific to the Adriatic and the Baltic, overrunning all Southern Asia and Eastern Europe. The Mongols were probably allied to the Huns. After their victory on the Kalka in 1224, they held Russia subject for two and a half centuries. In the latter half of the thirteenth century, after the withdrawal of the Mongols from Hungary, its king invited immigration, and obtained many Italian, Flemish, and Saxon settlers. The empire of Tamerlane (1363–1405) again spread the Mongolian power over all Southern Asia; the conquest of Hindustan was effected in 1399, and Delhi afterward became the capital of the Great Mogul.

The crusades (1095, 1147, 1189, 1202, 1217, 1227, 1248, 1270), though involving great emigrations, created no permanent states.

The Ottomans had partially established themselves in Europe in 1356; by 1460 they had overrun Turkey. In 1550 the Turkish power was at its zenith, reaching from the Tigris to the Carpathian chain, from the snows of the Caucasus to the deserts of Abyssinia. The expulsion of the Mohammedans from Western Europe was an affair of centuries. They were driven out of Sicily in 1091; Valencia, 1238; Portugal, 1252; Granada, 1492.

From 1552 to 1577 the Russians pushed their conquests over the Mongolian races through two continents, and, crossing the Pacific to a third, effected settlements in North America, which in 1794 were estimated as containing 50,000 souls. The measures which culminated in the Revocation of the Edict of Nantes (1685) caused the Huguenot emigration from France, which numbered from 250,000 to 300,000 souls; Sismondi assigns even a higher figure. In 1739 India was subjected to a terrible invasion by the Persians; in 1765 the British conquest followed, and after it came a steady flow of Englishmen. The French emigration consequent on the revolution of 1790 consisted of noble families, and was exceptional in this characteristic. The czars, beginning with Peter the Great, have made notable and successful efforts in inducing foreigners to form colonies within their domain; and the last important movement of emigration within Europe was after Napoleon's wars, when Russia, by liberal offers, obtained 250,000 settlers, principally from her Western neighbors. In the Franco-German war (1870) 102,000 Germans were expelled from France, and after the war there was a large movement of the French population from Alsace and Lorraine, and subsequently an emigration thither from Germany.

There are evidences of extensive movements among the native populations of America before the advent of Columbus. The Esquimaux—or, as they call themselves, the Inuit—inhabiting the northern and northwestern coasts of America, are of a race found at the N. in the eastern hemisphere. The North American tribes of the interior were nomadic, but have left few definite records of their wanderings; the mound-builders spread all over the valley of the Mississippi and its tributaries, but did not reach the Atlantic coast, and the dates of their progress and extinction are alike unknown. The Shawanese within historic times moved down from the Northern Alleghanies along their western slope, and penetrated nearly to the Gulf of Mexico. There are records of many of the great movements of the races in the southern portion of North America. Torquemada, among earlier, and Clavigero, among later historians, have shown that the Toltecs, who during 104 years were advancing into Mexico from a region to the N. W. of it, founded the kingdom of Toltecan in the latter part of the sixth century. A famine nearly destroyed this nation in 1052; it was replaced in the next century by the less-civilized Chichimecas, and in the century following by other races from the N. and N. W., including the Aztecs or Mexicans from California. During the supremacy of the Toltecs in Mexico their fifth king invaded Guatemala, and there established a dynasty of Toltec sovereigns, of whom the eighteenth was reigning when the Spaniards arrived. In South America the Toupis emigrated from the northern borders of the Amazon, spread to the Caribbean Sea and most of its islands, and advanced southerly along the Atlantic coast to S. lat. 32°, penetrating inland to the headwaters of the Rio de la Plata; through all this vast region one native language was spoken. The origin of the race that entered Peru and built the monuments around Lake Titicaca is unknown.

With the progress of civilization the large movements of population *en masse* have been lessened, but the aggregate movement of individuals greatly increased. Large numbers of Europeans, in particular, have moved to other parts of the world, either in organized bodies to found states of their own—colonization—or to become citizens of states already established—immigration. Of the aggregate amount of such colonization or immigration it is hard to obtain full statistics. For the U. S. the facts are more accessible, and will be presented, together with the discussion of the social problems to which they give rise, under the heading IMMIGRATION (*q. v.*). See also COLONY and LIBERIA.

Revised by A. T. HADLEY.

Émigrés [Fr., emigrants]: in a special sense, those who fled from France during the Revolution. The movement began a few days after the storming of the Bastile, July 14, 1789, when the Prince of Condé and many of the nobles, alarmed at the course events were taking, emigrated to the Netherlands and Germany; it was renewed on a larger scale in October of that year, after the violence of the mob had caused the removal of the royal family from Versailles to Paris and made them virtual prisoners at the Tuileries; and when the constitution of 1791 was adopted, with its subversion of the ecclesiastical system and destruction of the privileges of the nobility, the number of fugitives greatly increased. The effect of this course upon the Revolution was very important. It deprived France of a conservative element at a time when such an element was most needed; it exposed the king's party at home to the suspicion of plotting with their absent friends; and, above all, by the intrigues of the *émigrés* with the powers hostile to the Revolution for the restoration of the old *régime* the mob was driven to its worst excesses. Their headquarters were at Coblentz, where, through their efforts, an army of 80,000 men was collected under the Duke of Brunswick. It was with the design of joining the forces of the *émigrés* that the king made his foolish and disastrous attempt at flight on the night of June 20, 1791. Under the Prince of Condé they followed the Prussian army into Champagne, with the result of bringing upon them the charge of high treason by the French Government, which passed against them and their sympathizers a series of most stringent laws, confiscating their lands, proclaiming the death penalty upon all who should communicate with or aid them, and placing 30,000 names on the list of perpetual exiles. After the failure to land at Quiberon in 1795, they gave up the hope of entering France by force, and many sought permission from the Directory to return. Under the general amnesty granted by the First Consul they returned in great numbers; but, though treated with honor, they could not by the terms of the charter of 1814 regain either their estates or their privileges. Yet during the reactionary reigns of Louis XVIII. and Charles X. the Ultras persistently agitated for their reinstatement and indemnification, and Villèle's ministry in 1825 brought about the granting of an annual compensation of 30,000,000 fr. for the loss of their estates; but the July revolution caused the withdrawal of the grant. F. M. COLBY.

Emil'ia [Lat. *Æmilia*, called after the celebrated Via Æmilia of the Romans, a continuation of the Via Flaminia forming the great highway through Northern Italy]: the ancient name of that part of Northern Italy which contains the former duchies of Parma and Modena and the papal delegations of the Romagna. The name was revived in 1859, and applied to a province of modern Italy lying S. of the Po, N. of the Appenines, E. of Piedmont, and comprising the eight compartments of Bologna, Ferrara, Forli, Modena, Parma, Piacenza, Ravenna, and Reggio Emilia. Area, 7,921 sq. miles. Pop (1890) 2,253,104.

Eminence: town (founded in 1849); Henry co., Ky. (for location of county, see map of Kentucky, ref. 2–G); on L. and N. Railroad; 40 miles E. by N. of Louisville. It has 4 churches, 2 colleges, a large flouring-mill, a harness-factory, a tobacco-factory, and a large distillery. The principal business is farming and stock-raising. The location is healthful, surrounded by a beautiful blue-grass region. There is a valuble mineral spring in the vicinity. Pop. (1880) 1,043; (1890) 1,002; (1900) 1,018.

EDITOR OF "CONSTITUTIONALIST."

Eminent Domain: the inherent sovereign power retained by the people or government over the estates or private property of individuals to resume or appropriate the same for public uses, and for public uses only. The difference between the power of taxation and the right of eminent domain should be carefully noted. Taxation proceeds upon the notion of contribution; it falls upon a class of persons, and is apportioned among them by rule. In the exercise of the right of eminent domain the state takes from an individual his property without reference to a burden imposed upon any other person. The right can be exercised in the U. S. either by a State or by the Federal Government. The power to decide whether the property should be taken for any public use rests with the Legislature, and its discretion is not reviewable by the courts, though it is conceived that the judicial power has the right to determine whether the use itself is public rather than private. Were this not so, the Legislature might, under pretense of taking property for public uses, transfer one man's property to another.

It is not necessary, however, that the exercise of the power should benefit the entire public. It is enough if it promotes the industrial capacity or resources of a considerable number of inhabitants, or in any manner indirectly contributes to the general welfare. It is not necessary that the State should act directly. The power may be delegated to a municipal body or to a private corporation. A State may delegate it to the U. S. The mode of excising it is regulated by constitutional provisions and by statutes. In some cases only an easement in land is acquired; at other times the entire fee is appropriated. The constitutional prohibition (U. S. Constitution, Amendments, Art. V.) against taking private property for public use without just compensation is a limitation on the power of the Federal Government, and not on that of the States. There are similar provisions in the State constitutions, binding the State legislatures. The compensation includes not only the property actually taken, but consequential damages to adjoining property. This has been carried so far in England that the House of Lords has held that a riparian owner on the banks of a navigable stream (the Thames) is entitled to compensation for the act of cutting off his approach to the river. The ground taken was that the right of access to a tide-water stream is a legal right, which would justify an action by the owner against one who interfered with it, unless Parliament had sanctioned the interference. (*Case of the Duke of Buccleuch*, *Law Reports*, 5, *House of Lords Cases*, 478, A. D. 1872.) Still, if *no* property is taken, a claim can not be made for consequential damages. The same right to compensation as is secured in the U. S. by constitutional provisions is recognized generally among civilized nations, and may be considered as a general rule in jurisprudence.

T. W. DWIGHT.

Emin' Pasha': assumed name of Eduard Schnitzer, an African explorer; b. in Oppeln, Prussian Silesia, in 1840. He was educated in the gymnasium at Neisse and the universities of Breslau and Berlin; graduated in 1864 as M. D.; went to Turkey in the same year and obtained a position on the staff of Hakki Pasha, whom he accompanied on a series of official journeys through Armenia, Syria, and Arabia. Hakki died in 1873, and Emin remained in Constantinople until 1875, when he returned to Germany. In 1876 he entered the service of the Khedive of Egypt as Dr. Emin Effendi, adopting the name Emin to avoid the Mohammedan prejudice against Europeans. He followed Gen. Gordon to the Sudan and in 1878 was appointed by him governor of the Equatorial province with the title of bey, and the Khedive made him pasha in 1887. In the catastrophes that followed the Mahdist rebellion he was left isolated, but still in control of his province. Here he remained until 1889, spending the time from 1881–85 at Lado, on the Bahr-el-Jebel, in lat. 5° N., and 1885–88 at Wadelai, 150 miles farther up the river. Meantime the fate of this oasis of civilization in the center of Africa attracted the attention of the civilized world, and Stanley's expedition for his relief was organized. Stanley met Emin on the Albert Nyanza on Apr. 29, 1888. After some delay and many vicissitudes in Emin's province they both made their way to Zanzibar, where, however, Emin met with an accident which prevented his return to Europe. On his recovery he entered the German service, and started from Bagamoyo, Apr. 26, 1890, at the head of an expedition 1,000 strong, to govern German territory between Tanganyika and Victoria. After establishing Bukoba on the west coast of Lake Victoria, he surveyed Lake Albert Edward, and vainly endeavored to penetrate the regions to the N. W. of Lake Albert. An outbreak of smallpox having compelled him to send most of his followers to Bukoba, he set out, on Mar. 9, 1892, without authority from his Government, for the Congo in the company of a band of Arabs, but was murdered by their leader, Oct. 23, 1892, when within a few days' march of the river. Emin's work as a naturalist and linguist placed him in the front rank of African explorers. His last expedition is described in *Mit Emin Pascha ins Herz von Afrika* (1894), by his companion, Dr. Franz Stuhlmann.

M. W. HARRINGTON.

Em'maus [Heb. *Hhammath*, hot spring]: a village in Palestine; about 7½ miles from Jerusalem; associated with one of the appearances of Christ on the day of his resurrection (Luke xxiv. 13). It was destroyed by an earthquake in 131 A. D., and when rebuilt in the third century was called Nicopolis. It is now only a small village, the modern Amwas.

Emmensite: See EXPLOSIVES (*The Picrates*).

Emmenthal Cheeses: See CHEESE.

Emmerich, em'mer-ich (anc. *Embrica*): town of Prussia; on the right bank of the Rhine; about 50 miles N. N. W. of Düsseldorf and 20 miles S. E. of Arnheim, with both of which it is connected by a railway (see map of German Empire, ref. 4–C). It has a custom-house, gymnasium, and several churches, also manufactures of iron, glass, woolen cloth, linens, hosiery, etc., and an active trade in wine. Pop. (1890) 9,622.

Emmet, ROBERT: patriot and orator; b. in Cork, Ireland, in 1778; son of a physician, and for a time a student in Trinity College, Dublin. He was a leader of the United Irishmen, who desired to liberate their country from British domination, and visited France in 1802 in behalf of the cause. Having secretly collected arms and powder in Dublin and formed a conspiracy, he and his friends revolted in July, 1803. The insurgents killed the chief justice, Lord Kilwarden, but were soon dispersed by a party of soldiers. Emmet fled to the Wicklow Mountains, but having returned to visit the daughter of John Philpot Curran, the orator, was arrested and tried for treason. He pleaded his own cause in a long and very eloquent speech, which has been preserved, but he was convicted and executed Sept. 20, 1803. His fate and his affection for Miss Curran are the subjects of two of Moore's *Irish Melodies*. See Madden, *Lives of the United Irishmen* (3d series, vol. iii. 1846).

Emmet, THOMAS ADDIS, LL. D.: lawyer; a brother of Robert Emmet; b. in Cork in 1764. He graduated at Trinity College, Dublin, and was admitted to the Dublin bar in 1791, soon attaining distinction, but was a leader of the United Irishmen, and as such was arrested in 1798, and confined in prison for nearly three years. His sentence was commuted into exile, and he emigrated in 1804 to New York city, where he practiced law with distinction. He was elected attorney-general of the State of New York in 1812. He was an eloquent advocate, and had great qualities as an orator. Some sketches of Irish history by Mr. Emmet are included in McNevin's *Pieces of Irish History* (New York, 1807). D. in New York, Nov. 14, 1827.

Emmetsburg: city (founded in 1868); capital of Palo Alto co., Ia. (for location, see map of Iowa, ref. 2–E); on the Des Moines river, and the Chi., Milwaukee and St. Paul and Burlington, Ced. Rap. and N. R. Rs.; 55 miles N. N. W. of Fort Dodge and 25 miles W. of Algona. It has 3 churches (5 church societies), 3 public-school buildings, a large packing-house, flouring-mill, water-works, etc., and is the center of a dairying and stock-raising district. Pop. (1890) 1,584; (1900) 2,361. EDITOR OF "REPORTER."

Emmitsburg: village; on railway; Frederick co., Md. (for location of county, see map of Maryland, ref. 2–D); 8 miles N. of Mechanicstown, 1 mile from Mason and Dixon's line, and 10 miles from Gettysburg, Pa. It was laid out by William Emmitt, its founder, about the year 1773. The original settlers were Scotch and Irish. Mt. St. Mary's College was established near it in 1809 by Rev. John Dubois, Bishop of New York; it is a Roman Catholic institution, one of the largest in the U. S. St. Joseph's Academy, about half a mile from town, was established in 1810, by Mrs. Eliza Ann Seton, of New York. It is the mother-house of the Sisters of Charity in the U. S., numbers 2,000 members, and has one of the largest educational buildings in Maryland. Pop. (1880) 847; (1890) 844; (1900) 849.

Emmius, UBBO: historian; b. at Greith, in the province of Ost-Friesland, Holland, Dec. 5, 1547. He studied at Emden, Bremen, Norden, and Rostock, but returned to his native town in 1570. In 1574 he set out on a new trip through the Rhine countries down to Geneva, where he was converted by Beza to Protestantism. Having returned through France, he was in 1579 made rector of the school of Norden, but refused in 1587 to subscribe the Confession of Augsburg, and was consequently expelled by the Lutherans. In 1594 he was made director of the college of Liers, and in a few years he made it one of the most celebrated educational institutions in Holland. Among his works are *Opus Chronologicum novum* (Groningen, 1619), an attempt at a chronological arrangement of history from creation; *Vetus Græcia illustrata* (Leyden, 1626), several times reprinted; *De origine et antiquitate Frisiorum* (Groningen, 1603); *Rerum Frisicarum Historia* (Franeker, 1596), a work which encountered considerable opposition on account of its invectives against the Roman Catholic Church. D. at Groningen, Dec. 9, 1626.

Emmons, NATHANAEL, D. D.: theologian; b. at East Haddam, Conn., Apr. 20, 1745; graduated at Yale College in 1767. He was ordained pastor of the Congregational church in Franklin, Mass., in 1773, and was its pastor until his death, and its sole pastor for fifty-four years. In addition, he trained fifty-seven young men for the ministry, many of whom became eminent. He was also a prominent advocate of foreign missions and of the anti-slavery cause. His theological views were nearly those of his friend Dr. Samuel Hopkins. The distinctive tenets of his system are: "Holiness and sin consist in free, voluntary exercises. Men act freely under the divine agency. The least transgression of the divine law deserves eternal punishment. Right and wrong are founded in the nature of things. God exercises mere grace in pardoning or justifying penitent believers through the atonement of Christ, and mere goodness in rewarding them for their good works. Notwithstanding the total depravity of sinners, God has a right to require them to turn from sin to holiness." His sermons were distinguished by logical thought and by dignity and power of style. D. in Franklin, Mass., Sept. 23, 1840. His works (sermons, essays, etc.), published at different times during his life, were after his death published (Boston, 1842) in seven and afterward (Andover, 1861) in six volumes, with memoirs of his life by J. Ide, D. D., in the first edition, and a full biography by Prof. E. A. Park in the second.

Emory, JOHN, D. D.: bishop of the Methodist Episcopal Church; b. in Queen Anne co., Md., Apr. 11, 1789; graduated at Washington College, Md., 1804; was admitted to the bar, 1808, but became a Methodist preacher in 1810; preached for many years through the Middle States; and was sent as delegate of his denomination, in 1820, to the British Wesleyan conference. He was elected in 1824 assistant book agent at New York, agent in 1828, and bishop in 1832. In 1817 he had a pamphlet controversy with Bishop White, of Philadelphia. He was author of *The Divinity of Christ Vindicated*, *Defense of Our Fathers*, and other publications, which show much logical ability and a pure and vigorous style. D. at Reisterstown, Md., Dec. 16, 1835. See his *Life* by his son Robert (New York, 1840).

Emory, WILLIAM HEMSLEY: U. S. army officer; cousin of John Emory; b. in Queen Anne co., Md., Sept. 9, 1811; graduated at West Point in 1831, and was appointed lieutenant of artillery; served chiefly at seaports in the Eastern States, and in the Creek nation 1831–38; appointed first lieutenant topographical engineers 1838; on staff of Gen. Kearny in California and during the Mexican war; astronomer of boundary between California and Mexico 1848–53; and commissioner and astronomer 1854–57 (brevet lieutenant-colonel); resigned in 1861, and was reappointed; appointed brigadier-general of volunteers in 1862; commanded a division under Gen. Banks in Louisiana 1863, and a corps in 1864; in 1864 fought with distinction at Pleasant Hill, Opequan Creek, and at Cedar Creek (brevet major-general); in command of department of West Virginia 1865–66, of Washington 1869–71, and of the Gulf 1871–75; retired as brigadier-general 1876. D. Dec. 1, 1887.

Emory College: an institution of learning located in Oxford, Ga.; 41 miles E. of Atlanta and a mile from the Georgia Railway. The college was chartered in 1837, and was opened in 1838 under the presidency of the Rev. Ignatius A. Few, D. D., LL. D. The college curriculum is full in all the departments taught in first-class institutions in the U. S. There are 14 members in the faculty, and the enrollment for 1899–1900 numbered 289 students. The college is well supplied with buildings for recitation and other uses. It has an endowment of $225,000, much of it being the gift of Mr. George I. Seney, president of the Metropolitan Bank, New York. Its president is C. E. Dowman, A. M., D. D. The institution is under the patronage of the Methodist Episcopal Church South, but it has gathered students from all Protestant denominations.

Emotional Expression: See the Appendix.

Emotions: See IDEAL FEELINGS.

Emped'ocles (in Gr. Ἐμπεδοκλῆς): Greek philosopher; b. at Agrigentum in Sicily; lived about 450 B. C. He acquired great fame and influence by his talents and varied attainments in science. It is said that his fellow-citizens offered him the crown, but he declined it, and used his influence to found a republic in his native state. He was regarded as a public benefactor, a great poet, and a great prophet. He maintained the theory that the world is developed from or compounded of four primary elements, fire, air, earth, and water, and that there are two forces, love and hate (attraction and repulsion). He wrote, besides other works, a poem on *Nature*, of which numerous and important fragments are extant which show a truly poetical vein. It appears that he accepted the doctrine that the souls of some men, at least, are destined to migrate through animal or vegetable bodies in order to purify them. The story that he threw himself into the crater of Mt. Etna to immortalize his name seems to be mere fable. He was admired by Aristotle and Lucretius, the latter of whom eulogizes him in his poem *De Rerum Naturâ*. The fragments of Empedocles have been edited by Stein (1852) and others. See Ritter, *History of Philosophy*; Zeller, *Philosophie der Griechen* (vol. i.); Zeller, *Pre-Socratic Philosophy* (vol. ii.); Mullach, *Fragmenta Philosophiæ Græcæ*; Gladisch, *Empedocles und die Ägypter* (1858.) Revised by B. L. GILDERSLEEVE.

Emperor [from Lat. *impera'tor*, commander, deriv. of *impera're*, command]: a sovereign who rules over an empire. The title *imperator* was conferred by the ancient Romans on their consuls in their military capacity, after this authority had been confirmed to them by the *comitia curiata.* The signification of imperator depended on that of *imperium*, which was the name given to the supreme power of the senate and people of Rome over the city and subject provinces. An officer clothed with authority by law exercised this imperium within the limits and time of his command. After any great victory the soldiers were accustomed to salute their commander as imperator as a compliment, though, as exercising the imperium attached to his command, he was already such in fact. He might be a consul or a proconsul, and the imperium was as necessary for a governor of a province as for a general who merely commanded an army. Under the republic there might be many *imperatores* at one time. On the subversion of the republic the title was conferred on Augustus for life. The authority of the Roman emperors was acquired by the combination of the chief offices of the former republic in a single person, besides which some extraordinary powers were granted or usurped. Thus Octavius held the title of imperator and the office of consul by successive elections. He was made tribune, which gave inviolability to his person, and pontifex maximus and censor, which gave him control of religion and morals. He was also invested with perpetual proconsular authority, which gave him supreme control in all the provinces, and declared chief (*princeps*) of the senate, and Augustus. The last designation was assumed by his successors. The title imperator was assumed by the emperors on the occasion of victories by themselves or their armies. Aurelius is represented on a coin as imperator for the eighth time. With the early Roman emperors the term imperator did not denote the sovereign power. It is not easy to determine at what time the word came to be used in the modern sense of emperor as the proper name for the sovereign of the Roman state. The term *princeps* was used as a convertible term with it. The Roman emperors appointed their own successors, who received the title of cæsar during the life of the emperor who appointed them. After the court was removed to Constantinople the old titles and forms of the republic gradually vanished, and the emperors assumed the style of Oriental princes. The title of emperor of the Romans was conferred on Charlemagne by Pope Leo III. in 800 A. D., and was borne by his successors until the dissolution of the Holy Roman Empire in 1806.

After the Greek empire had been divided into two parts in 1204, the rulers of both parts continued to bear the title of emperor, the Latin emperor residing at Constantinople, and the Greek emperor at Nicæa. In 1263 the two parts were reunited, and in 1328 the Greek empire was again divided into the empire of Constantinople and that of Trebizond. After the Turks had conquered these empires the sultans assumed the title of emperor, which was recognized by the European powers in 1606. Czar Peter I. of Russia assumed the imperial title in 1721. After the dissolution of the Holy Roman Empire in 1806 the rulers of Austria assumed the title of Emperor of Austria. On Jan. 18, 1871, King William I. of Prussia assumed the title of Emperor of Germany at the request of all the German princes. In France Napoleon I. assumed the imperial style in 1804, and Napoleon III. in 1852. Several attempts have been made to establish empires in America, but all have failed. In Mexico Iturbide assumed the title of emperor in 1822, and Maximilian of Austria in 1864. In Haiti the Negroes Christophe, in 1811, and Soulouque, in 1849, reigned for a short time as emperors, but were soon deposed. The rulers of Morocco, China, and Japan are also sometimes called emperors. The modern idea of an empire in general seems to be a union of states, each with a local government, under the protection or political preponderance of one powerful state. The personal sovereign of such a state may by conquest or election become the emperor, sustaining a special governing relation to his own hereditary dominions, and a general control as emperor over the confederated, yet subordinate, states of the empire. But there is a tendency toward a looser use of the term as a mere title of the head of a kingdom. Revised by C. K. ADAMS.

Emperor Goose: See GOOSE.

Emperor Moth: the largest British lepidopterous insect (*Saturnia pavonia minor*); allied to the silkworm moth; belonging to the *Bombycidæ*. Its wings when expanded measure 3½ inches, each wing having a large transparent spot. The peacock moth (*Saturnia pavonia major*) is 5 inches across the wings, and is the largest species in Europe. Silk is had from cocoons of certain species of this genus.

Emphyse'ma [Gr. ἐμφύσημα, a puffing up; ἐν, in + φυσᾶειν, blow, distend]: in pathology, an inflation produced by air or gas in the cellular tissue. Emphysema of the lungs is owing to dilatation of the air-vesicles.

Emphyteu'sis [Gr. ἐμφύτευσις, an implanting; ἐν, in + φυτεύειν, plant]: in Roman law, a species of perpetual lease of land for a fixed annual payment. This for a long time was confined to the public lands, but was eventually extended to private lands. The person who received the right of emphyteusis could treat the land almost exactly as if he were owner. He could lease it, pledge it, or sell it, and at his death it descended to his heirs. In case of a sale, however, he had to first offer it to the owner at the same price, and the latter could take it or demand a fee for his acceptance of the new occupant. It resembles, but is distinct from, the Scottish grant in feu-farm.

Revised by F. STURGES ALLEN.

Empire: See EMPEROR.

Empiric [from Gr. ἐμπειρικός, experienced (οἱ ἐμπειρικοί, a sect of physicians who held that practice (ἡ ἐμπειρική) was the basis of their art), deriv. of ἔμπειρος, skilled; ἐν, in + πεῖρα, trial]: one whose knowledge or skill is founded on experience or experiment. In the time of Celsus and Galen there was a medical sect called *Empirici*, supposed to have originated with Philinus of Cos and Serapion. These empirics were opposed to the *Dogmatic* sect or school, and considered that medical science should be based on experience rather than on theory. But they extended their idea of theory so far that they excluded anatomy from the medical study as a mere theoretical dream, and they narrowed their idea of experience so much that their whole art came to consist in prescribing certain remedies for certain ailments, without paying any regard to the natural requirements of the individual patient or the peculiar exigencies of the particular case. They became so notorious for ignorance that the term empiric is generally applied to quacks and practitioners who are ignorant of medical science. In its application to philosophy empiric denotes one who depends for truth entirely upon sensual experience, independent of those limitations of the mind's constitution which condition and supplement it. (See SENSATIONALISM.) Empiricism is a name applied by many of the German schools of philosophy to the system which may be called that of observation and induction, relying upon phenomena which are made evident in consciousness. They apply the term to the methods of Locke, Reid, and Stewart, without properly discriminating them from the materialists, to whom the term, in both ancient and modern times, has been legitimately applied.

Empiricus: See SEXTUS EMPIRICUS.

Employer's Liability: See MASTER AND SERVANT and NEGLIGENCE.

Empoli: town of Italy; province of Tuscany; on the river Arno; 16 miles W. of Florence (see map of Italy, ref. 4–D). It has an interesting church, founded in 1093, and adorned with paintings by Giotto; also manufactures of cotton fabrics, straw hats, etc. Pop. 7,500.

Emporia: city and railway center; capital of Lyon co., Kan. (for location, see map of Kansas, ref. 6–I); on the A., T. and S. F. and the M., K. and T. R. Rs.; 6 miles above the junction of the Neosho and Cottonwood rivers, in a fine agricultural and stock-raising region; has a State normal school, the College of Emporia (Presbyterian), endowed by the synod of Kansas, excellent graded schools, a business college, conservatory of music, a canning-factory, street railways, gas, and electric lights, excellent water-works, etc. Pop. (1880) 4,631; (1890) 7,551; (1900) 8,223. EDITOR OF "REPUBLICAN."

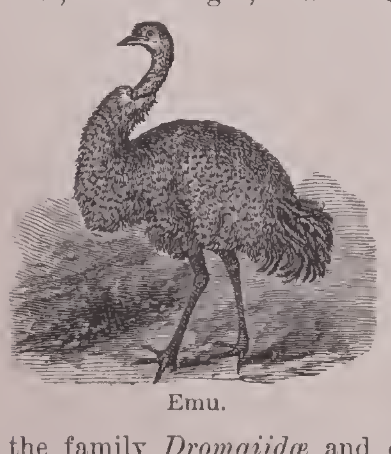
Emporium: borough and railway junction; capital of Cameron co., Pa. (for location of county, see map of Pennsylvania, ref. 3–D); 99 miles W. N. W. of Williamsport. It has iron-works and an important trade in lumber and coal. In the vicinity are valuable salt-wells. Pop. (1880) 1,156; (1890) 2,147; (1900) 2,463. EDITOR OF "CAMERON COUNTY PRESS."

Empson, Sir RICHARD: the extortionate minister of Henry VII. and associate of EDMUND DUDLEY (*q. v.*) in levying the taxes and collecting the fines imposed by the king; was Speaker of the House of Commons in 1491, and subsequently held other important offices. He was brought to trial soon after the accession of Henry VIII., and, in spite of his defense claiming the strict legality of all his acts, was convicted of constructive treason and executed with Dudley on Tower Hill, in Aug., 1510.

Ems, (anc. *Ami'sia* or *Ami'sius*): a river of Germany; rises in Prussian Westphalia, near Paderborn. Its general direction is northward. After a course of about 200 miles it enters the Dollart, an inlet of the North Sea, near the town of Emden. It is connected by a canal with the Lippe.

Ems (anc. *Amisia*), or **Bad-Ems**, baat'ems' (i. e. bath of Ems): a watering-place in Hesse Nassau, Germany; on the river Lahn; about 7 miles S. E. of Coblentz (see map of German Empire, ref. 5–D). It is surrounded by picturesque scenery, and is situated in a beautiful valley among wooded hills. Here are warm mineral saline springs, the temperature of which varies from 93° to 135° F. It has good hotels, and is frequented by many visitors, both native and foreign. In 1785 the Archbishops of Treves, Mayence, Cologne, and Salzburg formed an agreement here, called the Punctation of Ems, in which they demanded in twenty-three articles the change of several papal privileges in favor of the German archbishops. The real object, however, was the establishment of a national German Church. But in consequence of the opposition of their own bishops and the firmness of the pope, they were compelled to submit to the authority of the pope within a year. On July 13, 1870, the French ambassador, Count Benedetti, had at Ems the famous interview with King William of Prussia which precipitated the outbreak of the great war between France and Germany. Pop. (1890) 6,356.

Em'ser, HIERONYMUS: Roman Catholic theologian and adversary of Luther; b. at Ulm, Germany, Mar. 26, 1477. He studied at Tübingen and Basel; accompanied Cardinal Raymond, of Petrandi, on his tour of visitation through Germany; lectured afterward in the true humanist manner at Erfurt, where he had Luther among his hearers; and finally became private secretary to Duke Georg of Saxony and the incumbent of several rich benefices. His first literary efforts were some essays on the propriety of giving toasts when drinking, on the improvement of wine, beer, and vinegar, etc. Then followed a life of Bishop Benno, which is found in the *Acta Sanctorum*. His principal work, however, is his notes on Luther's translation of the Bible, which Luther approved in many cases. His own translation (1527) from the Vulgate is, however, dependent on Luther's. See edition of his writings by Enders (Halle, 1890). D. at Dresden, Nov. 8, 1527.



Emu.

Emu, or **Emeu**: a large Australian bird (*Dromaius novæ hollandiæ*), belonging to the family *Dromaiidæ* and order *Casuarii*, and allied to the ostrich and cassowary. It differs from the cassowary in being taller, having the bill horizontally depressed, and in being destitute of the bony crest and pendent wattles. When full-grown it is of a brown color, mottled with gray. It has only rudimentary wings, but is exceedingly fleet in running. The eggs are dark green, and about seven in number. Both the eggs and flesh are esteemed excellent for the table. Its plumage is long and almost hair-like. The plumes are readily dyed of various colors, and appear to some extent in commerce as a substitute for ostrich-feathers. The emu has become rare in the more settled parts of Australia, having been hunted for the sake of its oil, which the skin contains in large quantities. It feeds mostly on fruit, herbage, etc., and is easily domesticated.

Emu Wren: a passerine bird (*Stipiturus malachurus*) of Australia; a member of the thrush family (*Turdidæ*). The genus includes about a dozen Australian species. This

Emu wren.

bird haunts marshy districts, never alighting on high trees, and seldom taking to flight, but running rapidly about the grass with its long tail-feathers erect. It takes its name from these feathers, which are six in number and from the looseness of their barbs suggest those of an emu. F. A. L.

Emulsin (*Synaptase*): an albuminous substance found in almonds. It acts as a ferment upon the glucoside amygdalin of bitter almonds, transforming it into bitter almond oil (hydride of benzoyl), hydrocyanic (prussic) acid, and glucose (grape-sugar).

Emydidæ [deriv. of *Emys*, the typical genus; from Lat. *emys*, Gr. ἐμύς, fresh-water tortoise]: a family of turtles containing the majority of the smaller fresh-water and land turtles; in all, some sixty species. The upper and under shells (carapace and plastron) are well developed; the feet are usually webbed and adapted for both walking and swimming; and, with few exceptions, there are five claws on the fore feet, four on the hind. Some species of the family, like the box-turtle (*Cistudo*, or *Terrapene carolina*), are exclusively terrestrial, and have the high, arched back, but not the club feet of the true tortoises. A few dwell in brackish water, but the majority are found in the fresh waters of the north temperate and tropical regions. These turtles are rather omnivorous, feeding on various plants, fishes, and worms. The family numbers among its members some which are quite extensively used for food, the most noted being the diamond-back terrapin (*Malacoclemmys palustris*) of the Southern U. S. By some authorities the *Emydidæ* are considered as belonging to the *Testudinidæ*, while others consider the box-turtle as forming a distinct family, the *Cistudinidæ*. See TESTUDINATA.

F. A. LUCAS.

Enaliosau'rians [from Gr. ἐνάλιος, marine (ἐν, in + ἅλς, sea) + σαῦρος, lizard]: a group of extinct saurians having paddles for swimming instead of true feet, and having crocodilian teeth and biconcave vertebræ like those of fishes. Their remains first appear in the Carboniferous rocks, and disappear in the Cretaceous, being most numerous in the Jurassic strata. They appear to have been mostly or all marine. *Ichthyosaurus* is one of the most important of the genera.

Énambuc, or **Esnambuc**, PIERRE VANDROSQUE DIEL, d': founder of the French colonies in the West Indies; b. at Dieppe about 1570. He engaged in privateering cruises, and in 1625 commanded a Dieppe vessel in the West Indies; attacked by a Spanish fleet he took refuge in the island of St. Christopher on the same day that the crew of an English vessel landed there. The French and English agreed to divide the island between them and found permanent colonies. In this plan they were supported by their respective governments, and d'Énambuc formed in France a company for colonizing the West Indies. He took out 530 immigrants in 1626, and others in 1629, and, though the Spaniards drove him from St. Christopher in Dec., 1629, he returned, strengthened his colony and founded others in various islands. D. at St. Christopher, Dec., 1636.
HERBERT H. SMITH.

Enamel [pref. *in*, *en* + O. Fr. *esmal*, *esmail* > Mod. Fr. *émail* : Ital. *smalto*, a loan-word from Teutonic]: a soft and easily melted glass, which is used in many of the arts. It is sometimes opaque, as the white coating of a watch-face, or the lining of some cooking-vessels, and sometimes transparent, as the glaze on fine porcelain. Enamel is generally delivered either in small sticks or cakes to those who work in it. These are ground, and the fine powder is applied to the surface which is to receive it with the brush, and a medium of some kind, usually water. Exposure to heat fuses it, and it cools in a solid skin attached to the background. In the fine arts both the opaque and the transparent kinds are much used. Sometimes the enamel serves as a surface to paint upon in vitrifiable colors. For this purpose the enamel is spread upon a metal plate, usually copper, exactly as is done with watch-faces. The painting may be in monochrome or in vivid colors, and gold can be used very easily. The best known and most important variety of this painted enamel is that known as *Limoges enamel*, the best of which belongs to the middle of the sixteenth century, when there were produced splendid plaques, goblets, and tankards which now bring enormous prices. *Battersea enamel*, produced in England in the eighteenth century, is another variety. Much painted enamel in small pieces for insertion in jewelry was made in France between 1865 and 1885. Much is made in China, with light ground covered with flowers and patterns, and applied to decorative and even to useful vessels. In all these the enamel serves as a background to paint upon exactly as pottery or porcelain would. In other cases the enamel itself, colored in its own substance, forms the pattern. In *cloisonné enamel* a metal background has little strips of wire of a square section fastened to it, outlining the pattern; the enamel powder of different colors is put into these compartments, and the heat fuses them all into smoothness. The whole surface is generally, but not always, ground even and polished. This is the kind most commonly used by the Chinese and Japanese for vases, etc. In *champlevé enamel* a part of the metal surface of an object is engraved rather deeply in a sort of pattern, the hollow being filled with the enamel, which thus shows on a background of the metal. This has always been more common in Europe, and it is much used for jewelry. *Enamel en basse taille* is a variety of this, its peculiarity being that the enamel is transparent and shows a pattern in relief left at the bottom of the hollow in the metal. No decorative art allows of more brilliant color-effects than work in enamel.

The enamel applied to porcelain is of the nature of a thin glaze. Some of the painting applied to the piece is put on before the enamel, some upon the enamel, and the colors are distinguished in this way. See POTTERY and PORCELAIN.
RUSSELL STURGIS.

Enameled Leather: leather the surface of which is rendered glossy by successive coats of linseed oil, and finally of a varnish of copal and asphaltum. See LEATHER.

Enamel Painting: the art of applying painting to glass, pottery, or the metals, much glass-staining being simply enamel painting. The various colors (chiefly oxides of lead, platinum, gold, titanium, uranium, chromium, etc.) are mixed with some glass or "flux," ground, made into a paint with oil of spike or some other volatile oil, and then applied with a soft brush, the outline being usually first applied and then burnt in. Some faint idea of the needed skill may be formed from the fact that the painter has to work not with actual colors, but with substances which he knows will produce these colors after firing.

Encaustic Painting [*encaustic* is from Gr. ἡ ἐγκαυστική (sc. τέχνη, art), the encaustic art, deriv. of ἐγκαύειν, burn in]: a durable species or method of painting which was practiced by the ancient Greeks upon the inner and outer walls of buildings and upon sculptures in marble, and which was one of the commonest kinds of painting among the artists of the Roman empire. It was so called from the process of burning the picture when completed. The pictures were executed with wax colors (*ceræ*), and finished by the application of a hot iron. The effect of an encaustic picture was similar to that of an ordinary *tempera* or water-color painting, but with a somewhat more glossy surface. Encaustic painting has not been practiced with much success or to much extent by the moderns.

Encaustic Tiles: See TILES.

Enceinte, äañ'sañt' [Fr. < Lat. *in* + *cincta*, partic. of *cin'gere*, gird]: in fortification, the main inclosure or the (generally) continuous inclosing line of wall and parapet of a fort or fortress. It is the inner boundary of the main ditch, and, according to its trace or system, upon which its contour is broken, it distinguishes the character of the work as bastioned, polygonal, tenaillé, etc. See FORTIFICATION.

Enchasing: See CHASING.

Enchorial: See DEMOTIC WRITING.

Encina, or **Enzina**, JUAN, del: the "Father of the Spanish drama"; b. in Encina, near Salamanca, about the year 1469. After completing his studies at the University of Salamanca, he found employment as a court poet in the house of D. Fadrique de Toledo, first Duke of Alba. In 1496 he published a collection of his poetical works entitled *Cancionero*, containing, besides a treatise on the art of poetry, a number of lyric and dramatic poems. These latter are partly mysteries, partly pastoral pieces called by Encina *eglogas*. Being represented before a cultivated audience in the house of the Duke of Alba, independently of religious festivals, and drawing their characters from real life instead of from the liturgy, Encina's plays became the starting-point of the secular drama of Spain. Of another dramatical poem attributed to Encina, entitled *Farsa de Plácido é Vitoriano*, all that is known is that it was printed in Rome in 1514. In 1519 Encina made a pilgrimage to Palestine. He spent the last years of his life in his native country, and died at Salamanca in 1534. HENRY R. LANG.

Enciso, MARTIN FERNANDEZ, de: Spanish lawyer; b. about 1470. In 1500 he went to America with the expedition of Bastidas, and remained at Santo Domingo, where he became a prosperous lawyer. When, in 1509, Ojeda stopped at Santo Domingo on his way to colonize Tierra Firme, he induced Enciso to invest his fortune in the enterprise, making him lieutenant. Ojeda sailed in Nov., 1509, and Enciso followed six months later with another ship. He found only a handful of survivors of Ojeda's colony; with these and his own men he founded DARIEN (*q. v.*). Deposed soon after by Balboa, he went to Spain, but returned in 1514 as a legal officer in the company brought by Pedrarias; thereafter he was one of the most determined foes of Balboa. Enciso published in 1519 a *Suma de geografía*, which contains the first Spanish account of the New World, and is otherwise valuable. D. after 1528. HERBERT H. SMITH.

Encke, en'ke, JOHANN FRANZ: astronomer; b. in Hamburg, Germany, Sept. 23, 1791. One of his best-known works is his discussion of the transits of Venus of 1761 and 1769, leading to a distance of the sun equal to 95,000,000 miles. This result is now known to be more than 2,000,000 miles too great. In 1825 he was appointed director of the Royal Observatory at Berlin and secretary of the Academy of Sciences. He investigated the orbit and movements of the comet which Pons discovered in 1818, and which is now designated Encke's comet. In 1830 he began to edit the *Astronomische Jahrbücher*. D. at Spandau, Aug. 26, 1865.

Encke's Comet: a comet observed by Pons on Nov. 26, 1818. In 1819 Encke first demonstrated that the same comet had been seen as early as 1786, and several times subsequently. He also found that its period was about 1,200 days (3·303 years), its successive returns being accelerated and its period shortened by a minute interval of time. It has the shortest period and the least aphelion distance of all the known comets.

En'cratites [Gr. Ἐγκρατῖται, the self-controlling], also called Hydroparastatæ, from their substitution of water for wine in the Eucharist: an heretical sect dating from the second century, which inculcated and practiced total abstinence from flesh, wine, and marriage. Subsequently the name was applied to the ascetic Gnostics generally.

Encrinite [deriv. of *encrinus*; Gr. ἐν, in + κρίνον, lily]: the popular name for crinoids, radiated animals which form an order in the class *Echinodermata*. The encrinites comprise many genera and species, nearly all of which are fossil. They abound in the Paleozoic rocks, and are quite numerous in the Mesozoic formations. Encrinites are exceedingly rare, and for many years only one species (*Pentacrinus caput medusæ* of the West Indian seas) was known. Deep-sea dredging expeditions brought to light two or three more. *Comatula* in its early stage of existence so much resembles the encrinites that it was described as a crinoid (*Pentacrinus europæus*), but in *Comatula* the stem is temporary, in the crinoids permanent. The stem consists of disks like button-moulds in form, set in a pile together, and in the living animal has some flexibility. It is mostly round or pentagonal, and is often finely sculptured on the articulating surfaces. Each joint of the arms is furnished with two cirri or appendages, which the animal uses in capturing its prey. The number of joints in the *Pentacrinus briareus* is, according to Buckland, about 150,000. Immense numbers of these animals lived in the seas of the Paleozoic ages.

Revised by J. S. KINGSLEY.

Encumbrance: See INCUMBRANCE.

Encyclopæ'dia, or **Cyclopædia** [*encyclopædia* is from Gr. ἐγκυκλοπαιδεία, a questionable compound for ἐγκύκλιος παιδεία, regular (course of) education, the liberal curriculum]: a compilation usually, but not always, in alphabetic arrangement, which professes to impart information, more or less complete, upon the whole circle or range of human knowledge. The most noted of the earlier cyclopædic works were the work of Speusippus (the nephew of Plato, d. B. C. 339), not now extant; the great collections of Varro, of the Elder Pliny, of Stobæus, Suidas, Isidorus, and Capella, crude summaries of the then known arts and sciences; the *Speculum Majus*, in four parts, of Vincent de Beauvais (3 vols., 1264); and other similar compilations. The work of Alfarabi, of Bagdad (d. A. D. 950) is also worthy of mention. The Chinese in the course of their long history have compiled and issued many remarkable and usually very voluminous encyclopædias. Among them may be mentioned the *Tai-ping-yu-lan* in 1,000 books, compiled by order of the second emperor of the Sung dynasty, and completed in 983. In 1568 a new edition of 500 sets was printed from movable type, and a later one in 1812. In the reign of the second emperor of the Ming dynasty another great cyclopædia, called the *Yung-lŏ-ta-tien*, was compiled in 22,877 books (with 60 books of tables of contents). It comprised the whole round of Chinese learning—classical, historical, philosophical, and literary, embracing astronomy, geography, medicine, the occult sciences, Buddhism, Taoism, and the arts. Over 2,000 scholars were engaged in the work, which was finished in 1407, and ready for printing two years later. No complete copy is now in existence. In the period K'ang-hi, the second of the present dynasty, another great cyclopædia, the *T'u-shu-tseih-ch'ing*, in 10,000 books, forming 5,020 volumes, was prepared, and printed at Peking by imperial command, from movable copper type (in two sizes) in the following reign (1726). A copy of this immense and valuable work was secured in 1877 for the British Museum in London. Its subjects are arranged in six categories and thirty-two sections, under 6,109 headings. The indexes extend to twenty volumes more.

The earliest modern encyclopædia was that of J. H. Alsted (b. 1588, d. 1638), which appeared in 35 books in the year 1630. L. Moréri's *Grand Dictionnaire* appeared in 1673; Hofmann's *Lexicon Universale* (2 vols.) in 1677; T. Corneille's *Dictionnaire des Arts* (2 vols.) in 1694; and P. Bayle's *Dictionnaire Historique et Critique* (4 vols.) in 1697. In the eighteenth century the principal works were J. Harris's *Lexicon Technicum* (2 vols. folio, London, 1710); Ephraim Chambers's *Cyclopædia* (2 vols. folio, 1728); Zedler's *Universal-Lexikon* (64 vols., Leipzig, 1732–50); the French *Encyclopédie* of the "Encyclopédists" Diderot, d'Alembert, Voltaire, Rousseau, Grimm, and Helvétius (28 vols., 1751–72; 7 vols., 1776–80); the *Encyclopædia Britannica* (3 vols., 1771; 2d ed. in 10 vols., 1776–83; 3d ed. in 18 vols., 1797); the *Deutsche Encyklopädie* of Köster and Roos (1778–1804); and the *Encyclopédie Méthodique par Ordre des Matières* (201 vols., 1781–1832). In the nineteenth century the first European work was Dr. A. Ree's *Cyclopædia* (45 vols., 1802–19). A work called the *British Encyclopædia*, edited by Thomas Dobson, was published in Philadelphia, 1798–1804; Dr. Brewster's *Edinburgh Encyclopædia* (18 vols., 1810–30) followed. The *Conversations-Lexikon* of F. Brockhaus (Leipzig, 1813), of which thirteen editions have appeared, was the basis of many other cyclopædias. The *Encyclopædia Metropolitana* (30 vols. 4to, 1818–45) was a series of scientific treatises, as was also *Lardner's Cyclopædia*. The *Encyclopædia Americana* (1829–33, 13 vols., and supp. vol., 1848), edited by Prof. Lieber, was based on the *Conversations-Lexikon*. The *Penny Cyclopædia* (28 vols., 1833–43), subsequently rearranged in four divisions and twenty-seven volumes as the *English Cyclopædia*; the *Encyclopædia Britannica* (4th to 9th editions, of which the ninth appeared in 24 vols. and index vol., 1875–89); the *London Encyclopædia* (22 vols., 1829); and Messrs. W. & R. Chambers's *Encyclopædia* (10 vols., 1859–68; new ed. 1888–92), are the principal British cyclopædias of the nineteenth century. The *Allgemeine Encyklopädie* of Ersch and Gruber (160 vols., 1818, *seq.*); Meyer's *Grosse Conversations-Lexikon* (52 vols., 1840–55); Pierer's *Universal-Lexikon* (34 vols., 1840–46; 5th ed. 19 vols., 1867–71); Brockhaus (13th ed. 1882–87) and Meyers' *Conversations-Lexikon* (16 vols. and 2 supps., 1885–91) are the best cyclopædias in German. Of the small encyclopædias, the *Hand-Lexicon* of Meyer (2 vols., 1892–93) is by far the best. The French have *Encyclopédie des Gens du Monde* (22 vols. 8vo, 1833–44); *Encyclopédie Moderne* (36 vols. 8vo, 1848–57); *Encyclopédie Catholique* (18 vols. and sup.); and Larousse, *Grand Dictionnaire Universelle du XIX*me *Siècle*, published in fifteen volumes, large quarto, with two supplementary volumes of the same size. This work was intended to replace the famous *Encyclopédie* of the eighteenth century (Paris, 1865–80). The later cyclopædias published in the U. S. have been *The New American Cyclopædia* (16 vols., 1857–63), revised as *The American Cyclopædia* (16 vols., 1873–76); Zell's *Encyclopædia* (2 vols. large 4to, 1869–72; an abridgment in 1 vol. 4to, 1872); *The National Encyclopædia* (8vo, 1872, *seq.*); an edition of Chambers's *Encyclopædia*, printed from imported plates (10 vols. 8vo); Schem's *German-American Encyclopædia* (8 vols., 1869); *Johnson's New Universal Cyclopædia* (4 imp. 8vo vols., 1874–77); *People's Cyclopædia of Universal Knowledge* (3 vols., 1881–83); *Johnson's New General Cyclopædia and Copper-plate Hand-atlas of the World* (2 vols. 8vo, 1885); *International Cyclopædia* (15 vols., 8vo, prepared on the basis of a former ed. of Chambers's); *Johnson's Universal Cyclopædia, Revised* (1893–99, 12 vols.). See also DICTIONARY, LEXICON, BIBLIOGRAPHY, and BIOGRAPHICAL DICTIONARIES.

Revised by C. K. ADAMS.

Endele'chius, SEVERUS SANCTUS: Christian Latin poet, perhaps from Gaul, who taught rhetoric at Rome toward the end of the fourth century. He is the author of an amœbean pastoral, relative to a murrain among cattle (*De Mortibus Boum*). Tityrus ascribes the preservation of his herd to the sign of the cross impressed upon their foreheads. See Riese's *Anthologia*, 893, and a separate edition by J. A. Giles (London, 1838).

M. WARREN.

Endellionite: See BOURNONITE.

Endemic [from Gr. ἐν, in + δῆμος, people]: peculiar to some locality; often occurring in a particular region; said of diseases. The investigations of endemic influences deal with climate, topography, geology, water-supply, personal habits and character, moral, religious, and political conditions, and (since the origin of the germ-theory of disease) with the study of minute animal and vegetable organisms. The study of endemic influences has given rise to the new science of medical geography. See Mühry, *Noso-Geographie* (2 vols.); Boudin, *Traité de Géographie et de Statistique Médicales, et de Maladies Endémiques* (2 vols., 1857); Sir Ranald Martin, *On the Influence of Tropical Climate*; the *British Army Medical Reports*, annual since 1859.

Endermic Method [*endermic* is from Gr. ἐν, in + δέρμα, skin]: a manner of administering medicines formerly sometimes employed, by which the skin was made to absorb the remedy used. In some instances a blister was raised, and the medicine—for example, sulphate of morphia—was applied to the blistered surface. This plan, though often surprisingly effective, has been superseded by the hypodermic method, in which the medicine is introduced under the skin by a small needle-pointed syringe.

Endicott, John: Colonial Governor of Massachusetts; b. at Dorchester, England, in 1589; removed to America in 1628, was acting Governor of the Massachusetts Bay Colony in 1629–30, and was elected to that office in 1644, again in 1649, and re-elected to it every year from 1650 to 1665, except in 1654. A bold and energetic man, a zealous Puritan, he was intolerant of whatever he considered wrong. To meet the needs of the colony he established a mint in spite of a law forbidding such action, and cut out the red cross of St. George from the military standard because, as he claimed, the emblem savored of popery. Under his administration, from 1659 to 1661, four Quakers who refused to obey the laws, which banished them from the colony, under pain of death if they returned, were put to death in Boston. D. in Boston, Mass., Mar. 15, 1665.

Endicott, William Crowninshield: lawyer; b. at Salem, Mass., Nov. 19, 1827; a lineal descendant of John Endicott and of Jacob Crowninshield, Secretary of the Navy in Jefferson's cabinet 1805–09. He studied law and was admitted to the Massachusetts bar in 1850; was a judge of the Supreme Court 1873–82; and was Secretary of War in the cabinet of President Cleveland 1885–89. D. May 6, 1900.

Endive [from Fr. *endive*: Ital. *endivia* < Lat. **intibea*, deriv. of *in'tibum*, *in'tibus*, or *in'tybum*, endive, chicory] (*Cicho'rium endi'via*): a biennial herbaceous plant of the family *Compositæ*, cultivated in the gardens of Europe and America. Its blanched radical leaves are used as a salad. It is a native of the Mediterranean basin.

Endless Screw: a piece of mechanism formed by combining the screw with a cog-wheel, or by making a screw act on the threads of a female screw sunk in the edge of a wheel. The axis of the screw may be either in the plane of the wheel or at right angles to it; in the latter case it is called the American endless screw. In its mechanical principle the endless screw is a combination of the inclined plane and the lever.

Endlicher, ent'lich-er, Stephen Ladislaus: botanist and linguist; b. at Pressburg, Hungary, June 24, 1804. He studied several Oriental languages and the natural sciences. In 1828 he became director of the Imperial Library of Vienna, and in 1840 Professor of Botany in the university of that city. Among his botanical works are *Genera Plantarum* (1836–40); *Iconographia Generum Plantarum* (1838); *Enchiridion Botanicum* (1841): and *Synopsis Coniferarum* (1847). D. in Vienna, Mar. 28, 1849.

Endocardi'tis [*endocardium* + *-itis*, of Greek origin, used in names of diseases to denote inflammation]: an inflammation of the endocardium. It is generally of rheumatic character, and, though not often immediately fatal, it is a frequent cause of organic disease and deformity of the heart and its valves. It is frequently associated with pericarditis, and its occurrence is one of the results always to be feared in rheumatic fever. It is usually attended by pain or discomfort about the heart, and is detected by auscultation. It produces peculiar murmurs in the heart, the significance of which can only be appreciated by the trained physician. The disease is very intractable. Sedatives, such as morphia, hydrocyanic acid or aconite, and digitalis, may be useful in acute stages. The alkaline treatment for rheumatism is often advantageous. Patients sometimes, though not very frequently, entirely recover.

Endocar'dium [from Gr. ἔνδον, within + καρδία, heart]: the serous membrane lining the chambers and valves of the heart.

Endocarp [from Gr. ἔνδον, within + καρπός, fruit]: the inner coat or layer of a fruit, as the stone of the cherry and peach. See Drupe.

Endochrome [from Gr. ἔνδον, within + χρῶμα, color]: an old name for the coloring-matters in plant-cells, including diatomin, phycocyanin, phycoerythrin, phycoxanthin, etc., all to be regarded as forms or modifications of Chlorophyll (*q. v.*).

Endogamy: See Ethnology.

En'dogens, or **Endog'enous Plants** [from Gr. ἔνδον, within + -γενης, produced; cf. ἐνδογενής, born in the house]: See Monocotyledons.

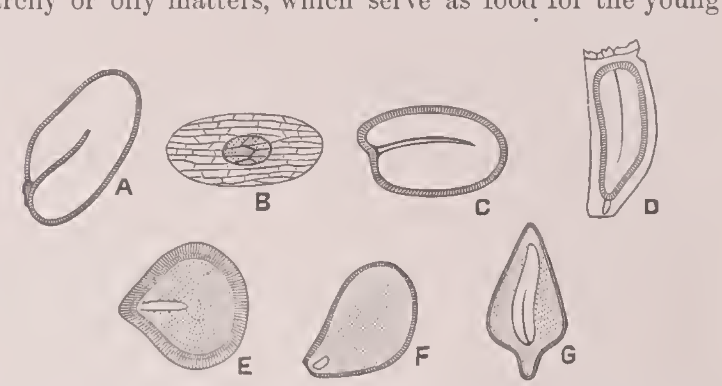
Endophlœum: See Bast.

En'dor: an ancient village of Palestine; on the northern declivity of Little Mt. Hermon, 18 miles S. E. of Acre (see map of Palestine, ref. 6–E); long held by the Canaanites against the Israelites, and celebrated as the scene of Saul's interview with the witch. (See 1 Samuel xxviii.) It contains about twenty rude houses and some cave-dwellings.

Endorse [readapted to Lat. original from Mid. Eng. *endosse* = O. Fr. *endosser*; *en* < Lat. *in* + *dosser*, deriv. of *dos*: Ital. *dosso* < Lat. *dorsum*, back—i. e. write upon the back]: in commercial law, to write one's name on the back of a note, check, bill of exchange, or the like, in order to transfer the property in it or the rights arising under it, or to guarantee its due satisfaction. See Indorse and Bill of Exchange.

Endosmo'sis and **Exosmosis**: See Liquid Diffusion.

En'dosperm [Gr. ἔνδον, within + σπέρμα, seed]: the cellular matter (formerly called *albumen*) surrounding or at the side of the embryo, and within the seed-coats of many seeds. It is developed in the embryo-sac of the seed after fertilization, and in many seeds is all absorbed before the ripening of the seed by the growing embryo (in seeds "without endosperm"); while in others only a part is so used (in seeds "with endosperm"). It is usually filled with starchy or oily matters, which serve as food for the young



A to D, seeds without endosperm; E to G, seeds with endosperm; A, Alisma; B, Orchis; C, Barbarea; D, Chicory; E, Iris; F, Ranunculus; G, Rumex.

plant during the period of germination. In wheat, oats, maize, buckwheat, etc., it is very starchy, and on being crushed yields flour. In a few seeds a starchy matter develops outside of the embryo-sac; this is distinguished as "perisperm." Charles E. Bessey.

Endym'ion (in Gr. Ἐνδυμίων): in Greek mythology, a beautiful youth beloved by Diana (Selene), who cast him into an everlasting sleep. One tradition represents him as a son of Zeus (Jupiter), who granted him immortality and the privilege of sleeping as much as he desired. Some persons suppose that Endymion is a personification of the sun or of the plunge of the setting sun into the sea.

Enemy [from O. Fr. *enemi* > Mod. Fr. *ennemi*: Ital. *nemico*: Span. *enemigo* < Lat. *inimi'cus*; *in*, not + *ami'cus*, friend]: in international law, a state which has publicly declared war against another state, or against which the latter state has made such a declaration. This declaration must be made by a duly organized state or kingdom, for such a declaration by any turbulent body of men is not sufficient. Hostilities having been formally declared, every subject or citizen of the hostile nations becomes in theory an enemy of the opposing state, and all intercourse or communication between the citizens of one hostile state and those of the other is unlawful. Thus the term enemy includes both combatants, to whom the actual combat is intrusted, and non-combatants, who are exempted from the operations of war as far as possible. An enemy can not, as a general rule, enter into any contract which can be enforced in the courts of law; except, for example, when a state permits expressly its own citizens to trade with the enemy; and perhaps a contract for necessaries or for money to enable the individual to get home, or for ransom, though not by English usage, might be enforced. In the U. S. an alien enemy can not, in general, sue, during the war, a citizen of the U. S., either in the federal courts or those of the several States. The word *enemy*, in a still more extended sense, includes all who have begun, or who have made preparations for beginning, hostilities against a state, or are participating in a war against a state, though their own state may be in amity with it. The Latins had a particular term (*hostis*) to denote a public enemy, and denoted a private enemy by the term *inimicus*. See War.

Revised by T. S. Woolsey.

Energy [from Gr. ἐνέργεια, force, activity, deriv. of ἐνεργής, active; ἐν, in + ἔργον, work]: an ideal physical quantity which serves as a common measure of certain forces or results of action in nature. There is a remarkable analogy between the ideas of energy and of matter, in that neither of them can be created or destroyed. When matter disappears from sight, for example, when water evaporates, its form is merely changed into that of an invisible vapor, which, if condensed, will again turn into the original quantity of water. At first sight it would seem that other things than matter can be created out of nothing, and lapse back again into nothingness, without any change of form. Motion is an example of this. A stone allowed to drop acquires motion; when it reaches the ground the motion ceases. So far as ordinary observation goes, nothing has been expended to make this motion, nor has the motion yielded anything that can afterward be used. So electricity can apparently be made out of nothing by rubbing two bodies together. When thus created it can apparently be destroyed without producing any result.

Modern research seems to indicate that these conclusions are not true, but that all physical effects are subject to the law of causation; that they can not be produced except by expending or using up a proportional quantity of some active agent, which may then be regarded as their cause. Thus arises the idea that the expenditure of the cause in producing an effect is simply a transformation of one thing into another, like that which takes place when water is transformed into vapor. This idea has been developed historically in the following way: When mechanics was reduced to a science, by applying mathematical analysis to Newton's law of motion, the following general theorem was discovered: Let there be any number of bodies (for example, those which compose the solar system) moving under the influence of their mutual gravitation, but never coming into actual collision. Conceive the following two quantities to be formed: (1) the sum of all the products obtained by multiplying the mass of each body into half the square of its velocity; (2) the sum of the quotients obtained by dividing the products of every pair of masses, taken two and two, by their mutual distance. In algebraic language, if we represent by m_1, m_2, m_3, etc., the masses of the bodies, the unit of mass being taken as that quantity of matter which will attract an equal quantity with unit force at unit distance; v_1, v_2, v_3, etc., the velocities with which the several bodies are moving at any instant; r_{12}, r_{13}, r_{23}, etc., the distances apart of the first body from the second, of the first from the third, of the second from the third, etc.; then if we represent the first quantity above defined by T and the second by P, their algebraic expressions will be

$$T = \tfrac{1}{2}(m_1v_1^2 + m_2v_2^2 + m_3v_3^2 + \text{etc.})$$
$$P = \frac{m_1m_2}{r_{12}} + \frac{m_1m_3}{r_{13}} + \frac{m_2m_3}{r_{23}} + \text{etc.}$$

In modern physics the quantity T is called the kinetic energy of the system of bodies.

Owing to the continually varying velocities of the bodies and their varying distances, the two quantities T and P are continually varying, but the conclusion of the theorem is that *their difference never varies* so long as no external force acts on the bodies. Thus we may write the equation

$$T - P = \text{a constant},$$
$$\text{or } T = P + C.$$

If the negative of P be regarded as the representative of another quantity, called the potential energy of the body, putting

$$E = \text{potential energy} = -P$$
$$\text{then } T + E = \text{a constant},$$

so that whenever T increases the potential energy will diminish by the same amount, and *vice versa*. Thus arises the conception that through all the motion of the bodies there is a transformation of one of these forms of energy into the other without any gain or loss. Such was the idea as developed by the geometers of the time of Lagrange and Laplace.

An apparent exception was seen to occur if two of the bodies came into collision. It was shown that then the kinetic energy T would be lost, without any potential energy being gained, so that there would be an apparent loss in the sum of the two. But Rumford showed that in such a case, although energy disappeared, something else took its place—namely, *heat*. That is, he showed that by using up energy, or the forces which could be changed into energy, a corresponding amount of heat could be produced. Thus if H be put for a quantity proportional to heat produced, there will result the equation

$$T + E + H = \text{constant}.$$

Subsequently Joule, and after him a number of experimenters, determined the exact amount of energy which had to disappear in order to obtain a given amount of heat. To explain the constant relation thus arising, the relation between energy and work must be shown.

Work is said to be done whenever a force acts upon a body in motion. The amount of work is equal to the product of the force into the distance through which the body is moved under its action. For example, if a weight of 1 lb. is raised to a height of 16 feet, an amount of work is done which may be called 16 foot-pounds. Suppose that the effect of this work is undone or annihilated by letting the body fall back through the 16 feet. Apparently when it reaches the ground the work is undone without any effect being produced. But really a certain quantity of heat has been generated by the blow in striking, and there is an exact correlation between the amount of the fall, the energy with which the body struck the ground, and the amount of heat generated. This relation may be expressed by saying that the temperature of the water at the bottom of Niagara Falls must be a quarter of a degree Fahrenheit higher than at the top, in consequence of the energy produced by the fall being changed into heat. The amount of heat generated or absorbed in various processes may be accurately measured, and a common measure is that necessary to raise a kilogramme of water from 0° C. to 1°C., called a CALORIE (*q. v.*). The instrument used in measurement is called a CALORIMETER (*q. v.*).

There are two forms of potential energy—the one, that already described, dependent on the positions of bodies, the other dependent on their internal constitution or chemical combinations. For example, let us touch with a flame a mixture of oxygen and hydrogen. An enormous amount of heat is instantly produced, apparently out of nothing. But the mixture of gases is changed into water, or, more precisely, into steam. We therefore conclude that oxygen and hydrogen, as pure gases, have stored up in them a definite quantity of potential energy which is spent or transformed into heat when they combine to form water. The truth of the theory is shown by the fact that the water requires the expenditure of a corresponding amount of energy in some other form to be decomposed into its elements. If it is decomposed by an electric current from a dynamo, then the amount of work done by the dynamo is the exact equivalent of the heat which was evolved by the combination of the gases and a condensation of the steam which they formed.

There is still a fourth form into which the three forms already described may be transformed, namely, electricity. To produce electricity of a given potential, one of the other forms of energy must be expended, or work of some kind, internal or external, must be done.

The general principles of the subject having been illustrated, certain more exact numerical statements respecting it are necessary. The various forms of the physical quantity called energy may be classified as follows:

(1) *Actual or kinetic energy*, exhibited whenever a body is set in motion, and measured by the product of the mass of the body into half the square of its velocity. (2) *Potential energy*, which means a quantity dependent on the position or internal state of a body, of such a nature that it changes by a certain amount whenever that condition or position changes. (3) *Work* done, which has already been defined as the product of a force acting upon a body into the distance through which the body moves in the direction of the force. Strictly, however, work should not be regarded as a distinct form of energy; it is simply the process of changing the amount of potential energy. (4) *Electricity*, or, to speak more exactly, electric potential. (5) *Heat*.

Each of these quantities may be taken to have a certain value or price in nature, as measured by the others. Their production and expenditure is then subject to the law that no one of them can be produced except at the expense of one or more of the others, and can never be annihilated except by producing one or more of the other four. They were formerly called *forces*, and the relations between them were called the *correlation of forces*.

The law that no energy is created or destroyed is called the law of *conservation of energy*. See ENERGY, CONSERVATION OF.

The operations of an electric railway run by a storage battery afford one of the best examples of the way in which these various forms of energy may be transmuted into each other. Begin with the fuel which heats the water in the engine. In this fuel, considered in relation to the oxygen in the atmosphere, is stored a certain definite amount of potential energy. By combustion this potential energy is changed into such a quantity of heat that every pound of coal burned creates heat enough to raise the temperature of 8,000 lb. of water one degree centigrade. If the heat thus applied to the water in the boiler were allowed to accumulate it would speedily burst it; but the water is first converted into steam. Part of the heat produced by the combustion thus disappears, and in its place appears a change of water into steam. This change involves an increase of potential energy exactly equivalent to the heat which has disappeared. The steam now drives the piston of the engine against the resistance of the machinery and of the currents in the dynamo, and in the act of doing so is changed back into water. A part of the potential energy which thus disappears is expended in heating the water of the condenser; the remainder in the work of running the dynamo, where it reappears as electricity. The electric current is now passed through the storage battery, where the potential energy disappears as fast as the dynamo creates it, and in its place a chemical change is produced in the materials of the battery, and this change is the exact equivalent of the heat which has disappeared. It must be understood that all the heat does not thus disappear; probably nine-tenths of it has been expended in heating the water in the condenser and in warming the air by the products of combustion, and only one-tenth has been utilized as actual potential energy. The storage battery thus charged with potential is put into the electric car. The moment the car begins to move the friction of the wheels acts against it, and work is done. This work is turned into heat by the friction of the car along the road, provided the latter is level; but if the car has to go up a hill, the work of raising the car against gravity has also to be done. Thus the potential of the storage battery disappears and in its place appear two physical effects—the production of heat and the raising of the car against the force of gravity. If the car runs down hill either more heat will be produced or the potential of the storage battery will be increased accordingly. The beautiful result is this: Supposing the storage battery of a car to have just enough potential energy to run the car all day and bring it back to its starting-place, the friction on the tracks will reproduce exactly the amount of heat which was generated in the combustion of the coal, less the amount which has been already reproduced in other ways, as by the friction of the engine, the heating of the dynamo, etc. But suppose that at night the car is at the top of a hill from the foot of which it started in the morning, and that the difference of level is 430 meters, then the heat which has been produced in all these ways will be less than that given out by the combustion of the coal by just enough to heat a quantity of water of the same weight as the car 1° C. or 1⅘° F. Now, let the car run to the bottom of the hill by its own weight and this lost heat will be reproduced by friction and by the act of stopping the car. To the eye of the physicist, all the operations of nature consist in transformations of energy from one form into another. The great storehouse of energy is the sun, which continually supplies it to our earth in the form of heat. A part of the heat is spent in evaporating the waters of the ocean, raising the clouds, and keeping up the processes of animal and vegetable life. When these processes cease, and when the clouds reach the ocean in the form of rivers, the heat is reproduced. The heat of the sun can not generally be utilized with advantage for driving ships and machinery except in the case of water-power. The heat which the sun radiates from a clear sky upon the deck of a steamship would suffice to drive her at a fair speed could it only be turned into work. But the practical difficulties in the transformation are insuperable. The work of machinery has therefore to be done by utilizing the potential energy stored up in the coal beneath the surface of the globe. See POTENTIAL. S. NEWCOMB.

Energy, Conservation of: the general law, developed in the article ENERGY, that no form of energy can ever be produced except by the expenditure of some other form, nor annihilated except by being reproduced in another form. Consequently, the sum total of energy in the universe, like the sum total of matter, must always remain the same. This law was formerly known as that of the *conservation of force*; but the ambiguity of the word force led to the use of the term "energy" to express the physical quantity in question. S. NEWCOMB.

Energy, Dissipation of: a general theory or phenomenon of physics first pointed out by Sir William Thomson, and bearing directly upon the nebular hypothesis, though quite independent of it. It may be expressed by saying that there is a constant tendency in all known forms of energy to be converted into heat, and that this heat radiates into space and is apparently lost forever. The great storehouse of energy is the sun, but its heat is being constantly radiated into space and never returned to it, so far as we can discover. Since the quantity of heat is limited, the time must arrive when the sun will become a cool, dark body like the earth. Even when heat is for the time being turned into power, this power ultimately disappears by the generation of heat through friction. This heat is communicated to the earth, air, and ocean, and radiated off into space. If any arrangement existed by which the heat could be returned to the earth or to the sun, we might imagine its ultimate recovery; but all the known laws of radiation lead to the conclusion that the lost heat goes off in straight lines through infinite space, never to be again recovered. This remarkable fact leads us to set both a beginning and an end to the existing order of things, but does not in itself explain the beginning. The only end to which it points is one in which life can no longer exist, the sun ceasing to give light or heat, and the earth and planets becoming cold in the embrace of death. S. NEWCOMB.

Enfantin, aăṅ'faăṅ'tăṅ', BARTHÉLEMY PROSPER: French socialist and leader of the Saint-Simonians; b. in Paris, Feb. 8, 1796. He was destined for the army and educated in the École Polytechnique; but when Louis XVIII. closed the school, in 1815, he sought employment in mercantile business. After traveling for several years in Russia, Germany, and the Netherlands as agent for a French winehouse, Enfantin entered a French banking-house in St. Petersburg in 1821, and became in 1823 cashier in the Caisse Hypothécaire in Paris. In 1825 he made the acquaintance of Saint-Simon, and was completely captivated by his ideas. Shortly after the death of the master he founded, together with a brother pupil, Olinde Rodriguez, a communistic paper, *Le Producteur*. Though the paper was stopped very soon, the sect continued spreading, and after the revolution of 1830 it was organized under the lead of Enfantin and Bazard. They soon came to represent widely divergent views, the former introducing novel ideas of moral and religious reform, the latter confining himself more strictly to the political and philosophical ends contemplated by Saint-Simon. At last Enfantin's declaration against marriage and in favor of free love caused a split in the organization, and his imprisonment in 1832 for offenses against public morality finally led to its dissolution. He afterward spent some years in Egypt, was appointed postmaster near Lyons in 1841, and director of the Paris-Lyons Railway in 1845, and founded the paper *Le Crédit* in 1850; but he continued true to the last to his ideas. Among his writings are *Doctrine de Saint-Simon* (1830); *Économie politique et Politique* (1831); *La vie éternelle* (1861); and a great number of articles in the papers. D. in Paris, Sept. 1, 1864.

Enfield: a town of Middlesex, England; on the London and Cambridge Railway; 10 miles N. of London (see map of England, ref. 12–J). Here is a large Government manufactory of small-arms. Pop. (1891) 31,532.

Enfield Rifle-musket: a variety of small-arms manufactured at Enfield, England, at the royal small-arms factories from 1853 to 1864. During the civil war in the U. S. the Federal and the Confederate Governments each purchased large quantities of these and other European arms on account of the difficulty of supplying the large numbers of troops with the necessary weapons. The Enfield rifle, though a very serviceable weapon, much better than the Belgian and Austrian arms then imported, was in almost every respect inferior to the old Springfield (U. S.) rifle-musket, which it much resembled. All these weapons have given place to various breech-loading arms.

Enfilade [Fr., deriv. of *enfiler*, to thread on a string; *en* (< Lat. *in*) + deriv. of *fil*, thread < Lat. *filum*]: a discharge of musketry or artillery made in a direction parallel to the length of a line of troops or of a line of rampart, so that the shot rakes the whole line. A trench or parapet is said to be *enfiladed* when guns are so placed that the shot can be fired into it in a direction coincident with its length.

Eng (right) and **Chang** (left): the Siamese Twins; b. at Bangesau, Siam, Apr. 15, 1811, the offspring of a Chinese father and a Chino-Siamese mother. They were brought to the U. S. in 1829, and after a number of tours of exhibition lived about twenty years as Eng and Chang Bunker near Mt. Airy, N. C., and died in Jan., 1874. They differed widely in appearance, character, and strength, performed their physical functions separately, and were addicted to

Eng and Chang (the Siamese Twins).

different habits, Chang being intemperate and irritable, Eng sober and patient. Both were married and had large families of children, a number of whom died young, but none exhibited any malformation. Chang received a paralytic stroke in Aug., 1870. He died unexpectedly while his brother was asleep, and Eng died a few hours afterward, probably chiefly from the nervous shock on learning the sudden death of his brother. They are the best known of the "double monsters" on record, none others of whom ever lived to the advanced age of sixty-three.

The connection of the Siamese twins was near the navel. The connecting band was a few inches long, after having elongated a little during the long life of the twins, and 8 inches in circumference (2½ in diameter). Inside the skin there was normal subcutaneous and muscular tissue, portions of the muscles of one crossing those of the other. The interior was occupied by the prolongations of the peritoneum crossing from one to the other.

The livers of the twins were located in close proximity to the connecting band, and connected with each other by small blood-vessels, which were lined with a thin layer of genuine liver tissue. It is possible that by operation the twins might have been separated, though the necessary injury to the peritoneum of both and the division of the connecting blood-vessels and accompanying liver tissue might easily have led to a fatal result.

Revised by William Pepper.

Engadine, en-ga-deen', or **Engadin**: the upper part of the valley of the river Inn, in the canton of Grisons, Switzerland; about 65 miles long, with an average width of 1½ miles; separated by the noble Bernina Mountains from the Valtelline. For 30 miles the mean height is 5,500 feet above sea-level, while the village of St. Moritz on the banks of the Inn is at a height of 6,090 feet. The climate, which is very cold, even in the summer, has been found very beneficial to certain classes of invalids, and the Engadine has become a popular resort for European tourists, who are attracted as well by the great beauty of the valley, especially of the Upper Engadine. The inhabitants, a pious, simple class of peasants mostly of the Protestant faith, number about 12,000, and speak a peculiar Romanic dialect, called Ladin. The young men are known throughout Europe as good confectioners and coffee-house keepers. They usually amass a competence, and return to enjoy their small fortunes in their native valley. The government is a pure democracy.

Engano, en-gaa'nō: an island of the Malay Archipelago; lat. 5° 21' S., lon. 102° 20' E.; 75 miles from the southwest coast of Sumatra. It has an area of 128 sq. miles, and is rather high and well wooded. The people are of Malay race, and are included in the Dutch Sumatran government of Benkulen. The island has a good harbor, but is mostly surrounded by coral-reefs. Pop. 6,400.

Engedi, en-ged'ē [Heb. *Eyn Gedi*, spring of the king]: a town several times mentioned in the Bible (e. g. Josh. xv. 62; Song i. 14; Ezek. xlvii. 10), and also called *Hazezon-tamar* (city of palm-trees, Gen. xiv. 7), alluding to its palm-trees, which have now disappeared. It stood, as its ruins show, on the west side of the Dead Sea, at a point about equally distant from its north and south extremities, and in a very fertile spot near the fine fountain which gave it a name. There are numerous caves in the vicinity. These served as hiding-places for David (1 Sam. xxiv. 1–4) and his followers in the days of their outlawry during the reign of Saul.

Eng'el, Ernst: statistician; b. in Dresden, Germany, Mar. 26, 1821; studied in Freiburg and later in Paris; had charge of the bureau of statistics in Dresden for nearly a decade; in 1860 became a director of the bureau of statistics in Berlin; and in 1863 presided at the International Statistical Congress in Berlin. He published the *Zeitschrift des statistischen Bureau* (begun in 1860); the *Jahrbuch für die amtliche Statistik des Preussischen Staates* (1865–76); *Preussische Statistik* (begun in 1861); and numerous other statistical works. He retired from Prussian service in 1882, and removed to Oberlössnitz, near Dresden. D. Dec. 8, 1896.

Engel, Johann Jakob: author; b. at Parchim, in Mecklenburg, Germany, Sept. 11, 1741; educated in Rostock, Bützow, and Leipzig; became Professor of Belles-Lettres in Berlin in 1776. Among his works are *Ideen zu einer Mimic* (2 vols., 1785), and *Lorenz Stark* (1795), a romance which was very popular. His works are characterized by a refined taste and elegance of diction. D. at Parchim, June 28, 1802.

Engel, Joseph: anatomist; b. in Vienna, Jan. 29, 1816; educated in Vienna; became Professor of Descriptive Anatomy at the University of Zurich in 1844, Professor of Pathological Anatomy in Prague in 1849, and of Descriptive Anatomy at the Joseph Academy in Vienna in 1854. He published, among other works, *Specielle pathologische Anatomie* (1856); *Das Knochengerüst des Menschlichen Antlitzes* (1850); *Compendium der topographischen Anatomie* (1859); and *Allgemeine pathologische Anatomie* (1865).

Engelberg, eng'el-bārch: village of the canton of Unterwalden, Switzerland; in Engelberg valley, at the foot of Mt. Titlis (see map of Switzerland, ref. 5–F). It is famous for its school, which is connected with a stately Benedictine abbey, *Mons Angelorum*, founded by Pope Calixtus II. in 1120, and rebuilt in 1729. It has a good library of old works and some valuable paintings. Here is also a famous cheese-cellar of great extent. Pop. (1888) 1,973.

Engelbert: a Benedictine author of noble parentage; abbot of Admont in Styria; b. about 1250; educated at Prague and Padua; became abbot in 1297. Of his numerous works the most important was a Roman history, *De ortu, progressu et fine imperii Romani*, published in 1553, 1610, and later. Several theological tractates of his production have been published by Pez, with a biography and a full list of his works. D. in 1331.

Engelbert, Saint: son of Engelbert, Count of Berg, and of Margaretha, daughter of the Count of Geldern; b. in 1185; studied at Cologne; was chosen cathedral provost in 1199, but was deposed in 1206 and not restored for two years. He repented of his lax life and became strict. In 1216 he became Archbishop of Cologne and elector of the empire of Germany, having when twenty-two years old declined the bishopric of Münster. He paid off the debt of the electorate, enlarged its territories, and reformed its administration. When the Emperor Frederick II. went to Italy, Engelbert was the principal regent in Germany. He reformed the corrupt clergy, checked the power of the nobles, and zealously advanced that of the Church. His energy and rigor made many enemies, and he was murdered by his own nephew at Gevelsberg, near Schwelm, Westphalia, Nov. 7, 1225. The murderer, Count von Isenburg, was broken on the wheel, and his accomplices, the Bishops of Osnabrück and Münster, received excommunication. St. Engelbert is one of the characteristic figures of German mediæval history, recalling Saints Dunstan and Thomas Becket, but he seems to have possessed more zeal for the purity of the Church than they showed, and an energy equal to theirs in extending its power. His life was written by Cæsar, of Heisterbach, first published in 1570, best ed. by J. F. Bohmer (*Fontes rerum Germanicarum*, Stuttgart, 1843, *sqq.*, vol. ii.), and by J. Ficker (Cologne, 1853).

Engelbrecht, eng'el-brecht, JOHANN: religious enthusiast; b. at Brunswick, Germany, in 1599. He was a tailor's son, and worked at his father's trade until his health failed. He was liable to cataleptic attacks, during which he went for many days without food or drink. In 1622 he set himself up for a prophet, in all sincerity regarding himself as a divinely inspired teacher. His writings have been in part translated into English. (*The German Lazarus*, London, 1707; *The Divine Visions of Johann Engelbrecht*, 2 vols., Northampton, 1780.) Though he was quite unlettered, some of Engelbrecht's books, like his addresses, display considerable power and an insight into spiritual things. After suffering imprisonment and enduring much obloquy, he retired from public life and died in 1642.

Engelmann, GEORGE, M. D.: botanist; b. at Frankfort-on-the-Main, Feb. 2, 1809; educated at Heidelberg, Berlin, and Würzburg; for a time was connected with the University of Berlin; in 1832 emigrated to the U. S., and in 1835 settled in St. Louis, Mo., where he became prominent as a physician. In 1836 he founded *Das Westland*, a newspaper which became well known by reason of its excellent articles on life and manners in the U. S. As a botanist Dr. Engelmann became more widely known. He devoted especial attention to North American vines, and to studies of the cacti, dodders, rushes, spurges, pines, and other difficult groups, many of his papers, which in all number about 100, appearing in Government reports. His herbarium and library became the property of the Missouri Botanical Garden at St. Louis. D. in St. Louis, Feb. 4, 1884.

Eng'elstoft, CHRISTIAN THORNING: theologian; b. in Næsberg, Denmark, Aug. 8, 1805; became in 1845 Professor of Theology at the University of Copenhagen, and in 1851 Bishop of Fühnen. He wrote, among other works, a *Reformantes et catholici tempore quo sacra emendata sunt in Dania concertantes* (1836); *Liturgiens eller Altertogens og Kirkeritualets historiei Danemark* (1841); *Taller ved forskjellije Keleigheder* (1858).

Enghien, aan'gi-ăn': a town of Belgium, province of Hainaut; about 20 miles S. W. of Brussels, with which it is connected by railway (see map of Holland and Belgium, ref. 10–D). It has a superb château of the Aremberg family, and manufactures of cotton and linen fabrics. The family of Bourbon-Condé derived from it the title of duke. The Great Condé was styled in his youth Duc d'Enghien. Pop. (1891) 4,313.

Enghien, LOUIS ANTOINE HENRI DE BOURBON, Duc d': French prince; b. at Chantilly, Aug. 2, 1772; eldest son of the Duke of Bourbon. He became an ÉMIGRÉ (*q. v.*) in 1789, and joined in 1792 the army of the Prince of Condé, who was his grandfather. He fought against the French republic until 1799. In 1804 he married the Princess Charlotte of Rohan-Rochefort, and became a resident of Ettenheim in Baden. Here he was seized by the order of Bonaparte, carried to Vincennes, tried by a military court, and shot Mar. 21, 1804, on the pretext that he was an accomplice of Cadoudal in a conspiracy against Bonaparte. This act excited great indignation, as it was generally believed that D'Enghien was not guilty.

Engine [from O. Fr. *engin*, cunning, machine: Ital. *ingegno* < Lat. *inge'nium*, talent, sense, skill]: any contrivance for the production of a mechanical effect, although the word is commonly applied only to the heavier and more powerful classes of machinery, and especially to the prime motors, as the heat-engines, air, gas, and steam engines, having some complexity of structure. Such contrivances as windmills and water-wheels are less frequently called engines, but might properly be so designated.

The usual conception has come to be a "train of mechanism," consisting of several elementary parts so "paired" and enchained that their motion must be mutually dependent and synchronous, and of fixed relative range and power. In this sense the engine is a contrivance for the performance of a specified task in a specified manner through the operation of one or more series of connected parts, driven from a source of energy, and applying that energy more or less efficiently to that act or series of acts which constitute the specific task of the machine. The prime movers best illustrate this definition, and the term, unqualified, has come to have this signification, popularly.

Engines may be classed as (*a*) prime movers, (*b*) secondary motors, (*c*) machines transmitting energy from motor to a follower, and (*d*) machines performing special tasks. These several classes are illustrated by (*a*) the heat-engines, (*b*) compressed-air engines, (*c*) dynamometers of the transmission kind, and (*d*) machine-tools, spinning-machines and looms, or other mechanisms substituted for manual labor. In the early days of the steam-engine, when Savery introduced his plan of construction, it was recognized as an improvement upon Worcester's *fire-engine*; Newcomen displaced this machine by his *atmospheric steam-engine*; and all later machines of this class have been known as steam-engines. The common machinist's lathe is often called an *engine-lathe*; Blanchard invented the *engine* for turning irregular forms; the engraver employs the "rose-engine" to produce certain geometrical patterns, and this machine is also called the geometrical *lathe*, or engine. Electro-dynamic machinery includes the electro-dynamic *engine*, which is sometimes substituted for the steam-engine or the water-wheel, supplying power from the electric current, instead of from thermodynamic or hydraulic sources. The ancients called their catapults and other machines used in warfare *engines of war*. The term has now come to convey so universally the idea of power and means of conveying or of applying power that it has taken many figurative aspects, and a plan, a method, or an artifice is often spoken of as an engine. Bacon speaks of the edict of Julianus as a "pernicious *engine*" against the Christian faith, and elsewhere of the state as a great *engine*. Thomson and Tait speak of the earth and sun as together constituting a "thermodynamic *engine*." In some cases the term takes a technical and limited meaning, as when the locomotive is mentioned, usually, not as a locomotive engine, but as an *engine*.

Engines are sometimes combined in pairs in the same class, as when Savery erected his "fire-engines" in the neighborhood of Manchester, England, to drive water-wheels, the latter, in turn, to drive the machinery of mills, and where Papin applied the same device to impelling the paddle-wheels of his steamboat of 1707.

Hydraulic engines are usually machines constructed very much like the steam-engine, but employing the pressure of water under a high head, natural or artificial. They are not applicable under low heads.

See STEAM-ENGINE, HYDRAULIC ENGINE, WINDMILLS, ELECTRICITY, and MACHINE-TOOLS. R. H. THURSTON.

Engineer: one who constructs or operates engines. "The engineer is he who, by art and science, makes the mechanical properties of matter serve the ends of man," as it is put by Rankine. In the most modern sense, the engineer is a person skilled in both the science and the art of some department of construction, as in either of the grand divisions described in the article on ENGINEERING (*q. v.*), and the specific or special branch pursued by him professionally gives the specific name to the engineer, as the military, the naval, the civil, the mining, the mechanical engineer. The accomplished engineer, as now bred in the technical or engineering school or college, and as perfected in his professional capacity by experience, must be conversant with applied mathematics, especially applied mechanics; with the physical sciences, especially the chemistry of materials and their preparation for use, and the physics of heat and electricity; with the principles of design and proportioning parts of structures and complete constructions; and with the best and most permanently economical methods of adapting and applying such constructions to their defined purposes under exactly prescribed conditions of work and wear. As no one person can accomplish this with reference to the whole range of engineering, he can only become professionally successful by securing, first, a general knowledge of the fundamental principles, facts, and methods, and then making himself familiar with the details of some single line of professional practice.

The *arts* of engineering, upon which the profession is as essentially based as upon scientific principles, are the trades which are utilized in the various branches of construction, as carpentry, masonry, forging, founding, machinist work, boiler-making, surveying, gun-making, armor-plate making. Every engineer must be sufficiently familiar with such of these trades as he is required to employ in his own work to secure good work, and rapid and economical construction.

This usually implies a practical knowledge and even, in some departments, experience in the art so applied. It is for this reason customary to teach something of the arts subsidiary to engineering as an advanced system of "manual training" in the schools of engineering. R. H. Thurston.

Engineering: the art of construction. During the earlier periods of the history of engineering all constructions were directed by men of rank, who were also necessarily soldiers, and were usually military officers, but as civil constructions became more general, and as the military element fell into the background, the art was more and more generally applied to the provision of the needs of the people in times of peace, and finally came to be divided into two grand departments, civil engineering and military engineering. Up to the early part of the nineteenth century civil engineering included the building both of structures and of machinery, and Smeaton, the greatest engineer of his time and a contemporary of Watt, constructed roads, bridges, aqueducts, canals, harbors, and other hydraulic works, and also became famous for his success in the building of steam-engines. The extensive introduction of the now familiar forms of motors, as heat-engines and water-wheels, and the innumerable machines used in the textile manufactures rendered the extent of the art too great for any one man to compass, and it gradually came to be recognized that civil engineering must be further divided, and mechanical engineering became known as the division relating to the construction of all kinds of machinery, the designation civil engineering becoming thus restricted to that department which has to do with static as distinguished from dynamic constructions. Still later, the development of the applications of electric energy and the construction of electrical apparatus and machinery have led to the separation of this branch from the older division of mechanical engineering, and "electrical engineering" has come to be another important subdivision of the art of engineering. The following classifications may meet the requirements of modern times as logically as any, but the continual increase in the complexity of construction is constantly modifying the relative extent and character of these various branches of the great constructive profession, and it is impossible to say what will be their final form:

Military Engineering.—The construction of works for offensive and defensive warfare, including the two main divisions, army or military engineering proper, and naval engineering, including the construction of engines, ships, and armor, and, in both sections, the construction of ordnance, which last is almost a profession by itself.

Civil engineering, now restricted largely by the assignment of other branches to special departments; the construction of "public works," as railroads, canals, harbors, and bridges.

Mining Engineering.—That department which assumes charge of all mining construction and operations from the preliminary location to the final operation of the completely organized and working establishment.

Mechanical Engineering.—The designing and construction of all forms of machinery. This is sometimes termed, in contradistinction with the preceding, "dynamic" engineering, as having to do only with moving structures, while civil engineering, concerned mainly with permanent structures, is sometimes called "static" engineering.

Electrical Engineering.—A modern branch or offshoot of mechanical engineering, dealing with the design, construction, and operation of the mechanism employed in the production, transmission, and utilization of electrical energy, as derived by transformation from some other form of energy, through an appropriate system of "prime motors."

Architecture should probably be classed as a branch of engineering, in which are combined the arts of carpentry and general construction with the fine arts, which latter are essential in all successful architecture in decoration. Civil engineering and architecture are often classed together.

The profession of engineering thus has for its province the construction of all classes of important works, whether static or dynamic, civil or military, public or private. It has for its basis the constructive *arts*, and for its code the principles of applied mechanics and the physical sciences. Its origin dates back to the prehistoric period when smiths, in the person of Vulcan, were deified, and to the days of Tubal Cain, "who was an artificer in brass and in iron." The Temple of Karnac, the Egyptian pyramids, the Roman roads and water-works, the Saracenic constructions of Southern Europe, and later public works, illustrate the progress of the art and its sciences. In the earlier days engineering was monopolized by the rulers of nations for the purposes of promoting their conquests, and military engineering thus antedated the engineering of civil life. While the engineer of modern times is neither an artificer nor a man of science, yet he is required to be so familiar with the arts and trades that he may direct constructions and distinguish good work, and, if needs be, show how he expects work to be done. He is also expected to be so familiar with mathematics and the physical sciences that he may readily make application of the principles of the sciences to the purposes of the work in hand. This is well illustrated in the case of electrical engineering, for example, by the fact that the engineer must in this case be an electrician as well; in marine engineering the engineer must be familiar with the principles of wave-motion, of fluid friction, and of resistances of "ship-shape" forms, as well as with the art of ship-building and marine-engine designing, embodying, as does the latter, the principles of chemistry, of heat-production, and of applied thermodynamics, as well as of the strength and proportions of the elements of machinery.

The training of the engineer, in modern times, is begun in the technical schools, and he is there taught the sciences and often something of the arts which underlie his profession. These schools usually offer more difficult and engrossing courses of instruction than the older institutions of learning, and exact severe work of their students, the general result being the elimination of those unfitted for the work and the final entrance into the profession of but a small proportion of all aspirants entering them. The profession has come to be fully the equal, in respect to preparation by special education, of the other so-called "learned professions," and, in respect to adaptation by selection, is in advance of either of its older congeners. Specialization is going on so rapidly, in consequence of the development of the arts and sciences and their more general application to the purposes of modern life, that the subdivision above indidicated is continually becoming more and more marked, and even in any one branch, as civil engineering, a practitioner, as a rule, is compelled to confine himself to some single subdivision, as to bridge-building, to railway work, to canal construction, or to harbor improvement, and having himself comparatively little knowledge of the art of building mechanisms, commonly goes to the mechanical engineer for his machinery. In mechanical engineering, similarly, the practitioner, who as a rule has little "expert knowledge" of roads or canals, takes up as a specialty either the design or construction of the steam-engine, the building of hydraulic motors and machinery, the construction of locomotives, or the application of energy through electrical transmissions from the prime motor. Only the specialist in engineering is usually fully successful.

R. H. Thurston.

Engineering, Experimental: the investigation of problems arising in the practice of the engineer. Since about the middle of the nineteenth century this has become a department of professional work of exceptional importance, and researches in applied science are regarded as essential to success in the improvement of the arts subsidiary to engineering. In modern technical schools the course of instruction, where systematically arranged, usually includes investigations in regard to the strength and other valuable properties of the material employed in engineering construction and in the operation of machines, e. g. wood and the metals, oils and the fuels; investigations in regard to the effect of stress and strain upon structures or on the elements of structures and machines; test-trials of heat-engines, water-wheels, dynamo-electric machinery, and other apparatus, in order to ascertain the distribution and the extent of the utilization or waste of energy in their operation under known conditions, etc.

At first work of this kind was carried on in what were known as "mechanical laboratories" attached to a few of the older technical schools, mainly for research and commercial gain rather than for purposes of instruction. The first in the U. S. was established by the writer in a small way in 1872, and results of researches were made public in 1873. At the organization in 1885 of the Sibley College of Mechanical Engineering and the Mechanic Arts at Cornell University, experimental engineering was made a part of the courses of undergraduate instruction, and now all important technical schools include such courses of instruction. Some European laboratories have been longer established than those of the U. S., but are mainly for research, and seldom, if at all, intended for the instruction of students in engineering.

See R. C. Carpenter's *Experimental Engineering*, which illustrates the courses of instruction in Sibley College; the treatise of W. C. Unwin on the laboratory work at South Kensington, London; and the works of the writer on the *Materials of Engineering*, in which the apparatus and methods of such instruction and such research are described and the results of their employment are illustrated.

R. H. Thurston.

Engineering Laboratory: See Laboratory, Engineering.

Engineers, Corps of: the branch of an army having charge of the engineering operations involved in war. Among all modern nations assuming to be military powers, the engineering service is organized into separate corps (see Engineering), and for the training of *élèves* for service in them, special military schools are generally provided. (For information as to the organization of these corps see Heydt, *Recherches sur l'organisation du Corps du Génie en Europe.*) In the U. S. the existing Corps of Engineers owes its origin to the act of Congress of Mar. 16, 1802, by which the President was authorized to organize and establish a Corps of Engineers, which was (ultimately) to consist of 1 colonel, 1 lieutenant-colonel, 2 majors, 4 captains, 4 first lieutenants, 4 second lieutenants, and a limited number of cadets (i. e. the *total* number not to exceed 20); and it was further provided that the said corps, when so organized, shall be stationed at West Point, in the State of New York, and shall constitute a Military Academy; and the engineers, assistant engineers, and the cadets of the said corps shall be subject at all times to do duty in such places and on such service as the President of the U. S. shall direct. Thus by their common organic law the Corps of Engineers and the Military Academy were *identical*. The sixty-third Article of War (Apr. 10, 1806) says: "The functions of the engineers being generally confined to the most elevated branch of military science, they are not to assume, nor are they subject to be ordered on, any duty beyond the line of their immediate profession, except by the special order of the President of the U. S.," etc.

Many of the officers of the newly created corps were soon called to duties along the seaboard in constructing fortifications, while, as the wants of the service and of the academy have become more clearly recognized, the number of cadets has been increased, to supply not only the engineers and artillery, but officers of all arms of the service; and the various professorships and departments of instruction now existing have been established at the academy.

In 1838 (July 5) the corps was increased to number forty-seven officers, and at the same time a corps of Topographical Engineers of about the same number (engineers under the designation having been before authorized) was organized. In 1846 (May 15) a company of "sappers, miners, and pontoniers" was authorized to be "attached to and compose a part of the Corps of Engineers, and be officered by officers of that corps, as at present organized; they shall be instructed in and perform all the duties of sappers, miners, and pontoniers, and shall aid in giving practical instructions in these branches at the Military Academy," etc. With some slight changes these corps were thus constituted at the commencement of the civil war. In 1861 three additional companies of engineer soldiers were authorized by Congress, which, with that already existing, were styled the "battalion of engineers"; and a company was also organized for the Corps of Topographical Engineers. In 1863 the latter corps was abolished, and its officers merged with the Corps of Engineers, the organization of which, as confirmed by the peace establishment of 1866, is 1 chief of engineers, with the rank, pay, and emoluments of a brigadier-general; 6 colonels, 12 lieutenant-colonels, 24 majors, 30 captains, and 26 first and 10 second lieutenants. Under this organization the Corps of Engineers, embracing its commissioned officers and companies of sappers, miners, and pontoniers, constitutes a special arm of the service, and is charged with all duties relating to the selection, purchase, and survey of the sites, and the plan, construction, and repair of all fortifications, whether permanent or temporary, and their care when not garrisoned; with all channel and river obstructions, including torpedoes, required for coast defense; with all works for the attack and defense of places; with all fixed and movable bridges for the passage of rivers; with all lines, redoubts, intrenched camps, bridge-heads, etc., required for the movements and operations of armies in the field; and with making such reconnoissances and surveys as may be required for these objects. It is also charged with the survey, plan, and construction of harbor and river improvements; with military and geographical explorations, reconnoissances, and surveys, including the geodetic survey of the lakes; and with all engineer duties confided to other departments than that of war, which may be specially assigned to the corps by acts of Congress or orders of the President of the U. S.

By act of Congress of July 13, 1866, the superintendency of the Military Academy, which had still been confined to the corps, was opened to all arms of the service; and at that date the intimate connection between the academy and the corps with which it was originally identified may be said to have terminated. See Willet's Point.

England (in Lat. *Anglia*; Fr. *Angleterre*; Germ. *England*): that part of the island of Great Britain which lies S. of Scotland and E. of Wales. It has an area of 50,823 sq. miles, is divided into forty counties, and is the principal member of the United Kingdom of Great Britain and Ireland. This is England proper, but the name England sometimes includes Wales, which for administrative purposes was united to England in 1535, and both are treated in this article. All that belongs to the United Kingdom at large, its geography and statistics, as well as its history from the time when the permanent union of Scotland with England and Ireland united the three countries into one empire, will be treated of under the head of Great Britain (*q. v.*).

England (in this extended sense) is bounded N. by Scotland, E. by the German Ocean, S. by the Straits of Dover and the English Channel, S. W. by the Atlantic, and W. by St. George's Channel and the Irish Sea. It is situated between lat. 49° 57′ and 55° 47′ N., and lon. 1° 46′ E. and 5° 41′ W., the greatest length N. and S. being 400 miles, and the greatest breadth 280 miles. In shape it resembles a triangle, of which Berwick may be considered the apex, and a line from the Land's End to the North Foreland the base. The area amounts to 58,186 sq. miles, of which 7,363 belong to Wales and 50,823 to England proper.

Coast.—The seacoast, if measured from one headland to another, is about 1,200 miles in length, but if the principal indentations are followed, about 1,900 miles. No place in the country lies at a greater distance from the sea than 70 miles. Its features exhibit largely the geological structure of the country. The eastern coast is unbroken, and there are only few bays or natural harbors affording shelter to shipping, a deficiency compensated for to some extent by the existence of several estuaries of rivers, among which the Humber and Thames are the most important. A flat shore predominates, and where cliffs occur they are, as a rule, composed of chalk, sand, or clay, which offer but little resistance to the destructive action of the waves. All around the sand-choked bay called the Wash, the Fens form an extensive marshland. In many parts the sea has encroached upon the land, but elsewhere considerable tracts of country have been recovered from the sea, and are defended against its onslaughts by dikes and embankments.

The western coast opens out upon the Irish Sea and the open Atlantic, and its features are far more diversified than on the east. Three broad bays open into the Irish Sea—viz., the Solway Firth, Morecambe Bay, and Liverpool Bay (with the estuaries of Mersey and Dee). They all abound in sandbanks, which render navigation exceedingly intricate. The peninsula of Wales has generally bold and rugged coasts. Menai Strait, hardly 600 feet in width, separates it from the island of Anglesey. The wide sweep of Cardigan Bay opens here toward the W., and Milford Haven penetrates far inland toward the S. W. This is one of the most secure harbors of the British islands, though, owing to its geographical position, it is but little used. Bristol Channel and the estuary of the Severn separate South Wales from the counties of Somerset and Devon. The most important bays along it are those of Carmarthen and Swansea on the coast of Wales, and of Barnstaple on the coast of Devonshire. The navigation of its upper portion is obstructed by sandbanks. Devon and Cornwall form a peninsula, terminating in the Land's End (50° 4′ N., 5° 42′ W.), the most westerly point of England. The Scilly islands lie off this cape, and have proved fatal to many a homeward-bound merchantman. The coasts of this peninsula are generally steep, and celebrated for their picturesqueness. There are several excellent harbors, among which we may mention Mount's Bay, the harbor of Falmouth, and Plymouth Sound; the last is protected by a magnificent breakwater, and the celebrated Eddystone lighthouse points out the way to it. The remainder of the south coast of England is generally level. The Bill of Portland, a rocky promontory joined to the mainland by the Chesil Bank, bounds the roadstead of that name to the W. The only other secure harbors on the south coast are those of Southampton and of Portsmouth, opposite the Isle of Wight, the latter the most important naval station of Great Britain. Spithead is a secure roadstead between it and the Isle of Wight. Farther to the E. the South Downs gradually approach the coast and form the bold Beachy Head (564 feet). The coast then again becomes level and, at Dungeness, marshy, but from Sandgate to the North Foreland it is formed of white chalk cliffs. These "white cliffs of Old England" have become proverbial, though their extent is very limited. They owe their prominence in the popular estimation principally to the fact of their first meeting the eye of a traveler coming from the Continent.* There are no natural harbors along this coast (that of Dover has been created artificially), but the roadstead called the "Downs," lying between the land and the Goodwin Sands, offers some shelter to shipping. The estuary of the Thames is bounded by low coasts, and sandbanks render its navigation exceedingly intricate. The estuary of the Medway, which opens into it, forms one of the most secure harbors, and has been strongly fortified. See CHATHAM.

RELIEF.—The surface, as a rule, is undulating. Toward the sea the country occasionally broadens out into plains, while furze-clad hills of no inconsiderable height rise in the north, in Wales, and in the southwestern parts of the country. Loveliness rather than grandeur is the distinctive feature of English scenery—verdant plains, carefully kept fields inclosed within living hedges, clumps and groves of trees, and numerous gently flowing rivers and rivulets.

Northern England, from the foot of the Cheviots (which separate it from Scotland) to the middle of Stafford and Derbyshire, is intersected by a range of mountains forming the water-parting between the German Ocean and the Irish Sea. By geographers these mountains are called the Pennine chain; locally they are known by a great variety of designations. The depression which separates this hilly region from the Cheviots is marked by the line of the old Roman wall which extended from Carlisle to Newcastle, and only rises 445 feet above the level of the sea. The Pennines divide themselves into two groups, separated by a depression at the heads of the rivers Ribble and Aire, where the Liverpool and Leeds Canal crosses them at an elevation of 500 feet. The northernmost of these groups culminates in the Cross Fell (2,892 feet), and is but loosely connected with the picturesque Cumbrian Mountains toward the W., which abound in lakes, shady woods, and rich pastures. Scafell Pike (3,216 feet), the highest summit of the Cumbrian Mountains, is at the same time the culminating point of all England. The southern group of the Pennine chain is far less elevated than the northern, and the Peak of Derbyshire, its culminating point, only rises to a height of 2,080 feet. It terminates with the Weaver Hill, in lat. 53° N. (1,154 feet). The region of the Pennine Mountains is one of the most sterile of England, and its moorlands are of great extent. In the rest of England there are no hill-ranges equal in importance to the Pennine chain, and the general level of the central portions of the country even but rarely exceeds 500 feet in height. The bands of lias and oölite which extend from Yorkshire to Dorset form a series of hills, interrupted by table-lands or plains, and having generally a steep escarpment to the W., and sloping down gently toward the E. Among these may be mentioned the North York moors (1,489 feet), to the N. of the Ouse; the Lincoln Heights, to the S. of it; the Cotswold Hills (1,134 feet), to the E. of the Severn; and the Dorset Heights. The valley of the Thames is bounded on the N. and S. by chalk hills, affording generally excellent pasturage. Those on the N. extend from Wiltshire into Suffolk, and attain an elevation of 904 feet in Wendower Hill. The southern chalk hills are known as the Downs, and attain scarcely an elevation of 1,000 feet; Inkpen Beacon (1,011 feet), on the boundary of Hants and Berks, is their culminating point. The Northern Downs (Leith Hill, 965 feet) extend from it to the coast of Kent, at Dover, where they form white cliffs; the Southern Downs terminate in the Beachy Head (564 feet), on the coast of Sussex. These two ranges bound a fertile region called the Weald, formerly a forest of oak, at present one of the most productive agricultural districts of the country. Geologists describe the Weald as a valley of denudation, and frequently refer to it in illustration of that kind of geological action. The Mendip Hills (1,067 feet), near the mouth of the Severn, are already beyond the chalk region of Southern England, for they consist of mountain limestone, and the Exmoor (1,407 feet), a range on the southern shore of the Bristol Channel, consists of Devonian rocks, which, with members of the Carboniferous series, occupy the greater portion of Devonshire and Cornwall, and are intruded by granite and other igneous rocks. To this intrusion is due the origin of the so-called "Dartmoor Forest," a desolate moor region rising in Yes Tor to a height of 2,077 feet. The fertile plain of Cheshire and the valley of the Severn form the natural boundary between England and the mountain region of Wales, next to Scotland the most considerable in the British islands. It is frequently distinguished as the "Cambrian Mountains," though "Welsh Hills" is the more popular designation. The highest summit is Snowdon (3,571 feet), close to the Menai Strait. A natural depression at the head of the Severn divides North from South Wales, and the hills of the latter are particularly distinguished by their barrenness, their highest range being known as Black Mountains (Brecknock Beacon, 2,910 feet), from the color of the heather which covers them. The Welsh Hills, toward the E., merge into the table-lands of Salop, Hereford, and Gloucester, where several outlying hill-ranges rise, among which may be mentioned the Malvern Hills (1,395 feet), the Clee Hills (1,805 feet), and the isolated Wrekin (1,342 feet) in the center of Shropshire. Several of the valleys of this Cambrian region are distinguished for their loveliness, and among these that of the Wye in the S. and of the upper Dee in the N. carry off the palm for beauty.

HYDROGRAPHY.—The rivers of England are mere brooks if compared with those of America, but as they all carry an abundant supply of water throughout the year, and many of them are navigable for a considerable distance of their course, they are, nevertheless, of considerable importance to commerce and industry. They belong to four oceanic drainage basins, viz., those of the German Ocean (Tyne, Humber, Ouse and Trent), the English Channel, the Bristol Channel (Severn), and the Irish Sea. The most considerable of these rivers are the Humber (catchment basin 9,293 sq. miles, length 204 miles), Severn (8,119 sq. miles, 186 miles), Thames (5,935 sq. miles, 215 miles), the Great Ouse (2,766 sq. miles, 156 miles), and the Mersey (1,722 sq. miles, 85 miles).

The Mersey rises on the confines of Cheshire and Derbyshire, and forms a wide estuary at its mouth, on which is situated Liverpool, the first shipping-port of Europe. Its tributary, the Irwell, is navigable for barges as far as Manchester, and canals connect it with the principal rivers of the rest of England. The Severn rises on the slope of Plynlimmon in Wales, and becomes navigable at Welshpool, 170 miles above its mouth. It traverses the fertile plain of Shrewsbury and the vale of Gloucester, and enters the Bristol Channel below the town of that name. The tides at its mouth are of tremendous height (60–70 feet), and the country is protected against them by embankments. Its most important tributaries are the Wye and the Avon. Bristol is situated on the latter.

The Thames rises at Thameshead, 376 feet above the level of the sea, and enters the German Ocean at the Nore Light, between Shoeburyness and Sheerness. At its mouth it is 5 miles wide, at London bridge, 46 miles above it, 692 feet, and as far as the latter it is navigable for vessels of 300 tons. Its most important tributary is the Medway, which forms an excellent harbor. The Ouse rises in Northamptonshire, and is navigable from Retford, 46 miles above its mouth. It enters the Wash at King's Lynn. The Humber, properly speaking, is an arm of the sea, into which the Trent and Yorkshire Ouse pour their waters, and extends 37 miles inland. Hull, an important commercial town, is situated on its north coast at the mouth of the small river Hull. The Trent rises in the moorlands of Staffordshire, intersects an exceedingly fertile district, and becomes navigable at Burton-upon-Trent. Small sea-going vessels can ascend it as high up as Gainsborough. The Ouse descends from the Pennine chain, and is navigable for small craft as far as York. Still higher up the coast are the Tees and the

* The name "Albion" which is bestowed sometimes upon Great Britain is not derived from *albus*, white, but from the Gaelic *albainn*, which means "mountain island."

Tyne, neither of great size, but of some importance on account of the emporia which lie at their mouths.

England may boast of numerous lakes in the Cumbrian Mountains, the so-called "Lake District," but, though they are distinguished for picturesque beauty, the largest among them, Windermere, covers an area of only 4 sq. miles. Wales is even poorer in lakes.

Tepid and mineral springs are numerous, but few of them have a great reputation, and none can vie in popularity with the famous health resorts of continental Europe. Among the springs may be mentioned Bath, Buxton, and Matlock. Noted for their mineral springs are Harrogate, Malvern, Cheltenham, Scarborough, Tunbridge Wells, Epsom, Leamington, and Droitwich.

Climate.—For the general features of the climate, see Great Britain. The following table exhibits the climatological features of a few towns:

TOWNS.	Latitude.	MEAN TEMPERATURE.			Rain, inches.
		January.	July.	Year.	
Carlisle	54° 54′	36°	58°	47°	31
Liverpool	53 25	41	62	50	35
Bristol	51 27	36	67	51	24
Penzance	50 71	43	62	52	46
London	51 30	38	64	51	25
Hull	53 45	39	61	50	18
Birmingham	52 55	37	62	49	32

For remarks on the *Geology*, *Flora*, and *Fauna*, see Great Britain.

Population.—The population of England and Wales has steadily increased since 1800, notwithstanding emigration, which annually carries away thousands into other parts of the world. The population, which in 1801 numbered 8,892,536 souls, had grown to 29,001,018 by the beginning of 1891, an increase amounting to 226 per cent. (1871–81, 14·5 per cent.; 1881–91, 11·6 per cent.). This increase affected different parts of the country variously. It was most rapid in the great centers of commerce and industry, less so in the rural parts, and of late the towns have grown at an ever-increasing rate at the expense of the country. Between 1881–91 the town population increased 15·3 per cent., the rural population only 3·4 per cent. In fourteen entire counties (nine of them in Wales) the population actually decreased. The manner in which emigration and immigration have influenced the increase of the population may be judged from the following figures: The number of persons of English origin who emigrated between 1871 and 1891 was 2,545,333; the population during these twenty years increased 6,288,752 souls, while the births exceeded the deaths by 7,071,373. Hence the loss due to emigration, and not compensated by the return of emigrants, or direct immigration, amounted to 782,641 souls. That immigration into England and Wales is a factor of some importance is clearly shown by the classification of the inhabitants according to their place of birth. In 1881 95·69 per cent. were natives of England and Wales; 2·17 per cent. (562,374) of Ireland; 0.98 per cent. (253,528) of Scotland; 0·47 per cent. (123,715) of British colonies; and 0·67 per cent. (174,372) of foreign parts. See Great Britain.

The following table gives the population of England and Wales according to the advance bulletins of the census of March 31, 1901:

Agriculture.—The cultivation of the soil is no longer the remunerative industry which it was before competition with North America became keen, but it would be wrong to assume that land has actually gone out of cultivation. The English farmer has perhaps been rather slow to adapt himself to the changed circumstances, but he has now learned by experience that cattle-farming will pay better than corn-growing. Hence much land has been laid down with grass. In 1872 40 per cent. of the total area consisted of arable land; in 1892 only 35 per cent. On the other hand, the permanent pastures had grown from 31 to 41 per cent. In 1885 there were 475,140 "holdings" (farmsteads), inclusive of 136,425 under 5 acres each. Efforts have been made to encourage market gardening, spade husbandry, and poultry-breeding, by enabling laborers and others to obtain small allotments; but although 455,000 of these allotments (all of less than 1 acre) had been granted in 1891, their influence upon the agricultural position of the country appears to have been very trifling. Wheat is principally grown in the southeast; oats succeed best in the north; Cheshire and Lancashire are noted for potatoes; fruit-trees are most numerous in the west and southwest; and large quantities of grapes are produced in hothouses.

The live stock consisted in 1900 of 491,143 horses, used in agriculture or for breeding; 4,608,443 cattle; 4,386,697 sheep; and 1,268,474 pigs. The counties of Cheshire, Gloucester, and Leicester (Stilton) are noted for their cheese; Devonshire for its cream; Cambridge, Suffolk, York, Somerset, and Oxford, besides the counties already named, for their butter.

Fisheries.—The fisheries employed (1899) 108,513 persons, and 430,240 tons of seafish, valued at £6,342,022, were landed, besides 50,000,000 oysters, and 532,492 cwt. of lobsters and other shellfish. See Fisheries.

For information on *Mines*, *Manufactures*, and *Commerce*, see Great Britain.

Religion, and Provisions for its Support.—England still retains an Established (state) Church, of which the sovereign is the supreme governor (see the next article). Its bishops are appointed by the responsible ministers of the crown, and they have a seat in the House of Lords; its revenues are largely derived from tithes; its priests are introduced to their livings by patrons, and not elected by the congregations. There are 2 archbishops—namely, those of Canterbury and York—33 bishops, and 14,684 ecclesiastical parishes. There is a clerical parliament (convocation), as also a house of "laymen," but the influence of these bodies upon the government of the Church is next to nothing. The annual income of the Church from *all* sources is estimated at £7,250,000. No civil disabilities whatever attach to non-adherence to the Church. Persons can be married by a civil registrar; they may decline to be sworn in a court of justice, if they declare that an oath has no binding force upon them; and they no longer pay church-rates. The disestablishment of the Church is merely a question of time. Among Dissenting bodies the leading ones are the Methodists, the Independents or Congregationalists, the Baptists, and the Presbyterians, among whom may be included those English Presbyterians who now usually call themselves Unitarians. The Roman Catholics, who have gained strength through Irish immigration, are organized under an archbishop (Westminster), 14 bishops, and 2,837 priests (1871, 1,620).

No religious census has ever been taken in England, but there can be no doubt that the members of the Church of England outnumber the adherents of all other religious communions. The number of Roman Catholics does not probably exceed 1,250,000, while the number of Jews falls short of 100,000. The number of secularists, positivists, and agnostics is ever on the increase, and that not only among the upper classes.

Education.—Elementary education has made considerable strides in advance since an act passed in 1870 compelled each locality to provide school accommodation for all children between the ages of five and thirteen, and provided for the election of school boards in all those districts where this accommodation had not been provided by voluntary agencies. These public elementary schools are annually inspected by Government officials, and they receive grants in aid out of the public treasury, in addition to what they may raise by rates or receive from voluntary contributions. All schools supported from the rates are undenominational, and no dogmatic teaching is permitted. In 1899 there existed 20,064 elementary schools: viz., 5,632 under school boards; 11,824 connected with the Church of England; 1,037 Roman Catholic; 1,571 others. There were present at the inspection 5,654,092 children; but the average attendance was only 4,636,938. See Common Schools.

Middle-class education is mainly left to private enterprise. There are 3 universities (Oxford, Cambridge, and Durham) and 15 colleges, with 1,162 professors and 17,443 students, besides 4 university colleges for ladies, medical schools attached to the hospitals of most of the large towns, and a large number of technical and art schools. London university is merely a board of examiners.

Local Government.—By the Local Government Act of 1888 England was divided into 122 administrative counties, inclusive of 62 county boroughs, all of which have over 50,000 inhabitants. The crown is represented in each county by a lord-lieutenant, a sheriff, and justices of the peace. The duties of the lord-lieutenant are at the present time merely nominal, while the justices of the peace, who not long ago carried on nearly the whole of the local administration outside the municipalities, now exercise hardly any but judicial functions. Each county has its county council, consisting of a chairman (mayor), aldermen, and councilors. The councilors are elected by the ratepayers for three years; the aldermen by the councilors (not necessarily out of their own number). Smaller towns still retain a large measure of administrative independence. The whole of the administration of the poor laws is intrusted to guardians elected by the ratepayers, while elected schoolboards administer the public schools. Women have votes in the election of these local authorities, and can themselves be elected guardians or members of school boards, but not county councilors. There exist, in addition to the above, rural sanitary authorities, highway boards, drainage and embankment authorities, harbor and pilotage authorities, etc. The total receipts of the local authorities (1897-98) amounted to £83,876,900. Out of the expenditure, £10,828,276 was for paupers, £10,081,770 for schools. The local debt at the close of 1898 amounted to £262,017,152.

Administration of Justice.—The judicial systems of England and of the U. S. are very similar. A distinction is made between common and statute law, and only occasionally, in admiralty and ecclesiastical cases, is recourse had to Roman or canon law. Four ancient corporations or "inns" enjoy the privilege of calling persons to the bar. King's counsel, as well as judges, are appointed by the Lord Chancellor, who likewise appoints many of the inferior judges, and thus exercises a considerable amount of political patronage. The Supreme Court of Judicature, with twenty-nine judges, none of whom is paid less than £5,000 a year, includes a court of appeal, a chancery division, a king's bench division, a court of probate, divorce and admiralty cases, and a court of arches (for ecclesiastical cases). Thrice a year these judges go on circuit, and hold assizes in the principal towns. A central criminal court exists for the especial benefit of the metropolis, and is presided over by the recorder and the common sergeant of the city of London. The justices of the peace (magistrates) are appointed by the Lord Chancellor, and receive no salary. They hold petty and quarter sessions; these latter are frequently presided over by a paid recorder. In London there are sixteen police courts. The seventy county courts, whose judges are paid from £1,500 to £1,800 a year, exercise only civil jurisdiction, while the coroner with his jury holds inquests into the cause of all violent or suspicious deaths. See Courts.

The police force of England numbers 43,450 men (of whom about one-half are in London). Of 11,044 persons committed for trial in 1899, 8,749 were found guilty.

History.—England first became known to the Western world through the Phœnicians and Massilians, who traded with it for tin; but its real history does not begin until the establishment of the Roman rule by Cæsar in 55 b. c. The rule of the Romans, who called the present island of Great Britain *Britannia*, lasted till the beginning of the fifth century, when they withdrew. (See Britannia.) In consequence of the inroads of the Picts and Scots from the north, and the quarrels of the British chiefs among themselves, the country appears to have soon become a prey to complete anarchy. A British Prince of Kent, Vortigern (Gwrtheyrn), is said to have been the first to secure the aid of two Saxon chiefs, commonly called Hengist and Horsa, in his struggles against the northern invaders. The statements as to the first appearance of the Saxons in England are conflicting and untrustworthy, and even the names of their leaders are considered fabulous. Certain it is that in the course of about 130 years the Saxons, Jutes, and Angles completed the conquest of the greater part of England, establishing three Saxon kingdoms (Sussex, Wessex, and Essex), one Jutish (Kent), and four Anglian (Bernicia, Deira, East Anglia, and Mercia). The British maintained for a somewhat longer period five states (Strath-Clyde, Cumbria, North and South Wales, and Cornwall). Egbert, King of Wessex, is commonly believed to have become the first King of all England. During his reign began the invasions of the Danes about 830, who for a period of twenty-four years (1017–42) became masters of the kingdom. In 1042 the crown again devolved on an Anglo-Saxon prince, Edward the Confessor, but his authority was little more than nominal, six powerful earls, Danes and English, dividing the country between them.

The Norman Conquest.—Edward the Confessor died childless in 1066, and Harold, the son of Goodwin, was elected by the nobles to the throne; but in the decisive battle of Hastings (Oct. 14, 1066) against another claimant to the throne, William, Duke of Normandy, he was defeated and killed. With the reign of William, surnamed "the Conqueror," a new era of English history begins. The lands were divided among 600 tenants *in capite*, all followers of the Conqueror as feudal lords, and thus on the solid basis of extensive landed estates the firm foundation was laid of a powerful aristocracy, which amid the social revolutions of centuries has more successfully defended its ascendency than that of any other country of Europe. The population of England at this time appears to have been at most 2,000,000, and about 100 boroughs were governed by municipal customs or under the protection of the kings, nobles, or prelates, from whom in after times they purchased their franchises. In the course of time the distinction between the Norman conquerors and the conquered Saxons passed away, and from their union arose the English people as it now exists. The Norman line gave to England only three kings—William I. and his two sons, William II. and Henry I. The death of the latter in 1135 was followed by a war of succession between Stephen of Blois, his nephew, and his only daughter, Matilda, who was married to Geoffrey Plantagenet. In 1154 the son of Matilda, Henry II., was generally recognized as King of England. He was the founder of the house of Plantagenet, which in direct line ruled in England until 1485. Henry possessed, besides England, the provinces of Anjou, Touraine, and Maine in France, to which he added Guienne and Poitou by marriage and Brittany by conquest. He conquered Ireland in 1171, and by the Constitutions of Clarendon in 1164 curtailed the privileges of the Church, but was forced, in consequence of the assassination of Archbishop Becket, to make his peace with the Church. He was in 1189 succeeded by his eldest son, Richard I. (Cœur de Lion), who distinguished himself in the crusades, but could not prevent the nobility from increasing their power at the expense of the crown. The reign of his younger brother, John (Lackland, 1199–1216), is one of the most inglorious in the English annals. He lost nearly all the possessions of the English sovereigns in France, and in 1213 consented to hold the English crown as a gift from Rome. His weakness, however, had some good results for the people of England.

The Beginnings of Constitutional Liberty and Representative Government.—The separation of the Normans of England from those of France hastened the consolidation of the English nation; and when involved in disputes with the pope, John had to conciliate the barons, who were backed by the people, by the concession of the celebrated Great Charter (*Magna Charta*), signed at Runnymede in 1215. The charter secured to the English people, in advance of any other people of Europe, two great rights—that no man should suffer arbitrary imprisonment, and that no tax should be imposed without the consent of the council of the nation.

When John showed an unwillingness to carry out some of his promises, the barons called Louis of France (son of the king, Philip Augustus) to their aid, who conquered a large portion of the country, but was compelled, soon after the death of John (Oct. 17, 1216), to make peace and renounce the project of annexing England to France. But while the national pride of the English people successfully prevented its subjection to France, anarchy rapidly increased during the reign of John's son, Henry III. (1216–72). As Henry at the death of his father was only a boy of nine years, the government was carried on first by the Earl of Pembroke, and after his death by Hubert de Burgh and the Bishop of Winchester, neither of whom was able to check the demands of the nobility for greater power. When Henry assumed the government himself, an open war soon broke out with the barons, who extorted from the king an enlargement of the Great Charter, and in 1264, at the battle of Lewes, took him and his eldest son, Edward, captives. The next year the first English Parliament was convened by the leader of the rebels, Simon de Montfort, Earl of Leicester; but soon Prince Edward, who had been set free, broke the power of the barons in the battle of Evesham (Aug. 4, 1265), in which de Montfort fell, and restored the authority of the king. Henry deemed it, however, best to assume a conciliatory policy, and in particular to confirm the Great Charter. Edward I. (1272–1307) had sufficient energy and statesmanship to put an end to the confusion into which the country in the latter years of his father's reign seemed to relapse, and considerably promoted the consolidation of the kingdom.

Conquest of Wales and War with Scotland.—In 1282 Edward conquered the last Prince of Wales, and united this country, which thus far had been semi-independent, forever with England, conferring on his eldest son the title of Prince of Wales, which has ever since been borne by the eldest son of the English sovereign. He obtained a decisive victory over Scotland in the battle of Dunbar (1296), defeated William Wallace at Falkirk (1298), led a third large army into Scotland (1303), but died on the eve of a fourth invasion, "in sight of that country which he had devoted to destruction." His barbarous warfare first aroused feelings of hostility between the Scotch and English, which subsequently did much mischief. For the development of the English constitution his reign was of the greatest importance, as the council of the realm assumed a form resembling that of the modern Parliament by the separation of the greater barons from the tenants in chief, the latter ceasing to be summoned to Parliament, and being present only through their representatives. The first sitting of the Commons in a separate chamber took place in 1296, and in the following year (1297) the famous statute was passed that no manner of tax should be imposed without the common consent of the bishops, barons, and burgesses of the realm. Edward II. (1307–27) lost the footing which his father had gained in Scotland, was defeated by Robert Bruce in the battle of Bannockburn 1314, and was finally murdered in prison.

The Period of the Hundred Years' War.—The reign of Edward III. (1327–77), is regarded as one of the most brilliant periods of English history. His claim to the throne of France involved him in the HUNDRED YEARS' WAR (*q. v*), which, with several intervals of peace, lasted from 1337 to 1453, and which, notwithstanding the brilliant English victories of Crécy (1346) and Poitiers (1356), finally led to the surrender by the English king of all the English possessions in France except Guines and Calais. The great expenditures required by the war made the king dependent on his Parliament, which henceforth was directed by statute to be summoned annually. Another important result of the war was the entire fusion of the Normans and Saxons into the English nationality. The spirit of chivalry attained at the court of Edward its highest point of exaltation, but, on the other hand, the laboring classes made their power felt for the first time; for as their service had become more valuable in consequence of the terrible ravages of the great pestilence in 1349, they demanded and received higher wages, and a series of despotic edicts, known as the Statutes of Laborers, ordering them to work at the former wages, proved entirely inefficient. During the reign of Edward, Wycliffe began (about 1360) his attacks upon the abuses in the Church, and he was supported by Edward's fourth son, John of Gaunt, and by some of the principal nobility. As the king's eldest son, Edward, Prince of Wales, known as the "Black Prince," died one year before his father (1376), the latter was succeeded by his grandson, Richard II. (1377–99), during whose weak reign an attempt to enforce a poll-tax brought on the famous rebellion of the peasantry under Wat Tyler, which was suppressed with much bloodshed. Richard was dethroned by his cousin Henry, Duke of Lancaster, who ascended the throne as Henry IV. (1399–1413). His reign, which was greatly disturbed by rebellions and conspiracies, is remarkable for two events in the history of the English constitution—the fixing by statute of the parliamentary right of election for counties in all freeholders, and the recognition of the two houses as bodies possessing distinct privileges, not to be interfered with by each other. The religious reformation of Wycliffe found in Henry a determined opponent, the act for the punishment of heretics under which so many atrocities were committed for nearly two hundred years being passed during his reign (1401). His son, Henry V. (1413–22), put down the religious movement of the Lollards with a strong hand, and renewed the claims of his ancestors to France. The new war between the two countries was favorable to England; Henry landed with 30,000 men in Normandy, won the battle of Agincourt Oct. 25, 1415, and on his death a large portion of France recognized, with England, his son, Henry VI. (1422–61), then only a boy of nine months, as king. After many campaigns the French were, however, ultimately successful, the exploits of Joan of Arc, Dunois, and other French leaders putting forever an end to the English attempts to conquer France.

War of the Roses.—Soon after, the war known as the war of the Red and White Roses (or of the Lancastrians and Yorkists) began. Richard, Duke of York, a descendant of the Duke of Clarence, third son of Edward III., claimed a title to the throne preferable to that of King Henry, on the ground that the latter was only a descendant of the fourth son of Edward III., and that the pretensions of the king's grandfather, Henry IV., to be descendant from Edward, Earl of Lancaster, according to popular tradition the eldest son of Henry III., and excluded from the succession on account of deformity, were apocryphal. Richard, Duke of York, was taken prisoner in the battle of Wakefield, Dec. 30, 1460, and executed, leaving his claims to his eldest son, Edward, the Earl of March, a youth of nineteen, who was proclaimed king as Edward IV. in 1461, and maintained himself until his death (1483), with a short interruption (1470–71), when the rebellion of the Earl of Warwick, the "king-maker," formerly the most prominent among his supporters, compelled him to flee to Holland, and restored for the time Henry VI. The son of Edward (Edward V.), a minor, was after a reign of only thirteen days dethroned by his uncle, the Duke of Gloucester, placed in confinement, and soon disappeared. The usurper made himself king under the name of Richard III. (1483–85), but soon a coalition of disaffected Yorkists and of the Lancastrians was formed against him, at the head of whom was Henry Tudor, Earl of Richmond, who through his mother descended from the house of Lancaster, and to satisfy the Yorkists was to marry Elizabeth, the eldest daughter of Edward IV. In the decisive battle of Bosworth Field, in 1485, Richard lost his life, and Tudor ascended the throne as Henry VII. With him a new era begins in English history. The first years of Henry (1485–1509) were greatly disturbed by pretenders to the throne, who, personating the head of the house of York, claimed to be the legitimate heirs to the crown. But the chief feature of his reign is the large increase of the royal power at the expense of the high nobility and the Parliament. Many of the principal nobles having perished in the wars of the Roses, Henry succeeded in enforcing against the barons the laws forbidding them to give badges and liveries and to employ retainers. The change thus produced in the relation of the nobility to royalty became still greater from the fact that the former began to value money payments from their tenants and dependents higher than personal services, while the lower classes of the people began to understand that hereafter they had to support themselves and to respect the laws, instead of looking to the nobility for support and for impunity in case they had committed lawless acts.

The Reformation.—The great event in the reign of his son, Henry VIII. (1509–47), was the separation of the Church of England from Rome. Henry was a violent opponent of Luther and the German Reformation, but when the pope refused to grant him a divorce from his wife, Catharine of Aragon, he renounced his communion with the pope and assumed the title of the Head of the Church, and alike persecuted Catholics who refused to recognize his "supremacy" and Protestants. (See ENGLAND, CHURCH OF.) His only son, Edward VI. (1547–53), succeeded at the age of nine years, and the country thenceforth was governed by a council of regency favorable to the Reformation, which now advanced from questions of government to questions of doctrine. The Duke of Northumberland, who had caused one of his sons to marry Lady Jane Grey, great-granddaughter of Henry VII., induced Edward to bequeath the crown to his daughter-in-law; but the reign of Lady Jane lasted only ten days when "bloody" Mary (1553–58), the daughter of Henry VIII. and his first wife, Catharine of Aragon, ascended the throne. Mary was a devout Catholic, who obtained the consent of her Parliament to repeal (1553) the legislation of Edward VI., and that (1555) of Henry VIII., thus re-establishing the papal authority. When the chiefs of the Protestant party opposed the counter-reformation 290 of them suffered at the stake, including Cranmer, Ridley, and Latimer. Her marriage with Philip II. of Spain did not, however, save to the Catholic Church its ascendency in England, for Mary died in 1558 without issue, and, on the other hand, it cost England the last possession in France, Calais, which was taken by the Duke of Guise. Mary was succeeded by her half-sister, Elizabeth (1558–1603), the daughter of Henry VIII. by his second wife, Anne Boleyn. She was strongly opposed to the supremacy of the pope, by whom she had been declared to be a bastard. Parliament in 1559 restored the royal supremacy of the Church, which by the adjustment of the Prayer-book and the Thirty-nine Articles, substantially received the form in which it still exists. The power of the Roman Catholics in England was completely broken; and when most of them embraced the cause of Mary, Queen of Scotland, who, on seeking an asylum in England, had been imprisoned, Elizabeth ordered Mary to be executed. Abroad she aided the Protestants of France and the Netherlands, and the crushing defeat of the Spaniards, whose armada was destroyed in 1588, elevated England to a higher position among the countries of Europe than she ever had held before. Ireland was reduced to a state of entire submission, and the commerce and naval power of England received a wonderful impulse by the establishment of commercial intercourse with India (East India Company chartered 1600). Elizabeth was the last sovereign of the house of Tudor; she was succeeded by James VI., the son of the unfortunate Mary. Thus England, Scotland, and Ireland became united under one sovereign, and although the legislative union with Scotland was not consummated until 1707, and that of Ireland not until 1800, the three countries were in fact one empire.

The Struggle between Parliamentary Privilege and Royal Prerogative.—James VI.—or, as he was called after his succession to the throne of England, James I.—was proclaimed Mar 24, 1603, crowned July 25, assumed the title of King of "Great Britain, France, and Ireland" Oct. 24, and reigned till Mar. 27, 1625. He had received a good education, and showed great interest for science and literature, but he was pedantic and inconsistent. After the discovery of the Gunpowder Plot (Nov. 5, 1605) he banished the Jesuits and seminary priests from England, and afterward wrote several treatises himself in defense of pure Protestantism. But he failed to give his son-in-law, the elector palatine, from whom descends the house of Hanover, the aid he had promised him; and one of the principal reasons why he disappointed his Protestant allies in Germany was his eagerness to marry his son to a Roman Catholic princess of Spain. In his time the translation of the Bible into English and the colonization of Virginia and New England took place. Meanwhile the political tendencies which at this time were carried out with such great success in France by Richelieu—namely, the consolidation of the royal power and the concentration of all authority in the crown—also began to show themselves in England. During the time of James I. there was much talk about "the king by God's grace," and hardly had his son, Charles I. (1625–49), ascended the throne when the conflict actually began between the king and the Parliament. He had declared that he would not be a Venetian doge, and his two first Parliaments he dissolved. But the third, which sat in 1628, passed the so-called Petition of Right, in which the constitutional rights of an Englishman are clearly defined, and the king was compelled to give his consent to the petition. After this event, however, he convoked no Parliament for eleven years, but ruled as arbitrarily as if there had never been a Parliament or a constitution. Justice was administered by the Star Chamber, money was levied by proclamations, and the Puritans and other Nonconformists were cruelly persecuted. Charles wished to introduce the liturgy in Scotland (1637), but the Scottish people rose in arms, subscribed the National Covenant, invaded England, and defeated the royal troops at Newburn-on-Tyne. In Nov., 1640, the Long Parliament assembled, and began business by impeaching Strafford and Laud. The Star Chamber was broken up, the dispensing power abolished; but when the Parliament went further and demanded that the king should give up his right to dissolve Parliament, and even resign the supreme military command, open war broke out between the king and the Parliament.

The Civil War.—In the beginning the king was successful, gaining several small victories; but in 1644 he was defeated at Marston Moor, and in the following year he was so thoroughly beaten at Naseby that he had to flee for his life, and finally gave himself up to the Scottish army, which gave him into the hands of the English Parliament. A high court was appointed, before which King Charles was tried. He was convicted, and beheaded Jan. 30, 1649. Oliver Cromwell, who commanded the right wing in the battle of Naseby and contributed much to the victory, controlled the army, which belonged to the party of the Independents; and after the so-called Pride's Purge, in Dec., 1648, when forty-one Presbyterian members were driven out of the Parliament, he also controlled that assembly. In 1649 he went to Ireland as lord-lieutenant, and put down the royalist rebellion there with extreme severity. In 1650 he was appointed commander-in-chief against the Scottish rising in favor of Charles II., and subdued the rebellion after the battles of Dunbar and Worcester. He was now the most powerful man in the kingdom, and in 1653 he assumed the title of Lord Protector of the Commonwealth, and governed as a monarch till his death, Sept. 3, 1658.

The Restoration.—Cromwell was succeeded by his son, but almost immediately after his death a strong royalist reaction set in, and in 1660 Charles II. returned to England and was hailed with great enthusiasm. His reign (1660–85) was one of the most shameful periods in English history. The court was dissipated and licentious, and moral contamination spread from it into the upper strata of society. The Parliament, which was very subservient at first and afterward only feebly contending against the evil, was broken up into factions and corrupted by bribery. With respect to a foreign policy, the king and the country as well became subservient to Louis XIV. of France. The two wars with Holland (1665–67 and 1672–74), which brought the English arms very little glory, were carried on in the French interest. The king in 1675 received 500,000 crowns from Louis in order to prorogue Parliament, and for several years he also received an annual pension in reward of his subserviency to the French policy. As base was his internal policy. He had given the most binding promises of amnesty and loyalty. Nevertheless, in 1662 the Presbyterian divines were ejected from their livings. This act, however, did not cause any great excitement. Indeed, Parliament itself voted that the bodies of Cromwell, Bradshaw, and Ireton should be disinterred and hanged upon the gibbet of Tyburn. But when in the same year he issued his declaration of indulgence to the Roman Catholics, people became suspicious; and when his brother, the Duke of York, heir-apparent to the crown, openly professed the Roman Catholic faith, a bill for his exclusion from the succession was brought into Parliament and passed by the House of Commons. It was rejected, however, by the House of Lords, and on the death of Charles II., James II. succeeded (1685–88).

The Revolution of 1688.—It was evidently James's intention to overthrow the constitutional system of England and restore the Roman Catholic Church. For the accomplishment of the first purpose he meant to create a large standing army, and, in spite of the great difficulties he had to encounter on this point, he partly succeeded. For the restoration of the Roman Catholic Church he first allied himself with the Episcopalians, afterward with the Dissenters. But he was much less successful on this point, and when in 1688 he issued a declaration of indulgence to the Roman Catholics, and ordered it read in all the churches, the crisis came. The Archbishop of Canterbury and six bishops petitioned the king against the order, but were sent to the Tower and tried on the charge of libel. Another event of decisive importance took place just at the same time. James II. had hitherto had no son, and it was hoped that on his death his Protestant daughter Mary, married to William of Orange, would succeed to the throne. But on

June 10, 1688, Queen Mary gave birth to a son, afterward known as the Pretender. People generally considered this child spurious, and on June 30 an invitation to invade England was signed by the Earls of Shrewsbury, Devonshire, and Danby, Lord Lumley, Henry Sidney, Edward Russell, and Henry Compton, and sent to William and Mary. They landed at Torbay (Nov. 5) with an army of 15,000 men, and as James II. saw himself deserted immediately almost by all, even by his own daughter, Anne, he fled to France. In Feb., 1689, a convention of the estates of the realm of England formally established William and Mary on the English throne, and the risings which took place in Scotland and Ireland in favor of the fugitive James II. were successfully subdued—in the former country by Sir John Dalrymple after the massacre of the Macdonalds in 1692, and in the latter by William himself in the battle of the Boyne July 1, 1690, and by Ginkel in 1691.

The War of the Spanish Succession.—Mary died Dec. 28, 1694, and William now reigned alone. In his foreign policy he was so far successful that he actually checked the progress of Louis XIV., and the result of his internal government was the firm establishment of the English constitution. By an act of settlement adopted by Parliament in 1701 the house of Stuart was formally excluded from the throne of England, which, after the death of William and his sister-in-law, Anne, was settled on the house of Hanover. After the death of James II., however, his son, the Pretender, was recognized by Louis XIV. as King of England, and this, in connection with Louis's breach of a newly concluded treaty concerning the Spanish succession, caused William to prepare for war. He died Feb. 21, 1702. His policy, however, was continued by his successor, Anne (1702–14), and led to brilliant results. The queen herself was weak both in intellect and character, but the splendid victories of Marlborough annihilated the ambitious plans of Louis XIV., and led to the conquest of Gibraltar. William had not always been successful in the field, and he proved himself greater in the council-chamber than on the battle-ground; but he knew that an army is not only a useless, but even a dangerous, instrument when not in perfect order; and the army which was placed under the command of Marlborough was probably the best organized and best disciplined body of troops then existing. The result answered his expectations. The first part of the war, from the capture of Liège (Oct. 23, 1702) to the battle of Blenheim (Aug. 13, 1704), was very brilliant; and when, in spite of an unbroken series of victories, from the battle of Tirlemont (July 18, 1705) to the battle of Malplaquet (Sept. 11, 1709), the war still dragged on, this was probably due to underhand intrigues of various sorts. In literary respects the reign of Anne was also a remarkable period, and has been called, not altogether without reason, the Augustan age of English literature, Addison, Pope, Steele, and Swift forming its most conspicuous ornaments. May 1, 1707, the complete union of England and Scotland was accomplished. For the further history of the two countries, see GREAT BRITAIN.

CHRONOLOGICAL TABLE OF THE SOVEREIGNS OF ENGLAND.

Saxon House of Cerdic.—Egbert, first King of all England, 827–36; Ethelwulf, 839–58; Ethelbald, 858–60; Ethelbert, 858–66; †Ethelred, 866–71; Alfred the Great, 871–901; Edward the Elder, 901–25; Athelstan, 925–40; Edmund, 940–46; Edred, 946–55; Edwy, 955–58; Edgar, 958–75; Edward the Martyr, 975–79; Ethelred II., the Unready, 978–1016; Edmund Ironside, 1016.

Danes.—Canute, 1017–35; Harold I., 1035–40; Hardicanute, 1040–42.

House of Cerdic.—Edward the Confessor, 1042–66; †Harold II., 1066.

The House of Normandy.—William I., the Conqueror, 1066–87; ‡William II., Rufus, 1087–1100; Henry I., Beauclerc, 1100–35; Stephen of Blois, 1135–54.

The House of Plantagenet.—Henry II., 1154–89; †Richard I., Cœur de Lion, 1189–99; John Lackland, 1199–1216; Henry III., 1216–72; Edward I., 1272–1307; ‡Edward II., 1307–27; Edward III., 1327–77; ‡Richard II., 1377–99 (deposed).

The House of Lancaster.—Henry IV., 1399–1413; Henry V., 1413–22; ‡Henry VI., 1422–61 (deposed and executed).

The House of York.—Edward IV., 1461–83; ‡Edward V., 1483; †Richard III., 1483–85.

The House of Tudor.—Henry VII., 1485–1509; Henry VIII., 1509–47; Edward VI., 1547–53; Mary I., the Bloody, 1553–58; Elizabeth, 1558–1603.

The House of Stuart.—James I. (VI. of Scotland), 1603–25; Charles I., 1625–49.

Commonwealth, 1649–59 (see CROMWELL).

The House of Stuart Restored.—Charles II., 1660–85; James II., 1685–88 (expelled); William III. of Orange and Mary II. (d. 1694), 1689–1702; Anne of Denmark, 1702–14.

The House of Hanover.—George I., 1714–27; George II., 1727–60; George III., 1760–1820; George IV. (regent in 1811), 1820–30; William IV., 1830–37; Victoria, 1837.

E. G. RAVENSTEIN.

† Killed in battle. ‡ Murdered or executed.

England, Church of: that portion of the Christian Church which has existed in England since the time of St. Augustine (A. D. 597), the early Church in England being known as the British Church. The title Church of England is also sometimes given to the English Church with reference only to the period since the Reformation, but not with accuracy, since the Church of England, like the other national churches of Europe, is, both in law and fact, a continuous body, and this continuity is recognized by the law of the land, by the acts of Parliament, and by the undisputed succession of bishops in their sees from the time these sees were founded. Christianity was introduced into England, if not in the days of the apostles, at least very soon after them; and it speedily made its way even beyond the limits of the Roman settlements. The abandonment of Britain by the Romans, the invasion of the Saxons, and the consequent neglect or persecution of the native Christians, gave a serious check to the progress of the infant Church, and in the sixth century its influence was limited to the northern part of the island, whither many of the Britons had retired to escape from the invaders. The mission of Augustine, however, was strictly to the heathen Saxons. Pope Gregory the Great had contemplated undertaking this mission in person, but upon his elevation to the papal throne had been compelled to abandon his design. Augustine (or Austin), prior of St. Andrew's monastery at Rome, was selected as his substitute. After a brief delay in France, where he was consecrated bishop by Vigilius of Arles, St. Augustine arrived in Kent in the autumn of 596. His labors were crowned with great though temporary success. The conversion of the kingdom of Kent was followed by the triumph of Christianity in all the kingdoms of the heptarchy. The influence of the Italian missionaries, however, did not extend far, if at all, beyond the limits of the kingdom of Kent. The whole northern part of England was converted by British and Irish clergy, and was governed by bishops of British consecration. There was also, for many years, much jealousy between the native and foreign churchmen, but in process of time the two missions melted into one church, and although it has long been customary to date the historical beginning of the Church of England and the succession of its prelates from the foundation of the see of Canterbury by St. Augustine (A. D. 597), still its historic connection with the ancient British Church should never be forgotten, nor the apostolical succession from the early British bishops, such as Chad of Lichfield, Wilfred of Lincoln and afterward Archbishop of York, and St. David of Caerleon, founder of St. David's, Wales.

At that time there was but one Christian Church, and the doctrines of the Church of England were of course the common faith of Christendom. In considering, as will be done presently, the events of the sixteenth century in England, it should be borne in mind that the abuses which were then removed had no existence in the sixth. The primacy of the pope had not then developed into a supremacy, and, as appears from the letters which passed between Gregory the Great and St. Augustine, the authority of the former was limited to giving advice and counsel. The controversies about image-worship, which gave occasion to the Councils of Nice and Frankfort, did not reach their height until the eighth century. The mediæval teachings of purgatory and pardons were not fully developed until the twelfth, and the growth of the idea of papal supremacy was necessarily kept in check by the Eastern patriarchs until the eleventh. The final impetus was given to its growth by the separation of the Eastern and Western churches, and the general acceptance in the West of the pseudo-Isidorian decretals.

As time went on these teachings made progress in England, as they did in the rest of Western Europe. As the papal authority took the obnoxious form of claiming a right to confirm the nominations of bishops and to hear appeals, it was met with frequent and vigorous opposition—not only in England, but also in the other kingdoms of Europe. Appeals to Rome had been prohibited in England from a very early period, and a vacancy in an episcopal see was apt to lead to a protracted controversy between the pope and the reigning sovereign, neither of whom was willing to admit the pretensions of the other.

When in the reign of Henry VIII. the Church and Parliament of England resolved to put an end to appeals to Rome, and to the claims of the pontiffs to a right to confirm the nominations of bishops (which, under certain circumstances, had been stretched into a claim to nominate in the first instance), they conceived that they were merely re-asserting those ancient rights of the Church of England which, though they had been suffered to fall into disuse, had never been abandoned. This position was taken with great unanimity, and was adhered to consistently by Bishop Gardiner and the national (or, as it might now be called, the old Catholic) party in England. The king was drawn into the violent measures of the dissolution of the monasteries and the spoliation of the Church by other counselors.

The efforts of the Church of England to regain its ancient liberties were contemporaneous with, though distinct from, the continental Reformation. That event, however, was not without its influence in England, and in the reign of Edward VI. men who sympathized with Luther or Calvin, or even with the teachings of Zwingli, had gained control over the English Church and nation. Under their influence England was becoming rapidly Protestantized, and, in all likelihood, had not their career been cut short by the death of the king, the religious condition of England would have been much the same as that of Switzerland or Scotland.

The accession of Queen Mary led to a violent reaction. The Protestant school of Cranmer and Ridley was forcibly suppressed, and the national party, of which Gardiner was the leader, was compelled to change its ground. The authority of the pope was restored in more than mediæval plenitude. Attempts were made not only to revive the state of things which existed in the early part of the reign of Henry III., but actually to destroy the ancient liberties of the Church of England. It is a grave question among historians whether Edward or Mary, both acting doubtless from the most conscientious motives, would, had their reigns been prolonged, have done more serious injury to the Church.

Queen Elizabeth, on coming to the throne, found herself encompassed with difficulties. There were then three schools or parties in the English Church: first, that of Gardiner and his followers, which had changed its ground, and was now disposed to maintain the papal supremacy, with all that it involved; second, that of Parker, which went beyond the former national school in its desire to reform what it believed to be abuses; and third, the Protestants, many of whom had taken refuge in Switzerland during the reign of Mary, and these returned full of admiration of the form of religion which they found established there, and anxious to introduce it into England. The private opinions of the queen, if indeed she had any, were not distinctly known, and it was for some time doubtful to which school she would give her influence and approbation. It may seem strange to minds educated in the ideas of the nineteenth century that the religious belief of great nations should have been directed or influenced by the private opinions of their sovereigns; but in the sixteenth century, and even later, the Church formed a part of the constitution of the nations of Western Europe. There was no idea that there could be more than one religious society in a nation, and therefore no idea of toleration or religious liberty. The history of England in the sixteenth century is not different from that of other European states. If the civil authority could carry out a reformation of religion in England and Sweden, it could suppress it in France and Spain and Italy.

Thus it was the purpose of any party that might succeed in gaining the favor of the queen to become not merely dominant but exclusive. Its peculiar views were to be forced on all men. The Protestant (or, as it was soon afterward called, the Puritan) school speedily put itself out of the question by the fact that its teachings would have led to the destruction of the Church of England, and the establishment of a new form of religion upon the plan adopted at Geneva. Various circumstances tended to alienate the queen from the papal (or, as it began to be styled, the Roman Catholic) party. The haughty discourtesy with which Pope Paul IV. received the information of her accession, which she sent to him in the usual form; the assumption of the title of Queen of England by Mary of Scotland, with the great probability that France and Spain would proceed to assert the claims of the Scottish queen by force of arms; and the persistent attitude of opposition to all reforms maintained by the Marian bishops, compelled Elizabeth to put herself in the hands of the national or reforming party, of which Matthew Parker was the acknowledged leader. Like the national party in the reign of Henry VIII., this school was prepared to remove the jurisdiction which the pope had exercised within the realm of England. Like those earlier leaders, it desired to preserve the faith and discipline of the Church unaltered, but it went beyond them in proposing to remove certain abuses of teaching and practice which it conceived had led the people into superstition. These were the use of images, the invocation of the saints, the popular idea of purgatory, and the peculiar definition of the manner of the Real Presence in the blessed sacrament which is known as transubstantiation. These were doubtless developments, but, in the view of the school of thought which became dominant in England, unlawful developments of true doctrines. The Reformers thought that they could trace the progress of variation from the simpler teachings of the earlier Church, and their purpose was to carry back the Church of England, as nearly as possible, to its primitive simplicity. Whether they succeeded or not is a question which need not be now discussed; it will be sufficient to say that they proceeded to carry out their plans with promptitude and vigor. Parker was made Archbishop of Canterbury in the place of Pole, who had died almost at the same time as Queen Mary. The majority of the bishops, refusing to co-operate with him, were removed or resigned their sees, and their places were filled by men whom he could trust. Attention was at once given to the reform of the service-books of the Church. Two prayer-books, compiled partly from the old Latin Uses of the Church of England, had been set forth in 1549 and 1552, but had been suppressed in the reign of Mary. After much deliberation, it was determined to make the second of these the basis of the Prayer-book, which was henceforth to be in English. The reforms in doctrine to which allusion has been made were indeed carried out, but care was taken to avoid touching any part of the common faith of Christendom. The famous principle of Vincent of Lerins, of universal acceptance as the test of Christian truth, was affirmed, and the authority of general councils was acknowledged. These arrangements received the approbation of Convocation and Parliament. Concessions had been made to both the extreme parties—to the Puritans, in adopting the second instead of the first prayer-book of Edward VI.; to the Roman Catholics, in leaving out certain expressions which were justly obnoxious to them—and it was thought that religious unity would thenceforward prevail in England.

This settlement, the joint work of Convocation and Parliament, was accepted by the great body of the nation; and, since all men continued to frequent the parish churches for about ten years, it was hoped that the unity of the English Church would continue unbroken. In 1570, however, after the excommunication of Queen Elizabeth by Pius V., the party afterward called Roman Catholics, acting under the direction of the pope, separated from the church. In those ages politics and religion were so singularly intermingled in Western Europe that any religious agitation commonly involved plots and treasons against the state, and sometimes open war. In this respect England was no better nor worse than other countries; and in this condition of affairs the true motive is to be found for the stringent laws which were enacted and put in force against "popish recusants." The penal laws, however, were the work of the state rather than of the Church; and they were intended not as a measure of unnecessary persecution, but as a precaution against the plots for the destruction of queen and government, which followed one another in quick succession.

Some of the extreme Protestants followed the example of separation in 1580 under the leadership of Robert Brown, who, however, returned to the Church and died in its communion. They were at first called Brownists or Separatists, afterward Independents, and finally Congregationalists. Others remained in the Church and demanded a further reformation, which, however, has never been conceded. The Prayer-book has indeed been twice revised, but the tendency on both occasions has been to bring it into nearer accordance with the first book of Edward VI., which is supposed to have contained the true sentiments of the earlier Reformers.

The remaining history of the Church of England may be passed over briefly. After its suppression during the civil war—the success of which has, by some writers, been attributed to a temporary though secret combination between the extreme sections of its enemies—it was restored in 1660, since which time no change has been made in its doctrine or discipline. In 1662 the Book of Common Prayer, as now established, was set forth. The changes which were made in this book were in the direction of a clearer setting forth of the Catholic position of the Church, and expressly made the reception of episcopal ordination necessary for holding benefices. The Act of Uniformity emphasized this position of the ordinal, thus summarily ejecting the intrusive ministers of various ordinations, or of none at all, from the cures they had occupied during the great rebellion. The exciting scenes of the sixteenth and seventeenth centuries, the successive attempts to restore the supremacy of the pope, culminating in the ill-advised measures of James II. and the consequent irritation of the people, led, first, to a reaction, and after the revolution of 1688 to a long period of religious indifference. The latter part of the seventeenth century was an age of immorality; the earlier part of the eighteenth was a time of negligence and indifference. Since the middle or early part of the eighteenth century there have been three great religious revivals. The first was that of John and Charles Wesley, both priests of the Church of England, who set themselves to the task of developing personal holiness (the great want of an age of religious indifference and immorality) in the members of their Church. Their labors were crowned with great and immediate success; but, partly by reason of the absence of encouragement from the leaders of the Church, and partly from the impatience of some of their own followers, they failed in accomplishing their designs. The Wesleys themselves lived and died in the communion of the Church, but many of their followers withdrew from it and formed a new body of Dissenters.

The second revival was that of the "Evangelicals," as they were called, about 1798, of which such men as the Rev. Charles Simeon, of Cambridge, and Bishop Daniel Wilson, Metropolitan of Calcutta, were the leaders. The guiding thought in this movement also was the development of personal holiness. The movement was well adapted to the times, and may be regarded as successful while it lasted, but it lacked the elements of permanence. Its weakness lay in neglecting definite dogma, which experience has shown to be essential to any form of religion. The work of these good men, however, is worthy of all reverence. They accomplished a great deal in their generation, and they prepared the way for the revival which is now in progress.

The third revival was the movement indicated by the term TRACTARIANISM (*q. v.*). While the aim of the Oxford divines, as its leaders were called, was, equally with the others, the development of personal holiness, they endeavored to avoid the tendency of the first to schism, and of the second either to neglect dogma altogether or to give undue prominence to one or two points of Christian doctrine. Hence they naturally dwelt much upon the authority of the Church; and their object seems, in their early history (1833–63), to have been simply to teach the Church to carry out in practice the doctrine, discipline, and manner of life which are set forth in the Prayer-book. Later, however, the leaders of this school have given much thought to the relations of the Church of England to the rest of Christendom, and to the question of the restoration of visible unity among Christians. These points are discussed in the *Eirenicon* of the celebrated Dr. Pusey. Hence much attention has been given to the study of church history, and the history of the English Church may be said to have been rewritten since 1833.

Both these schools still exist, and are commonly known as Low Church and High Church. The former claims, and no doubt justly, to be the representative of the Protestant or Puritan part of the Church in the reign of Elizabeth; the latter, of the Catholic or national school, which then gained the predominance, and, with the exception of the forty years of the evangelical revival, has always retained it. The peculiar character of the former is its claim to great liberty of private judgment; of the latter, its deference to authority. With the exception of a small party known as Broad Church, of which Frederick William Robertson, of Brighton (d. 1853), and Frederick Denison Maurice (d. 1872) were among the founders, and Dean Stanley was one of the leaders, and which is somewhat eclectic in its teachings, these two great historical schools may be regarded as comprising the whole Church of England.

The discipline of the Church of England has continued unchanged for many centuries. The bishoprics, with the addition of two or three which were created by Henry VIII., and those of Ripon, Manchester, St. Albans, Truro, Liverpool, Wakefield, Newcastle-on-Tyne, and Southwell, erected within the nineteenth century, still remain in their ancient seats; and the succession of the bishops, of whom lists are extant, is traced in them to the sixth or seventh century. England and Wales are divided into two provinces, under the Archbishops of Canterbury and York. The former has under him a larger number of bishops than the latter. The episcopal incomes amount to about £156,000. The population of England and Wales is about 30,000,000; the church sittings are estimated at over 6,000,000. The actual population connected with the Established Church is about 18,000,000. The system of parishes introduced by Theodore, the seventh Archbishop of Canterbury (668–693), still exists. The number of parish priests and curates is upward of 25,000. There are about 11,600 schools under the care of the Church, and 30 training colleges for teachers. The canon law, derived from the acts of successive English councils, antedating Parliament and the English constitution itself, still forms the basis of the ecclesiastical system. The annual revenue of the Church, the greater part of which is derived from ancient endowments, is estimated at £7,000,000. During 1900 the amount received by the Church by voluntary contribution for elementary education was £1,177,288 15*s.* 7*d.*: the contributions to foreign missions, exclusive of funds derived from rents, dividends, or interest, balances on hand from previous years, or foreign contributions, was £772,246 9*s.* 1*d.*; amount of voluntary offerings for the building, restoration, and furnishing of churches, endowment of benefices, building of parsonages, and the enlargement of burial-grounds, about £1,000,000; amount of voluntary offerings for home missions, temperance work, clubs, and charities, about £548,881 4*s.* The total voluntary contributions for the year 1900 amounted to £7,464,434 4*s.* 11*d.*

The great achievement of the English Church during the nineteenth century has been the increase of the colonial episcopate. The first colonial bishop was Dr. Charles Inglis, consecrated Lord Bishop of Nova Scotia Aug. 12, 1787. Bishop Heber was sent to Calcutta in 1814. In 1892 there were 77 dioceses in the British colonies and in missions, and about 3,500 clergymen. These numbers are constantly increasing.

From time immemorial the Archbishop of Canterbury has been held to be entitled to the dignity, though he has never borne the name, of a patriarch. That this is something more than an empty dignity would seem to be implied by the unanimity with which Archbishop Longley was accepted as a president of the conference or synod of bishops which sat at Lambeth, London, in 1867, and by the general disposition to consider him as the spiritual head of the Anglican communion, saving, of course, the rights of autonomous churches. This includes the Church of England (with Wales), of Ireland, the Church in the colonies, and the Episcopal Church in Scotland and in the U. S. of America. These churches, while they are one in doctrine, regulate their internal affairs for themselves, yet they may meet, as they have done thrice, in a synod of their bishops when any question of general interest arises. The whole number of episcopal sees and jurisdictions, as at present arranged, is nearly or quite 200, though the actual number of bishops, including those retired from their sees but still living and often actively at work, is considerably larger. There are nearly or quite 30,000 priests and deacons.

LITERATURE.—Bede, *Opera*, edited by Giles (12 vols., Oxford, 1843–45); Ussher, *Ed. Britannicarum Antiquitates*, edited by Elrington (16 vols., Dublin, 1847–62); Thomas Fuller, *Church History of Britain* (1655; best edition by Nichols, 3 vols., London, 1868); Jeremy Collier, *Ecclesiastical History of Great Britain* (1708; best edition, 9 vols., London, 1840); Cardwell, *Documentary Annals of the Reformed Church of England* (Oxford, 1839–42); G. G. Perry, *History of the Church of England* (3 vols., London, 1864; new ed., 1881; reprinted with a chapter on the American Episcopal Church by Rev. Dr. J. A. Spencer, 1878); J. Stoughton, *Ecclesiastical History of England* (7 vols., London, 1867–78); R. W. Dixon, *History of the Church of England from the Abolition of the Roman Jurisdiction* (4 vols., London, 1878–91); F. G. Lee, *The Church under Queen Elizabeth* (2 vols., London, 1880); A. H. Hore, *Eighteen*

Centuries of the Church of England (Oxford, 1881). Especially on church-law, see Blunt and Phillimore, *Law of the Church of England* (2 vols., London).

BEVERLEY R. BETTS.
Revised by WILLIAM STEVENS PERRY.

England, JOHN, D. D.: ecclesiastic; b. in Cork, Ireland, Sept. 23, 1786. He was educated at Carlow College, and took orders in the Roman Catholic Church in 1808. He was soon after appointed lecturer at the North Chapel and chaplain of the prisons, and in 1809 he began the publication of the *Religious Repertory*, a monthly. He was greatly distinguished for his zeal, his benevolence, and his bold championship of Catholic emancipation. He was also a prominent journalist, and was once fined £500 for his boldness in discussing political questions. In 1820 he became Bishop of Charleston, S. C., and there founded the *Catholic Miscellany*, the first journal of his Church in the U. S. His works, in five volumes, appeared in Baltimore 1849. Bishop England's heroic behavior during an epidemic of yellow fever in Charleston endeared him to all classes of citizens. He was a man of great energy and profound learning. D. in Charleston, S. C., Apr. 11, 1842.

England, Sir RICHARD, G. C. B.: general; b. in Detroit, Mich., in 1793; son of Lieut.-Gen. Sir Richard England, an officer of Irish origin, distinguished in the British service during the Revolutionary war in North America. The younger Sir Richard entered the British army at the age of sixteen, and served against Napoleon I. He subsequently gained distinction in South Africa, India, Afghanistan, and the Crimea, and was made a full general in the army in 1863. He also became a grand officer of the Legion of Honor, colonel of the Forty-first Foot, etc. D. Jan., 1883.

Engles, WILLIAM MORRISON, D. D.: author; b. in Philadelphia, Pa., Oct. 12, 1797; graduated at the University of Pennsylvania in 1815. In 1820 he became pastor of the Seventh Presbyterian church in Philadelphia; in 1834 editor of the *Presbyterian*; and in 1863 president of the Presbyterian Board of Publication. He published *Records of the Presbyterian Church* (Philadelphia, 1840); a *Bible Dictionary* (1850); *Sailor's Companion* (1857); *Sick-room Devotion* (1846); *Soldier's Pocket-book* (1861); and other works, chiefly devotional. D. in Philadelphia, Nov. 27, 1867.

Englewood, eng'l-wŏŏd: town and railway junction, now incorporated in Chicago; Cook co., Ill. (for location of county, see map of Illinois, ref. 2–C). It is the site of the county normal school (opened in 1868), which has a normal department, a training-school, and a high-school department.

EDITOR OF "CALL."

Englewood: city (1896); Bergen co., N. J. (for location, see map of New Jersey, ref. 2–E); on N. R. R. of New Jersey; 14 miles N. of Jersey City, near the Palisades of the Hudson river. Englewood township was organized in 1871 from part of Hackensack. Pop. (1890) 4,785; city (1900) 6,253.

English: a term used in billiards. See BILLIARDS.

English, EARL: rear-admiral U. S. navy; b. in Burlington co., N. J., Feb. 18, 1834; entered the navy as a midshipman Feb. 25, 1840. He was in the engagement with the Barrier forts at the entrance to the Canton river, China, in 1856, and during 1862 and 1863 commanded several vessels of the Gulf blockading squadron. In 1864 and 1865 he commanded the steamer Wyalusing of the North Atlantic blockading squadron, and in Oct., 1864, took part in the capture of Plymouth, N. C. Retired Feb. 18, 1886. D. at Washington, D. C., July 16, 1893.

English, GEORGE BETHUNE: adventurer and author; b. at Cambridge, Mass., Mar. 7, 1787; graduated at Harvard in 1807; was admitted to the bar, next was licensed to preach; published in 1813 *The Grounds of Christianity Examined*, a work favoring Judaism, which was replied to by Edward Everett and others, and was followed on English's part by *Five Smooth Stones out of the Brook* (1815). After editing a newspaper for a short time, English entered the U. S. navy, but soon resigned to enter the Egyptian service, and gained distinction as an officer of artillery. Subsequently he was U. S. agent in the Levant; returned to the U. S. in 1827. Among other works published by him was a *Narrative of the Expedition to Dongola and Sennaar* (1823). D. in Washington, D. C., Sept. 20, 1828.

English, JAMES EDWARD: statesman; b. in New Haven, Conn., Mar. 13, 1812; became a successful merchant and manufacturer; Democratic member of Congress 1861–65; Governor of Connecticut 1867–69 and 1870–71. He was appointed to fill a vacancy in the U. S. Senate caused by the death of Orris S. Ferry, Nov. 21, 1875, and was nominated for Governor of Connecticut by the Democrats Aug. 18, 1880. D. in New Haven, Mar. 2, 1890.

English, THOMAS DUNN: poet, lawyer, and physician; b. in Philadelphia, Pa., June 29, 1819; graduated at the medical school of the University of Pennsylvania 1839; was admitted to the Philadelphia bar in 1842; edited some short-lived periodicals; became in 1859 a medical practitioner near New York city. Among his works are several successful dramas, numerous novels, among them *Walter Woolfe* (1844), a volume of poems (1855), and *American Ballads* (1882). The best known of his poems is the popular ballad, *Ben Bolt*.

Revised by H. A. BEERS.

English, WILLIAM HAYDEN: lawyer and politician; b. at Lexington, Ind., Aug. 27, 1822; educated at South Hanover College; practiced law, and was postmaster of Lexington, Ind.; clerk of Indiana House of Representatives in 1843; was four years in the U. S. Treasury department; secretary in 1850 of convention at Indianapolis to revise the constitution of Indiana; member of Indiana Legislature in 1851, and of the U. S. House of Representatives in 1852; was three times re-elected to the latter, retiring in 1860; president of First National Bank of Indianapolis 1863–87; was nominated for Vice-President of the U. S. by the Democratic convention at Cincinnati, O., June 24, 1880. He was president of the Indiana Historical Society, and the author of works on the History and Constitution of that State. D. in Indianapolis, Feb. 7, 1896.

English Channel (in Fr. *La Manche*, the sleeve): that portion of the Atlantic which separates England from France. It extends on the English side from Dover to Land's End, and on the French from Calais to the island of Ushant. On the E. it communicates with the German Ocean by the Strait of Dover, 21 miles wide, and on the W. it opens into the Atlantic by an entrance 100 miles wide. Its greatest width is about 150 miles. On the English side, off the coast of Hampshire, lies the beautiful Isle of Wight. Guernsey, Jersey, and the other Channel islands are situated off the north coast of France. The channel has a current that sets from the westward, and it is noted for its roughness, which causes its passage to be dreaded by tourists.

English Gothic, or **Gothic**: See FAN VAULTING.

English Harbor: one of the finest ports in the West Indies; on the south side of the island of Antigua; in lat. 17° 3′ N., lon. 61° 45′ W. It is capable of receiving vessels of the largest class, has a dockyard and a naval hospital, and is perfectly sheltered in all winds.

English Language: the language of the people descended from the Germanic tribes which, in the fifth century or earlier, took possession of the greater part of the island before known as Britain. From the time of their settled possession of that country their language was called English, and their land England, at home and abroad. The term Anglo-Saxon, employed before the year 1000 to distinguish the Saxons of England from those of the Continent, but never to designate their language, was, on the revival of Old English learning after 1600, employed by historians and philologists to denote the entire English people and language before the Norman conquest. The name Anglo-Saxon, properly understood, never signified a union of Angles and Saxons, but, as stated above, English Saxons; it is important to bear this fact in mind, since the opposite view is suggested by the fact that the invaders of England were chiefly composed of two tribes, the Angles and the Saxons, with whom, in smaller numbers, were another tribe called the Jutes, of whom little more is known than their name. As nearly as can be ascertained, the Saxons came from the region between the Elbe and the Rhine, the Angles from the district still called Angeln, in the south of Schleswig, and the Jutes from the north of Schleswig.

Affinities of Native English.—These tribes were an offshoot of that branch of the Indo-European, or Aryan, race known as the Germanic or Teutonic family, which itself branched into two divisions—the East Germanic and the West Germanic. To the East Germanic branch are assigned the Scandinavian tongues, subdivided into East and West Scandinavian, and the Gothic. The Scandinavian division went northward; its representatives are now the people of Norway, Sweden, Iceland, and Denmark. The Gothic branch was the southernmost. It has perished by absorption, and the only remnants of its language, which has been dead for nearly a thousand years, are a mutilated translation of the Gospels, St. Paul's Epistles, Esdras, and Nehemiah, made by Bishop Ulfilas about A. D. 350, together with a calendar. The West Germanic branch filled the country now somewhat vaguely known as Germany. Of this two branches are distinguished—the High Germanic, the language of Upper or Southern Germany, and the Low Germanic, the language of Northern Germany and the Netherlands. Among the various subdivisions of Low Germanic the chief ancient ones, besides Old English, are the Old Saxon and Frisian; the chief modern ones are Dutch and Flemish. The English language is therefore, by origin and main affinity, a Low German tongue. Among living tongues it is nearest of kin to the Frisian, which is still spoken in a few places on the shore of the North Sea, on the borders of Holland, nearest to Denmark. Accordingly, English may be classed as a member of the Anglo-Frisian group of the Low Germanic languages (cf. Siebs, *Zur Geschichte der Englisch-Friesischen Sprache*, Halle, 1889). The English, or "Anglo-Saxon," language must have been spoken in the country from which the Angles and the Saxons came, but no trace of it was left there, chiefly because the emigration of the people to Britain was so complete that it left the country for a time almost deserted.

Periods of English.—The changes which have taken place in the language have indeed been considerable, but they have been effected so gradually that it is difficult to lay down fixed lines of demarkation between the successive stages. Three periods, however, stand out with sufficient clearness in their main features, though they shade off at beginning and end in a manner which precludes the assignment of any other than approximate dates. The first extends from the English occupancy of Britain till about the year 1200, and is known as Old English. The second extends from 1200 or thereabouts till the neighborhood of 1500, and is called Middle English. The third extends from 1500 to the present day, and is that called Modern English. There are different points of view from which these periods might be characterized, but the accepted basis of classification is inflection. According to this, Old English is the period of *full* inflections (*mōna*, *sunne*, *sunu*), Middle English is the period of *leveled* inflections (*mōne*, *sunne*, *sune*), and Modern English is the period of *lost* inflections (*moon*, *sun*, *son*). Each of these periods may in turn be subdivided into *early* and *late*, and, in addition, periods of transition between the principal stages may be recognized. The latest attempt to assign dates to these various periods is by Dr. Henry Sweet, in his *New English Grammar*. His classification is as follows:

Early Old English (English of Alfred)	700–900
Late Old English (English of Ælfric)	900–1100
Transition Old English (English of Layamon)	1100–1200
Early Middle English (English of the Ancren Riwle)	1200–1300
Late Middle English (English of Chaucer)	1300–1400
Transition Middle English (Caxton English)	1400–1500
Early Modern English (Tudor English; English of Shakspeare)	1500–1650
Late Modern English	1650–

Dialects.—In Old English there were two main dialects, possessing strongly marked characteristics, the Northern and the Southern, or the Anglian and the Saxon. The Anglian dialect, which was more nearly akin to the Frisian and the Scandinavian, comprised the Northumbrian and the Mercian; the Southern dialect, more archaic and less progressive, included the West Saxon and the Kentish. The chief representatives of these dialects in the Old English period are the Northumbrian and the West Saxon respectively; of each of these there are specimens representing both an early and a late period, while of Mercian, for example, only the later period has remains, and these suspected of admixture with West Saxon. Northumbrian was the literary language of England in the seventh and eighth centuries, but was largely supplanted by West Saxon in the ninth, tenth, and eleventh; hence it is that most of the poetry, though probably composed in Northumbrian, is now extant only in a West Saxon transcription, in which, however, Northern elements and forms can still be discerned.

In the Middle English period a third principal dialect was added to the Northern and Southern, namely, the Midland or Mercian. The Mercians, men of the "march" or boundary (cf. the Welsh and Scottish Marches), inhabited the district between the Thames and the Humber, while the Northumbrians, as the etymology of the name signifies, dwelt north of the Humber, as far as the Firth of Forth, and the Saxons were settled for the most part south of the Thames, and well on toward the west. The Mercian of the older period, as already stated, is represented by but scanty and uncertain remains, but in the Middle English time, under the name of the Midland speech, it emerges into prominence, and becomes the basis of the standard or literary English tongue. The existence of the dialect, as well as one of the reasons for its prominence, is authenticated by the testimony of Higden, a writer of the first half of the fourteenth century. The passage, as translated by John Trevisa, is in part as follows: "Also Englysch men . . . hadde fram the bygynnyng thre maner speche, Southeron, Northeron, and Myddel speche (in the myddel of the lond), as hy [i. e. they] come of thre maner people of Germania. . . . Men of the Est with men of the West, as hit [i. e. it] were undur the same party of hevene, acordeth more in sounyng of speche than men of the North with men of the South; therfore hyt is that Mercii, that buth [i. e. beeth, are] men of Myddel Engelond, as hit were parteners of the endes, undurstondeth betre the syde longages, Northeron and Southeron, than Northeron and Southeron undurstondeth eyther other." The emergence of the Midland dialect was accompanied by an all but total disappearance of the Northern; that is, from toward the end of the tenth century till toward the end of the thirteenth no Northumbrian documents are found; the Southern, on the other hand, continued to flourish.

In Modern English, the Scotch of Burns and other Lowland writers represents the Northumbrian; the standard literary language in the main represents the Mercian or Midland; while the Southern may be studied in William Barnes's *Poems of Rural Life.* The following specimen of the modern Southern dialect is from Barnes's lyric, *The Spring*:

When wintry weather's all a-done,
An' brooks do sparkle in the zun,
An' nâisy-builden rooks do vlee
Wi' sticks toward their elem tree;
When birds do zing, an' we can zee
Upon the boughs the buds o' spring—
Then I'm as happy as a king,
A-vield wi' health an' zunsheen.

But besides the modern English dialects represented in literature, there are a large number which exist only as forms of popular speech in the mouths of the illiterate, and which stand for varieties or blendings of the great dialects described above.

Old English.—Old English (700–1200) was the most highly cultivated of the Teutonic languages of its time; it was adequate for the accurate and easy translation of the Latin classics, and it has original literature worthy of study. Its chief interest, however, is as the mother tongue of the English. It has given us the names of the objects, relations, and affections which we speak of most, the words laden with the dearest associations, the idioms on which the beauty of our poetry and the power of eloquence, wit, and humor depend. From it almost all our grammatical forms are derived. It furnishes modern standard English with its strength, its stability, its vitality, and its real character. It is the distinctive element of our speech; and not only so, but it forms, except from a lexicographer's point of view, the bulk of the spoken language. If all other elements were taken away, the language would still exist with its life and vigor unimpaired. We could live and love and hate and work and play and worship, and express all our wants and feelings, tell tales and sing songs. But were this element to be removed, the language would fall to pieces in heterogeneous, disconnected, and lifeless masses. And yet in all copious dictionaries of the English language the words of other than purely English origin constitute three-fourths of the whole vocabulary. This seeming paradox is owing to the fact that all or almost all our words of commonest and most necessary use, including those particles which connect the others and modify their meaning, are pure English, while those which belong to literature, science, and art, which express abstract ideas and the subtle variations of thought, are, in the main, of foreign, and chiefly of Romanic, origin. The words which are used by all, men, women, and children, learned and unlearned, and used by all most often, belong to the former class; those which are used chiefly by the more or less learned classes, and much the greater number of them rarely even by these, belong to the latter. This is a phenomenon which appears in no other language, at least in anything like so great a degree. It makes modern English a two-sided—and, as we have words of both classes for many nearly identical thoughts and things—almost a double-faced language.

Influences Affecting Old English.—The English language, as it was taken into Britain by the men who were to supplant the Britons and to change the very name of the country, was simple and unmixed, except for a small proportion of Latin words, acquired by our continental ancestors through their intercourse with the Romans; and, for the most part, it so remained for centuries. The Celtic dialect of the subdued Britains had but little influence upon the sturdy speech of the Teutonic invaders, who ere long filled the whole island from the Grampians to the English Channel with their language as with themselves.

More influence was exerted by the Latin, which was constantly being read, translated, and imitated by learned men, who were then almost exclusively the clergy. Soon after the landing of Augustine and the missionaries accompanying him (A. D. 597), excellent schools were established, and the culture of the time, largely contained in the works of the Christian Fathers, but to some extent also in classics like Vergil and Horace, was enthusiastically fostered in England. In the year 669 Archbishop Theodore, a native of Tarsus, in company with Abbot Hadrian, an African by birth, arrived at Canterbury, and immediately established a school. The historian Bede relates of them (bk. 4, ch. ii.): "And forasmuch as both of them were, as has been said before, well read both in sacred and secular literature, they gathered a crowd of disciples, and there daily flowed to them rivers of knowledge to water the hearts of their hearers; and together with the books of Holy Writ, they also taught them the arts of ecclesiastical poetry, astronomy, and arithmetic. A testimony of which is that *there are still living at this day some of their scholars, who are as well versed in the Greek and Latin tongues as in their own, in which they were born.*" The same statement is explicitly made concerning Abbot Albinus (bk. 5, ch. xx.) and Bishop Tobias (bk. 5, ch. xxiii.). The consequence is that there is found in the Old English writings no inconsiderable number of Latin words, chiefly those in ecclesiastical use, many of which had been naturalized from the Greek. Prof. Lounsbury says (*History of the English Language*, p. 42): "Before the Norman Conquest six hundred words at least had been introduced from Latin into the Anglo-Saxon. Some of them occur but once or twice in the literature handed down, others are met with frequently. Were we to include in this list of borrowed terms the compounds into which the borrowed terms enter, the whole number would be swelled to three or four times that above given. It is also to be marked that not only were nouns directly borrowed, but also adjectives and verbs, though to a far less extent." This computation doubtless includes the words which our ancestors brought with them from the Continent, and which have only recently been distinguished from the later borrowings (Paul, *Grundriss der Germanischen Philologie*, vol. i., p. 309 ff.), but a goodly residue will still be left, including words not confined to ecclesiastical usage, but yet familiar to the monks and clergy. From these classes may be instanced such as *mæsse*, mass (Lat. *missa*); *prēost*, priest (Lat. *presbyter*); *mynster*, monastery (Lat. *monasterium*); *sealm*, psalm (Lat. *psalmus*); *scōl*, school (Lat. *schola*); *popæg*, poppy (Lat. *papaver*); *pihten*, comb (Lat. *pecten*); *rose*, rose (Lat. *rosa*); *dihtian*, compose (Lat. *dictare*), etc. But the influence of Latin upon Old English was not confined to the vocabulary. It must also have had a considerable effect upon the syntax, though the latter has not been sufficiently investigated to enable positive and specific statements to be made.

Less important was the Scandinavian influence due to the incursions and settlements of the tribes which history conveniently comprehends under the general title of the Danes. They began their inroads near the close of the eighth century, and effected a permanent settlement as early as 855. They at last distributed themselves over the northeastern part of the island, and even obtained control over it, under Cnut, for about fifty years. When they were driven out as a ruling power they left behind them, of course, many descendants, and also memorials of their presence in many words which had been taken into the language, and in many names of places. The termination *by*, as in Derby, Whitby, Naseby, Holdenby, etc., marks their presence, but so do also a number of words occurring in Late Old English, especially in the English Chronicle and the Laws. Examples are *eorl*, earl (Old Norse *jarl*); *cnīf*, knife (O. N. *knīfr*); *ūtlah*, outlaw (O. N. *ūtlagr*); *wrang*, wrong (O. N. *vrang*). A full list of the words thus far discovered may be found in Paul, *Grundriss der Germanischen Philologie*, vol. i., pp. 786–787, though this by no means represents all that must have been borrowed before the Norman conquest, since literature, and especially if scanty in amount, is but an imperfect record of speech, and the large number of Scandinavian words found in the Middle English period points to the same conclusion.

A Specimen of Old English Prose.—Before stating the grammatical characteristics of Old English, a short specimen will be given of the language in its Late Old English stage:

"Ðā-ðā hig fērdon, ðā cōmon sume ðā weardas on ðā ceastre, and cȳðdon ðǣra sācerda ealdrum ealle ðā ðing ðe ðǣr gewordene wǣron. Ðā gesamnodon ðā ealdras hig and worhton gemōt, and sealdon ðǣm þegnum mycel feoh, and cwǣdon, Secgeað ðæt hys leorning-cnihtas cōmon nihtes, and forstǣlon hyne, ðā wē slēpon."

This passage is not to be understood by any reader, however intelligent and well instructed, who has not made a special study of the language in which it is written, although its meaning is familiar to almost every person, literate or illiterate. Only three words, *and*, *we*, and *hys*, would seem to him at all vernacular, and yet it was the everyday English of English people who lived in England. It is the Old English version of verses 11, 12, and 13 of Matthew, ch. xxviii. with our present version of which it would be well to compare it:

"Now while they were going, behold, some of the guard came into the city, and told unto the chief priests all the things that were come to pass. And when they were assembled with the elders, and had taken counsel, they gave large money unto the soldiers, saying, Say ye his disciples came by night and stole him away while we slept."

Strange and foreign to us as at first the passage seems—as foreign as French or German—a brief examination of it will make clear to any person, although entirely unacquainted with Old English, that it is written in a tongue with the accents of which he is not entirely unfamiliar. *Fērdon* is fared, went; *cōmon*, came; *sume*, some; *weardas*, wards, watch; *ceastre*, caster, city (as in Lancaster); *sācerda*, priests (sacred persons); *ealdrum*, elders; *ealle*, all; *wǣron*, were; *worhton*, worked; *gemōt*, a meeting; *sealdon*, sold, gave; *þegnum*, thanes; *mycel*, mickle, much; *feoh*, fee, pay, money; *secgeað*, say; *leorning-cnihtas*, learning-knights, disciples; *nihtes*, (o') nights; *forstǣlon*, stole; *hyne*, him; *slēpon*, slept. It thus appears that almost all the words in this passage are essentially English now, though it must be borne in mind that the Modern English word is not in all cases the *direct* descendant of the Old English word here given (e. g. *worhton* gives *wrought* rather than *worked*, and *him* and *slept* come from *collateral* forms of *hyne* and *slēpon*, that is from the dative *him* and the *weak* preterit *slǣpton*). In the lapse of eleven hundred years they have changed somewhat in form, and somewhat, but not vitally, in meaning.

Pronunciation of Old English.—The vowels sounded nearly as in German: *a* as in *far*, but shorter; *ā* as in *far*; *æ* as *a* in *glad*; *ǣ* as *a* in *dare*; *e* as in *let*: *ē* as in *they*; *i* as in *dim*; *ī* as *ee* in *deem*; *o* as in *opine*; *ō* as in *holy*; *u* as in *full*; *ū* as *oo* in *fool*; *y* like the French *u* or the German *ü*; *ȳ* the same sound prolonged.

The diphthongs *ea*, *eo*, *ie*, both short and long, are pronounced like combinations of the respective vowels; but the stress is always upon the first vowel of the combination, the second reducing to a neutral sound, scarcely more than a glide. The consonants are pronounced nearly as in modern English. Still, it must be observed, *c* is sometimes *k*, sometimes nearly *ch*; *f* between vowels, occasionally elsewhere, has the sound of *v*, *s* of *z*, and ð (þ) of *th* in *the* (otherwise as *f*, *s*, and *th* in *thin*); *g* is sometimes hard *g*, sometimes nearly *y*; *cg*, which stands for *gg*, almost like *dg* in *bridge*; *h*, when not initial, sounded like *ch* in German *ich*, *auch*. It is to be noted that there are no silent letters in Old English; every vowel and consonant was pronounced, though the vowels of unstressed syllables had a less distinct sound.

Phonology of Old English.—The phonological system of Old English, or the relations of its speech-sounds among themselves and to those of its sister languages, is too complicated for exposition here. The most important modifications to which vowels are subject through the influence of other sounds within the same words are umlaut and breaking. Umlaut is the change effected in the vowel of a root-syllable by the anticipation of a vowel of a following unstressed syllable. When the latter vowel is *i* (or *y*, represented by *j*) the change is called *i*-umlaut; when *u* or *o*, these vowels give name to the umlaut. The latter is less important; the former causes such phenomena as are observable in *man, men*; *goose, geese*; *mouse, mice*. In Old English these pairs occur as *mann, menn*; *gōs, gēs*; *mūs, mȳs*. In a prehistoric stage of the language they would have been *mann, manni*; *gōs, gōsi*; *mūs, mūsi*. The tendency to anticipate the sound of *i* (ĭh) while pronouncing the root-syllable led to a blending of it with that of the root-vowel: *a* blended with *i* gave *e*; *ō* with *i*, *ē*; *ū* with *i*, *ȳ*. In the *u*- and *o*- umlaut the process was the same, but the number of words affected was much smaller.

Breaking is the effect produced by *l* and *r* when followed by a consonant, and by *h* when final or followed by a consonant, upon a preceding *e* or *æ* (from *a*). This effect is due to a deep, guttural pronunciation of the consonant, which rendered it difficult to pass from the vowel sound to it without the generation of an intermediate vowel. This intermediate vowel, neutral or obscure in sound, was represented by *a* or *o*. Thus *hærd*, hard (for *hard*), became *hæard*, and *erðe*, earth, became *eorðe*; *hæard* was then spelled *heard*, though the sound of *æ* was retained. A similar phenomenon may be observed in Shakspeare, where certain monosyllables containing *l* or *r* are pronounced almost as disyllables. Compare, for example, the following line from Henry VIII. (iii. 2, 117):

> Strikes his breast hard and anon he casts,

where *hard* is pronounced almost like *hah-urd*, as the meter shows.

Ablaut is another phonological trait of Old English, though it did not originate there. It is the vowel-variation familiar to us in such words as *sing, sang, sung*; *drive, drove, driven*. Its cause is obscure, and any attempt at explanation would transcend our limits.

In general, it may be said that the influence of neighboring sounds upon each other is greater than in Modern English, and hence the language appears more unstable and, as it were, fluid. The fixity of Modern English spelling, however, tends to conceal the changes which are now taking place.

Old English an Inflectional Tongue.—Old English was a synthetic or inflectional language; that is, it, like the Latin and the Greek, expressed time, condition, number, and person by changes in the forms of words, and only exceptionally by the use of "auxiliary" words.

Thus, in the passage quoted above, *-on* is the sign of the pret. plural of the verbs; *-as* (*weardas, cnihtas*) indicates the nom. (acc.) plur. of the most numerous class of strong nouns; *-a* (*sācerda*) is the sign of the genitive plural; *-um* (*ealdrum*) that of the dative plural, etc.

Inflection of Nouns.—There was a threefold grammatical gender in Old English. Besides, a noun of any gender might be of either the strong or the weak declension. In the weak declension the oblique cases were formed by the addition of *n*, with or without other letters, as the case might be; in the strong declension *n* was not used for this purpose. There were four cases: nominative, accusative, genitive, and dative, the first and second being often alike. The dat. plur. always ended in *-um*, and the gen. plur. in *-a* or *-ena*. The inflection of a strong masculine, *fisc*, fish, is as follows: nom. acc. *fisc*, gen. *fisces*, dat. *fisce*; pl. nom. acc. *fiscas*, gen. *fisca*, dat. *fiscum*. If the stem contained *æ*, as in *dæg*, day, this vowel became *a* in the plural. Neuters of this declension inflect like masculines, except that the pl. nom. acc. is formed in *-u*, which is lost after a long root-syllable: *scipu*, ships; *word*, words. Disyllabic nouns generally lose the vowel of the second syllable before all endings, when the stem is long by nature or position, if the second or unstressed syllable is not long by position: thus nom. *engel*, angel, *dryhten*, lord, gen. *engles*, *dryhtnes*, not *engeles*, *dryhtenes*. There is a class of so-called umlaut masculines which form the dat. sing. and nom. acc. plur. by umlaut of the radical vowel, and without ending, the other cases being regular. Thus *fōt*, foot, has the dat. sing. and nom. acc. plur. *fēt*; *mann*, man, forms the same cases in *menn*, etc.

Strong feminines have a declension of their own. If the stem is short, the nom. sing. ends in *-u*, like the nom. acc. plur. of neuters; if long, it is monosyllabic, again like the same neuters. The declension of *giefu*, gift, is as follows: nom. *giefu*, gen. dat. acc. *giefe*; pl. nom. acc. *giefa*, or *giefe*, gen. *giefa*, sometimes *giefena*, dat. *giefum*. *Glōf*, glove, a long stem, has the oblique cases and the plural like *giefu*. The acc. sing. of a tolerably large class of feminine long stems takes no ending. A few feminines take an umlaut declension, like the masculines mentioned above; among them are *gōs*, goose, *mūs*, mouse, *bōc*, book, *burg*, city. Besides the dat. sing. and nom. acc. plur., these occasionally form the gen. sing. in the same way. These cases of the words specified are accordingly *gēs*, *mȳs*, *bēc*, and *byr*(*i*)*g* respectively, from the first two of which came Mod. Eng. *geese* and *mice*.

The weak declension of masculines is as follows: nom. *oxa*, ox, acc. gen. dat. *oxan*; pl. nom. acc. *oxan*, gen. *oxena*, dat. *oxum*. There are but two weak neuters: *ēage*, eye, and *ēare*, ear; they decline like the masculines, except that the acc. sing. is like the nom. Weak feminines are decidedly fewer than the masculines; they have the nom. sing. in *-e*, instead of the masc. *-a*, but otherwise resemble them in declension.

Proper names, when native, are declined like common nouns; when foreign, they sometimes retain their original declension, either wholly or in part, and are sometimes treated as if native.

Inflection of Adjectives.—Adjectives, like nouns, have two declensions, a strong and a weak, but, unlike nouns, it is the same adjective which takes either strong or weak endings, according to circumstances. Adjectives are inflected weak when in the comparative, and usually when in the superlative, when ordinals, when preceded by a demonstrative, and sometimes when preceded by a possessive pronoun of the first or second person. Otherwise the strong form is used. The weak declension is precisely the same as that of nouns, except that the gen. plur. usually takes *-ra* instead of *-ena*. Adjectives, when strong, are declined like the corresponding nouns of the various genders, with the following exceptions: dat. masc. neut. in *-um*, instead of *-e*; acc. masc. in *-ne*, instead of —; gen. dat. fem. sing. in *-re*, instead of *-e*; nom. acc. plur. masc. in *-e*, instead of *-as*; gen. plur. of all genders in *-ra*.

Adjectives are normally compared by adding *-ra* for the comparative, and *-osta* or *-esta* for the superlative. In some words the stem-vowel of the comparative and superlative takes *i*- umlaut, but this is not the rule. Without umlaut: *heard*, hard, comparative *heardra*, superlative *heardosta*. With umlaut: *eald*, old, *ieldra*, *ieldesta*. From the umlaut forms are derived Mod. Eng. *elder*, *eldest*, as against a newly formed *older*, *oldest*. Besides the regular comparison, there are a few instances of much irregularity.

Numerals.—The cardinals run as follows: *ān*, one; *twēgen*, twain. *twā*, two; *ðrēo*, three; *fēower*, four; *fīf*, five; *siex*, six; *seofon*, seven; *eahta*, eight; *nigon*, nine; *tīen*, ten; *endlefan*, eleven; *twelf*, twelve; *ðrēotīene*, thirteen, etc.; *twēntig*, twenty; *ðrītig*, thirty, etc.; but *hund-seofontig*, seventy; *hund-eahtatig*, eighty; *hund-nigontig*, ninety; then *hund* or *hundtēontig*, hundred; *hundtwelftig*, hundred and twenty, etc.; *ðūsend*, thousand.

The ordinals are *fyrsta* (besides other forms), first; *ōðer*, (literally other), second; *ðridda*, third; *fēorða*, fourth; *fīfta*, fifth; *siexta*, sixth; *seofoða*, seventh, etc.; *ðrēotēoða*, thirteenth, etc.; *twēntigoða*, twentieth, etc.

Inflection of Pronouns.—In the first and second persons the personal pronouns have a dual, which, however, is not of frequent occurrence. The declension of the first person is, in the order nom., gen., dat., acc., as follows: *ic*, *mīn*, *mē*, *mē* (*mec*); dual, *wit*, *uncer*, *unc*, *unc*; plur., *wē*, *ūre*, *ūs*, *ūs*. The second person runs: *ðū*, *ðīn*, *ðē*, *ðē* (*ðec*); dual, *git*, *incer*, *inc*, *inc*; plur., *gē* (*gīe*), *ēower*, *ēow*, *ēow*. The third person has the same plural throughout: *hīe*, *hiera*, *him*, *hīe*. The masc. sing. is *hē*, *his*, *him*, *hine*. The neut. sing. is *hit*, *his*, *him*, *hit*. The fem. sing. is *hēo*, *hi*(*e*)*re*, *hi*(*e*)*re*, *hīe*. The personal pronoun is likewise used in place of the reflexive.

The possessive pronouns are identical in form with the genitive of the personal pronoun. Those formed from the first and second persons are declined like strong adjectives, those from the third are indeclinable.

The article and demonstrative *se*, that, the, is thus declined:

Singular.

<table>
<tr><th></th><th>MASC.</th><th>NEUT.</th><th>FEM.</th></tr>
<tr><td>Nom.</td><td>se</td><td>ðæt</td><td>sēo</td></tr>
<tr><td>Gen.</td><td colspan="2">ðæs</td><td>ðǣre</td></tr>
<tr><td>Dat.</td><td colspan="2">ðǣm (ðām)</td><td>ðǣre</td></tr>
<tr><td>Acc.</td><td>ðone</td><td>ðæt</td><td>ðā</td></tr>
<tr><td>Inst.</td><td colspan="2">ðȳ, ðon</td><td></td></tr>
</table>

Plural.

Nom. Acc.	ðā
Gen.	ðǣra (ðāra)
Dat.	ðǣm (ðām)

The demonstrative ðes, this, is thus declined:

Singular.

	MASC.	NEUT.	FEM.
Nom.	ðes	ðis	ðēos
Gen.	ðisses	ðisses	ðisse
Dat.	ðissum	ðissum	ðisse
Acc.	ðisne	ðis	ðās

Plural.

Nom. Acc.	ðās
Gen.	ðissa
Dat.	ðissum

The interrogative *hwā*, *hwæt*, who, what, is thus declined:

	MASC. FEM.	NEUT.
Nom.	hwā	hwæt
Gen.	hwæs	hwæs
Dat.	hwǣm (hwām)	hwǣm (hwām)
Acc.	hwone	hwæt
Inst.		hwȳ

There is no inflected relative pronoun other than the demonstrative, which sometimes assumes its function.

There are a number of indefinites, which are mostly declined like strong adjectives.

Inflection of Verbs.—Verbs have four moods, the indicative, optative, imperative, and infinitive; two principal tenses, the present and preterit, the former being frequently employed for the future. The passive voice is formed by auxiliary verbs, much as in Modern English. Verbs are divided into strong and weak.

Strong verbs change the radical vowel to form the different tense-stems, like the verbs called irregular in Modern English. As in Modern English the verb *drive* has the preterit *drove* and past participle *driven*, so in Old English the same verb has the preterit singular *drāf* and past participle *drifen*. However, instead of the three tense-stems of Modern English, there are four in Old English for strong verbs, the preterit being subdivided into preterit singular and preterit plural. The four stems of *drīfan*, drive, are:

PRESENT.	PRET. SING.	PRET. PLUR.	PAST PART.
drīf-	drāf	drif-	drif-

which are usually cited under the forms—

INFINITIVE.	PRET. SING.	PRET. PLUR.	PAST PART.
drīfan	drāf	drifon	drifen

Of such strong verbs there are seven classes in all, besides three classes of weak verbs.

Weak verbs in some cases have a variation of vowel between the present and the preterit, but their distinguishing characteristic is that the preterit is formed by the addition to the stem of *-de* for the singular and *-don* for the plural, and the past participle by the addition of *-ed*. Sometimes these endings take a vowel before them, and sometimes a neighboring sound converts the *d* into *t*; but this does not affect the essential nature of the distinction between them and the strong verbs.

The conjugation of a strong verb may be represented by that of *bindan*, bind:

		INDICATIVE.	OPTATIVE.
Pres. sing.	1.	binde	binde
	2.	bindest / bintst	binde
	3.	bindeð / bint	binde
Plur.		bindað	binden
Pret. sing.	1.	band	bunde
	2.	bunde	bunde
	3.	band	bunde
Plur.		bundon	bunden

Imper. sing., *bind*; plur., *bindað*; infin., *bindan*; pres. part., *bindende*; past part., *bunden*; gerund, *tō bindanne*.

The typical scheme for the conjugation of a weak verb may be inferred from that of the strong, if the mode of forming the preterit and past participle is borne in mind.

There are a few preteritive presents from which are derived the modern auxiliary verbs *may*, *can*, etc. Their present is an old preterit, and their new preterit is formed as if the verb were weak.

The optative is used for our potential and imperative, as well as for the optative proper. Relics of these uses are in English: *It were a grievous fault* = It *would be* a grievous fault; *Be it so* = *Let it be so*. But a periphrastic potential with the auxiliaries *may*, *can*, *must*, *might*, etc., is used in Old as in Modern English. The infinitive is regularly without *to*, hence forms with auxiliaries still reject it, as do familiar idioms in which the infinitive is the object of a verb, and *to* is not needed to express purpose or the like.

There was a verbal noun ending in *-ing*, *-ung*, which seems to have been confused with the participle in *-ende*, and given form to our present participle.

The two tenses given above answer for all times—one for all past time, the other for present and future; but forms with auxiliaries are also used. *Hæbbe*, have, for the perfect, and *hæfde*, had, for the pluperfect, are in full use: *he hæfð mann geworhtne*, he has made man.

For the future, *sceal*, shall, and *wille*, will, are common, though seldom free from some meaning of *duty*, *promise*, *determination*, such as indeed goes with them in English. The present distinction between *shall* and *will* in the different persons is not established in Old English. The future perfect is not discriminated.

Adverbs.—Adverbs are frequently formed from adjectives, less frequently from nouns. From adjectives they are formed by the addition of *-e*: *wīd*, wide—*wīde*; of *-lice*: *heard*, hard—*heardlice*; of *-unga*: *eall*, all—*eallunga*, entirely; or an oblique case of an adjective is employed as an adverb; thus the acc.: *genōg*, enough: the gen.: *micel*, much—*micles*, very; the dat.: *miclum*, very. Of nouns the gen. is used: *dæg*, day—*dæges*, by day; or the dat. plur.: *dropmǣlum*, drop by drop; or rarely the inst.: *sār*, sore—*sāre*, sorely. Another important class is adverbs of place, such as ðǣr, there, ð*ider*, thither, the latter being representative of those formed from pronominal stems.

Syntax.—There is nothing in which Old English differs more from Modern English than its syntax, which is that of a highly inflected language like Latin or Greek. The most general laws are common to all speech; a much larger number are common to all Indo-European tongues. The frequency with which different combinations are used by each makes the great difference between them. Apparent anomalies of English syntax may often be easily understood by study of the Old English from which they sprang: *Me thinks I saw him*, seems strange; but in Old English the *thinks* is found to be a different verb from the common English *think*, and to mean *seem*, and govern a dative; *it seems to me* = *methinks*. *He taught me grammar*—tǣcan, *teach*, governs an accusative and dative—*taught to me*. *I asked him a question*—āscian, *ask*, governs an accusative of the person asked. *He went a-hunting*—*a* is the preposition *on* in Old English. *I loved him the more*—*the* is in Old English the instrumental case of the demonstrative (ðȳ, ðē), meaning *by that*. And so examples might be given without end. No difficult point in English syntax can be safely discussed by one who does not know its history.

Metre.—Old English verse reposes on stress and alliteration, rime being only an occasional ornament. There are at least four stressed syllables to each verse, two in each half-line, the half-lines being divided by a cæsura. Two of these stressed syllables in the first half-line and one in the second begin with the same consonant sound or combination, or else with a vowel. Instead of three alliterative sounds to the line, there may be only two, one to each half-line, or four, two to each half-line, and exceptionally more. This metrical structure may be illustrated by a few lines from the poem of *Judith* (202–206), in which the alliterative letters are printed in Italics:

*f*ōron tō ge*f*eohte	*f*orð on gerihte
*h*æleð under *h*elmum	of ðǣre *h*ālgan byrig
on ðæt *d*ægred sylf;	*d*ynedan scildas,
*h*lūde *h*lummon.	Ðæs se *h*lanca gefeah
*w*ulf in *w*alde,	and se *w*anna hrefn.

The effect of which may be rudely represented by the following version:

*F*ared to the *f*ight	*f*orth by the straight road,
*H*eroes with *h*elms,	from that *h*oly city,
At the day-*d*awning;	shields loudly *d*inned,
*R*ang and *r*esounded.	Then *r*eveled the lank one,
The *w*olf in the *w*ood,	with the *w*an bird, the raven.

Effects of the Norman Conquest.—Upon a country harried, distracted, and oppressed by the Danish invasions and tyrannies there came yet another change—that of the conquest by William of Normandy, 1066. The Normans took absolute possession of the island, over which they spread themselves, carrying with them their retainers, and bringing with them their priests; England became a Norman possession and colony, the speech of the conquerors becoming, consequently, that of the court, of courtly circles, and of all public documents and transactions. The Normans belonged to the Scandinavian branch of the Teutonic stock, which had spread northward, even to Iceland. Sailing southward, some of them had taken possession of a province of France, called from them Normandy; but these retained neither their Scandinavian tongue nor manners. They adopted those of the French whose land they had seized. Although they had been in Normandy only about 200 years when William set out for his invasion of England, they then spoke a dialect which is known as Norman-French. For their day they were an accomplished and an elegant people. The Old English tongue, being reduced to the position of a language spoken only by artisans and tillers of the soil, soon lost its distinctive forms and nicer inflections; a process by which, although at the time deteriorating, it was prepared to become with greater ease an analytical language on its amalgamation with the Norman-French. Yet it never became in any sense French or Romanic, but remained in its essence and in its structure English.

Elements of Present English.—The elements of the modern composite English are therefore (1) pure English or "Anglo-Saxon," (2) British or Celtic, (3) Danish or Norse, (4) Norman-French, (5) Latin, (6) Greek, (7) words adopted from all languages, including Arabic, Hebrew, and even those of the savage aborigines of Africa and America. Words of the last class are comparatively few in number; their presence in the language does not at all affect it in its structural or historical aspect, nor do they in any way distinguish it from other Indo-European tongues.

Interfusion of English and French.—For about 100 years after the Norman conquest the conquerors and the conquered held themselves as much as possible aloof from each other—in scorn on the one side and sullenness on the other. And for nearly two centuries more the government of England, politically and ecclesiastically, was carried on in Latin and in Norman-French. These two languages prevailed in the court, in the universities, in Parliament, and in the courts of law; and even in the grammar schools the boys construed their Latin into Norman-French. But as the Normans were few and politic, and the English were many and sturdy, there was unavoidably some mingling of the two languages as well as of the two peoples, and the English gradually prevailed. Political and patriotic motives, which can not be here noticed in detail, combined with the natural influences already mentioned to turn Normans into Englishmen, both in feeling and in speech, until, about 1350, English took the place of Latin in the schools and in the courts of law, and the speech of the whole of the people of England became English. It was not, however, the English which the Norman invader heard at Hastings which obtained this compensating victory, but a speech much modified, and largely mixed with strange elements. The interfusion of the languages was the consequence and the sign of an interfusion of the people. Englishmen did not become Normans—that was impossible, but the Normans became Englishmen—Englishmen of a high and haughty class, a noble order, but still Englishmen; and taking for their own use the language of the people whose country they had also taken for their own use, they brought a large and in most respects a valuable store of words from the speech of their race as their contribution to the common stock. The introduction of French words was largely due, there can be no doubt, to the influence of the priests. These men were dependent upon the Norman nobles; they were their beneficiaries, their chaplains. The higher members of the priesthood, and a very large proportion of the whole order, were of Norman race. Their professional language was Latin, of which Norman-French was a dialect. Their intimate relations with the women and children of the parish, and the reverence felt for their office, gave to these priests an influence upon the language of the country which can hardly be overrated.

No Standard Middle English before 1350.—Of the English written between 1100 and 1350 that of hardly any two authors was alike. The language, having no recognized standard, was used by each scribe according to the mode of speech that prevailed among the people among whom he was bred and for whom he wrote. Writing was therefore as dialectical as speech, and, owing to the immobility of the people and the lack of communication between them, a separation of 50 miles made a difference of dialect which is quite perceptible upon close comparison.

A Specimen of the Transformed Language.—The nature of the change which took place in the language within the compass of 400 years will be, perhaps, better understood by comparing with the Old English version of Matt. xxviii. 11–13, quoted above, another version of the passage—Wycliffe's, as revised by Purvey (about 1388).

"And whanne thei weren goon, lo! summe of the keperis camen in to the citee, and telden to the princis of prestis alle thingis that weren doon. And whanne thei weren gaderid togidere with the elder men, and hadden take her counseil, thei ȝauen to the kniȝtis miche monei, and seiden, Seie ȝe, that hise disciplis camen bi nyȝt, and han stolen hym, while ȝe slepten."

This passage in the Wycliffite version gives some notion of the nature and extent of the changes which have taken place during that period, for, although antiquated, it is unmistakably English—almost as easily understood by any intelligent person as if it had been written to-day, although it was written about 500 years ago. But certain forms in it at once attract attention. They are *hadden* (had), *camen* (came), *telden* (told), *weren* (were), *han* (have). This ending in *en* is no rude or dialectical form of language. It will be found that the nominatives to all these verbs are plural. They are therefore plural forms of the verb which have been dropped since Wycliffe's day. They are a remnant of the elder form of the language; for, looking back to the earlier version, one finds like plural terminations, *on* taking the place of *en*; *fērdon* (fared) *cōmon* (came), *wǣron* (were), *worhton* (wrought), etc. In the Wycliffite version are found also the plural forms *keperis*, *prestis*, *thingis*, *kniȝtis*, which since Wycliffe's day have passed into *keepers*, *priests*, *things*, and *knights*. In the earlier version is found a like syllabic plural in *s*, but instead of *is*, *as*—*weardas* (wards), *ealdras* (elders), *cnihtas* (knights). Besides the forms already remarked upon, there is found in the earlier version *ealdrum*, meaning elders, as *ealdras* does, but elders in another relation, the same which is indicated by a like termination in *ðegnum*. *Secgeað* is "say," but it is "say" imperatively. The old imperative therefore was in *th*, but this had begun to pass away 500 years ago, for Wycliffe writes *seie* (say). Another form in the earlier version attracts attention: *nihtes*, meaning "by night"; but this *nihtes* is a genitive form, and means "of night";* but so even nowadays, among some people, we hear such phrases as "He came o' nights"; and Shakspeare has (*Twelfth Night*, i. 3, 5), "You must come in earlier o' nights." But the fashion of expressing this thought by a change in the word *niht* had in a measure passed away before Wycliffe's day, for he uses a preposition, and writes "by night."

Inflectional Changes Occurring in Middle English.—By this brief comparison of these passages one has a suggestive illustration, though nothing more, of the changes which the Old English language underwent in the course of years, until, about 1525, it assumed substantially the form in which we have it now. Those changes may be succinctly said to have been the gradual disappearance of the case-endings of nouns, except the possessive, which was contracted from *es* to *'s*, and the nominative plural, which was changed from *as* to *es*, and in many words to simple *s*; a like change, but complete, in the adjective, which loses all distinction of the form and the sense of case and of number, and does not conform to or agree with its substantive; the entire disappearance of grammatical gender; the loss of the infinitive and imperative forms of the verb, with the distinctions of persons except in the third person singular; the only other inflectional changes remaining being those of the preterit, and the present or indefinite participle, of weak verbs (*love*, *loved*, *loving*), to which must be added the perfect or definite participle in the strong verbs (*sing*, *singing*, *sang*, *sung*). The verb *to be* is not at variance with this assertion, its several tenses and even persons being taken from three distinct verbs, as appears to have been the case in the whole Indo-European family of speech, the Sanskrit included, from the earliest

* The true genitive of *niht* is *niht* or *nihte*, and *nihtes* is apparently formed by analogy with *dæges*. *Dæges* and *nihtes* means, "of (or by) day and of (or by) night."

ages. Truly inflected case and personal endings are preserved only in the pronouns.

Words Derived from the Latin.—But the changes which the language underwent in the course of its transformation to modern English were, as has been seen, not wholly inflectional. A large number of new words were introduced, the most of them being from the Latin. As this foreign element is the most important, a few words may be devoted to its consideration. The words which came directly or indirectly from the Latin language are of three sorts: First, those which came through the Norman-French, and which are ours by inheritance from the Normans who 800 years ago made England their home, and who in the course of two centuries became fused with the English people; of which *castle*, *faith*, *spy*, *person*, *poor*, *custom*, *sermon*, *voice*, *place*, and *rage* are examples. Secondly, words of general use formed by scholars in later years directly from the Latin, or from some one of the Romanic languages, or which have been adopted without modification from those languages; examples of the first sort under this class being *index*, *consul*, *circus*, *opera*; of the second, *trait*, *chagrin*, *portmanteau*, *puisne*, or *puny*. Thirdly, words common to science in several languages, which have come into simple or metaphorical use in English by reason of the diffusion of knowledge and the immediate, everyday connection of science with the affairs of common life. Examples of this class are *zenith*, *diameter*, *tangent*, *ellipse*, *fulcrum*.

Growing Depth and Richness of English.—Any discussion of English which leaves out of account its increasing capacity to express subtle distinctions of thought and the whole range of emotion is necessarily incomplete. This power has largely resulted from the multiplication of metaphorical and other new senses of words, from the formation of new phrasal combinations upon the analogy of existing ones, from an imitation of such excellences of other tongues as could be conformed to English idiom, and, in general, from the greater flexibility imparted by thought to its chief instrument and medium. The history of these changes is the history of English literature, in which there is no considerable author who has not added something to the stores bequeathed him by his predecessors. To trace this progress, though in the barest outline, is beyond the scope of the present article, and for suggestions under this head the reader is referred to the subjoined bibliography and to the article on ENGLISH LITERATURE.

Revised by ALBERT S. COOK.

English Literature: the written or printed expression of the thought of English-speaking races, wherever produced. The subject is divided according to historical periods, Old or Early English literature, comprising all prose and verse written before the Norman conquest of England, or, to speak with definiteness, from A. D. 450 to 1066, being classed as Anglo-Saxon. See ANGLO-SAXON LITERATURE.

MIDDLE ENGLISH.

The Norman conquest not only made a break in the natural growth of English speech, but brought in new intellectual influences and novel literary forms. The English language was displaced from many of its former uses. From 1066 to the middle of the fourteenth century the learned literature of the country was mostly in Latin and the polite literature in French. English did not cease to be a written tongue, but its extant remains down to the year 1200 are few and unimportant, if we except the continuation of the Anglo-Saxon Chronicle, which was carried on to 1154. After 1200 English came more and more into use in books, but mainly at first in translations and imitations from the French. The Normans were the most brilliant race of mediæval Europe, and their literature reflected their chivalrous, adventurous character, their passion for prowess and courtesy, their love of pleasure and magnificence. A people fond of exploits and devoted to deeds of knight-errantry naturally took delight in the narrative of such deeds. Chronicles in Latin prose, history mingled with fiction and put into Norman-French verse (*chansons de geste*), and fabulous tales of marvelous adventure (*romans d'aventures*) were their favorite reading. These metrical romances or chivalry stories were the most characteristic contribution of the Normans to English poetry. They were sung or recited by minstrels and wandering *jongleurs*, and numbers of them were turned into English verse during the thirteenth, fourteenth, and fifteenth centuries. Some of the earliest English romances were *Havelok the Dane*, *King Horn*, and *Sir Tristram*. The heroes of some of these romances were from national history or legend, as Richard Cœur de Lion, Guy of Warwick, and Bevis of Hampton. Others were of various times and places, as King Alexander, Sir Troilus of Troy, and Charlemagne. Still others were entirely fabulous, as in the romances of *William of Palerme*, *The King of Tarsus*, *Amis and Amiloun*, etc. The native alliterative verse was now generally abandoned for French meter and rhyme, the commonest form in the romances being the eight-syllabled couplet.

The favorite Anglo-Norman romance hero was that mythical Arthur of Britain whom Welsh legend had celebrated as the most formidable enemy of the Saxon invaders. Arthur had figured among other fabulous British kings in the *Historia Britonum*, a Latin pseudo-chronicle produced about 1135 by Geoffrey of Monmouth, a Benedictine monk, seemingly of Welsh descent. In 1155 the Norman Wace turned Geoffrey's history into French verse under the title

Geste des Bretons (afterward known as *Brut d'Engleterre*—i. e. Chronicle of England). About the year 1200 Wace's poem was translated into English by Layamon, a priest of Arley Regis, on the Severn. Layamon's *Brut* is in 30,000 lines, partly alliterative and partly rhymed. The style is rude but vigorous, and at times highly imaginative. The story of Arthur, however, received its fullest development in a series of French romances, composed partly in France and partly in England in the latter part of the twelfth century.

The English paraphrases and imitations of the French metrical chivalry tales are interesting for their illustrations of manners and ideals in the Middle Ages, but they have very little literary art. The French *trouvère* told his story in a straightforward, prosaic fashion, omitting no details in the action and unrolling endless descriptions of dresses, trappings, gardens, etc. His romance sometimes extended to thirty, forty, or fifty thousand lines. The English paraphrases had usually the prolixity of the originals, with greater rudeness of style and verse. The romances, however, abound in situations and characters, of which the poets of a more artistic though less inventive age have made a noble use—poets such as Tennyson, Swinburne, Matthew Arnold, and William Morris.

With the discontinuance of the Anglo-Saxon Chronicle English history written in English prose ceased for 300 years. The thread of the nation's story was kept up in Latin chronicles, compiled by writers partly of Norman and partly of English blood. The earliest of these, such as Ordericus Vitalis, Simeon of Durham, Henry of Huntingdon, and William of Malmesbury, were contemporary with the later entries of the Saxon Chronicle. The last of them, Matthew of Westminster, finished his work in 1273. About 1300 Robert, a monk of Gloucester, composed a chronicle in English verse, following in the main the authority of the Latin chronicles; and he was succeeded by other rhyming chroniclers, the most important of whom was Robert Mannyng, a priest of Brunne (now Bourn), in Lincolnshire, whose *History of England* was finished in 1338. In these chronicles the line between fact and fable was gradually obliterated, and the true history, of the Anglo-Saxon period especially, was overlaid with a mass of legendary material derived from such sources as Geoffrey of Monmouth's *Historia Britonum* and popular romances like *Guy of Warwick*.

Religious Literature.—Besides chronicles and romances there is a considerable body of religious literature, consisting of homilies in prose and verse, books of devotion, like the *Ancren Riwle* (Rule of Anchoresses), 1225, and *The Ayentite of Inwyt* (Remorse of Conscience), 1340, written in the Kentish dialect by Dan Michel, of Northgate, an Augustin monk at Canterbury. Both of these were in prose. In verse were Robert Mannyng's *Handling Synne* (1303); the *Cursor Mundi* (1320), a sacred history, intermixed with homiletic elements drawn from biblical, apocryphal, and legendary sources; and the *Prick of Conscience*, by Robert Rolle, a hermit of Hampole, in Yorkshire. There were also verse paraphrases of portions of the Bible, such as *The Ormulum*, or Book of Orm (1205), a version of the gospels for the day made by an Augustin monk named Orm in unrhymed metrical verse; the *Genesis* and *Exodus*, not much later, in rhyming couplets; and numerous renderings of the Creed, the Psalter, the Pater Noster, and the Commandments. There were also legends and miracles of saints. A particularly noteworthy collection of such was prepared toward the end of the thirteenth century at the great abbey of Gloucester. There were poems in praise of virginity; on the contempt of the world; on the five joys of the Virgin, the five wounds of Christ, the eleven pains of hell, the seven deadly sins, the fifteen tokens of the coming judgment; dialogues between the soul and the body; legends of the Holy Rood, of the childhood of Christ, of the Assumption of the Virgin; and prose allegories, such as the *Wohunge of Ure Laverde* (Wooing of Our Lord) and *Sawles Warde* (Soul's Ward). These were the work not only of the monks, but of the begging friars, and, in smaller part, of the parish priests. They are the literature of barbarism and superstition, instinct with the ascetic piety of the Middle Ages, with a childish belief in the marvelous, with the fear of hell, and with a profound sense of the misery of life, the quick coming of death and judgment, the vileness and corruption of the human body, and the wickedness of the human soul. Now and then a single poem rises above the general level of this monkish literature. Such is the poem known as the *Poema Morale*, composed perhaps as early as the middle of the twelfth century on the border of Dorset, Wilts, and Hampshire. This has a certain intensity of feeling and a personal note which distinguish it from other things of the kind, and it seems to have been widely influential in Middle English religious verse. Another poem similarly distinguished is *A Luve Ron* (A Love Counsel), of Thomas de Hales, a Franciscan friar of the reign of Henry III. This song, like many of the thirteenth and fourteenth century hymns to Christ and the Virgin, uses erotic imagery and language more appropriate to earthly passion than to divine love.* Three very noteworthy religious poems, *Clannesse* (Purity), *Pacience*, and *The Perle*, are attributed to an unknown poet who wrote about 1360 or 1370, and was therefore contemporary with Langland and Chaucer. The first of these poems illustrates its theme from the history of the deluge, of the destruction of Sodom, and of the fall of Belshazzar; the second from the story of Jonah. *The Perle* is a mystical poem of great beauty, describing a Dantesque vision in which a bereaved father sees his daughter among the glorified. *Clannesse* and *Pacience* are written in unrhymed alliterative verse, of which there was a revival shortly after the middle of the fourteenth century. One of the finest of the Old English romances, *Sir Gawayne and the Green Knight*, also attributed to the author of *The Perle*, is written in alliterative strophes of uneven length, each strophe closing with a few short rhyming lines.

Secular Poetry.—Among the few Middle English poems on secular subjects worthy of mention is *The Owl and the Nightingale*, generally assigned to the reign of Henry III. (1216–79), belonging to the class of pieces designated in Old French as *estrifs* or *disputoisons*. In this debate, which is conducted with some spirit and a free use of proverbial wisdom, the owl represents the ascetic and the nightingale the æsthetic view of life. In *The Flower and the Leaf*, a fifteenth century poem formerly attributed to Chaucer, this same conflict between utility and beauty is presented under other emblems, and with the machinery of court allegory which the *Roman de la Rose* had brought into fashion. *The Land of Cokaygne* is a piquant little thirteenth century poem of some two hundred lines, belonging to the species known in France as *fabliaux*, short, humorous, or satirical tales in verse. It describes a lubberland, or fool's paradise, where the geese fly down all roasted on the spit, bringing garlic in their bills for their own dressing, and where there is a nunnery upon a river of sweet milk and an abbey of white monks and gray, whose walls are of pastry, with cakes for the shingles and puddings for the pins.

A few songs dating from about 1300, and mostly found in a single collection (Harleian MS. 2,253), are among the very few English verses before Chaucer which have any lyrical art or any grace of diction or sweetness of modulation to a modern ear. These are written in French strophic forms, in the Southern dialect, and sometimes have an intermixture of French and Latin lines. They are fresh, simple, and often pretty. Some of them celebrate the coming of spring with its cuckoos and throstle-cocks, its daisies and woodruff.

> When the nightingalë sings the woodës waxen green,
> Leaf and grass and blossom spring in Averil I ween.

Others are love songs, and not unfrequently employ a burden or refrain, such as

> Blow, northern wind,
> Blow thou me my sweeting.
> Blow, northern wind, blow, blow, blow.

The oldest English song whose musical notes have been handed down with the text is the famous *Cuckoo Song*, dating seemingly from the middle of the thirteenth century, and beginning,

> Sumer is icumen in, lhude sing cuccu !
> Groweth sed and bloweth med and springth the wde nu.
> Sing cuccu !

Langland.—Standing between the old English and the new, uniting the form of the one to the spirit of the other, is the author of *Visio Willelmi de Petro le Plowman*, or *Piers Ploughman*, an anonymous work of which there is reason to believe that the author was William Langland, Longland, or Langley, a clerk or churchman of some grade, who was born at Cleobury Mortimer in Shropshire. *The*

* A number of such pieces are reprinted in Morris's *Old English Miscellany*, Wright's *Reliquiae Antiquae*, and the *Political, Religious, and Love Songs* in the publications of the Early English Text Society.

Vision of Piers Ploughman, to which some other writer afterward added *The Creed*, is a satirical poem written in alliterative verse. Together they form a national work, the first great original work in English literature. Neither the *Vision* nor the *Creed* has much coherence of plan, but the latter has more than the former. Langland was a humane satirist, and his purpose was to set forth the wrongs of his humbler countrymen, suffered at the hands of nobles and priests and lawyers, but chiefly at those of the priesthood. He gave voice to the sorrow, the shame, and the subdued indignation of a deceived, oppressed, and pillaged people. The tiller of the soil, from whose labors nearly all wealth springs, and who then, as often since, starved amid the food that he raised for others, found in him an advocate, and the grasping noble and the corrupt churchman a just judge and a pitiless satirist. The pathos and the humor of his work are not less remarkable than its causticity. It is in these respects, as in all others, thoroughly English in its tone and character; and as an exposition of popular feeling, and no less a picture of contemporary manners, it has not a superior in the whole range of literature. The following brief passages* are characteristic of the author's style and of his subject-matter:

And thanne cam Coveitise · kan I hym naght discryve,
So hungrily and holwe · sire Hervey hym loked.
He was bitel-browed · and babber-lipped also,
With two blered eighen · as a blynd hagge;
And as a lethern purs · lolled hise chekes
Wel sidder than his chyn · thei cheveled for elde;
And as a bondman of his bacon · his berd was bi-draveled,
With an hood on his heed · a lousy hat above
And in a tawny tabard · of twelve wynter age,
Al so torn and baudy · and ful of lys crepyng
But if that a lous couthe · han lopen the bettre,
She sholde noght han walked on that welthe · so was it thred-bare.
Vision, Passus v.

And as I wente by the way · wepynge for sorowe
I seigh a sely man me by · opon the plough hongen.
His cote was of a cloute · that cary was y-called;
His hod was ful of holes · and his heare oute
With his knoppede shon · clouted ful thykke;
His ton toteden out · as he the lond tredede;
His hosen over-hongen his hok-shynes · on everiche a syde
Al beslomered in fen · as he the plow folowed.
Tweye myteynes as meter · maad al of cloutes,
The fyngres weren for-werd · and ful of fen honged
This wit waseled in the feen · almost to the ancle
Foure sotheren hym byforne · that feble were worthi:
Men mighte reknen ich a ryb · so senful they weren.
His wiif walked hym with · with a long gode,
In a cuttede cote · cutted ful heyghe,
Wrapped in a wynwe shete · to weren her fro wederes
Bar-fot on the bare iis · that the blod folwede.
And at the londes ende lyth · a little crom-bolle,
And thereon lay a lytel chylde · lapped in cloutes
And tweyne of tweie yeres olde · opon another syde
And al they songen o songe · that sorwe was to heren;
They crieden alle o cry · a kareful note
The sely man sighed sore · and seyde, Children, beth stille.
The Creed, etc.

It is worthy of remark that the first great work in English literature was written in a language formed neither by scholars nor courtiers, but by the people at large, and that it was a protest against wrong, against fraud, against priestcraft and hypocrisy—a demand for the recognition of human rights, for personal freedom and liberty of conscience.

Wycliffe.—The *Vision* and the *Creed* of Piers Ploughman bear the stamp of a great historical period. At the time of their production John Wycliffe and his followers were disturbing the established religion of England at its very foundations, and the author or authors of *Piers Ploughman*, if not openly attached to the Lollard party, must be reckoned as of it. As regards the *Creed*, this fact was recognized in the most emphatic manner by the ministers of the prevailing religion, for they caused the copies of it to be so thoroughly destroyed that, whereas the old manuscripts of the *Vision* are many, of the *Creed* not one is known to exist. *Piers Ploughman*, itself equally valuable as a record of the condition of language and religion, was thus one of the writings that ushered in that great work, itself equally important as to religion and language, the Wycliffite translation of the Bible. This was made from the Latin Vulgate by Wycliffe and some of his followers about 1380. No other single work ever exercised so much influence upon the political, moral, literary, and linguistic future of a people as the Wycliffite Bible did, except, perhaps, Luther's translation of the same Scriptures into High German nearly 200 years afterward. It was the beginning of a revolution which freed Englishmen from the rule of a foreign hierarchy, and ended in the deposition of the Stuarts and in the Bill of Rights. Although it added little to the English vocabulary, it enriched English expression—we might almost say English idiom—with a strong and peculiar phraseology which sprang from the contact between Hebraic thought and English speech, and which, having been preserved through 300 years, even to the revised translation of 1611, and having been read and listened to and taken to heart by so many generations of Englishmen, came to affect in a measure the whole popular cast of thought and of speech. It was the Wycliffite version that did this; for although there was, as has been seen, an Old English version of the Bible, this did not spread among the English people; and being almost forgotten and quite incomprehensible to the English people at the middle of the fourteenth century, there was no such connection between it and the Wycliffite version as there was between the latter and the received translation; in fact, there was no connection at all. This translation, completed about 1380, was revised by John Purvey, a learned Wycliffite writer who had made the subject of translation a profound study, and who sought to render this version more exact and more conformed to English idiom, which end he attained with admirable skill, finishing his work about 1390. Apart from the peculiar Anglo-Hebraic phraseology before mentioned, this translation tended to modernize the language. It was, as to simplicity of forms of words and the untrammelled construction of the sentence, in advance of the general English writing of its day; and its unparalleled literary influence led to the confirmation of this freedom from grammatical restraint among all English people, particularly those of the middle and lower classes.

Chaucer.—Geoffrey Chaucer was a younger contemporary of the author or authors of *Piers Ploughman*, as he was born about 1340, and died about 1400. He was connected with the court, having married the sister-in-law of John of Gaunt, the father of Henry IV. He was pensioned, employed in diplomacy, and made comptroller of the customs. As Langland's poems were addressed to the middle and lower classes, and written in their interest, so Chaucer wrote for the nobles and gentry; and the tone of his poems was suited to the temper of his audience.

Chaucer was a voluminous writer, but his chief works are *The Canterbury Tales*, *Troilus and Creseide*, and *The Romaunt of the Rose*. Of these the *Canterbury Tales* are the most original and the most characteristic of his genius, although *Troilus and Creseide* is as fine a narrative poem, not of the heroic cast, as exists in any literature. Chaucer is essentially a narrative poet. He is the earliest poet since the revival of literature after the Dark Ages who has awakened an enduring sympathy in the characters and the feelings and the fate of his personages. He is the first, indeed, who portrays real individuality of character. Each one of the personages in the pilgrimage to Canterbury, which is the occasion of the *Tales*, exists to this day in the minds of his readers as a living character that has as real and independent a being as any creature of flesh and blood that is met in one's daily life. In this respect he is a rival of Scott (in his novels), and almost of Shakspeare. Like the former, he paints them; like the latter, he makes them unconsciously paint themselves. He is English in all the traits of his mind and his style; and in nothing more so than in his humor. So early (also in *Piers Ploughman*) did this peculiar trait of English literature, in which it is unrivalled by that of any other people, appear, and with all its inexpressible and humanizing charms in fullest bloom and subtlest fragrance. As an historical picture of the time in which they were written, the *Canterbury Tales* are as if the veil of five centuries were lifted and we looked in upon a gathering of our forefathers in the free enjoyment of each other's society. But above all Chaucer's other charms is that of his strong and clear imagination. What he described he saw in his mind's eye as clearly as if it appeared before him in the body. We see with him the very personal traits and tricks of the people that he sets before us, no less

* As these passages are quoted for their matter, and not for their language, I have chosen the text edited by Wright, and with him have modernized the þ and the ȝ, in preference to following the more accurate but less generally readable text of Skeat.

than the adventures through which they pass or which they relate. There is all the freshest charm of nature in him, joined with the elegance of an accomplished man of the world. So in his language there lingers some of the homely roughness of early English, while at the same time it is strongly marked with the dainty splendor of the speech that, like some other pretenders, came over with the Conqueror. Chaucer stands alone, not only in his merits but in his literary position. He had no fellows; few contemporaries worth mentioning; and after his period a darkness fell upon English literature, through which glimmered a few dim and struggling lights whose only function was to make darkness visible.

Gower.—John Gower, a barrister (b. about 1325; d. 1408), was the chief of Chaucer's contemporaries. His reputation was great. Chaucer himself speaks of him with deference, and calls him the "moral Gower." But the dull, dead weight of his style has sunk him out of sight, and left only his name floating upon oblivion. His *Confessio Amantis* (Confession of the Lover) is a long nondescript poem, to read which requires the patient, self-sacrificing courage of a conscientious investigator of the history of our older literature. It has little claim to attention even as a contemporary record of manners and morals.

Barbour.—Of all the poets of Chaucer's day, John Barbour was the only one worthy even of comparison with him. Barbour (b. about 1316; d. 1395) was, according to the political division of the country, a Scotchman. But political divisions have nothing to do with literature or with language, and Barbour merely wrote in Northern English as Chaucer wrote in Southern. Barbour and his neighbors rightly called their language English, and so it continued to be called until toward the end of the sixteenth century, when local pride and political jealousy caused it to be called Scotch—a change of designation which has been the cause of much misapprehension and confusion. Nothing more truly English in speech or in spirit was ever written than this passage from Barbour's principal work—a long epic, or at least historical narrative poem, *The Bruce*:

> Ah! fredome is a noble thing
> Fredome mayss man to haiff liking
> Fredome all solace to man giffis
> He levys at ess that frely levys.
> A noble hart may haiff nane ess,
> Na ellys nocht that may him pless,
> Gyff fredome failyhe: for fre liking
> Is yharnyt our all othir thyng.
> Na he that ay hass levyt fre
> May nocht knaw well the propyrte,
> The anger na the wretchyt dome
> That is cowplyt to foule thyrldome.
> But gyff he had assayit it
> That all perquer he suld it wyt;
> And suld think fredome mar to pryss
> Than all the gold in warld that is.
>
> *Book I.*, ll. 225–240.

No less remarkable than the sudden uprising of such a poet as Chaucer, and one may even say of Barbour, is the fact that within their century there appeared no writers of either poetry or prose who were worthy of being called their followers, and that for nearly 200 years after the death of Chaucer the standard of literature was low. For this there were two reasons that can now be seen—perhaps others hidden by the distance of time. The first is the violent repression of all free thought which was brought about by the efforts of the Church to crush Lollardism and extinguish the very embers and sparks of the fire kindled by the Wycliffites; next the desolating civil War of the Roses, which broke out in 1455, and afflicted England with its consequences for quite half a century, although the war itself lasted but thirty years. Of the anti-Wycliffite writers the most eminent was Bishop Pecocke, who had some vivacity of style if no strength of thought. The most remarkable prose book of the latter part of the fifteenth century is the *Morte d'Arthur* of Sir Thomas Mallory (b. about 1430), compiled and translated from the French about 1470—a work which in its animation, and sometimes its simplicity and tenderness of style, does something to relieve the literary barrenness of its century. Mallory's language is remarkable for its freedom from Romanic words, to which fact it owes much of its directness and its strength.

Caxton.—At this period printing was introduced into England by William Caxton, who in 1474 printed his first book, a *History of Troy*, translated from the French. Caxton was a translator and an adapter as well as a printer, but not even his wonderful mechanical art had at first much influence upon either literature or language. Of poets, or writers of rhyming verse, in this period we have Occleve (about 1370–1454) and Lydgate (about 1370–1450), whose names only need be mentioned in a sketch like this.

It was in the North that the best literary work was done at this period, although Andrew of Wyntoun, a clerical chronicler in verse who flourished about the beginning of the fifteenth century, is little more than a rude rhymester, the value of whose work is chiefly historical. But James I. of Scotland, in his *King's Quair*, shows fancy, fine conceit, and the fruit of a careful study of Chaucer, whose works soon began to exercise a great influence upon poetical literature. Robert Henryson (or Henderson) not only studied and imitated him, but also wrote a continuation of *Troilus and Creseide*, which he called *The Testament of Fair Creseide*, which has been with some reason deemed not unworthy of being printed in company with Chaucer's poem. Of all the extreme Northern English poets, Henryson and James I. show most the influence of the Southern language and literature. Henryson, who lived until about 1500, is the author of other poems of merit, among them the beautiful pastoral *Robin and Makeyne*, which was reprinted in the Percy Collection. A poet known as Henry the Minstrel, or Blind Harry, composed a long poem of which the life of William Wallace was the theme. It is a genuine strong piece of poetical "making," quite Homeric in a rude and humble way, and full of hatred of "the Saxon"; Blind Harry himself being probably as good a Saxon or "Anglo-Saxon" as there was to be found south of the Tweed. After this period the so-called Scots literature shows a wider divergence in spirit and in form from that of the South, or of England proper.

MODERN ENGLISH.

More.—The first part of the sixteenth century produced in Sir Thomas More (1478–1535), King Henry VIII.'s second lord chancellor, the first English prose-writer of merit after Chaucer, whose prose was, like his poetry, the best of its kind that England saw for more than a century. More was a man of learning for his time, wise, humorous, penetrative, and of noble impulse and purpose. He wrote many controversial works of timely interest, and in Latin his famous *Utopia*. Of his English writings the most important is his *Life and Reign of Edward V.* (called his *Life of Richard III.*). In this his narrative power and his characterization of the personages whom he sets before us give him a conspicuous as well as an early place in the true historical English literature. His writings were produced between about 1515 and 1535, when he was beheaded. About the same time Sir Thomas Elyot (b. before 1490; d. 1546) wrote his political work, *The Governour*.

Tyndale.—It was theology, however, which gave new life to English literature, upon which William Tyndale and his followers conferred a benefit only inferior in degree to that which they bestowed upon the cause of freedom of conscience and purity of religion. Tyndale (b. about 1484; burnt at the stake 1536) made the first translations of parts of the Bible into English from the original Hebrew and Greek. But although he went to the original tongues, he did not lay aside the Wycliffite version, but on the contrary he kept it in mind, if not before his eye, and seems to have endeavored to preserve its phraseology as far as was consistent with a faithful rendering of the original text and a necessary conformity to the general speech of his own day. To this endeavor is due the continued life of that grand, strong, simple phraseology which English-speaking men recognize at once as "the language of the Bible," and which has for more than 450 years exercised an elevating and purifying influence upon the English language and literature. Tyndale's translation is the most important literary and philological fact between the time of Chaucer and that known as the Elizabethan period. Tyndale was also a voluminous writer in commentary and controversy, and a stout and a successful disputant with Sir Thomas More. His English, like his thought, is notably vigorous, manly, and clear, and he with his followers—among whom John Frith (b. about 1503), a Kentishman, was conspicuous—were the salt of English literature in the first part of the sixteenth century. These men wrote in a simpler, homelier style, and in more nearly unmixed English words, than any writers after the beginning of the third quarter of their century. Archbishop Cranmer (1489–1556), and notably Bishop Latimer (b. about 1485; d. 1555), were in their sermons and controversial writings apostles of simple English as well as of gospel truth. Latimer preached to the common people in their daily speech and with the most unstudied homeliness of diction and illustration. About this time there was an effort at English purism. Sir John Cheke (1514–57), one of the few Greek scholars in England, began a translation of the New Testament, in which, as in his other writings, he was studious to represent Greek words by English equivalents, and went so far as to coin such words as *fore-shewers* for prophets, *hundreders* for centurions, and *again-birth* for regeneration.

Ascham.—Cheke's friend Roger Ascham (1515–68) wrote his *Toxophilus* less to teach his countrymen how to draw the bow, which they had drawn pretty well at Hastings, than to show them an example of a pure, idiomatic, and elegant English style, which he did most effectually. In this effort he was seconded by Thomas Wilson (d. 1581) in his *Arte of Rhetoricke* (1553), and thirty years later by George Puttenham in his *Arte of English Poesy.*

The Northern poet, Gawin Douglas (b. about 1474), deserves a passing notice for his translation of the *Æneid*, said to be the first version of that classic published in Britain. Next come the poets and prose-writers who were to usher in the brightest period of the world's literature since that outburst of Greek genius which took place in the age of Pericles.

Skelton.—John Skelton, Lord Surrey, and Sir Thomas Wyat (1503–42) were almost contemporary poets, but the first was singularly unlike the last two. Skelton (b. about 1460; d. 1529) was the more learned, and in his day had the greater reputation, Erasmus having styled him the light and ornament of English letters. But Erasmus doubtless had in mind only his Latin verses, which are esteemed by scholars as remarkably pure; for anything written in a "vulgar"—i. e. a living—tongue was even then regarded as much unworthy the consideration of such a scholar as Erasmus. Skelton's English poetry is fantastic, extravagant, sometimes so incoherent as to be almost incomprehensible, and often so coarse as to be repulsive. But he introduced liveliness of movement and freedom of versification, much needed in English poetical literature, and with all his coarseness he was not without brightness of fancy and grace of expression. His *Philip Sparrow*, a poem of nearly 1,400 lines, has many passages distinguished in these respects.

Wyat.—Sir Thomas Wyat, a traveler, courtier, satirist, and writer of lyric poetry, was born in 1503. He and Lord Surrey (Henry Howard, b. about 1516)—who translated part of the *Æneid*, introduced blank verse into English poetry, and first wrote English sonnets—were the first true refiners of modern English style. They became the models of grace and elegance to their contemporaries and immediate successors. They died within a short time of each other, the former in 1542, the latter, on the block, in 1547. Wyat's poems were published in 1557.

Thomas Tusser (1527–80) wrote *A Hundred Points of Good Husbandrie*, but his verses have value only as bucolical antiquities; George Gascoigne, a dramatist, satirist, and critic of merit, who was one of the earliest English writers of blank verse (d. 1577); and Thomas Sackville, Earl of Dorset (1527–1608), the author with Thomas Norton, of the first regular English tragedy, *Gorboduc, or Ferrex and Porrex*, which was also written in blank verse. But more than a passing notice must be taken of Sir Walter Raleigh (1552–1618), whose bright intellect, daring spirit, and checkered life make him one of the most conspicuous figures in English history and literature. He was praised by Spenser, and his praise added to Spenser's glory. His poetry is remarkable for manly simplicity and freshness of feeling, mingled with sententiousness; his political writing for sagacity and knowledge of mankind; and his *History of the World* is full of wisdom, and closes with one of the grandest passages in English prose.

Sidney.—Somewhat like Raleigh in the circumstances of his life, although not in the character of his mind, was Sir Philip Sidney (1554–86). A younger scion of a noble family, he too was a soldier, a courtier, a scholar, and a poet. According to all accounts, he was the most accomplished, the most admirable, and the most lovable among English gentlemen of his day. He was a patron of literature as well as a man of letters. His claim to notice as an author in the history of English literature rests upon his *Arcadia*, a collection of romantic and chivalric tales bound together with a slender thread of plan, somewhat extended and wearisome, but full of graceful and animated passages; some poems, generally cold and deceitful, but in a few instances lofty in tone and lovely in imagery; but chiefly upon his *Apologie for Poetry*, the earliest example of æsthetic criticism in English literature, and admirable for the beauty of its style and the soundness of its critical judgments, few of which have been set aside or superseded.

Spenser.—Sidney probably deserves the credit of having made possible the poetical career of one of England's greatest poets, Edmund Spenser. Spenser, born about 1552, after having written *The Shepherd's Calendar*, it is supposed at Penshurst, the seat of the Sidneys, where his friend Sir Philip took him to reside for some years, received a grant of 3,000 acres of crown land in Ireland, whither he went and where he wrote the first three books of his *Fairie Queen*, when, going to London to have them printed, Raleigh presented him to Queen Elizabeth, who, in consideration of his poem, gave him, in addition to his lands, a pension of £50, quite equal to $1.500 now. There and then he wrote, among other poems, *Mother Hubbard's Tale.* Returning to Ireland in 1592 he wrote two more books and two cantos of a third of his great poem; his series of eighty-eight sonnets, *Amoretti*, celebrating his courtship of the lady whom he married; his *Epithalamion* on his marriage; *Colin Clout's Come Home Again, Astrophel*, and other poems. He returned to London in 1598, and died there in 1599. If not the greatest of the poets of the Elizabethan period (which may be regarded as including the half century from 1575 to 1625), Spenser was second to one only, and he was the greatest of all those who lived entirely in Elizabeth's reign. Among all English poets he has but two superiors—Shakspeare and Milton—although it is only in the elevation of his aim and in the fine and luminous flame of his fancy that he surpasses Chaucer. Spenser is the most purely poetical of all English poets. His great work, *The Fairie Queen*, is poetry, and nothing else. It is not dramatic, or theological, or satirical, or, strictly speaking, narrative; and although it did fashion "the twelve moral Virtues," it is not didactic after the weary fashion of most moral poems. It is allegorical, but its peculiar merit is not in the allegory; rather is the allegory somewhat of a hindrance to the reader who is not capable of setting the didactic purpose of the poem aside and enjoying for itself the golden wealth of its rich fancy. The language employed was somewhat old-fashioned for Spenser's own day. He used words that were not then familiar household words, and forms and inflections that had passed away—for instance, the old plural in *en.*

Among the Elizabethan writers a theologian like Richard Hooker (about 1553–1600) must at least be mentioned. His sagacity and the logical clearness of his thought gained him the title of "the judicious," and his style places him high among the masters of English prose.

Lyly.—The writings of John Lyly (about 1554–1606) mark a change in the character of that prose. He introduced an almost fantastical style of writing. He affected fine phrases, and wrote for courtiers and those who would have finer bread than is made of wheat. The title, *The Euphuist* (one who speaks well), is derived from his principal work, *Euphues and his England*, which had much influence, and even brought about a style of speech and writing called euphuism. But it would be very wrong to assume that this work is a mass of fanciful folly in affected language. The book is full of good sense and knowledge of the world. He also wrote six court comedies, which have little genuine dramatic interest, but which are very elegant and highly finished productions of their kind.

Fulke Greville, Lord Brooke (1554–1628), "friend to Sir Philip Sidney," a poet, dramatist, and critical writer, whose style is cumbrous, but whose thought is far-reaching and weighty, can only be thus mentioned.

In the galaxy of poets that lighted up the Elizabethan sky even a merely superficial glance distinguishes William Warner (b. about 1558; d. 1609), Samuel Daniel (1562–1619), Michael Drayton (1563–1631), Bishop Joseph Hall (1574–1656), Joshua Sylvester (1563–1618), and George Chapman (1557–1634), the first translator of the whole of Homer's poems into English, and whose version, often inexact and rude, has an occasional sinewy strength and pithiness and a felicity of phrase which his more polished and scholarly successors have not attained. Chapman was also a dramatist, but his dramatic work, although always indicative of poetic ability, was loose in structure and in style confused and headlong.

Marlowe.—Next comes the consideration of that remarkable school of writers, the Elizabethan dramatists proper. At this period the theater was the chief intellectual entertainment of all classes and conditions of men, from the highest to the lowest. It filled the place now occupied by the novel and the newspaper. Young men of literary ability who found themselves in need of money in London turned to the stage as a means of supplying their necessities. The proprietors of the theaters kept poets in their pay, and ordered plays to be written sometimes by one, sometimes by two, and sometimes by half a dozen of their retainers. Conspicuous among these dramatic adventurers was Christopher or "Kit" Marlowe, a man of genius, but of genius wild, irregular, ill-trained. Both mind and man (if a man may be separated from his mind) lacked moral balance. The fierce extravagance and gilded bombast of his style can hardly be overrated; but from this turbid mass flash out gleams of brightest poetry. His characterization is often so strong as to be mere caricature, but it *is* characterization; his personages have individuality; and he first introduced the modern style of dramatic writing. To him also is due the introduction of free and flowing blank verse upon the stage. His principal dramas are *Faustus*, *Tamburlaine the Great*, and *Edward II.* Born about 1564, after a life of wretched irregularity he was killed in a brawl, 1593. Co-laborers with Marlowe were George Peele (about 1552–98) and Robert Greene (about 1560–92), men of much lighter weight and smaller caliber; the former an agreeable versifier and capable of tenderness; the latter essentially comic in the bent of his genius, giving foretaste both of the high and the low comedy of after years. With these men there was a crowd of others who have left names, and even works, known to literary antiquarians, but long ago forgotten in literature and on the stage; but from among them sprang one in all supreme—the greatest poet, the greatest dramatist, the brightest intellect of recorded time.

Shakspeare.—William Shakspeare, of English or "Anglo-Saxon" blood (b. 1564), when about twenty-one years of age went to London as an adventurer; became a player and a playwright; obtained an interest in the company which played at the Blackfriars and the Globe theaters, and by the plays which he wrote for this company—writing them as daily labor, just as a journalist nowadays writes leading articles and criticisms—he made himself "the greatest name in all literature." To attempt here a criticism upon Shakspeare's genius would be futile. Briefly, it may be said that he owed nothing either to his predecessors or to his contemporaries, if we except the language in which he wrote and the form of his dramas, which were those of his time. He attempted nothing new; he simply was new himself—the most original, inexplicable, and hitherto absolutely unexplained fact in the history of literature. He seemed to know the secrets of nature and of man's heart, and to penetrate the depths of wisdom and of philosophy by intuition. He was a creator of his kind, for at a touch of his pen he spoke men and women into an existence individual and immortal. His style can hardly be described, it can not be analyzed, and it has never been imitated. And there was no limit to the capacity of his genius. He sounded man's nature and the range of human thought from the top to the bottom of its compass. The grandest and the profoundest of all writers, he was at the same time not only the most delicate and the most fanciful, but the most comic. There is no tragedy, no philosophy, no pathos, no fancy, no humor like Shakspeare's tragedy, Shakspeare's philosophy, Shakspeare's pathos, Shakspeare's fancy, and Shakspeare's humor. All is said that can be said when they are called Shakspearian. To mention the titles of his principal dramas is quite needless. All the world knows that *Hamlet*, *King Lear*, *Othello*, and *Macbeth* are his greatest tragedies, but it may well be said that his wisest play is one never played now and too little read—*Troilus and Cressida*. He wrote at first in conjunction with other playwrights, after the manner of his time, but his facility in composition soon freed him almost altogether from the trammels of collaboration, and nearly all the great comedies, histories, and tragedies that bear his name are of his own unaided production. His sonnets are inferior in thought and in expression only to his best plays. They alone would have won him immortality. His most inferior works are those upon which he labored most and rested the only literary fame he coveted—his poems *Venus and Adonis* and *Lucrece*. He attained his purpose and retired to Stratford in the prime of life, a prosperous gentleman; and there he died in 1616, entirely regardless of his poetic fame, having no predecessors or successors except in the order of time. None of his contemporaries were like him. There was an Elizabethan period of poetry and of the drama, but no Shakspearian school of either.

Jonson.—Chief among Shakspeare's contemporaries was his friend Ben Jonson (b. about 1573; d. 1637), who for some time was regarded by the critical, but never by the public, as his superior. But gifted as Jonson was, the difference between them is absolutely immeasurable. Jonson's best comic work, as in *Every Man in his Humor*, *The Alchemist*, and *Bartholomew Fair*, is simply a humorous—and yet not very humorous—picture of what passed before his eyes—persons and manners. His tragedy is an unsuccessful attempt at the imitation of classic models. In some of his tragedies, founded on classic subjects—e. g. *Sejanus*—no inconsiderable part of the speeches are translations, more or less free, from Latin authors. He was overlaid with his learning. He was nevertheless a robust thinker, and at times a graceful one. Some of his minor poems, particularly his songs, have a peculiar charm which makes them the best known of all his works. He wrote one of the earliest English grammars, and in his *Timber* some of the earliest literary criticism in the English language.

Beaumont and Fletcher.—Francis Beaumont (1584–1616) and John Fletcher (1579–1625), wrote together, although there are many plays by Fletcher alone. They were poets, wits, and dramatists, but not of a very high order, although of the high imaginative school. Comedy was their forte, and they first brought upon the English stage the comedy of intrigue. Their works are very voluminous, and suffer from a diffusion of powers by no means exhaustless. If they had written less they would have written better. Their most meritorious works are *The Maid's Tragedy*, *The Elder Brother*, *Philaster*, and *The Faithful Shepherdess*, the last of which was written by Fletcher alone, who had more fertility, more constructive power, and a livelier fancy than Beaumont.

Among the second-rate men of this period whose names only can be mentioned here were Philip Massinger (1584–1640), who had tragic powers, but who was destitute of fancy and humor; John Ford (1586–about 1639), whose forte was pathos; John Webster and John Marston (b. about 1575; d. 1634), who dealt in the tragedy of horrors; Thomas Dekker (b. about 1570), who had in a marked degree both pathos and humor, but whose wretched life gave him little opportunity to finish his work; Thomas Middleton (b. about 1570, d. 1627), a man of pleasing mediocrity; and Thomas Heywood, the most voluminous of them all, that being his chief distinction. James Shirley (1596–1666) closes the array of Elizabethan dramatists, and is the link between the times of Elizabeth and James and those of Charles and the Commonwealth.

Bacon.—Among the great intellects of the Elizabethan era only one man—and it might almost be said hardly he—is more conspicuous than Francis Bacon (1561–1626). His misnomer is a notable recognition of his greatness. He became Lord High Chancellor and a peer, his title being Lord Verulam, but the man was far above his peerage, and is called Lord Bacon. His distinction was in this, that he was the wisest man of modern times, almost the wisest of the sons of men. To no man since the revival of learning may the term "philosopher" be so well applied. As a scientific investigator he has had many superiors; his scheme of inductive philosophy may not be original; but if he had not written the *Novum Organum* he would yet have taken the stand which he has held for two centuries, adown which from his sun-like mind has poured a blaze of intellectual light; for he had the grandeur and the poise and the far-reaching power which make a central luminary, and whatever he uttered bore the stamp of his supremacy. To English literature, strictly speaking, his contributions were not large, for the most of his writings were in Latin. His *Essays*, by which he is chiefly known to general readers, were written in English, and they alone would have made his name immortal. Such a solid body of clear, compact wisdom was never uttered to the world from an uninspired source before his day or since. They show in every page the largeness, the breadth, and depth of his great intellect. In style they are models of concentration, giving results, not processes, and yet revealing the foundations of eternal truth upon which their judgments stand. It is worthy of remark that there is no evidence in the writings of either that he and Shakspeare, the two brightest intellects of modern times, strictly contemporaries and living in the same place, knew of each other's existence; the reason of which strange fact is that one was a statesman and a philosopher, the other a player and a playwright.

Burton.—In the reign of James, Robert Burton (1577–1640) produced the *Anatomy of Melancholy*, a compound of curious learning, made piquant by the spice of splenetic humor and jocular sneers with which the quoted passages are seasoned to bring out their flavor. It is so filled with Latin that it is hardly an English book, but it is a typical specimen of a school or fashion of learned writing which prevailed about this time; and notwithstanding its pedantic air it has been, and ever will be, a source of delight and a quarry of suggestion to a large class of highly cultivated readers, and greatly so to those who themselves are writers. The names of Donne (1573–1631), a metaphysical poet; of Sir Thomas Overbury (1581–1613), the author of *The Wife*; of Richard Sibbes (1577–1635), a Puritan divine; of John Hales (1584–1656), a theologian and the author of *Golden Remaines*; and of William Drummond of Hawthornden (1585–1649), a Scotch poet of merit and a historian of Scotland—must be mentioned in an attempt to give a view of English literature at this period.

A notably important fact in regard to the Elizabethan era in literature is that the English language, which was fully formed at the beginning of the sixteenth century, was used in that era with a freedom from formal restraint that since then has been unknown. The parts of speech changed places at the will of the writer. Not only were adverbs used as adjectives, and adjectives as adverbs, but adverbs as nouns, and not only nouns, but even pronouns were used as verbs. A like freedom reigned as to other parts of speech and in the construction of the sentence. Thus was born, in full strength and activity, the genius of the English language, which is that the nature and quality of a word depend not upon its form, but upon its place in the sentence and its logical relation to other words. Thus the English of the Elizabethan period was more truly and absolutely English than that of any period before or since. This freedom prevailed most remarkably in the writings of the poets and the dramatists of the period, and chiefest of all the latter. But it pervaded all writing and all speech. That it was prevented from degenerating into chaotic license is probably due in a large measure to the preparation and diffusion of the revised or King James's translation of the Bible, which was published in 1611.

King James's Translation of the Bible.—In this translation, made with extremest care and the interchanged labor of forty-seven of the most competent scholars in England, the language of the previous versions was not only kept in view, but retained whenever it was consistent with the original, and sufficiently modern to be comprehensible without losing the dignity which pertains to antiquity, or taking on the strangeness which goes with novelty. The translators touched the sacred old structure with reverent hands, and while they renovated and strengthened it they did not whitewash the mellow tints of time with glaring newness. This book was at once published abroad throughout England, and since that time it has been printed and reprinted and scattered, and read daily by people of English race as no other book was ever read by any other people. Its influence upon English literature has been as great as upon the morality of English life. It has been the treasure-house and the stronghold of the English language. It contains the best, the purest, the manliest, and the sweetest English that was ever written. Its narrative style is beyond that of all other writing in its own or in other tongues for simplicity, for clearness, and for strength. No exhortation is like its exhortation, and no other counsel comes clothed in such impressive dignity of phrase. In it the rich and glowing diction of its Oriental original is preserved, and yet tempered with something of the cool directness, the honesty, and the homely freshness of the Anglo-Saxon nature. Its influence upon the English language has been the most pervading and the most wholesomely conservative that was ever exercised by a single force. Its authority has surpassed that of any possible academy.

After the death of Bacon and of James I. a few names of note attract attention before the period of the Commonwealth is reached: George Wither (1588–1667), a poet chiefly sacred, nervous in style, and remarkable for his simple, clear English; Thomas Hobbes (1588–1679), who wrote upon social and moral subjects and translated Homer into halting verse —a strong, clear, but not always logical thinker, and the first English master of regularity and symmetry of style; Thomas Carew (d. about 1639), a tender and graceful writer of light amatory verse, which, based upon French models, has the merit of character; Robert Herrick (1591–1674), who, writing both sacred and amatory verse, is known chiefly by the latter, in which he clothes his exquisite conceits in a rich style; Isaac Walton (1593–1683), a meek and pious angler, who wrote *The Complete Angler* and the lives of Donne, Hooker, and other divines, and whose love of nature and simple pedestrianism of life and style win him admirers generation after generation; George Herbert (1593–1633), whose collection of short poems called *The Temple* had an amazing popular favor, 20,000 copies having been sold, according to his biographer Walton, in a few years. Herbert belongs to the metaphysical school of Donne. His thoughts are almost a continued succession of quaint conceits and are steeped in ecclesiasticism; but they are pervaded with the spirit of true piety and uttered in English notably simple and manly.

Waller.—To the time of the Commonwealth and the Restoration belongs Edmund Waller, who was born in 1605, and who devoted himself to politics and to literature. His verse unites grace and dignity, although he is sometimes tempted into extravagance. His lines *On a Girdle* express one of the most exquisite amatory fancies in love-literature. He had a charming fancy, but little imagination. Contemporary with him were Thomas Randolph (1605–34), whose poems are tame, but in whose plays there linger echoes of the Elizabethan grandeur and freedom; Sir William Davenant, playwright and poet-laureate, but a poor creature; Sir John Suckling (1609–42), a dainty poet and an amorous; and the gallant Richard Lovelace (b. 1618; d. 1658), whose songs give the soul of chivalry and true love voice.

Milton.—All the poets of this period were eclipsed by the grand and luminous shadow of John Milton (1608–74). His prose works, chiefly controversial, and chiefly inspired by the great civil war, need not be noticed, except by name. Their value was chiefly for their time, and neither in them nor in any other of his prose works did his genius show, except fitfully, its peculiar power. Indeed, his prose, although strong in thought, is in style involved, cumbrous, and awkward. Of these the ablest are *Eikonoklastes, A Defence of the People of England, Tetrachordon, The Doctrine and Discipline of Divorce, The Tenure of Kings and Magistrates, A Tractate of Education*, and *Areopagitica, a Plea for the Liberty of Unlicensed Printing.* But it is as a poet that Milton lives in the world's memory, and of modern epic poets he is incomparably the greatest. His earlier and minor works have a serene and lofty grace of expression, united with a sustained power, that preludes the coming epos. But their merits, great as they are, are less imaginative than fanciful, although the fancy is of the very highest order. *L'Allegro* shows that he could even be playful. His sonnets have been much praised, particularly since Wordsworth said of him that in his hand the sonnet "became a trumpet." His powers were better displayed in his great epic poem, *Paradise Lost*, which has the singular advantage of the grandest theme, the theme most interesting to all Christendom, and the most suggestive of sublime thought, that could have been chosen. The style of the *Paradise Lost* in its finest and most characteristic passages has an almost indescribable grandeur and strength. Its lines are adorned with a wealth of illustration compelled from all literature and all history, sacred and profane; and its author marches along his royal road of verse like some great conqueror whose triumph is made splendid with the spoils of subject peoples. But these are the mere tokens and decorations of his own power. His thought and his purpose are always supreme. In the *Paradise Lost* and the *Paradise Regained* the poet worked out to the utmost bound of possibility mere hints in the sacred writings of the Hebrews and the Christians, and thus became the originator of many of the popular views of theology since his day. Milton is not, properly speaking, an English poet, or an English prose-writer. His style and the very character of his thought are eminently un-English. His spirit is Hebraic, his form that of Latin and Greek models. His last work, and one of his greatest, *Samson Agonistes*, is remarkable in this respect. In its form it is modeled upon Æschylus; its spirit is caught from Joshua, from Ezekiel, and from Isaiah. In one remarkable respect Milton is eminently un-English: he is entirely without humor, that peculiarly English, or at least

Teutonic, quality of mind which manifests itself in some degree in almost every other eminent writer of that race. Milton, celebrated as a controversial writer and a scholar almost from his youth, did not achieve fame as a poet during his life-time. The *Paradise Lost* was not appreciated highly, not to say at its full worth, until after a series of criticisms by Addison in the *Spectator*, and *Comus* and his other minor poems were first brought into general notice by Pope and Warburton. Milton, great as he was, does not stand in the front rank of poets—that is occupied by but three men, Homer, Dante, and Shakspeare—but first in the second rank without a doubt is the author of the *Paradise Lost.*

Cowley.—Abraham Cowley (1618–67) was a contemporary of Milton of whom great things were thought during his lifetime and long afterward. Cowley produced no work of large design, but made translations and wrote *Pindaric Odes, The Mistress*, a collection of amatory verse, *Davideis*, elegies, and the like. He belonged to the metaphysical school of Donne, of whom he was a weak imitator. His cold conceits and extravagant fancies are passing into deserved oblivion. Sir John Denham (1615–69) was his superior in every natural gift, and wrote in a much higher school, philosophical but cold. His *Cooper's Hill*, his best work, will always command admiration for its nervous thought and fine imagery. It contains the fine apostrophe to the Thames:

> Oh, could I flow like thee, and make thy stream
> My great example, as it is my theme—
> Though deep, yet clear; though gentle, yet not dull;
> Strong without rage; without o'erflowing, full;

which is perhaps the most-to-be-admired example of that mosaic verse which was so much in vogue in the early part of the next century.

Of the prose-writers of the period of the Commonwealth, the most conspicuous and characteristic are Sir Thomas Browne (1605–82), Thomas Fuller (1608–61), Jeremy Taylor (1613–67), the Earl of Clarendon (1609–74), and Richard Baxter (1615–91). Browne wrote *Religio Medici, Pseudodoxia Epidemica, or a Treatise on Vulgar Errors, Hydriotaphia, or a Treatise on Urn-burial*, and *The Garden of Cyrus.* But notwithstanding the nature of these subjects and the fact that he was a physician, the interest of his writings does not consist in any contribution that he makes to morals, to science, or to the history of art. Their charm is only in the strange, fantastic thoughts which he weaves around his subjects in language which would have won him the applause of John Lyly, the Euphuist. His vocabulary is so Romanized that it is hardly English.

Jeremy Taylor.—Jeremy Taylor was a cavalier clergyman who became Bishop of Down and Connor, and has been called the Shakspeare and the Spenser of English prose. The latter comparison is the better. His style is like a rich tapestry full of glowing color and striking figures, that would be startling but for their beauty and their harmonious succession. Through the splendor of his fancy there runs a vein of sweet and tender yet glowing piety. His *Holy Living* and *Holy Dying* beget, even in this faithless day, a religious fervor in the reader. He has the honorable distinction of being the first earnest advocate of complete and absolute religious toleration, his argument for which is set forth in *Theologia Eclectica, a Discourse of the Liberty of Prophesying.* Fuller exhibited in the highest, most typical form the witty divine—a character assumed by many of the clergymen of his period. He has the credit of being one of the wittiest, although not one of the most humorous, of English writers. His principal works are *The Holy and Profane State, History of the Holy War*, and *The Worthies of England.* Clarendon was the first of the regular historians. His *History of the Rebellion and Civil Wars* is valuable chiefly because he was a witness of the facts which he relates with his judgment of the actors. His style is poor, often cumbrous, and often incorrect. Baxter was also a typical man. He was almost a perfect example of a clergyman who was a purely religious writer, rather than ecclesiastical or even theological. Fervor is his chief characteristic. His style is pure, and for its purpose it can hardly be, and never has been, surpassed. He wrote much, but is now chiefly known as the author of the *Saint's Everlasting Rest* and the *Call to the Unconverted.*

Bunyan.—Above all the prose-writers of this period, and high among those of any country of any time, rises the mighty figure of the Puritan tinker of Elstow, John Bunyan (1628–88). *The Pilgrim's Progress*, the book which has won its author a fame that like an English oak strengthens and broadens with the lapse of centuries, is an allegory purely religious in its original purpose; and of all allegories ever written it is the one which most effectually attained its end. It is a work of fiction, a tale of human experience and of human passion, a story of trial, of struggle, of sorrow, and of triumph. Thus considered, it is matchless; in all literature there is nothing like it. The secret of its influence is Bunyan's marvelous union of dramatic insight and dramatic power with a vivid and fiery imagination, beside which the imagination of all other prose-writers is pale and feebly imitative. Moreover, the style of *The Pilgrim's Progress*—not always correct, according to the laws of pedants and grammarians—shows a mastery of English in which its writer has no rival. It is an unconscious mastery, and it unites in absolute perfection, strength and delicacy. Of no book except the Bible, and perhaps Shakspeare's plays, have so many copies been printed; and of no book without exception have so many copies been read through and through again. It has been translated into nearly all the languages of the world; and of all peoples above the level of barbarism it has taken a mighty hold. Bunyan wrote another allegory of almost equal power, *The Holy War*; and his other works show his peculiar vigor of thought and of style.

To the period of the Commonwealth is assigned the appearance of the newspaper, which was to have such an influence upon society and upon literature. News-letters, as they were called, had been published earlier in the century, the oldest known being *News Out of Holland*, published in 1619; but it was not until the exciting times of the Long Parliament that the genuine newspaper was demanded by the eagerness of the public for information as to what was taking place from day to day. Published at first once a week, newspapers at last came to be published every other day.

Butler.—The political, religious, and social influences which were dominant during the Commonwealth were of an ascetic character, and tended to the repression of the lighter forms of literature. For several years the theaters were closed, the drama was crushed, and lyric poetry languished. Upon the Restoration the repressed forces of society burst forth, and with the extravagance of reaction ran riot in high carnival. One of the earliest of the enduring fruits of the rank new growth was *Hudibras*, a satirical poem by Samuel Butler (1612–80). The germ of this highly witty and humorous although coarse performance was in *Don Quixote.* In Butler's poem the hero is a Puritan knight in whom selfishness and hypocrisy take the place of the crazy chivalry and extravagant gallantry of the Knight of the Rueful Countenance. He, too, has a squire who greatly aids the dramatic movement of the composition. *Hudibras* was of course unfair to the Puritans, but it is choke full of knowledge of human nature, which is ventilated in witty expressions that succeed each other so rapidly and so sharply that it is like the letting off of a pack of fire-crackers. Not only Puritanism, but astrology, one of the weaknesses of the age, suffers dreadful exposure under the author's remorseless knife. Butler was the first English poet to make free use of double rhymes, upon the ridiculous effect of which many of his fine points depend. The couplet

> Compound for sins they are inclined to
> By damning those they have no mind to,

is a characteristic specimen of the gnomic portions of this immortal *jeu d'esprit.*

The dramatists of a period to which the court of Charles II. gave the tone were, as might be expected, not only free and gay, but licentious to the last degree. They reveled in the violation of external decency, and the nature of their plots was such that it would seem as if they were intended to illustrate the life of their royal master. All that they sought to present on the stage was amorous intrigue and wit; and it must be admitted that in both points they succeeded to admiration. Of the minor poets and wits of this period brief mention only can be made of Charles Cotton (1630–87), who, besides his indecent verse, wrote the second part of the *Compleat Angler* and translated Montaigne into sound and nervous English; Sir George Etherege (about 1636–91), who wrote three plays, the best of which is *The Man of Mode*, and who is the father of the modern comedy of intrigue; Sir Charles Sedley (1639–1701), a writer of exquisite wit and no less charming style; Wycherley (about

1640–1715); and the Earl of Rochester (1647–80), the most indecent and perhaps the most gifted of them all, and the author of the best epigram (written on the bed-chamber door of Charles II.) in the language:

> Here lies our sovereign lord the king,
> Whose word no man relies on;
> He never says a foolish thing,
> And never does a wise one.

Dryden.—The chief poet of this period was John Dryden, the son of a Puritan gentleman of Northamptonshire. He was born in 1631 and died in 1700. He began to write as early as 1649, but his most active period began in 1662. Dryden began his poetical career in the school of Donne and Cowley, and in the extravagant absurdity of his conceits he out-Heroded Herod. Whoever wishes to learn what conceit is in poetry may best learn by studying it in the form of monstrous and loathsome caricature in Dryden's *Lines on the Death of Lord Hastings.* But there was other stuff than this in the man, who merely began as most young geniuses do, whether in literature, in music, or in painting, by imitating some one of their predecessors. Dryden, however, was nearly forty years old before he showed his power, which is that of an impetuous flow of versification, embodying cogent argument, stinging satire, or graphic portraiture. Of passion, of tenderness, and of pathos he showed none in his poetry, having, it would seem, none in his nature. He is fierce, but never warm, impetuous, but never earnest. He shows great strength, but not the greatest, which always carries with it a delicacy of touch to which weakness can never attain. His sentiments are never of the highest or the purest kind. He belongs to the race of time-servers and men-pleasers. But his satirical power is almost equal to Juvenal's, and his portraits of his contemporaries—as, for instance, in *Absalom and Achitophel,* the best of his more important works—are grand historic caricatures, heroic in scale and in spirit. His best lyric composition, *Alexander's Feast,* was once thought the finest thing of the kind in English literature, but time has been gradually, and surely and justly, diminishing its reputation. He wrote thirty plays, both comedies and tragedies. They have little poetic merit and no real dramatic power. They were, however, written as many of the best works in literature were written, merely for the money they would bring. But in the prefaces to some of these plays Dryden stepped upon the field of dramatic criticism, of which he showed himself a master. They are the earliest work of the kind in the language, and they remain among the very best. Dryden was not a great poet, but he seems like a great poet in arrested development. The perpetuity of his fame is due to the splendor of his style and the vigorous freedom of his versification. He was in these respects, and by his power of crowding an epigram into a couplet or touching off a portrait in a quatrain, the introducer of a new school in poetry, which prevailed during the early part of the century succeeding his death.

The latter part of the seventeenth century was adorned by several prose-writers of eminence other than those already mentioned: Ralph Cudworth (1617–88), Andrew Marvell—also distinguished as a poet (1621–78), Algernon Sydney (1622–83), Sir William Temple (1628–98), Isaac Barrow (1630–77), John Tillotson (1630–94), Robert South (1633–1716), and Gilbert Burnet (1643–1715); as to whom, however, there is room enough only for their names.

Locke.—One man of this period, John Locke (1632–1704), demands particular attention as being an original thinker and one of the most eminent of England's philosophical writers. Locke is indeed the father of political and social ideas which since his time have shaped the political and the social development of the English race in Great Britain and America. In his *Considerations of the Consequences of Lowering the Interest and Raising the Value of Money* he first taught the political and commercial necessity of absolute good faith on the part of government as the creator of the legal representative of value and the medium of exchange of commodities, and that the issue of a depreciated currency was a breach of good faith. In his *Letter concerning Toleration* he not only nobly sustains the arguments of Milton and Jeremy Taylor on the same subject, but he broaches the theory now established and acted upon, that the function of government is to make secure the personal liberty and the civil interests of the individual, and that when it attempts to do more it oversteps its proper limits. His *Treatises on Civil Government* develop and enforce this important political theory, resting it chiefly on an implied contract between the governing power and the governed. His *Thoughts concerning Education* have controlled, and wisely controlled, the action of the English peoples almost until the present time, although the cold austerity of his views has been modified by a warmer infusion of parental feeling. But it is his *Essay concerning Human Understanding* which has given him his most enduring fame and power, in that he was the first to popularize the study of mental philosophy, and to turn the mind's eye of the whole world inward upon itself. To John Locke more than to any other writer is owing the introspective character of the literature, even the imaginative and fictitious literature, of the nineteenth century. Of Locke it was admirably said by Mackintosh that "his writings have diffused throughout the world the love of civil liberty, the spirit of toleration in religious differences, the disposition to reject whatever is obscure, fantastical, or hypothetical in speculation, to reduce verbal disputes to their proper value, to abandon problems which admit of no solution, to distrust whatever can not be clearly expressed, to render theory the simple explanation of facts, and to prefer those studies which most directly contribute to human happiness." His style has the fault of being in spirit unimaginative and in form too diffuse and vague.

Newton.—Contemporary with Locke were two distinguished men of science, one of them very eminent—Robert Hooke and Sir Isaac Newton. Hooke (1635–1703) was an investigator and an inventor, but chiefly a critic and a disputant, presuming, ill-tempered, and insolent. He did not hesitate to attack Newton's theory of light and colors. Newton (1642–1727) is admitted to have been the greatest master of exact science that ever lived. His discoveries of the law according to which the force of gravitation acts, and of the refraction and composite nature of the ray of light, are the most important in their kind of modern times. His genius, although sublime and far reaching, was eminently practical; and to him England was indebted for the regulation of the dire confusion of her coinage. His works hardly come within the range of pure literature, but the splendor of his genius and the grandeur of his fame forbid them to be passed by without notice.

Locke and Newton were the great literary and philosophical ornaments of the reign of William and Mary, which was sadly in need of all the glory that could be shed upon it by their genius; for the Revolution of 1688 crushed literature far more effectually than that did which brought in the Commonwealth; one reason of which doubtless is that there was a much feebler thing to crush. For twenty years the annals of literature are bare of interest except that which attaches to Locke and to an early performance of Matthew Prior's *The Country Mouse and City Mouse.* But Prior's career (1664–1721) stretched well into the eighteenth century, in the first quarter of which appeared that galaxy of admirable writers known as the wits of Queen Anne, among whom Prior must be reckoned. The others were Swift, Pope, Steele, Addison, Gay, Garth, and Arbuthnot, of whom the last three, with Prior, may be passed without further notice.

Swift.—Jonathan Swift (1667–1745), Irish by birth but the most English of men by blood and nature, first appeared in literature by the publication in 1704 of his *Tale of a Tub* and *Battle of the Books,* the former a religious satire, the latter a literary one, both highly flavored with a coarse kind of comedy. The success of these works was very great, and their reputation has continued even to the present day. But it is safe to say that only their reputation has survived; and that there are few even of the most cultivated readers nowadays who can read these comic allegories (for such they are) with much enjoyment of their wit, or even with a very keen appreciation of their satire. But their writer has few equals as a wit or as a satirist in any literature. When he stepped upon the broad field of human nature he produced that which will be the source of delight and instruction until human nature has become other than that which he found it. It is as the author of *Travels by Lemuel Gulliver* that he commands the widest circle of readers. This production had a political purpose, like most of its author's works, and contains allusions to and caricatures of some of the statesmen, churchmen, and other public men of that day; but the genius of its author impelled him to deal with mankind even more than with party, and his satire is upon the human race. This is indeed the weakness as well as the strength of Swift's writing—his contempt for his fellow men. His own personal tastes, no less than his personal feelings, put in a strong appearance in all his writings; and nothing does he show with so little reserve as his aversion from his kind. The disgust which he makes the king of the horses in his *Houyhnhnms* feel for the Yahoos is plainly but an utterance of his own sentiments. Notwithstanding an indecency which does not consist in a public exposure of those ardent passions which the least reserved of men conceal, but in a reveling in physical filth, Swift's insight into men's motives is so keen, his satire is so splendid, as well as so savage, his wit and humor are so fine and so continuous, and his style so simple and so nervous, that great pleasure and good counsel can be extracted from almost all that he wrote. He has been compared to both Rabelais and Cervantes. He was far below either in spirit and purpose, but more like the former than the latter in his style. He wrote poetry, or rather verse, which had all the characteristics of his prose, and no others, being entirely without imagination, fancy, or beauty of form. His best known works, in addition to those already mentioned, are the *Drapier Letters*, *Polite Conversation*, *Directions for Servants*, and *Modest Proposal for preventing the Children of Poor People in Ireland from being a Burden to their Parents, and for making them Beneficial to the Publick*—to wit, by eating them.

Pope.—Alexander Pope, born 1688, began to write verses in his childhood, and before he was thirty years old had amassed a moderate fortune by his pen, and had taken a position which makes his name the most illustrious in the literary roll of the eighteenth century. Pope's first work of conspicuous merit was the *Essay on Criticism*, written when he was but twenty-one or twenty-two years old. Containing no new or striking views of literature, it is yet admirable for the soundness of its judgments and the epigrammatic elegance of its style. His *Rape of the Lock*, a mock-heroic poem—in fact, a burlesque social epic—is the most charming and exquisitely finished composition of its kind ever written. Pope was, like Dryden, whom he began by imitating, a satirist, and, like Swift, an egoist. But, unlike either of them, he had tact and delicacy, and was an accomplished man of the world. Where one used a broadsword, and the other a bludgeon, he used a rapier. His mind had also a strong philosophical turn, and this he showed in his *Essay on Man*, which is the finest didactic poem in any language, unmatched for closeness of thought, felicity of illustration, and delicacy of finish. He never wrote with passion or with strong imagination, but in his *Epistles of Eloisa to Abelard* and *Sappho to Phaon* he did attain a warmth of feeling which is almost like the fervor of real love; and in writing of his own feeble, crippled, weary, physical life (*Epistle to Arbuthnot*) he utters his woes with a simple pathos which is touching and dignified. With the assistance of some minor versifiers of the day he translated Homer, making a brilliant and very readable version, which has the one great defect of misrepresenting the original both in form and in spirit. He edited Shakspeare, but his real editorial work is of little worth, and the only valuable part of the edition is in the preface, which is full of excellent criticism written generally in admirable English. Pope was not a great poet; he was rather a colossal epigrammatist and the most skillful of versifiers. He wrote almost always in a ten-syllable heroic couplet, which he brought to the highest perfection of which it seems to be capable. He died in affluence in 1744, having established a school of poetry, and left hosts of imitators, who filled the first half of the eighteenth century with evidences of how easy it was to imitate his form, but how hard to attain his finish or to approach his style of thought. His last important work was the *Dunciad*, a savage satire not easily understood now by those who are not familiar with the literary squabbles of his day.

Steele and Addison.—Two of the eminent men of this period, Richard Steele and Joseph Addison, are free from the reproach of injurious motives and of egoism, and remarkable for the humanizing and elevating purpose of their writings. The former deserves praise for introducing into English literature the brief periodical essay, which since his time has held such an important place, and additional praise for bringing to light the remarkable powers of the latter, the master of this kind of writing. Steele began the publication of the *Tatler* in 1709. It appeared three times a week, and only a few numbers had been published when he induced Addison to become one of its regular contributors, the others being Swift and Hughes. Addison wrote about fifty papers. Afterward in the *Spectator* Addison assumed a more important position, and wrote most of the papers which gave that publication its unrivaled reputation. The purpose of Steele and Addison was the elevation of English society in intellectual and moral tone, and in manners. This they accomplished by a series of papers which have never been surpassed in the easy charm of their style, and in which wit and satire were directed, not against individuals, but against grossness, meanness, and frivolity, and did more than any one other single agency to diffuse a taste for literature, for art, and for all the refinements of social life among English-speaking peoples. Addison's style, although not nearly so correct as it was once supposed to be, deserves for many qualities all the admiration that it has received. For its constant grace and its general clearness, for lambent humor, for good nature, wit which like Ariel's music gives delight and hurts not, for a certain tone of social elegance, and for a purity far remote from squeamishness, it has no superior, hardly an equal. Addison's literary criticisms in the *Spectator* first raised that department of English literature into a recognized art. To him, as it has been said above, English literature owes the establishment of Milton's fame. In this respect, as in matters of society, he was a benefactor to the English people. Nor was Steele much behind him. Less profound and subtle than his great colleague, less exquisite in his humor, he had a larger heart and a richer nature, and there is a warm cordiality in his writing, the lack of which is Addison's chief defect. But throughout the papers published by this admirable pair, there is a dignified familiarity which has a peculiar charm, and the characters to which they introduce the reader become valued acquaintances, and almost friends. Sir Roger de Coverley is not only an historical type, but a man whom one grows to love and admire. Steele and Addison both wrote plays, the former a few comedies of some merit, the latter a cold, didactic, classical tragedy, *Cato*, which enjoyed for a time a considerable reputation. But it is as the essayists of the *Tatler*, the *Spectator*, and the *Guardian*, that their names live in grateful memories. Addison died in 1719, Steele in 1729. Like Pope, they established a school, and their century was filled with their imitators, whose writings, often not without merit, demand no particular attention. But mention should be made, also, of Lady Mary Wortley Montague (1690–1762), whose letters are models of the familiar epistolary style.

Congreve.—Three writers who gave some brilliancy to the English stage in the reigns of William III. and of Anne—William Congreve (1670–1729), Sir John Vanbrugh (1666–1726), and George Farquhar 1678–1707). Congreve was the man of the highest aims. He was poetical, if not a poet, and wrote sententious verse in a dramatic form. His tragedy, *The Mourning Bride*, contains some passages which are still remembered; in his comedies his wit keeps up a continual flash as of heat-lightning. But he created no character and had no real dramatic force. Vanbrugh had what Congreve lacked, and lacked what Congreve had, except wit. His plots are ingeniously constructed, and his characters are strongly if not truthfully drawn. Farquhar's comedies are chiefly remarkable for a flow of animal spirits. But no one of these men added much to the real glory of the English drama.

Defoe.—In the year 1719 there appeared a work of fiction which has been more widely read than any other in English fiction, except, perhaps, *The Pilgrim's Progress*. It was *The Life and Strange Surpassing Adventures of Robinson Crusoe, Mariner*. Its author, Daniel Defoe (1661–1731), was then fifty-eight years old, having passed his life until that very mature period chiefly in writing an almost incredible number of political pamphlets in favor of liberal or Whig principles. *Robinson Crusoe* immediately commanded the attention of all sorts and conditions of men. It was read with avidity, and not only with avidity, but with credulity. It was not looked upon as a novel, a fiction from beginning to end: it was accepted as a plain, unvarnished narrative of fact. And in the quality which caused it to produce this impression is its great and its only merit. Defoe has, in a greater degree than any other writer, the art of giving to fiction the air of reality. This effect is a consequence of a certain strength of imagination; but it is also due in a great measure to the continuous relation of trifling, matter-of-course, and utterly insignificant events, which, being told naturally, seem as if they were part of a life passing minute by minute before us—an inferior kind of imagination and of constructiveness, reducing that which is produced by it to the lowest level of the real school of art. Defoe was a manly and incorruptible political writer; but as a literary artist he had the grand and fatal defects of a want of passion, of sentiment, and of tenderness, and also of any remarkable insight into character and power of portraying it. His *History of the Plague* is as real-seeming as *Robinson Crusoe*, and is almost as purely fiction. His other works are now little read, and his satirical poem, *The Trueborn Englishman*, is known chiefly by name.

After Swift and Pope and Addison and Steele had ceased to write there was a long dearth of originality in English literature. But contemporary with them, or immediately following them, are the poets Matthew Prior (1664–1742); Isaac Watts (1674–1748); Edward Young (1681–1765); Thomas Warton (1687–1745); John Gay (1685–1732); William Collins (1721–59), whose *Odes* are among the best in the language; and, far superior to all the others, yet still a poet of the third or fourth class, James Thomson (1700–48), author of *The Seasons* and *The Castle of Indolence*. Among the prose-writers of the period the following demand honorable mention: Richard Bentley (1662–1742), eminent as a classical scholar and critic; Lord Shaftesbury (1671–1713), whose *Characteristics* is elegant, independent, thoughtful, but not profound; George Berkeley (1684–1753), who became Bishop of Cloyne, and who broached an ideal system of philosophy, the cardinal principle of which was that perception is all that is known of reality; and Lord Chesterfield (1694–1773), the apostle of etiquette and good breeding.

Richardson.—In the middle of the eighteenth century the English people were startled by the appearance in fiction of *nature*, an element which had been previously unknown. Defoe's power had been that of reality, which is akin to nature, but is not nature. The new style was introduced by Samuel Richardson (1689–1761), a man born in humble life, bred to a mechanical trade, and finally a bookseller. At the age of fifty-two he produced *Pamela*, which was followed by *Clarissa Harlowe* and *Sir Charles Grandison*. The success of these books, particularly of the first and second, was prodigious. But as one looks back at them, and wades through the endless succession of letters from and to their high-strung, sentimental heroines, he wonders at the avidity with which such masses of moral "spooning" were devoured, and can attribute such appetites only to a long course of starvation. Or, as Scott, in his explanation of this phenomenon, says, "Had we been acquainted with the huge folios of inanity over which our ancestors yawned we should have understood the delight they must have experienced from this unexpected return to truth and nature." Richardson was minute, like Defoe, and his personages being flesh-and-blood creatures of the period, and his sentiment genuine of its kind, although inordinate in quantity, he also awakened the keen interest which always watches over the vicissitudes of those whose experience is what we feel that ours might have been. But his books are a weariness to the flesh. It may be possible for some people now to read all of *Pamela*, but who for two generations has been able to struggle through *Clarissa Harlowe* and *Sir Charles Grandison*?—the hero of which is like a Washington in plain clothes turned beau, and eternally bowing over the hand of some pretty piece of female propriety, who worships him as if he were a fetish. But Richardson was the occasion of the appearance of a real master of human nature. Henry Fielding (1707–54), a gentleman by birth and a man of liberal education, was tempted to write a burlesque of *Pamela*; and, as in the case of some other performances of like motive, the burlesque proved more true to nature than the original. Fielding's novel was *Joseph Andrews*; and as *Pamela's* chief object of life was to preserve through six or seven volumes the point of female honor, so Joseph, her supposed brother, devotes himself to the assertion and preservation of his continence against the wiles of the opposite sex. The vigor and spirit of Fielding's style and his creative power have never been surpassed. He showed that highest ability in fiction, the power of creating personages which are at once individuals and types. His Parson Adams, Lady Booby, Squire Western, Tom Jones, and Amelia have a vitality and a truth far above that which is producible by the most elaborate work in the realistic school. They come from a knowledge of the real, from which the truth of highest art eliminates the non-essential. They are created from within, not built up from without. Fielding's humor is rich, free, and pervades his comic scenes like the natural atmosphere. That he was sometimes coarse, according to modern standards of taste, is the fault of his time. Tobias Smollett (1721–71), who soon appeared upon the field, was a much coarser artist. His object seems merely to tickle his reader into laughter by a succession of scenes which seem like farce put into narrative form. But he has fine touches of satirical humor, and his *Peregrine Pickle* and *Roderick Random* and *Humphrey Clinker* will always give pleasure to readers of robust tastes and strong stomachs. In the latter part of his life he wrote a continuation of the history of England from the point to which it was brought down by David Hume.

Hume.—David Hume (1711–76) a Scotchman, first appeared in the field of philosophy, in which he showed himself an original and daring thinker. His philosophical works are a *Treatise on Human Nature* (republished as *Philosophical Essays concerning the Human Understanding*), *An Inquiry concerning the Principles of Morals*, and *The Natural History of Religion*. In the treatment of these subjects he disregarded authority and accepted belief, making fact and reason his only guides. He was by nature a doubter and an inquirer. These works placed him in the front rank of modern moral and metaphysical writers, and produced an effect which seems destined to be permanent. His views as to the possibility and the necessity of miracles arrayed against him all the theologians of his day; but a large number of the ablest and most sincere theologians of the present time accept his views as being sound in the main and not at war with the interests of true religion. Having taken this position, he turned his attention to history, and wrote in three instalments what is known as his *History of England*, bringing his work down to the Revolution of 1688. This work is not of high authority as to matters of fact, and it is strongly tinctured with the writer's personal prejudices. But its happy arrangement, the clearness and vivacity of its style, its charity and toleration of spirit, notwithstanding the obvious prejudices before referred to, make it one of the most interesting of modern histories, as it was the first of the modern school of historical writing. Hume's style is too strongly marked with Northern peculiarities to be regarded as a good example of standard English.

Gibbon.—Contemporary with Hume, but younger, was Edward Gibbon (1737–94), who produced between 1776 and 1788 his *History of the Decline and Fall of the Roman Empire*, a work upon which he was engaged for twenty years. The magnificent plan of this history, the vast extent of time which it covers, its colossal erudition—it being the fruit of original investigation of facts hidden for the most part in the dimmest recesses of the Dark Ages—and its imposing style, make it the greatest work of its kind known to literature. Its style, however, is too conscious, too pretentious, too much infested with Romanic words and Gallic forms of thought, to be regarded as really English.

Contemporary with the two distinguished historical writers, though not as eminent as they, was William Robertson (1721–93), who wrote the history of Scotland, of Charles V., and of America—works of sound and unpretending merit, written in an agreeable style, somewhat too strongly marked with Scotticisms.

Gray.—The middle of the eighteenth century was adorned by the highly finished poems of Thomas Gray (1716–71), whose function in poetry seemed to be to show how high a point could be reached by a man who had a poetic nature, strong poetic feeling, and an exquisite ear for rhythm, but was without genuine poetic inspiration. Gray's *Elegy Written in a Country Churchyard* has probably been more widely read than any other poem in the language, and it has certainly furnished more phrases to its collection of household words than any other that ever was written; almost the whole of it has become a part of familiar speech. It is a beautiful union of tender thoughtfulness and graceful expression. Contemporary with Gray was William Shenstone (1714–63), a poet of considerable merit, whose best-remembered work is *The Schoolmistress*, an admirable imitation of Spenser's style, but more admirable as a poetical picture of a type and of a time.

Sterne.—To this period, too, belong the works of Laurence Sterne (1713–68), one of the greatest humorists found in any literature. His is the only humor that could be named with that of Shakspeare or of Cervantes. His satire has the charm of a delicacy so exquisite that it seems like pungent aroma filling the atmosphere of his thought. His style has a corresponding daintiness, although it is sometimes disfigured with affectation. Admiration of *The Life and Opinions of Tristram Shandy* and of *A Sentimental Journey through France and Italy* has grown with the passage of each year since their first appearance.

Johnson.—Throwing the shadow of its sad humanity all athwart the latter half of the eighteenth century stands the burly bulk of Samuel Johnson (1709–84), one of the most miscellaneous, and really one of the most desultory, of writers. He was a poet, a dramatist, an essayist, a biographer, and a lexicographer. In fact, like many other literary men of equal and of less note, he wrote for bread that which he was called upon to write; but he impressed upon all that he did write the stamp of his own strong individuality. His purely literary fame was acquired chiefly as a moral and a critical writer. Not always just, not always right, he is distinguished by a love of truth and of purity, by sturdy independence and colossal common sense. Of original thought he produced little, but he added to axioms the charm of novelty by the earnestness and the weight with which he gave them utterance. His style, too ponderous and too formal, has nevertheless the great merit of clearness and of strength; and slipshod writers would do well to take a hint from his advice in regard to Addison, and devote their time to the study of "the Johnsonian period." His *Rambler* essays, which he wrote twice a week for two years, exhibit in their most characteristic form his merits and his defects as a writer. If heavy sometimes in style, they are always laden with the weight of humanity. Johnson's *Dictionary*, having been compiled before the establishment of the modern school of comparative philology, has comparatively little etymological value, but it was the first English dictionary made upon the proper principle of an investigation of the history of words as exhibited in English literature; and it has been the model and the quarry of almost all subsequent works of its kind. Johnson is, however, best known through the minute report of his daily life and his intercourse with his literary friends, furnished in his memoirs by James Boswell. He was a sort of king in the literary circles of his time, and exercised a personal influence, the effects of which long survived him.

Adam Smith.—Among Johnson's eminent contemporaries two must be passed by with mention inadequate to their fame—Adam Smith (1723–90), who has the honor to be the founder of the science of political economy; and the unknown writer who, under the signature of *Junius*, was a terror to the statesmen of his time, and even of his party, and who remains the great English master of invective. The style of the letters of Junius is still worthy of all the admiration of which they were ever made the subject; and that of the best political leading articles in the journalism of subsequent times owes much to those celebrated letters, which may be said to have founded the modern school of anonymous and irresponsible journalism.

Burke.—It is remarkable that of the great masters of modern English, four of the greatest were by birth and early education Irishmen—Swift, Sterne, Goldsmith, and Burke—and of these the foremost is the last. Edmund Burke (b. about 1738) is the greatest master of English prose. Goldsmith is his equal in purity, simplicity, and grace; but in Burke there is a fullness of thought, a wealth of words, a sustained power of utterance, a grand sweep of the period, with a subtle yet most naturally inwrought richness of illustration, to say nothing of mere accuracy of expression and clearness of construction, which place him far beyond all other writers. Burke's mastery of language is like Beethoven's mastery of melody and harmony. His department of literature is that of philosophical statesmanship, in which he stands side by side with Cicero, if not a little before the great Roman. The saying that he to party "gave up what was meant for mankind" is one of those glittering fallacies of thought which poets have unfortunately the power of perpetuating. On the contrary, his fault as a party man was that he thought too much of mankind and had too much poetic feeling—thought perhaps not always logically, and sometimes with too much sentiment of the highest kind, but rarely in unwisdom. Indeed, he is the wisest of all modern politicians. His *Reflections on the Revolution in France*, *Letter on a Regicide Peace*, and *Letter to a Noble Lord* are his principal works. Of his purely literary essays, that on *The Sublime and Beautiful* was at first widely known and read. But among the earliest fruits of his laborious life it is that of the least permanent value. His strength grew with his years, and his most powerful as well as his most brilliant efforts were made after he had passed his meridian, and even just before his death, which took place in 1797.

Goldsmith.—Of Oliver Goldsmith (1728–74) Dr. Johnson well wrote, "Nullum quod tetigit non ornavit," and he touched many things, but he lives in literature as the author of four works: a novel, *The Vicar of Wakefield*, a comedy, *She Stoops to Conquer*, a poem, *The Deserted Village*, and a satirical criticism of society, *The Citizen of the World*. He wrote other poems, many essays, and much criticism, all charming in style and full of humor and a gentle wisdom, but the works named above are his masterpieces. The *Vicar of Wakefield*, faulty in construction, is matchless and immortal as a gentle revelation of the weakness of human nature, and stands first among novels of English domestic life; and *She Stoops to Conquer* is, whether for its construction or its humor, the best comedy of the same range in English dramatic literature.

Cowper.—The eighteenth century was rounded with the life of a poet, William Cowper (1731–1800), who to minds of a religious tone and unspeculative cast speaks in accents which comfort them and sustain their faith. He is pre-eminently the poet of Christian morality, of true piety, and of all the softer and sweeter social graces. Incapable of bitterness, he was not incapable of gentle and dignified satire; and although his style has too much of the formality and conscious precision of his time, he has many passages marked with great sweetness and freshness of feeling. His longest and most ambitious original works are *The Table Talk* and *The Task*, but incomparably his best are his *Lines on my Mother's Picture*, and *John Gilpin*, an outburst of pure fun and humor strangely and delightfully incongruous with his usual style. He translated Homer very ambitiously, but without corresponding success.

Burns.—Robert Burns (1759–96), who died only four years before Cowper, was the greatest writer of English poetry born north of the Tweed. He is regarded as a "Scotch" poet, but even his "Scotch" poems are in a mere dialect of the English language, as has been remarked; some of his more serious poems, and not a few of his songs, are in as pure standard English as any compositions of his contemporary, Cowper himself. As a lyric poet, Burns, when we consider both the number of his poems and their merit, must be placed at the head of his class. No songs so full of the direct utterance of passion, of tenderness, and of love-lit fancy exist in the English language—hardly in any other; and his idyls spring from the soil like grass, and with the purple bloom and the sweetness of heather. Entirely uninstructed, he was fashioned by Nature from his cradle to be her singer. The very trials of his shifting life, the very failings of his unstable character, were to him sources of the purest poetic utterance. He indeed did learn in suffering what he taught in song. Having wrecked his life upon his passions, and wreaked his woes upon expression, he died in misery, and left a name around which burns a glow of tender glory. Two of his countrymen deserve mention among the poets of their land—James Hogg (1770–1835) and Allan Cunningham (1784–1842).

Colonial Authors.—In the eighteenth century the English race began to manifest its power in a new land. The men who had left the old England, and had crossed the Atlantic to found a new England free from some of the civil and religious restraints which galled them in the land of their birth, were, very many of them, not only energetic and enterprising, but intelligent, and of more than moderate intellectual and social culture. In New England education was one of their earliest cares. Colonial literature has, however, nothing worthy of notice in a sketch like the present (for the Mathers, Increase, the father, and Cotton, the son, produced nothing that has any intrinsic literary value) until Jonathan Edwards (1703–58) is reached, a theological and metaphysical writer whose power was at once recognized in the mother country, and whose *Enquiry into the Freedom of the Will* is still the stronghold of the necessitarian theologists. He merited the judgment pronounced by his biographer, Mark Hopkins, that he was a man of considerable learning, extensive reading, sound judgment, and great argumentative acuteness.

Franklin.—The next author eminent among his countrymen was Benjamin Franklin (1706–90), apostle of common sense. Franklin was a philosopher, but in his company Philosophy wore her homeliest garb and addressed herself by the simplest means to the most practically useful ends. He was above all things "utilitarian," of which school in social science he was one of the founders. He is hardly better known for his discoveries in electricity and the great diplomatic services he rendered the colonies at European courts than for the prudential maxims of his *Poor Richard's Almanac*. His style is very plain, clear, and convincing. Among Franklin's younger contemporaries were the men who roused the colonists to resistance to the tyrannical government of George III., and finally brought about the severance from the mother country—John Adams (1735–1826), Thomas Jefferson (1743–1826), Patrick Henry (1736–99), Thomas Paine (1737–1809), John Trumbull (1750–1831), Philip Freneau (1752–1832), and Alexander Hamilton (1757–1804). Of these, Adams was sound in judgment, logical in reasoning, a lawyer, and a man having respect for authority and demanding respect for it; Jefferson, a calm but earnest and persistent advocate of equality before the law in all things, whose authorship of the Declaration of Independence not only secures him immortality, but gives him some claim to having helped to light the fires of the French Revolution; Patrick Henry, an orator of masculine tone and fervid phrase, equally daring and dexterous; Thomas Paine, an intellectual iconoclast and a rebel against all authority, whose *Common Sense* and *Rights of Man* have done more to spread skepticism, if not to quicken it, than any other books ever written; Philip Freneau, a poet of genuine patriotic feeling and lyrical skill; Hamilton, a statesman of true formative power, who was endowed with the ability of uttering his schemes and putting his arguments in a style of remarkable elegance and force. He was the principal author of *The Federalist*, a series of papers which did much to bring about the formation of the American Union. But the place of all these men in literature is not a notable one, and is very inconsiderable compared with that which they filled in the great political movement of their time. They had very little influence on the literary tone of their own country, and are hardly discernible in the great stream of English literature which now flows yearly fuller and stronger with the inpouring of its American tributary. But it was not until well on in the first quarter of the nineteenth century that Anglo-American writers showed native, independent power.

NINETEENTH CENTURY.

The period succeeding the American war of Independence and the French Revolution was one of great activity in English literature, all departments of which were filled by a throng of new writers who sprang up with the spontaneousness of mushrooms, but not with their shortness of life. And now, as the names of authors increase—authorship having become so common that everybody writes, learned and unlearned—and as a period within the memory of living men has been reached, remarks, even upon writers of eminence, must be more brief than they have been heretofore, and for the sake of convenience the various departments of literature will be considered each by itself.

Poetry.—The bonds of continuity between eras, however unlike, are rarely if ever entirely wanting unless they are broken by some prolonged as well as violent political and social convulsion, such as has been remarked in the case of the Wars of the Roses; and the link that binds the poetry of the eighteenth century to that of the nineteenth is George Crabbe (1754–1832), in whose works both the form and the spirit which more or less pervaded English poetry from the time of Pope to that of Wordsworth are so manifest, yet with the modification produced by a tendency toward the contemplation of simple nature and of the reality of lowly life, as to win him the sobriquet of "Pope in worsted stockings." Crabbe's poems show close observation, a loving sympathy with nature, and not a little shrewd humor. Walter Scott (1771–1832), who followed soon after him, was very unlike him in the choice of his subjects and the style of his versification. Scott is the poet of chivalry and romance, and the story of his poems is always removed from modern times; he writes loosely and freely, but with great spirit and vivacity of movement; his fancy flies low, but his imagination is strong, and his love of nature and of the external signs of man's presence, as churches, castles, and buildings of all kinds, is very great. No poems ever received so quickly so large a share of public attention as his. They effected an entire change in the poetic taste of the time. After working his peculiar vein out, he turned his pen to prose fiction.

Byron.—Scott was replaced in favor, as a poet, by Lord Byron (George Gordon Noel, 1788–1824), who, entirely unlike him in the spirit of his poetry, had strong points of resemblance to him in the form and structure of his compositions. Like Scott's, Byron's principal poems are narrative, and have a freedom of versification and ease of style entirely opposed to the eighteenth-century manner. The heroic couplet and the epigrammatic period had disappeared from English literature, perhaps for ever. Byron's style is rich, sensuous, and brilliant; his motive rarely high or pure. He is satirical, but because of a contempt for his kind rather than a hatred of what is bad and base. His descriptions, whether of natural objects or human action, are truly splendid; and in some passages, notably in his greatest work, *Childe Harold*, he rises into the higher regions of poetry. But the tendency of his writings is debasing, less because of their sensual and epicurean tone than by reason of their derangement of the moral perceptions and their defiance of the moral sense. His heroes are unnatural combinations of incongruous qualities; his women mere compounds of beauty and unrestrained passions; and a gloomy and fierce egoism pervades his writing. But he is the richest in style and the most copious in fancy of all modern English poets. He was followed in public favor by his friend Thomas Moore (1779–1852), a poet of Irish birth, who wrote *Lalla Rookh*, *The Loves of the Angels*, and *Irish Melodies*, but whose real excellence was in lyric compositions. Moore's songs are charming in their tenderness, their lively fancy, and the sweet cadence of their verse, but they do not rise into the highest range of lyric writing. They smack of society, and have about them the odor either of the drawing-room or the dinner-table.

Campbell.—Next in the galaxy of poets which distinguished the reign of George IV. comes Thomas Campbell (1777–1844), a Scotsman by birth and a Celt by blood, who yet stands high in the annals of English literature. His *Pleasures of Hope* and *Gertrude of Wyoming* are his longest and his most ambitious poems. They are full of bright fancy, generous sentiment, and earnest humanity of feeling. But his lyric poems are his best, and they are of a very high order. They have the true fire and energy of the highest lyric school, mingling in rare combination, fancy, passion, and reflection. His critical and biographical writings added largely to his literary reputation. Percy Bysshe Shelley (1792–1822) and John Keats (1795–1821) should be noticed here, although greater names await mention. They both lived uncompleted lives, neither of them producing a work which attained the excellence of which they seemed capable. Shelley's life was one of revolt against society, and his longer poems are an utterance of his rebellious spirit. His minor poems express the exquisite tenderness and sweet fancies of a really lovely nature. Keats's *Endymion* and *Eve of St. Agnes*, full of beautiful passages, lack the coherence and consistency of style requisite in poetry of a high order; but perhaps it may justly be said that he died too young for us to know the real caliber of his mind.

Among the poetical writers of this period these must be mentioned: the brothers Horace (1779–1849) and James Smith (1775–1839), the authors of the famous *Rejected Addresses*, parodies or burlesques of subtle humor and inherent merit; Mrs. Felicia Hemans (1793–1835) and Miss Letitia E. Landon (1802–38), both graceful and sentimental poets; Robert Montgomery (1807–55), the author of *Satan* and other religious poems; Theodore Hook (1788–1841), the author of irreligious poems and jests that belied his name; Joanna Baillie (1762–1851), known as the authoress of an elaborate series of *Plays on the Passions* which could not be played and are never read; and Sir Thomas Noon Talfourd, a common-law judge, whose one tragedy, *Ion*, made a lasting reputation for him and for more than one representative of its title part, and is read with delight by those who eschew the theater.

Wordsworth.—At this time appeared what was styled the Lake school of poets, the first of whom was William Wordsworth (1770–1850), whose poem, *An Evening Walk, addressed to a Young Lady from the Lakes of the North of England*, was probably the occasion of the name given to him and his imitators. Wordsworth began to write in the old style, as appears by some poems written in 1786 which he preserved. But reaching manhood, he broke loose from this style, and set out to reform English poetry, and his effort was toward an admirable end—simplicity and truth to nature. One means by which he hoped to attain his end was, in his own language, "fitting to metrical arrangement a selection of the real language of men in a state of vivid sensation." He failed in accomplishing this end, which is incompatible with the requirements of any poetry; and one result of his efforts in this direction was the putting in some form of verse, generally a sonnet, almost every incident of an externally prosaic life. All his best works had their excellence (as his friend Coleridge said) in a treatment entirely at variance with his own theory, in conforming to which he produced of what was good only some short and simple poems of a remarkably picturesque beauty; but the rest of his verses, wrought out according to his theory, excited only the ridicule of his contemporaries, and have fallen into merited oblivion. Wordsworth in the best manifestation of his powers was a descriptive philosophical poet. He lacked passion, had no dramatic power, even enough to take himself out of himself, and his constructive ability was small. Of lyric power he had none whatever, and his versification has no peculiar charm. But in two styles of poetry he is without a superior, almost without an equal, in English literature. The first which is almost peculiar to himself, is marked with a thoughtful and tender simplicity in the expression of the feelings of very humble people. It may be regarded as a very refined and elevated style of ballad-writing, the fidelity of the best old ballad style to the facts of nature being carefully preserved. The other style—and that in which the greater part of his best poetry is written—is speculative, deeply penetrative into the human heart and the relations of man with God and nature. It is grand, but when prolonged becomes somewhat wearisome. His sonnets, which are very numerous, are, with a few conspicuous exceptions, cold and dry, and seem, too many of them, to have been written under the pressure of a sense of duty. He wrote much, but room can not be spared even for the enumeration of his important works. He was made poet-laureate in 1844, succeeding Southey. Robert Southey (1774–1843) wrote much verse, but little that can be termed poetry. What he might have produced had he concentrated his efforts can not be told. But he surely might have been one of the first of English prose-writers. The amount of writing that he did in verse and prose is really prodigious. But the essence of poetry is concentrated thought, or at least concentrated expression of thought; and that he lacked. He was in all things diffuse, although clear and simple and manly in style. His English is much admired by the best critics. But he was without originality even in style. Of all his verse not a line or a phrase has passed into the phraseology of common life except one—"deeply, darkly, beautifully blue"—which owes its circulation to Byron's having quoted it. Of all his works only his rambling, humorous *Doctor* is now read; but he was one of the most conspicuous literary personages of his time.

Coleridge.—Among the associates of Robert Southey and Wordsworth was Samuel Taylor Coleridge (1772–1834), a man who, if he had been content with being only a poet, would have been a poet of the highest rank, excluding the three who stand together—Homer, Dante, and Shakspeare. Coleridge began life by being an enlisted dragoon; he next projected a utopian republic on the banks of the Susquehanna; next he became a Unitarian preacher; he afterward turned Trinitarian and Tory; and he passed the remainder of his life writing and talking with a marvelous mingling of grandeur and subtlety, but leaving nothing complete except a few short poems. He was one of the last of the great talkers, the very last being Macaulay; and like him he spoke soliloquy. The author of *The Ancient Mariner*, of *Christabel*, of *Love*, of *Genevieve*, of the *Hymn to Chamouni*, of *The Devil's Walk*, of the lines upon *Cologne*, and the translator of *Wallenstein* had the capacity of a great poet of very varied powers. But he was beset by the demon of criticism, that foe of the creative faculty; he could not resist the temptation to wander away into the fields of metaphysical speculation; he sapped his mind and shattered his body with opium-eating; and so he ended his life, a splendid wreck, leaving the wealth that he bore scattered upon the shores of immortality.

Samuel Rogers (1763–1855), the banker-poet and the author of the *Pleasures of Imagination*, was a writer who formed himself rather upon the eighteenth-century models, and who, as Byron said, "when he was delivered of a couplet took to his bed and tied up his knocker." Thomas Hood (1799–1845) was one of the most charming of English humorous poets, and one who combined his humor with a pathos peculiarly his own, whose *Song of a Shirt* and *Bridge of Sighs* have touched, and will ever touch, all true hearts with sadness.

Bryant.—Among the conspicuous later poets are Bryant, Longfellow, and Tennyson. William Cullen Bryant (1794–1878) first commanded attention by a poem, *Thanatopsis*, written when he was nineteen years old—a grand monody upon the end appointed for all living, the inspiration of which was perhaps caught from a passage in *Measure for Measure*, and which has taken a place among the classic poems in the English language. After reaching the age of seventy years he made a translation of Homer which disputes the palm of superiority with all its predecessors. Between these periods of a laborious life he wrote not much poetry, but none unworthy of the fame he won so early and sustained so late. In purity of style, in the finish of his verse, in the elevation of his thought, and in his loving portraiture of nature he is unsurpassed among the poets of his time. His writings lead one to wish that poetry had been the business and not the mere adornment of his life.

Longfellow.—Henry Wadsworth Longfellow (1807–82) passed his life in the pursuits of the higher literature. His two earliest books, *Outre Mer* and *Hyperion*, were prose, but the prose was that of a man of poetical temperament. Then came the *Voices of the Night*, which at once commanded the attention of the whole English-speaking public, and have been translated into German and into other languages. He subsequently gave to the world many volumes of poetry which have enjoyed as great a popularity in Europe as in America. Longfellow's poetry has the rare quality of addressing itself directly to the minds and hearts of all men. High and low, educated and uneducated, all acknowledge its charm. Singularly refined in his every utterance, he became the most popular English poetical writer of his time. His poems are galleries of characters uttering sentiments that sink into the general heart. To his original works he added a translation of Dante, the singular fidelity of which to the original in thought and in form shows no less his mastery of his own tongue than his thorough and subtle knowledge of that of the great Florentine poet.

Tennyson.—Alfred Tennyson (1809–92), on succeeding Wordsworth as poet-laureate, took the first place among living British poets. In his case almost the poet was made, not born, for his first volume, published in 1830, gave no promise of his future fame; and it was not until twelve years afterward, when Longfellow had published his *Voices of the Night*, his *Ballads and Other Poems*, his *Poems on Slavery*, and had in press *The Spanish Student*, by which his style of versification and the character of his thought were fully displayed, that Tennyson published his third book, *English Idyls* (2 vols.), in which the *Morte d'Arthur* and *Locksley Hall* gave unmistakable indications of his genius. These facts dispose of the assertion, which has been unwarily made, that the New England poet was an imitator of his British contemporary, a somewhat younger man and a very considerably later poet. After the publication last mentioned, Tennyson's poetic faculty grew greatly, and with it his fame. Tennyson is eminently a poet whose powers were developed, almost made, by discipline and by culture. Like Wordsworth he held himself apart from the world, consecrating his life to his Muse. His style is elevated, pure, and deeply thoughtful. He deals with the great problems of the human soul—but incidentally, none of his works having a distinctly metaphysical or even a moral aim. His *In Memoriam* is in this way very characteristic of his mind, and with his *Idyls of the King* presents the highest manifestation of his powers. He ever wrote with a high aim, but always showed a consciousness that he was doing so. The deficiency of his poetry is in spontaneousness and energetic utterance. He rarely catches "a grace beyond the reach of art." But some of his lyric poems, like the one beginning "Break, break, break on thy cold gray stones, O Sea!" have an exquisite charm of sentiment.

Browning.—If the dramatic writing of his day were worthy of classification as literature, Robert Browning (1812–90) should be regarded as at the head of the dramatic poets. This place would be his, not so much by virtue of his plays as because all that he wrote is imbued with the purest and highest dramatic spirit. He is not only the greatest English dramatist of the age, but the greatest since Shakspeare. He had that power so admirable, so rare, of creating living personages whose characters become known to us not by description, but by their own actions and utterances. In these characters he entirely lost his own identity, and even, it would seem, his own consciousness. He thought their thoughts, and felt their feelings. This is true in what seem to be descriptive poems; and the well-chosen names of two of these volumes, *Men and Women* and *Dramatic Lyrics*, show a consciousness on his part of this power. His versification is often rough, his style careless, his thought involved; but those who understand him forgive these defects (which he sometimes compels into charms, if not into beauties) for the delight they take in his rare dramatic genius. He married Elizabeth Barrett (1806–61), the most eminent of English poetesses, whose *Portuguese Sonnets* (in which the love crowned by that marriage is covered by a very transparent veil) are admirable for fervor and freedom of utterance, and whose *Aurora Leigh* is in fact a novel of society wrought skillfully into a charming narrative poem.

Lowell.—James Russell Lowell (1819–91) and Matthew Arnold (1822–88) are uncommon exemplars of the union of the poetical and the critical faculty. No one can read Mr. Lowell's *Legend of Brittany*, his *Sir Launfal*, his *Commemoration Ode*, and his minor poems without wishing that he had given his life to the development and the perfection of the great natural poetic gift which they indicate. As a humorist he has few equals, and he is most widely known by the *Biglow Papers*, a series of humorous satirical poems in the rustic New England dialect, of which Lowell is a perfect master. His critical essays, especially those in *Among my Books* and *My Study Windows*, are marked by searching independence of thought and the fruits of a wide range of reading, enlivened by touches of his rare and racy humor. Of Matthew Arnold's poems, his dramatic *Sohrab and Rustum* is the finest exhibition of his power in this direction. It has the true antique grandeur, with the antique simplicity and directness. His essays and critical writings, which are numerous, are marked by unusual subtlety of thought and an exquisite finish of style.

Swinburne.—Algernon Charles Swinburne (b. 1837), the most prominent, if not the most admirable, of the younger English poets, first commanded attention by his drama, *Atalanta in Calydon*, remarkable for its exquisite fancy, its wealth of language, and its strong infusion of the old Greek spirit. His other dramatic poems, although not equal to this, delight admirers of strong passion and unreserved utterance. A volume of *Poems and Ballads* exhibits the same qualities in a greater degree, clothed in a versification the external richness and strength of which compel an admiration sometimes unwillingly given to such exhibitions of nakedness of soul and body.

Morris.—There are two kinds of nakedness: of soul, and of body; the purer kind never was seen in a more alluring form than in the poems of William Morris (1834–96), whose *Jason* and *Earthly Paradise* have placed him high in the second rank of English poets. Morris goes to the legends of ancient Greece and of the Middle Ages for his subjects; and he tells these old tales with such vividness of imagination, such picturesque and sensuous richness of description, and such sweet simplicity of feeling that he renews and freshens all their old beauty and adds to it a charm of his own. His versification is remarkable for its easy flow and for the luscious richness of its sound. But his great strength lies in his imagination. He sees before him the subject of his verse. As a narrative poet he has no superior or equal but Chaucer, of whom he professes himself the scholar.

Whittier.—Of the poets of minor fame John Greenleaf Whittier (1807–92) produced some fine examples of true ballad poetry—high praise, for the true ballad, one of the most charming forms of lyric composition, is in modern days among the rarest of poetical productions; and the author of *Barclay of Ury*, *Maud Muller*, and *Barbara Frietchie*, always pure, fervid, and direct, will be remembered when many a more voluminous and ambitious writer is forgotten. Mention should also be made of Thomas Williams Parsons (1819–92), the master of a true and strong poetic utterance; Jean Ingelow; Bret Harte, whose humorous poems in dialect have qualities regarded as peculiarly "American"; Bayard Taylor (1825–78), who has made the best translation of *Faust*; Richard Henry Stoddard, George Henry Boker (1842–90), Edmund Clarence Stedman, and Walt Whitman (1819–92), who amid heaps of commonplace rubbish in fantastic form has dropped some lines weighted with thought and true feeling.

The principal dramatists of the nineteenth century are James Sheridan Knowles (1784–1862), Dion Boucicault (1822–90), Tom Taylor (1817–80), and Thomas William Robertson (1829–71), but no one of them wrote a play which has any value except upon the stage. In the English language dramatic literature seems to have ceased to exist. Richard Brinsley Sheridan (1751–1816), the author of *The Rivals* and *The School for Scandal*, belonging partly to the eighteenth century, is the last of the dramatic school. But even his comedies are comedies of wit, not of character, and the wit is always that of Sheridan, not of the personages who utter it.

Novels.—In no department of literature has the increased intellectual activity of the nineteenth century been so copiously manifested as in that of prose fiction. The writers of novels are to be numbered nowadays by the hundred. Merely mentioning the names of Hannah More (1745–1833), the author of *Cœlebs in Search of a Wife* and other writings of a pietistic-social purpose; William Beckford (1759–1844), whose *Vathek*, originally written in French, does not for its merit deserve a notable place in English literature; Anne Radcliffe (1764–1823) and Matthew Gregory Lewis (1775–1818) (called "Monk" Lewis, from the title of his most celebrated work), both of whom reveled in horrors and mysteries; and the two sisters, Jane (1776–1850) and Anna Maria Porter (1780–1832), the priestesses of the goddess of sensibility—all of whom belong rather in spirit, as they do much in time, to the eighteenth century—let us pass to the consideration of the later and stronger writers of fiction, only the most eminent and characteristic of whom can be noticed here.

Scott.—The great novelist of the century, of the English language—and it is not too much to say of the world—is Sir Walter Scott, who, as has been seen, holds also so high a place among its poets. *The Waverley Novels*, so called from the title of the first one of the series, are chiefly historical—that is, their plots are interwoven with historical incidents, and some of their principal personages are figures taken from history. In correctness of historical detail, as also in correctness of style, they are open to adverse criticism. But trifles of that kind are, or ought to be, disregarded by even the best-informed and most cultivated readers as they are borne onward upon the strong, steady stream of the story. Scott was simply the greatest writer of stories that ever lived. His imaginative realization of his personages, and his dramatic evolution of their characters and management of their intercourse with each other are inferior only to Shakspeare's, from whom, in imaginative writing, criticism may take one great leap to him. No other writer but Shakspeare has filled the world's memory with such a throng of living figures, so varied in their types, so lifelike and real-seeming in their action. He spends little time in analyzing motives and in dissecting character; but with strong, clear touches, every one of which has meaning, he places the man or the woman before us, and we know them, as we know our friends or our enemies, forever after, and at once we become interested in their feelings, their actions, their experience, and their fate. Scott is a singularly healthful writer. There is in his works hardly a morbid passage or one in any sense injurious. One rises from them refreshed, delighted, invigorated, elevated. In narrative power, in truthfulness, in picturesqueness, in life-like action, in the clear management of a complicated action, in united strength and delicacy of portraiture, in grandeur of movement, in humor, and in charm of style he is without a rival. Jane Austen (1775–1817), who followed him as a younger contemporary, is one of the best of English domestic novelists. Her works will always be read for their intrinsic interest and as faithful and pleasing pictures of the society of her time. George P. R. James (1801–60) was an imitator of Scott, and although a prolific writer and a favorite with the public of his day, he has shared the fate of all imitators, and is now little read. But the author of *Philip Augustus* and *One in a Thousand* was a novelist of no mean powers.

Bulwer.—Edward Lytton Bulwer (1803–73), afterward Lord Lytton, in his novel *Pelham* introduced to the world what is distinctively known as the novel of fashionable society. He afterward extended his field and wrote historical novels, sentimental novels, novels descript and nondescript. A man of high culture, of various acquirements, and a writer of considerable power, he commanded for many years the admiration of a wide circle of readers. But he was in no way original; his sentiment was equally false and excessive; his style was artificial; he had no dramatic power; and his personages have no true life or character, but are bundles of clothes with something in them that talks what Edward Bulwer thought. No one of them lives except Pelham, a typical high-class dandy of the latest Georgian era. His best works are *The Caxtons* and *My Novel*, written in imitation of Sterne.

Disraeli.—Benjamin Disraeli (1804–81)—the son of Isaac Disraeli (1766–1848), a Hebrew who was converted to Christianity, and who is widely known as the author of *The Curiosities of Literature*, *The Amenities of Literature*, and *The Calamities of Authors*—was the author of several novels, the earliest of which is *Vivian Grey* (1825) and the last *Endymion* (1880). His works are brilliant, and have always commanded attention, but they are fantastic, extravagant, and untruthful as representations of human nature or of society at any time or in any country. Most of them have a political or a social purpose, and are believed to contain portraits of contemporary politicians and other persons of distinction. But *Henrietta Temple* has been regarded by some critics as one of the most natural love-stories ever written. His writings indicate a strong prepossession in favor of the Hebrew race. His chief distinction was in the field of politics.

Dickens.—Charles Dickens (1812–70), a man of singularly original powers, next appeared upon this field. He was a humorist, and found congenial subjects among characters of low, or at least of humble, life. Of these his caricatures—for he rarely drew except to caricature—are infinitely amusing. His attempts to rise above this plane were, with one notable exception, *The Tale of Two Cities*, conspicuous failures. His sentiment is generally exaggerated, and his pathos often false. But as a humorist, pure and simple, he is unrivaled in the present generation. William Makepeace Thackeray (1811–62), also a humorist, was a writer of a very different stamp. His novels are satires upon society. But his style is pure, his satire delicate, his caricature little exaggerated, and his pathos is true and often profound. His personages generally belong to the cultivated classes of society, and his representations of gentlemen and ladies, both as to their manners and their motives, are always worthy of admiration. The author of *Vanity Fair*, *Pendennis*, and *Henry Esmond* has a high and a permanent place among English writers of fiction. Charles Kingsley (1819–75) was the author of novels of very considerable merit, among which are *Alton Locke*, *Yeast*, and *Amyas Leigh*.

George Eliot.—Among women who have written novels, Charlotte Brontë (1816–55), the author of *Jane Eyre*, holds a conspicuous place. Her few works are chiefly remarkable as giving, with great subtlety of perception and boldness of utterance, the woman-view of man's character, and as to women their view of themselves in relation to man. Very introspective and analytic, they dissect motives with a hand at once bold and delicate. In this respect, however, as in all others, she must yield to the writer who appeared under the name of George Eliot, but whose real name was Mary Ann Evans (1819–80). George Eliot's constructive power was small; she was not a great teller of tales. In her subtle analysis of character and revelation of motives she allowed the movement of her story to lag: she crowded her canvas with too many figures, all painted like miniatures, until she and the reader both began to forget the main purpose in hand. To this criticism, however, her earlier sketches, her first novel, *Adam Bede*, and above all *Romola*, are in a great measure exceptions. *Romola*, as the history of two lives, and in the revelation of character and the motives—the unacknowledged and almost self-unknown motives—of its principal male character, Tito—is a marvelous work of art. George Eliot, like the generality of female writers, was most successful in describing what she had seen. Her personages are studies from life, but she had a vivid imagination and great dramatic power. Her views of life and of human nature are gloomy and depressing. Her style is in all respects admirable. Elizabeth (Stevenson) Gaskell (1810–65) must not be forgotten, her *Life of Charlotte Brontë* and her works of fiction, such as *Mary Barton* and *Cranford*, possessing rare merit.

Reade.—Charles Reade (1814–84) wrote novels which by their vividness of portraiture, their vivacity of movement, and their humor took a firm hold upon the public. Whatever the nicely fastidious may think of the taste of much that he wrote, even they can not fail to be interested in the fortunes of his personages. His effects are theatrical, and sometimes seem as if they were contrived for the stage. He leaves little impression of reserved power. His best works are *Christie Johnstone*, *Peg Woffington*, and *The Cloister and the Hearth*; the last an historical novel which needed only condensation to have taken a high place among works of that class.

Writers of Fiction in the U. S.—To prose fiction the U. S. has contributed little of a very high order. In the eighteenth century, Charles Brockden Brown (1771–1810) wrote several novels which have some power of enlisting the attention, but the morbid tone of which made them repulsive, and they have been wisely allowed to pass into oblivion. James Fenimore Cooper (1789–1851) attained a greater and more enduring celebrity. This was chiefly, however, because his scenes depicted frontier life, that of hunters, trappers, and Indians. They pleased those whose taste delighted in adventure, and in Europe they commanded attention because they were regarded as peculiarly "American." As tales of adventure they are interesting to those who are not fastidious as to the truthful seeming of what they read; but they have no value as studies or pictures of human nature. The characters are impossible, and the style is poor, mean, and unpolished. They are chiefly adapted to the tastes of very young men and boys. Cooper's sea novels are of greater merit, if not of a higher order.

Hawthorne.—After Cooper there was no novelist worthy of special notice until the appearance of Nathaniel Hawthorne (1804–64), whose *Scarlet Letter* at once commanded the admiration of the whole literary world. Hawthorne was a writer of the most marked originality and at the same time of the highest finish in style. His novels are highly dramatic; but their dramatic power is as unlike that of Scott's, for instance, as can be. He deals with the inner life of his personages. We see them indeed, but chiefly we live their lives. His death cut short what promised to be a brilliant career, but he left enough behind him to secure an enduring fame. Edgar Allan Poe (1809–49) produced no novel, but as a writer of tales, the strange incidents of which he had the singular power of making seem not only probable but actual and real, he attained distinction at home and abroad. He writes like a gifted reporter of extraordinary and incredible scenes which pass before his eyes. With him it is difficult to draw the line where the possible ends and the impossible begins. His fanciful poems and his trenchant criticisms added to his reputation, but he does not take a place among those who have nature as a model. Probably no other modern work of fiction has been so widely read as *Uncle Tom's Cabin*, by Mrs. Harriet Beecher Stowe (1812–96); but the interest which it excited was due chiefly to the sensitiveness of the public mind all over the world upon the subject of slavery in the U. S. Mrs. Stowe's other novels, although superior to that which made her known, failed to receive anything like equal marks of public favor.

Trollope.—The novel of modern society has attained what would seem to be its highest development in the voluminous works of Anthony Trollope (1815–82). His discernment of character was subtle and true; his appreciation of social relations and of their effects upon external and internal life has never been equaled, and it would seem can not be surpassed, because it is perfect. He is not specially humorous, or satirical, or sentimental, or sensational; and yet humor and satire and sentiment and sensation all appear in his novels, simply by their being so true a reflex of individual and social life. If his stories are ever tame and commonplace, it is because society is tame and commonplace; and their many characters which are noble, and their many passages which are colored with the warm hues of strong or tender feeling, show that all that is artificial and conventional in modern society does not repress, but sometimes tends even to heighten and to quicken, the emotions of unchanging human nature. In the completest contrast to the novels of this author are the vivid and picturesque sketches of California life, in prose and verse, of Francis Bret Harte (b. 1831), who rapidly attained the reputation of being the first writer of fiction whose works are marked by a peculiarly "American" tone and atmosphere; and possibly there may be something in them of this kind which is not due only to their characters and the social conditions which they represent. However this may be, their interest is peculiar and their humor delicious.

Hughes.—Thomas Hughes (1823–96) became celebrated as the author of *Tom Brown's Schooldays* and *Tom Brown at Oxford*, written for very young readers; but, like all good books of that kind, they were full of interest for those of riper years. The manliness of style and tone in these books, their sound morals, far removed from all priggish pretension to goodness, and the thorough understanding of boy nature which they show, have made them classics in their kind. Charles William Shirley Brooks (1816–74) should be mentioned as a society novelist of very considerable powers, and William Wilkie Collins (1824–89) as the author of tales remarkable for their intricate and well-contrived but not very probable plots.

Among the crowd of novelists of the day whose very names can not be mentioned except in their aggregate form of legion, that of George Meredith (b. 1828), author of

The Ordeal of Richard Feverel, Beauchamp's Career, and other works, takes high rank for vigor and individuality, though unknown to the general reader. Richard Doddridge Blackmore (b. 1825) has produced one book (*Lorna Doone*) that has become a classic. Walter Besant (b. 1838) has dealt with social problems in many of his novels—in *All Sorts and Conditions of Men*, for instance—and given a decided impetus to the work of social reform. John Henry Shorthouse (b. 1834), the author of *John Inglesant*; William Black (1840–98), the author of *A Princess of Thule*; and J. M. Barrie (b. 1860), the author of *The Little Minister*, men differing widely in style, have acquired great popularity.

Hardy.—Thomas Hardy (b. 1840), the author of *The Return of the Native, The Hand of Ethelberta, Tess*, and a number of other stories, is one of the most original of English novelists. His plots are distinguished by piquant situations, the talk of his rustics has the quaintness of Shakspeare's simple folk, and his heroines are fallible but charming. The most vivid and truthful presentation of social life in the U. S. in the center of its wealth and commerce that has yet appeared is *Never Again*, by William Starbuck Mayo, M. D. (1812–95). George William Curtis (1824–92) also wrote one novel, *Trumps*, but he will rather be remembered as the author of *Prue and I*, a series of confessions of a simple-minded old bookkeeper of exquisite tenderness and sweetness of sentiment, and of the *Potiphar Papers*, a burlesque of New York society, and of the *Howadji* travels, in the style of Kinglake's *Eothen*. The latest school of society fiction is represented in America by William Dean Howells (b. 1837), author, of *A Chance Acquaintance, A Modern Instance, The Rise of Silas Lapham*, etc.; and Henry James, Jr. (b. 1843), author of *Daisy Miller, The Europeans, The Bostonians*, etc. Both of these novelists are subtly analytic in method, dealing largely in manners and in delicate shades of character, and discarding the old-fashioned "plot." They have originated "international" fiction, in which the opposing ideals of American and foreign society are brought into amusing contrast. In their minuteness of observation and truth of detail they sometimes resemble Trollope, though their literary principles ally them more closely to recent continental fiction than to the English.

Essayists and Miscellaneous Writers.—Few tasks are more difficult than the classification of books and their writers. Where shall be placed William Cobbett (1762–1835), who wrote upon politics, gardening, and what not? It is chiefly as a political essayist, however, that he will be remembered. His writings show strong common sense, strong prejudices, independence of thought, set forth in a direct, manly, incisive style. William Godwin (1756–1836) wrote a novel, *Caleb Williams*, the fame of which still lives, but his chief distinction was that of a political essayist and historian of robust mind and strong liberal tendencies. His wife, Mary Wollstonecraft (1759–97), by her *Vindication of the Rights of Woman*, took the lead in a movement which seems to be still advancing. Charles Lamb (1775–1836) will be always read, and always loved, for the gentleness of soul and the exquisite humor, sometimes falling into mere personal whim, which appear in his *Essays of Elia* and his correspondence. To him there could not be a stronger contrast than Walter Savage Landor (1775–1864), who had all the virtues and most of the faults peculiar to the Anglo-Saxon race, and embodied them in his writings, although his peculiarities of temper kept him so at war with his kindred, and even his country, that he passed most of his life in voluntary exile. His *Pericles and Aspasia, Imaginary Conversations, Last Fruit off an Old Tree*, and *Dry Sticks* show a wide range of learning and strong critical sense, but narrow sympathies, and an absence of that great lubricator of the friction of life—humor. John Wilson (1785–1854), although he wrote some poetry, is remembered for his *Christopher North* papers upon literature and sporting subjects, which were published in *Blackwood's Magazine*, of which in its earlier years he was editor. His critical taste was sound, but much of his writing is mere animal spirits put on paper, and he was chief of a school all of whose pages reek with the fumes of whisky and tobacco, which can not, however, entirely becloud their strong sense and their scholarship.

De Quincey.—For whisky and tobacco Thomas De Quincey (1785–1859) substituted opium, to which we owe his *Confessions of an Opium-Eater*, and perhaps its effects may be traced in *Suspiria de Profundis* and in many of his subsequent voluminous writings, which are crowded with the evidences of a wide range of desultory scholarship, with subtle criticism, rich fancy, and a peculiar humor, all embodied in a style of remarkable richness and splendor. William Hazlitt (1778–1830) lived from early manhood until his death, not very happily, upon the miscellaneous products of his pen as a contributor to various periodical publications of his day. He was consequently able to do little as we may be sure he would have liked and was able to do it. But as a critic of literature and art and of society he holds a high place, which he owes in a great measure to his manly and thoroughly English style. James Henry Leigh Hunt (1784–1859), another writer of the same sort, has less force, but is always graceful and pleasing. But the great modern master in English of grace and ease, and of a lambent humor much like that of Addison, is Washington Irving (1783–1859), whose *Sketch Book, Knickerbocker's History of New York*, and *Legends of Sleepy Hollow* do more to secure his enduring fame than most of his more ambitious works, including his *Life of George Washington.*

Carlyle.—Unlike Irving in every way was Thomas Carlyle (1795–1881), whose style is rugged and whose humor grim, but who was a critic of the first class, and whose *Sartor Resartus* is a subsoil plow driving deep beneath the surface conventionalities of society. A like purpose prevails in his *Latter-Day Pamphlets* and *Hero-Worship.* It is to be remarked that Carlyle's peculiar style—so peculiar that it has been called "Carlylese"—does not appear in his earlier works. Mr. Carlyle the reformer appears as a scornful, scourging critic, and in that spirit he wrote his historical works, *The French Revolution* and *Frederick the Great.* To him Ralph Waldo Emerson (1803–82) has been not very happily compared. The purpose of the two writers may be the same, but their manner is entirely different. Emerson had the calm observance and the serene thoughtfulness of a philosopher, and he showed a strong love of external nature of which Carlyle seemed scarcely conscious. His style is aphoristic and epigrammatic, and both his prose and his poetry are full of wisdom. Caroline Elizabeth Norton (1808–77), a miscellaneous writer, inherited some of the talent of her grandfather, the great Sheridan.

Smith and Jerrold.—Among the wits of a past generation two were pre-eminent—Sydney Smith (1771–1845) and Douglas Jerrold (1803–57), but their wit was almost their only point of likeness. Jerrold's wit was a scourge, while Sydney Smith's was the genial laughter of a lover of his kind. His essays touch many of the most important topics in which men of these times are interested, and they are loaded with sagacity. His style is remarkable for its clearness and manly dignity. Another wit whose wisdom is greater than his wit is Oliver Wendell Holmes, M. D. (1809–94), of whose writings his *Breakfast-Table* books—the *Autocrat*, the *Poet*, and the *Professor*—exhibit his mind and his style at their best. They present a curious and careful study of that variety of human nature which is found in the New England of the nineteenth century, and are threaded through and through with gentle satire. The study of human follies and human weakness and of the conventional forms of modern society which took Holmes to the breakfast-table and Sydney Smith to the dinner-table, drove Henry David Thoreau (1827–62) to a hermit's life, in which he lived in a cabin of his own building, chiefly upon beans of his own growing. He studied birds and beasts and inanimate objects for the purpose of reflecting severely upon man. But his love of nature was genuine, his love and knowledge of literature great, and his own style beautiful. He can not be read without forgiveness for his gentle mistaken misanthropy.

Helps.—Arthur Helps (1813–75) won for himself a peculiar, and, if not a very high, a long-enduring place in literature. With little that is strikingly new in his thought, he commands the respectful attention of a large circle of the very highest class of readers. This he does by the very clear and earnest way in which he brings up and presses home half-forgotten truths which concern the daily life of all cultivated people. He presented homely common sense in the most elegant dress. He wrote two novels, *Realmah*, over which his Friends in Council entertain themselves and his readers with wise and witty chat, and *Ivan de Biron.* Among other writers of this class in America even such a sketch as this must notice Donald Grant Mitchell (b. 1822), a polished satirist of society and an observant critic of rural life; Thomas Wentworth Higginson (b. 1823), whose essays are strong protests against physical and mental weakness;

and Edward Everett Hale (b. 1822), whose sermons, essays, and sketches all show a strong, clear, subtle mind, a lover of freedom, and a Christian of the Broad Church.

A peculiarly national type of low or broad comic writing has been developed in the U. S., the two foremost representatives of which are Charles Farrar Brown, "Artemus Ward" (1834–67), and Samuel Langhorne Clemens, "Mark Twain" (b. 1835), the author of *Innocents Abroad*, *Adventures of Huckleberry Finn*, etc. These humorists and their numerous imitators have made free use of dialect, slang, cacography, and similar devices, and their fun is tinctured with extravagance, irreverence, caricature, and the wildest paradox. It is, however, unquestionably effective, and is a new thing in the humorous literature of the world.

Criticisms of the arts of design, like those arts themselves, sprang up late, and at first grew feebly, among the English-speaking peoples. The *Analysis of Beauty* of William Hogarth (1697–1764) and the *Lectures* of Sir Joshua Reynolds (1723–92), although not without suggestions of some value, are chiefly distinguished as the works of eminent painters. And Burke's *Essay on the Sublime and Beautiful* is all awry from its purpose. Its very style lacks all its author's peculiar charm. Rev. Archibald Alison (1757–1839) wrote *Essays on Taste* which promoted culture in this respect, but which are now rarely referred to; but Sir Uvedale Price's *Essays on the Picturesque*, published in 1810, may still be read with profit, and have since been reprinted. The works upon Christian art by Mrs. Anna Jameson (1794–1860) contain much that is valuable, both of history and criticism.

Ruskin.—It was not until the appearance of John Ruskin (b. 1819) that there arose a subtle, profound, and thoroughly qualified critic of fine art—one who to his critical perceptions joined the ability to communicate them with beauty and impressiveness of style. Mr. Ruskin's chief distinction as a critic is that he never writes without making his hearers think, even when they smile at his utopian theories of society and of political economy. James Jackson Jarves (1818–88) has written with knowledge, thoughtfulness, and honesty about art, and particularly ancient art; and Philip Gilbert Hamerton (1834–94) displayed the same qualities in *Etching and Etchers*, *The Graphic Arts*, and other important works.

Criticism has been raised to a special branch of literature during the nineteenth century, toward which the establishment of the great British periodicals, the *Edinburgh Review*, the London *Quarterly Review*, the *Westminster Review*, and in the U. S. the *North American Review*, contributed largely; their influence and example have been such that now no magazine or newspaper of the first class, either in Great Britain or North America, appears without such critical reviews of literature in all its branches, of art, and of science, as fifty years ago were produced nowhere, and which, with allowance for much ignorance, presumption, and bad taste, on the whole guide the public mind aright. In this department of literature many of the writers who have already been mentioned attained distinction.

Of those not hitherto mentioned, Lord Francis Jeffrey (1773–1850), William Gifford (1756–1826), and John Gibson Lockhart (1794–1854) deserve special mention. They were all severe, as well as able and generally honest, in their criticism, and did much toward the formation of the public taste in the early part of the century. Henry Hallam (1777–1859) in his *Literature of Europe* gives a mass of various learning and generally sound critical opinion. It is, and will probably remain, the standard work upon its subject in the English language.

Philology, using the word in its widest sense, includes all writing upon language, even the well-known grammar of Lindley Murray (1745–1826), the American Quaker who for so long gave the law of the construction of their language to English-speaking people. But comparative philology, which alone is worthy of the latter half of its name, is the product of the nineteenth century, and had its rise in the discovery and study of the Sanskrit language, the oldest known representative of the speech of the Aryan or Indo-European peoples. This discovery, which is due to Sir William Jones (1746–94), established a connection between the modern world and that of prehistoric times, and revealed the bond which binds together all the Indo-European peoples. But before this discovery an analytic philologist (or etymologist) of great ability, John Horne Tooke (1736–1812), had appeared in England. His *Diversions of Purley*, although not without errors, is a monument to his learning, sagacity, and fine linguistic sense. Joseph Bosworth (1788–1876) investigated the field of Teutonic and Scandinavian languages; George Perkins Marsh (1801–82) philosophically recorded the growth of the English language and its literature; Robert Gordon Latham (1812–88), with a profound and vast range of knowledge, developed theories of ethnological philology, dissected the English language, wrote its grammar on philological principles, and completed an English dictionary based upon Johnson's. William Dwight Whitney (1827–94) pushed his investigations of the Oriental languages and of the wide field of the higher philology to what seems almost the verge of attainable knowledge; James Hadley (1821–72) has shown that he might have been his rival; Max (Frederick Maximilian) Müller (b. 1827) has delighted and stimulated all students of philology by his brilliant generalizations in the "science of language" in its broadest sense; March has produced his great Anglo-Saxon grammar; and Trench and Farrar and Garnett and Helfenstein and Craik and Skeat and Child have distinguished themselves by works of narrower scope, but hardly of less interest. The Early English Text Society, under the management of the able and indefatigable Frederick James Furnivall (b. 1825), has published a great mass of well-edited English writing of the twelfth, thirteenth, and fourteenth centuries, and made accessible to eager students materials which they are using for the elucidation of the philology of their mother tongue.

History.—In no department of literature has a greater change been manifest during the nineteenth century, both in form and in spirit, than in history. This change—the result of the combined influences of the comparative system introduced by Niebuhr, of the strong tendency toward a positive or scientific treatment in all branches of intellectual endeavor which rest in any way upon facts, and of the increased appreciation of the value of the minutest matters of record which show the intellectual, moral, and social condition of a whole people, the middle and lower, as well as the noble and educated classes—has caused the historians of the modern school to extend their researches, to enlarge their plans, and to endeavor to portray upon a vast field not only the great vicissitudes of nations and the eminent individuals who controlled or seemed to control them, but the whole political, moral, and social life of the people and the periods whose stories they undertake to tell. Hence histories are now at once more fragmentary and more minute than they were of old.

English History.—Dr. John Lingard (1771–1851) wrote a history of England down to the abdication of James II., which is valuable for its research, the mass of facts accumulated, its calm tone, and its skillful arrangement. But it was written from the Romanist point of view, with a Romanist purpose; and its value is seriously impaired by its skillful perversions and suppressions of fact. The *History of the Anglo-Saxons and of England during the Middle Ages* of Sharon Turner (1768–1847) is the only thorough and systematic presentation of its subject in the English language. Trustworthy as to fact, it is deformed by an ambitious, involved, un-English style. Lord Mahon (Earl Stanhope, 1805–75) must be mentioned as the faithful and thoughtful, although somewhat spiritless, historian of England from 1718 to 1783. Sir James Mackintosh (1765–1832), who failed to do all that his unquestioned abilities gave reason to expect, produced a compact *History of England* (3 vols., Lardner's *Cyclopædia*), remarkable for a clear and philosophical treatment of political and constitutional questions.

Hallam.—The great constitutional historian of England is Henry Hallam (before mentioned). He is thorough, candid, and, although liberal in tendency, judicially calm, as becomes his subject. His *History of Europe during the Middle Ages* has the same qualities, but lacks picturesqueness of presentation. The subject of the constitutional history of England has been ably continued by Sir Thomas Erskine May (1815–86). Sir Archibald Alison (1792–1867) was the author of a *History of England* from the beginning of the French Revolution to the restoration of the Bourbons, which has the great value due to an industrious collection and systematic arrangement of facts by an almost contemporary writer. But it is diffuse, prolix, and deformed by a style both pretentious and ungraceful. It is best read in his own abridgment of it.

Macaulay.—Thomas Babington Macaulay (1800–59) produced, in his *History of England from the Accession of James II.*, the most striking and picturesque historical work of the century. Written with strong partisan prejudices, if not with a partisan purpose, it is filled with masses of moral light and shade, and must be read with corresponding allowance as to facts and its representation of individuals. But in its grouping of facts, in its pictures of social life, and in the splendor and the graceful ease of its style, it is without a rival in English literature. The research upon which it was founded and the minuteness of its picture-painting made it impossible for the author to bring it down, as he had intended, to a period within the memory of living men. Its five octavo volumes cover a period of only fifteen years. With its author's essays upon the characters of Bacon, Milton, Addison, Walpole, Johnson, Byron, and Hastings, it forms a body of historical writing of almost unequaled splendor and interest. James Anthony Froude (1818–94) produced a very valuable history of England during the times of the Reformation. His investigations led him to take new views of the character of Henry VIII. and of that of Elizabeth, which the authorities quoted by him seem to support; but upon the much-vexed question as to the characters of Mary of Scotland and Mary of England he ranges himself at the head of their condemners. On the history of Ireland he has also written vigorously, and after much original research. Edward Augustus Freeman (1823-92) is the author of a *History of the Norman Conquest* written from an entirely new point of view, in which he presents a philosophical appreciation of the causes which led to the invasion, of the condition of insular and continental society at that period, and of the social and political consequences of the conquest. Its great merit gave him at once a high position in historical literature. The various biographical works of Mr. John Forster (1812–76) have so marked an historical bearing that he deserves honorable mention as a writer in this department.

Continental history has been illustrated by two English writers of eminent ability. Thomas Carlyle's *History of the French Revolution* is rather an expression of the spirit of the time of that great event than a record of its facts, a knowledge of which is almost assumed by the writer. But it is perhaps the most complete and characteristic manifestation of its author's peculiar genius. His *History of Frederick the Great* is truly historical, and presents new results of original research. It is written in "Carlylese," and is full of fantastic and grimly humorous passages, but its truly historical value is nevertheless very great. John Lothrop Motley (1814–77) has taken the highest position as the historian of the Netherlands and the Dutch Republic. To the results of patient research and logical analysis he added the attraction of a fervid style and an enthusiastic love of his subject.

Bancroft.—The history of the United States was written by George Bancroft (1800–91) with a minuteness of detail which often produces the impression that he looked at small and commonplace occurrences through the glorifying medium of their consequences. His style may also be regarded as often too ambitious for the subject immediately in hand. But as a whole his work is worthy of the admiration it has received and of the authoritative position it has attained. Richard Hildreth (1807–65) wrote his *History of the United States* in a style directly opposite. It is cold, dry, unpicturesque, and rigidly judicial. But as a clear and well-connected record of facts it is of great value, and may be safely relied upon. James Parton (1822–91) produced several biographies of eminent citizens of the U. S. which have an historical purpose and value. John Gorham Palfrey (1796–1881) wrote a *History of New England* in a most interesting and impartial manner, and John Fiske (b. 1842) has further enriched the history of the Colonial and Revolutionary periods of the same section. Francis Parkman (1823–93) has given us in numerous volumes the history of the French explorations and settlements in North America. His pictures of Indian life and wilderness scenery have wonderful vividness and a romantic interest not inferior to the fictitious adventures of Cooper's backwoodsmen.

Prescott.—Spanish and Spanish-American history has been illustrated by William Hickling Prescott (1796–1859), perhaps the most charming of all English historical writers, and inferior to none in patient research. His histories of Ferdinand and Isabella, of Philip II., and of the conquest of Mexico and the conquest of Peru, are a most fascinating series of works. Arthur Helps (1813–75) wrote a *History of Slavery*, which, animated by a thoroughly humane and loftily philanthropic spirit, presents his subject with his characteristic calmness and reserve.

The history of Greece was written by William Mitford (1744–1827) with learning and the feeling of a true scholar for his great theme; Bishop Thirlwall (1797–1875) also produced a valuable history of the Hellenic peoples; but the work which displaces all others in English literature upon this subject is that of George Grote (1794–1871), who seems to have penetrated the very heart of Greek life, political, social, moral, and intellectual. His *History of Greece* and his *Plato* seem to present all that one can hope to know of the national experience and the best intellectual period of the great people who were the sources of modern civilization.

Arnold.—Roman history to the end of the Second Punic war was treated by Thomas Arnold (1795–1842), a worthy disciple of Niebuhr, who added a certain simple English tone and charm to the manner of his master. His *Lectures on Modern History* are also admirable in the same way. Charles Merivale (1808–93) wrote a *History of the Romans under the Empire*, which supplements acceptably Arnold's more vigorous work. Henry Hart Milman (1791–1868), a poet and the author of *Fazio*, a powerful and successful tragedy, wrote a *History of the Jews*, a *History of Greek Christianity*, and a *History of Latin Christianity*, which form an admirable trilogy of religious history.

Of war histories, the two most important are the *Fifteen Decisive Battles of the World* of Sir Edward Shepherd Creasy (1812–78) in which the author treats only of such battles as have had a manifest effect upon the course of civilization; and the *History of the Crimean War* by Alexander William Kinglake (1811–91), which as to fact is a clear result of careful investigation, but which in spirit is a fierce impeachment of the Emperor Louis Napoleon. Perhaps the volume of William Howard Russell (the well-known London *Times* correspondent) upon the same subject should here be mentioned. Of the histories of the civil war in the U. S. a few are of value; but most of them have been written by partisans living too near the events which they describe.

Buckle.—An entirely new kind of historical writing has been produced by the speculative spirit of the age. It is the history, not of nations or of men, but of man. Pre-eminent in this department is the *History of Civilization*, left unfinished by Henry Thomas Buckle (1821–62), who sought, with an admirable if not a perfect measure of success, to discover and describe the successive evolution of the moral influences which brought about the changes in the course of the history of the modern world. Of a like kind are the *History of Rationalism* and the *History of European Morals* written by William Lecky (b. 1838)—works which to a certain extent pluck out the heart of the mystery of man's moral nature and social life. And historians who deal with mere external facts now go beyond the historical period, and we have in such books as *Prehistoric Times* and *The Origin of Civilization*, by Sir John Lubbock (b. 1834), and *Prehistoric Man*, by Daniel Wilson (1816–92), ingenious attempts, marvelously successful to a certain point, in reconstructing the physical life of man at those dimly remote periods of which there is neither record nor tradition.

Books of travel are so considerable an element of modern literature, whether regarded as a means of literary entertainment or in their more important function of diffusing a knowledge of mankind and enabling us to study it under different climes and different forms and degrees of civilization, that they can not properly be passed over even in the briefest compendium of literary history. But so vast has been their number that only those can be noticed here which have some peculiar literary excellence, or which mark a period, or which have exercised some notable influence upon opinion.

Ledyard.—John Ledyard (1751–88) belongs in time to the eighteenth century, but he is noticeable as being the first of that series of travelers who set out with a purpose of establishing, verifying, or illustrating some cosmical fact—who are discoverers, not of new countries, but of the geographical relations and topographical condition of countries already known. Ledyard was the first of those travelers who have set out with the purpose of examining the Polar regions, and ended his life in Africa after making an unsuccessful attempt to discover the source of the Niger. Among the many British travelers who have described, or professed to describe, the condition and the character of the people of the U. S., Frances Trollope (1780–1863) did more than any other to form the opinion upon that subject which long prevailed in Europe. She was a keen observer, wrote in a clear and very pleasing style, and many of her most damaging assertions were literally true. But she entered the country at its then wildest and most uncultivated parts, the frontier towns of the Southern and the Western States, and did not become acquainted with the society which two centuries had developed in America until she was about leaving the country; and of this she said little. She thus produced a very amusing book and created a very erroneous impression, which the passage of a century will hardly obliterate. Another woman, Harriet Martineau (1802–76), of masculine traits of mind, treated the same subject in an entirely different spirit, and after careful and candid study produced in her *Society in America* a somewhat successful attempt at a calm and philosophical appreciation of the people of the U. S. and their political institutions. It will always be valuable as a record and an analysis of the facts and the spirit of life in the U. S. at the time when it was written.

Of Eastern travelers the most conspicuous are Eliot Bartholomew George Warburton (1810–52), the author of some novels, whose studies of Oriental life were embodied in *The Crescent and the Cross*; Sir Austin Henry Layard (1817–94), whose series of works giving the results of his excavations and investigations of the ruins of Nineveh are the most valuable contribution to the antiquarian and art history of the East ever made by an Englishman; and Alexander William Kinglake (1809–91), whose *Eothen* tells with such a wonderfully picturesque power the impressions which Oriental landscape, life, and manners make upon a civilized Christian from the West, and which has justly been called the most charming book of travel ever written.

Livingstone.—Africa and its geographical mysteries, particularly that of the source of the Nile, gave to Ledyard not a few followers. Among these are David Livingstone (1813–73), who penetrated to the heart of the country, crossing it twice at about 10° S. lat., traversing vast regions before wholly unknown to civilized man, and making geographical discoveries of very great importance; and Sir Samuel White Baker (1821–93), who followed the wonderful river up to a great lake which is one of its two principal reservoirs, and which he named the Albert N'yanza. The records of their toils, exposures, perils, observations, and discoveries by these two distinguished explorers have an interest which reaches the degree of fascination, and takes them to a certain extent out of the regions of geographical science into that of general literature.

The latest and not least brilliant chapter in the history of African discovery is furnished in the writings of Henry Moreland Stanley (b. 1840), who was detailed by the New York *Herald* in 1871 to find Dr. Livingstone; afterward explored the Congo and founded the Congo Free State, and in 1887–89 conducted a successful expedition for the relief of Emin Pasha.

Kane.—In the interest of his contribution to the literature of exploration, if not in the value of his discoveries, Elisha Kent Kane (1820–57) is eminent among those for whom the North Pole and a possible northwest passage from the Atlantic to the Pacific has had an irresistible attraction. His narrative of his experience in this region of icy blankness has the interest of romance with the stamp of literal truth, not surpassed even by the fiction of Defoe's *Robinson Crusoe*.

Conspicuous among American explorers, both in regard to antiquities and geography, is Ephraim George Squier (1821–88), whose works upon the mounds of the Mississippi valley and upon Nicaragua, Honduras, and contiguous regions of Central America, are recognized as having a great and permanent value. John Lloyd Stephens (1805–52) has also in his *Travels in Yucatan and Chiapas* revealed to the modern world a mass of interesting fact concerning the relics of the extinct races of Central America.

Olmsted.—Frederick Law Olmsted (b. 1822), first known by his *Walks and Talks of an American Farmer*, afterward wrote *A Journey in the Seaboard Slave States*, *A Journey through Texas*, and *A Journey in the Back Country*, which are historically among the most important books of travel that have been published in the nineteenth century, giving as they do, with all the candor and charity consistent with a love of freedom, an exact description of the social, moral, intellectual, and physical condition of the Southern U. S. a few years before the war of secession. Bayard Taylor (1825–78) visited no previously unknown, or even very remote, regions, but the extent of his travels, his careful observation, sound judgment, good nature, and agreeable style have gained his works in this department of literature a wide popularity.

Philosophy.—The philosophical writers of the English-speaking peoples during the nineteenth century have shown the influence of German or of Scotch thought, or have been chiefly critical of other writers or of earlier schools. Thomas Reid (1710–96), although belonging to the eighteenth century, has an affinity with the more modern Scotch metaphysical school, which he may be said to have founded by his *Inquiry into the Human Mind on the Principles of Common Sense*, and his *Essays on the Intellectual Powers*, *Essays on the Active Powers*, etc. He opposed the theory of Locke, and found in the innate and instinctive powers and consciousness of the mind the prime source of its knowledge and its stimulus to action. The objections against this theory were answered with great ability by Dugald Stewart (1753–1828), the next in order of the Scotch metaphysicians, whose *Elements of the Philosophy of the Human Mind* and *Dissertation on the Progress of Metaphysical and Ethical Philosophy*, the former by its acute analysis, the latter by its wide-reaching knowledge and attractive style, take a high place in philosophical writing of the second or non-originative class. Among works of this class Sir James Mackintosh's *View of the Progress of Ethical Philosophy* should be mentioned. Chief of this school, and perhaps ablest of modern metaphysicians, is Sir William Hamilton (1788–1856), whose writings upon the philosophy of perception, on eclecticism, and on logic are the fruit of a profundity and grasp of his deep and subtle subjects which, whatever may be thought of their absolute soundness, even their opponents regard as efforts in the very highest style of metaphysical dissertation. William Whewell (1794–1866) took an enviable position in this department of literature by his work on the inductive sciences. And here should be mentioned Richard Whately, Archbishop of Dublin (1787–1863), whose treatises on logic, on rhetoric, essays on some of the difficulties in the writings of St. Paul, and whose anti-Tractarian *Cautions for the Times*, and indeed all his writings, even those of a specially ecclesiastical character, are philosophical in tone and style, and almost so in purpose, and whose wide range of knowledge and vigorous intellect made a strong impression upon the general thought of his day.

Mill.—John Stuart Mill (1806–73), son of James Mill (1773–1836), author of *Analysis of the Human Mind* (1829), by his *Examination of Sir William Hamilton's Philosophy*, his *System of Logic*, and his *Dissertations and Discussions*, took a high place among modern philosophers of the Positive school, although he can not be regarded as a disciple or an apostle of Positivism according to Comte. His philosophic principles have been ably criticised by Dr. James McCosh (1811–94), who in a series of works, all opposed directly or indirectly to the positive and material tendencies of the day, took a prominent position on the conservative and religious side of philosophy. Of the same school was Dr. Francis Wayland (1796–1865), who gave to the American branch of the literature of morals and philosophy an admitted claim to the highest respect and consideration. Dr. Laurens Perseus Hickok (1798–1888), by his *Rational Psychology*, *Logic of Reason*, *Empirical Psychology*, and *Moral Science*, securely laid the foundation of a truly spiritual philosophy. George Henry Lewes (1817–78) should be mentioned as a contributor to philosophical literature by his *Biographical History of Philosophy*, *Aristotle*, and *History of Philosophy from Thales to Comte*—works of a philosophical interest and value not always merely historical. Nor should Henry James (1811–82), a subtle and aggressively independent thinker upon the philosophy of religion, and the master of a singularly impressive and suggestive style, be passed over; nor Dr. Mark Hopkins (1802–87), in virtue of his *Lectures on Moral Science* and *Love as Law and the Law of Love*; nor George Ripley (1802–80), the author of *Discourses on the Philosophy of Religion* and *Letters on the Latest Form of Infidelity*.

Theology.—As every clergyman is supposed to be more or less a man of education and of intellectual ability, and as every settled minister of a parish or congregation is required to prepare at least one sermon in every week, the amount of writing more or less theological in the English language is beyond computation, and increases weekly. Of this a quantity unaccountably large is printed. Only a very few even of the more distinguished clergymen who have made themselves known in literature in the nineteenth century can be noticed here.

Hall.—Robert Hall (1764–1831), a Baptist minister who for eloquence has been compared to Burke, and for fanciful richness of illustration to Jeremy Taylor, is distinguished not only by his sermons, but by his *Christianity Consistent with the Love of Freedom*, his *Apology for the Freedom of the Press*, and his *Modern Infidelity*. John Foster (1770–1843), also a Baptist minister, was not remarkable for pulpit eloquence, but his essays, particularly those on *Decision of Character* and the *Evils of Popular Ignorance*, are among the most thoughtful and weighty productions of their class in English literature. Thomas Chalmers (1780–1847) probably has been unapproached in eloquence and the vigor of his personality by any clergyman of the century. He was the most fervid and earnest of pulpit orators. His *Institutes of Theology*, *Commercial Discourses*, *Evidences of Christianity*, and *Astronomical Discourses* are his principal works. Isaac Taylor (1787–1865), a religious essayist of distinguished learning and ability, has discussed in *Ancient Christianity* the doctrine and the discipline of the early Christians, directing himself to the teachings of *Tracts for the Times*, a very remarkable and influential series of religious publications with a strong leaning toward Romanism, of which the principal writers were Edward Bouverie Pusey (1800–82), John Henry Newman (1801–90), John Keble (1792–1866), and Richard Hurrell Froude (1803–36), all clergymen of the Church of England and of the extreme High Church school, and all writers of independent theological works which have had a strong effect upon the tone of religious thought among the members of that Church.

Robertson.—Frederick W. Robertson (1816–53), a preacher whose sermons produced more effect upon the lives of men than those of any other modern minister of which there is record, stood at the ecclesiastical antipodes of the Tractarian men. His style was fervent, strong, and direct, his thought independent; he labored for the bettering of the working classes, and he was suspected of rationalism in religion and socialism in politics.

Bishop Colenso.—Doubts which must have occurred to many thoughtful readers as to the literal truth of many passages in the historical parts of the Old Testament, particularly in the earlier books, found strange and unreserved expression in a series of volumes by an eminent mathematician and clergyman of the Church of England, John William Colenso (1814–83), Bishop of Natal, the first of which was *The Pentateuch and the Book of Joshua Critically Examined*. Bishop Colenso had previously written several mathematical works, and he brought to his task habits of close reasoning and a calculating spirit, which led him to test these books by a standard to which Oriental writers, profane or sacred, never thought of conforming. Coming from such a quarter, his books, which he did not regard as at all impairing the divine origin of the Christian religion, produced a profound impression and very serious disturbance in the English Church, by the Convocation of which they were condemned.

Theodore Parker.—Theodore Parker (1810–60), at first a Unitarian minister, was a doubter of a very different character to Colenso. His faith was in God and in man, but not at all in revealed religion. A man of wide and varied learning, of independent spirit, of a tender and loving nature, the champion of the oppressed, the benefactor of the poor, his preaching the earnest utterance of his own strong personal convictions, he did much to unsettle the belief and to confirm the disbelief of a very large number of the most intelligent and purest minds in New England. Among his published works are *Sermons on Theism, Atheism, and Popular Theology*, and *Lessons from the World of Matter and the World of Mind*. Octavius Brooks Frothingham (1822–95), the ablest of his disciples, published little except from the pulpit; but his ability, his earnestness, and the polish of his style, in which he is superior to his master, make him a leader of rationalistic religion in the U. S. Henry Ward Beecher (1813–87), the ablest member of an intellectually gifted family, and a Congregational minister of the broadest and most liberal theological views, was regarded as the greatest pulpit orator in America—an eminence which the style of his published sermons hardly warrants. Andrew Martin Fairbairn (b. 1838), eminent among the Congregational ministers of Great Britain, has published a number of scholarly works dealing with religious questions.

Political and social science, properly speaking, is the product of the nineteenth century. Among the English works in this field the most important are those of Jeremy Bentham (1748–1832), to whom, next to Adam Smith, belongs the honor of originating the science of political economy. The mere titles of the various works produced by him in his laborious and self-sacrificing life would fill half this page. The spirit of all of them is concentrated in his famous saying, "The greatest good of the greatest number"—*good* here meaning material comfort and the happiness consequent thereupon. David Ricardo (1772–1823) published works of authority on the principles of political economy, giving his attention chiefly to the subjects of labor and currency.

Malthus.—Thomas Robert Malthus (1766–1834), also a political economist, in his *Essay on the Principles of Population as it Affects the Future Welfare of Society*, showed that population always rises to the level of possible subsistence. This work, says Brougham, "divides (with Ricardo) claims to a second place after the *Wealth of Nations*." The greatest of Bentham's disciples, John Stuart Mill, by his *Essays on Unsettled Questions in Political Economy*, his *Principles of Political Economy*, his essay on *Liberty*, his *Considerations of Representative Government*, and his *Subjection of Women*, has wrought into a systematic working form the principles of the Benthamite school, of which he was, and will probably long be, regarded as the chief apostle. His works are masterpieces of far-reaching thought and subtle reasoning. Of less note, but of high and well-deserved reputation, are the works of Henry Fawcett (1833–84). Francis Lieber (1800–72), born and educated in Germany, but for the greater part of his mature life a citizen of the U. S., was the author of several profound works in this department of literature, of which the most celebrated are his *Manual of Political Ethics*, *Legal and Political Hermeneutics*, *Essays on Property and Labor*, and *Civil Liberty and Self-Government*.

Carey.—Among champions of the "protective" system as opposed to free trade and unrestrained commercial intercourse, particularly in articles which are or may be of domestic manufacture, was Henry C. Carey (1793–1879), whose *Principles of Political Economy* and various other works embody in stringent phraseology all that can be said on this side of the question. Most of Mr. Carey's works have been translated into nearly all the languages of Europe. Herbert Spencer is the most eminent of recent writers in this department. His works cover the ground of psychology, biology, what he calls "sociology"—i. e. the philosophy of society—and morality, which it would be difficult to separate from the latter. In a word, he has attempted to work out a complete system of practical philosophy. His views on education are original and far-reaching. Indeed, he is one of the clearest and coolest thinkers of the age.

Of British writers upon education, one of the most important subdivisions of this department of literature, and one which has received attention commensurate with its importance, the Rev. Henry Parr Hamilton (1794–1880), the variously learned Francis William Newman (1805–97), and the distinguished physiologist Huxley (noticed again below), must be mentioned. In the U. S. two distinguished writers on education are Henry Barnard (b. 1811) and Frederick Augustus Porter Barnard (1809–89). The latter's *Letters on College Government* is regarded as "the ablest treatise on the higher education yet published in the U. S." He was also the historian of the U. S. Coast Survey and the author of an *Analytical Grammar*. Besides these, Horace Mann (1796–1859), Francis Wayland (1796–1865), Alexander Dallas Bache (1806–67), and William Torrey Harris (b. 1835) have written upon this subject with marked and widely recognized ability.

Jurisprudence is hardly a part of literature in the common acceptation of that term, but the *Commentaries* of Sir William Blackstone (1723–80) upon the laws of England added a charm to their dry and technical subject, and perhaps even deserved the conventional term "elegant" which was applied to them. They have certainly much of the interest of history. Appearing soon after the middle of the eighteenth century, they occupied this field with such a weight of authority that there seemed nothing to be done but to accept them and to comment upon them. In this department mention must be made of *The Constitution of England* of John Louis Delolme (about 1740–1806); *The Federalist*, a collection of papers by Alexander Hamilton, James Madison, and John Jay, which had a very important influence in bringing about the adoption of the Federal Constitution of the U. S.; the *Plan of the Penal Code of Louisiana* of Edward Livingstone (1764–1836), and his *System of Penal Law* for that State; John Marshall (1755–1835), whose judicial decisions, according to an eminent British critic, "would have done honor to Westminster Hall in the proud season of British law"; the *Commentaries on American Law* of James Kent (1763–1847), which, for their style as well as for their matter, are in Europe as well as in the U.S. successful rivals of Blackstone's great work; the *Commentary on the Constitution of the United States* of Joseph Story (1779–1845); the *Elements of International Law* of Henry Wheaton (1785–1848), which has become authoritative; the *Lives of the Lord Chancellors* and *Lives of the Chief Justices of England* of Lord John Campbell (1779–1861); the *Introduction to the Study of International Law*, which gave Theodore Dwight Woolsey (1801–89), distinguished as a classical scholar, an authoritative position universally recognized upon its subject; the *Comments on the Jurisprudence of . . . the Courts of the United States* and *History of the Constitution of the United States* of George Ticknor Curtis (1812–94); *The English Constitution* of Walter Bagehot (1826–77); *Ancient Law* and *Village Communities* of Sir Henry James Sumner Maine; and perhaps Sir Arthur Helps's wise treatise on *Government* should be added. This list is incomplete, but it is believed to include the principal works of this class which have been produced in the nineteenth century, and which can be regarded as within the pale of literature.

Lord Brougham.—Here, between the record of the literature of political and social science, of jurisprudence, and of natural science, may stand Henry, Lord Brougham (1779–1868), who wrote upon all these subjects, and who never wrote or spoke without impressing readers or hearers with the weight of his thought and the intelligent earnestness of his manner. The extent of his acquirements caused him to be called "a man of vast and various misinformation," and on his being made Lord Chancellor subjected him to the remark by Sugden, that "if the new Lord Chancellor only knew a little law, he would know a little of everything." But these were the jeers of specialists envious that the man who was great in their department of intellectual effort could also attain distinction in others—a not uncommon manifestation of human weakness. By his varied and voluminous writings Lord Brougham produced a marked and an enduring effect upon his time; and his efforts were always for the diffusion of knowledge, and toward liberty of thought and of action, subject to good morals and well-established law.

Natural science, like jurisprudence, is hardly literature (whence the distinction so constantly drawn, "science *and* literature"), but it would be difficult to deny a very high literary quality to the works of many of the naturalists who have given to the nineteenth century that scientific eminence which is its peculiar glory. Of these the most eminent are Joseph Priestley (1733–1804), a leader in the modern school of natural science, who, living into the nineteenth century, labored chiefly in the eighteenth, writing upon government, history, and grammar, although the works by which he impressed the world were those in which he brought natural science to the support of materialism; Thomas Young (1773–1829), the reviver and demonstrator of the truth of the undulatory theory of light, who first deciphered hieroglyphics by the aid of the inscriptions on the Rosetta Stone, whose *Lectures on Natural Philosophy* are even at this day a treasure-house of scientific truth to the investigator, and whom Tyndall has pronounced to be the greatest intellectual power in England since Newton's day; Sir Humphry Davy (1778–1829), who discovered the qualities of nitrous oxide and of the metals of the alkalies, and invented the miner's safety-lamp, and whose scientific sagacity was adorned with a charming style which makes his *Salmonia* and *Consolations in Travel* classic books; Sir David Brewster (1781–1868), whose works cover an extended field of science, including biographical appreciations of great natural philosophers, but whose most interesting philosophical writings are those which record his investigations and develop his theories upon light; Sir John Frederic William Herschel (1792–1871), the eminent son of an eminent father, whose principal works are his *Treatise on Physical Astronomy* and *Results of Astronomical Observations at the Cape of Good Hope*, which map out the whole starry heavens; Sir Charles Lyell (1797–1875), first of English geologists, by whom attention was drawn to the ancient changes in the earth and its inhabitants as illustrated by its geological monuments, and whose books of travel in the U. S. are among the few of much value; William Buckland (1784–1856), who brought a profound acquaintance with geology and mineralogy to the support of religion; Sir Charles Bell (1774–1842), who made surgery one of the fine arts, and by his work on *The Hand, its Mechanism and Vital Endowments*, revealed marvels and mysteries of design where the unlearned reader would least expect them; Sir Roderick Impey Murchison (1792–1871), who attained the highest geological distinction by the conception and establishment of his Silurian system, by which he brought under scientific light a formation of rock beneath the old red sandstone; this, named Silurian from the place in England where he studied it, he followed into Norway and Sweden, and finally into Russia, his book recording his geological survey of which vast country is one of the important works of modern science; Michael Faraday (1791–1867), the most eminent of English experimental chemists; Mary Somerville (1780–1872), one of the very few real women of science the world has seen (the womanhood being as true as the science), whose works on the *Mechanism of the Heavens* and the *Connection of the Physical Sciences* have won the highest approval both for their profundity and their clear and simple style; and Hugh Miller (1802–56), a quarryman, who from observations made during his daily labor became one of the leading geologists of his day, adding to exact knowledge a beauty of style and a richness of illustration rarely found in scientific books. He took his place among those men of science who seek to support revealed religion and to reconcile the Mosaic cosmogony with the records of nature. His principal works are *The Old Red Sandstone* and *The Testimony of the Rocks*. In 1845 appeared an anonymous volume, *Vestiges of the Natural History of Creation*, a work which, at first spoken of slightingly by scientific men as the fruit of presuming sciolism, proved to be the first utterance of the new school of development. Its style, no less than its startling views, won it worldwide attention. It is now known that its author was Robert Chambers, of Edinburgh.

Charles Darwin.—Charles R. Darwin (1809–82, grandson of Erasmus Darwin, 1731–1802, author of the *Botanic Garden* and *Zoönomia*) was the leader of the school of development. He had published several works on natural science, the high value of which was recognized when his *Origin of Species by means of Natural Selection* renewed the surprise which followed the publication of the *Vestiges of Creation*; and yet, although it prepared the way for, and led naturally to, his last work, *The Descent of Man and Selection in Relation to Sex*, that book was received with a mingling of admiration and horror for the author who seemed to prove that "man is descended from a hairy quadruped furnished with a tail and pointed ears, and probably arboreal in its habits." Louis John Rodolph Agassiz (1807–73) is eminent among the natural philosophers of the century by his works upon fishes, living and fossil, but chiefly by his glacial theory of certain geological formations, which he developed in his *Studies of Glaciers*. In comparative zoölogy and comparative physiology his investigations have been of great importance and interest. He did not accept the theory of development. John Tyndall (1820–93) is also distinguished for his glacial researches, his analysis of the solar ray, his discoveries as to light and heat, and is one of the school of philosophers to which Darwin and Huxley and the author of the *Vestiges of Creation* belong. His writings and his lectures have an intrinsic charm besides their scientific value.

Huxley.—Thomas Henry Huxley (1825–95) is the noted author of *Man's Place in Nature, Lectures on Comparative Anatomy, Lessons in Elementary Physiology*, and other works, all of a "positive" or quasi "positive" character and materialistic tendency. Of American scientific writers, some of the most distinguished are Alexander Dallas Bache (1806–67), whose place in education has already been mentioned, but who was eminent in magnetic and meteorological science, whose many contributions to the proceedings of the American Association for the Advancement of Science are among the most valuable in the repertory of that society. Samuel George Morton (1799–1851), naturalist and ethnologist, author of *Crania Americana* and *Crania Egyptiaca*; George Robins Gliddon (1809–57) and Josiah Clark Nott (1804–73), whose *Types of Mankind* and *Indigenous Races of the Earth*, although criticised by men of science and theologians, are filled with effective groupings of significant facts illustrated by ingenious suggestions; Asa Gray (1810–88), one of the most eminent botanists of the day, as he has shown in his various works upon the flora of North America; Benjamin Silliman (1779–1864), the geologist and mineralogist; John Torrey (1796–1873), botanist, chemist, and metallurgist; and Arnold Henry Guyot (1807–84), who brought to his adopted country a profound acquaintance with physical geography, previously set forth to the scientific world in works of recognized value, and now diffused among younger students by his books of elementary instruction.

Audubon.—Among naturalists, John James Audubon (1780–1851) must not be forgotten, because of his close observation of the habits of birds and his life-size paintings of the birds of America. Henry Maudsley's writings upon what may be called mental physiology are of the profoundest scientific and psychological interest, and have a singular literary charm. His *Body and Mind* and *Psychological Essays*—in the latter of which is a subtle appreciation of the character of Hamlet—and his *Physiology and Pathology of Mind*, are his principal works. The latter of these works, rich with the lore of various ages and climes, and seeking to penetrate to the very seat and reveal the very mode of thought, was published in 1873. To such a point has the English language and literature advanced.

The following standard works may be consulted for further information: Gustav Körting, *Grundriss der Geschichte der Englischen Litteratur* (Münster, 1887); Henry Morley, *English Writers* (9 vols., London, 1887–92); Hippolyte Adolphe Taine, *History of English Literature*, translated by H. Van Laun (2 vols., New York, 1871); George L. Craik, *Compendious History of English Literature* (2 vols., New York, 1863); Thomas Warton, *History of English Poetry* (3d ed. by W. Carew Hazlitt, London, 1871); John Earle, *Anglo-Saxon Literature* (London, 1884); Thomas Wright, *Biographia Britannica Literaria* (vol. i., Anglo-Saxon Period; vol. ii., Anglo-Norman Period, London, 1842–49); Bernhard ten Brink, *Early English Literature*, translated by H. M. Kennedy (New York, 1873); Bleibtren, *Geschichte der Englischen Litteratur im Zeitalter der Renaissance und der Klassizität* and *Geschichte der Englischen Litteratur im 19 Jahrhundert* (Leipzig, 1887); George Saintsbury, *History of Elizabethan Literature* (London, 1887); Edmund Gosse, *History of Eighteenth Century Literature* (London, 1889); Adolphus William Ward, *History of English Dramatic Literature* (2 vols., London, 1875); Edmund C. Stedman, *Victorian Poets* (Boston, 1886); M. C. Tyler, *History of American Literature, 1607–1765* (2 vols., New York, 1878); C. F. Richardson, *American Literature* (2 vols., New York, 1887). RICHARD GRANT WHITE.
Revised by HENRY A. BEERS.

English Pale, called also the **Irish Pale**, or simply **The Pale**: in history, that part of Ireland which was under English law previous to the final and complete subjugation of Ireland. In a general way the English Pale may be defined as corresponding with the present province of Leinster, besides Cork, Kerry, Waterford, Tipperary, and Limerick. But, in point of fact, the actual Pale, though of extremely variable limits, scarcely ever reached the dimensions indicated above. The counties of Dublin, Meath, Carlow, Kilkenny, and Louth were almost always within the Pale; Wexford and Waterford, though hardly within the Pale, were firmly English; while Wicklow and Kildare, though nominally within the Pale, were Celtic, and to a considerable extent independent. In strict language *the Pale* denotes the "boundary-line," but it is commonly used for the region itself.

English River: an estuary of Southeastern Africa, communicating with Delagoa Bay about lat. 25° 58′ S. and lon. 32° 36′ E. It receives several broad but unimportant streams (Tembia, Mattol, and Dundas rivers), and is surrounded with mangrove flats.

English River: a river of Iowa; formed by the union of two forks, the North and the South; flows eastward, entering the Iowa river 15 miles S. of Iowa City.—Another English river enters the Red Cedar river in Black Hawk co., Ia.

English Seventh-day Baptists: See SEVENTH-DAY BAPTISTS.

Engrafting: See GRAFTING.

Engrailed [partic. of vb. *engrail* < Mid. Eng. *engrele* < O. Fr. *engresler* or Mod. Fr. *engrêler*, probably meaning hailed upon, indented with hail; *en* < Lat. *in* + *grêle*, *gresle*, hail, loan-word from Teutonic; cf. O. H. G. *grioz*, coarse sand]: in heraldry, edged with small semicircles or crescents, the points of which are turned outward. The semicircular marks or dots around the edge of a coin are called engrailments.

Engra'tia, also called **Encratis**: a saint who lived at Saragossa, Spain, in 304. She was persecuted as a Christian under the Emperors Diocletian and Maximianus Hercules; and, according to the poet Prudentius, she underwent the most fearful tortures, but, notwithstanding the dreadful mutilations which she received, she survived to a great age, and died in the odor of sanctity. Her relics are preserved at Saragossa. Her festival, as observed by the Roman Catholic Church, occurs on Apr. 16.

Engraving [prefix *en* + vb. *grave* < O. Eng. *grafan*: Germ. *graben*, dig, carve. Not connected with Gr. γράφειν, write, which corresponds probably to Eng. *carve*]: the process of cutting grooves or small hollows in a hard surface, more especially letters, characters, or works of art; by extension, carving a surface with characters in relief, as in WOOD-ENGRAVING (*q. v.*). Engraving differs from chasing in the fact that the substance is cut away, while in chasing it is merely depressed or beaten down. Engraving on a large scale is seen in all incised lettering and cutting of emblems, characters, and the like, as on marble or stone; this was an art very much studied and followed among the ancient Greeks and Romans. (See INSCRIPTIONS.) Among the enormous number of inscriptions cut in marble which are left us from classical antiquity there are very few in which the letters are in relief; they are *engraved*, even when a bas-relief of figures is sculptured on the same piece of stone. Other engraving in large compositions, though the incised lines are narrow and not deep, is that to be seen in the numerous monumental brasses of the Middle Ages. A peculiar kind of relief sculpture, much used in Egyptian art for carving inscriptions and figure-subjects on very hard stones, and used also in the arts of China and Japan, is known as *cavo-rilievo* and by other names (see RELIEF), and may be considered a kind of engraving. Engraving on brass or bronze plates is used in modern times chiefly in memorials to the dead, and in simple lettering instead of the elaborate figure-subjects of the Middle Ages. Incised letters on marble, granite, or stone are common in tombstones and sepulchral monuments, but rare in other places in modern practice. On the other hand, the moderns carry further than the ancients seem to have done the art of engraving on metal in small ornamental designs for the purpose of decorating vessels for table use and for general display, such as gift-vases, race-cups, etc. Thus there are many showy pieces of silverware of the eighteenth and nineteenth centuries in which engraved festoons, wreaths, scrolls, and the like form the chief part of the ornamentation. Sometimes parts of the same vessel are chased in more or less high relief, and other parts are smooth and ornamented with engraving, the contrast between the two kinds of ornament being dwelt upon. The Orientals have sometimes used such engraving on metal with extraordinary skill and good taste, far surpassing the work of Europe in the effect produced by simple means; thus in Japanese metal-work of the eighteenth and nineteenth centuries small objects of silver and bronze, and even pieces as large as sword-sheaths, are adorned with engraved bouquets and sprays of flowers, suggestions of landscape, and the like, in which the varying width and depth of the incision are made to produce the most vigorous decorative effect. Other engraving on a small scale and on metal is seen in the *nielli* of the later Roman times, the Middle Ages, and of the Renaissance; it is common also in Russian art of the nineteenth century. (See NIELLO.) In these, as in the large monumental brasses of the Middle Ages, the incised line is filled up with a black compound, whereas in other ornamental engraving the play of light and shade in the V-shaped groove is enjoyed and counted on. In enamel-work also much use is made of engraving, *champlevé* enamels being prepared by engraving out the figure upon the background. (See ENAMEL.) Die-sinking is engraving upon fine steel which has previously been softened. (See DIE.) Dies so prepared are used in coinage of money, in striking medals, etc.; but dies are also cut for stamping seals in wax or upon paper, for raising ornamental letters on fancy stationery, etc. That important branch of engraving which consists in preparing plates from which impressions may be taken upon paper is treated of below.

In all these cases the tools used by the engraver are somewhat similar in character. They are straight, sharp, edged or pointed tools, impelled by hard pressure or by light taps of a mallet, and are used as chisels, stone being cut away by them in small fragments, and metal in curled-up shavings.

But there are some kinds of engraving which are done by rapidly revolving drills or wheels, in part or altogether. Of these the most important is the engraving of seals on very hard stones (see GEM); but there is a great deal of fine engraving done upon vases and cups of rock crystal, jade, agate, and the like. This work is mostly done with revolving wheels coated with emery powder, though the diamond point is used for very delicate and artistic work. Thick glass is also engraved, very much as is done with rock crystal; but as some acids attack glass readily, etching is resorted to in order to facilitate the work, and sometimes glass is ornamented wholly by etched patterns. See *Etching* (below).

The most important kind of engraving in modern times is that which is done for the purpose of making prints from the engraved surface. It was found in the fifteenth century that an engraved plate of metal would hold any coloring-matter, ink, or the like, so perfectly that an impression taken on paper would show every line, scratch, and dot of the engraving in uniform proportionate size and force of color, and that it would do this every time, so that a hundred impressions could be taken, all of which would be complete and practically the same. The tradition is that it was a *niello* used as a pax in the hands of a Florentine silversmith, Maso (i. e. Tomaso, or Thomas) Finiguerra, which first yielded an accidentally made print so good as to attract the artist's attention. Within a quarter of a century the new art process had become known throughout Western Europe. The different methods of engraving the plate of metal were introduced one after another, though some of them, as mezzotint, were not in use till two centuries later.

All the different ways of engraving a plate by hand, as distinguished from modern chemical processes (see PHOTO-ENGRAVING), may be classed under two heads: first, engraving by the hand and the steel tool alone; second, engraving by means of acid, which is guided by the work of the hand and the tool to attack certain portions of the plate and to spare others. In the first class come *line-engraving*, *stipple* (sometimes, and especially when used with line-engraving), *mezzotint*, *dry point*, and perhaps the dotted manner or *manière criblée*. In the second class come etching and aquatint. For work in either class almost any common metal will serve. Soft iron, steel, zinc, copper, have all been used; glass also has been used for etching, and stone for etching and dry-point work alike, which work upon stone has of course nothing to do with LITHOGRAPHY (*q. v.*), but is pure engraving in the strict sense. Copper has been from the outset much the most commonly used of all metals, but steel was employed from about 1815 for work from which many copies were to be taken. This again is becoming less common since the introduction of the process of steeling copper, by which the surface of an engraved plate can be covered with an electro deposit of steel so thin as to scarcely mar the delicacy of the work, while it is indefinitely capable of renewal, and serves to protect the soft copper, so that thousands of copies may be printed without injury to the plate.

Line-engraving is called also *burin-engraving*, from the name of the tool most used in it. This is a bar of steel, usually four-sided, and having the end cut off at such an angle as to leave a lozenge-shaped point. The other end is set in a short wooden handle, with a smooth rounded back upon which the hand presses, pushing the burin slowly along the line which it is to follow, where it turns up a curled shaving of metal. The lines cut in this way may be extremely fine, as in well-known engravings by Albert Dürer, mentioned below, or broad and deep, as in much foreground work in large compositions. The metal which is left clinging to the edge of the engraved line, like the soil turned up by the plowshare, is called the *burr*, and this is usually removed by the *scraper*. Burins of different sizes and with the points ground at different angles are used; each kind of work has its fitting tool, and each artist his own preferences. It is usual to begin the work of a line-engraving by drawing the whole subject on the plate in fine lines, by means of *etching*, or in parts, by the etching-needle alone without the use of acid—the *dry-point*, in short. Let us suppose that the engraving is to be a portrait of Mr. Gladstone. The engraver, whom we assume to be also a portrait-artist of ability, has made several studies of his subject and has secured photographs also of the head and body in the attitude fixed upon; he prepares now his definitive drawing of the subject complete, as he means to engrave it, background and details of dress and all, and this drawing in a sort of highly finished outline, or without masses of shade, etc., he wishes to transfer to his copper plate. Of course if he lays the drawing face downward on the plate and the lines can be so transferred, the image on the plate will be reversed, as in a looking-glass; but this is what is wanted, because then the impression taken from the plate upon paper will come right again. The plate is covered with a *ground*, as described below under *Etching*, and the outline drawing is rubbed off or transferred to this, where it shows plainly enough. Every line and dot of this drawing is then carried through to the copper by the etching-needle and acid or by the needle without acid, and when the ground has been melted off the highly polished plate is seen to have a lightly traced outline drawing, in which the whole subject is reversed. The plate is then inked and two or three impressions are taken upon dampened paper. As soon as the ink has begun to enter all the lines freely every lightest and faintest scratch comes off in black on the paper, and the artist can tell better by the study of this print than from the gleaming copper with its bright or blackened lines and its reversing whether any further touches are needed to bring his whole composition into shape. Any slight change can be made by the etching-needle if it is a question of adding something, or by the burnisher if something is to be taken out. Finally, work begins with the burin, and a patient toil of several months brings to perfection the plate from which are printed the black and white pictures erroneously called "engravings"; more properly, *prints*. Two years will sometimes be given to a large subject of many figures.

By far the greater number of modern line engravings have been copies of paintings by other artists than the engraver. In this common case the following device is often used to aid the engraver in making his first drawing: In front of the picture is placed a network of fine threads, crossing each other at right angles and having the squares left between them of exactly uniform size. Corresponding lines are applied to the sheet of paper on which the drawing is to be made. As each small square on the paper represents a square of the picture, the operation of copying the picture in outline goes on with comparative ease and rapidity.

If prints of the work of different engravers be compared, it will be seen that many different ways exist of using the engraved line. Sometimes it is very simple, indeed, as simple as a common pen-and-ink drawing; but sometimes an elaborate system is adopted, as where pains have been taken to make all the lines cross one another so as to leave lozenge-shaped spaces, in each one of which there is a dot or a cross. Nearly always such uniform systems are an abuse, as the engraver is then seeking this trivial effect instead of the best results of art in general. But the history of line engraving shows many such affectations and mannerisms, and it has always been unfortunate in being much employed for showy copies of famous pictures, generally inaccurate, and always misleading to the student of painting, while they are not the best employment work for the engraver. Of the great amount of excellent work and well-used skill which has been given to line engraving during 400 years, something will be said below.

Stipple-engraving, or simply *stipple*, is generally considered a branch of line-engraving. It is done by making points or dots instead of continuous lines. In almost any line-engraving, or in a print from it, it will be seen that the burin has ceased to draw its lines strongly and continuously in the spaces where the light is strongest; its lines have become broken rows of short dashes, or even rows of dots. *Stipple* consists merely in carrying somewhat further this way of getting light and shade. It is often, perhaps more usually, combined with ordinary line-engraving; thus in many modern portraits the head will be wholly modeled in stipple—that is, all its forms shown by means of light and shade, which is produced by dots, larger, smaller, more crowded, or more widely spaced—while the clothes, etc., are given in full line-engraving. Stipple may be done also by means of acid as stated below.

Dry-point work is done with a sharp-pointed tool like the etching-needle, but without acid (see *Etching*, lower down). The difference between this and burin-engraving is then very great: it is all the difference between *scratching* and *plowing*. The burin is held strongly in the hand, and the palm pushes the stiff steel bar before it, end on, with slow and continued pressure; but the etching-needle is held like a pencil or a pen, and its strokes are downward or sideways, like those of a pencil or pen when used in making a drawing. A *burr* is raised by the strokes of the needle, but this is small and fine, and when partly left on the plate it takes the ink readily, and yields a rich velvety bloom which is much admired in those prints which are called especially "dry-points." But apart from the plates which yield such prints as these, dry-point work is used continually in touching up and finishing all kinds of line engravings and etchings, and in these cases the burr is removed exactly as in line engraving.

Mezzotint, called by the French *la manière noire* (the black style), is produced by first scratching and notching the plate all over so that an ink-print from it would be one solid black, and then scraping and polishing parts of the plate so that it will no longer hold the ink, or at least not so much of it. This process is in one sense the reverse of burin-engraving and dry point, because in those the artist produces the dark upon the light, while in mezzotint the light is produced upon the dark. The plate may be roughened in any way that will produce a uniform surface, but the usual way is to employ what is called a "rocker" or "cradle," or in French *berceau*, a large blade like a chopping-knife, the edge of which is a regular curve, and is sharpened like a very fine saw, except that the teeth have sharp points. Philip Gilbert Hamerton, an excellent authority, has counted the teeth in his *berceau*. He reports 110 of them in a width of $2\frac{1}{2}$ inches, and he calculates that there will be 2,640,000 little points or dots produced by it in a plate 5 inches by 6, because the *berceau* must be rocked across the plate in different directions about eighty times to produce a well-prepared mezzotint plate. Upon this elaborately produced roughness the artist works with scrapers and burnishers. Where the copper is brought to perfect smoothness again the ink will be removed when the plate is wiped, and the paper will come white in the print; and between this and the complete solid blackness of the mezzotinting all gradations are easily obtainable. The fault of mezzotinting, in copper at least, is that it allows of so few good impressions. Twenty or thirty prints are all that can be taken perfectly; after that the plate must be retouched and reworked, or the prints are more and more feeble.

As for the *criblé*, or dotted manner, it is not known how the curious and rare early prints known by this name were produced; it is probable that they are from *relief-engravings*, not unlike wood-engravings in character.

Etching is much the most important process of engraving by means of acid. It is done by exposing the plate to the acid at all the lines and points which are to be engraved, and protecting it everywhere else; and by exposing some such lines or points for a longer time than others, if they are to be engraved deeper. The lines and points so engraved by the acid are said to be *bitten*, and the corroding itself is called the *biting-in*. The substance which protects the plate from the acid is called the *ground*, or the *etching-ground*; it is generally composed of a mixture of wax, some vegetable resin, such as mastic or white pitch, and asphaltum. This is spread all over the plate while hot, and then allowed to cool. This ground is blackened by smoking it over the flame of wax candles, and the black surface is made to look very smooth and uniform. Upon this smooth and slightly glossy black surface the artist draws with his etching-needle, which easily cuts its way through the ground so as just to lay bare the copper below, or even to scratch it slightly. Some etchers prefer a sharp point which scratches the plate decidedly, others a rounded point which glides over it. It is then ready for the acid bath. This is often nitric acid and water, though many different *mordants* are in use. It is quite possible to bite the whole plate at one time and to leave it so, but it is usual to expose some of the lines to the acid for a longer time than others, and even to use mordants of different powers. It is customary also to clean the plate and print from it on paper one or two proofs to enable the artist to judge of his work. The plate can then be regrounded by a simple apparatus which leaves unfilled the lines already cut in the copper, and these lines themselves can be protected from the acid at pleasure by *stopping-out* with a varnish of some sort which can be put on with a brush. An etched plate is, then, an engraving of which the sunken or engraved lines have been eaten out by acid, the metal having wholly disappeared from those sunken places, leaving the plate around them clean and smooth. Stipple-engraving, as in Bartolozzi's work, is partly done by acid, which bites deeper the points made by the graver; it is then a variety of etching.

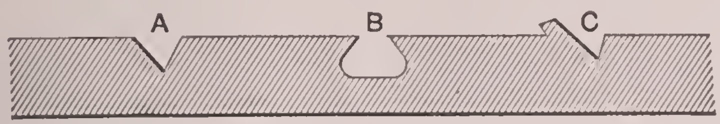
Aquatint is the only other important kind of engraving with acid, and it is of much less importance than etching because it has never been much in favor among artists. In itself it is a beautiful art, and the results are often delicate and forcible; but only a few workmen have found it to their taste, and it is used chiefly as a help in engravings of other kinds. The plate is covered with a ground which is much less solid and uniform than the etching-ground; usually some kind of resin is employed, either in powder or dissolved in alcohol, which solution, as it dries, leaves the resin in a surface much broken up by the shrinking of its parts. If the plate with this ground upon it be covered with acid, a somewhat uniform granulation is produced. By using different grounds in succession, applying the acid in each case to certain parts and not to others, different degrees of granulation are obtained; smaller parts of the plate are treated with varnish and a brush, and, after the acid has done all it can, the scraper and burnisher may be employed as in mezzotint.

Soft-ground etching is still another manner of engraving by means of a mordant. This also is not very frequently used by artists. It produces a print which strongly resembles a drawing in lead-pencil. The etching-ground used is made very soft; a sheet of paper is stretched tight upon it, and upon this paper the drawing is made. When this paper is removed, the ground comes away with it along all the lines of the drawing, and then the mordant is used as in ordinary etching.

These different processes are often combined one with another; thus there is very often pure etching to be seen in what is mainly a line-engraving; stipple and line engraving pass insensibly one into the other; dry point is used to touch and finish an etching, and a fine burin is used also by many etchers. But in addition to this there are some more deliberate and more notable combinations, as when a plate is etched with a design in what may be called outline, that is, the main lines only of the composition being given, and is then covered with mezzotinting or with aquatinting, in which second engraving the design is completed in light and shade and by the addition of many details. When a print is taken from such a finished plate, the soft gradations and tints given by the mezzotint or aquatint are re-enforced and made more vigorous and telling by the strong lines of the etching. This has been rarely done except by Earlom in the *Liber Veritatis* and in the important instance of Turner's *Liber Studiorum*.

Prints from plates prepared in any of these different ways require a certain care and skill if they are to be as good as possible. Although the ink is held readily by every large or small groove, scratch, or dot in the plate, and then comes out of it as readily when dampened paper is pressed against it, yet to keep the plate in perfect order, to apply so uniform a pressure that all the ink shall leave the plate at each separate impression, and also without wearing out the plate unduly—all requires training and some artistic skill, even in the simplest kind of printing. But printing is sometimes done in a much more elaborate way, the plate being left with its polished surface partly smeared with the ink instead of being wiped absolutely clean. When this is done, every separate print becomes a separate work of art, in a sense, for the printer has deliberately, and with calculated touches of a cloth, spread some of the ink which had been in the engraved lines over the smooth metal between the lines. No two impressions in such a case are really the same. No two prints of an edition printed in that way are facsimiles of one another. But as this process is very slow, and as there are but few printers living at any one time who can do such work well, nearly all printing is done simply, the plate inked with a roller (formerly with dabbers), and then cleaned off bright between the engraved lines. Etchings are printed in the artificial way more often than other kinds of engravings; burin-engravings very rarely. Different kinds of paper are used for prints. It is thought that certain Japanese papers take the ink with more uniformity, and show a clearer and more beautiful impression than any other sorts. What is called India paper comes next. This is generally stuck down fast to a sheet of heavy plate-paper, the thin India paper being cut only a little larger than the plate, and a broad margin of the heavier paper being left on all sides. These "proofs on India paper" have been in use for many years for prints from line-engravings, mezzotints, and all the kinds most used in the art trade, but Japan paper is more generally used for etchings and dry points.

Engraved plates wear down in printing in such a way that the engraved lines become less distinct. The prints, therefore, are less and less fine and desirable, beginning with the first print which is taken after the ink has thoroughly entered the engraved lines. From a mezzotint not more than twenty or thirty copies can be taken before a visible deterioration begins; from a dry point not more; from



Section of a metal plate engraved by lines in burin-work, etching, and dry point.

an etching perhaps twenty-five, perhaps fifty, according to the style of the work; from an aquatint about the same number. The process of steeling is not perfectly applicable to such plates, and does not protect them wholly. In the cut, B represents the cross-section of a line bitten by acid in an etching, the acid having eaten its way under the surface more widely than where the metal is protected by the ground. The groove made by the dry-point is as at C, the *burr* being left on one side, like the soil turned up by a plowshare. It is clear that these engraved lines will undergo rapid changes from contact with damp paper under heavy pressure, while the line A, produced by the burin, will suffer less. Moreover, steeling the plate will protect the one almost perfectly, especially if it is renewed, while B and C can not receive so much benefit from this process. But in practice steeling is not used for the finer and more artistical works of the engraver, and accordingly a great system of *proofs* and *early* impressions has been built up, partly a necessary and obvious resort, partly mere advertising.

The ordinary, large, showy prints of popular subjects are generally taken from their plates, according to some such classification as this: First, there are engravers' proofs, which are supposed to be taken by the engraver for his own guidance and not to be for sale; one of these will command a high price, just as a proof taken before the completion of the plate may command a high price, its necessary scarcity and a supposed interest in seeing the plate's condition at a time before the final touches bringing it into demand. The proofs that come first of the regular published edition are often *remarque* proofs; that is to say, a slight sketch with the point will have been made in the margin of the plate—a head, a dog, even a little group—and this sketch, which shows in the proofs, marks the fifty copies or so which are taken before its effacement. Then come artist's proofs, and all this time there are no letters of title or description added below, on the margin, so that all the proofs of these different classes are proofs *before the letter*. Sometimes the lettering is put on gradually; the engraver's name and that of the painter or draughtsman, if a different person from the engraver, will be added before the title, and more subdivisions of proofs are made possible in this way. Then there are proofs *before letters*—that is, before the title or legend is added—and, next, the proofs *with open letter*—that is, with the title or legend in outline. All of these proofs will probably be on India paper. Finally, and printed directly on plate paper, are the *prints*, commonly so called; one of these will cost the buyer a moderate sum, which will be doubled for an open-letter proof, and probably multiplied by ten for a *remarque* proof. No doubt all of this is open to the suspicion of being mainly advertisement, in the case of steel or steeled-copper plates, but it dates from a time when the copper plate really did wear away in a serious fashion. But etchings and dry-points and fine mezzotints will not yield so many impressions, and there is less ceremony about them. An early impression may be even more decidedly superior to a later one than in burin-engraving, but as the prints are rather for artists and specially instructed buyers there is less need to insist upon these distinctions. It often happens that a plate is announced as to yield fifty or one hundred copies only, all of which are supposed to be of equal value, and then to be destroyed; and the plate, duly scored across and across again with deep plowings of the burin, is exhibited, or impressions of it are exhibited, to confirm the assurance that no inferior prints shall ever be taken from it. The real test of the excellence of a print is of course the eye. It is so that we judge of and decide between impressions of ancient engravings, and it is so that one would always do with modern ones, when the opportunity is afforded. Comparison of one impression with another is especially to be sought for; very often a print seems good and even brilliant, when a moment's comparison with a better one will make it seem feeble.

The history of engraving for printing is rather the history of *prints*, for it is the latter which the student sees and studies. Few engraved plates of old masters of the art exist, and those few are not readily accessible. Prints from plates engraved for niello are the earliest (see first paragraph), and belong to the years about 1450–70. Here no artistic intention is to be presumed; the engraver was only proving his work as he went along, and never thought of preserving the paper prints. But one very skillful artist who worked for printing, Martin Schongauer, of Augsburg (d. 1488), left behind him a number of prints, and perhaps also engraved plates from which prints were taken after his death, and these are of very great merit as works of careful finish and apparent ease of execution. There is some fine Italian work almost as old; as the fifty "cards," or *Tarocchi of Mantegna*, as they are called, though they are not playing-cards in any usual sense; the prints marked by a caduceus and now ascribed to Jacopo di Barbari, and those rightly given to Mantegna. Many still earlier dates are given, but it is safe to say that artistic engraving on metal, for printing, dates from 1460 in South Germany, and perhaps 1470 in North Italy. Albert Dürer left prints of great beauty and showing extraordinary skill with the burin, but attracting more attention relatively than they deserve because of their poetical feeling and certain mystical character of some of them. Barthel Beham gave, in his *Portrait of Charles V.*, perhaps the most truly artistic burin-engraving that has ever been made. Henry Aldegrever was another able engraver; and contemporary with him, in the first half of the sixteenth century and in Germany, there were a body of "little masters," so called partly from their very diminutive engravings and partly from their rank as artists, assumed to be inferior to that of the greatest men of the time. Lukas van Leyden, who died in 1533, represents the art in Northwestern Europe at this time, and is a skillful engraver, though his power of artistic design is far inferior to that of some of the great Germans.

Meantime in Italy there were few artists who gave themselves up to engraving with the entire devotion of the Germans. Of the men who died before 1550 Giulio Campagnola and his two brothers deserve special mention; but much the most famous is Marcantonio Raimondi. His special celebrity is not in the excellence of his engraving, considered technically, but in the beauty of the compositions which he engraved. Some of these are known to be Rafael's, and very many of them are either his or founded upon him; and as the original drawings, etc., are generally lost, the engravings are the more precious. In the mere engraving neither Marcantonio nor any of the early Italians could compare for a moment with Dürer or Beham. In the hands of the Germans the burin was made to move almost as freely as a pencil, while to the Italians it was a difficult tool to manage. The Italians drew careful outlines with it, and then shaded the figure within these outlines; Mantegna with parallel, diagonal lines, nearly straight, Marcantonio with finer lines, often crossing, and somewhat more easily curved. In Mantegna's case the modeling of the figure by shading is admirably suggested, but only suggested; in Marcantonio's work the modeling is more elaborate but often very poor, while the backgrounds and details are generally trivial, and the skies of no value whatever, either of observation or rendering. Much of this is caused by the fact that Mantegna engraved his own designs, Marcantonio the masterly but slight drawings of a great painter, which he followed as far as they led and which then left him helpless. Marcantonio seems, moreover, to have been resolute not to do to his plate anything which it was not perfectly easy to do with the burin; and, as the designs he engraves are elaborate, this restraint is very noticeable. But Dürer, Beham, and in a less degree other Germans, united outline and shade in one, producing an effect far more like that of painting than of the awkwardly incised niellos which the Italians had not quite left behind them. Had engraving never gone beyond Marcantonio designs would have to be made of great severity and reserve, especially for interpretation by this means; whereas Dürer's work is on the track which engraving has followed since, trying everything, and using etching, dry point, and burin in free interchange to attain a result of great complexity, depth, and variety of shade and richness of tone.

The half-century following the deaths of Marcantonio and

Barthel Beham was not a time of great achievement in engraving. The prospect of its becoming a great independent art, bringing home artistic thought to people of small means as freely as printing was bringing to them literary thought, was growing dim; it was one more disappointment of the bright hopes raised by the Renaissance. Theological controversy, often taking the shape of bloody persecution and often of set and recognized war, was what men were thinking of, and the great living art of the time was protected by the Venetian lagoons. Italians like Giorgio Ghisi (d. 1582) were doing elegant work, more elaborate than Marcantonio. Stronger men, like Agostino Carracci (d. 1602), carried on the elaboration of work without losing themselves in prettiness, and their especial success was in portraits of their contemporaries. Flemings, of whom Henry Goltzius (d. 1617) was the chief, were eclectic in their tastes, now Italian in manner, now copying Dürer's ways closely—at their best in original portraiture, as in Goltzius's famous *Henry IV. of France.* Portrait-engraving was indeed the one distinct and original success for the art, and at intervals ever since this has been evident, so that no one branch is, on the whole, so well worthy of study. Thomas de Leeuw, called also De Leu, as having been long resident in France, left behind him, when he died about 1620, some 500 different works, most of which are portraits; these also mainly of his own drawing—admirable work, less in demand than it should be. Jacques Callot (d. 1635) engraved also many original portraits, but being a man of immense energy, leading a very irregular and adventurous life, he engraved also hundreds of plates of scenery, costume, biblical subjects, and what might be called *genre* in curiously made up sets, of the *Miseries of War*, of *Beggars*, of the *Twelve Months*, and many more. His work was mainly etching, but he never took full advantage of the freedom which that art allows, and a really great etcher he never became. Still, had he possessed more gravity and purpose, no man would have come nearer than he to realize the independent lifelong career of an artist-engraver. He left some 1,400 etchings, while George Cruikshank left 2,500. Should the community care for graphic art as much as it does for literature, it would find its needs well supplied by such men as these, for it would give them fitting subjects and encouragement to do their best instead of their slightest and hastiest.

A great change was now going on in the position of engraving in the world, one which was destined to lead to 200 years of mere copying. The great painter Rubens brought around him a number of very able technical engravers, and undertook to show them how to interpret his numerous pictures into black and white. The two brothers Bolswert, Vorsterman, Paul Pontius, and Peter Soutman are the best known among these able workmen, and to these should be added Jan Müller, as one of the most successful engravers after Rubens, though it is not known that he worked under that artist's immediate influence. The prints of these men have a great interest; they are in many ways right as renderings into one art of another and more rich and varied one, but they have this painful character, that they brought a great influence to bear on the side of copying as the only mission of the engraver. Another curious abuse in the art is to be seen in connection with the famous etchings of portrait heads by Antony van Dyk. That great painter undertook to etch the heads, and perhaps part of the dress, of a series of rather large and showy portrait-engravings, and other and inferior hands were to put in backgrounds and the like. Prints from many of these plates exist. Those taken from the unfinished plate, when, indeed, only the completely modeled head and slight indications of the body and dress are given, are most lovely and precious works of art; the mechanically finished portraits have but slight value. There were other able original portraitists at this time. Leon Gaultier, who died the same year as Van Dyk (1641), was one of them.

Good tendencies were at work, as well as bad; and the greatest of all original etchers was contemporary with Van Dyk, though destined to outlive him by nearly thirty years—Rembrandt, a master in portraiture as in everything that he touched. Cornelis Visscher (d. 1670) was another original portraitist, a burin-engraver, and a good one. As skillful, if less vivid and picturesque, was Robert Nanteuil (d. 1678), whose most famous portraits were engraved after Mignard and other painters, though the greater number of his works are original. In his hands the rendering of textures, as of armor, silk, and fur, reached great perfection. His contemporary, Wenceslaus Hollar, is one of the greatest of engravers, capable of anything, and yet his work looks archaic and incomplete to us, because he never invests it with full light and shade, but devotes himself to exact form, local color, and the study of texture and surface. Another contemporary was Claude Lorrain, the author of but a few etchings, but some of those of admitted excellence. The first English engraver of prominence was William Faithorne, who died in 1691.

The great school of French portrait-engraving was continued by Antoine Masson (d. 1700), G. Audran (d. 1703), and Gerard Edelinck (d. 1707), men worthy to rank with Visscher and Nanteuil, and by Pierre Drevet (d. 1738), and his son, Pierre Imbert Drevet, who died young, only a year later than his father. These are the great masters of seventeenth-century engraving. Their technical skill has never been excelled, and probably can not be; and their sense of keeping of the artistic proportion of all parts of a picture was greater than that of earlier men had been, so that even the most elaborate details keep their place in the composition. Portrait-engraving can hardly equal this hereafter. The day of rich and picturesque costume is gone, and it will not suffice for fine pictorial composition to have heads and hands alone of any interest, while costume, instead of a help, is almost wholly an incumbrance and a puzzle.

If any man could make a success of portrait-engraving under such untoward conditions it would be William Hogarth, who had around him, indeed, men and women more picturesquely dressed than those of the nineteenth century, but who took deliberately for his subject, not the elegant and graceful, but the rough and unseemly side of life. A good engraver, steadily at work at large and crowded plates, his example might have built up a popular use of engraving as a popular and accessible original art; but the epoch was not an artistical one. Another attempt, far removed from Hogarth's in spirit, but equally a popularizing of fine art by means of engraving, was that of Giambattista Piranesi (d. 1778) in his immense production of studies of Roman ruins; but Piranesi was far from being a faultless master of his art of etching, and his chosen subject could hardly be a popular one, limited as it is almost wholly to picturesque ruins and antique sculpture. Étienne Ficquet (d. 1794) may be considered the last of the French portrait school; his minute and delicate handling has preserved for us admirable studies of famous men and women of his time. Giovanni Volpato (d. 1803) was a skilled but uninventive workman, who did work to order from paintings and antiquities at Rome, and kept a school for engravers. Francesco Bartolozzi was fortunate in gaining the favor of influential persons in England, and perhaps owed this to the soft and delicate texture of the stipple-engraving which he practiced. A stronger man and a better artist was Charles Clément Bervic (d. 1822). His work, indeed, was chiefly reproducing the paintings of others, but he brought a fresh and original spirit to the task, and the great museum made by the first Napoleon at Paris gave him exceptional opportunities, as, for instance, the engraving of the Laocoon group from the marble, of which he made what is considered his masterpiece. A Spaniard of singular genius was Goya. Though not eminent as an engraver he must still be mentioned here as one of the men who, in untoward circumstances, were original and individual artists in an art almost wholly given up to copying.

The term *painter-engraver*, taken from the French *peintre-graveur*, has been applied to those engravers who carry out their own designs in their own art. These men and their work should undergo a wholly different criticism from those whose lives have been spent in reproduction only. The copyists have need of great and special ability, no doubt, in translating color into black and white by means of the graving-tools, but the painter-engraver is a man of a different class. What we have to add to this brief historical sketch is some mention of the attempts in the nineteenth century to give new life to engraving by artists of ability who have chosen to express themselves in this language.

David Wilkie is such an artist, and his few etchings and dry-points have a peculiar value of their own. But, though famous as a painter, he could never get people to look at his prints, and they are few and small. J. M. W. Turner in his great *Liber Studiorum* combined his own work with that of other engravers, and left about eighty compositions of wholly exceptional merit, where design and means of expression are perfectly well balanced, and nothing is lacking but the possibility of getting a proper number of prints from the mezzotinted plates. Charles Méryon was one of the most powerful of painter-engravers, and his few important plates contain a body of art-work beyond what would seem possible in such narrow space and severe limitations. Jean François Millet in his few larger etchings gives much of the noble pathos of his paintings. Claude Ferdinand Gaillard, who deserves the credit of having done, after four centuries of engraving for printing, something really new in the art, has produced the most remarkable finished portraits of the century. Jules Jacquemart (d. 1880) was one of the two or three great masters of the art of rendering truths of texture, light and shade, and delicate form; his etchings from the magnificent treasures of the Louvre (*Gemmes et Joyaux de la Couronne*) can hardly be equaled by any one who may follow him, and he etched many plates only second in importance to these. James Whistler has been called by an excellent judge the greatest etcher in line who has ever lived, excelling in this respect, in the force and right usage of the etched line, even Rembrandt himself. Francis Seymour Haden, though of far less originality and force, is one of the most skilled and accomplished of etchers, and has produced a great amount of attractive landscape. Alphonse Legros, less technically skillful, has a high and peculiar rank as artist, and has been called "an old master, belated." Finally, Leopold Flameng, Charles Albert Waltner, and Paul Rajon (d. 1888) must be mentioned as etchers who have pushed the art of reproducing other men's works beyond what had ever been known in true insight and faithfulness of rendering one art by another.

For a very complete list of works on engraving down to 1862, see Georges Duplessis, *Essai de Bibliographie contenant l'indication des ouvrages relatifs à l'histoire de la gravure et des graveurs.* For general reference to prints, description, cataloguing by means of numbers, etc., see the following: F. T. Palgrave, *Essay of the First Century of Italian Engraving*; J. D. Passavant, *Le Peintre-Graveur*; A. P. F. Robert Dusmenil, *Le Peintre-Graveur Français*; François Brulliot, *Dictionnaire des Monogrammes, Marques Figurées, Lettres, Initiales, etc.*; Adam Bartsch, *Le Peintre-Graveur* (Vienna, 1803–21; also later edition, not changed). For biographies of the engravers and of the painters, etc., whose works have been rendered by engraving, see Michael Bryan, *A Biographical and Critical Dictionary of Painters and Engravers* (new ed. revised by Robert Edmund Graves); *Nagler's Künstler Lexicon* (Munich, 1835–48, now scarce; a new edition has been begun under the direction of Dr. Julius Meyer, but the numbers are issued very slowly); A. Seubert, *Allgemeines Künstler Lexicon*; Spooner's *Biographical History of Fine Arts*; Beraldi, *Les Graveurs du Dix-Neuvième Siècle.* For general information and guidance in the study of prints, see Heinecken's *Idée Générale d'une Collection complète d'estampes, etc.*; Georges Duplessis, *Histoire de la Gravure en France* (Paris, 1861) and *Les Merveilles de la Gravure* (Paris, 1869); and *The Print-Collector, an Introduction to the Knowledge Necessary for forming a Collection of Ancient Prints* (London, 1848; attributed to the Rev. Joseph Maberly). For the practical work of engraving, see P. G. Hamerton, *Etching and Etchers* and *Graphic Arts*; De Lostalot, *Les Procédés de la Gravure*; Delaborde, *La Gravure*; Léon de Laborde, *Histoire de la Gravure en Manière Noire* (Paris, 1808). A good general and historical account of the art and guide to students is *An Introduction to the Study and Collection of Ancient Prints*, by William Hughes Willshire. Besides these are to be consulted the encyclopædias in different languages; Larousse, *Dictionnaire Universel du Dix-Neuvième Siècle*, and a very great number of monographs, that is, books devoted to the works of individual engravers.

RUSSELL STURGIS.

Engrossing [from Fr. *engrosser*, to write in large letters, to make big : Ital. *ingrossare*; Fr. *gros, grosse* : Ital. *grosso* < Lat. *grossus*, thick, big]: the writing of a deed in proper legible characters. Among lawyers it signifies especially the copying of any instrument or document on parchment or stamped paper. In the English statute law engrossing signified the purchase of large quantities of any commodity in order to sell it again, and was made an offense punishable by forfeiture and imprisonment. This was one of the many restrictions of trade that characterized the economic system of the Middle Ages. The penalties against the engrossing of corn were especially severe and by the statute of Edward VI. the pillory and confiscation followed the third offense. Other statutes of this nature were enacted, but in 1773 they were repealed, though the penal character of engrossing and FORESTALLING (*q. v.*) survived in the common law and was favored by the popular prejudice. In 1844 acts of this sort ceased to be offenses in England and Scotland.

Engstlen (engst'len) **Alp**: a place of resort, just S. W. of Engelberg, canton of Unterwalden, Switzerland. It has an altitude of 6,092 feet, and its beautiful pastures, with the neighboring lake, Engstlensee, the Wunderbrunnen (an intermittent spring), the falls of the Engstlenbach, the glaciers near at hand, and the loftier snow-clad peaks around, render it very attractive to tourists.

Eng'ström, JOHAN: a Swedish poet, novelist, traveler, and physician; b. Apr. 7, 1794, at Kärnebo, in the government of Kalmare; received his medical license in 1818, and until 1825 was employed as an army surgeon. Author of *Resa genom Norrland och Lappland* (1834); *Resa genom Södra Lappland, Jemtland, Trondhem och Dalarne* (1835–36); *Nordiska Dikter af Eivin* (1821); *Eols Harpan* (1830); *Förbundsbröderna* (1833–34); *Nybyggaren* (1838); *Björn Ulftand* (1840), etc. D. in 1870.

Enharmonic [from Gr. ἐναρμονικός, in accord; ἐν, in + ἁρμονία, harmony]: in music, one of the three genera (chromatic, diatonic, and enharmonic) of ancient music. The enharmonic genus of the Greeks was distinguished by the use of small intervals or quarter tones. In modern music, intervals much less than a semitone owe their origin to the slight difference of pitch which the same (nominal) note takes according as it is adjusted to one or another fundamental note or *tonic*. Thus C ♯ and D ♭ are, at least on keyed instruments, practically the same note, though strictly the former should be produced by $\frac{15}{16}$ of the whole string sounding; the latter by $\frac{9}{10}$. The passage from one to another of these intervals is called an "enharmonic change," and a change of key so effected an "enharmonic modulation."

Enigma [Gr. αἴνιγμα, riddle, dark saying; cf. αἶνος, tale]: an obscure question, a riddle; a proposition put in obscure or ambiguous terms to puzzle or exercise the ingenuity in discovering its meaning. Formerly it was deemed a matter of such importance that Eastern monarchs sometimes sent embassies for the solution of enigmas. Among the famous enigmas of antiquity were that which Samson proposed to the Philistines and that which the Sphinx propounded to Œdipus. See SPHINX.

Enim, or **Enin**: one of the forms of the EL DORADO myth (*q. v.*). It was supposed to be an immensely rich country, somewhere on the tributaries of the upper Amazon. One Francisco Bohorquez, a lying adventurer, declared in 1635 that he had actually been in this country and seen its king, who dwelt in a palace studded with gold and precious stones.

H. H. S.

Enkhuizen, enk-hoi'zen: a fortified seaport-town of the Netherlands; province of North Holland; on the Zuyder Zee; 30 miles N. E. of Amsterdam (see map of Holland and Belgium, ref. 4–G). It has a fine town-hall, several churches, a cannon-foundry, and several ship-building yards. Butter, cheese, timber, and fish are exported. The town was founded in 1200, and was sometimes called Enchusa. It was once a place of 40,000 inhabitants, and had a great herring-fleet, but the silting up of its harbor has wrought its decay. It still has a fine appearance from without. Its town-house, built in 1588, and the Westerkerk are the most remarkable buildings. Here Paul Potter, the great painter, was born in 1625. Pop. 5,900.

En'na: an ancient city of Sicily; near the center of the island, on a lofty hill, almost inaccessible, except at a few points. It was a place of great importance. Its site is now occupied by the decayed town of Castro Giovanni. Enna was a seat of the worship of Demeter, and the shore of a small lake near by was the scene of the mythical rape of Persephone, a favorite subject with poets and artists. Few remains of the ancient city survived the ravages of the Greek, Punic, Roman, Arabian, and Norman conquests.

En'neagon [from Gr. ἐννέα, nine + γωνία, angle]: a plane rectilineal figure having nine sides and angles. The area of a regular or equilateral enneagon is approximately 6·18182 times that of the square of one of its sides.

Enneking, JOHN JOSEPH: See the Appendix.

Ennemoser, en'ne-mō-zer, JOSEPH, M. D.: writer on physiology and animal magnetism; b. in the Tyrol, Nov. 15, 1787. He fought against Napoleon in 1813 and 1814, and graduated as M. D. at Berlin in 1816. He became Professor of Medicine at Bonn in 1820, and removed in 1841 to Munich, where he practiced with success. Among his works are *Der Magnetismus im Verhältniss zur Natur und Religion* (1842; 2d ed. 1853) and *Geschichte des tierischen Magnetismus* (1844), the first volume of which (the *History of Magic*) was translated into English by William Howitt (1854). D. in Egern, Sept. 19, 1854.

En'nerdale Lake: a picturesque sheet of water in the mountain region of Cumberland, England. 7 miles N. E. of Egremont. It is an expansion of the river Eken, 2½ miles long and less than a mile wide.

Ennis: market-town of Ireland; capital of the county of Clare; on the river Fergus; 20 miles W. N. W. of Limerick (see map of Ireland, ref. 10–D). It has a classical school called Ennis College founded in 1689, and the ruins of an abbey founded in 1240; also an asylum for lunatics, an infirmary, a hospital, a public library, a fine court-house, a brisk trade, and some manufactures, and a colossal statue of O'Connell by Cahill. Four bridges cross the Fergus, and railways extend to Limerick and Athenry. Ennis is one of the see-towns of the diocese of Killaloe (Roman Catholic). Pop. 6,300.

Ennis: city; Ellis co., Tex. (for location of county, see map of Texas, ref. 3–I); situated on railway, 34 miles S. by E. of Dallas; in a good cotton region; has a fine school, a very large cotton-compress, etc. Pop. (1880) 1,351; (1890) 2,171; (1900) 4,919. EDITOR OF "COMMERCIAL RECORDER."

En'niscorthy: market-town of Wexford, Ireland; on the river Slaney; 14 miles N. N. W. of Wexford (see map of Ireland, ref. 12–I). It has a fine Roman Catholic church, and a stately Norman castle many centuries old, but still entire. It has a large trade in grain, is at the head of barge navigation, is connected by railway with Dublin and Wexford, has a convent, five churches and chapels, and an asylum for lunatics. Enniscorthy was captured by Cromwell in 1649, and the Irish rebels took it by storm and burned it down in 1798. Pop. 5,660.

En'niskillen: a municipal borough of Ireland; capital of the county of Fermanagh; finely situated on the river Erne, which connects the Upper and Lower Lough Erne, about 75 miles W. S. W. of Belfast (see map of Ireland, ref. 5–G). It has 2 barracks, 6 churches and chapels, a prison, an infirmary, tanneries, straw-hat works, markets for flax, corn, pork, and butter, 2 forts, a linen-hall, and manufactures of cutlery. There are handsome mansions and beautiful scenery in the vicinity. The people of Enniskillen warmly supported the Protestant cause in 1689, when the troops of William III. here defeated those of James II. It is connected by railway with Dundalk, Londonderry, and Bundoran, and steamers ply on the Erne. Pop. 5,700.

Enniskillen, EARLS OF (1789): Viscounts Enniskillen, 1776; Barons Mountflorence (Ireland, 1760); have seats in Parliament as Barons Grinstead (United Kingdom, 1815).—WILLIAM WILLOUGHBY COLE, third earl, D. C. L., LL. D., F. R. S.; b. Jan. 25, 1807, and succeeded to the title of his father, John Willoughby Cole, in 1840. He was educated at Oxford, and before 1840 was distinguished in the House of Commons as Lord Cole, and acted in the Conservative interest. D. without issue, Sept. 5, 1886, and was succeeded by LOWRY EGERTON COLE, fourth earl; b. in 1845.

En'nius, QUINTUS: Roman poet; often called the Father of Latin Poetry; b. B. C. 239, at Rudiæ, a town in Southern Italy, not far from Tarentum. Greek was his native tongue, to which he early added a knowledge of Oscan and Latin. While in military service under the Romans in Sardinia, in 204 B. C., he met Cato, and by him was taken to Rome. Here he supported himself by teaching the Greek language, and adapting Greek plays to the Roman stage. He enjoyed the favor of the elder Scipio Africanus and of other distinguished men. In 189 M. Fulvius Nobilior, the consul, took him with him to his province Ætolia to be the herald of his deeds. For this service the son of Fulvius granted Ennius Roman citizenship in 184. In 169 he died of gout. A writer of great power and versatility, he contributed largely to the formation of the national literature of Rome. His most important work was an epic poem entitled *Annales*, treating in eighteen books the history of Rome, from the landing of Æneas down to his own times. This remained for a long time the most popular poem in the language, and was superseded only by Vergil's *Æneid*. Ennius also wrote tragedies, comedies, and satires. His poetry was greatly admired by Lucretius and by Cicero, who often quotes him. Of all his works only fragments remain. See editions by Vahlen (Leipzig, 1854), and Lucian Mueller (St. Petersburg, 1885), and Sellar, *Roman Poets of the Republic*, chap. iv.

M. WARREN.

Enno'dius, MAGNUS FELIX: a Latin writer; b. in Gaul in 474, of excellent family, and Bishop of Pavia from about 513 until his death in 521. His most important works are a biography of his predecessor, Epiphanius, and a turgid panegyric on Theodoric, written about 507. Also extant are a collection of his letters, two books of *Carmina* on various subjects, and twenty-eight speeches, including school debates. See the editions by W. Hartel (Vienna, 1882) and F. Vogel (Berlin, 1885). M. W.

Enns, or **Ens** (anc. *An'isus*, or *An'esus*): a river of Austria; rises in the crown-land of Salzburg, 12 miles S. of Radstadt. It flows through Styria, forms the boundary between Upper and Lower Austria, and enters the Danube 11 miles below Lintz. Length, about 190 miles, only the last 20 of which are navigable.

Enns (anc. *Laureacum*): town of Austria; on the Danube; at or near the mouth of the Enns; about 96 miles W. of Vienna (see map of Austria-Hungary, ref. 5–D). It has manufactures of iron, steel, and cotton. It was the headquarters of Napoleon in 1809. Pop. (1890) 4,674.

E'noch, or **He'noch** [Heb., initiated or teacher]: the name of five persons mentioned in the sacred books (canonical and apocryphal) of the Hebrews. The second in the order of time, and the most important, was "the seventh from Adam," who "prophesied," and was translated at the age of 365. (Gen. v. 23.)

Enoch, Book of: a book of 108 chapters, forming part of the Apocrypha, quoted by the apostle Jude (vv. 14, 15). It is of uncertain date, critical conjecture ranging from 144 B. C. to 132 A. D., but it was probably written in Hebrew by a Palestinian before the Christian era. The early Christian Fathers used it, but for some centuries only fragments of it were known to European scholars, till in 1773 James Bruce brought home with him from Africa three copies of an Ethiopic version of it, made apparently from the Greek about 350 or 400 A. D. It was published in 1838 at Oxford by Archbishop Laurence, who had previously (in 1821) published an English translation of it, and by Prof. Dillmann (Leipzig, 1851). The latter is the principal edition of the Ethiopic. The best translation which utilizes the newly discovered Greek text is by R. H. Charles (Oxford, 1893). The book contains many curious passages, but its leading idea is that of Divine justice dealing sternly with sinners.

E'nos (anc. *Æ'nos*, or *Ænus*): seaport-town of European Turkey; on the Ægean Sea, at the mouth of the river Maritza (*Hebrus*); 80 miles S. by W. from Adrianople, of which it was the port before the completion of the railway from Adrianople to the neighboring port of Dede-Agatch (see map of Turkey, ref. 4–D). Its harbor admits only small vessels. Pop. about 8,000. Here is a small bay called the Gulf of Enos. *Ænos* is mentioned by Homer in the *Iliad*, book iv.

Enriquez Gomez, ANTONIO, or **Enriquez de Paz**: dramatic author; the son of a converted Portuguese Jew; b. at Segovia, Spain, early in the seventeenth century; entered the army and rose to the rank of captain, but from the year 1629 devoted himself almost exclusively to literary work. About that date several comedies by him were represented on the stage at Madrid with success, and in 1635 appeared his *Fama póstuma á la vida y muerte de Lope de Vega*; but the fear of persecution on account of his alleged return to the Jewish religion drove him from Spain, and in 1638 he appeared in France, where he remained for eleven years. Removing to Amsterdam about 1656, he openly professed Judaism, for which he was burned in effigy at the *auto-da-fe* in Seville, 1660. The date of his death is not known. Twenty-two comedies were written by him and were all received with great favor, although they betray the faults of a facile but careless writer. His *A'lo que obliga el honor*, published with three other comedies under the title of *Academias morales de las Musas* (Rouen, 1642), is said to have suggested Calderon's *Medico de su honor*. The *Siglo pitagórico* (Rouen, 1647; Brussels, 1727) is a work of a somewhat mystical character, containing satirical sketches in prose and verse. Enriquez is thought by some to be the author of the comedies usually attributed to Fernando Zarate. See Ticknor's *History of Spanish Literature*.

Ensiform Cartilage, or **Xiphoid Cartilage** [*ensiform* is from Lat. *ensis*, sword + *forma*, form; *xiphoid* is from

Gr. ξίφος, sword + εἶδος, shape]: in human anatomy, the third and lowest piece of the sternum or breast-bone. It is smaller than either the first piece (*manubrium*) or the second (*gladiolus*). It is of various form, usually more or less dagger-shaped, sometimes perforated, sometimes two-pointed, and is usually cartilaginous until the seventeenth or eighteenth year, when a center of ossification appears in its upper part, and the whole takes on, very slowly, a somewhat bony character.

Ensign [from O. Fr. *enseine*, Mod. Fr. *enseigne* : Ital. *insegna* < Lat. *insig'nia*, emblem, standard, collec. plur. of *insig'ne*; *in*+*signum*, sign]: (1) the national flag or banner carried by a ship of war, and usually hoisted at the peak or on a flagstaff at the stern. Its chief purpose is to indicate the nationality of a ship when it meets another vessel at sea. In the navy of the U. S. the ensign is the national flag. All British men of war since 1864 carry the St. George's ensign—viz., a white ensign with a red cross, and a union jack in the left-hand upper quarter. The British ensign is a red, white, or blue flag, having the union in the upper corner next the mast, red for the merchant marine, white for the navy, and blue for the naval reserve.

(2) In the British army until 1871 the lowest grade of commissioned officers in the infantry, the senior of whom carried the regimental colors or ensign, thus corresponding to *cornet* in the cavalry. Officers of this rank are now called sub-lieutenants. The rank of ensign existed in the colonial militia of New England and in the Revolutionary army. The corresponding rank in the U. S. army is that of second lieutenant. The title of ensign was introduced into the U. S. navy in 1862, taking the place of that of passed midshipman. An ensign of the line is one of the lowest grade of commissioned officers, is a graduate of the Naval Academy, and ordinarily obtains his commission after four years' study on shore and two years of cruising.

Ensilage [Fr. deriv. of *ensiler* = Span. *ensilar*, to commit to a pit, or *silo* < Lat. *sīrus* = Gr. σιρός, pit]: a method of preserving forage plants in a green state; introduced into the Eastern U. S. from France about 1875. The term is also applied to the fodder thus preserved. Ensilaging green crops has become more common in the dairy districts of the U. S. than in France, Great Britain, or Germany. In many cases ensilaging green forage crops is the most economical way of preserving them, but it is not always satisfactory, as there is always some and frequently a large amount of loss of the ensilaged material, which is not infrequently acid or slightly mouldy. Silos may be built of wood, grout, or stone, either above ground or, better, below ground. When built of wood, they decay rapidly; if stone or grout, they are expensive. Rectangular silos are the most common, but circular ones are the best. A silo should be deep, strong, durable, air-tight, and inexpensive, as the material to be preserved is bulky in proportion to its value. The best and cheapest way to construct a silo, though not the most common, is to dig a circular pit 10 to 20 feet in diameter and 12 to 20 feet deep; the dirt thrown out may add 5 feet more to the depth. The sides of the pit are protected by a 4-inch wall of hard brick laid in cement; clay is packed behind the wall as the work proceeds. The top is contracted to about one-half the diameter of the bottom, and is protected by a circular iron flange upon which rests the cover of wood or iron; cement or rubber placed between the lid and flange serves to exclude the air, and earth placed upon the lid keeps out the frost. Great disappointment and loss have frequently resulted from departing from the original methods practiced by the Egyptians, Mexicans, and American Indians in keeping grains and other perishable products in simple earth-pits. The ensilage should be kept at all times at a temperature as low as that of the earth, and in an air-tight silo. The ancient method was to dig a pit in the dry sand, and, when filled, cover and compact the sand to a considerable depth over the mouth of the pit, thereby making a nearly air-tight seal. The methods of constructing and filling silos in the U. S. are very variable, as are also the material ensilaged and the treatment after filling. Sometimes doors are placed at the sides of the silo and removed as the ensilage is used, and sometimes no openings are left, the material being raised to the top by a horse when needed. Some empty the silo from the top, others cut down and feed out a section at a time. Some ensilage the material when it is very immature, others when it is nearly ripe; some fill rapidly to prevent heating, while others fill slowly so that the material may rise to 120° F.; some solidify while filling; some weight (150 lb. to the square foot) with stones, earth, or other material after a covering has been laid on, others simply cover with green weeds, grass, or straw, 1 to 2 feet deep. All these methods are imperfect, as more or less acid and mould are always present and a considerable loss occurs. The perfect silo is one which is absolutely air-tight, and from which all air is extracted after the pit is filled, but it is practically impossible to build one large enough for ordinary uses. The more nearly these conditions are fulfilled the more satisfactory will be the product. Carbonic acid gas suggests itself as a cheap and convenient material for replacing the air in the silo. At the Cornell University experiment station nearly mature green corn has been kept for three months in an air-tight silo filled with carbonic acid gas, buried in the earth, with no rise in temperature, and almost no change in color, taste, or weight. This method, however, is still in its experimental stage.

Many kinds of plants have been ensilaged with greater or less success, but Indian corn is now used most largely. Any broad-leaved dent variety which will ripen or nearly so in a given climate, the large sweet, and, where the season is short, the flint varieties, are now considered to be the leading kinds of ensilage corn. Some growers still sow or drill the seed thickly, but this prevents full development of ears, saccharine and coloring-matter, albuminoids and appetizing aromas. The aim should be to raise the greatest amount of grain possible, as then the greatest feeding value is secured. The corn should be glazed before it is cut, at which time it will contain from 60 to 70 per cent. of water. The best ears are often removed and dried, for, if the crop is good, the ensilage will be too rich in grain for most economical results in the dairy, if all the ears are ensilaged. Fifteen to twenty-five tons per acre may be secured at a cost, for raising and harvesting, of from $1 to $2 per ton.

M. Goffart's *Treatise on Ensilage of Maize*, translated from the French by J. B. Brown; *The Book of Ensilage*, by John M. Bailey; *On Ensilaging of Green Forage Crops in Silos*, by H. R. Stevens, are the leading works on the subject. I. P. ROBERTS.

Enslin, ens'lin, KARL: poet; b. at Frankfort-on-the-Main, Germany, Sept. 21, 1819; educated as a public-school teacher at Esslingen. He published several collections of his poems, which may be counted among the best contributions to juvenile literature in Germany. D. Oct. 14, 1875. J. G.

Ens Mar'tis [Lat., essence of Mars]: an old alchemical name for the ammonio-chloride of iron, formerly, used in medicine. It is an uncertain aperient and chalybeate tonic.

Entablature [adaptation of Ital. *intavolatura*; *in* + *tavola* < Lat. *ta'bula*, table]: in architecture of Greek, Roman, and revived classical styles, the portion of a building resting upon the columns. It consists of architrave, frieze, and cornice. In ordinary building the term is applied to the course of masonry on a wall immediately below the roof. See ORDERS OF ARCHITECTURE.

Entail' [from O. Fr. *entailler*; *en* + *taille*, cut, piece cut off, tax: Ital. *taglio* < Lat. *ta'lea*, or deriv. of *talia're*, to cut]: an estate in fee limited to certain classes of descendants. Thus a fee simple would be regularly created by the word "heirs," as, for example, to "A and his heirs," and would descend to any heirs, however remote. An estate given to A and "the heirs of his body" would be confined to descendants. This is an example of the proper words to create an estate tail. The descent might be still more strictly confined, as to male issue or the issue born of some specified mother. The peculiar features of an entail depend upon a well-known English statute termed *De donis*, the regular effect of which was to confine the property to the specified mode of descent. The result was that the tenant in tail had the general characteristics of owner, except that he could not sell, and that the land could not be seized for his debt. The courts permitted the entail to be destroyed by a fictitious legal proceeding called a fine, and more completely by another like proceeding called a common recovery, instituted in behalf of the tenant. He could thus, if he saw fit, become absolute owner. The common recovery is now abolished by statute in England, and under certain limitations the tenant may resort to a conveyance called a disentailing deed, and thus acquire a fee simple. In the U. S. words constituting an estate tail according to English law will usually be construed to create a fee simple, unless the property is given over to some other person on default of issue surviving the first taker; in which case the secondary gift would be upheld, and would take effect should no issue survive. See PERPETUITY.

En'tasis [Gr. ἔντασις; ἐν + τείνειν, strain, stretch]: a delicate and almost imperceptible swelling out in the taper of the shaft of a column, common in the architecture of ancient Greece. It was adopted to prevent the shafts being strictly frusta of cones, in which case there would, by a simple optical law, be an incorrect impression made upon the eye as to the proportions of the column. It was one of the most delicate yet important of the refinements of Greek architecture, and has not been accurately attained in modern imitations. In the columns of the Parthenon the entasis amounts to $\frac{1}{550}$ of the whole height of the column.

Entel'echy [from Gr. ἐντελέχεια, absoluteness, actuality, deriv. of phrase ἐντέλει ἔχειν, to be complete, or ἐντελής, perfect + ἔχειν, be]: a metaphysical term from the Aristotelian philosophy, denoting the fundamental idea of the whole system. Cicero defined this idea as *energy*, but the Greek philosophers who, in the fifteenth century, moved from Constantinople to Italy—and among them especially Argyropolus—ridiculed him for the definition, and gave *perfection* as the constituent element of the idea. Melanchthon, however, and Leibnitz, and all modern philosophers almost without exception, follow Cicero; and when the "Entelechy" of Aristotle is compared with the "Idea" of Plato or the "Absolute Negativität" of Hegel, or other fundamental ideas of other philosophical systems, it is evident that *energy* covers a much larger part of the Aristotelian idea than *perfection*. The abstract repose of the Platonic Idea is supplanted by the energy of reality in the Aristotelian Entelechy; its potentiality becomes actuality. Aristotle calls truth an idea, but the soul he defines as an ἐντελέχεια. The best explanations of the entelechy and its relations to the whole system of Aristotelian philosophy are given by Brandis in his *Aristoteles und seine Akademischen Zeitgenossen* (Berlin, 1857), and by Thurot in his *Études sur Aristote* (Paris, 1860).

Entellus Monkey, or **Hanuman**: a species of East Indian monkey (*Semnopithecus entellus*) about 2 feet in length, having long limbs and a very long and powerful but not prehensile tail. These monkeys are regarded as sacred by

Entellus monkey.

the Hindus, who dedicate temples to them, and erect hospitals for their benefit. The entellus monkeys exhibit a familiarity bordering on impudence, and often plunder gardens with impunity, as the Hindus feel honored when robbed by them. The Hindus also believe that they are metamorphosed princes, and to kill one is considered a deadly sin; hence these monkeys swarm in many places, especially in the vicinity of the temples.

Enteral'gia [from Gr. ἔντερον, intestine + ἄλγος, pain]: a name given in some medical works to colic, especially of the form attended by spasmodic contractions in the muscular coat of the intestine. See COLIC and NEURALGIA.

Enteri'tis [from Gr. ἔντερον, intestine + suffix of Greek origin *-itis*, applying to names of inflammatory diseases]: an inflammation of the small intestines. The term is somewhat vaguely used by medical writers. Active inflammation of the bowels, in adults at least, is frequently confined, for the most part, to the peritoneal coat, and the disease is then called peritonitis. When the mucous coat of the bowels alone is actively involved, it is frequently a fatal disease in children, but in adults, with care, the majority of cases recover. Catarrhal enteritis is benefited, and often cured, by gentle purgation. But in active disease of this kind cathartics will often greatly aggravate the evil. Such cases are best treated by rest, opiates, poultices to the abdomen, and bland nourishment. "Typhlitis," inflammation of or about the cæcum, when caused by abscess or perforation of the appendix cæci, is not unfrequently fatal; when otherwise caused, recovery may be looked for.

Revised by WILLIAM PEPPER.

Enteropneusta [from Gr. ἔντερον, intestine + πνεῖν, breathe]: a group of animals of very uncertain affinities, constituting one of the main divisions of the CHORDATA (*q. v.*). They have at various times been classed with the echinoderms, with the annelids, and are now usually associated with the vertebrates. They are worm-like in shape, and live buried in the sand of the ocean. In *Balanoglossus*, the principal genus, there is an acorn-shaped proboscis followed by a collar, and behind this the long body. The mouth is below at the base of the proboscis, and the throat is perforated with gill openings, in allusion to which the name Enteropneusta is given. In the proboscis there is a cartilaginous rod of tissue believed to be homologous with the notochord of vertebrates. Some species have a direct development, while others have a larval stage which closely resembles that of the echinoderms. The nineteen known species are distributed into four genera. Allied to them are probably the genera *Cephalodiscus* and *Rhabdopleura*, formerly included among the Polyzoa. J. S. KINGSLEY.

En'thymeme [from Gr. ἐνθύμημα, a consideration, thought, in Aristotle a "rhetorical syllogism," deriv. of ἐνθυμεῖσθαι, consider; ἐν, in + θυμός, soul, mind]: in logic, a syllogism of which one of the three parts (generally the major premise) is suppressed or held in mind—e. g. "The freedmen ought not to vote, because they can not read." According to De Quincey (*Historical Essays*, vol. ii., p. 215, *seq.*), the Aristotelian enthymeme is an argument in respect to matters probable rather than demonstrable. (So also Thomson, *Laws of Thought*, p. 284.) Aristotle's own definition for the rhetorical enthymeme is "a syllogism from probable propositions or from signs." By *probable propositions* he means those which are general, but not at all universal, as "injured men seek revenge." By *signs* he designates facts or marks, such as attend upon other facts or conceptions, so that from the presence of the sign we suspect or know that the thing signified is also present. The rhetorical enthymeme, when based on signs, is always affirmative, taking no account of negative indications. Its results are universal, and may amount to practical or even formal demonstration.

Entomology [from Gr. ἔντομος, cut in pieces (ἐν, in + τεμεῖν, cut; neut. plur. ἔντομα (sc. ζῷα, animals), insects so named from the divisions of their bodies, cf. Lat. *insecta*) + -λογία, discourse]: the department of zoölogy which treats of insects. For the purposes of this article the subject can be treated under three heads: (1) the anatomy of insects, (2) the metamorphoses of insects, and (3) the classification of insects.

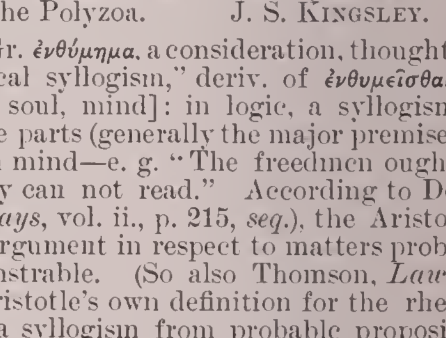


FIG. 1.—Figure of an insect, showing the grouping of the segments into *head*, *thorax*, and *abdomen*.

I. THE ANATOMY OF INSECTS.—*External Anatomy*.—Insects belong to that branch of the animal kingdom known as the *Arthropoda*, which is characterized by having the body composed of a series of segments, and furnished with jointed appendages. In insects the body segments are more or less distinctly grouped into three regions—the *head*, the *thorax*, and the *abdomen* (Fig. 1). The head is composed of at least four segments, which are so completely consolidated as to appear one. The thorax is composed of three segments, designated the *prothorax*, *mesothorax*, and *metathorax* respectively, and bears the organs of locomotion. The abdomen consists typically of eleven segments, but the full number is rarely distinguishable. In some insects (cuckoo-flies) only three or four abdominal segments are visible; but in the greater number of insects eight or nine segments can be distinguished in this region.

The head possesses the eyes, antennæ, and mouth-parts. In adult insects there exists on each side of the head an organ readily recognized as an eye; but when seen with a microscope, it presents an appearance very different from that of the eye of higher animals (Fig. 2). Its surface is divided into many six-sided portions, each of which is found on dissection to be the cornea of a distinct eye. This organ is therefore termed a *compound eye*, and each of the hexagonal divisions is termed an *ocellus*. The number of ocelli in the compound eye varies greatly in different insects; in some ants it is only about fifty, while in a dragon-fly or a butterfly there are many thousands. In addition to the compound eyes, many insects possess *simple eyes*. These vary in number from one to four, and are situated between the compound eyes.

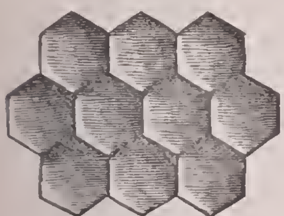

FIG. 2.—Part of compound eye greatly enlarged.

The *antennæ* are a pair of jointed appendages inserted in the head in front of the eyes or between them (Fig. 7, *a*). These are the organs commonly called the feelers. They vary greatly in form; in some insects they are thread-like, consisting of a series of similar segments; in others certain segments are greatly modified in form. In many insects each segment of the antennæ bears one or more appendages, which give the organ a feather-like appearance. The variations in form of the antennæ frequently afford excellent characters for distinguishing the groups of insects. Knowledge of the functions of the antennæ is still very incomplete. Minute structures are found upon them varying in form in different insects, which are doubtless organs of special sense, presumably of smell; and in some insects, as the male mosquito, other organs borne by the antennæ appear to act as organs of hearing. The minuteness of these organs of special sense renders their study very difficult. It is only recently that the methods of histological investigation have been sufficiently perfect to make possible the acquirement of exact knowledge regarding their structure.

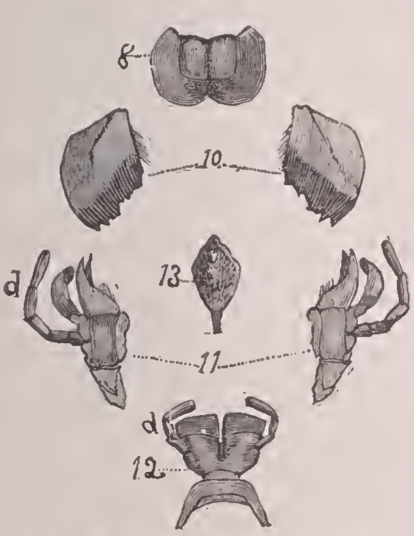

FIG. 3.—Mouth-parts of the red-legged locust: 8, labrum; 10, mandibles; 11, maxillæ; 11 *d*, maxillary palpi; 12, labium; 12 *d*, labial palpi; 13, hypopharynx.

The *mouth-parts* of insects are complicated organs consisting of several pairs of highly specialized appendages. The typical structure of the mouth-parts is best seen in the biting insects (Fig. 3). Here we find an upper lip, the *labrum*, an under lip, the *labium*, and two pairs of jaws, the *mandibles* and *maxillæ*, acting horizontally between them. Each mandible usually consists of a single stout piece which may be furnished with tooth-like processes fitting it for chewing or for seizing prey. The maxillæ or lower pair of jaws are much more complicated organs consisting of several pieces; each maxilla bears an organ consisting of several segments, the *maxillary palpi*; the lower lip is also a complicated organ, being formed of a pair of jaws grown together on the middle line. It bears a pair of jointed appendages, the *labial palpi*. There may be also within the mouth one or two tongue-like organs, the *epipharynx* and the *hypopharynx*. This type of mouth-parts is greatly modified in the different orders of insects. Thus the maxillæ of a butterfly are greatly developed, forming the well-known sucking tube of these insects; while the other parts, except

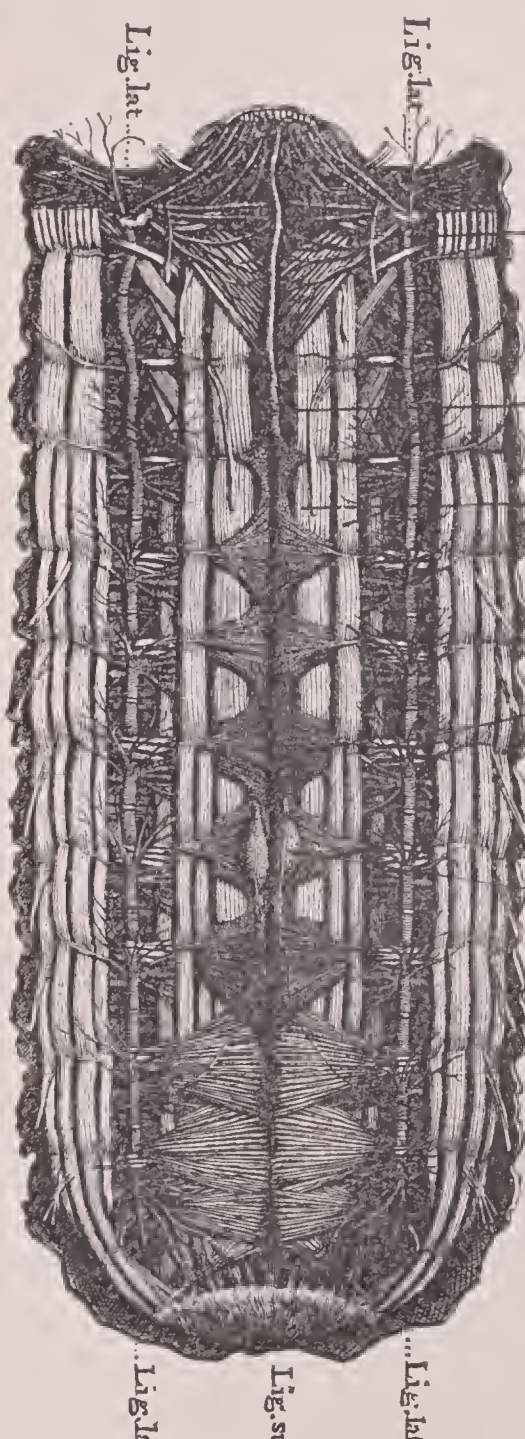

FIG. 4.

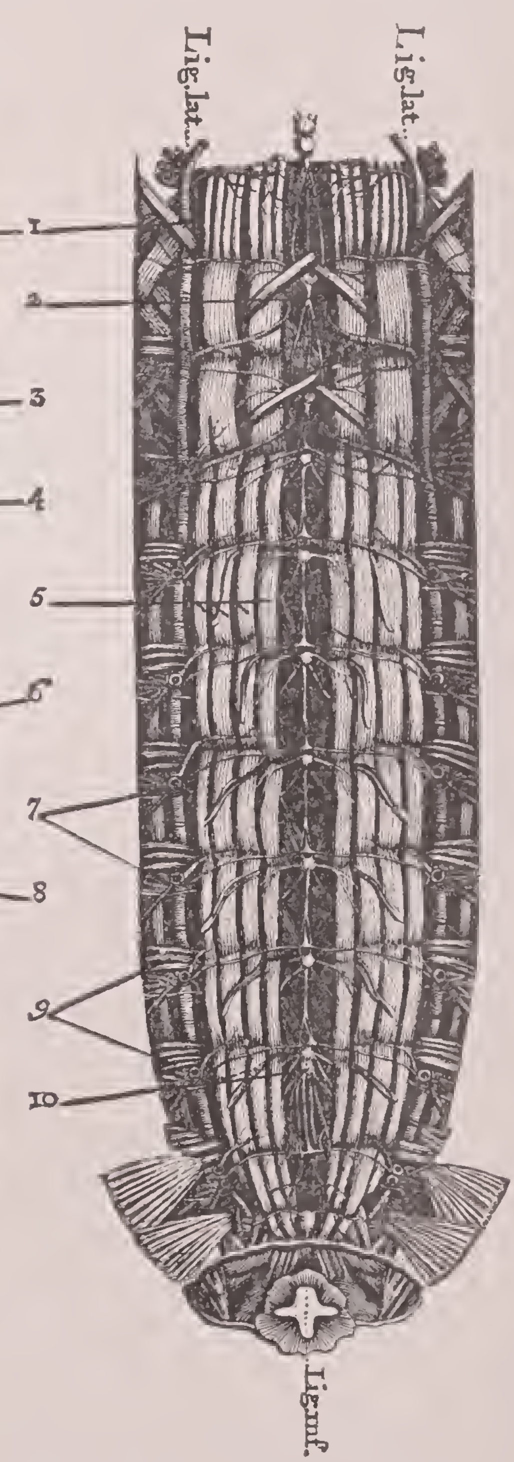

FIG. 5.

A caterpillar (*Cossus ligniperda*). (After Lyonet.)

FIG. 4.—Caterpillar opened on the ventral middle line. FIG. 5.—Caterpillar opened on the dorsal middle line. 1, principal longitudinal tracheæ; 2, central nervous system; 3, aorta; 4, longitudinal dorsal muscles; 5, longitudinal ventral muscles; 6, wings of the heart; 7, tracheal trunks arising near spiracles; 8, reproductive organs; 9, vertical muscles; 10, last abdominal ganglion.

the labial palpi, are but little if at all developed. In the flies and bugs the mandibles and maxillæ are bristle-like, fitted for piercing, and form with the lower lip an organ for sucking.

The appendages of the thorax are the organs of locomotion; these consist of the legs and wings. Of the former there are three pairs, of the latter never more than two pairs. Each segment of the thorax bears a pair of legs; the wings are borne by the second and third segments. Each leg consists of the following parts: coxa, trochanter, femur,

Fig. 6.—Leg of May-beetle, showing relation of skeleton and muscles.

tibia, and tarsus. The *coxa* is the segment by means of which the legs are joined to the body. The *trochanter* is the next division of the leg, and is usually an inconspicuous part; in certain *Hymenoptera* it consists of two segments. The *femur* is the principal segment of the leg. Following the femur is the *tibia*, consisting of a single segment. The remaining segments of the leg, varying in number from one to six, compose the *tarsus* or foot. The last segment of the tarsus is furnished with one or two claws.

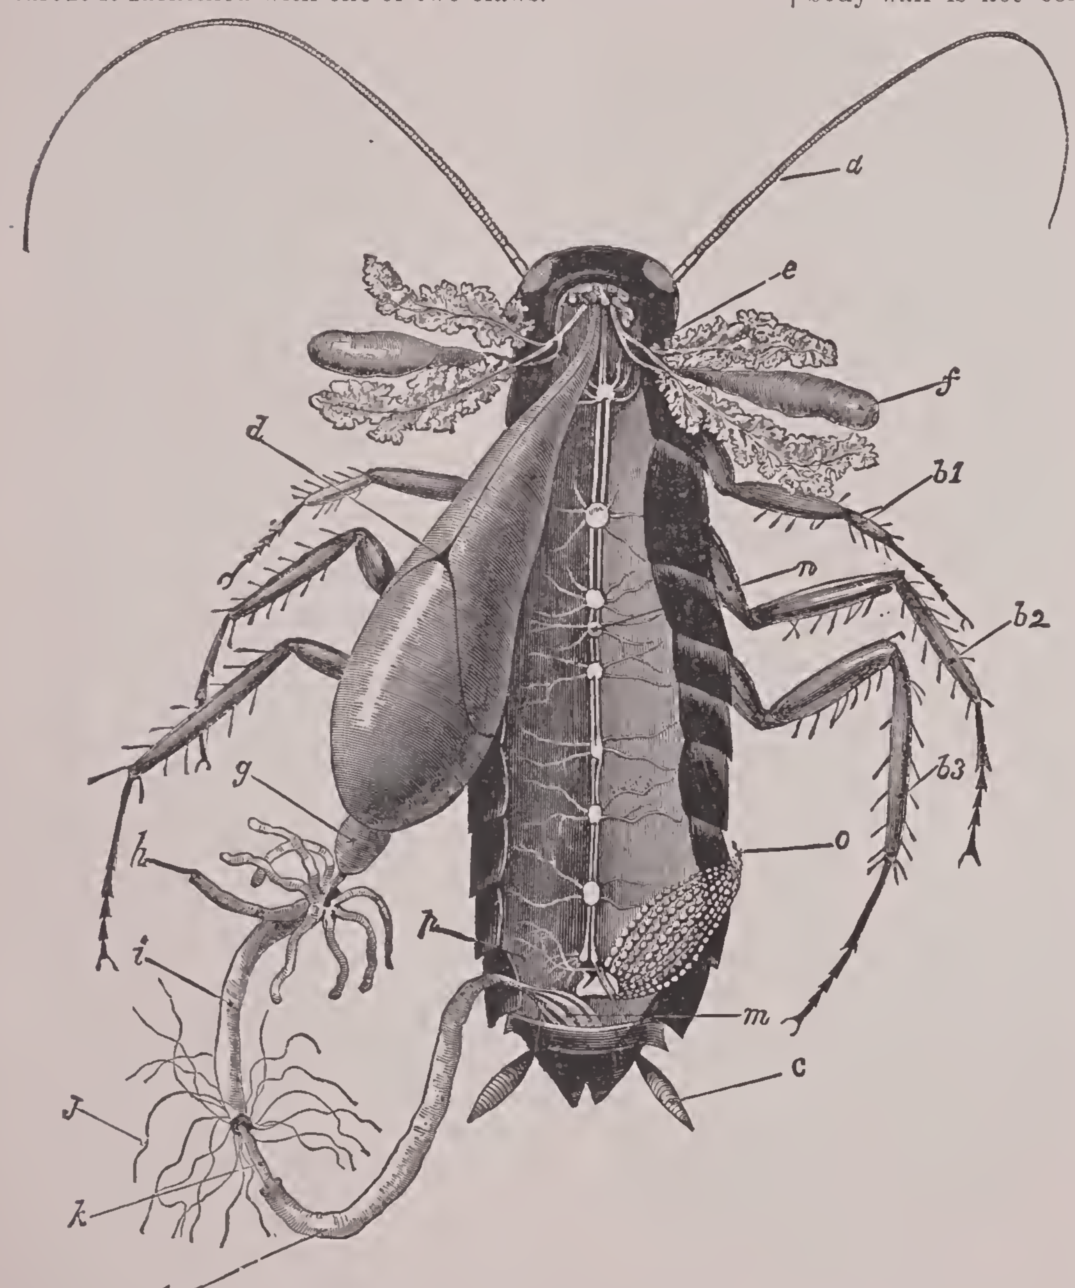

Fig. 7.—A cockroach (*Periplaneta orientalis*). (From Rolleston.)
a, antennæ; *b1*, *b2*, *b3*, tibiæ; *c*, anal cerci; *d*, ganglion on recurrent nerve upon the crop; *e*, salivary duct; *f*, salivary bladder; *g*, gizzard; *h*, hepatic cœca; *i*, chylific stomach; *j*, Malpighian vessels; *k*, small intestine; *l*, large intestine; *m*, rectum; *n*, first abdominal ganglion; *o*, ovary; *p*, sebaceous glands.

Although the normal number of wings is two pairs, many insects have only a single pair, and other insects are wingless. When but a single pair of wings is present it is almost invariably the first. Each wing is a plate-like or membranous expansion, which is at first developed as a sac-like projection of the body wall. The wing is usually strengthened by a firm network of thickened lines. These are termed the veins or nerves of the wing, and their arrangement, described as the venation or neuration of the wing, affords useful characters for determining the affinities of insects. Consequently, special names are given to the different veins and also to the cells, as the thin spaces circumscribed by the veins are termed.

Except in the first order of insects (*Thysanura*), the abdomen of the adult bears no locomotive appendages. But many larvæ have fleshy appendages which aid in locomotion; these are termed *prolegs*. In the adults the caudal end of the body is furnished with jointed filaments, the *cerci* and *caudal setæ* (Fig. 7, *c*). Frequently also the body is furnished in the males with organs for clasping, the *claspers*, and in the females with saws, pincers, or borers, the *ovipositor*. In the females of certain insects there is a sting, a modified ovipositor, which is used as an organ of defense, and the abdomen of plant-lice and certain other insects bears a pair of tubes or tubercles, through which honey-dew is excreted.

Internal Anatomy.—The outer wall of insects is more or less firm, being hardened by a horny substance termed *chitine*; this outer wall serves as a skeleton within which are the muscles and viscera. The *skeleton* is therefore in general outline a hollow cylinder. This hardening of the body wall is not continuous, but takes place in a series of more or less regular ring-like bands, that have the well known segmented appearance characteristic of insects and the animals closely allied to them. Between the horny ring-like segments the body wall remains soft and flexible. In this way provision is made for the various motions of the body. The movement of the legs, antennæ, and certain other appendages is provided for in the same way; each one is a cylinder made up of several segments, and between the segments the wall of the cylinder remains flexible. Although the skeleton of an insect is chiefly an external one, there are prolongations of it into the body cavity. As these form support for various organs, and attachment for many muscles, they are often described as the internal skeleton.

The *muscular system* of insects is composed of immense numbers of distinct isolated straight fibers, which are always free (i. e. not inclosed in tendinous sheaths as with Vertebrates). As a rule, the muscles that move the segments of the body are not furnished with tendons (Figs. 4 and 5), while those that move the appendages are thus united at the distal end (Fig. 6). In appearance the muscles are either colorless and transparent or yellowish white, and are of a soft, almost gelatinous consistence. There are several layers of muscles lining the body wall or external skeleton (Figs. 4 and 5). These provide for the movements of the body and its appendages, and constitute the chief part of the muscular system.

The *alimentary canal* is a tube passing from the mouth to the caudal end of the body; in its simplest form it is a straight tube occupying the axis of the cylindrical body. But usually it is longer than the body, and is consequently more or less convoluted; moreover, it is not of uniform structure, but, as in higher animals, different parts are adapted to different functions. The names applied to these parts are similar to those used in the anatomy of higher animals (Fig. 7).

The *circulatory system* of insects is an open one, the blood flowing in vessels during only a part of its course. The greater part of the circulation of this fluid takes place in the cavity of the body and its appendages. The only blood-vessel that exists in these animals lies just beneath the body wall above the alimentary canal (Fig. 4, 3). It extends from near the caudal end of the abdomen through the thorax into the head. That part of this vessel that lies in the abdomen is termed the heart, and consists of a series of chambers, corresponding to the segments of the body. The number of these chambers varies, but there are rarely more than eight. The chambers of the heart are separated by valves which permit the blood to flow only toward the head. There is in the wall of the heart a pair of lateral openings corresponding to each chamber; these also are furnished with valves which admit the blood to the heart, but prevent its exit. When, therefore, the chambers contract a stream of blood is forced toward the head, and when they expand the blood rushes into them through the lateral openings. The prolongation of the heart extends through the thorax and into the head near the brain, where it is usually somewhat branched. The branches are very short, and the blood passes from them directly into the body cavity. Here it bathes the viscera, receiving the products of digestion from the alimentary canal, giving up to the various glands their secretion, and carrying nourishment to all parts of the body. In its course through the body the blood flows in regular channels without walls, like the currents of the ocean.

The *blood* is usually colorless or slightly tinged with green, but its circulation is made conspicuous by the movements of the large corpuscles in which it abounds. In transparent insects it can be seen pouring forth from the cephalic end of the aorta, bathing first the brain and then passing to all parts of the body, even out into the appendages. By tracing the course of any one of these currents it will be found to flow sooner or later to the sinus in which the heart rests, and from which it receives its blood.

The central part of the *nervous system* (Fig. 5, 2; Fig. 7, *n*) consists of a ganglion in the head above the œsophagus, and a series of ganglia, typically one for each segment of the body, lying on the floor of the body cavity, and connected by two longitudinal cords. In the head one of these cords passes on each side of the œsophagus from the brain to another ganglion in the head below the œsophagus, thus forming a nervous collar about the alimentary canal. From each ganglion nerves arise, which supply the adjacent parts, and from the thoracic ganglia nerves extend to the legs and wings. This series of ganglia is really a double one; but each pair of ganglia is more or less closely united on the middle line of the body, and often appears as a single ganglion.

In connection with the nervous system reference should be made to the special senses of insects. Although, as has already been stated, comparatively little is known regarding the organs of special sense, it is probable that insects possess the five senses known to us, and perhaps they have others the nature of which we can not conceive. Even in the case of the five senses the range of perception may be very different from ours. Thus Lubbock has shown that ants perceive the ultra-violet rays which are invisible to us. There is, however, a great variation in the degree of development of different senses in different insects; for example, some are furnished with wonderful eyes, while others are blind. It is probable that in many cases the great development of one sense is correlated with a slight development of some other. As an illustration, we find that in the dragon-flies and cicadas, which are essentially directed by sight, the antennæ are rudimentary, and doubtless the same is true of the sense of smell. During the night these insects are passive, while during the day they trust to their powers of sight, or possibly also to hearing, as would seem to be the case with some of the cicadas. The best-known organs of special sense are the eyes; regarding the structure of these several very elaborate monographs have been written.

The most striking peculiarity in the structure of insects is presented by the *respiratory system.* If an insect be carefully examined there will be found along the sides of the body a series of openings. These can easily be seen in many caterpillars and other larvæ; they are the openings of the respiratory system, and are termed the *spiracles.* The number of spiracles varies greatly in different insects. There is, however, never more than one pair on a single segment of the body. They do not occur on the head (except in certain *Thysanura*), but are borne by each of the thoracic segments and by the first eight abdominal segments. Thus there are eleven segments that may bear spiracles, but one or more always lack them. The spiracles are either simple openings in the respiratory system, or are provided with valves, sieves, or fringes of hair for the exclusion of dirt. They lead into a system of air-tubes termed *tracheæ* (see 1 and 7 of Figs. 4 and 5). There is a short trunk arising from each spiracle; these are all connected together by a large longitudinal trunk on each side of the body, and by numerous transverse trunks. From these large tracheæ there arise a great number of smaller ones, which branch and subdivide, and extend to all parts of the body. The smaller branches of the tracheæ are exceedingly minute, and are intimately associated with the various tissues. By means of these fine tracheal trunks the air is carried to the various tissues, so that they are supplied with oxygen directly from the air without the intervention of blood as in higher animals. Although insects are, strictly speaking, air-breathing animals, many of them live in the water. Some of these have provision for carrying about with them a supply of air which they renew from time to time. Others are furnished with gill-like organs termed tracheal gills.

In insects the sexes are distinct. The *reproductive organs* vary greatly in form, but agree in general characteristics. They are contained in the abdomen, are paired, and usually open by a common duct near the caudal end of the body. One of the ovaries of a cockroach is represented at *o* in Fig. 7.

All insects are developed from eggs. But there are some apparent exceptions. Thus many flies retain their eggs until after they are hatched, if a proper place for laying them is not found earlier, and in some flies (the *Pupipara*) the young attain a considerable development before they are born. In the plant-lice (*Aphididæ*) there is a remarkable alternation of reproduction by budding with the sexual reproduction.

II. The Metamorphoses of Insects.—*Complete Metamorphosis.*—From the egg of the butterfly there emerges a worm-like creature, known as a *caterpillar*, which has upon superficial examination very little in common with its parents. This caterpillar eats and grows, and when fully grown changes to an oblong, apparently lifeless object, the *chrysalis.* After a time there bursts forth from this chrysalis a butterfly, like that which produced the egg. In a similar way from the egg laid by a fly upon a piece of meat there hatches, not a fly, but a footless, worm-like maggot. This when fully grown changes to a quiescent object corresponding to the chrysalis of a butterfly. Later from this object there escapes a winged fly like that which laid the egg. Those insects which, like the butterflies and flesh-flies, bear almost no resemblance in form to the adult insect when they emerge from the egg, are said to undergo a complete metamorphosis. In other words, the change of form undergone by the insect is a complete one.

Incomplete Metamorphosis.—There are, however, many insects which after leaving the egg do not undergo such a remarkable change of form as that indicated above. A young grasshopper just out of the egg can be easily recognized as a grasshopper. It is, of course, much smaller than the adult, and is not furnished with wings. Still the form of the body is essentially the same as that of the adult. After a time rudimentary wings appear, and these increase in size from time to time until the adult stage is reached. During this development there is no point at which the insect passes into a quiescent state corresponding to the chrysalis state of the butterfly. Those insects, like the grasshoppers, which when they emerge from the egg resemble the adult are said to undergo an incomplete metamorphosis. In other words, after leaving the egg they do not undergo a complete change of form.

Molting, Exuviæ.—The body wall of an insect is rendered more or less hard by the deposition within its cuticular layer of a horny substance known as chitine. The result of this hardening of the skin is to render it inelastic. Consequently, as the body of an insect increases in size its skin becomes too small for it. When this occurs a second soft skin is formed beneath the outer hard one. Then the outer skin splits open, usually along the back, and the insect works itself out from it. The new skin, being elastic, accommodates itself to the increased size of the body. In a short time this new skin becomes hardened, and as the insect grows it in turn is cast off. This shedding of the skin is termed *molting*, or *ecdysis.* The cast skins are sometimes referred to as the *exuviæ.* The number of molts varies greatly in different groups of insects. In Fig. 9 is shown the cast skin of a dragon-fly clinging to a reed.

The Egg.—The egg is the first of the four principal stages through which an insect passes in the course of its development. In a few instances the egg is retained within the body of the female until after it is hatched; in this case the insect is said to be *viviparous.* The eggs of insects vary greatly in their external characters. While many of them are furnished with smooth oval shells, in others the shells are beautifully ribbed or pitted (Fig. 10), or furnished with spines or other appendages. There exists also in one end of the egg of an insect one or more pores known as *micropyles*; through these the spermatozoa pass into the egg and thus fertilize it.

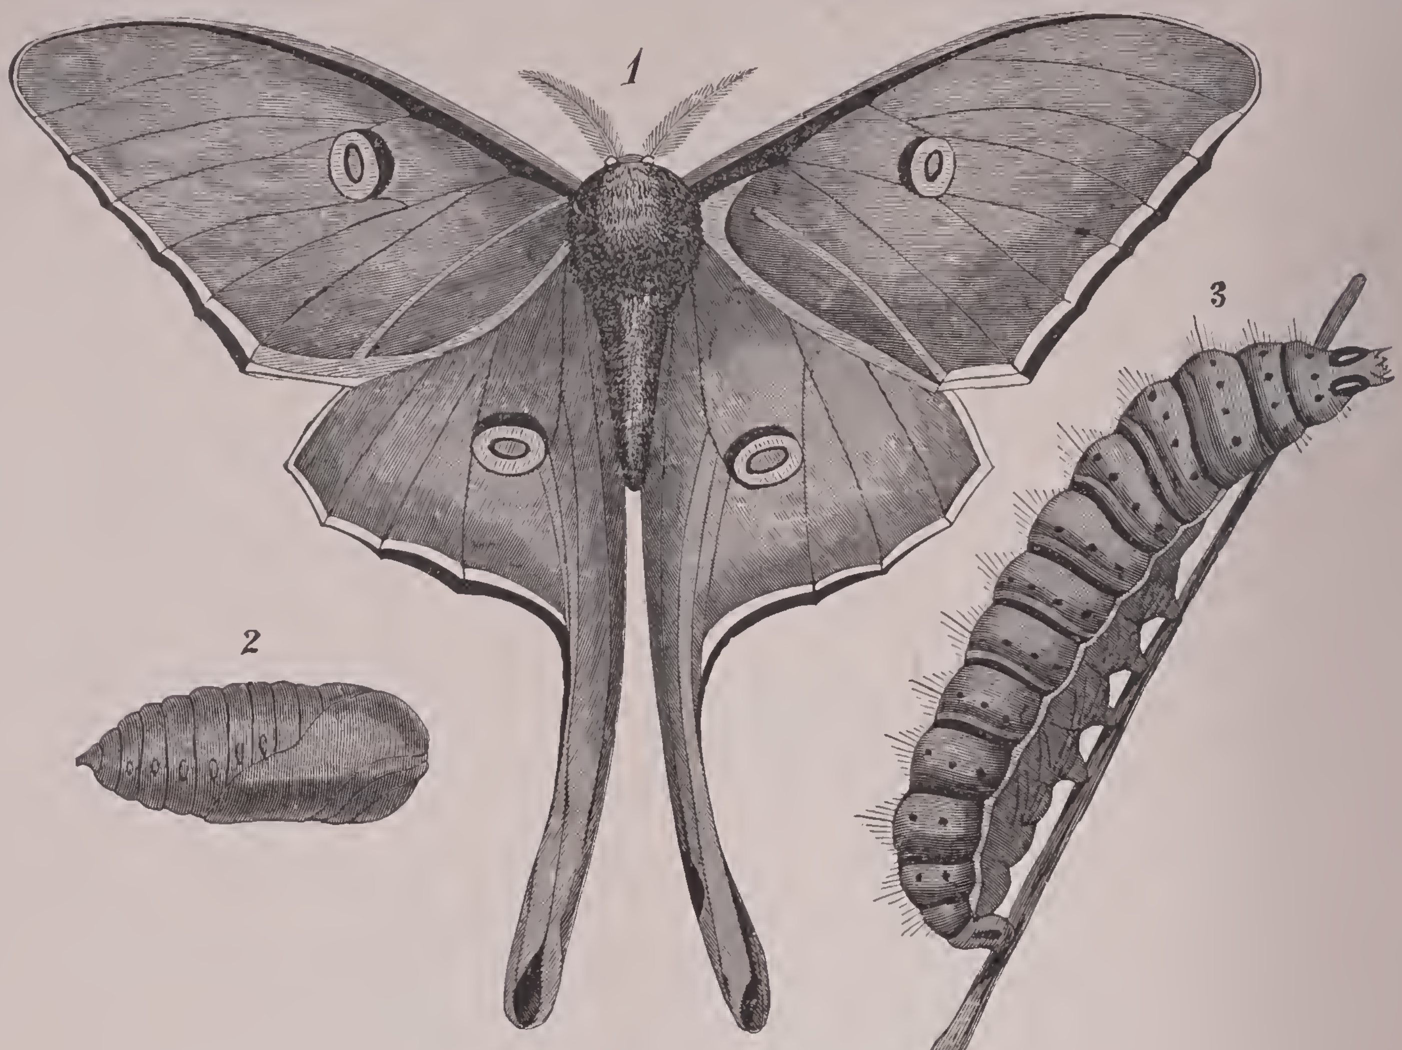

Fig. 8.–Luna moth, *Actias luna*: 1, Imago; 2, Pupa; 3, Larva.

The Larva.—The larva is the second of the four principal stages in the life of an insect. It is the stage in which the insect emerges from the egg. Familiar examples of larvæ are caterpillars, maggots, grubs, etc. (Fig. 8, 3). It is during the larval state that the growth of the insect is made, and consequently in this stage nearly all the molts are undergone. The molts subsequent to this period are simply those made when the insect changes from one stage to another.

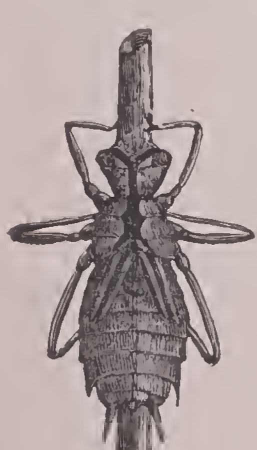

Fig. 9.—Exuviæ of a dragon-fly.

Nearly all of the creatures commonly known as worms are not true worms, but are the larvæ of insects. Away from the seashore but few worms are known to other than zoölogists; these are earth-worms, leeches, hair-worms, and the various species parasitic in the bodies of higher animals. The many worm-like animals found feeding upon the tissues of plants, as tomato-worms, apple-worms, etc., are the larvæ of insects. Other larvæ of insects are predaceous or parasitic.

The Pupa.—The pupa is the third of the four stages in the life of an insect. In this stage the insect is usually quiescent. But a few pupæ, as those of mosquitoes, are active. The change from the larval to the pupa state is made by molting the skin of the fully grown larva. In the pupa the legs and wings of the adult are represented in a rudimentary state. In the pupæ of butterflies and moths these organs are closely fastened to the breast of the insect (Fig. 8, 2), while in the pupæ of bees, wasps, and beetles they are free.

Chrysalis.—The term chrysalis is applied to the pupa of a butterfly. This name was suggested by the bright, metallic spots with which the pupæ of certain butterflies are marked. Two forms of this word are in use: chrysalis, plural chrysalides; and chrysalid, plural chrysalids.

The Cocoon.—Many larvæ, as those of moths when fully grown and before they change to pupæ, spin about the body a silken case within which the transformations are undergone. This case is termed a cocoon. Frequently these cocoons are made within a rolled leaf (Fig. 11), or on the surface of the ground, where they are covered with dry grass or other rubbish. Certain hairy caterpillars make their cocoons largely of their hair, which they fasten together by a thin film of silk.

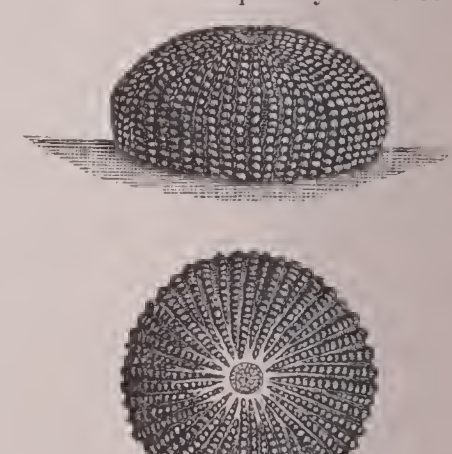

Fig. 10.—Egg of moth greatly enlarged.

Immature Forms of Insects with Incomplete Metamorphosis — The Nymph.—The terms larva and pupa are applicable only to the early stages of insects with a complete metamorphosis. In the case of those in which the transformation is an incomplete one the changes through which the immature insect passes after leaving the egg are so gradual that one can not indicate any point at which the insect ceases to be a larva and becomes a pupa. Recent writers have therefore used the term nymph (which was formerly used as a synonym of pupa) to designate the immature forms of insects with an incomplete metamorphosis. This term is applied to all the stages between the egg and the fully winged or adult state.

A nymph when it leaves the egg has no indications of wings. After undergoing a greater or less number of molts, differing in different species, small prolongations appear projecting from the dorsal aspect of the meso- and metathorax. These become larger and larger with each successive molt, assuming the form of pad-like wing-cases. But these wing-cases never approximate in length the perfect wings of insects in which these organs become fully developed. Consequently, there is usually a very marked change between the last nymph stage and the mature insect. This is illustrated by Figs. 12 and 13.

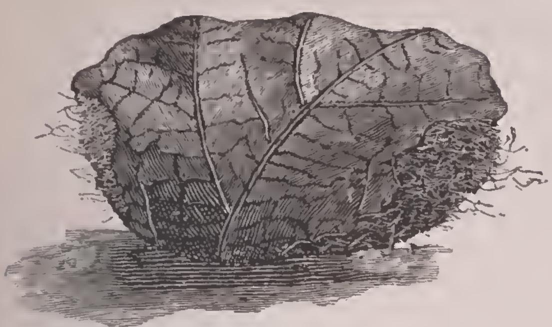

FIG. 11.—Cocoon made within a rolled leaf.

III. THE CLASSIFICATION OF INSECTS.—The term insect (from Lat. *in*, in + *sectus*, perf. ptc. of *seca're*, cut) refers to the fact that in the animals indicated by it the body is divided by transverse incisions into a series of segments. This insected form of the body is characteristic of the entire branch *Arthropoda* and of the worms as well, but the term insect has become restricted to a portion of this great series of animals. There is, however, a lack of uniformity in the use of the term among zoölogical writers. By some it is applied to all *Arthropoda* that breathe by means of a system of air-tubes (tracheæ) extending through the body. This includes centipedes, millipedes, spiders, and allied forms as well as six-footed insects. Other writers include among insects only those orders that are characterized by the possession of but six legs. It is in this restricted sense that the term insect has been used in this article; as thus restricted insects constitute the class *Hexapoda*.

FIG. 12.—Nymph of red-legged locust, last nymph stage.

Class *Hexapoda*.—This class includes those air-breathing *Arthropoda* in which the segments of the body are grouped into three regions—head, thorax, and abdomen. In the adult state the body is furnished with six legs and usually with wings. The class *Hexapoda* includes several orders, but entomologists are not agreed as to their number and limits. According to the classification that has been generally accepted till recently there are seven. But there are certain places in which this classification brings together insects which differ too widely to be classed in the same order; so that most of the leading entomologists advocate a considerable increase in the number of orders to be recognized. In the following list of the orders of the *Hexapoda* the names of the orders according to the old classification are given in the first column and the names of those adopted in this article in the second column.

FIG. 13.—Adult red-legged locust.

LIST OF ORDERS OF HEXAPODA.

NEUROPTERA.	1. Thysanura.
	2. Ephemerida.
	3. Odonata.
	4. Plecoptera.
	5. Isoptera.
	6. Corrodentia.
	7. Mallophaga.
	12. Neuroptera.
	13. Mecoptera.
	14. Trichoptera.
ORTHOPTERA.	8. Euplexoptera.
	9. Orthoptera.
HEMIPTERA.	10. Physopoda.
	11. Hemiptera.
LEPIDOPTERA.	15. Lepidoptera.
DIPTERA.	16. Diptera.
	17. Siphonaptera.
COLEOPTERA.	18. Coleoptera.
HYMENOPTERA.	19. Hymenoptera.

In the linear arrangement of the orders adopted in this article those orders are placed first which include insects having an incomplete metamorphosis, and second, those having a complete metamorphosis. By this arrangement three of the modern orders into which the Linnæan order *Neuroptera* (which was long the stumbling-block of all systems, inasmuch as its members combined the characters of most of the other orders) is divided are widely separated from the others, as indicated by the numbers in the second column in the table given above. Below is a brief tabular statement of the more important characters of the orders. This table will aid the reader in formulating the relation of the orders to each other, and will be of service in the classification of specimens.

TABULAR STATEMENT OF THE MORE IMPORTANT CHARACTERS OF THE ORDERS OF HEXAPODA.

A. Wingless insects which show no evidences of having descended from winged ancestors (i. e. in which the thorax is simple in structure), and which undergo no metamorphosis. 1. *Thysanura*.

AA. Winged insects, or wingless insects in which this condition is the result of a retrograde development, indicated by the complicated structure of the thorax, or by the presence of wings in closely allied forms.

B. Insects with an incomplete metamorphosis.

C. Mouth-parts formed for biting, i. e. with the mandibles and maxillæ in the form of jaws, or rudimentary.

D. The two pairs of wings similar in structure, membranous.

E. Not animal parasites.

F. Hind wings smaller than fore wings.

G. Wings with many veins and cross-veins. Mouth-parts rudimentary. 2. *Ephemerida*.

GG. Wings with comparatively few cross-veins. Mouth-parts formed for biting. 6. *Corrodentia*.

FF. Hind wings as large as or larger than fore wings.

G. Each wing with a joint-like structure, the *nodus*, near the middle of the front margin. 3. *Odonata*.

GG. Wings without nodus.

H. Hind wings much larger than the fore wings. Solitary insects. 4. *Plecoptera*.

HH. The two pairs of wings similar in form. Social insects. 5. *Isoptera*.

EE. Parasites of birds or mammals. 7. *Mallophaga*.

DD. The first pair of wings very short, leathery, without veins. Hind wings folded both longitudinally and transversely. Caudal end of abdomen with forcep-like appendages. 8. *Euplexoptera*.

DDD. The first pair of wings parchment-like; the second pair membranous and folded in plaits longitudinally. 9. *Orthoptera*.

CC. Mouth-parts intermediate in structure between those of the biting insects and those of the sucking insects; viz., with bristle-like mandibles and with flat, triangular maxillæ. 10. *Physopoda*.

CCC. Mouth-parts formed for sucking; viz., with the mandibles and maxillæ bristle-like. 11. *Hemiptera*.

BB. Insects with a complete metamorphosis.

C. Mouth-parts formed for biting; viz., both mandibles and maxillæ in the form of jaws, or rudimentary.

D. The two pairs of wings similar in structure, membranous, with many veins and cells.

E. Head prolonged into a beak. 13. *Mecoptera*.

EE. Head not prolonged into a beak.

F. Wings with numerous veins and with many cross-veins (except in a few rare forms, in which the wings are strengthened with a covering of whitish powder). 12. *Neuroptera*.

FF. Wings with numerous veins, but with only a few cross-veins. Wings more or less densely clothed with hairs. Insects moth-like. 14. *Trichoptera*.

DD. First pair of wings much thickened (horny) throughout their entire length, and meeting in a straight line down the back; the second pair membranous. 18. *Coleoptera*.

CC. Mouth-parts formed for both biting and sucking; viz., with the mandibles in the form of jaws, and with the maxillæ and labium fitted for taking liquid food. Both pairs of wings membranous, with few veins and cells. 19. *Hymenoptera*.

CCC. Mouth-parts formed for sucking.

D. With four wings clothed with minute imbricated scales; mandibles rudimentary; maxillæ developed into a sucking tube. 15. *Lepidoptera*.

DD. With only two wings; the hind wings represented by a pair of knobbed, thread-like organs; mandibles and maxillæ bristle-like. 16. *Diptera*.

DDD. Wingless parasites of animals (fleas). 17. *Siphonaptera*.

1. Order *Thysanura* (from Gr. ϑύσανος, fringe + οὐρά, tail).—The *Thysanura* includes the insects commonly known as bristle-tails, spring-tails, and fish-moths. These are wingless insects which undergo no metamorphosis, the larval form being retained by the adult. The mandibles and maxillæ are retracted within the cavity of the head, so that only their apices are visible; they have, however, some freedom of motion, and can be used for biting and chewing soft substances. True compound eyes are rarely present; but in some genera there is a group of agglomerated simple eyes on each side of the head. The abdomen is sometimes furnished with rudimentary legs, and in one genus there are well-developed abdominal legs.

Fig. 14.—*Lepisma saccharina*, a bristle-tail.

The absence of wings in this order is believed to represent the primitive condition of these insects. None of the species show any indication of the development of these organs, and the thorax does not present that complication of structure which is the result of the development of wing-muscles. In each of the higher orders we find wingless species; but in these cases there is good reason for believing that the wingless condition is the result of a retrograde development. In some cases this degradation is the result of parasitic habits, as with lice, fleas, and many other parasites; in other instances it is the result of the separation of the species into several castes, of which some do not require wings, as the workers and soldiers among Termes, the workers among ants, and the sedentary generations of the Aphides.

Fig. 15.—*Papirius fuscus*, a spring-tail.

This order comprises chiefly minute insects, which live on decaying vegetable matter, and can be found abundant in damp situations; some species, however, live in warm and dry places, and feed upon starched clothing and the binding of books and other dry substances. In the more common species the body is either elongated and furnished with six well-developed legs and two or more long, many-jointed caudal appendages (Fig. 14), or short, thick, and with a forked springing apparatus, bent under the abdomen, instead of the thread-like caudal appendages (Fig. 15).

The fish-moth, or silver-fish as it is sometimes called, *Lepisma saccharina* (Fig. 14), is a well-known pest in some parts of the U. S. It is silvery white, with a yellowish tinge about the abdomen and legs; it measures about one-third of an inch in length. It injures clothing, especially starched clothes, and the bindings of books. Sometimes it feeds upon the starch with which wall-paper is fastened in place.

2. Order *Ephemerida* (from Gr. ἐφήμερος, living but a day).—The order *Ephemerida* is composed of the insects commonly known as May-flies (Fig. 16). They have delicate, membranous wings furnished with a fine network of veins; the fore wings are large, and the hind wings are much smaller or wanting. The mouth-parts are rudimentary. The metamorphosis is complete. This order includes only a single family, the *Ephemeridæ*. The May-flies or Ephemerids are often very common insects in the vicinity of streams, ponds, and lakes; frequently the surface of such bodies of water is thickly strewn with them. They are attracted by light, and it is not an uncommon occurrence in summer-time to see hundreds of them flying about a street-lamp. The May-flies have received considerable attention in popular writings on account of their ephemeral existence in the adult state. All have read of the insects that live but a day. Reference is made in these accounts to members of this family; and although the popular idea is fallacious, it has some foundation in fact. Strictly speaking, the May-flies are long-lived insects; some species appear twice annually, once in the spring and again in the autumn; but, as a rule, one, two, or even three years are required for the development of a generation. The greater part of this time is passed, however, beneath the surface of the water, and after the insect emerges into the air and assumes the adult form its existence is very brief. With many species the individuals leave the water, undergo two transformations, mate, lay their eggs, and die in the course of an evening or within the early morning hours.

Fig. 16.—A May-fly.

With many species of May-flies there is great uniformity in the date of maturing of the individuals. Thus immense swarms of them will leave the water at about the same time, and in the course of a few days pass away, this being the only appearance of the species until another generation has been developed. The great swarms of "lake-flies" (*Ephemera simulans*) which appear along the lakes to the north of the U. S. about the third week in July afford good illustrations of this peculiarity.

3. Order *Odonata* (from Gr. ὀδούς, ὀδόντος, tooth).—The members of this order have four membranous wings, which are finely netted with veins; and each wing has near the middle of the front margin a joint-like structure, the nodus. The mouth-parts are furnished for biting. The metamorphosis is incomplete. The members of this order are commonly known as dragon-flies, darning-needles, spindles, and snake-doctors (Fig. 17). The eggs are laid in the water. In some species the female flies back and forth over the surface of the water, sweeping down at intervals to touch it with the tip of her abdomen, and thus wash off one or more eggs into it. In other cases the eggs are laid in a mass, attached to some aquatic plant. The nymphs of dragon-flies pass their lives in water. They are predaceous, feeding on such aquatic animals as they can overcome. When the nymph of a dragon-fly is fully grown it leaves the water to transform. The skin of the nymph splits open on the back of the thorax and head, and the adult emerges, leaving the empty skin of the nymph clinging to the object on which the transformation took place.

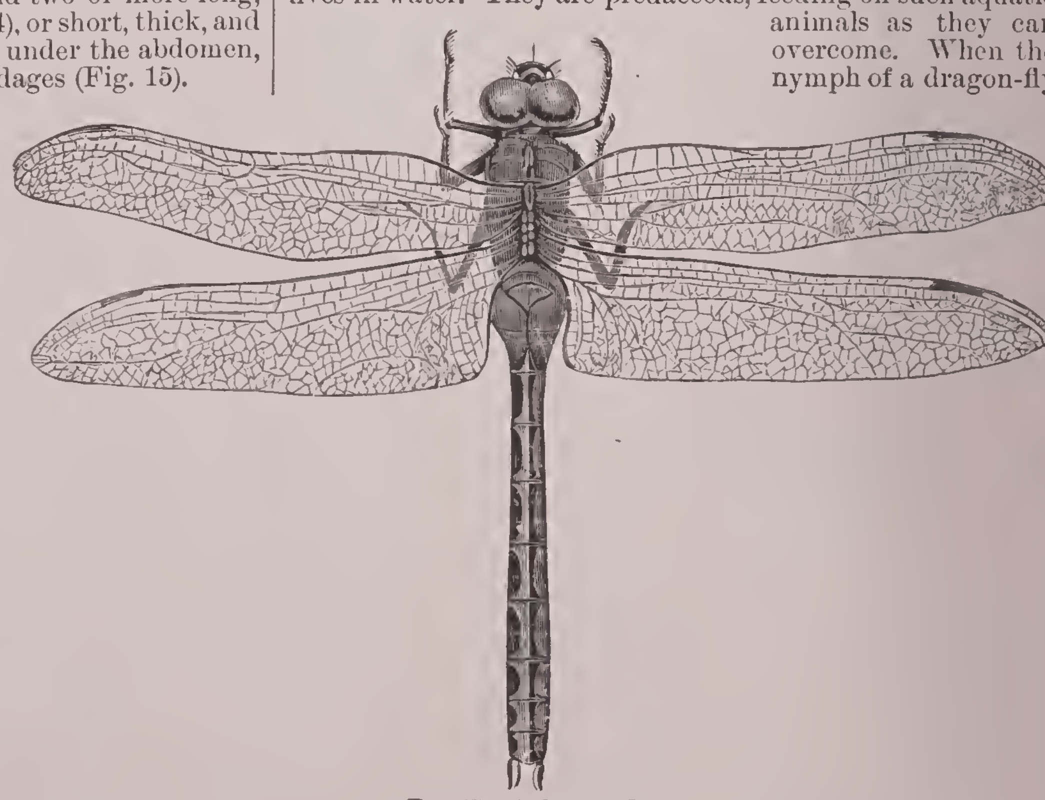

Fig. 17.—A dragon-fly.

Fig. 9 represents such a skin clinging to a water plant. The dragon-flies are predaceous in the adult as well as the nymph state, hence their vigorous flight and strong jaws render them formidable foes of less powerful insects. It is believed that they destroy many mosquitoes.

It is not strange that there should be popular superstitions regarding insects so conspicuous as these. It is a common belief among children that they have the power of sewing up the ears of people, hence the name darning-needle; while the Negroes in the Southern U. S. believe that dragon-flies hover over dead snakes, bringing them to life, and consequently call them snake-doctors.

4. Order *Plecoptera* (from Gr. πλέκειν, plait + πτερόν, wing).—The members of this order have four membranous wings, with comparatively few or with many cross-veins; the hind wings are much larger than the fore wings, and are folded in plaits and lie upon the abdomen when at rest. The mouth-parts are of the biting type of structure, but are often poorly developed. The metamorphosis is incomplete. This order includes a single family, the *Perlidæ*, or stone-flies (Fig. 18), including comparatively few species; but members of it are common about any of the creeks in the U. S. These insects are called stone-flies because the immature forms are very abundant under stones in the bed of streams. The adults are found flying about or resting upon herbage in the vicinity of water.

Fig. 18.—*Pteronarcys regalis*, a stone-fly.

It is easy to obtain the nymphs of these insects; by lifting stones from the water of swiftly flowing streams the young stone-flies may be found closely adhering to their lower surface. They present a wonderfully flattened appearance (Fig. 19); the body is depressed and closely applied to the stone; while the legs, antennæ, and caudal setæ radiate from it on the surface of the stone. In the common forms there is a tuft of hair-like tracheal gills just behind the base of each leg, and the more mature individuals present conspicuous wing-pads. The nymphs of stone-flies constitute an important element in the food of fishes, and probably are found more often than any other insect in the stomachs of brook trout. When about to transform to the adult state, the insect crawls from the water upon a stone or some other object. Their exuviæ are common in these situations.

Fig. 19.—Nymph of a stone-fly, *Acroneura*.

5. Order *Isoptera* (from Gr. ἴσος, equal + πτερόν, wing).—This order comprises the Termites, or white ants, social insects in which each species consists of several distinct castes, of which only the "kings" and the "queens" are winged. These have four long narrow wings which are somewhat leathery in structure, and which are furnished with numerous but more or less indistinct veins. The two pairs of wings are similar in form and structure, and are laid flat upon the back when not in use. The mouth-parts are formed for biting. The metamorphosis is incomplete. The order includes only a single family, the *Termitidæ*.

These insects can be easily recognized by the pale color of the greater number of individuals of which a colony is composed, by the fact of their living in large ant-like colonies, and by the form of the abdomen, which is broadly joined to the thorax instead of being pedunculate as in the ants.

The Termites are commonly called white ants on account of their color and of a resemblance in form and habits to true ants. These resemblances, however, are only very general. In structure the Termites and ants are widely separated, as the former are among the lowest of winged insects, while the latter stand near the head of the series. In habits there is little more in common than that both are social, and the fact that in each the function of reproduction is restricted to a few individuals; while the greater number differ in form from the sexually mature males and females, and are especially adapted to the performance of the labors of the community. There are always at least three distinct castes, each represented by both sexes—the workers, the soldiers, and the sexual forms. Sometimes when the true sexual forms are lacking, a fourth caste, the complemental males and females, are developed as a substitute. The true sexual forms alone are winged. As each of the four castes is represented by both sexes, a single species of Termites may be represented by eight forms of individuals.

Fig. 20.—*Termes flavipes*, worker.

The form of the *worker* is represented by Fig. 20. The members of this caste may be looked upon as individuals whose physical, and especially sexual, development has been checked while yet nymphæ and never carried further. But the development of their instinctive powers is truly remarkable; for it is this caste that builds the nests, collects the provisions, and cares for the young. Associated with the workers, and resembling them in color and in being wingless, there occur numerous representatives of another caste, which can be recognized by the enormous size of their heads (Fig. 21). These are the *soldiers*, upon whom devolves the protection of the colony. They are well adapted for this work, their powerfully developed mandibles rendering them formidable. In some species the male and female soldiers differ externally, so that they can be distinguished without dissection. But here, as with the workers, the reproductive organs are rudimentary.

Fig. 21.—*Termes flavipes*, soldier.

The sexually perfect *males* and *females* are developed in large numbers at a certain season of the year, late spring or early summer for the species common in the U. S. In May or June these winged males and females leave the nest in a body. Sometimes clouds of them appear. After flying a greater or less distance they alight on the ground and then shed their wings. At this time the males seek the females, seizing them with their mandibles; but it is believed that pairing does not take place till a later period. The greater number of individuals composing one of these swarms soon perish. But in a few cases a couple is taken in charge by some workers, and thus is founded a new colony. There is usually at the head of the colony only a single pair of sexual individuals. These have been termed the king and queen. A cell is provided by the worker Termites for them, shaped like an inverted watch-glass, and is furnished at first with a single small opening; later there are several. Within this cell the royal pair remain prisoners, but they are carefully attended by numerous workers. As the eggs develop in the body of the female her abdomen becomes greatly extended. Fig. 22 represents such a queen, natural size. The dark spots along the middle of the dorsal wall of the abdomen are the chitinized parts of that region; the lighter portions are made up of the very much stretched membrane uniting the segments; along each side of the abdomen the spiracles are visible. The specimen figured is a comparatively small one; in some species the queen becomes 6 or 8 inches in length.

Fig. 22.—Queen white-ant, *Termes gilvus*.

In addition to the winged males and females just described, there are sometimes developed wingless sexual individuals which never leave the nest. These are termed *complemental males* and *females*, and they serve as substitutes for the winged males and females whenever a community does not find a true king or queen. The complemental females produce comparatively few eggs, and consequently never become as large as do the true queens. It requires several of these to replace a queen. Fritz Müller found in one case a king living in company with thirty-one complemental females. As these wingless males and females never leave the nest, they pair with their near relatives. The development of winged sexual forms is therefore necessary in order to provide for intercrossing of individuals not closely related. Doubtless here, as with the true ants, the winged males and females emerge from many nests at the same time and mingle in a single swarm; in this way there is opportunity for intercrossing.

There is space here for but little regarding the habits of these wonderful insects. In the tropics certain species build nests of great size. Some of these are mounds 10 or 12 feet in height. Other species build large globular masses upon the trunks or branches of trees. All of the Termites are miners, and all avoid the light. They therefore build covered ways from their nests to such places as they wish to visit. In some hot countries they are the worst of all pests. They will feed upon almost any organic matter; they destroy wooden structures of all kinds, including buildings and furniture. Libraries are often completely ruined by them. In infesting anything composed of wood they usually eat out the interior, leaving a thin film on the outside. Thus a table may appear to be sound, but will crumble to pieces beneath a slight weight, entrance having been made through the floor of the house and the legs of the table.

The mounds of Termites are composed chiefly of the excreted undigested wood upon which the insects have fed. This is molded into the desired form, and on drying it becomes solid. The species that occur in the U. S. do not build mounds, but make their nest in the ground and in logs, stumps, and other wood.

6. Order *Corrodentia* (from Lat. *corrodere*, gnaw).—The winged members of this order have four membranous wings, with the veins prominent and with comparatively few cross-veins; the fore wings are larger than the hind wings, and both pairs when not in use are placed roof-like over the body, being almost vertical and not folded in plates. The mouth-parts are formed for biting. The metamorphosis is incomplete. The best-known representatives of this order are the minute insects found in old books—the book-lice. These wingless creatures form, however, but a small part of the order. The more typical forms (Fig. 23) bear a strong resemblance to plant-lice (*Aphides*), and occur upon the leaves and trunks of trees and on stone walls and palings. They feed upon lichens and probably upon other dry vegetable matter, and are frequently gregarious, occurring in communities of 100 or more closely huddled together.

Fig. 23.—*Psocus venosus.*

7. Order *Mallophaga* (from Gr. μαλλός, lock of wool + φαγεῖν, eat).—The members of this order are wingless parasitic insects, with biting mouth-parts. Their metamorphosis is incomplete. Although some species infest sheep and goats, feeding upon their wool, by far the greater number live among the feathers of birds; consequently, the name bird-lice is applied to the entire order. Fig. 24 represents a species which infests the horse. The bird-lice resemble the true lice in form, being wingless, and with the body more or less flattened, but differ in having biting mouth-parts. Certain species which infest domestic fowls are well-known examples. They feed upon feathers, hair, and dermal scales, while the true lice (family *Pediculidæ*, order *Hemiptera*) have sucking mouth-parts, feed upon blood, and infest only mammals. *Menopon pallidum* is one of the species which infest the hen. It is to free themselves from this and allied parasites that hens wallow in dust and scatter it among their feathers.

Fig. 24.—*Trichodectes æqui*, a bird-louse.

8. Order *Euplexoptera* (from Gr. εὖ, well + πλέκειν, fold + πτερόν, wing).—This order includes only the earwigs (family *Forficulidæ*). With these insects the first pair of wings are leathery, very small, without veins, and when at rest meet in a straight line down the back, partially covering the second pair of wings (Fig. 25). These wing-covers strongly resemble those of the rove-beetles. The second pair of wings (Fig. 26) are furnished with radiating veins which extend from a point near the end of the basal third of the wing over the distal part of this organ. When the wing is not in use this part is folded in plaits like a fan, and the wing is folded twice transversely. The most striking character of this family is the form of the cerci, which are horny, and resemble forceps.

Fig. 25.—An earwig.

The earwigs are rare in the U. S., especially in the North. But in Europe they are common, and are often troublesome pests. They are nocturnal, hiding in the daytime among leaves and in all kinds of crevices, and coming out by night. They feed upon the corollas or flowers, fruit, and other vegetable substances. When troublesome they may be trapped with hollow objects, into which they can crawl and hide during the daytime. The name of the typical genus, *Forficula*, is the Latin word for scissors. It was suggested by the curious form of the cerci. The common name, earwig, has reference to a widely spread fancy that these insects creep into the ears of sleeping persons.

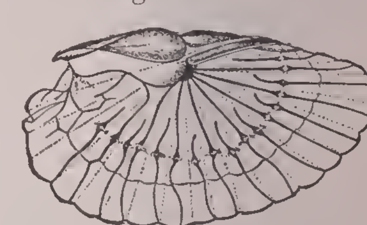

Fig. 26.—Wing of an earwig.

9. Order *Orthoptera* (from Gr. ὀρθός, straight + πτερόν, wing).—The members of this order have four wings; the first pair are thickened, and overlap when at rest; the second pair are thinner, and are folded in plaits like a fan. The mouth-parts are formed for biting. The metamorphosis is incomplete. This order includes the cockroaches, locusts or grasshoppers, katydids, crickets, walking-sticks, and soothsayers or praying mantes. The most familiar examples are the locusts, commonly called grasshoppers in the U. S. (Fig. 27). They abound everywhere, and occasionally

Fig. 27.—The crested locust.

multiply to such an extent as to cause serious injury to vegetation. Scarcely less abundant are the crickets. Their chirping is a sexual call produced by the males by rubbing together the wing-covers, as the first pair of wings are termed in these insects. Upon each of the wing-covers there is a strong cross-vein furnished with ridges like a file, and on the inner edge of the wing-cover there is a hardened portion, the scraper. In chirping the cricket elevates its wing-covers, and rubs the file of one against the scraper of the other. In this way the wing-cover is thrown into rapid vibration and the chirp is produced. The cry of the katydid is produced in a similar manner.

The *Orthoptera* as a whole are injurious to vegetation; but the soothsayers or praying mantes are predaceous.

10. Order *Physopoda* (from Gr. φυσᾶν, blow up + πούς, ποδός, foot).—This order includes the insects commonly known as thrips (Fig. 28). These are insects of minute size, rarely exceeding one-eighth of an inch in length, and usually much smaller. They abound in various flowers, especially those of the daisy and clover. Ordinarily it is only necessary to pull apart one of these flowers to find several of these insects. Their most striking character and the one which suggested the name of the order is the form of the tarsi. These are bladder-like at the tip, and without claws. The two pairs of wings are similar in form. Each wing is long, narrow, membranous, not folded, with but few or no veins, rarely with cross-veins, fringed with long hairs, and laid horizontally along the back when at rest. The mouth-parts are probably used chiefly for sucking; they are intermediate in form between those of the sucking and those of the biting insects. The metamorphosis is incomplete.

Fig. 28.—A thrips, greatly enlarged.

11. Order *Hemiptera* (from Gr. ἡμι, half + πτερόν, wing).—The winged members of this order have four wings; in one suborder the first pair of wings are thickened at the base, with thinner extremities which overlap on the back; in another sub-order the first pair of wings are of the same thickness throughout, and usually slope at the side of the body. The mouth-parts are formed for sucking. The metamorphosis is incomplete.

This order includes three well-marked groups, which are ranked as sub-orders. The first of these, the *Heteroptera*, includes the true bugs. In this sub-order the first pair of wings are thickened at the base, while the tips, which overlap each other on the back of the insect, are thin and transparent. The most familiar examples are the well-known stink-bugs (Fig. 29). Here belong also the squash-bug, the chinch-bug, and many other well-known pests of the agriculturists. The second sub-order, the *Parasita*, includes certain parasites of man and other mammals, commonly known as lice. They are wingless, and differ from other *Hemiptera* in having the beak fleshy and not jointed. Fig. 30 represents a common species, *Hæmatopinus eurysternus*, which infests the cow. Three species infest man: the head-louse, *Pediculus capitis*; the body-louse, *Pediculus vestimenti*: and the crab-louse, *Phthirius pubis*. It will be remembered that the true lice differ from the bird-lice, order *Mallophaga*, in having sucking mouth-parts. The true lice live on the skin of mammals and suck their blood. The third sub-order, the *Homoptera*, includes insects of widely diversified forms, which agree, however, in having the wings when present of the same thickness throughout, and usually sloping roof-like at the sides of the body when at rest. This sub-order includes the cicadas, the aphids, the scale-bugs, and many other common forms. The largest representatives that are natives of the U. S. are the cicadas (Fig. 31). These are well known on account of the shrill cry of the male; and one species, the periodical cicada (improperly termed the seventeen-year locust), attracts much attention on account of the great numbers in which it appears. Among the more important enemies of fruit-trees are the aphids and the scale-bugs.

Fig. 29.—A bug.

Fig. 30.—Louse of cow.

Fig. 31.—*Cicada tibicen.*

12. Order *Neuroptera* (from Gr. νεῦρον, nerve + πτερόν, wing). — The members of this order have four wings; these are membranous and furnished with many veins, and usually with many cross-veins. The head is not prolonged into a beak. The mouth-parts are formed for biting. The metamorphosis is complete. The order *Neuroptera* as now restricted is represented in the U. S. by only two families. To one of these the well-known Hellgrammite-fly, *Corydalis cornuta* (Fig. 32), belongs; the other includes the aphis-lions and the ant-lions.

Fig. 32.—*Corydalis cornuta.*

13. Order *Mecoptera* (from Gr. μῆκος, length + πτερόν, wing). — The members of this order have four wings; these are membranous and furnished with numerous veins. The head is prolonged into a beak, at the end of which biting mouth-parts are situated. The metamorphosis is complete. The most common members of this order are the scorpion-flies, *Panorpa* (Fig. 33), so called on account of the peculiar form of the caudal part of the abdomen of the male, which at first sight suggests the corresponding part of a scorpion.

14. Order *Trichoptera* (from Gr. θρίξ, τριχός, a hair + πτερόν, wing).—This order includes the caddice-flies, which are moth-like insects in appearance. They have four wings, which are membranous, furnished with numerous veins, but with only few cross-veins, and more or less densely clothed with hair. These insects are most likely to attract attention in the larval stage, owing to the curious habit the larvæ have of building tube-like cases in which they live. Fig. 34 represents a common species in its case. These larvæ live in water, and the various species make cases of different forms.

Fig. 33.—*Panorpa.*

15. Order *Lepidoptera* (from Gr. λεπίς, -ίδος, a scale + πτερόν, wing).—This order includes the moths and the butterflies. These insects have four membranous wings which are covered with overlapping scales. The mouth-parts are formed for sucking. The metamorphosis is complete. Moths and butterflies are readily distinguished by their well-known form and by the clothing of scales with which the body and wings are covered. These scales are modified hairs, and every gradation in form from that of a hair to a short broad scale can be found on a single insect. In the more primitive moths the scales are scattered irregularly over the wings; but in the more specialized forms the scales are arranged with great regularity in overlapping rows. The larvæ of the *Lepidoptera* are caterpillars, and as a rule are injurious to vegetation. Among the more important species are the codlin-moth (found in apples), the peach-tree

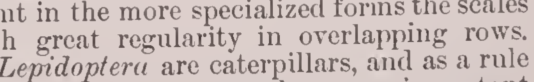

Fig. 34.—Caddice-worm and case.

borer, the army-worm, the cabbage-worm, the cotton-worm, and the boll-worm. A few caterpillars feed upon scale-bugs, and must therefore be classed among beneficial insects. But the most important member of this order is the silk-worm (Fig. 35). The luna-moth (Fig. 8) is one of the most striking in appearance of the moths native in the U. S.

FIG. 35.—The silkworm in all its stages.

16. Order *Diptera* (from Gr. δι, δίς, twice + πτερόν, wing).—This order includes the flies, which differ from other insects in possessing only a single pair of wings. The second pair of wings is represented by a pair of knobbed threads, termed *halteres*. The mouth-parts are formed for sucking. The metamorphosis is complete. The larvæ of flies are maggots; they are usually cylindrical in form, and are footless. Most species transform within the dried skin of the larvæ; a few have naked pupæ, and some make a cocoon. The different species vary much in habits. Some are very annoying to man: as the mosquito which attacks his person; the flesh-flies which infest his food; the bot-flies and gad-flies which torment his cattle; and the gall-gnats which destroy his crops. Other species are very beneficial, as the various species that are parasitic upon other insects, as well as many other species which feed upon decaying animal and vegetable matter, thus acting as scavengers. Fig. 36 represents a species which is parasitic upon the army-worm. In the lower part of the figure is represented the fore part of an army-worm bearing eggs of the fly; the larva is shown on the left, the pupa on the right, and the adult in the middle.

FIG. 36.—*Nemoræa leucaniæ*, a dipterous parasite of the army-worm.

17. Order *Siphonaptera* (from Gr. σίφων, tube + ἄπτερος, wingless).—This order includes the fleas, and the famous jigger of tropical America. In these insects the three segments of the thorax are distinct and nearly equal. The mesothorax and metathorax bear short leaf-like appendages in the place of wings. The mouth-parts are formed for sucking. The metamorphosis is complete. The larvæ are worm-like in form, being long and slender. They can be found in the sleeping-places of cats and other animals. When full grown they spin a silken cocoon within which the pupa state is passed. The body of the adult is much compressed, admitting of free movement among the hairs of the host, and the legs are fitted for leaping.

18. Order *Coleoptera* (from Gr. κολεός, sheath + πτερόν, wing).—The members of this order have four wings, the first pair of which are termed *elytra*, and are much thickened, meeting in a straight line down the back; the second pair are membranous, and when not in use are folded beneath the elytra. The mouth-parts are formed for biting. The metamorphosis is complete. This order includes only the beetles, which can be distinguished from all other insects, except the earwigs, by the peculiar form of the fore wings or elytra; they differ from the earwigs in lacking the caudal forceps characteristic of those insects. The larvæ of beetles are commonly called grubs. They are usually furnished with six thoracic legs, and often with a single proleg at the caudal end of the body. The pupæ have the partially developed legs and wings folded upon the breast, but in distinct sheaths. These insects usually transform in rude cocoons made of earth or bits of wood fastened together by a viscid substance excreted by the larva. Both beetles and their larvæ vary greatly in habits. Many species are predaceous, and are thus beneficial to man by destroying insect pests; but others feed upon vegetable matter, and are thus noxious. Among the important pests are many species of borers infesting trees. Other species feed upon the foliage of plants, as the Colorado beetle. Fig. 37 will serve to illustrate the form of the members of this order.

19. Order *Hymenoptera* (from Gr. ὑμήν, membrane + πτερόν, wing).—The members of this order have four wings; these are membranous, and furnished with comparatively few or with no transverse veins. The second pair of wings is smaller than the first. The mouth-parts are formed both for sucking and biting. The abdomen of the female is usually furnished with a sting, piercer, or saw. The metamorphosis is complete. The members of this order are well known to every observer. They are among the first of insects to attract attention, abounding wherever flowers bloom; and the habits of certain forms, as the ants, bees, and wasps, have excited wonder and admiration from the earliest time. Fig. 1 represents a member of this order.

The larvæ of *Hymenoptera* are usually footless, maggot-like creatures, incapable of any extended motion, and entirely dependent on the provision made for them by the adult insects. But in the two lower families, the saw-flies and the horn-tails, the larvæ are furnished with legs, and frequently have a striking resemblance to caterpillars both in form and habits. As a rule, the larvæ of saw-flies (*Tenthredinidæ*) feed upon the foliage of plants, and the larvæ of the horn-tails (*Siricidæ*) bore in the more solid parts. The gall-flies (*Cynipidæ*) also feed upon vegetable matter; but their method of attack is peculiar. The gall-fly lays her egg within the tissue of the plant; when the egg hatches the young larva begins to feed upon the plant, and immediately there takes place an abnormal growth of the plant about the larva. The larva is thus inclosed in what is known as a gall. Galls are familiar objects, especially upon oaks.

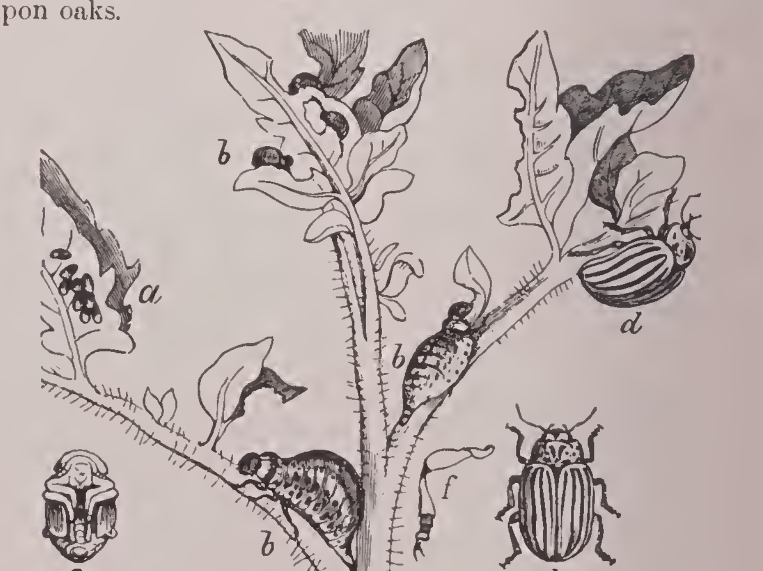

FIG. 37.—Colorado potato-beetle: *a*, eggs; *b*, *b*, *b*, larvæ; *c*, pupa; *d*, *d*, beetle from side and back. Colors, *a*, orange; *b*, Venetian red; *c*, pale orange; *d*, black and yellow.

Several families of this order are parasites. The eggs are laid either in or upon the bodies of other insects; and the larvæ obtain their growth within the body of the host. These parasitic *Hymenoptera* play an important part in preventing the undue increase of insects injurious to vegetation.

In the higher families of the order is found the most remarkable development of instinctive powers known. Many volumes have been written on the habits of the bees, wasps, ants, and digger-wasps. Among the bees, wasps, and ants, we find social insects. Here each species consists of three castes—males, females, and workers. The workers are females in which the reproductive organs are usually imperfectly developed, although occasionally they are fertile.

Bibliography.—The literature of entomology is very extensive. Insects are discussed not only in the books and journals treating of general zoölogy, but there is also an immense number of special entomological works. As an illustration it can be stated that there are being published regularly at least thirty important journals devoted exclusively to this subject, and this number does not include the minor journals and those merely of local interest. The more important are the following: *The Transactions of the American Entomological Society* (Philadelphia); *Insect Life* (Washington); *Entomological News* (Philadelphia); *Psyche* (Cambridge, Mass.); *Canadian Entomologist* (London, Ontario); *Transactions of the Entomological Society of London* (London, England); *The Entomologist* (London); *Entomologists' Monthly Magazine* (London); *Annales de la Société Entomologique* (Paris); *Bulletin d'Insectologie Agricole* (Paris); *Berliner Entomologische Zeitschrift* (Berlin); *Deutsche Entomologische Zeitschrift* (Berlin); *Wiener Entomologische Zeitung* (Vienna); *Entomologische Zeitung* (Stettin); *Mittheilungen der Entomologischen Gesellschaft* (Schaffhausen); *Tijdschrift voor Entomologie* (The Hague); *Entomologisk Tidskrift* (Stockholm).

The following are important works of reference: Hagen, *Bibliotheca Entomologica*, which gives the titles of all works on entomology published before 1862; Taschenberg, *Bibliotheca Zoölogica II.*, which includes a catalogue of zoölogical papers published in periodicals during the years 1861–80; *Bericht über die wissenschaftlichen Leistungen im Gebiete der Entomologie*, an annual record of the progress of entomology, now forming one part of the *Deutsche Entomologische Zeitschrift*. The entomological portions of the *Zoölogical Record* and of the *Zoölogischer Jahresbericht* should also be consulted. *Bulletin No. 19* of the division of entomology of the U. S. Department of Agriculture consists of a classified list of the published synopses, catalogues, and lists of North American insects.

The principal general text-books treating of American insects are those of Packard and Comstock. *Insects Injurious to Vegetation*, by Harris, has done more than any other American book to stimulate a love for entomology, and although it is limited in its scope, as indicated by its title, it should be one of the first books in any entomological library. *Introduction to Entomology*, by Kirby and Spence, is the best popular work on the habits of insects. This is also a very old book and is out of print, but it can be found in almost any public library. John Henry Comstock.

Entomoph'aga [from Gr. ἔντομα (sc. ζῷα), insects + φαγεῖν, eat]: a term applied by different zoölogists to groups of very diverse insect-eating animals. The name was given by Owen in 1839 to a division of *Marsupialia* containing the bandicoots and opossums, by Huxley to a group of the *Edentata*, comprising the ant-eaters, pangolins, and aardvarks, and by Woodward to a division of *Hymenoptera*, including insectivorous or parasitic forms such as the ichneumons, *Chalcididæ*, and others. It is also used for the small insectivorous bats or *Microcheiroptera*, as distinguished from the large fruit-eating bats, the *Megacheiroptera* or *Frugivora*. F. A. Lucas.

Entomos'traca [from Gr. ἔντομος, cut in pieces + ὄστρακον, shell]: the lowest sub-class of Crustacea. The body consists of a variable number of segments, those of the hinder portion being frequently without appendages. There is always, at least in the young, a single median eye, and frequently paired eyes are present. Frequently there is developed a dorsal shield which may become folded into a bivalve shell. The number of appendages varies from eight to over sixty pairs. All pass through a metamorphosis, a nauplius larva (see Crustacea) escaping from the egg, and this usually transforms into a cyclops-like or a cypris-like form. Most of the species are small, and many become extremely modified by parasitism. (See Degeneration.) All are aquatic, and as they are enormously abundant they form a very important element in the food of fishes. They are divided into five orders, Phyllopoda, Cladocera, Ostracoda, Copepoda, and Cirripedia (*qq. v.*). J. S. Kingsley.

Entozo'a [from Gr. ἐντός, within + ζῷον, animal]: a name formerly used for various parasitic animals usually grouped together as worms, but which have no other bond of union than the fact that they live within the bodies of other animals. The important ones belong to the Vermes (true worms), the lowest form of articulate animals. They are divided into (1) cestoid worms, or tapeworms, which are all more or less jointed, of a ribbon-like form, each joint of hermaphrodite conformation, and dwelling in the intestines. The embryonic worms penetrate the tissues, become surrounded by a cyst, and are known as "cystic" worms. They have no alimentary canal. (2) The flukes or trematode worms, of flat, oval form, smooth, soft, and not jointed. They have an hermaphrodite development, the sexual organs pervading a great part of the body of the adult. They afford many wonderful examples of the so-called alternate generation and of parthenogenesis in some of the generations. The disease called rot in sheep is caused by their presence in the biliary passages. In man they cause the hæmaturia prevailing at the Cape of Good Hope and an endemic diarrhœa of Egypt. They inhabit the liver, kidneys, lungs, etc. Among the genera are *Distoma*, *Bilharzia*, and many others. When perfect they have an alimentary canal without vent. (3) The nematodes or round worms, having long, cylindroid forms, and in the more perfect forms an intestinal canal with mouth and vent, and distinct sexes. This class includes pinworms, *Ascarides*, the *Trichina*, the Guinea worm, and many others. Besides the Vermes there are innumerable lower forms infesting the alimentary tract. Of these, the *Amœba coli*, a form supposed to produce dysentery and certain other protozoa, the *Coccidia*, have been studied with great interest. See Cestoid Worms, Nematelmia, Nematoidea, Trematoda, Trichina, and Parasites.
Revised by William Pepper.

Entrecasteaux, Joseph Antoine Bruni, d', daañt'r'kaas'tō': navigator; b. at Aix, France, 1739; commanded a frigate in 1778, and distinguished himself by his successful protection of some merchant vessels against pirates; in 1785 he was placed in command of the East India fleet, and was afterward sent in search of La Pérouse. Though he failed in the object of this search, he made important discoveries. D. at sea near Java, July 20, 1793. His name is perpetuated in the d'Entrecasteaux Archipelago (*q. v.*), in d'Entrecasteaux Point on the southwestern coast of Western Australia, and in d'Entrecasteaux Channel between Tasmania and Bruni island.

Entre Douro e Minho: See Minho.

Entre Rios: a province of Argentina; occupying the southern portion of the peninsula between the rivers Paraná and Uruguay; bounded N. by Corrientes, E. by Uruguay, S. by Buenos Ayres, and W. by Santa Fé. Area, 45,000 sq. miles. The river Gualeguay flows southward through nearly the whole length of the province, and its watershed is divided from those of the Uruguay and Paraná by two ranges of low hills (called *cuchillas*) which unite toward the north. In the southern part there are extensive low swampy tracts near the Paraná and Uruguay. The whole country is well watered and fertile, forming one of the finest districts of the republic. Most of the land is open, but there are extensive forests in the north. The principal industry is grazing, immense herds of cattle and horses and flocks of sheep being raised on the great *estancias*; in connection with these are large meat-drying establishments, tanneries, etc. Wheat, maize, barley, flax, and tobacco are grown. The only mineral product of importance is lime. The Central Entreriano Railroad runs across the province from Paraná to Concepcion. Entre Rios formerly included all the region between the Paraná and Uruguay; Corrientes was separated in 1814. The progress of the province during the nineteenth century has been phenomenal. Pop. (1895) 290,994. The principal cities are Paraná, the capital, with 24,100 inhabitants; and Gualeguaychú, Gualeguay, Concordia, and Concepcion del Uruguay, each with more than 10,000. Herbert H. Smith.

Entry: the act of entering. In criminal law, in addition to breaking, entry is necessary to constitute the crime of burglary, but this need not be with the whole body. If any part of the person or of an instrument be introduced within the building with intent to commit a felony, it is sufficient; but if only the instrument intended to be used in the breaking enters, it is not enough to constitute the offense. See Burglary.

In the law of real estate, entry is the taking actual possession of land. By the common law a person had a right, when deprived of the possession of his land by a person whose original entry was unlawful, to regain his legal possession by a formal and peaceable act of entering upon it with the declaration that he thereby takes possession. When the disseizor's original entry was lawful the owner was driven to an action. The common-law action of *writ of entry* is now disused. Any going upon the land of another is often termed an entry, and unless done with the permission of the owner is in most instances unlawful and a trespass. Revised by F. STURGES ALLEN.

Environment: in zoölogy and botany, the sum of the conditions or surroundings of an animal or plant. Climate, the physical features of a country, absence or presence of enemies, and ease or difficulty of procuring food are among the more important factors of environment. F. A. L.

Envoy [*envoy* is from O. Fr. *envoye* (Mod. Fr. *envoi*), deriv. of *envoiier* (Mod. Fr. *envoyer*), send: Ital. *inviare*: Span. *inviar* < Lat. *in* + *via*, way]: a messenger; in political matters a person deputed by a ruler or government for transacting business with a foreign ruler or government. In diplomacy the term envoy extraordinary and minister plenipotentiary is applied to a diplomatic agent of rank next below an ambassador. See AMBASSADOR, DIPLOMATIC AGENTS, and INTERNATIONAL LAW.

Enzina, JUAN DEL: See ENCINA.

Enzio, or **Enzo**: soldier; natural son of the Emperor Frederick II. of Germany; b. 1225; fought at his father's side in the battle of Cortenuova at the age of thirteen; in the following year married Adelasia, the widow of Waldo Visconti and heiress of Sardinia and Corsica, and received the title of King of Sardinia. In 1239 he was made vicar imperial, with the task of subduing the Guelph cities of Northern Italy, and in spite of his youth became the ablest of Ghibelline leaders. The cities of Umbria were reduced to obedience, and the best military talent of his enemies was enlisted against him in vain. Toward the end of the year he was excommunicated by the pope. Taking command of the allied imperial and Pisan fleets, he defeated the Genoese in 1241 near the island of Meloria, sank three and captured nineteen of their vessels, and took 4,000 prisoners, including many prelates of high rank who were journeying to the Roman council. His next service to the emperor was his victory conjointly with his brother over the Tartars on the river Delphos. In 1247 he was again active in Northern Italy against the Guelphs, whose revolt, however, could not be suppressed, and though he captured Arola, where his murder of prisoners left a stain on his reputation, all but Modena and Reggio were lost to the emperor. Gathering his forces for a final effort, he met the Bolognese in battle on the banks of the Fossalta, but was defeated and taken prisoner. So great was the fear felt for him by his captors that the senate and people of Bologna decreed his perpetual confinement. Neither the offer of ransom nor the threats of punishment made by the emperor could procure the release of Enzio, who, however, was treated with honor, and experienced no hardship save the loss of his liberty. His captivity lasted twenty-three years. D. Mar. 14 or 15, 1272. F. M. COLBY.

E'ocene Period [*eocene* is from Gr. ἠώς, dawn + καινός, new]: the division of geologic time following the Cretaceous period and preceding the Neocene: the earlier part of the CENOZOIC (*q. v.*) or Tertiary era. Eocene life is distinguished from Cretaceous by the disappearance or subordination of archaic and the substitution of modern types. Among vertebrates domination passed from the reptiles to the mammals. The Ammonites and their aberrant congeners, as well as the Rudistes and Inocerami, became extinct, and were replaced by representatives of such familiar genera as *Ceritheum*, *Conus*, *Fusus*, *Voluta*, and *Cardium*. Arborescent ferns and cycads gradually disappeared, leaving the aspect of the forest essentially modern.

In the U. S. Eocene rocks occupy a broad belt parallel but not adjacent to the Gulf and Atlantic coasts, from Texas to North Carolina. In the Mississippi valley an extension of the belt reaches northward to the mouth of the Ohio, and there is another in Florida. A narrower belt crosses New Jersey, Delaware, Maryland, and Virginia. A few smaller areas are known in California, Oregon, and Washington, and extensive lacustrine beds of the same age occur in Wyoming, Utah, Colorado, and New Mexico. The strata include marls of agricultural value in the eastern district, phosphates in Florida, and coal in the interior. See GEOLOGY. G. K. G.

Eohip'pus [from Gr. ἠώς, dawn + ἵππος, horse]: an extinct genus of the horse family occurring in the Lower Eocene deposits of the West, and allied to *Orohippus* (see HORSE, FOSSIL), but of a less specialized form, and apparently in the direct ancestral line. The feet had four toes in front and three behind, with a rudiment of the outer or fifth metatarsal, and may have had a rudiment of the first toe in the fore foot. This genus is represented by species from the lowest Eocene beds of New Mexico and Wyoming.

Eolian Harp: See ÆOLIAN HARP.

Eon (or **Eudo**) **de Stella**: a fanatic of the twelfth century; an ignorant (and perhaps insane) nobleman of Bretagne, who, having heard, during the act of exorcism, the words "through Him" (*per Eum*, etc., in Latin) "who will come to judge the quick and dead," concluded, from the resemblance between his own name *Eon* and the Latin *Eum*, that he was the one appointed as the final judge of mankind. He taught a reformed doctrine, and gained many disciples. He was captured in 1148, and many of his followers (called Eonians) were burned, but Eon himself was pronounced insane, and seems to have been spared.

E'os [a personification of Ion. Gr. ἠώς, Attic Gr. ἕως, dawn; cf. Lat. *auro'ra*, Sanskr. *usha's-*]: in the Greek mythology, a daughter of Hyperion, a sister of Helios (the sun), and the wife of Tithonus. See AURORA.

Eosin: See PHTHALIC ACID.

Eötvös, or **Eoetvoes**, ā'öt-vösh, JOSEPH, Freiherr von: Hungarian author and statesman; b. in Buda, Sept. 13, 1813; educated at the University of Pesth. About the age of twenty he produced *Boszú*, a tragedy, and two successful comedies entitled *Kritikusok* and *Hazasulok*. He also gained distinction as a political writer and orator of the popular party. Among his works are a political novel entitled *Falusi jegyző* (The Village Notary; 1844–46), which was translated into English, and another on *Der Einfluss der herrschenden Ideen des 19. Jahrhunderts auf den Staat* (Vienna and Leipzig, 1851–54). He was minister of public instruction in 1848, but he resigned the same year. In 1865 he began to edit a political paper. In 1867, after the reconciliation between the Magyars and the Emperor of Austria had been effected, he was again appointed Minister of Public Instruction, which place he retained until his death. D. in Pesth, Feb. 3, 1871.

Eozoön [from Gr. ἠώς, dawn + ζῷον, living being]: a peculiar mineral structure supposed to represent an organism, first discovered in the pre-Cambrian or Archean limestones of Canada (see ARCHEAN ERA), composed of concentric layers of dark-green serpentine with interstices filled with calcite or dolomite, or with irregular canals of those minerals running through it. The name was applied to these objects by Sir William Dawson, who interpreted them to be the fossil remains of foraminifer-like organisms, giving the name *Eozoön canadense* to those first described. On account of the great antiquity of the formations (Laurentian) from which they came, and the uncertainty as to the relationship of the structure to any known organism, much doubt has been cast upon the correctness of Dawson's interpretation.

If organic, it represents the most ancient known organism. While some palæontologists and geologists believe it to be organic, many others, and particularly those experts in the knowledge of mineralogy and petrography, consider eozoön to be purely inorganic in origin. H. S. WILLIAMS.

E'pact [from Gr. ἐπακτός, deriv. of ἐπάγειν, intercalate; ἐπί, upon, to + ἄγειν, bring]: the excess of the mean solar month (the twelfth part of a tropical year) over the mean lunar synodical month, or mean lunation—that is, inasmuch as the mean lunation is less than the mean solar month, the epact is properly the amount to be added to the former to bring it up, or make it equal, to the latter. Practically, in the Church calendar, however, the epact is the number of days which intervene between the end of the ecclesiastical year in December and the first day of January succeeding; or, as it is commonly expressed, the epact is the age of the moon, estimated in entire days, at the beginning of the civil year. According to the definition given first above, it is manifest that the epact must increase from month to month, but for the purposes of the ecclesiastical calendar this monthly increase is not considered, the entire increase for each year being supposed to take place at the end of the year. This calendar is extremely artificial, the calendar moon being a sort of fiction of which the periods only approximately correspond with those of the moon in the heavens; so that the calendar months and the true or mean astronomical lunar months rarely begin or end exactly together. In the reckoning of the epact the following arbitrary assumptions are made: 1. The mean synodical month is $29\frac{1}{2}$ days long (it is, in fact, 44 minutes 2·84 seconds longer). 2. The lunar year consists of 12 lunar months, or 354 days. 3. The solar year is always 365 days (it is really 5 hours 48 minutes 46·05444 seconds longer). 4. The calendar months are alternately 30 days and 29 days long. Thus the first day of the second ecclesiastical month is Jan. 31; the first day of the third ecclesiastical month is Mar. 1; of the fourth, Mar. 31; of the fifth, Apr. 29, and so on. Thus the last day of the lunar year is Dec. 20; so that if new moon occurs at the beginning of the civil year exactly, the epact at the beginning of the next civil year is 11. In another year this epact will be doubled and become 22; and at the end of a third it will be 33 days, or more than a month; so that on Jan. 1 the moon will be somewhat advanced in a second lunation. The completed lunation is counted 30 days, and the epact is thus reduced to *three* days at the beginning of the fourth year. The month thus passed over, or dropped, is called an *embolismic* month. As the epacts accumulate, six such embolismic months of 30 days each are dropped; and finally we reach a point where the epact is 29, which we consider to be a complete embolismic month also, and drop it; so that the next following year begins with the epact 0, like the first. This occurs at the end of the nineteenth year, so that in every cycle of nineteen years the epacts recur in the same order.

All the foregoing assumptions are separately inexact, but in combination their inaccuracies nearly balance each other; and accordingly it happens that, at the end of the nineteen-year cycle, the calendar moon, the true moon, and the sun occupy almost exactly the same relative places as at the beginning. That is, supposing the sun and the true moon to leave some determinate point—say the equinox—together at the beginning of the cycle; then at the end of the nineteenth year or the beginning of the twentieth the sun will be truly in the equinox again, and the moon very nearly so, but not quite, being behind by about two hours and four and a half minutes. In something less than twelve cycles (about 220 years), therefore, the true moon will have lost a day on her epact. If the calendar moon lost nothing, its epact would consequently be too great. But the calendar moon loses more than the true moon, as will appear from the following comparison, made for a period of four cycles, or 76 true astronomical (tropical) years and 940 lunations:

940 calendar lunations, of $29\frac{1}{2}$ days each, give...........	27,730 days.
24 embolismic months too long, and 4 too short, add.....	10 "
19 intercalary days, ignored in the lunar calendar.......	19 "
Total days in 4 calendar cycles.....................	27,759.000
" " 940 true lunations......................	27,758.753
" " 76 true years..........................	27,758.407

It thus appears that the calendar moon falls behind the true moon 0·247 of a day, or nearly 6 hours, in 76 years; and its epact not only absolutely diminishes, but diminishes relatively to that of the true moon also. The effect of this is to cause the successive calendar new moons to occur too late by an amount slowly but constantly increasing; the increase amounting to one entire day in something more than 4 times 76, or 304 years—more exactly 308 years. No account of this circumstance was taken, however, for nearly sixteen centuries after the commencement of our era. At the time of the reformation of the calendar by Pope Gregory XIII., in 1582, the epact had become too small by nearly five days. See CALENDAR.

The use of the epact of the year in the calendar of Pope Gregory was to lead to the determination of paschal full moon, and so, by consequence, of Easter. (See EASTER.) The epact being the age of the moon in entire days at the beginning of the (lunar) month, the place of new moon in March would be found by counting backward from Mar. 30 (which we have seen to be the last day of the third lunar month), including this 30th day itself in the count, a number of days equal to the epact. The date in March thus found is the *first* day of the moon, and thirteen days more added brings us to the fourteenth; the day of March thus found will be the date of paschal full moon, unless it happens to be less than the 21st. In this latter case we must go to the month of April, and count backward from the end of the fourth lunar month, which is Apr. 29. To facilitate this counting backward, or to make actual counting unnecessary, Clavius introduced a row of numeral letters into the calendar page opposite the days of the month, in reversed order, I. being opposite Mar. 30, and XXX., or 0, standing opposite Mar. 1. This is extended through all the months in the year, as in the following illustration, which presents the months of March and April only:

Day of month.	MARCH. Epact.	Letter.	Day of month.	APRIL. Epact.	Letter.
1	0, or XXX.	D	1	XXIX.	G
2	XXIX.	E	2	XXVIII.	A
3	XXVIII.	F	3	XXVII.	B
4	XXVII.	G	4	XXVI., 25	C
5	XXVI., 25	A	5	XXIV., XXV.	D
6	XXV.	B	6	XXIII.	E
7	XXIV.	C	7	XXII.	F
8	XXIII.	D	8	XXI.	G
9	XXII.	E	9	XX.	A
10	XXI.	F	10	XIX.	B
11	XX.	G	11	XVIII.	C
12	XIX.	A	12	XVII.	D
13	XVIII.	B	13	XVI.	E
14	XVII.	C	14	XV.	F
15	XVI.	D	15	XIV.	G
16	XV.	E	16	XIII.	A
17	XIV.	F	17	XII.	B
18	XIII.	G	18	XI.	C
19	XII.	A	19	X.	D
20	XI.	B	20	IX.	E
21	X.	C	21	VIII.	F
22	IX.	D	22	VII.	G
23	VIII.	E	23	VI.	A
24	VII.	F	24	V.	B
25	VI.	G	25	IV.	C
26	V.	A	26	III.	D
27	IV.	B	27	II.	E
28	III.	C	28	I.	F
29	II.	D	29	0. or XXX.	G
30	I.	E	30	XXIX.	A
31	0, or XXX.	F			

In this table one peculiarity will attract attention. Though the third lunar month has thirty days, and the fourth only twenty-nine, yet each has thirty epact numbers. There seemed to be a necessity for this; otherwise, when the epact is XXIX. it would be equivalent to zero in the short months (the hollow months as they were called), but not so in the full months. The epacts XXIV. and XXV. are therefore placed opposite the same day. During the same cycle three consecutive numbers like XXIV., XXV., and XXVI. will never all be found among the epacts. When XXIV. and XXV. are both present, XXVI. will be absent; and in that case XXV. is transferred to the place of XXVI., as indicated by the Arabic numeral 25 opposite that epact. Thus, notwithstanding this duplication, two epacts will never fall on the same day of the month.

The use of epacts for finding paschal full moon and Easter is not very convenient. The simple rules given in the article on EASTER will be found much more so. But this is a suitable place to explain how to find the value of the numerical term proper to be used in calculating the date of paschal full moon in the article referred to. The General Table II. of the Prayer-book contains the resultant corrections of the epact for all the centuries from 1600 to 8500. From 1600 to 1700 this correction was zero. From 1700 to 1800, and further from 1800 to 1900, it is 1, and in subsequent centuries it goes on, somewhat irregularly, to increase. Now, the numerical term in the formula given in the article EASTER for computing the date of paschal full moon (when the golden number is odd) is at present 10, from 1600 to 1700 was 9, and after 1900 will be 11. It is, in short, always 9, increased by the correction of the epact found in the General Table II. just mentioned, which for convenience we may call the secular correction of the epact. And an extremely simple rule for finding this numerical term is the following: *From the number of the centuries in the given year of our Lord take its fourth part and its third part (disregarding fractions), and increase the result by* TWO. This is true up to 4200. But in that year and the centuries following, up to 6700, the number of the century must be diminished by *one* before taking the *third* part. In other respects the rule remains unaltered. In 6700 and the centuries following, up to 9200, the number of the century must be diminished by *two* before taking the third part. In 9200, and up to 11,700, the rule is the same as given at first, except that the result is to be increased by *three* instead of *two*. The Gregorian calendar will, however, itself require correction before the year 4000. As an example, let it be required to find the numerical term for the computation of paschal full moon during the century beginning with 4100 and ending with 4200. Putting S for this term, we have

$S = 41 - \frac{1}{4}(41) - \frac{1}{3}(41) + 2 = 41 - 10 - 13 + 2 = 20$. In General Table II. of the Prayer-book we find opposite to 4100 the number 11. And $11 + 9 = 20$, thus verifying the statement made above.

Epaminon'das (in Gr. Ἐπαμεινώνδας, or Ἐπαμινώνδας): Greek statesman and general: b. at Thebes about 418 B. C. He was a pupil of Lysis, a Pythagorean philosopher. His youth was passed in retirement and study. He was temperate and virtuous, and is said to have despised riches. He formed an intimate friendship with Pelopidas. In 385 he served with distinction at the battle of Mantinea, after which he passed many years in private life. He was one of the deputies sent by Thebes in 371 B. C. to a congress of the Grecian states, in which he opposed the policy of Sparta and defended the interest and rights of Thebes in an eloquent speech. War speedily ensued between Sparta and Thebes, and Epaminondas was chosen commander of the Theban army, which amounted to only 6,500 men. He defeated the Spartans at the battle of Leuctra, July 6, 371 B. C., which was fatal to the supremacy of Sparta. In this action he displayed great military genius, and owed his success partly to his novel manœuvers and combinations. He invaded Peloponnesus in 369, and marched against Sparta, which was defended with success by Agesilaus. He commanded the Theban army which defeated the Spartans at the battle of Mantinea, July 3, 362 B. C., but was killed in this action. He left a pure and exalted reputation as a patriot, a statesman, and a sage, and is universally admitted to have been one of the greatest captains of antiquity. Cicero expressed the opinion that Epaminondas was the greatest man that Greece has produced. See Cornelius Nepos, *Epaminondas*; Grote, *History of Greece*, chaps. lxviii., lxix., and lxxx.; and Curtius, *History of Greece*.

Ep'arch [from Gr. ἔπαρχος, governor, used to translate the Lat. *præfectus*; ἐπί, upon, over + ἄρχειν, rule]: in ancient Greece, the title of the governor of a province, a ship's master, a satrap, or the prefect of a region under the Roman rule. The province itself was called an eparchy. In modern Greece the primary subdivision of a nomarchy is called an eparchy. In Russia an eparchy is the diocese or archdiocese of a bishop or archbishop of the Greek Church.

Epaulement [Fr. *épaulement*, deriv. of *épaule*, shoulder < Lat. *spa'tula*]: a military term which, from its derivation, would signify a *side* work, a work to cover *sidewise*—e. g. a *traverse*, or a short parapet made at the flank of a battery or end of a parallel; but practically its meaning is extended to any covering made of earth, stone, wood, or iron, when intended simply as a screen—e. g. to cover cavalry waiting to be brought into action. See Mahan's *Military Engineering*.

Epaulette [Fr. *épaulette*, deriv. of *épaule*, shoulder < Lat. *spa'tula*]: an ornamental article of uniform of military and naval officers, worn on the shoulders; a plate or strap extending along the shoulder from near the collar, and terminating with a fringe of gold or silver bullion, which falls over the shoulder. Rank is indicated by the size of the bullion and by devices on the strap, such as stars, anchors, crowns, etc. In the U. S. army the epaulette is confined to general officers, its place being supplied, for the lower grades, by the "shoulder-knot" of gilt cord, but in the navy it is worn by officers of all grades. The practice varies in the different services of Europe.

Epeira [from Gr. ἐπείρομαι, I examine]: a genus of spiders in which the eight eyes are arranged in two rows, the middle four forming a square; the two anterior pairs of legs are longer than the others, and the abdomen is large, ovoid, and usually brightly colored. Epeira and its allies are known as "orb-weavers," from the fact that they build circular webs with radiating threads and concentric cross-threads. J. S. K.

Epeirus: See EPIRUS.

Epenceph'alon [from Gr. ἐπί, upon, near + ἐγκέφαλος, brain]: See BRAIN.

Eperies, *ā-pā-ri-esh'*, or **Presova** (Lat. *Eperiæ* or *Fragopolis*): an old town of Hungary; the capital of the county of Saros; on the river Tarcza; about 148 miles N. E. of Budapest (see map of Austria-Hungary, ref. 4–I). It is surrounded by walls, and is one of the most beautiful towns of Upper Hungary. It is a bishop's see, has five churches, a college, and manufactures of linens, woolen goods, and earthenware. A royal salt mine is worked in the vicinity. Pop. (1890) 10,400.

Épernay, *ā'pār'nā'* (Lat. *Aquæ Perennes*): a town of France; department of Marne; on the river Marne; about 80 miles E. by N. from Paris (see map of France, ref. 3–G). It is on the railway from Paris to Châlons, 20 miles W. N. W. of the latter. It is well built, clean, and well paved, and has a public library, manufactures of hosiery, earthenware, and refined sugar, and many elegant villas, with wine-vaults. Épernay is a great entrepôt or market for champagne produced in the vicinity. Pop. (1896) 19,377.

Ephebe: See the Appendix.

Ephem'era [from Gr. ἐφήμερος, living but a day; ἐπί, upon + ἡμέρα, day]: a genus of pseudoneuropterous insects, commonly called day-fly, or May-fly, belonging to the family *Ephemeridæ*, and allied to the dragon-flies, or *Libellulidæ*. In the larva and pupa states they live a year or more in the water, but their existence in the perfect state is very brief. They give name to the family *Ephemeridæ*, of which many species occur in the U. S. See ENTOMOLOGY.

Ephem'eris [Gr. ἐφημερίς, diary, journal; ἐπί, upon + ἡμέρα, day]: in astronomy, a table giving the positions of any heavenly body from time to time for a considerable period. Thus we have an ephemeris of the fixed stars, showing the place of the principal stars for every tenth day of the year. An ephemeris of the planets gives the position of each planet, usually for noon or midnight of every day, sometimes also for every transit over the meridian of some one place.

The astronomical tables which household almanacs contain are given with little precision, and are for the most part adapted only to a particular latitude. Such tables are said to have been constructed even in the time of Ptolemy. They were indispensable to the astrologers of later days, who doubtless used them for finding the positions of the planets at some future or past date, and were compiled with sufficient accuracy for their prognostications.

An *astronomical ephemeris* is a collection of such ephemerides for a particular year or series of years, with the times of eclipses, occultations, and other astronomical phenomena, or the means of determining them. The more complete works of this kind are intended to furnish the astronomical observer, whether at an observatory, in the field of a survey, or at sea, with all the data relating to the sun, moon, planets, and some of the principal fixed stars, which he needs to facilitate the prosecution of his work. From the design of some portions of them to the wants of navigators, they are also called *nautical almanacs*.

Such publications were issued by astronomers from the time that astronomy was extensively cultivated as a science. During the eighteenth and nineteenth centuries they have generally been issued by governments, and during the nineteenth century most of the governments of Europe have had some sort of an ephemeris or nautical almanac. Those best known belong to France, Great Britain, Germany, and the U. S.

The earliest astronomical ephemeris noticed in bibliographies is that of Iarchus in 1150; the first printed ephemerides were published in 1475 for the years 1475 to 1506, and in 1499 for the years 1475 to 1531, though doubtless portions were prepared earlier; both were prepared by Regiomontanus. The latter extends through three cycles of nineteen years, and gives the longitudes of the sun and moon, and the phases of the moon and of eclipses occurring from 1483 to 1530, with explanations and useful tables. These have been the precursors of a succession of ephemerides, defective at first, but improving as astronomy advanced.

The *Connaissance des Temps ou des Mouvements célestes*, commenced by Picard for the year 1679, has appeared for each succeeding year, without interruption, to the present time. Additions and improvements were made by La Lande in 1760, who subsequently added lunar distances, with the design of making the book more useful at sea. This and almost all the subsequent volumes have been enriched by valuable memoirs by the most eminent French astronomers, thus carrying out the purpose of La Lande to make this annual a journal of astronomy. For many years it has been prepared under the direction of the Bureau des Longitudes of France. Improvements have been made in it from time to time by the use of more precise tables in its preparation.

The *Nautical Almanac and Astronomical Ephemeris*, published by the British Admiralty, was commenced by Maskelyne for the year 1767. He undertook its preparation, after a plan sketched by La Caille, for the purpose of meeting the wants of navigators, and especially of supplying facilities for using the method of finding the longitude by the distance of the moon from the sun or a star, which Halley had proposed in 1731. Mayer's new tables of the moon for the first time gave the moon's place with sufficient precision to make this method available. The successive annual volumes have been issued, three or four years in advance, to the present time. It was not until 1834 that it came up to the requirements of an astronomical ephemeris. Other improvements and additions have since been made. Under the superintendency of Mr. J. R. Hind, new tables of the sun, moon, and all but two of the planets were introduced, so that it has no superior either as an astronomical ephemeris or an almanac for the use of navigators.

The *Berliner Astronomisches Jahrbuch* first appeared for the year 1776, and has since been continued without interruption. It was mainly designed to supply the wants of astronomers, though those of the navigator were not overlooked. As an astronomical ephemeris it was in advance of all others until the later improvements in its British contemporary. Its volumes contain valuable astronomical memoirs from many of the most distinguished German astronomers.

The preparation of the *American Ephemeris and Nautical Almanac* was begun in 1849 under the superintendence of Lieut. (afterward Rear-Admiral) Davis, U. S. navy, in accordance with act of Congress of the U. S. The theoretical portions of the work were placed under the special direction of Prof. Benjamin Peirce, of Harvard University. The construction of tables of the moon and of some of the planets, with corrected elements and in a form which would facilitate the computation of their ephemerides, was first undertaken, and so successfully accomplished that from its commencement the *American Ephemeris* has ranked among the highest works of this class in extent, completeness, and adaptation to the wants of astronomers and navigators. The first volume was published in 1855. In the preparation of later volumes new and more accurate tables of the sun and planets have been employed. Several of its volumes contain valuable papers by American astronomers. It consists of two parts—the first arranged specially for the use of navigators, and computed for the meridian of Greenwich; the other prepared for astronomers, and adapted to the meridian at Washington. The first part is also published separately. Tables of the moon, Mercury, Venus, the standard stars, and four asteroids have also been published, and new and complete tables of all the planets are in course of preparation, to be used from and after 1900. In 1860 Prof. Joseph Winlock, afterward director of the Harvard Observatory, succeeded Admiral Davis in charge of the work. In 1866 it was placed under the superintendence of J. H. C. Coffin, U. S. navy, who remained in charge until his retirement in 1877. In the latter year Prof. S. Newcomb, U. S. navy, was appointed superintendent. The successive volumes have appeared for each year since its commencement without interruption. Revised by S. Newcomb.

Ephemeral Fever: See Febricula.

Ephemeroptera [from Gr. ἐφήμερος, living but a day + πτερόν, wing]: an order of insects. See Plectoptera.

Ephe'sians, The Epistle of St. Paul to the: one of the books of the New Testament; written probably in the year 61 or 62, during the apostle's first imprisonment at Rome, and about the same time with the Epistle to the Colossians. The words ἐν Ἐφέσῳ, at Ephesus (i. 1), are wanting in the *Codex Sinaiticus* and some other MSS., but the weight of diplomatic evidence on the whole preponderates in their favor. The absence of personal greetings is easily explained by its encyclical character. It is one of the richest and most glowing of the Pauline Epistles. The first three chapters are doctrinal; the last three, hortatory and practical. Of the many commentaries which have been written, those of Harless (German), 1834–58, Eadie (Scotch), 1854, and Meyer and Ellicott (5th ed. 1884) are among the best.

Eph'esus (in Gr. Ἔφεσος; Fr. *Éphèse*): one of the twelve cities of the Ionian confederation; on the river Cayster, which falls into the Gulf of Scala Nova on the western coast of Asia Minor. Its earliest traditions connect it with the birthplace of the goddess Diana, who was worshiped here as the personification of the reproductive and nutritive powers of nature. (See Diana, second article.) Herodotus states that Hercules founded a city in the Ephesian territory B. C. 1250. Androclus the Athenian (B. C. 1044) drove out the inhabitants, and with his followers established a Greek colony. Ephesus increased in importance with the culture of the worship of Diana, which attracted multitudes from all parts, who remained to worship at the shrine of the goddess and to benefit themselves by the commerce of the city, which became the chief mart of Asia and the metropolis. Ephesus was in turn ruled by tyrants, oligarchies, and republics. It paid tribute to Persia for two centuries from the time of Cyrus to Darius III. Ephesus was chiefly remarkable for its magnificent temple dedicated to Diana, which was burnt by Eratostratus in B. C. 356, the day Alexander the Great was born. (See Diana, Temple of.) The Romans finally possessed themselves of this and other cities in Asia Minor (B. C. 41), and under Cæsar Augustus and the succeeding emperors the city was rebuilt. The city was sacked by the Goths A. D. 262. The temple was then destroyed, and from that time the city declined in importance. For many centuries it was in the hands of various adventurers, and it declined into a mere suburb when the Turks built a considerable town at Ayasalouk toward the end of the thirteenth century. See Edward Falkener, *Ephesus and the Temple of Diana* (1862); Fergusson, *The Temple of Diana at Ephesus* (1883); Wood, *Discoveries at Ephesus* (1877), of which an abstract appeared in 1890 entitled *Modern Discoveries on the Site of Ephesus.*

Ephial'tes: the name of a famous giant in the Greek mythology, said to have been a son of Neptune.

Eph'od [Heb. *ēphōd*, deriv. of *āphad*, to put on]: a Jewish robe or tunic worn originally by the high priest (Exodus xxviii. 4); afterward by all priests (1 Sam. xxii. 18). It was made of fine linen. The ephod of the high priest had a breastplate attached to it containing twelve precious stones, on which were engraved the names of the twelve tribes. The relation of these twelve stones to the Urim and Thummim is still an open question.

Eph'ori, or **Eph'ors** [from Gr. ἔφοροι, overseers; ἐπί, upon + root Ϝορ-, watch, cf. ὁρᾶν, see]: the title of magistrates common to many of the Dorian states of ancient Greece. In the political constitution of Sparta the ephors exercised supreme power. The Spartan ephors were five in number, and were elected from the body of the ruling caste. Their term of office was one year. Besides their judicial authority, they exercised a control over the functions of the kings and the senate, and sometimes recalled the former from their foreign expeditions. They negotiated treaties with foreign states, and possessed nearly all the executive power of the government. The office was abolished by Cleomenes III., who came to the throne 236 B. C.

Ephorus of Cyme, in Asia Minor: Greek historian; b. about 400 B. C.; pupil of Isocrates, who said that Ephorus needed the spur, as Theopompus the bit. Ephorus began as a rhetorician, but at the suggestion of his master made history the work of his life, and prepared a universal history in thirty books (professedly omitting the mythical age), from the return of the Heracleidæ (*q. v.*) to the siege of Perinthus (340 B. C.). Each book had an introduction and was complete in itself. It was a famous work, much valued and read on account of the wealth of its material. A man of words not deeds, neither soldier nor statesman, Ephorus was the first of the closet historians. Nor was his critical faculty great. His style has a rather lazy flow; yet he was a popular author. Polybius has an occasional good word for him, and he is a favorite source of Diodorus. See Klügmann, *De Ephoro historico* (1860). Fragments in Muller's *Fragmenta Historicorum Græcorum* (vol. i., pp. 234–277). B. L. Gildersleeve.

Ephraim (double fruitfulness, Gen. xli. 52): one of the Hebrew patriarchs, second son of Joseph, and the head or founder of one of the twelve tribes of Israel. The territory of the tribe of Ephraim extended from the river Jordan to the Mediterranean Sea, and was bounded on the N. by Manasseh and on the S. by Benjamin and Dan; and was about 55 miles from E. to W. by 70 from N. to S.

E'phrem (or **Ephraim**) **the Syrian**: ecclesiastic and writer; b. probably about 308 A. D. at Nisibis, in Asia Minor. He was a zealous opponent of Arianism and other heresies; became a hermit or anchorite in the prime of life, and lived in a cave near Edessa. He was venerated as a saint and a prophet by his contemporaries, and received the offer of the bishopric of Edessa, but declined it. He wrote in Syriac numerous religious works, among which are hymns and commentaries on Scripture. His poetry is metrical, with occasional use of rhyme and assonance, and he is fond of the acrostic arrangement. But of his many works only a small number exist in the original Syrian text, the rest surviving in Greek, Latin, Armenian, and Slavic translations. It is doubtful whether he himself understood Greek; the Greek versions of his works, however, are certainly translations. A complete list of his writings is given by I. S. Assemani in the *Bibliotheca Orientalis* (i. 59–164), and in the preface to the Roman edition of the Greek text of his works. The principal edition of the Syrian and Greek texts is that which appeared in Rome in 6 vols. (1732–46), under papal authority; 3 vols. Greek text with Latin translation, and 3 vols. Syrian text, also with Latin translation, by the brothers Assemani. The hymns and sermons were published, with Latin translation, by T. J. Lamy (Mechlin, Belgium, 1882–89). A German translation of a selection of his works was published by Zingerle (6 vols., 1830–37). English translation of selections by J. B. Morris (Oxford, 1847) and of hymns and homilies by H. Burgess (London, 1853). D. 373. Revised by C. H. Toy.

Epicharmus: Greek comic poet and thinker; b. in the island of Cos about 540 B. C.; emigrated to Sicily in early childhood; settled in Syracuse, and died at the age of ninety. The Pythagoreans claimed him as a member of their order on the strength of his wise sentences, and it was on this account that Plato ranked him in comedy with Homer in epic. Epicharmus gave artistic form to Sicilian comedy, of which the great features are the travesty of mythology and the representation of typical characters from daily life. His language is the local Doric dialect, and the "rapidity" said to be characteristic of his comedies is ascribed now to his verse, now to his plot, now to both. Scant fragments are to be found in Ahrens, *De Græcæ linguæ dialectis* (vol. ii., appendix). See Müller's *Dorians*; Lorenz, *De Epicharmo* (1864). B. L. Gildersleeve.

Epic Poetry, or **The Epos**: poetry which narrates a series of adventures or events, usually of an heroic or supernatural order. No thoroughly satisfactory definition of epic poetry, however, has ever been given. Perhaps as good as any is that of the Italian scholar Pio Rajna, "any poetic narration of memorable things" (*Le Origini dell' Epopea francese*, p. 3): yet it would be easy to find critical objections to this. All authorities are agreed that an epic poem must be a narrative, and of an imaginative rather than literal kind; but as to the kind of "memorable things" suited to such narrative there remains great divergence of opinion. It is best therefore to pass from a theoretical to an historical view of the subject.

Even a slight study of existing epics, so called, brings out the fact that under this name are included poems of very different characters, at least in so far as the method of their genesis is concerned. On the one side are works like the *Iliad* and *Odyssey*, of a singularly objective and impersonal kind; on the other, poems like the *Æneid*, the *Gerusalemme Liberata*, and *Paradise Lost*, which are the products of individual geniuses, working in perfectly well-known conditions, and impressing their own personalities upon all that they write. When we try to pass from the works of Homer to Homer himself, and to imagine what manner of man he was, we find ourselves instantly at a loss. We can not even determine whether he was one or many, much less distinguish his personal opinions, sympathies, or qualities. All we are sure of is a certain poetic matter laid out before us with the noblest and most beautiful art. The poet has completely sunk himself in his subject, and has apparently taken no thought of preserving his own name and fame. And this subject, this poetic matter, furthermore, is evidently not something of the poet's own contrivance or invention. It existed and was esteemed before him; so that it was enough for him to present it as clearly and charmingly as he could. It belonged to his audience, not to him; and his audience required of him that he should be in the highest sense true to it. His office was to revive and fix in beautiful forms certain precious memorials cherished by all persons of his race and time. Hence the impersonality of the product. Accordingly, all that is left is the study of the poem, not of the poet.

This compulsory transference of attention to the subject-matter of poems like the *Iliad* and the *Odyssey* makes still clearer the difference between them and poems like the *Æneid*. The former are essentially the spontaneous and natural expression of the ethical and imaginative life of a whole society, a whole race; the latter are the products of a personal and intellectual art. Nor is this all. A still deeper study of the genesis of the great popular epics shows us that they are the perfected result of long poetic preparation, of what M. Gaston Paris has well called "*une fermentation épique*" (*Litt. française au Moyen Âge*, p. 36, 1890). Behind them are not epic models, but epic experiments, and experiments in the same line as themselves. In the "personal" or "literary" epics, on the other hand, even the greatest, there are everywhere the signs of imitation, of the effort to come up to standards evidently derived from without. Homer, whoever he was, thought only of telling again the familiar heroic story of Troy; Milton was concerned quite as much with preserving in his poems the true epic manner—the manner of Homer and Vergil—as with telling of the Fall and the Redemption of man.

The scientific study of epic poetry must begin therefore with the investigation of such periods of poetic preparation, or "epic fermentation," as produced or might (but for accident) have produced great spontaneous and natural epics. The chief of these periods are undoubtedly that which in Greece culminated in the *Iliad* and the *Odyssey*, that which in India culminated in the *Mahâbhârata*, and that which in mediæval France produced the *Chansons de Geste* (of which the *Chanson de Roland* is the best representative). Besides these, however, we have numerous periods when essentially the same processes were going on among other peoples, though the product was either through obstructing causes rendered less complete, or was less directly and perfectly the outcome of the epic fermentation itself. Thus among the Celts, both Cymric and Gaelic, a true epic material was developed far toward ultimate fullness and power; but the unhappy fortunes of the Celtic race left this material to be used by aliens. Among the Anglo-Saxons, as the poem of *Beowulf* shows us, only the premature (in the poetic sense) invasion of Christianity prevented the creation of great national works. Among the Scandinavian peoples we have in certain of the lays of the *Elder Edda* and in parts of the *Volsunga Saga* (though the latter is in prose) a near approach to epic success. The Spaniards began the preparation of material for epics, as the *Poem of the Cid* and the ballads prove; and apparently only the attraction of foreign culture (that of Provence and France and Italy) for the upper class, separating it in its imaginative life for a time from the mass of the people, caused this material to be left unused, except upon a minor scale. The Slavic races have rich funds of heroic matter peculiar to themselves; but they also too early came under the influence of other more developed peoples, and have made little use of their own. The mediæval and modern Greeks, too, show traces of the matter from which epics are formed. On the other hand, the Germans saw their heroic traditions, which Christianity with its accompaniments of classical education and French culture had caused to be in the main neglected from the time of Charlemagne down to the twelfth century, revived and embodied in two great poems, the *Nibelungen* and the *Gudrun*. But in these innumerable evidences of the influence of foreign social and literary ideals testify to a gap in the continuity of true epic creation. Again, the Persians have in their *Shah-Nameh* a work which only a long previous poetic working over of the traditions of the race could have made possible. Yet the author of it, Firdausī, was after all a court poet, belonging to a circle of such, and too much of an artistic individual, too much of a scholar, to be a perfect representative of epic art. Finally, the Finns possessed in their popular lays heroic matter of considerable epic possibilities; but the *Kalevala*, in which Lönnrot, a modern scholar familiar with Wolf's hypothesis and all the discussions of the philologists, has attempted to weld these lays into an epic whole, is far from fulfilling the requirements of an epic masterpiece of the spontaneous and natural kind.

Still, much may be learned of the genesis and nature of epic poetry from the study of all these periods and works. Far the richest of the periods for this purpose is undoubtedly that of the production of the French *Chansons de Geste*. To be sure, there were produced then no works of the incomparable excellence of the *Iliad* and the *Odyssey*. But the latter stand at the very beginning of Greek literature, not merely not preceded or accompanied by other poems of a similar character, but not even lighted up by hints in contemporary literature of other kinds. All we can learn of the manner of their production must come through the analogy of other epic periods, confirmed by the internal evidence of the poems themselves. In mediæval France, on the contrary, though on many points we know far too little, we yet have information and hints enough to reveal the birth of a splendid and powerful art. There we can follow the process by which the actual life of a race is transformed into imaginative life, by which real persons and events acquire an ideal character, and by which the enthusiasms, the aspirations, the dreams of a whole society come to embody themselves in poetic form. It is worth while, then, briefly to describe this process, as the results of critical investigation have made it known to us, because it must be taken as typical of what took place wherever epic poetry has grown or began to grow.

The true origin of French epic is not to be sought before the time when the invading Germans had practically destroyed for the great body of the population of Gaul the culture of the Roman world. These Germans, as Tacitus and other writers tell us, and as we know from remains of their own early poetry, were in the habit of celebrating in songs the gods, the heroes, and the great achievements of their race. (See Pio Rajna, *Le Origini dell' Epopea francese*, Florence, 1884.) Among them these songs and the singers of them had an almost sacred function. Nor were only ancient traditions thus preserved; new heroes and their deeds were sung as they appeared. When the Germans had possessed themselves of their new homes in the former Roman world, they did not forget this habit of theirs. Those of them who had remained in the German land continued to transmit from generation to generation their purely national songs. These Charlemagne knew and loved, and he had a collection of them made which unhappily is lost to us, though the legends themselves lived on. Those Germans, however, who had settled in the more southern territory, in the midst of a population more numerous than they, did not find it easy to retain their ancient traditions. The presence, too, of large numbers of popular artists—mountebanks, players, singers—perhaps diminished the dignity of the old Germanic poet. He became rather a popular entertainer than a prophet and sage. Yet he did not lose the tradition of his art. He still seized upon great names and great deeds, and rendered them into songs. We have many testimonies to the existence of such songs. They even attracted the attention of would-be serious persons, and, as Pio Rajna has beautifully shown, the pages of Gregory of Tours, Fredegarius, and the *Gesta Regum Francorum* abound in passages in which the Merovingian kings are transformed into poetic rather than historical characters. These kings, however, were not as yet representative of the patriotic and moral life of the French people. Indeed, the French people was not as yet constituted—its political and social institutions were still in confusion, its ideals of conduct were only beginning to form themselves, it had not yet felt an impulse of united and patriotic zeal. Not till the time of the Carolingians did the effort against the Saracens make the people one; not before Charles Martel and Charlemagne did the people find leaders of truly heroic proportions. From the time of these monarchs therefore must be dated the determinate poetic agitation that was finally to produce French epic. By the side of Charlemagne and the Carlovingians, to be sure, memories of other leaders and of events in which the great family had no part were preserved. Yet it is not too much to say that the existence of the poems devoted to these memories was largely due to the interest and incitement of the Carolingian story. Exactly in what form these epic traditions were handed down we unfortunately do not know. There has been much controversy among scholars over the so-called *cantilenae*, as the contemporary Latin writers call the poems about popular heroes. Some have imagined that these were short ballads, similar to the existing Spanish ballads dealing with separate episodes of story, and that finally the completed epics were composed by welding together series of such *cantilenae*. This is evidently an echo of the Wolf-Lachmann hypothesis about the formation of the *Iliad* and *Odyssey*. Others (chief among them Pio Rajna) have supposed that the *cantilenae* were in themselves incipient epics, and that from the constant reworking of these our epics came. Be this as it may, what is certain is that parallel with the constitution of mediæval French society went on the constitution of the imaginative matter of which the French epics were to be made. By the middle of the eleventh century this new society was essentially complete. The population of the land had become one; it had arranged itself in feudal classes; the higher of these classes was working out a new ideal of individual and social life—what we call the chivalric ideal. The nation was becoming conscious of itself and proud of its own past as well as of its present. Among the upper classes there was wealth, and splendor, and delight in courtly life and something of leisure. These were the conditions necessary for the maturing of the epic fruit that had been so long perfecting itself. In the end of the eleventh century this fruit began to appear, and one of the first, as well as finest, specimens of it was the *Song of Roland*, a truly heroic rendering of an episode connected with Charlemagne's career. During the next century epic production went on in France with ever-increasing rapidity. These poems were found to have an immense attraction for all classes in society, and the popular singers, the *jongleurs*, saw their fortune made by the amplification in verse of the history of every available hero or event that had left a trace in the popular memory. To such a pitch were interest and curiosity roused that not merely the great heroes and their legendary achievements were described, but gradually the need was felt of enlarging knowledge about them, and whole cycles of poems were devoted to the heroic deeds of ancestors and descendants—deeds most of them pure and arbitrary inventions of the singers. The constant need of new materials even led to the use of stories having no connection with the national history, and thus tales of the heroes of ancient Greece and Rome, and epic legends of the Celts, became a part of the narrative literature of France.

The process that has just been described enables us to arrive at important deductions as to the manner in which all great epics are generated. The creation of poems like the *Song of Roland*, the *Iliad*, the *Mahâbhârata* demands in the first place a certain condition of national culture and feeling. The races that produce them must have passed through stirring experiences, must have had striking leaders, and must proudly have preserved the memory of them. Then a certain state of society seems to be necessary. The social organization must be aristocratic, and in the upper class there must be wealth, splendor of living, and some degree of leisure, for though the populace may remember fragments of old legend, and enjoy the poetic rendering of them, it will not have the time or patience for amplified versions of them. Then this rich and splendid upper class must feel its own pride engaged and stirred by the national traditions, and must delight in listening to them dressed out as splendidly as its entertainer, the minstrel or poet, knows how. All this implies a society considerably advanced in culture, and yet it must not have advanced so far as to produce or be interested in distinct and powerful personalities in the realm of thought or art. All its ideals of greatness must still belong to the realm of action, and the poet must still feel that his matter is of infinitely more importance than himself—that, great as may be his honor if he hold and please his audience, it is not because *he* is memorable, but rather because he represents for the moment the noblest recollections and ideals of the persons to whom he sings.

When such a society as this, addressed by such poets, has formed itself, or, better, is in process of forming itself, the poetic successes of these poets will be transmitted from generation to generation by word of mouth. At first they will be crude, disjointed, undiscriminating. As time goes on certain of them will be found to have superior attractions for audiences; and naturally such will be given the preference. The themes of these will become the popular themes, and will throw into the shade the less interesting. Thus the process of natural selection will be initiated, and the themes that survive will be treated with greater and greater fullness. Successive poets, seeing the opportunity to fill here and there a gap, will do so. They will transfer to the narrations they find most popular episodes from others that are less popular and are about to be abandoned. Thus the strong themes devour the weak—as in mediæval French epic one Charles, Saturn-like, swallows up another. And by these processes of exclusion and contamination, as well as by the purely inventive additions of successive singers, the strong themes enlarge and perfect themselves. And at last the time comes when both the themes and the society to which they are addressed have reached the right point of development for poets of a larger aim to appear—poets who will venture to bring together into extensive wholes the materials prepared by their predecessors. These wholes will be epic poems in the proper sense of the word; and out of many such a few will by accident of happy theme and inspired singer have such transcendent beauty and power as to be remembered, and at last written down and preserved.

The application of these principles to other epics than the

Chansons de Geste must rest, as has already been indicated, to a considerable extent upon analogy. In the case of the *Iliad* and the *Odyssey* we have absolutely no hint as to the epic process until it appears in its perfection in these masterpieces. Yet the poems themselves upon examination bear out well the theory in its essential elements. The Homeric ἀοιδός clearly corresponds in every important detail with the French *jongleur*. Like him he is an entertainer, though perhaps with somewhat more of dignity. Like him he addresses an aristocratic society, proud of its past, loving splendor, and having leisure which must be adorned. Then the very persistence among scholars of the theory which Wolf suggested (*Prolegomena ad Homerum*, 1795), and which Lachmann amplified in his so-called *Kleinlieder-Theorie*, however wild the applications of it may often have been, would seem to be proof enough that the matter of the Homeric poems has not the unity and consistency of an effort of an individual imagination. On the contrary, there appear in it traces of the long and various working over of traditional materials. Finally, all that we know of the later reciters of Homer, the rhapsodists and Homeridæ, as well as of the cyclic poems, corresponds well with our information about the later *jongleurs* and the crop of French genealogical poems of the twelfth and thirteenth centuries.

If we turn now to the *Mahâbhârata*, we shall obtain the same results, though it may be said that we have here more hints as to the preliminary processes than is the case with Homer. It is certain that in India heroic song was from immemorial antiquity cultivated at the courts of princes and generally among the knightly class (*Kshatriyas*). In the *Mahâbhârata* itself the transmission of epic legend is connected with the Sûtas, a caste which resulted from the union of *Kshatriya* men and *Brâhmana* women, and which supplied charioteers and heralds as well as professional minstrels. The legends which these minstrels made use of were partly historical, partly mythological, in their character. But in India, as in Greece, it was rather history than mythology that was the mainspring of epic song. Divine beings, whatever their origin, must be associated as determinate individuals with men before they can be employed in an epic action. The singer looking back into antiquity discovers gods involved by every possible tie of relationship and interest with his heroes, and he naturally does not discriminate between the two in his story. It will hardly do, after the fashion of certain ardent mythologists, to allow the mythical elements of epic to assume the more important *rôle*, and attempt to resolve everything else into mythology.

Already in the later Vedic literature we find specimens of the material later used in the *Mahâbhârata*. Such material is there called *Itihâsa*, *Purâna*, or *Âkhyâna*—that is, tales, old stories, or legends. Some of these tales are reproduced bodily in the *Mahâbhârata*; and that the whole of this poem was felt to be little more than a collection of such is shown by the fact that the supposititious author is in the poem itself called *Vyâsa*—"arranger," or "diaskeuast." In fact, in the now enormous whole of 100,000 slokas, or double verses, there are evidences (confirmed by the testimony of the poem) of three distinct handlings, and perhaps of a complete reversal of the original political and religious tendency. Furthermore, we find there matter both of the original epic impulse and of the later explanatory and amplificatory kind. It is as if we had the *Iliad* and *Odyssey* fused into one with the cyclic poems, or the *Chanson de Roland* combined with the long list of poems of the *Geste du Roi*. All this, however, but makes the *Mahâbhârata* the more significant for the student of the genesis of epic poetry.

Did the limits of this article permit, these investigations might be pursued in the other epic periods of which mention has been made, and in all the facts would be found to agree with those outlined above. In Persia Firdausī based his *Shah-Namah* on collections of old Iranian traditions that had begun to be made before the conquest of Persia by Islam. (See Firdausī.) Among the Celts we have bards (*file*, the Irish called them), corresponding on one side at least to the ἀοιδοί and the *jongleurs*, using the combined historical experiences and mythological traditions of the race for the elaboration of the epic stories of heroes like Arthur and Tristram. Among the Germanic peoples we have the *Scôps*, maintainers of the memorials of the past, and producing poems like *Beowulf*, giving shape to materials that were later and under different conditions to be used for the *Nibelungen* and *Gudrun* in Germany, the *Eddas* and the *Volsunga Saga* in the Scandinavian lands. Among the Finns alone do we seem to find somewhat different conditions. Their lays are rather a possession of the whole people than of a class of singers appealing to an aristocratic upper class. Yet here, too, it is national pride that preserves them, and they are consecrated to the memory of a period of struggle against the inferior Lapps and of conquest over them. It may be remarked also that but for the peculiar circumstances that produced a modern scholar like Lönnrot, no Finnish epic in the large sense would ever have been born.

Such being the manner in which the great spontaneous popular epics are born, the question remains what connection there is between them and that other class of epics of which mention has been made—the "personal" or "literary" epics. The gap between the two kinds is certainly a wide one, yet perhaps not so wide as would appear at first sight. The latter are indeed due to efforts of individual genius striving to render after the great epic models subject-matters of personal interest and choice. Yet even so, it will generally be found that where success has been attained the part of tradition has been greater than would *a priori* be supposed. As society advances in culture beyond the point at which spontaneous epic production is possible, as experience and reflection increase the dignity of the individual, and especially of the artist, it is natural that efforts should be made to obtain personal honor and fame by the imitation of works that have general renown. In almost every country where epics have been produced we find this tendency. In India the traditional *Mahâbhârata* is succeeded by epic forms written by single known poets. These are known as Kâvyas, the works of *kâvis*, i. e. definite poets. The most famous of these is the *Râmâyana*, written by Vâlmîki, which in certain ways is so near the old tradition as to be almost a great popular epic. The traces of the individual hand, however, everywhere appear in it, and historical legend is allegorized according to the tendencies of a single mind. Later than the *Râmâyana* we have a series of Indian epics frankly artistic in character, two of them ascribed to the famous dramatist Kâlidâsa. These with four others have been called by Indian rhetoricians *Mahâkâvya*, or great poems, as especially worthy of study. The subject matter of all six, however, is drawn from the *Mahâbhârata* or the *Râmâyana*. In Persia the success of Firdausī's great work led to other attempts by court poets in the same line. First, additional episodes in the national history were treated, and especially the heroic deeds of the members of the family of Rustem. Then other heroes were celebrated, and the series of would-be epics extends down into the nineteenth century.

Leaving the Orient for the Occident the same tendencies are observed among the Greeks, though in a less marked degree, because the growth of other powerful poetic forms, as well as the very unsurpassableness of Homer, made the temptation to imitate him less. Still epics continued to be written, such as the *Heracleia* of Pisander of Cameirus, the *Heracleia* of Panyasis, uncle of Herodotus, the *Thebais* of Antimachus of Colophon, the *Perseis* of Chœribus of Samos, the *Argonautica* of Apollonius the Rhodian, the *Dionysiaca* of Nonnus, and the *Sequel to Homer* (τὰ μεθ' Ὅμηρον) of Quintus Smyrnæus. Not in Greece, however, but in Rome the first great literary epic was written—the *Æneid* of Vergil. And here it is worth noting that although for Vergil the epic form and manner are matters of imitation, not of direct poetic inheritance, yet in a certain way the conditions of his writing approximate those of true epic creation. It was a kind of new national pride and hope that animated him, and he recited traditions that had become associated with the noblest ideals of the Latin race. He freely used, too, the works of his predecessors—Nævius, Ennius, Attius, A. Furius of Antium, and probably others. Still, undoubtedly, the plan, the structure, the coloring of the *Æneid* are all his own; and we feel its success to be of a very different order from that of the *Iliad*. Of the Latin epics subsequent to Vergil—the *Pharsalia* of Lucan, the *Punica* of Silius Italicus, the *Thebais* and *Achilleis* of Statius—it is unnecessary to speak in detail. In them the double imitation of Homer and Vergil alone gives semblance of epic value.

After the fall of the Roman empire, with the decline of the literary life in general, literary epics ceased for a time to be written. This, indeed, was what made possible the birth of that spontaneous mediæval epic which has already been described. One material only, subsequently to be used by great masters, began to assume its epic shape—the story of the fall and the redemption of man as told in the Old and New Testaments. Beginning with the poetic version of the four Gospels by the Spanish Juvencus (330 A. D.), this material was gradually brought into epic form during the fourth and fifth centuries. (See AVITUS.) Here, too, the imitation of Vergil determined the manner of treatment. After the mediæval period proper had come to an end, and the great return to the study of antiquity which we call the Renaissance had restored to man a sense of his individual power and worth, there was an immediate revival of the writing of literary epics. Homer and Vergil had now become the great masters in this kind of composition, and fame was assured for any one who could, even if not rival, at least seem to approach the standard of these poets. The number of epics since the Renaissance is almost countless, and they still continue to appear.

In his *Essai sur la Poésie épique*, affixed to the *Henriade* (1732), Voltaire, after discussing Homer, Vergil, and Lucan, deems the following modern epics worthy of mention: The *Italia Liberata* of the Italian Trissino, the *Lusiads* of the Portuguese Camoens, the *Gerusalemme Liberata* of Torquato Tasso, the *Araucana* of the Spanish Alonzo de Ercilla, the *Paradise Lost* of Milton. It may perhaps be doubted whether the *Italia Liberata* and the *Araucana* have maintained their position as epics of universal interest, so hard is it for single imaginations to fulfill the work of many. If, however, these names must be stricken from Voltaire's list, two or three others should perhaps be added. Of these the *Henriade* itself, despite its contemporary repute, is hardly one. It has great merits, but it is dull. There can be little hesitation, however, in placing in the list the *Messias* of the German Klopstock; and, on the whole, the name of another poem belongs there—one of the most famous and popular of modern Europe, though in some ways romantic narrative rather than true epic—the *Orlando Furioso* of Ariosto. Still another great example of essentially epic work we have had of late years in the librettos of the musician Wagner.

It is worth noting that in this list as it remains the majority of the works are those in which epic tradition has still a great part. The *Paradise Lost* and the *Messias* belong to that long line of Bible epics whose beginning has already been noted. Wagner's greatest librettos renew the Germanic legends of which the *Nibelungen* is made. The *Orlando Furioso*, as may be seen in Pio Rajna's learned and charming book (*Le Fonti dell' Orlando Furioso*, Florence, 1876), gives us a romantic and ironical rendering of the story of that same Roland who is the hero of the *Chanson de Roland*. Born in France, this story had passed over into Italy, taken new root in the twelfth and thirteenth centuries, lived on in the popular imagination, and, finally, in the Renaissance, been treated by the grotesque Pulei in his *Morgante Maggiore* and the satirical Boiardo in his *Orlando Innamorato*. By this long route did it come into Ariosto's hands. At the last, therefore, we have but two poets left, Tasso and Camoens, who can be said to have transformed by efforts of their single imaginations historical themes into epic works of acknowledged power. And even these poets, though they had not the co-operation of the popular imagination, were inspired by the religious enthusiasm and patriotic pride of their fellow men.

A. R. MARSH.

Epicte'tus (in Gr. Ἐπίκτητος; Fr. *Épictète*; Germ. *Epiktet*; Ital. *Epitetto*): Stoic philosopher; b. at Hierapolis, in Phrygia, about 60 A. D. He was in his youth a slave of Epaphroditus, a favorite of the Emperor Nero, and lived at Rome. He became a freedman, and was banished with other philosophers from Rome by Domitian in 89 A. D., after which he lived at Nicopolis in Epirus. He was a man of excellent moral character, and acquired a high reputation as a teacher of philosophy, but he wrote little if anything. His temper and doctrines were less austere than those of most other Stoics, and were essentially Christian in their nature. It does not appear, however, that he had any connection with the Christian Church, or that he was a believer in the mysteries of that religion. Among his favorite maxims was "Suffer and abstain." His disciple Arrian collected his maxims and doctrines; his manual called *Enchiridion* has been translated into English by Mrs. Carter (1758), and by T. W. Higginson (1865). See Ritter, *History of Philosophy*; G. Boileau, *Vie d'Épictète et sa Philosophie* (1655; in English by J. Davies, 1670); Farrar, *Seekers after God* (1869).

Epicurean Philosophy: a system of philosophical teaching which took its name from Epicurus (337–270 B. C.), its founder. It originated in a reaction against the teachings of Socrates and his followers. Throughout the period of Greek decline and the last ages of republican Rome it exercised a profound influence, which was perpetuated through the days of the Roman empire, in spite of the opposition of Stoicism and of Christianity. It is a remarkable fact that it always remained substantially as Epicurus left it.

The writings of Epicurus are lost, with the exception of fragments chiefly preserved by Cicero, Seneca, and Diogenes Laertius, but the sublime poem of Lucretius, *De Rerum Naturâ*, is an exposition of the teachings of Epicurus.

In theology, Epicureanism was essentially atheism. The gods were eternal, immutable, and entirely unconscious of human affairs. Human responsibility for wrong-doing was consequently reduced to the minimum. The highest positive duty was made to be the pursuit of pleasure—not necessarily sensual enjoyment, for Epicurus himself taught that repose was the highest pleasure. Whatever the virtues of Epicurus may have been, the results of his system of ethics were thoroughly bad. The moral corruption of ancient Greece and Rome was in part the fruit of this system. The genial temper, the elegant habits of life, and the moral indifference exhibited in the writings of Horace were among the least objectionable of the effects of the Epicurean teachings.

The physical doctrine taught by Epicurus and Lucretius was not unlike that of certain modern evolutionists. They held that matter is uncreated, indestructible, and that all material things were self-evolved, without a supervising or directing Intelligence. See Lucretius, *De Rerum Naturâ*; Gassendi, *Syntagma Philosophiæ Epicuri*; and Henne's article *Epicure* in the *Dictionnaire des Sciences Philosophiques*.

Epicu'rus (in Gr. Ἐπίκουρος): Greek philosopher; founder of the EPICUREAN PHILOSOPHY (*q. v.*); b. in the island of Samos in 337 (or, as some say, 341) B. C. He was a son of Neocles, an Athenian, and is said to have been a pupil of Xenocrates, but he professed to be self-taught. At the age of eighteen he visited Athens, afterward traveled in Ionia, and opened a school at Mitylene, where he taught new doctrines. About the year 307 he removed to Athens, where he purchased a garden and founded a celebrated school of philosophy. He was very popular as a teacher, and gained a great number of disciples. He recognized pleasure as the chief good, and consequently was calumniated by the Stoics, but it appears that his habits were temperate and virtuous. Epicurus took no part in political affairs. He wrote numerous works on ethics, natural philosophy, etc., which are not extant, but several of his letters have been preserved by Diogenes Laertius. His opponents admitted that he was personally amiable and virtuous. Knowledge of his doctrines is derived chiefly from the works of Cicero and Lucretius, who in his poem *De Rerum Naturâ* amply illustrates his philosophy, and expresses great admiration of Epicurus. Among the eminent men who favored Epicurean principles were Horace, Atticus, Gassendi, Rousseau, and Voltaire. D. in 270 B. C. See Gassendi, *De Vita et Moribus Epicuri* (1647); Ritter, *History of Philosophy*; Zeller's *Stoics, Epicureans, and Skeptics.*

Epicycle [Gr. ἐπίκυκλος; ἐπί, upon + κύκλος, circle]: in ancient astronomy, a circle having its center moving along the circumference of another circle. It was a favorite opinion of the Greek astronomers that all the celestial motions must be uniform and circular, because the circle is the most perfect of plane figures. The phenomena of the stations and retrogradations of the planets were apparently inconsistent with this notion; and in order to explain them, Apollonius of Perga imagined the theory of *epicycles* and *deferents.* He supposed every planet to move uniformly in the small circle, or epicycle, the center of which is carried uniformly forward along the circumference of the large circle or deferent, of which the earth occupies the center. Hipparchus, having discovered the eccentricity of the solar orbit, supposed the motions to be performed in eccentric circles. The celebrated astronomer Ptolemy adopted the hypotheses both of Apollonius and Hipparchus; that is, he supposed the earth to be placed at a small distance from the center of the deferent circle (which consequently was called an *eccentric*), and the planet to move uniformly in the epicycle, the center of which also moves uniformly in the deferent. By means of these suppositions, and by assigning proper ratios (determined by observation) between the radius of the deferent and the radius of the epicycle, and also between the velocity of the planet in the epicycle and the velocity of the center of the epicycle on the deferent, he was enabled to represent with considerable accuracy the apparent motions of the planets, and particularly their stations and retrogradations. As a first step toward connecting the sciences of astronomy and geometry the hypothesis of epicycles does great honor to its inventors.

Epicycloid [from *epicycle* + *-oid*, a suffix from Gr. εἶδος, form]: a curve traced by a point on the circumference of a circle which rolls on the convex side of a given fixed circle. It belongs to the class of curves called roulettes, and is not invariably a transcendental curve. It is always of a finite order when the circumferences of the two circles are commensurable. The normal of the epicycloid is easily constructed; it always coincides with the line which joins the generating point to the corresponding point of contact of the two circles. The evolute of the epicycloid is a similar epicycloid, the radii of the circles being merely altered in a certain ratio. When the circles are equal the epicycloid is similar, and similarly placed to the pedal of the fixed circle with respect to a point in the circumference. The curve is the cardioid, which is the inverse of a parabola. The epicycloid was invented by Romer, the Danish astronomer, who about 1674 proposed this curve as the best form for the teeth of wheels, in order to prevent friction. Newton gave its rectification in his *Principia.*

Epidam'nus: See DURAZZO.

Epidau'rus (in Gr. 'Επίδαυρος): an ancient town of Greece, on the east coast of the Peloponnesus and on the Saronic Gulf, about 45 miles S. W. of Athens. It was an independent state, and possessed a small territory called *Epidauria.* As early as 600 B. C. it was one of the chief commercial cities of the Peloponnesus. It derived much importance from its temple of Æsculapius (situated 5 miles from the town), which was one of the most celebrated sanctuaries in Greece, and was frequented by patients from all of the Hellenic states seeking a cure for their diseases. Here are the ruins of a magnificent theater, 370 feet in diameter, with fifty-five rows of seats. Once in four years, nine days after the Isthmian games at Corinth, a festival was celebrated here in honor of Æsculapius, with musical and gymnastic games. On or near the site of Epidaurus is a small village called *Neá-Epidavro*, or Pidavro, at which the first national assembly of modern Greece assembled in 1822, and drew up the instrument known as the Constitution of Epidaurus.

Epidemics [from Gr. ἐπιδήμιος, among the people, sojourning among; ἐπί, to, upon + δῆμος, people; the word commonly implies, as does also the verb, ἐπιδημεῖν, the sojourning of foreigners, as distinguished from ἔνδημος, ἐνδήμιος, native; hence the distinction *epidemic* versus *endemic*]: Diseases which appear from time to time in a certain locality and spread widely, affecting large numbers of people. *Endemic* diseases, on the other hand, are such as are constantly met with, isolated cases occurring now and then. Many epidemic diseases are endemic in certain countries where the conditions are eminently favorable, as in the case of cholera, which is endemic on the deltas of the Ganges, and yellow fever, which is constantly present in certain of the South American states. Some affections are apparently only epidemic, but the number of such is exceedingly small. Certain diseases which are endemic as a rule become epidemic when atmospheric or other influences predispose the community to general infection. This is seen in the U. S. in the case of typhoid fever and dysentery, as well as other diseases. An interesting instance in point is the epidemic spread of malaria which sometimes attends extensive excavations along the banks of rivers, where malaria, originally prevalent, became unknown as the result of suitable drainage.

The study of epidemics and the causes leading to them is one of the most interesting and important branches of medical history and pathology, and has occasioned the widest differences of opinion. This was largely the result of ignorance of the causes of the various epidemic diseases, and has been to a large extent removed by a fuller knowledge of micro-organisms and their relation to disease. Formerly atmospheric and telluric conditions, such as humidity, winds, the character of the soil, soil moisture, and the like, were given the most prominent place in the causation of epidemics; but, though there are still some who maintain the pre-eminence of these causes, the majority of hygienists are now strongly inclined to regard them of secondary importance to the actual causes, micro-organisms. The study of epidemiology is therefore intimately concerned with that of bacteriology on the one hand and preventative medicine on the other hand, and a knowledge of the causes of epidemics has in many instances led to almost complete eradication of certain diseases. This was seen in the case of scurvy, formerly the scourge of seamen and of armies, but now unknown excepting where the grossest carelessness or untoward circumstances prevent a suitable dietary. In the case of childbed fever, which in certain places and at certain times has attained epidemic characters, the practice of antiseptic precautions has almost exterminated the disease.

Diseases which are epidemic are for the most part of the group designated as infectious, and which are considered to be due to certain micro-organisms. Of these diseases, some, as typhoid fever, diphtheria, and scarlet fever, are also included among the contagious diseases—that is, they are communicated to other individuals by mere contact, while others, as typhoid fever, cholera, and malaria, are non-contagious, and are never communicated directly from person to person, excepting through water, food, or other matters infected by the affected individual. Exact lines can not be drawn between non-contagious and contagious diseases, and in the case of certain diseases there is doubt as to the class to which they belong.

Aside from epidemics of infectious diseases there are sometimes curious epidemics of mental or nervous diseases, some of which in a measure are exaggerations of what are generally recognized as waves of popular belief. Thus from time to time a war spirit prevails, as in 1770 to 1795 or in 1848. The crusades were in a measure instances of epidemic mental influences. The children's crusade was an extreme instance, bordering on a pathological condition. Epidemics of dancing mania, of witchcraft, of suicide, and the like are distinctly cases of mental aberrations.

Sometimes certain diseases are associated and prevail as epidemics simultaneously. This was the case with typhus fever and spotted fever in several epidemics, and is not infrequently noted in the case of other diseases. On the other hand, it is occasionally noted that one disease follows another in epidemic form, and by successive plagues whole populations may be exterminated. A study of the epidemics of the thirteenth, fourteenth, and fifteenth centuries gives abundant evidence of this.

As a rule, the first period of an epidemic is the worst, for susceptible individuals fall an easy prey, but sometimes the latter days are worse than the onset. As there is a difference in the severity of the disease from time to time in an epidemic, so there may be differences in different epidemics. Every physician recognizes that the typhoid fever of one epidemic is by no means of the severity of that in another outbreak, and the same thing is even more noticeable in the case of diphtheria or scarlet fever.

Curious cycles are often observed in the outbreak of certain epidemics, and it is noted that smallpox, cholera, and other diseases appear at somewhat regular intervals. A partial explanation of this may be found in the fact that persons once affected are for the most part immune from subsequent attacks, and that an interval must pass before new susceptible individuals have grown up. This is manifestly but a partial and imperfect explanation.

Epidemics spread from place to place in various ways. Sometimes the poison is carried by affected persons, by clothing, or by food, and it may be noted, as in the case of cholera, that the disease extends along the lines of travel and with the rapidity with which travel is effected. Other epidemics, as typhoid fever, are carried along water-ways, and infection is generally accomplished through drinking water. In another class, to which influenza notably belongs, dissemination occurs through the air, and so widely that the term " pandemic " is appropriately applied.

Fortunately the knowledge of certain principles regarding infectious diseases gives promise of extermination of epidemics in a way quite different from these before referred to. These principles, which are strikingly exemplified in vaccination, indicate the possibility of protective inoculation against other diseases, and the possibility of rendering man immune from infections of all kinds. Much patient work remains to be done in this direction, but the sciences of bacteriology and pathological physiology have opened the channels of experimentation. See CLIMATE.

WILLIAM PEPPER.

Epiden'drum [from Gr. ἐπί, upon + δένδρον, tree]: a large Linnæan genus of epiphytic orchids, which, as originally constituted, includes the vanilla and many other species. The species, about 400 in number, abound in the tropics and many have very showy flowers. The only tree orchids native to the U. S. belong to this genus. The *Epidendrum conopseum* grows principally upon magnolia-trees, and is found in South Carolina, Georgia, and Florida. Several species are confined to Florida. The blossoms, although rather pretty, are not conspicuous.

Epider'mis [Gr. ἐπιδερμίς, the outer skin; ἐπί, upon + δέρμα, skin]: called also **Cuticle**, or **Scarf-skin**; in anatomy, a modification of the epithelium, accurately molded to the papillary layer of the true skin or derma. When exposed to pressure and friction it becomes hard and thick, as in the palms of the hands; otherwise it is soft. It is composed of agglutinated, flattened cells, but in the deep layers the cells are rounded or cuboidal, and filled with soft contents. In most races of men these deep cells contain more or less pigmentary matter, which gives the skin its various shades from black to white. The epidermis is penetrated by the ducts of the sweat-glands and oil-glands of the skin. Its cells are developed by multiplication of the cuboidal cells of the deeper layers. The hair and nails in man, and also the horns in lower animals, are modifications of the epidermis. See HISTOLOGY.

The epidermis in plants is a layer of thick-walled cells, of character varying extremely in different species. It is entirely homologous in structure with animal epidermis. Upon leaves it is penetrated by the stomata, and both transmits exhalations and absorbs carbonic acid, the most important part of the plant's food.

Epidote [as if from Gr. *ἐπίδοτος, deriv. of ἐπιδιδόναι, to superadd; ἐπί, upon + διδόναι, give—said to be so named because the series of the secondary forms are an enlargement on the base of the primary]: a mineral which consists essentially of silica and alumina, combined with portions of lime, oxide of iron, or peroxide of manganese. Some of the clear varieties are used as gems; these are chiefly from Untersulzbachthal, in the Tyrol. Epidote occurs in the crystalline rocks of the Eastern U. S. at many places, but not of gem quality. A variety containing lime is called *zoisite*, and another containing manganese is termed *pistacite*. It is often found crystallized in prisms, and sometimes occurs massive. The color is generally some shade of olive color, from nearly black to golden green, yellow, brown or red.

Revised by G. F. KUNZ.

Epigæ'a [from Gr. ἐπίγαιος, upon the earth; ἐπί, upon + γαῖα, earth]: a genus of plants belonging to the *Ericaceæ* or heath family, and comprising two species. *Epigæa repens*, popularly known as trailing arbutus, is a prostrate plant with evergreen and heart-shaped alternate leaves and clusters of rose-colored or white flowers, which appear in early spring and exhale a delightful fragrance. It is found in sandy woods, especially under evergreens, sometimes in rocky soil, and ranges from Canada to Texas. In New England it is somewhat inappropriately called mayflower, and in the Southern States ground laurel. The plant has diuretic powers. The other species of *Epigæa* is Asiatic.

Epiglot'tis [Gr. ἐπιγλωττίς; ἐπί, upon + γλῶττα, tongue; so named in allusion to its position]: the lid which closes the entrance to the larynx during deglutition. It is composed of fibro-cartilage covered with mucous membrane. During respiration the epiglottis is vertical, and in the act of swallowing it automatically falls backward and downward and closes the larynx, thus preventing the passage of food into that organ. Revised by WILLIAM PEPPER.

Epig'oni [Lat. form of Gr. ἐπίγονοι, those born afterward, descendants; ἐπί, upon + root γεν-, be born, become]: literally, successors or heirs; a collective appellation of the sons of the seven Greek chiefs who conducted the expedition against Thebes. Their names were Alcmaeon, Thersander, Diomedes, Ægialeus, Promachus, Euryalus, and Sthenelus. They renewed the war and took Thebes. Æschylus made the story of these chiefs the subject of a tragedy, *The Seven against Thebes*. In the history of literature the name is sometimes applied to those writers who confine themselves to the further development of the ideas of the great masters of the classic period.

Epigram [from Gr. ἐπίγραμμα, an inscription, an epitaph, a short pithy stanza such as those used in epitaphs; ἐπί, upon + γράφειν, write]: originally an inscription or brief writing; a short poem or piece of verse which has only one subject, and ends with a witty or ingenious turn of thought; an interesting idea expressed happily in a few words. The Greek epigram was at first a short collection of lines inscribed on a monument or statue, and the word was afterward transferred to short poems suitable for inscriptions. The general characteristics of Greek epigrams are perfect simplicity and the seemingly studied absence of that *point* which characterizes the modern epigram. But perhaps this seeming pointlessness is due to our ignorance of the circumstances under which they were written and to which they allude. It appears that the first and indispensable requirement of an epigram is not brevity nor sharpness, but *antithesis*. Epigrams are nearly all in one form of metre, the elegiac. Some of the epigrams of Catullus and Martial present the modern epigrammatic character; and Martial has in fact afforded the model on which the modern epigram has been framed. The French writers have been more successful in epigrams than any other modern writers, and they excel especially in those which are intended to be satirical and piquant.

Epigraphy [Gr. ἐπιγραφή, inscription; from ἐπί, upon + γράφειν, write]: the science of deciphering and explaining INSCRIPTIONS (*q. v.*).

Epig'ynous [from Gr. ἐπί, upon + γυνή, a female]: a botanical term applied to stamens and petals which grow on the summit of the ovary. These sometimes appear to be inserted on the ovary, in consequence of the coherence of the calyx with the ovary.

Epilepsy [from Gr. ἐπιληψία, ἐπίληψις, seizure, epilepsy; ἐπί, upon + λαβεῖν, seize]: a chronic disease of the nervous system characterized by short periods of unconsciousness, with or without convulsive movements; called also FITS and FALLING SICKNESS. It has been known since the earliest times, and its history is closely associated with that of witchcraft and sorcery. It was long thought to be of supernatural origin, and its victims were looked upon with mingled awe and fear. It is only within the nineteenth century that epilepsy has been studied scientifically. But little is known of its causation. It is more apt to begin in childhood. Direct inheritance plays a smaller part than is popularly supposed, but insanity, drunkenness, and hysteria in the parents strongly predispose to it. Fright, over-eating, worms, teething, are all said to be causative. Cases have been cured after the removal of foreign bodies from the ear, cutting out a painful cicatrix, and circumcision. Such instances are, however, very rare. The seat of the disease, it is quite well established, is in the gray matter of the surface of the hemispheres of the brain. There are three varieties of epilepsy: *petit mal*, *grand mal*, and Jacksonian, or local, or focal epilepsy.

In *petit mal* there is momentary unconsciousness without convulsion. Often the patient feels faint, or has a sensation of vertigo. He drops whatever he may have in his hands, ceases speaking, and turns pale, with eyes wide open and staring. In a moment consciousness returns, and he continues whatever he may have been doing.

Grand mal presents a very different picture. Often the patient can foretell an attack by means of a localized sensation called an *aura*. The commonest aura is an uneasy sensation in the pit of the stomach. There may be, however, simply a feeling of terror, a flash of light, or a distinct visual hallucination. In one case the patient always saw a landscape. Again, there may be noises or sounds of music or voices in the ears. Almost immediately after the aura the patient cries out, falls unconscious, becomes rigid for a moment, and then is seized with violent convulsive movements of the entire body. The eyes roll, the lids open and shut, and the face is livid and contorted into the most horrible grimaces. Froth, mixed perhaps with blood from the bitten tongue, escapes from the mouth. After a few minutes the convulsion ceases. A profound stupor succeeds, and the breathing is deep and noisy. After a time the patient can be aroused, but if left alone he will sleep for some hours. Sometimes fit follows fit rapidly, without the patient ever regaining consciousness, producing the condition called *status epilepticus*. Death usually follows from exhaustion. Epileptic convulsions are sometimes followed by curious mental phenomena. The patient may pass into a condition of trance in which, like a somnambulist, he may perform the most complicated acts without any subsequent recollection. Again a fit may be followed, or even replaced, by an attack of acute mania, in which the patient may have homicidal or suicidal tendencies. This is a fact of great moment in medical jurisprudence, as no doubt many apparently causelesss and motiveless assaults are committed while in this condition. The tendency in epilepsy is toward chronic mental degeneration, though it may accompany the soundest intellect. Napoleon, Peter the Great, and Julius Cæsar were all afflicted with it. Indeed, the Italian school of psychologists claim that genius is an epileptical degeneration; but of this there is no sufficient evidence. Napoleon was a genius in spite of epilepsy, not because of it.

One of the rarer forms of the disease is the so-called *epilepsia procursiva*, which is characterized by attacks of violent running, either in a straight line or a circle, sometimes ending by a fall and coma. In *epilepsia nutans* there are nodding movements of the head from side to side, and up and down, lasting a few moments.

In *epilepsia loquax* the patient repeats time and again some one word.

In *Jacksonian epilepsy* consciousness is unaffected, and the spasm is localized to one extremity or side of the face. It is usually due to a gross localized lesion in the motor region of the brain—a tumor, abscess, meningitis, or injury.

The treatment of epilepsy depends upon the cause and the variety of the disease with which the patient is affected. During the fit the clothes should be loosened, and the patient only restrained enough to prevent his injuring himself.

William Pepper and Charles W. Burr.

Epilo'bium [from Gr. ἐπί, upon + λοβός, lobe of ear, pod], or **Willow Herb**: a genus of herbaceous perennial plants of the family *Onagraceæ*, natives of temperate and cold climates. They have eight stamens and four petals. The fruit is an elongated many-seeded pod or capsule. Some of the species bear beautiful flowers. The *Epilobium angustifolium*, a native of Europe and of the U. S., has showy pink-purple flowers, and is sometimes planted in gardens. Several other species are indigenous in the U. S. The popular name willow herb was given in reference to the leaves, which resemble those of a willow. These leaves have astringent properties, and are reputed to have other active powers.

Epilogue [from Greek ἐπίλογος, closing discourse as in a drama or oration, in contrast to πρόλογος, introduction; ἐπί, upon + λογός, discourse]: in dramatic poetry, the closing address to the audience at the end of a play. It was usually spoken by one of the actors, and was cheerful and familiar in tone. The term is sometimes applied to the conclusion of an oration.

Epim'achus [apparently from Gr. ἐπίμαχος, assailable, that may easily be attacked; ἐπί, upon + μάχη, battle]: a genus of birds belonging to the *Paradiseidæ*, or birds of paradise, having a slender bill, densely feathered nostrils,

Epimachus speciosus, or grand plume bird.

and a long tail. Sometimes made the type of a separate sub-family, the *Epimachinæ*. Two species are known, the largest being the grand plume bird (*Epimachus speciosus*), an inhabitant of New Guinea. This magnificent bird is a little over 2 feet in length, of a velvety black above and below, with touches of coppery green about the head and back. On each side of the breast is a fan-shaped tuft of plumes tipped with a band of steel blue. The two central tail feathers are steel blue, and other parts of the plumage are marked with metallic reflections. F. A. Lucas.

Epimen'ides (in Gr. Ἐπιμενίδης; Fr. *Épiménide*): Greek poet and prophet; a native of Crete; flourished about 600 B. C. According to tradition he fell asleep in a cave, and awaked after a lapse of more than fifty years, with a large increase of wisdom and inspiration. A poem on the voyage of the Argonauts is ascribed to him. At the request of the Athenians, who were afflicted with the plague, he visited Athens about 596 B. C. and purified that city. Goethe wrote a poem called *Des Epimenides Erwachen*.

Epime'theus [Gr. Ἐπιμηθεύς, so named in presumed contrast to *Prometheus*, as if to mean *after*-thought as opposed to *fore*-thought]: in the Greek mythology, a brother of Prometheus and the husband of Pandora. His daughter Pyrrha became the wife of Deucalion.

Épinal, *ā'pēe'naal'*: town of France; capital of the department of Vosges; pleasantly situated at the western base of the Vosges Mountains, on both sides of the Moselle, about 200 miles E. S. E. of Paris (see map of France, ref. 4–II). It is defended by three forts, and has a ruined castle, a fine Gothic church, a theater, a hospital, a public library, a museum of pictures and antiquities, and manufactures of cutlery, paper, hosiery, lace, chemicals, pottery, and linen fabrics. Pop. (1896) 26,525.

Épinay, *ā'pēe'nā'*, LOUISE FLORENCE PÉTRONILLE DE LA LIVE, Madame d': author; b. in France about 1725. She was married at an early age to her cousin, M. d'Épinay, but they were soon separated. She was intimate with Rousseau, for whom she built the hermitage at Montmorenci, and with Friedrich Grimm. Her work on education, entitled *Conversations of Émilie* (1783), gained a prize of the French Academy. D. Apr. 17, 1783, leaving autobiographic memoirs (3 vols., 1818). See Fallu, *La Marquise d'Épinay* (1866); Perey, *Jeunesse de Madame d'Épinay* (1882).

Epiphania: See HAMAH.

Epipha'nius (in Gr. Ἐπιφάνιος; Fr. *Épiphane*), SAINT: a bishop and theologian; b. at Besanduke, near Eleutheropolis, in Palestine, about 310 A. D. He was educated in Egypt by monks, who instilled into his mind ascetic notions, and became afterward a disciple of Hilarion. In 367 he was made Bishop of Constantia (formerly Salamis), in the island of Cyprus. He was an adversary of Origen, whom he denounced as a heretic, and he co-operated with those who deposed Chrysostom. He wrote, besides other works in Greek, a treatise against heresies, entitled *Panarium*, which is one of the most important sources of information for the history of the ancient Christian Church. The best edition of his works is by W. Dindorf (5 vols., 1859–63). D. on board ship returning home from Constantinople, in the spring of 403. See R. A. Lipsius, *Zur Quellenkritik des Epiphanius* (Vienna, 1865).

Epiph'any [from Gr. ἐπιφάνεια, appearance, manifestation, also from ἐπιφάνια (sc. ἱερά) neut. plur., the Christian festival of the manifestation, deriv. of ἐπιφαίνεσθαι, appear]: a festival in the Christian Church, celebrated the twelfth day after Christmas (Jan. 6), to commemorate four events: (1) Christ's baptism; (2) his birth; (3) his manifestation to the magi; (4) the manifestation of his divinity in the miracle at Cana. Later, especially in the Western Church, it popularly commemorated the visit of the three wise men to the infant Jesus. It was Eastern in its origin, and to-day in the Greek and other Oriental Churches it is the season for baptisms and of the solemn blessing of the waters. The eve of Epiphany, called Twelfth Night in England and Three Kings' Night in Germany, was anciently a great popular festival. Its celebration is still kept up. In the English and American Prayer-books services with collects, epistles, and gospels are provided for six Sundays after the Epiphany.

Epipharynx: See ENTOMOLOGY.

Epiphe'gus [from Gr. ἐπί, upon + φηγός, oak, used here inaccurately in sense of its Lat. cognate *fāgus*, beech-tree]: a genus of herbs of the family *Orobanchaceæ*. They are root-parasites growing apparently from the ground, but really from the roots of trees. This genus is found only under beech-trees (whence the name *beech-drops*); the herbs are purplish or yellow brown, slender branched, with scale-like leaves, and from 6 to 12 inches high. The *Epiphegus virginiana*, common in the U. S., is called cancer root, from the idea that it is curative of cancer.

Epiphyte [from Gr. ἐπί, upon + φυτόν, plant]: a plant which attaches itself to the bark of trees, and derives nourishment chiefly from the air, whence the popular name of air-plant. Such plants are found generally in tropical countries, and prefer moist and shady situations. The orchideous epiphytes are cultivated with great success in greenhouses. Many of them are of exquisite beauty, and others are remarkable for their grotesque forms.

Epi'rus, or **Epei'rus** (in Gr. Ἤπειρος; Fr. *Épire*): a country of ancient Greece; bounded E. by the chain of Pindus, S. by the Ambracian Gulf, and W. by the Ionian Sea. It corresponds to the southern portion of the modern Albania, a wild and mountainous region which in all ages has been occupied by semi-civilized and robber tribes, called *Epirots* or *Epirotes*. It is adapted to pastoral pursuits, and its fine horses, oxen, and Molossian dogs were celebrated in antiquity. The three most important tribes of Epirots were the Chaones, Molossi, and Thesproti. The Molossi eventually became the masters of all Epirus. Among the Molossian kings was Alexander, whose sister Olympias was married to Philip of Macedon. The most celebrated king of Epirus was PYRRHUS (*q. v.*), under whose reign this kingdom attained its greatest power and splendor. He waged war against the Romans in Italy. D. in 272 B. C. Epirus became a Roman province in 168 B. C., and was conquered by the Turks in 1466. The chief towns of Epirus were Ambracia, Buthrotum, and Dodona. This region is still frequently called Epirus or "the Epirus." See Merleker, *Das Land und die Bewohner von Epirus* (1841).

Episcopal Church, The Protestant: the religious body formerly known as "the Church of England in America," and generally styled by Bishop William White, long its revered presiding bishop, the "American Church," or by the Connecticut churchmen in convocation in 1783 the "American Episcopal Church." The full legal title of this communion is "The Protestant Episcopal Church in the United States of America," a name originally assumed at an informal meeting of three Maryland clergymen and twenty-four vestrymen in 1780, it has been surmised, to distinguish it from those Christians, on the one hand, who acknowledge the papal supremacy, and from those, on the other, who reject the authority of bishops. Whether this were really intended or not is perhaps doubtful; the name, however, describes with sufficient accuracy the relations of this Church to the other religious bodies in the U. S.

The Episcopal Church is the descendant and representative of that branch of the Church of England which was established in the North American colonies in the seventeenth century. The English adventurers of that and the preceding age, like the Spaniards and Portuguese, carried their national religion with them, and introduced it wherever they gained a footing. The instructions given to Sir Humphrey Gilbert in 1578 gave him authority to settle in any country which was not in the possession of any Christian prince. He was to govern his colonies by laws agreeable to the policy of England, and not against the Christian faith professed in the Church of England. This expedition terminated, indeed, in disaster and in the death of the commander: but similar principles guided all expeditions which set sail for the "western parts of America."

The first services of the reformed Church of England within the territory now occupied by the U. S. were held probably at Point Réyes, Drake's Bay, on the California coast, in June and July, 1579. Francis Fletcher, priest and preacher of the little company in the Golden Hind, in which Sir Francis Drake at this time circumnavigated the globe, records in the *World Encompassed* the use of the Church's prayers on the eve, or on the festival, of St. John Baptist, June 24, at which service sailors and savages were the worshipers, and the crew of the Golden Hind besought their God in behalf of the natives attracted to these solemn rites that He would "open their blinded eyes to the knowledge of Him, and of Jesus Christ the salvation of the Gentiles." Fletcher records the maintenance of services for the six weeks of the adventurers' stay, and notes the auriferous nature of the soil, a fact not fully revealed until California had become a part of the U. S., and was freed from the controlling influence of the Latin civilization and the Latin faith.

A little later, on the Atlantic coast, in Raleigh's colony at Roanoke, N. C., on Aug. 13, the ninth Sunday after Trinity, 1587, Manteo, an Indian chief, who had visited England twice and was friendly to the settlers, was baptized according to the Prayer-book form, and a week later Virginia Dare, daughter of one of the assistants of the colony, Ananias Dare and Eleanor his wife, "the first Christian born in Virginia," was also baptized. In the summer of 1605 Waymouth's expedition, when off the coast of Maine, had natives at the daily prayers "who behaved themselves very civilly, neither laughing or talking all the time."

In 1607 an expedition under the command of Capt. Newport, of which the Rev. Robert Hunt, a man of energy and ability in civil affairs, as well as a learned and devout divine, was the chaplain, made a successful settlement at the mouth of the James river, Va. Under his guidance and the supervision of the saintly Hunt the foundations of the Church in Virginia were laid, and, although it doubtless suffered from his early death, it gradually increased in strength and influence, and became the established religion of that colony. In the same year, at Sagadahoc, on the coast of Maine, the first church building erected by the

English race on the North American continent was built within the walls of Fort St. George, and the Rev. Richard Seymour, a priest of the English Church, ministered here thirteen years before the landing on Plymouth Rock. In Maryland, and in what are now called the Middle States, the Church of England was introduced at an early date. In New England, where Puritanism had a predominating influence, the churchmen of the seventeenth and eighteenth centuries were longer in gaining a footing, which, when gained, they were obliged to make good against determined opposition.

Without tracing the history of the Church through the colonial period, it may be sufficient to say that, notwithstanding many drawbacks, it had in the year 1776 gained a very respectable position. It had been all along, however, obliged to contend not only with open enemies, but with injudicious friends. The violent measures of Andros and others had tended in some places to increase the dislike to the English Church which was felt by the Puritans of New England and New York, and by the numerous sectaries who, attracted by Lord Baltimore's proclamation of a general toleration, had swarmed into Maryland. The attempts which were made from time to time to procure bishops for America had failed, principally from political causes, and the Church, thus deprived of the presence of the highest order of its ministry, was necessarily crippled in the performance of its functions. The want of bishops threw difficulties in the way of raising up a native ministry. Young men who sought holy orders were obliged to make a long and perilous voyage to England to be ordained, and they were fortunate if they returned in safety. The smallpox in the eighteenth century was the peculiar scourge of the colonists who visited England, and this disease, justly dreaded in those days, carried off many of the most promising of the young men. The devotion of colonial churchmen, however, to their religion continued firm and unwavering, and although they encountered further trials at the time of the Revolution, they were able not merely to overcome them, but to place their Church in a position which has enabled it ever since to increase in influence and members.

At the beginning of the Revolutionary war there were in the Middle and Eastern States about eighty parochial clergymen. These gentlemen, with the exception of those in the great cities, were for the most part dependent for their support upon the Society for the Propagation of the Gospel. This society, however, withdrew its gifts after the termination of the war. In other respects, also, the conclusion of peace left the Church in a depressed condition. Although the large body of church clergy and laity were on the side of the friends of freedom, still many of the clergy and laity had adhered to the crown during the struggle, and most of these at its close withdrew themselves to England or to the colonies which continued "loyal." The peace was soon followed by the confiscation of the landed endowments of the Church in Virginia, and the numerous churchmen in that State were thrown upon their own resources. The Church was poor, and its prospects were not hopeful.

Two important measures were immediately necessary—to obtain the episcopate, and to promote a closer union between the churches in the several States. The first was necessary to the existence, the second to the well-being, of the Church. Under the old confederation the States regarded themselves as independent sovereignties, and by consequence the churches in them conceived themselves to be so many national churches. This position, if it had continued, would not indeed have affected their faith and doctrine, which are unchangeable, but it might nevertheless have produced many inconveniences. By the principles of the Church of England, every national church, while it is bound to adhere to the common faith of Christendom as a heritage from the apostles, has a wide liberty in regulating its own ceremonial, discipline, and worship. Thus the Prayer-book might have been altered in a different way in different States, and divergences in discipline and government might have been developed to such an extent as to make the relations between the churches an alliance rather than a union. This danger was averted, almost by an accident. A few clergymen from New York, New Jersey, and Pennsylvania met at New Brunswick, in New Jersey, to take measures for reviving an old society (which still exists) for the support of the widows and children of the clergy. They naturally discussed the condition of the Church, and made arrangements for a larger meeting to be held soon afterward in New York, to which representatives of the laity were to be invited. This meeting, however, did little more than lay down certain general principles—with reference particularly to episcopacy and the Common Prayer-book, which they rightly conceived would tend to promote a real union between the churches in the several States—and issue a call for a similar meeting to be held the next year in Philadelphia. This was the beginning of the General Convention, which has ever since been regarded as the governing body of the Church in the U. S.

The constitution of this body, as it was soon afterward established, required it to consist of all the bishops, and of four clergymen and as many laymen from each State. By later amendments, when more than one bishop was placed in a State, every diocese or episcopal jurisdiction became entitled to a representation of four clerical and four lay deputies, and the lay deputies were required to be communicants. All the bishops were entitled to seats *ex officio*; and it was arranged that as soon as there should be three or more they should sit in a separate house. Every act was to receive the approbation of both houses. Authority was given to the General Convention to prescribe the qualifications for ordination and to set forth a Book of Common Prayer—the two things that were most necessary for establishing such a union as was desired. It was also directed that there should be a convention in every State, consisting of clergy and laity, the powers of which were not in any way defined. It seems to have been assumed, however, that these conventions were to exercise supervision over the affairs of the Church in every State—or, to use the more recent expression, in every diocese—in all matters not coming within the immediate jurisdiction of the bishop.

This constitution was adopted in the several States, though not immediately in all. The convention of 1785 had consisted of delegates from what were afterward called the Middle States, and from Maryland, Virginia, and South Carolina. Much doubt was felt in the East, particularly in Connecticut, as to the wisdom of some of its legislation. The introduction of the laity especially, into what was conceived to be a Church council, was regarded as an experiment of questionable expediency, and some of the powers which were given them were thought to be without precedent. These objections, however, were gradually obviated or waived; and in 1789 Bishop Seabury, with a deputation from the churches in New England, took his seat in the General Convention, and the union of the Episcopal churches in the U. S. was completed. Although the constitution proposed in 1785, and adopted in an amended and completed form in 1786, all along contemplated the presence of bishops, there really were none in the U. S. at that time except Bishop Seabury, who took no part in the proceedings of these conventions. This gentleman (the second of a family which for five generations has furnished a line of clergymen, all able and some distinguished) had been sent to England soon after the peace by the clergy of Connecticut to obtain consecration. Ten of the Connecticut clergy had met on the Feast of the Annunciation, Mar. 25, 1783, at Woodbury in that State, and had chosen Dr. Seabury as their bishop, instructing him to seek consecration first in England, and failing there to go to Scotland for the coveted apostolical commission. In England he had found an obstacle, however, in the oath of allegiance, which forms a part of the English consecration office, and which, of course, could not be taken by any one but a British subject. After some delay, and much negotiation, he succeeded in obtaining consecration from the Scottish bishops on Nov. 14, 1784, at Aberdeen, and, returning to the U. S. in 1785, was received as Bishop of Connecticut and, later, of Rhode Island.

The rule of the Church, believed to have come down from the apostles themselves, requires the presence of at least three bishops at every consecration; and it was necessary that there should be at least that number in the U. S. to maintain an episcopal succession. Application was therefore made in 1786 to the English bishops in behalf of the Rev. William White and the Rev. Samuel Provoost who had been chosen to the episcopate in Pennsylvania and New York. The obstacle arising from the oath of allegiance was removed by an act of Parliament; but a new difficulty was found in a revised Prayer-book known as the "Proposed Book," which had been proposed for use in the U. S. in 1785, and in which the English bishops thought that they perceived indications of a disposition to depart from the doctrine of the Church of England. After a correspondence between some of the most learned divines in England and the U. S., in which the principle was clearly brought out that "this Church does not intend to depart from the Church of England in any essential point of doctrine, discipline, or worship, or further than local circumstances require," it was agreed to proceed with the consecration of these gentlemen, and they were accordingly consecrated bishops on Feb. 4, 1787, in the archbishop's chapel at Lambeth, by the Most Rev. John Moore, Archbishop of Canterbury, assisted by other bishops. Partly because it was desirable that there should be more than the lowest number of bishops necessary to maintain a succession, and partly to keep up the succession in the English line, the Rev. James Madison obtained consecration in 1790 as Bishop of Virginia.

The "Proposed Prayer-book," as it was called, which had never met with much favor, was allowed to fall into oblivion, and it has now become one of the curiosities of ritual literature. A new revision of the Prayer-book was made as soon as the union of the churches was effected. The English Prayer-book was followed, with such alterations as were necessary to adapt it to the changes in the political condition of the country, and with many other (chiefly verbal) modifications. The promise, however, to adhere to the doctrine, discipline, and worship of the Church of England was, upon the whole, strictly adhered to. The most important changes were the introduction of a communion office closely resembling that of the Scottish Episcopal Church, and more nearly approaching the older liturgies of England, which was done at the request of Bishop Seabury and at the instance of the Scottish bishops, in fulfillment of an implied pledge indicated in the "Concordat" agreed to at his consecration by Bishop Seabury and his Scotch consecrators; the omission of the Athanasian Creed; and the leaving out the precise directions about confession which occur in the English Office for the Visitation of the Sick. This omission was perhaps balanced, and the mind of the Church sufficiently declared, by the stringent rules about confession which are found in the Office for the Visitation of Prisoners, borrowed from the Irish Prayer-book. The Prayer-book, thus revised, was ratified in 1789. It came into immediate and general use, and has been for a century, without material alteration, the "use of the Church in the U. S." A revision begun in 1883 and finally consummated at the General Convention of Oct., 1892, in the adoption of a carefully prepared "Standard," was conducted on conservative lines, returning to the English use in restoring the *Magnificat* and the *Benedictus* and other English services left out in 1789; adding proper prefaces in the Office for the Holy Communion and additional selections of psalms, increasing the number of occasional prayers and thanksgivings and making many verbal changes, in no case, however, affecting statements of doctrine. The new Standard was published at Easter, 1893. It is now in general use.

The two objects which the convention had in view in 1785 were thus attained in 1789. There was a sufficient number of bishops, and the union of the Church in the U. S. was perfected. Since that time 170 bishops have been consecrated, of whom 84, including 4 retired missionary bishops, were living in 1900. There are upward of 4,250 priests and deacons, and the number of registered communicants is 714,575. The Church has extended into every State and Territory, and its missionaries have penetrated into Western Africa, Greece, China, Japan, Mexico, Brazil, and Cuba. In the General Convention of 1789 (that in which the union of the Church was perfected) 2 bishops sat, with 29 clerical and lay deputies. That of 1892 consisted of 73 bishops and 467 clergymen and laymen. The number of churches and chapels is estimated at about 6,600. There is a general theological seminary in the city of New York, and there are divinity schools in Connecticut, Illinois, Iowa, Massachusetts, Minnesota, Ohio, Pennsylvania, Virginia, and Wisconsin. Several colleges are connected with this church, among which are Trinity College, Hartford, Conn.; Hobart College, Geneva, N. Y.; Griswold College, Davenport, Iowa; Racine College, Wis.; St. John's College, Denver, Col.; and Burlington College, New Jersey. The University of the South was begun some years before the civil war, and has been revived, endowed, and developed into one of the most promising institutions of learning in the land. Faculties of divinity and grammar schools are attached to several of the colleges. St. Stephen's College, Annandale, N. Y., receives at an early age youths who are designed for holy orders, and carries them to the point at which they begin their theological training. Lehigh University, South Bethlehem, Pa., is under church control. Trinity School, New York, an endowed grammar school established in 1706, receives seventy-two boys on the foundation.

The doctrine of the Episcopal Church is that of the Church of England, believed to have been the common faith of Christendom while it continued undivided. The relations of this Church to the rest of Christendom were clearly defined by the bishops who met in conference at Lambeth in 1867, in 1878, and again in 1888. In 1868 more than seventy bishops from England, Scotland, Ireland, the colonies, and the U. S. met in that year to take into consideration the state and best interests of the churches of the Anglican communion. One of their first acts was to express the deep sorrow with which they viewed "the divided condition of the flock of Christ throughout the world," and to record their conviction that "unity will be most effectually promoted by maintaining the faith in its purity and integrity, as taught in the Holy Scriptures, held by the primitive Church, summed up by the creeds, and affirmed by the undisputed general councils; and by drawing each of us closer to our common Lord, by giving ourselves to much prayer and intercession, by the cultivation of a spirit of charity and a love of the Lord's appearing."

The Episcopal Church, while it receives the Holy Scriptures as the ultimate rule of faith, does not throw them open to the varying interpretations of every man's private judgment, but explains them by the aid of traditions which it believes to have come down through an unbroken line of teachers from the apostles themselves, by the creeds, and by the definitions of Christian doctrine made by the general councils. Candidates for baptism are required to confess their faith in the words of the Apostles' Creed—adults in person, and infants by their sponsors. Communicants must receive also the Nicene Creed, which contains the same teachings in a more expanded form. Nothing is required from laymen, beyond acceptance of the Prayer-book and a proper deference to the instructions of the clergy, who are believed to derive their doctrine and their right to teach by a succession from the apostles. The thirty-nine Articles of the Church of England (except the twenty-first, "of the power of Christian princes in relation to general councils") are still bound up with the American Prayer-book, with a separate title-page, however, but the practice of signing them has been laid aside since the Revolution. The clergy sign, instead, a general declaration that they "believe the Holy Scriptures of the Old and New Testament to be the Word of God, and to contain all things necessary to salvation"; and they "solemnly engage to conform to the doctrines and worship of the Protestant Episcopal Church in the United States." The mode in which the teachings of Holy Scriptures are ascertained has been already pointed out.

Thus the Protestant Episcopal Church in the U. S. would seem to be one of the most liberal and comprehensive of religious bodies. It *may* contain within itself (it is not, however, asserted that it *does*) those, on the one hand, who apparently differ from Roman Catholics in little more than in denying the pope's jurisdiction in countries which are or have been included in the British empire, infallibility, and Mariolatry; and, on the other, those who are to be distinguished from Presbyterians only by their acceptance of episcopacy and the Prayer-book. Within these possible limits there would appear to be ample scope for religious thought; and the great freedom of religious thought accounts for the schools of teaching which have long existed. As men incline toward authority on the one hand, or individual judgment on the other, they are said to be High Church or Low Church. The lines of thought, however, are not sharply drawn, and the schools melt into each other by imperceptible degrees. The principles laid down by the bishops at Lambeth (themselves men of every conceivable school of thought) have been long tested, and have been found sufficient to maintain the unity and harmony of the Church. As reaffirmed in 1888 and formulated in the Lambeth propositions for unity of Christendom, they offer to divided Protestantism a basis for reunion with the primitive, apostolic, Catholic Church which would eradicate divisions while permitting the liberty of thought and worship which true Catholicity requires. This basis for union—the same, with verbal variations, as that proposed by the House of Bishops of the American Church at the General Convention at Chicago, 1886—is as follows:

(*a*) The Holy Scriptures of the Old and New Testaments, as "containing all things necessary to salvation," and as being the rule and ultimate standard of faith.

(*b*) The Apostles' Creed as the baptismal symbol, and the Nicene Creed as the sufficient statement of the Christian faith.

(*c*) The two sacraments ordained by Christ himself—baptism and the supper of the Lord—ministered with unfailing use of Christ's words of institution, and of the elements ordained by him.

(*d*) The historic episcopate, locally adapted in the methods of its administration to the varying needs of the nations and peoples called of God into the unity of his Church.

See *The Lambeth Conferences of 1867, 1878, and 1888*, edited by Randall T. Davidson (1889), *Church Reunion Discussed on the Basis of the Lambeth Propositions of 1888* (reprinted from the *Church Review*, 1890), and Bishop Perry's *Accounts of the Second and Third Lambeth Conferences*, the one printed in 1879, the other in 1891.

The dioceses and missionary districts of the American Episcopal Church cover every portion of the territory of the U. S. There were, according to the statistical *Year Book* of the Church for 1900, fifty-nine dioceses and seventeen missionary jurisdictions or districts with eight foreign jurisdictions. The five dioceses of New York form a federate council. The three dioceses of Illinois are organized as a province. There are twelve missionary districts. There are three foreign missionary episcopates, viz.: Cape Palmas, Africa (west coast); Shanghai, China; Tokio, Japan. Missions, besides, exist in Greece, Mexico, Brazil, Cuba, and Haiti. A bishop has been consecrated for the Church in Haiti, and one was consecrated for Mexico, who subsequently resigned. The churches on the continent of Europe at Paris, Rome, Florence, Geneva, Nice, Dresden, and Lucerne are organized into a convocation. Eighty-four bishops are living, and in 1900 there were 4,863 clergy, 506 candidates for orders, and 6,667 parishes and missions. During the year 1900 there were 60,052 baptisms and 43,419 confirmations, and the total contributions for religious purposes amounted to $16,102,-467.52. There were 46,222 Sunday-school teachers and 430,901 pupils.

LITERATURE.—For the general history, consult Bishop W. S. Perry's *History of the American Episcopal Church, 1587–1883* (2 vols., 1885); Anderson, *History of the Church of England in the Colonies and Foreign Dependencies of the British Empire* (3 vols., 1846; 2d ed., rearranged and enlarged, 1856); Wilberforce, *History of the Protestant Episcopal Church of America* (1846); McConnell's *History of the American Episcopal Church from the Planting of the Colonies to the end of the Civil War* (1890); Hawkins, *Historical Notices of the Missions of the Church of England in the North American Colonies* (1845); Updike, *History of the Narragansett (R. I.) Church* (1847); Bolton, *History of the Protestant Episcopal Church in the County of Westchester* (1855). For original sources of information, see Bishop Perry's *Historical Collections of the American Colonial Church* (1871–78); Perry, *Journals of General Conventions, 1785–1835* (3 vols., 1874); Perry's *Historical Notes and Documents Illustrating the Organization of the Protestant Episcopal Church* (1874); Hawks and Perry, *Documentary History of the Church in Connecticut* (2 vols., 1863–64); *The Churchman's Year-book* (2 vols., 1870–71); *Connection of the Church of England with Early American Colonization* (1863); and *Historical Sketch of the Protestant Episcopal Church in the United States, 1784–1884* (1884); Bishop White, *Memoirs of the Protestant Episcopal Church in the United States* (1820; 2d ed. by Francis Lister Hawks, 1836; 3d ed. by Rev. Dr. B. F. De Costa, 1880); Beardsley's *History of the Episcopal Church in Connecticut* (2 vols., 1865; 4th ed. 1883); *Life and Correspondence of Samuel Johnson, D. D., Missionary in Connecticut and First President of Columbia College* (1874); and *Life and Correspondence of Bishop Seabury* (1881); Dalcho, *Historical Account of the Protestant Episcopal Church in South Carolina* (1820); Perry's *Handbook of the General Convention* (3d ed. 1880), and his ed. of Proctor *On the History of the Common Prayer* (1863–89); Hill's *History of the Church in Burlington* (1876; 2d ed., enlarged, 1885); Dorr's *History of Christ Church* (Philadelphia, 1856); Dr. J. B. Cheshire's *Church in the Province of North Carolina* (1890); and numerous monographs, etc. The legislation of the Church is embodied in the *Journals of the General Convention*, published triennially and oftener (1785–1892); the journals of the early and preliminary conventions (1785–1814) were edited by Bishop White (Philadelphia, 1814); those from 1785–1835 were published by authority of the General Convention, and edited by Bishop Perry in 3 vols., with notes, etc.

Revised by WILLIAM STEVENS PERRY.

Episcopal System: in the Roman Catholic Church, that theory according to which the highest clerical power is vested in the whole body of bishops. This theory was most prominently brought forward in the papal elections of the fourteenth century, and its followers declared the Church, as represented in its general assemblies, to be above the pope. In France the University of Paris was the chief supporter of this theory, and the Gallican Church accepted it as one of its fundamental laws. In Germany the coadjutant bishop of Treves, Nikolaus von Hontheim, who was one of its chief supporters, wrote under the pseudonym of Justinus Febronius a celebrated book, in which he clearly defined the episcopal system, *De statu ecclesiæ et legitima potestate Romani Pontificis* (Frankfort-on-the-Main, 1763). The Punctations of Ems (see EMS) had the same fundamental idea, and, although they failed in their purpose, the system continued to spread in Germany. But the declaration of papal infallibility has put an end to these differences, and made an impossibility of the episcopal system. In the German Protestant churches the episcopal system is that theory according to which the authority of the bishops, which had been suspended in the Protestant countries in consequence of the peace of 1555, was transferred to the ruler of the country.

Episco'pius, SIMON: a divine whose original name was *Bishop*, or *Biscop*; b. in Amsterdam, Holland, Jan. 1, 1583; studied at Leyden. He was distinguished for his liberality, moderation, and other virtues, and became the chief pillar and champion of the Arminians, or Remonstrants. He was appointed Professor of Theology in the University of Leyden in 1612, but he was accused of Socinianism by the Calvinists (Gomarists), and was banished in 1618 by the Synod of Dort. He retired to France, returned to Holland in 1626, and lived in Rotterdam, and became first Professor of Theology in the newly established Remonstrant Seminary in Amsterdam in 1634. His principal works are the *Confession of the Remonstrants* (1621) and *Institutiones Theologicæ*. His complete works appeared Amsterdam (2 vols., 1650–65). See his *Life* by F. Calder (London, 1835; New York, 1837). D. in Amsterdam, Apr. 4, 1643.

Episode [from Gr. ἐπεισόδιον, a parenthetic addition, in the Greek drama a dialogue introduced between the choral songs, neut. of ἐπεισόδιος, coming in besides; ἐπί, upon, in addition + εἴσοδος, entrance (εἰς, into + ὁδός, way)]: originally, one of those parts of an ancient classical drama which were performed between the entrances of the chorus. In modern use it signifies an incidental narrative or digression in the poem, more or less connected with the main plot, but not essential to its development.

Epis'tates [Gr. ἐπιστάτης, commander, president; ἐπί, upon + στῆναι, stand]: the title of the presidents of the two great councils of the ancient Athenians—viz., the Ecclesia and the senate of Five Hundred. Their term of office was one day.

Epistaxis [from Gr. ἐπιστάζειν, to bleed at the nose; ἐπί, upon + στάζειν, to drop]: the technical medical term for bleeding from the nose; a symptom traceable to various causes. It may be of slight importance, as very often in certain children who have repeated slight bleedings from the nose. In these there is no diseased condition discoverable. Again, it is of slight importance in persons in whom headache or confinement in a close room is apt to lead to bleeding, and indeed in such cases not rarely a measure of relief is afforded by the epistaxis. Besides these cases there are many serious diseases in which nosebleed occurs. Such are the various forms of diseases of the blood, purpura, and hæmophilia; diseases of the heart or kidneys in which the blood-vessels are apt to be diseased and congestions occur; and in whooping-cough during the paroxysms. Epistaxis is a symptom of considerable value as indicating the onset of typhoid fever, as it is very common during the first week, when the general symptoms are ambiguous. Bleeding from the nose as a result of injury, or in children from picking with the fingers, is easily recognized.

Generally the hæmorrhage soon stops of its own accord, but sometimes it requires treatment. Cold water, tannin, alum, and other agents may suffice. Pressure inward against the septum may prove efficacious. In more serious cases active medicinal agents may be required, or even firm packing of the cavity. Very rarely the bleeding is most obstinate, and in blood diseases, or less frequently other conditions, may be the immediate cause of death.

WILLIAM PEPPER.

Epistemology [from Gr. ἐπιστήμη, knowledge + λογία, deriv. of λόγος, discourse]: the theory of the grounds of knowledge or science. J. F. Ferrier, in his *Institutes of Metaphysics*, treats of Epistemology, or theory of knowing, Agnoiology, or theory of ignorance, and of Ontology, or theory of being. See EPISTEMOLOGY in the Appendix.

Epistle [from Lat. *epis'tola* = Gr. ἐπιστολή, message, command, deriv. of ἐπιστέλλειν, send to, enjoin upon; ἐπί, to, upon + στέλλειν, send]: literally, a thing *sent*, hence a letter. The name is now given especially to the twenty-one epistles of the New Testament. The writings ascribed to the so-called Apostolic Fathers (Clement of Rome, Barnabas, Ignatius, Polycarp, and Hermas) are for the most part epistolary in form. Of quite inferior dignity and value are the following undoubtedly spurious epistles: Abgarus of Edessa to Christ, and Christ to Abgarus; Lentulus to the Roman Senate; several of the Virgin Mary; Paul to the Laodiceans; the Third of Paul to the Corinthians, and one of the Corinthians to Paul; Peter to James; eight of Seneca the philosopher to Paul, and six of Paul to Seneca.

Epis'tolæ Obscuro'rum Viro'rum [Lat., letters of obscure men]: a famous collection of satirical letters directed against the monks and the Roman Catholic Church. They were published in three parts—the first at Haguenau (1515), the second at Basel (1517), and a third at a later date. They were probably written jointly by Ulrich von Hutten, Crotus Rubianus, and Buschius. They are an admirable imitation of the barbarous Latinity of the monks of those days. Certain Dominicans at Cologne, under the lead of one Pfefferkorn, a baptized Jew, advocated the expulsion of all Jews from Germany, the forcible education of their children in Christian doctrine, and the burning of their books. This attempt was opposed by Reuchlin, and pending the decision of the question by the pope the *Epistolæ* appeared. Says Sir William Hamilton: "The *Epistolæ* are at once the most cruel and most natural of satires, and as such they were the most effective. They converted the tragedy of Reuchlin's persecution into a farce; annihilated, in public estimation, the enemies of intellectual improvement; and even the friends of Luther, in Luther's lifetime, acknowledged that no other writings had contributed so powerfully to the downfall of the papal domination." Many editions of the *Epistolæ* have been published, the best of which is that of Boecking (Leipzig, 1858); German trans. by W. Binder (Stuttgart, 1876).

Epithala'mium [Lat. *epithala'mium*, from Gr. ἐπιθαλάμιος, -ον, at the door of bridal chamber, ὁ or ἡ ἐπιθαλάμιος (sc. ὕμνος or ᾠδή), song before door of bridal chamber; ἐπί, upon + θάλαμος, chamber]: a bridal hymn; a chorus sung, in ancient Greece, near the door of the bridal chamber. It appears to have been a formal part of the marriage ceremony. Among the ancient Romans the rude Fescennine songs, which seem to have been of a phallic character, were often sung at weddings, and are hence called epithalamia. The term is often given to formal poems composed in honor of a particular marriage. Anacreon and Pindar composed poems of this kind. The most perfect example of it now extant is the epithalamium of Peleus and Thetis, by Catullus.

Epithelio'ma [mod. deriv. by suffix *-ōma*, as in *carcinoma* = καρκίνωμα, cancer, from EPITHELIUM (*q. v.*)]: a variety of cancer which attacks most frequently the surfaces which are covered with pavement or cylindrical epithelium, constituting, in the former situation, flat-celled cancer; in the latter, cylindrical-celled. Many pathologists class the former with "cancroid" disease, because it appears to be less malignant than true cancer. Indeed, if removed early, the patient has a fair prospect of future exemption from the disease, but in neglected cases it assumes the malignancy and other dreadful characters of true cancer. The lips, especially the upper lip, are the most frequent seat of epithelioma, but it may attack even internal organs. Histologically, it is composed of epithelial elements. See CANCER. Revised by WILLIAM PEPPER.

Epithe'lium [Mod. Lat. from Gr. ἐπί, upon + θηλή, nipple, used in sense of Lat. *papilla*, pl. *papillae*, i. e. of the skin]: in anatomy, the layer of cells which line the mucous (or open) cavities of the body, the mucous epithelium being continuous with the epidermis, which is also a form of epithelium.

Epithelium is of various kinds, according to the shape of the cells, thus: squamous or flat cells, cylindrical cells, cuboidal cells, etc. A peculiar variety of cylindrical is the "ciliated epithelium," which is provided with fine hair-like processes (cilia), whose length varies from $\frac{1}{1000}$ to $\frac{1}{12000}$ of an inch. These cilia have a rapid automatic motion in one direction, moving from 150 to 250 times in a minute. These motions are no doubt highly important in physiology, but their mechanism is little understood. In some instances these motions obviously assist in discharging excretions, etc., but in others their use is quite unknown. The epithelial cells have a very important part in the secretion of many fluids. For example, mucus is formed by the bursting of epithelial cells and the discharge of their soft contents, mingled with the *débris* of the old cell-walls. This process of destruction is attended by continual renewal of the cells.
Revised by WILLIAM PEPPER.

Epithet [from Gr. ἐπίθετος, -ον, attributed; ἐπί, upon + θεῖναι, put]: a word or clause which expresses some attribute of an object that is prominent in thought, but is not made the basis of a discrimination or classification; e. g. "*Frail* man is mortal"; "Earthly pleasures, *which are fleeting and unsubstantial*, are not the highest for man." Used in opposition to definitive (from Lat. *definire*, to define, to mark out the *fines* or boundaries), by which we understand a word or clause which expresses some attribute that *is* made the basis of a discrimination or classification; e. g. "*Good* men [i. e. only good men] are a blessing to the community"; "Those pleasures *that are from the earth* are not the highest for man."

Great care should be taken that epithets be not too frequently employed, and that there be something in the thought to which they actually and exactly correspond. The felicitous employment of epithets is one of the attributes of genius which gives to literature its highest charm; as in Milton's

Drew iron tears down Pluto's cheek.

Epitome, ĕe-pit'ō-mēe [Gr. ἐπιτομή, abridgment, deriv. of ἐπιτέμνειν, cut into, abridge]: in literature, an abridgment; a work in which the contents of a former work are reduced into a smaller space by curtailment and condensation. In the declining age of the Western Roman empire the practice of epitomizing the works of older writers, especially in history, became very prevalent. In several instances a valuable original work has been lost which perhaps would have been preserved if an epitome had not been substituted for it. Among the best-known works of this class are the epitome of Florus, *Epitome Rerum Romanarum*, and that of Eutropius, *Breviarum Historiæ Romanæ*, both abridgments of the history of Rome.

Epitro'choid [from Gr. ἐπί, upon + τροχός, wheel + suffix *-oid* (-οειδης), having the appearance of]: a curve traced by a point in the plane of a circle which rolls on the convex side of a fixed circle. The curve thus generated is one of the family of roulettes, and becomes an epicycloid when the generating point is in the circumference of the rolling circle. When the two circles are equal the epitrochoid becomes similar to the pedal of the fixed circle with respect to a certain fixed point in its plane. But the pedal being always the inverse of the reciprocal of the primitive curve, the epitrochoid in this case must be the inverse of a conic with respect to one of its foci, which latter is a curve of the fourth order, belonging to the Cartesian ovals, and called the *limaçon*. Epitrochoids are generally transcendental curves; it is only when the circumferences of the fixed and rolling circles are commensurable that the epitrochoid returns into itself and becomes an algebraical curve.

Epizo'a [from Gr. ἐπί, upon + ζῷον, animal]: animals, mostly arthropods, which are parasitic upon other animals. The term is one which refers to habits, and has no systematic value. J. S. K.

Epizoöt'ic [from Gr. ἐπί, upon, to + ζῷον, animal, the prefix *epi* being used to give force of temporarily prevalent in distinction from *enzoötic*; cf. *epidemic* vs. *endemic* of diseases among human beings]: a disease which attacks the lower animals, or any one species of them, as epidemics attack men. The term is objectionable, because, with some limitations, these diseases chiefly attack but one species, instead of all animals; and, moreover, as man is an animal, all epidemics are epizoötics. The so-called epizoötic diseases follow the general laws of epidemics, as they seem to attack especially the domesticated animals. Some diseases attack both man and the lower animals. Thus smallpox affects the horse, cow, and sheep, assuming in each a modified form. Among the more important epizoötic diseases are the rinderpest, the contagious pleuro-pneumonia, and the "foot-and-mouth disease" (all attacking neat cattle); the remarkable influenza which attacked horses and mules, arising in Canada, Sept. 30, 1872, and rapidly moving southward and westward over the whole of North America; the scab, foot-rot, and other diseases of sheep. The "reds," the *muscardine*, *pébrine*, and other diseases of the silk-worm have been the cause of serious calamities to operatives, and at times have almost threatened the existence of the silk manufacture.

The epizoötic influenza of 1872–73, above alluded to, destroyed, according to Dr. A. B. Judson, of New York, 1,500 horses and mules in New York, or 4 per cent. of the total number in the city. The disease reached Chicago Oct. 29, St. Louis Dec. 1, Salt Lake Jan. 11, 1873, and San Francisco Apr. 15. It is thought that the disease spread chiefly by contagion, and not by atmospheric influence.

E Plu'ribus U'num [Lat., intended to mean one composed of many]: the motto of the U. S. After the Declaration of their independence had been announced by the States on July 4, 1776, and before the adjournment of that day's session, it was resolved, "That Dr. Franklin, Mr. J. Adams, and Mr. Jefferson be a committee to prepare a device for a seal for the United States of America." The result of their joint work was the present seal of the U. S., which has not been changed since its first adoption. The six sections, or quarterings, upon the escutcheon or shield were intended to denote the countries (England, Scotland, Ireland, France, Germany, and Holland) from which the States so united had been, respectively, chiefly peopled. The motto adopted on this seal, and retained ever since, was intended to denote the character of the federal government in its formation.

Epode [from Gr. ἐπῳδός, sung after]: in ancient prosody, 1, (ὁ ἐπῳδός) the shorter, usually the second, verse of a couplet, as an iambic trimeter and dimeter; hence a poem consisting of such couplets, as the *Epodes* of Horace. Though the Elegiac Distich (*q. v.*) is epodic, elegies are not usually called epodes. 2, (ἡ ἐπῳδός) in Greek poetry, a lyric system like a Strophe (*q. v.*), occurring after a pair of strophes (strophe and antistrophe), so that the three sometimes form a compound unit, called a *triad*. All the odes of Pindar, some lyric fragments, and some choric odes of the drama contain epodes. Milton W. Humphreys.

Epping: town of Essex, England; at the north end of Epping Forest; 16 miles N. N. E. of London (see map of England, ref. 12–J). It is noted for its cream, butter, and sausages. Epping Royal Forest, formerly Waltham Forest, covers 60,000 acres, but was once much more extensive, covering the whole of Essex almost to the very gates of London. Now only 13,000 acres are in woods and wastes, and the rest is inclosed as private property. It was formerly the seat of a famous fair held every year around Fairlop Oak, and of a stag-hunt held on Easter Monday. In the midst of the forest Queen Elizabeth's hunting lodge is still standing. Pop. 2,500.

Epsom: market-town of Surrey, England; 14 miles by railway S. S. W. of London (see map of England, ref. 12–J). It has mineral springs containing sulphate of magnesia, which derives from this place the name of Epsom salt. They were first discovered in 1618, and for some time drew great numbers of visitors to the town. Charles II. and Prince Jörgen, of Denmark, the spouse of Queen Anne, often resorted to them. Gradually, however, they were deserted. Epsom has a royal medical college, and is famous for its horse-races, which are held yearly on the Downs, $1\frac{1}{2}$ miles S. of the town. The races last four days, one of which is called Derby Day, and are more numerously attended than any other races in the kingdom. They were permanently established in 1730. Pop. (1891) 8,417.

Epsom Salt (in Lat. *magnesiæ sulphas*—i. e. sulphate of magnesium; Germ. *Schwefelsaure Magnesia*): the magnesium sulphate ($MgSO_4.7H_2O$), a salt, when pure, usually found in colorless acicular crystals derived from the right rhombic prism, and containing 51·22 per cent. of water of crystallization. It is somewhat efflorescent, for at 32° F. water will dissolve over one-fourth its weight of the anhydrous salt, and as the temperature is raised the solubility increases. The salt was formerly manufactured from the waters of the mineral spring of Epsom, England. It also exists largely in sea-water, from which it was formerly prepared in large quantities. In Italy it is prepared from a schistose rock; in England from dolomite; in Pennsylvania and Maryland from magnesite. This salt is used in medicine as a cooling and generally safe cathartic. The dose is from half an ounce to an ounce in a glass of water. It is nauseous to the taste, but may be easily taken in "soda-water," with lemon sirup. In the household it is an excellent addition to starch, decidedly increasing its stiffening powers. Mixed with ordinary whitewash, it gives a fine pearly whiteness to walls.

Epworth League: a voluntary organization composed of young people of the Methodist Episcopal Church; having for its object the promotion of piety in its members and their development along social, intellectual, and religious lines. It was organized at Cleveland, O., May 14 and 15, 1889, at a convention of the representatives of five general young people's societies of the Methodist Episcopal Church. Its headquarters are at Chicago, where also is published weekly *The Epworth Herald*, its official organ. The league has now (1901) 5,838 chapters and 306,580 members. It was officially adopted and indorsed by the General Conference at Omaha, May, 1892. The Methodist Church of Canada and the Methodist Episcopal Church South have adopted the Epworth League for their work among young people. See Christian Endeavor, Young People's Society of.

John F. Hurst.

Equation [from Lat. *æqua'tio*, a making equal]: in algebra, a statement that two quantities having different algebraic expressions are equal. The equality is expressed by writing the sign = between the expressions asserted to be equal. Each of the equal expressions is called a member of the equation. Equations are of two kinds—identical and conditional. An *identical* equation is one in which the two expressions must be equal from their very nature or meaning; as, for example, $3 + 3 = 6$ and $(a + b)^2 - 2ab = a^2 + b^2$. In either of these equations the two members are equal because they express the same quantity in different ways, and so remain equal whatever values we assign to the quantities. *Conditional* equations are those in which the two expressions are not equal for all values of the quantities, but which imply certain relations between them. For example, if we have the equation $x + y = 6$, this equation is not true from the nature of the case, nor is it true for all values of x and y. It is true only on condition that the quantities x and y are so chosen that their sum shall be 6. It is because of this that such equations are called conditional.

Equations, Theory of.—The theory of equations is that branch of algebra which treats of the equations called algebraic, namely, those which can be reduced to the form

$$x^n + ax^{n-1} + bx^{n-2} + cx^{n-3} + \text{etc.} = 0,$$

x being the unknown quantity, n a positive integer, and a, b, c, etc., any coefficients whatever which do not contain x. The roots of such an equation are those special values of x which, being substituted in the equation, will satisfy it by reducing the algebraic sum of its terms identically to zero.

The degree of an equation is the exponent, n, of the highest power of x. Equations of the second degree are called quadratic, of the third cubic, of the fourth quartic, or biquadratic, etc. The fundamental theorem of the subject is that the roots of every such equation are equal in number to the exponent, n, of the highest power of the unknown quantity which enters into it. But two or more of the roots may be equal.

The principles involved in such equations, the relations between their roots, and the possibility of expressing a root algebraically in terms of the coefficients, have been developed into a most extensive and interesting branch of mathematics. The solution of an algebraic equation consists in finding an expression for x which, being substituted in the equation, will satisfy it. The possibility of a solution will depend on the nature of the equation. One in which the coefficients of the powers of x, which we have called a, b, c, etc., are all separate and independent quantities, is called a *general equation*. General equations are classified according to their degree, as just defined. It was long since found that the general equations of the second, third, and fourth degrees admitted of being solved. But the equation of the fifth degree defied all the efforts of the mathematicians who attacked it. At length, early in the nineteenth century, it occurred to the illustrious Abel to inquire whether a solution was possible. By a profound analysis he succeeded in demonstrating the proposition that the solution of the general equation of the fifth degree was impossible;

that is to say, that no possible algebraic expression could be formed which, being substituted for x in the equation, would satisfy the latter. Thus the question is forever set at rest. But it is possible to write special equations of the fifth or higher degrees which admit of being solved. The conditions under which this may be done are now well understood, but belong to the highest branch of algebra. See SUBSTITUTIONS, THEORY OF.

The solution of equations of the third and fourth degree is effected as follows:

Solution of the Cubic Equation.—Let the equation be

$$x^3 + ax^2 + bx + c = 0. \qquad (1)$$

Replace x by a new quantity, x', thus:

$$x = x' - \tfrac{1}{3}a. \qquad (2)$$

By this substitution the second term of the equation will disappear, and the latter will be reduced to the form

$$x^3 + px + q = 0, \qquad (3)$$

p and q being simple functions of a, b, and c, and the accent being omitted from x'.

In this equation put for x the sum of two quantities, to be afterward determined:

$$x = y + z. \qquad (4)$$

We then have

$$(y + z)^3 + p(y + z) + q = 0,$$

or

$$y^3 + z^3 + (y + z)(3yz + p) + q = 0. \qquad (5)$$

Let us now determine the quantities y and z, so as to satisfy the condition

$$3yz + p = 0. \qquad (6)$$

We then have

$$z = -\frac{p}{3y}, \qquad (7)$$

and by substituting this value of z in (5)

$$y^6 + qy^3 - \frac{p^3}{27} = 0. \qquad (8)$$

This equation may be solved by quadratics, so as to give the value of y^3 from which z^3 is found by (7). Then extracting the cube roots we have the values of y and z, which, being substituted in (4), will give the value of x as follows:

$$x = \sqrt[3]{\frac{-q}{2} \pm \mathrm{R}} + \sqrt[3]{\frac{-q}{2} \mp \mathrm{R}},$$

where we put, for brevity,

$$\mathrm{R} = \frac{q^2}{4} + \frac{p^3}{27}.$$

Solution of the General Equation of the Fourth Degree, or Biquadratic Equation.—Let the equation be

$$x^4 + px^3 + qx^2 + rx + s = 0. \qquad (1)$$

We may reduce this equation to the form

$$(x^2 + \tfrac{1}{2}px)^2 = \left(\frac{p^2}{4} - q\right)x^2 - rx - s, \qquad (2)$$

which it will be seen is equivalent to the original one. We have now to add to both members of this equation such a quantity as shall make them perfect squares. In order that the first member may thus be made a perfect square, the quantity to be added must be in the form

$$2(x^2 + \tfrac{1}{2}px)y + y^2, \qquad (3)$$

which will make the first member a square, no matter what the value of y. We must afterward choose y so as to make the second member a perfect square. This member will become

$$\left(\frac{p^2}{4} - q + 2y\right)x^2 + (py - r)x + y^2 - s. \qquad (4)$$

Imagine this equation written in the form

$$\mathrm{A}x^2 + \mathrm{B}x + \mathrm{C} = 0. \qquad (5)$$

The condition that it shall be a perfect square is

$$\mathrm{B}^2 - 4\mathrm{AC} = 0. \qquad (6)$$

or

$$(py - r)^2 - 4\left(\frac{p^2}{4} - q + 2y\right)(y^2 - s) = 0.$$

This is a cubic equation in y, which can be solved by the method of cubic equations. With this value, the second member of (2), with the expression (3) added to it, will become a perfect square, while the first member will be the square of

$$x + \tfrac{1}{2}px + y,$$

and thus the equation will admit of solution.

The actual algebraic expressions which enter into the solution are too complicated to be written here.

S. NEWCOMB.

Equation of Time: the difference in mean solar time between the sun's apparent or true right ascension and its mean right ascension; or, in other words, the difference between sun time and clock time. This difference arises—(1) from the sun's unequal motion in longitude because of the eccentricity of the earth's orbit; (2) from the obliquity of the ecliptic; and (3) to some small extent from the perturbations of the moon and planets. Sun time and clock time agree about Dec. 25, Apr. 16, June 16, and Sept. 1. The equation of time is greatest about Nov. 1, when the clock is sixteen minutes and sixteen seconds faster than the sun. See TIME.

Equation, Personal: the constant which must be applied to every time observation recorded by an observer (as in astronomy) in order to make the mean of such observations agree with those of another observer. It is found by experience that different persons, in recording the results of observations, will make various errors, some anticipating the event, but others failing to record it at the proper time. When it is found possible, by examining a long series of records made of the same events by two observers, to discover the average difference between their records of events, a very important correction of time-intervals may sometimes be introduced into a computation based upon such records. Such a correction is called the relative personal equation of the two astronomers. When it is found that an observer habitually makes, or is likely to make, a certain error in his time-records, such error (or absolute personal equation) can be readily allowed for.

Equator [Lat., an equalizer, deriv. of *æqua're*, to make equal]: in geography, a great circle of the terrestrial sphere which is equidistant from the two poles, and divides the earth into northern and southern hemispheres. Latitudes are counted from the equator along the meridian, and longitudes are measured on the equator or on some circle parallel with it. See EARTH.

EQUATOR, in astronomy, is the great circle of the celestial sphere, of which the plane is perpendicular to the axis of the earth's diurnal motion. It is called the equator because when the sun is in its plane the days and nights are exactly equal all over the world. The equator divides the sphere into northern and southern hemispheres, and is often styled the *equinoctial*. The apparent diurnal motions of all the celestial bodies are performed in circles which are parallel to it. The right ascensions are measured on it.

Equatorial Telescope: a telescope mounted upon a fixed axis parallel to the axis of the earth, and turning also upon a second movable axis parallel to the equator, for the continuous observation of heavenly bodies, and for noting their right ascension and declination. The motion of the telescope round its fixed or "polar" axis is necessarily parallel to the equator, and this gives the instrument its name. In order to maintain the object observed steadily in the field of view, the telescope is made to revolve round the polar axis by an attached clockwork, which admits of being regulated so as to vary the volocity of rotation, according as the object under examination is the sun, the moon, a planet, or a fixed star.

Equestrian Order, also called **Knights**: an important division of the citizens of ancient Rome. They were originally a military organization, and formed the cavalry of the Roman army. According to Livy, Romulus constituted three centuries (300) of equites, to whom he gave the several names of Ramnenses, Titienses, and Luceres. Down to the year 123 B. C. the equites formed simply a division of the army, and their centuries were composed of patricians and plebeians, but C. Gracchus in that year procured the passage of the *Lex Sempronia*, which instituted a new class or political order called *ordo equestris*, from whom all the *judices* (judges) must be selected. The reform of Sulla deprived them of the sole right of being chosen as judices, who thenceforth were selected from the senators, equites, and *tribuni ærarii*. The equites also enjoyed the privilege of officiating as *publicani* or farmers of the public revenue. According to Cicero, who belonged to this order, these publicani "comprised the flower of the Roman chivalry, the ornament of Rome, the firm support (*firmamentum*) of the republic." The badges of the equites were a gold ring and a robe with a narrow purple border.

Equestrian Statue: a complete figure of a person on horseback, executed generally in bronze or stone. In ancient Greece, where plastic art attained its highest perfection, statues of men and horses were often of the first excellence; but horses were more commonly represented as attached to the chariot. In Rome, equestrian statues of the emperors were common. The finest extant Roman work of the kind is a bronze equestrian statue of M. Aurelius Antoninus. Two remarkable statues of this kind have come down to us from the time of the Renaissance—that of Bartolomeo Colleoni at Venice, by Verrocchio and Leopardi, and that of Gatamelata, at Padua, by Donatello. Among the famous modern equestrian works are the noble colossal statue of Peter the Great at St. Petersburg, and that of Frederick the Great at Berlin, by Rauch.

Eq'uidæ [from Lat. *e'quus*, horse]: the family of which the genus *Equus* (including the horse, ass, etc.) is a type, and which is a section (*Solidungula*) of the order *Ungulata*. The most characteristic feature of the *Equidæ* is the solid, one-toed foot formed by the union of the central phalanges and the atrophy of the lateral ones. Single-toed horses began in the Pliocene. In the Miocene epoch horses were represented by *Hipparion*, etc., which had two small lateral toes or hoofs, of which some traces may be often found in living horses. In the Lower Miocene *Anchitherium* represents the *Equidæ*, and connects the horse with *Palæotherium*, *Pliolophus*, etc., of the Eocene and with the tapirs of the present day. The genealogy of the *Equidæ* is better known and more instructive than that of any other group of mammals. Nearly twenty species of equine quadrupeds have been described from the Tertiary and Quaternary deposits of America, but it is supposed that no horse existed in the New World at the time of the advent of the Europeans. See HORSE and HIPPARION.

Equilateral [from Lat. *æ'quus*, equal + *latus*, *-eris*, side]: having equal sides. In geometry, a rectilinear figure is said to be equilateral when all its sides are equal. If, moreover, its angles are all equal, it is called *regular*. Every equilateral figure inscribed in a circle is equiangular, and therefore regular. The converse theorem, however, is true only for polygons with an odd number of sides. An equilateral hyperbola is that of which the axes are equal.

Equilibrium [Lat. *æquili'brium*; *æquus*, even + *libra*, scale]: the state of rest produced by two or more mutually counteracting forces; equipoise. Equilibrium is the foundation of the theory of mechanics; it is, in its generalized meaning, *the physical law of the universe*. EQUILIBRIUM, in the fine arts, is the just place or balance of a figure or other object, so that it may appear to stand firmly. Also the due equipoise of objects, lights, shadows, etc., against each other.

Equinoctial: See EQUINOX.

Equinoctial Points: the two opposite points of the celestial sphere in which the ecliptic and equator intersect each other, the one being the first point of Aries, and the other the first point of Libra. These points do not retain a fixed position in relation to the stars, but retrograde from E. to W. with a slow motion, requiring 25,000 years to accomplish a complete revolution. This motion is called the PRECESSION OF THE EQUINOXES (*q. v.*).

Equinox [from O. Fr. *equinoxe* < Lat. *æquinoc'tium*; *æquus*, equal + *nox*, night]: in astronomy, the time when the sun passes through the equator in one of the equinoctial points. When the sun is in the equator the days and nights are equal all over the world, hence the derivation of the term. This happens twice every year—viz., about Mar. 21 and Sept. 22; the former is called the *vernal*, and the latter the *autumnal* equinox. The equinoxes do not divide the year into portions of equal length, but the interval from the vernal to the autumnal equinox is greater than that from the autumnal to the vernal; in other words, the sun continues longer on the northern than on the southern side of the equator, because it is more distant from the earth in our summer than in winter, and its angular motion in its orbit is consequently slower between March and September than in the other part of the year. In 1800 the difference amounted to seven days, sixteen hours and fifty-one minutes.

Equiseta'ceæ [from EQUISETUM (*q. v.*), the only genus]: a family of cryptogamous plants, with hollow and jointed stems, growing in ditches, wet ground, and rivers in many parts of the world. They are related to the ferns and the extinct Calamites. They are found fossil in coal, and were in ancient geologic periods very much larger and more numerous than at present. This family is now the sole representative of the single surviving order (*Equisetaceæ*) of the class *Equisetinæ*, the lowest class of the great division of the vegetable kingdom known as the fernworts (*Pteridophyta*). See FERNWORTS and PLANTS, FOSSIL.

Revised by CHARLES E. BESSEY.

Equise'tum [Lat. *equisetum*, the horsetail; *equus*, horse + *sæta*, *sēta*, bristles, coarse hair]: a genus of plants of the family *Equisetaceæ*, comprising numerous species called horsetail. The fructification is in the form of a spore-bearing cone at the summit of the stem. The *Equisetum hyemale* (scouring rush) is indigenous in the U. S. and also in Europe. The abundant silica in its cuticle renders it useful for polishing furniture and for scouring utensils. The U. S. have also several other species. True Equiseta date back to the Triassic, when they were numerous, and attained the height of 20 feet. In the Carboniferous rocks the Equiseta are represented by *Equisetites*, as well as by the related *Calamites*, *Calamodendron*, etc. Revised by CHARLES E. BESSEY.

Equites: See EQUESTRIAN ORDER.

Equity [from Lat. *æ'quitas*, equality, fairness; deriv. of *æquus*, even]: a portion of the mass of English jurisprudence, derived from the decisions of courts and the rules of approved text-writers. It originated in the same general way as that branch of jurisprudence technically called "common law." It is, in a sense, common law itself when considered in contrast with statutes. The relation of equity to common law can be best understood by a brief historical survey. After the Norman conquest of England the king was deemed to be the fountain of justice. Ultimately, certain great courts of general jurisdiction came into active operation, known as "king's courts." These were the common pleas, the king's bench, and the exchequer. At first, their functions were quite distinct, but in course of time, by fictions of law, jurisdiction was assumed, so that in some respects it became concurrent in these tribunals. The regular mode of bringing a question before one of these courts for adjudication was by an action, in which there was a plaintiff and a defendant. A formal statement of the plaintiff's claim and of the defendant's defense was made in written allegations termed pleadings, and the question thus raised was called the issue. A judge and jury disposed of issues of fact. The action must be commenced by a so-called *writ*, purporting to emanate from the king and addressed to the sheriff, who caused the defendant to be brought before the court. There was an office in chancery, from which the writs issued. They were framed in a technical manner. The clerks would only grant a writ when they could find a precise precedent in their office. Actions were real, personal, or mixed. A real action was adapted to the recovery of land; personal actions were used to recover money; and the two were combined in a mixed action. The personal actions were framed on the theory either of contract or wrong (technically called tort). Originally, they were debt, covenant, and detinue in cases of contract; and in case of tort, trespass, trover, and replevin. The object of the action of debt was to recover a specific sum of money due to the plaintiff. The action of covenant was brought upon an instrument under seal. "Detinue" was resorted to in order to recover a specific chattel which the defendant had received as a bailee. The action of trespass was instituted for an immediate and direct injury to person or property; trover was the appropriate means to recover the value of personal property wrongfully converted by the defendant; while replevin was used to recover the property itself.

It was found at an early day that the personal actions were quite insufficient to give full relief. A statute was enacted in 13 Edw. I. (ch. 24) which led to the introduction of a new form of action, termed "trespass on the case." This was a comprehensive name for all actions for wrongs where the injury was indirect and consequential, as in the case of negligence. It also included many cases now recognized as strictly actions upon contract, and called "assumpsit." If this statute had been wisely interpreted, no court of equity would have been necessary, nor would any probably have arisen. But the judges of the so-called common-law courts adopted very strict and narrow rules of construction, and confined the remedy under the statute to the same kind of relief as had been already recognized. All the relief granted in these courts may be summed up in a single phrase: one can recover money only or specific real or personal property. As society advanced in wealth and civilization, such a system of remedial justice was lamentably imperfect. Out of its imperfection grew the jurisdiction of courts of equity. The residuum of justice not granted to the common-law courts remained in the king. It became a practice to address petitions to him in particular cases for relief, which those courts could not grant. These were referred to the privy council, a powerful body of men selected by the monarch for their wealth or capacity. In process of time the disposal of these petitions devolved upon one of their number, the lord chancellor, who was a great officer, and who had usually the legal training which would fit him to dispose of the important questions submitted to him. Such matters were not presented by writ, as in the common-law courts, but by an application in the nature of a petition; and this commonly closed with the stereotyped phrase that the petitioner, having no sufficient remedy at common law, asked for relief "for the love of God and in the way of charity." At an early day the chancellor devised a writ, called a writ of subpœna, whereby a party to a suit could be compelled to disclose upon his oath facts bearing upon the controversy between him and the opposite party. This is called "discovery." No such power inhered in common-law courts. In this way the court of chancery became a regular tribunal for the administration of justice. It followed precedent, and has worked out a scientific system of equity jurisprudence. It has now become so bound down by rules that new principles can be introduced only by legislation. This point is treated in a masterly manner by Maine in his work on *Ancient Law*. It should be remarked that other courts besides the court of chancery acquired equity jurisdiction. Thus the court of exchequer had until modern times equity powers. There may thus be courts of *equity* which are not strictly courts of *chancery*.

When English jurisprudence had assumed a precise and fixed character, there were thus two sets of tribunals, called respectively courts of common law and courts of equity. In some cases the jurisdiction of the two courts was concurrent; in others the equity court had exclusive authority, as in the case of trusts. The courts differed in three principal respects; two of these were in matters of procedure, while the third distinction was radical and substantial. They differed as to the mode of proof and of trial, and in respect to the nature of the relief granted. The first two distinctions have been largely modified in the U. S. in a considerable number of the States. In these law and equity are administered by a single court and under the same system of pleading, so that there is no distinction between an action at law and a suit in equity. Even in these States the difference in relief still continues. When the action is for the recovery of money only, or of specific real or personal property, a writ issues to the sheriff to carry the judgment into effect. In other (or equity) actions, as when a defendant is required to execute or cancel a written instrument, or to refrain from doing an act, the order of the court is directed to him; and if he willfully disobeys it, he may be punished for contempt of court. This consolidation of law and equity was first attempted in a code of procedure adopted in New York in 1848. This has been substantially enacted in a number of other States, and has had much effect upon legal opinion in England. Courts of equity have adopted certain maxims which have had a large influence on the development of the system. They are such as these: (1) Equity follows the law; (2) He who comes into equity must come with clean hands; (3) He who asks equity must do equity; (4) Where the equities are equal, the legal title must prevail; (5) Equality is equity; (6) Equity regards that as done which ought to be done.

A brief exposition of a few of these maxims will show the principles which guide the action of the court. The maxim that "he who comes into equity must come with clean hands" does not refer to general moral delinquency. It only applies to the subject before the court. It then assumes a comprehensive meaning. Under it the court would not protect the copyright of an immoral book, or a trademark which was so used as to deceive the public. The maxim that "he who asks equity must do equity" means that the court will grant relief to a plaintiff only upon the condition that he will render justice to the defendant. For example, a borrower could not succeed in setting aside an instrument on the ground of usury, except upon the condition of paying to the creditor the debt and lawful interest. The maxim that "where the equities are equal, the legal title must prevail," means that the court will not, on the application of a plaintiff, deprive a defendant, being a purchaser for a valuable consideration, of a title recognized in a court of common law, unless he has acted in bad faith or with notice of the existing rights of the plaintiff. An illustration will show its application. If A has taken an informal mortgage upon land, and accordingly one not valid in law, and yet a good claim in equity, and B, without notice of A's rights, has taken for a valuable consideration a subsequent regular or formal mortgage or conveyance, B will have superior legal rights, which will be recognized in a court of equity. If B had acted with notice of the informal mortgage, A's equity would have been superior. The rule that "equality is equity" is applied to persons who ought to bear a common burden equally, as in case of the duty of co-sureties to contribute equally to pay the debt for which they are bound, or in cases of general average in the law of shipping. It is the principle which underlies the distribution of assets among creditors in cases of bankruptcy, or in the administration of the estates of intestates. The rule that "equity regards that as done which ought to be done" is one of great importance. It leads to a doctrine peculiar to this court, known as "equitable conversion." This phrase means that the owner of property, by the mere expression of his will according to legal rules, can change its legal character, and thus give to money the qualities of land, or to land those of money. Thus if a testator orders his land to be sold and converted into money, the land from the moment of his death is deemed to be personal property. The same result would follow if he had directed money to be laid out in land. So, if an owner of land contracts to sell it, his interest before any conveyance is made is deemed to be money, while that of the purchaser is regarded as land. This doctrine is attended with important practical consequences, to which the limits of this article do not permit a reference.

It is an important rule that the jurisdiction of this court attaches to the person of a litigant, without reference to the situation of the property in controversy. Thus the court of chancery in England might order a defendant within its jurisdiction to execute a conveyance of land situated in the U. S. It would proceed upon the theory that he was under a legal duty or obligation to do the act which as a matter of conscience he was bound to perform. The court was at one time termed a "court of conscience," and in the older law digests or abridgments the equity law is placed under that head. It should be added that mere gratuitous executory promises are not enforceable in this court. Attention is only paid to the claims of purchasers for a valuable consideration.

The topics of equity jurisprudence are usually considered by text-writers in their relations to the jurisdiction of the courts of common law. In this aspect equity jurisdiction may be regarded either as auxiliary to the jurisdiction of those courts, or as concurrent or exclusive. This method is necessarily discarded in those States where law and equity are administered under a uniform system of pleading and practice, as in New York. The principal subjects may be enumerated under the following heads: Cases of accident or mistake (as where a clause is omitted from an instrument by accident); cases of fraud, either actual or constructive; specific performance of contracts (e. g. requiring a party who has promised to execute a conveyance to fulfill his contract); cases of interpleader, whereby a mere stakeholder can be relieved from the results of a litigation; cases of accounts, including a variety of instances; cases of trusts, whether created by express words or arising from implication of law. The court also protects all persons under actual or legal disability, such as infants, married women, and persons of unsound mind. Under these and other heads the court may cancel, modify, or reinstate instruments, and in general adjust the rights of the respective parties to the controversy. In some of these cases actions may be brought in a court of law. Thus in case of fraud, if the injured party desired pecuniary damages, he would bring his action at law; if he desired to set an instrument aside, he would proceed in equity. A person who would have a good defense on the ground of fraud to an action at law may in some instances become plaintiff in equity, and have the instrument canceled, as in the case of a negotiable promissory note. The most extensive of all of these topics is the subject of trusts. Strict trusts are solely cognizable in this court.

The remedies in this court are flexible and readily adapted to the exigencies of the case. The most liberal rules prevail as to parties. Every person can be made a party whose presence is necessary to a complete determination of the matter in controversy. The court has power to prevent apprehended injuries to property by means of an injunction, or to place the property itself in the possession of one of its own officers, termed a receiver, until the rights of the parties are finally established.

The tendency of modern times would seem to be to blend the two systems of common law and equity jurisprudence into one, when the common law will prevail as *modified* by the rules of equity. T. W. Dwight.

Equity of Redemption: the right which the owner of mortgaged property has to redeem it after the condition of the mortgage has been broken. A mortgage is in form a conveyance of property, with a provision that it shall be void on the performance by the maker, within a given time, of a certain condition, usually the payment of a sum of money; and by the common law, if the condition is not performed the conveyance becomes absolute, and the maker of the mortgage, called the mortgagor, loses all right to the property. But the English court of chancery, an equity tribunal, as early as the reign of Charles I. asserted its power to remedy this hardship by compelling the mortgagee to give up the land on payment of the debt with interest. This right in equity to redeem the property after the conveyance has become absolute at law has in modern times come to be regarded as an estate in the land, and can be conveyed or mortgaged or devised by its owner. It passes by descent to his heirs; it is liable for the debts of his creditors, and can be sold on execution against him, and is subject to dower and curtesy. This right to redeem lasts till cut off by foreclosure of the mortgage, which is usually effected by an action in a court of equity. The foreclosure may result in giving a complete title to the mortgagee (called a *strict* foreclosure), or it may result in a sale of the premises and the payment of the debt out of the proceeds, the surplus being returned to the mortgagor or to those who claim under him. The right to redeem from the mortgage extends to all who acquire an interest in the land under the mortgagor after the making of the mortgage; and all such persons must be made parties to a proceeding to foreclose the mortgage, otherwise their right to redeem will not be affected. Formerly, unless restrained by some clause in the mortgage, the mortgagee could at once take possession of the premises, although equity compelled him to account for the rents and profits upon redemption. Now, however, the mortgagor has in general the right of possession till the condition is broken, and in some parts of the U. S. till foreclosure, except when after default, where the security is inadequate, a receiver is appointed to take charge of the property under the direction of the court. T. W. Dwight.

Equus: the typical genus of the family Equidæ (*q. v.*).

Era, Christian: See Christian Era.

Era of Martyrs: See Diocletian Era.

Érard, *ā*'raar', Sébastien: an inventor and maker of musical instruments; b. in Strassburg, Apr. 5, 1752; son of a poor cabinet-maker. His first pianoforte, constructed in 1780, may be said to have introduced that instrument into France. He soon became the best pianoforte manufacturer in Europe, and in connection with his brother established a manufactory in London. To Érard the piano owes some of its noblest qualities as a musical instrument. The grand piano, with single and double action, was his invention. He built the great organ for the royal chapel of the Tuileries. Érard was also the inventor of a double-action harp which had immense popularity in London, and took out patents for many other improvements, all of which were of value. D. near Paris, 1831. See Pianoforte.

Erasis'tratus (in Gr. Ἐρασίστρατος): a Greek physician and anatomist; supposed to have been a native of the island of Ceos. He flourished about 300–260 b. c., and practiced for many years at Alexandria, where he taught anatomy and founded a school. His principal discoveries were those of the *viæ lacteæ* and the functions of the brain and nerves. A few fragments of his works are extant. See Surgery.

Erasmus, Desiderius: scholar and philosopher; b. at Rotterdam, Holland, Oct. 27–8, 1467 (or 1466). He was a son of Gerard de Praet of Tergouw and Margaret of Zevenbergen in Brabant, who were married all but in name, and was called in his childhood Geert Geerts (i. e. Geert's or Gerard's son), which name he exchanged for the Latin and Greek equivalents of Gerard, each signifying "the well-beloved." He attended from his ninth to his thirteenth year the school of the Brethren of the Common Life at Deventer, where he was a pupil of Alexander Hegius. Having become an orphan about 1478, he was urged by his guardians to enter a monastery, in order that they might defraud him of his patrimony. Although he regarded a monastic life with aversion, he was at length induced in 1482 or 1483 to enter the Augustinian convent of Steyn by the hope that he might there have opportunity for study. He pursued the study of the classics and distinguished himself as a Latin scholar. He became in 1492 a priest and secretary to the Bishop of Cambray, with whom he remained nearly five years, and in 1496 went to Paris, probably for the purpose of completing his education. He was then nearly destitute of pecuniary resources, and gained a subsistence in Paris by teaching school. Between 1498 and 1500 he passed about two years in England, where he formed friendships with Sir Thomas More and John Colet. He resided at both the universities, and during his third and longest visit (1511–14) was Professor of Greek at Cambridge. Impelled by a strong passion for travel, he visited various countries of Europe, and never remained long in one place. In 1506 he commenced a tour in Italy, where he passed several years, perfected his knowledge of the Greek language, and associated with the most eminent scholars. He obtained from the pope a dispensation from his monastic dress, and received the degree of D. D. at Turin in 1506. Ten years later he was absolved from his monastic vows. In 1511 he published *The Praise of Folly* (Encomium Moriæ), a witty satire, in which he exposed the follies and foibles of monks, priests, and men of various other professions. It was generally admired and obtained a large circulation (modern Eng. trans. London, 1878).

Having established his reputation as the most eminent scholar and the most witty writer of his time, he received invitations from several monarchs, and in 1514 visited the court of the Archduke Charles of Austria (afterward Charles V.), who gave him the title of royal councilor, with a pension of 400 florins, and liberty to travel or reside wherever he might prefer. He produced in 1516 a good edition of the Greek New Testament—the first edition ever published—with a corrected Latin version and notes. He was on friendly terms with Luther in the first stage of the Reformation, which he efficiently promoted by his witty satires against the monks and priests, and by his censure of the corruptions of the Church of Rome. But he disliked dogmatism, was too liberal and moderate to please the zealous supporters of either side in a religious controversy, and he dissented from some of the doctrines of Luther, who denounced him in severe terms as a coward and time-server.

Erasmus became a resident of Basel about the year 1521, and published there in 1524 his celebrated *Colloquia* (Colloquies; Eng. trans., 2 vols., London, 1878), which some consider his capital work. It is ostensibly intended for the instruction of youth in Latin and morals, but abounds in satire and invective directed against the monks and the abuses of the Roman Church. It is stated that 24,000 copies of it were sold in one year. He was involved in a dispute with Luther on the doctrine of free will in 1524, and wrote on that subject *De Libero Arbitrio* (1526). He was condemned as a heretic by the Sorbonne of Paris, but he persisted in maintaining the attitude of a neutral or mediator, and never formally revolted against the pope. In 1529 he removed to Freiburg, where he passed several years. He died, when on a visit in Basel, on July 12, 1536. Among his works is *Adagia* (Venice, 1508; Eng. trans., 2 vols., London, 1814), a collection of proverbs, which displays immense learning. He greatly excelled as an editor of the Greek and Latin classics, for which he was qualified by superior critical sagacity as well as accurate scholarship. He was pre-eminent as a restorer of classical learning and sound philosophy. His voluminous *Epistles* contain valuable materials for literary history. His complete works were published by Beatus Rhenanus (9 vols., 1541), and best by Leclerc (10 vols., Leyden, 1603–06). See his *Life* by R. B. Drummond (2 vols., London, 1873).

Revised by S. M. Jackson.

Erastians: a name originally applied to a distinct party in the Westminster Assembly (*q. v.*), headed by Selden, Lightfoot, Coleman, and Whitelocke, because they advocated the views of THOMAS ERASTUS (*q. v.*) with regard to church discipline. During the conflict in the Church of Scotland, which led to the establishment in 1843 of the Free Church, those who maintained that the Church had no power to nullify by law the operation of lay patronage were called by their opponents Erastians, but they protested against this use of the word. See R. I. Wilberforce, *A Sketch of the History of Erastianism* (London, 1857).

Revised by S. M. JACKSON.

Erastus, THOMAS, M. D.: physician and theologian, whose proper name was LIEBLER or LIEBER, which he Græcized; b. at Baden in Switzerland (according to others at Auggen, near Badenweiler, Germany), Sept. 7, 1524. He studied theology at Basel, philosophy and medicine at Bologna and Padua, became body physician to the Elector Palatine Otto Heinrich, and Professor of Medicine at Heidelberg 1558; Professor of Medicine at Basel in 1580, to which branch he added ethics in 1583. He wrote several medical treatises and was a skillful practitioner. As a natural philosopher, he opposed the alchemists and the school of Paracelsus, but defended the burning of witches. As a member of the Sacramentarian conferences held at Heidelberg in 1560 and at Maulbronn in 1564, he vindicated the Zwinglian doctrine of the Lord's Supper, and in 1568 he circulated in manuscript some theses opposing the use by Protestant churches of ecclesiastical censures and punishments, and insisting that the Church ought merely to decide who, on account of soundness of faith, were to be regarded as members, but should not take upon herself to punish moral offenses by withholding her privileges. He was unjustly charged with Socinianism and excommunicated (1570), and was not restored till 1575. His opinions were developed in a volume printed six years after his death, entitled *Explicatio Gravissimæ quæstionis utrum excommunicatio . . . mandato nitatur divino an excogitata sit ab hominibus* (Pesclav, Switzerland [really London], 1589; English translation, *The Nullity of Church Censures*, London, 1659; new ed. by R. Lee, *The Theses of Erastus touching Excommunication*, 1844). To it Beza replied in his *De Vera Excommunicatione et Christiano Presbyterio* (Geneva, 1590). Erastus died at Basel, Dec. 31, 1583. S. M. J.

Erato: See MUSES.

Eratos'thenes (in Gr. Ἐρατοσθένης): Greek astronomer and geometer, and the first scholar to bear the name philologian; b. at Cyrene in 276 B. C.; a pupil of Callimachus the poet. He became superintendent of the great library of Alexandria in the reign of Ptolemy Euergetes, and rendered important services to the sciences of astronomy and geography. He displayed great versatility of genius, and wrote numerous works on philosophy, history, grammar, etc. Among his memorable performances was the measurement of the obliquity of the ecliptic, which he computed to be 23° 51′ 20″. In an attempt to ascertain the dimensions of the earth he invented a method which has been employed with success in modern times. His writings are not extant, but fragments of his work on chronology have been preserved by Syncellus (published by Bernhardy, 1822). "Eratosthenes was," says Bunsen, "next to Aristotle, the most illustrious of Greek men of learning, and as far superior to him in the extent of his knowledge as inferior in grasp of intellect." D. about 196 B. C.

Erben, HENRY: See the Appendix.

Er'bium [from *Ytterby*, a town of Sweden, whence gadolinite is procured]: a rare dyad earth-metal, chiefly procured, as an oxide called *erbia*, from gadolinite, along with yttria, both earths existing naturally as silicates. Metallic erbium (symbol E; atomic weight, 112·6) has not been separated. Its salts have mostly a rose color.

Ercilla y Zuñiga, ăr-thēēl'yăă-ee-thoon-yee'găă, ALONSO: epic poet; b. in Madrid, Aug. 7, 1533; a son of Fortunio Garcia, lord of Ercilla. He was in his youth a page of Philip II., whom he accompanied on a voyage to England in 1554. Having enlisted in the army, he went to South America in that year to fight against the Araucanians, a warlike tribe whom the Spaniards were never able to subjugate. He served with distinction in this war, returned to Spain in 1562, and published his *Araucana* (first part, 1569), which is considered the best heroic poem in the Spanish language, and is said to be a faithful narrative of the events which he had witnessed. He was afterward a gentleman of the bedchamber to the Emperor Rudolph II., but appears to have passed his latter years in poverty and obscurity. D. in Madrid, Nov. 29, 1594. See Ticknor, *History of Spanish Literature*.

Erckmann-Chatrian, ărk'măăn-shăă'tri-ăăn': the names of two French novelists whose works for many years were jointly produced, and whose names, like those of Beaumont and Fletcher, are inseparably united. ÉMILE ERCKMANN, b. at Pfalzburg, May 20, 1822, was the son of a bookseller, and after studying at the college of Pfalzburg applied himself to reading law in Paris. ALEXANDRE CHATRIAN, b. at Soldatenthal, near Pfalzburg, Dec. 18, 1826, was an usher in the Pfalzburg College when he made the acquaintance of Erckmann in 1847. The two became fast friends, and composed numerous stories, *feuilletons*, and dramatic pieces without much success. Unable to live in this way, Erckmann applied himself to the law, while Chatrian found employment in a railway office. *L'Illustre Docteur Mathéus* (1859) was the first of their writings which attained any popularity; it was followed by *Contes fantastiques* (1860); *Madame Thérèse* (1863), etc. Their novels upon the events of the Revolution and the first empire, *Histoire d'un conscrit de 1813* (1864), *L'Invasion* (1865), etc., were much read, and after the German annexation of Alsace they produced a novel under the title of *Histoire du plébiscite racontée par un des 7,500,000 oui* (1872), which made a sensation. Also their dramas, *Le Juif Polonais* (1869) and *L'Ami Fritz* (1876), though only dramatizations of novels, were very successful. Their literary partnership came to an end in 1889, when a quarrel and lawsuit terminated their friendship. Chatrian died in Villemomble, Sept. 4, 1890; Erckmann in Berlin, Mar. 14, 1899.

Erdmann, ărt'măăn, JOHANN EDUARD: philosopher; b. at Wolmar, Livonia, June 13, 1805; studied at Dorpat and Berlin; became Professor of Philosophy at Halle in 1836. He wrote, among other works, *Versuch einer wissenschaftlichen Darstellung der Geschichte der neueren Philosophie* (3 vols., Leipzig, 1834–53); *Grundriss der Logik und Metaphysik* (Halle, 1841; 4th ed. 1864); and *Grundriss der Geschichte der Philosophie* (2 vols., Berlin, 1866; Eng. trans. ed. by W. S. Hough, 3 vols., London, 1890; 2d ed. 1893). D. at Halle, June 12, 1892.

Er'ebus [Gr. ἔρεβος, darkness : Sanskr. *rajas* : Goth. *riqiz-*]: in classic mythology, the son of Chaos; also a dark and gloomy region or subterranean cavern through which souls were supposed to pass after death.

Erebus, Mount, and **Mount Terror**: two volcanoes in South Victoria Land, in lat. 77½° S., discovered by J. C. Ross Jan. 27, 1841. Mt. Erebus, 12,400 feet high, is, as far as is known, the volcano nearest to the south pole, and when discovered was emitting flame and smoke. Mt. Terror, 10,900 feet high, is believed to be an extinct volcano. These two mountains were named from the British ships in which Ross's expedition sailed.

Erechthe'um (in Gr. Ἐρέχθειον): in ancient Athens a sacred edifice on the Acropolis, containing the temple of Athena Polias and several other shrines. Its name was derived from ERECHTHEUS (*q. v.*), and a part of it is thought to be the "house" or shrine of that hero. It was burned by the Persians, rebuilt about 393 B. C., and became the most sacred of all the Athenian sanctuaries. The renewed Erechtheum was a most beautiful structure of the Ionic order. Unlike other Grecian temples, it had three porticoes—one to the east and occupying the whole width of the main structure, the other two facing the north and south, somewhat like the transepts of a Mediæval church. How the west end was finished is not well understood. It anciently contained a salt-well made by Poseidon's trident, also the sacred olive-tree of Athena, and the olive-wood image of that goddess, which is fabled to have fallen from the sky. The ruins of the Erechtheum stand north of the Parthenon, and are among the most interesting relics of antiquity. The six caryatides (female figures, larger than life, gracefully draped and carrying capitals upon their heads) which supported the roof of the southern portico are particularly fine. One of these is in the British Museum, and its place is filled by a terra cotta copy.

Erech'theus (in Gr. Ἐρεχθεύς; Fr. *Érecthée*): a hero of ancient Greek legends; said to be a son of Vulcan or of Pandion, and the father of Cecrops. Homer represents him as a king of Athens. According to tradition, he was the founder of the Erechtheum, a temple of Minerva on the Acropolis of Athens. He was sometimes called *Erichthonius*.

Eremacausis: See FERMENTATION.

Ere'tria (in Gr. Ἐρέτρια; Fr. *Érétrie*): an ancient city on the island of Eubœa mentioned by Homer (*Iliad*, book ii.). At an early period it was a prosperous and independent state, and one of the chief maritime cities of Greece. It was captured and ruined by the Persians in 490 B. C., but was soon rebuilt. Eretria was the seat of a celebrated school of philosophy, founded by Menedemus about 330 B. C.

Erfurt, ār'foort, or **Erfurth** (in Lat. *Erphordia* and *Erfurtum*): town of Prussian Saxony; on the river Gera and the Thuringian Railway; 15 miles W. of Weimar and 14 miles E. of Gotha (see map of German Empire, ref. 5–E). It has an old Gothic cathedral with a bell which weighs 275 cwt., fourteen Protestant churches, a royal academy, a public library of about 60,000 volumes, a normal school, and an edifice formerly occupied by the University of Erfurt, which was founded in 1392 and closed in the year 1816. The Augustine convent of which Luther was an inmate for several years is now used as an orphan asylum. Erfurt has manufactures of silk, cotton, and woolen fabrics, hosiery, shoes, leather, etc. It was more populous in the Middle Ages than it is now. The Congress of Erfurt, held here in Sept.–Oct., 1808, was attended by Napoleon, Alexander I. of Russia, and several of the German princes. In Mar. and Apr., 1850, the so-called Union Parliament held its sessions here. See GERMANY. Pop. (1885) 58,385; (1895) 78,167.

Erg, ėrg: the absolute (C. G. S.) unit of work or of energy. It is the work of one dyne acting through a centimeter distance. The relation of the erg to the usual practical units of work and power is as follows:

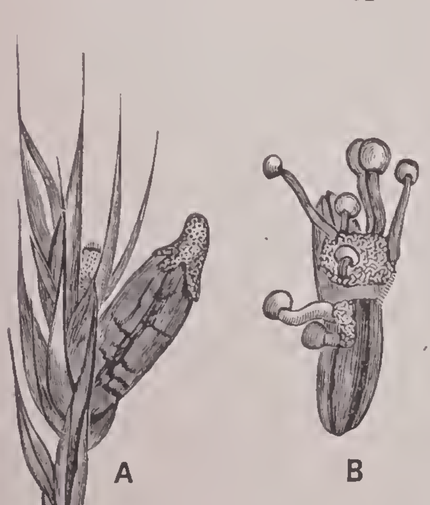
1 kilogrammeter = 100,000 g. ergs.
1 foot-pound = 13,825 g. ergs.
1 watt = 10^7 ergs per second.
1 horse-power = 746×10^7 ergs per second.
1 horse-power (French) = 736×10^7 ergs per second.

E. L. NICHOLS.

Erg: the most northern of the areas of sand wastes in the Sahara Desert. These sand regions are called by various names by the tribes around them. Those just S. of Algeria are called Erg or Areg, and divided by the Wadi Mia into East and West Erg. The East Erg is the best known sand region of the Sahara. Singing sands are found in the Erg, and in many places the sand is heaped into great dunes. See Duveyrier, *Le Pays Touareg*. C. C. ADAMS.

Ergograph: See RECORDING APPARATUS, PSYCHOLOGICAL, in the Appendix.

Ergot, or **Spur** [Fr. *ergot*, a cock's spur; etymol. unknown]: a curious fungus, the compact mycelium of the *Claviceps purpurea* of Tulasne, growing frequently in the heads of rye (then often called spurred rye), though found on all grasses and some *Cyperaceæ*. It was long believed to consist of diseased kernels of rye, but microscopical examination shows that it has nothing at all in common with the rye, but, growing originally from the ovary, it naturally assumes something of the shape of the mould in which it grows.



Ergot: A, in head of rye; B, ergot germinating. In the little heads many spores are produced which serve to propagate the fungus.

Ergot is usually shaped somewhat like a cock's spur, and is from half an inch to $1\frac{1}{2}$ inches long. It contains alkaloids, ergotine and ecboline, sclerotic or sclerotinic acid, and several other compounds which are little understood, including an oil which appears to be inert, and mycose, a peculiar sugar.

Ergot is much used in medicine, especially for the purpose of exciting uterine contractions after the child's head is born. As a rule, it should never be administered except by persons skilled in its use. The contractions induced by ergot differ from the natural uterine effort, which is intermittent, with intervals of more or less perfect rest, while ergot causes a uniform and constant expulsive effort. In skilled hands it is a remedy of great value. Administered late in labor, it often prevents dangerous loss of blood, and it is further useful in some cases of menorrhagia and other hæmorrhages. It is also useful in vertigo, and probably in other diseases requiring treatment because of functional disorder of the muscular coat of the blood-vessels.

Revised by CHARLES E. BESSEY and H. A. HARE.

Ergotism: a disease or condition resulting from long-continued use of grain in which ergot is mixed. This condition is one which has been known from remote times, and most devastating epidemics of it have occurred in Europe. In America no cases have ever been observed; but it is said that in 1819 an epizoötic of this nature occurred among cattle in a part of New York, caused by ergot in the blue-grass crop. The symptoms of ergotism may be roughly classified in two groups, the nervous and the gangrenous, though cases usually present a mixed type. In the nervous form there is tingling and twitching, with later more or less spasmodic condition of the muscles, and as the disease grows more severe mental disturbances, delirium, stupor, and coma. At the same time various gastric disturbances manifest themselves, but especially ravenous hunger. Recovery may ensue, but not infrequently the patient is left palsied, or subject to habitual spasms, mental aberration, or even idiocy. In the gangrenous form intense itching and tingling of the skin, followed by appearance of a red or darkish spot on the extremities, and after this a form of dry gangrene, as a result of which the hands or feet may be lost, or death ensue.

The cause of ergotism lies in the consumption as food of rye or oats tainted with the ergot parasite, and in many cases it seems the lack of sufficient food played some part in the causation aside from the specific action of the ergot itself. In certain years, especially when the summer is cold and damp, the grain is more apt to be diseased than in other years. Nothing can be done in the way of treatment, except to maintain the strength and minister to the comfort of the patient. The medicinal use of ergot may lead to a form of acute poisoning in which vomiting, purging, and progressive loss of power play a part, but very few cases of chronic ergotism have arisen in this way.

WILLIAM PEPPER.

Er'ic XIV.: King of Sweden; b. Dec. 13, 1533; a son of Gustavus Vasa, whom he succeeded in 1560. He made overtures of marriage to Queen Elizabeth of England, to Mary Queen of Scots, and others, but finally married a Swedish peasant named Catharine Monsdotter. He was capricious, imprudent, momentarily insane, and always addicted to violent paroxysms of anger and cruelty. In his reign Sweden was involved in a war against Denmark. Several noblemen were unjustly put to death by his order. A conspiracy was formed against him by his own brothers and other nobles, who deposed him in 1568, and confined him in prison, where he died Feb. 16, 1577.

Ericsson, JOHN, Ph. D., LL. D.: engineer, naval constructor, physicist, and inventor; b. at Långbanshyttan, Sweden, July 31, 1803; fourth in descent from Magnus Stadig, a miner, who died in 1739. His father, Olof Ericsson, was a graduate of the gymnasium of Karlstad, and John received a thorough training in the studies fitting him for his profession, having the advantage of instruction by engineers sent by Thomas Telford from England to superintend the construction of the Göta Canal. In 1814 he was appointed a cadet of the Swedish Corps of Engineers, and in 1820 an ensign in the Swedish army, where he rose to the rank of captain. In the army he acquired valuable experience as an artillerist, and gained such skill in topographical drawing that while engaged in surveying and mapping Northern Sweden his labor was counted as that of two men. He showed precocious talent as an inventor, designing at the age of ten years a pump to drain the mines, and inventing before he reached his majority a machine for engraving and a flame-engine. The desire to find a larger field for his flame-engine induced him to resign from the army, and remove in 1826 to England, where he remained until Nov. 1, 1839, engaging in business there as a partner of John Braithwaite. He made use of surface condensation as applied to steam in Sir John Ross's arctic vessel the Victory in 1827. In 1828 he employed compressed air to convey power to a Cornwall tin-mine lying off the shore, and in 1829 he used artificial draught in a steam fire-engine designed by him and successfully tested in England and on the Continent. In the same year he applied artificial draught to his locomotive the Novelty, which entered the lists against Stephenson's Rocket in the famous contest at Rainhill in Oct., 1829, that opened the era of travel by rail. Leading engineers of that time placed on record the statement that the Novelty was the first engine that ever ran really fast, as it ran a mile in fifty-six seconds, and that it was long remembered as a beau-ideal of a locomotive. In 1832 Ericsson made the first use of the centrifugal fan-blower in the Corsair, and he used steam in many new and ingenious ways. In 1833 he patented a "caloric" engine with an "organ-pipe regenerator." This excited extraordinary interest in London, and laid the foundation for his future inventions in that line. In 1833 he conducted experiments with submerged propellers, and in 1838, in the iron screw-steamer the Robert F. Stockton, made the first really successful application of the screw to steam-navigation, coupling his engine directly to the propeller shaft. Discouraged by English indifference to his advanced ideas, Ericsson removed to the U. S., arriving Nov. 23, 1839, in New York, where he continued to reside until his death. During the years immediately succeeding his removal he made extensive application of the screw-propeller to merchant vessels on the inland waters of the U. S., and in 1843 caused a revolution in naval warfare by applying the screw to the U. S. S. Princeton by making use of ideas and inventions formerly regarded as inapplicable to the conditions of war. He was the first to employ a range-finder, to discard the use of breeching for heavy guns, to put his machinery below the water-line and to protect it with coal armor. The first practical application of twin-screws was made by Ericsson in the Marmora in 1843. During the twenty years from 1841 to 1861 he was engaged at intervals in work upon revenue marine and other Government vessels, some of which were used during the war with Mexico, 1846–47. He also undertook various bold inventions and constructions, not all of which were successful. Chief of these was the caloric ship Ericsson, which voyaged, Feb., 1853, between New York and Washington, and demonstrated the impossibility of superseding steam with hot air. However, Ericsson successfully applied hot air to the production of small powers, and thus made it a commercial success. His studies in the application of steam-power to war-vessels culminated in the invention of the Monitor armor-clad, made in 1854 and first practically applied in the original Monitor, which defeated the Merrimac in Hampton Roads, Va., Mar. 9, 1862, stayed the rising tide of Confederate success, and compelled the reconstruction of every great navy, substantially upon the lines laid down by Ericsson. During the civil war, from 1862 to 1865, he was occupied in the work of building a monitor fleet for the U. S. In 1869 he built for Spain a fleet of gunboats designed for Cuban waters. In 1878 he developed in the torpedo-boat Destroyer ideas included in his scheme of naval warfare first conceived and submitted to Napoleon III. in 1854. In 1866 he entered upon the study of solar physics and devoted most of the remaining twenty-three years of his life to this, expending $100,000 in experiments and the construction of ingenious apparatus to facilitate his studies. Most of this apparatus was transferred upon his death to the Metropolitan Museum of Art, New York. He invented a solar engine, which he left as a legacy for the future time, when the coal mines shall cease to supply the world with concentrated heat. The main purposes of Ericsson's inventive studies through life were (1) to secure an economical substitute for the steam-engine or lessen its waste of power; (2) to devise some simpler and less dangerous motor; and finally so to improve the mechanism of defense in war that the weaker nations should no longer be at the mercy of the strong. Ericsson died in New York city, Mar. 8, 1889, the anniversary of the battle between the Monitor and the Merrimac. He was a man of extraordinary physique, having the muscular strength of two ordinary men, and retained his ability to work twelve or fourteen hours a day almost up to his dying hour. Numerous titles, diplomas, medals, and orders of knighthood testified to the public appreciation of his services. After his death the Swedish Government asked for the return of his body to his native land, and it was transferred with distinguished honors, in the U. S. S. Baltimore, to Stockholm, where it was received with like honors and conveyed to its final resting-place in a mortuary chapel at Långbanshyttan. He left no descendants, his only son dying before him without issue. In 1890 the Legislature of New York appropriated $10,000 for the erection of a monument to this great inventor, and the ceremony of unveiling took place in Battery Park, New York city, Apr. 26, 1893.

WILLIAM CONANT CHURCH.

Ericsson, NILS: brother of John Ericsson; engineer; b. at Långbanshyttan, Sweden, Jan. 31, 1802. He was in 1814 appointed cadet of the Swedish Corps of Mechanical Engineers, and engaged upon the Göta Canal, ultimately being placed in control of it and completing it. He was then given charge of the construction of a system of Government railways, and on completing them, in 1862, he was created a baron and retired with the largest pension ever bestowed upon a Swedish subject. He and two of his sons were members of the Swedish Diet, and the eldest son, John, who inherited the title of baron, is governor of Jemtland, Sweden. Nils Ericsson died in Stockholm, Sept. 8, 1870.

WILLIAM CONANT CHURCH.

Erie: city (founded in 1867); capital of Neosho co., Kan. (for location, see map of Kansas, ref. 7–J); on Atch.. Top. and S. Fé and M., K. and T. Railways; 116 miles S. by W. of Kansas City; near the Neosho river, which supplies excellent water-power. The city has four churches. The chief industries are agriculture and stock-raising. Pop. (1880) 270; (1890) 1,176; (1900) 1,111. EDITOR OF "REPUBLICAN RECORD."

Erie: city and important railway and commercial center; capital of Erie co., Pa. (for location of county, see map of Pennsylvania, ref. 1–A); the only lake port of the State; has the largest landlocked harbor on Lake Erie, 5 miles in length by one in width. A line of first-class propellers runs between this port and the upper lakes; the imports are principally grain, lumber, iron ore, limestone, and plaster, and the exports bituminous and anthracite coal, engines, boilers, and other manufactured products of the city. Railway facilities are excellent. Erie is on the L. S. and M. S. and the N. Y. C. and St. L. railways; it is the western terminus of the Phila. and Erie Railroad, penetrating the lumber and upper oil regions of the State, and connecting with Harrisburg, Philadelphia, and the anthracite coal-fields; and is also the northern terminus of the Erie and Pittsburg and the Pittsburg, Shenango and Lake Erie railways, which pass through the bituminous coal sections and the lower oil regions of the State, and furnish direct connection at Pittsburg with all rail and river routes.

Manufactures, etc.—The facilities for receipt of raw material and cheap fuel, and for the shipment of products by rail and water, make Erie an important manufacturing center. Articles in great variety are manufactured here; among the chief are the products of foundries, machine-shops, and flouring-mills. Erie is the market for a rich farming country. It has a fine Government building, in which are located the post-office, customs and internal revenue offices, district court-rooms, and signal-service station; an academy, electric street railways and street lighting, and an excellent water-works system, owned by the city and valued at $1,500,000. It is the largest and most central point in a section covering the ten northwestern counties of Pennsylvania. Pop. (1880) 27,737; (1890) 40,634; (1900) 52,733.

EDITOR OF "DISPATCH."

Erie Canal: the most important, as well as the largest, canal in the U. S., extending from Buffalo to Albany, N. Y., 363 miles long. De Witt Clinton, whose name is identified with the construction of this great public work, was in 1810 appointed a member of a commission to explore and survey a route for the proposed canal from the lakes to the Hudson; and his memorial to the State Legislature in 1815 insured the success of the undertaking. The bill for its construction was passed in 1817; but the "canal policy" was for years strenuously opposed. In 1825 the canal was completed at a cost of $7,602,000, and navigation was opened in October. Clinton was at that time Governor of the State of New York, and at the head of a grand naval procession he sailed down the Hudson from Albany to the sea, and poured a keg of the water of Lake Erie into the Atlantic Ocean. In construction the canal presents features of paramount interest. It is carried over several large streams on stone aqueducts whose construction required the greatest engineering skill. It crosses the Mohawk river twice, at Schenectady and at Cohoes. It has in all 72 locks, of which 57 are double and 15 single. At Albany it rises 20 feet by two double locks, 110 by 18 feet, and at West Troy it is carried over a ridge 188½ feet high by 16 double lift-locks. The commercial importance of this canal is very great. It is chiefly employed for transporting grain and such articles as do not require quick transit, and its navigation is free. It is being deepened and widened for the passage of larger vessels. See CANALS and CLINTON, DE WITT.

Erie Clay: one of the Pleistocene formations of the region of the Laurentian lakes. It occupies lowlands about Lakes Ontario and Erie, and about the southern parts of Lakes Huron and Michigan. Like the till on which it rests, it contains pebbles and bowlders, scratched and polished by glacial action; unlike the till, it is finely laminated. Its color is usually some shade of gray or blue, changing at top, through oxidation, to yellow. The clay was deposited in a series of lakes which bordered the great Pleistocene ice-sheet during its final retreat. See GEOLOGY, HISTORIC; also PLEISTOCENE. G. K. G.

Erie, Lake: one of the chain of great lakes drained by the St. Lawrence; constitutes part of the boundary between the U. S. and Canada. The province of Ontario adjoins it on the north, and the States of New York, Pennsylvania, Ohio, and Michigan on the south, east, and west. The Detroit river, entering from the north near its west end, brings the discharge of the upper lakes, and is its largest tributary. The Grand enters from the north, the Maumee from the west, and the Cuyahoga from the south. Its outlet, the Niagara, flows northward from its east end. The length of the lake is 246 miles, its greatest width 58 miles, and its area 9,900 sq. miles. Its surface lies 573 feet above the sea and 326 feet above Lake Ontario. It is the shallowest of the great lakes, its general depth being less than 100 feet and its deepest sounding 210 feet. A group of islands near its west end are celebrated for their vineyards. Its commerce is large, passing westward through the Detroit river to the upper lakes, eastward through the Welland Canal to Lake Ontario, and southeastward viâ the ports of Buffalo, Erie, and Cleveland.

The important BATTLE OF LAKE ERIE was fought near the western extremity of the lake between a squadron of U. S. vessels commanded by Lieutenant (afterward Commodore) Perry, and a British squadron of six vessels under Capt. Barclay, Sept. 10, 1813. Perry's squadron, consisting of nine vessels, but manned by an inferior force and mounting fewer guns, captured the entire British squadron after three hours' combat. This battle gave the U. S. the supremacy on the lake, and permitted the co-operation of the land and naval forces in the West, with the result of freeing Michigan from the British occupation. G. K. G.

Eries: See IROQUOIAN INDIANS.

Erie Shale: the name given by the Ohio geologists to the westward extension of the Chemung and Upper Portage rocks of New York. The oil-wells of Western Pennsylvania are bored on this foundation, though the petroleum which is found in it emanates from the Huron shale below.

Erig'ena, JOHANNES SCOTUS: the boldest and most brilliant thinker of the ninth century. The events of his life are involved in some obscurity. He was born probably in Ireland between 800–815 A. D., and educated in the Irish monasteries. His name, Erigena, is probably a corruption of Hierugena, i. e. "of the Holy Isle," a common designation of Ireland. About 843 he appears to have gone to France, where he was patronized by Charles the Bald. He is credited with one of the best repartees on record. At table one day the king asked him, "Quid distat inter sotum et Scotum?" (What is the difference between a sot and a Scot?). Erigena instantly replied, "Mensa tantum" (Only the table). What happened to him after the death of Charles the Bald, in 877, is not so clear, but he died soon after, probably in France. According to another account, he went to England about 883, on the invitation of Alfred the Great, and was murdered by his pupils at Malmesbury in 891. Some who deny the Malmesbury story say that Scotus Erigena has been confounded with an Anglo-Saxon monk whom Alfred invited over from France to teach at Oxford. Erigena has been called "the morning star of scholasticism." He rebelled against Augustinianism, asserted the supremacy of reason, and wrought out a vague pantheism. He also translated into Latin the works (spurious) of Dionysius the Areopagite (of the fourth or fifth century), and thus planted the seeds of the mediæval mysticism. He wrote against Gottschalk (851 A. D.) on predestination, and against Paschasius Radbertus on transubstantiation, and was condemned as a heretic at Paris in 1209. Of his other works, the most important is a treatise in five books, *De Divisione Naturæ*. It was printed at Oxford in 1681. The best editions are those by C. B. Schlüter (Münster, 1838) and H. L. Floss (Paris, 1853, see below); German translation by L. Noack (3 pts., Leipzig, 1874–77). It is written in the form of a dialogue, and the process of reasoning moves on through syllogisms. But his speculation is very free and bold. It is not the given system of theology he will explain, but an original aspect of the universe which he wishes to set forth, and in the exposition of which he appeals to no external authority. In direct opposition to the theologians of his time, and to the schoolmen in general, he does not start from a conception of the body of theological doctrines as being the truth, needing only elucidation. His starting-point is a philosophical conception of the universe. Pope Honorius III., in 1225, characterized his book as "teeming with the vermin of heretical depravity," and ordered all copies of it to be burned. His works, edited by H. L. Floss, are in Migne's *Patrologia Latina, CXXII.* (Paris, 1853). See Christlieb, *Leben und Lehre des Johannes Scotus Erigena* (Gotha, 1860), and Huber, *Johannes Scotus Erigena* (Munich, 1861). Revised by S. M. JACKSON.

Erigeron, ĕe-rig'e-rŏn [Gr. ἠριγέρων, early-old; ἦρι, early + γέρων, old man; so named in allusion to their hoary appearance]: a genus of herbs of the family *Compositæ*, including the fleabanes (which are weeds of several species, very common in Europe and North America) and other plants, such as robin's plantain (*Erigeron bellidifolius*), etc. The *Erigeron philadelphicus*, *Erigeron canadensis*, and others are used as diuretics, and contain a volatile oil which varies somewhat in different species. The oil has a pungent, disagreeable odor, and sometimes also a tarry or oleo-resinous character. It is used in medicine.

Revised by CHARLES E. BESSEY.

Erik the Red: the discoverer of Greenland, and, Greenland being a part of the western hemisphere, probably the first white man who visited America. He was born about the year 950 in Jædern, in Norway, whence he with his father, Thorwald Osvaldson, removed to Iceland on account of manslaughter. From Iceland he was banished on account of another case of manslaughter, and so he set out on a voyage of discovery. One Gunnbjorn, son of Ulf Krage, had seen land lying in the ocean to the west of Iceland, when in the year 876 he was driven out to sea in a storm. Erik the Red resolved to go in search of the land that Gunnbjorn had seen. He sailed W. from Iceland, and in 982 he discovered the unknown land, which he called Greenland, in order, as he said, to attract settlers, who would be favorably impressed with so pleasing a name. After remaining there three years he returned to Iceland. In 986 he returned to Greenland, accompanied by many new settlers, who established a colony in Eriksfjord, which is thought to correspond to the present Tunnudliarbik and surroundings. Erik the Red lived at Bratlahlid, which after the death of Erik's descendants became the residence of the lagman. Erik's son Leif was the discoverer of America (Vinland). See LEIF ERICSSON and VINLAND.

RASMUS B. ANDERSON.

Erin: See IRELAND.

Erina'ceus [Lat. *erina'ceus*, hedgehog]: the genus that includes the hedgehogs of the Old World, of which there are several species, inhabiting Asia, Africa, and Europe. The common hedgehog of England may be considered a type of the group. It is a harmless little nocturnal animal, which subsists mainly on insects, though sometimes eating fruit and even reptiles. The back of the hedgehog is covered with spines, and when attacked he rolls himself into a ball from which they radiate in every direction, and serve as a defense that enables him to defy all his enemies but man. Zoölogically the hedgehog is of special interest, as he stands at the head of the order of Insectivora. See HEDGEHOG.

Erin'na (in Gr. Ἤριννα): a Greek poet who lived about 600 B. C., and was a friend of Sappho. She acquired a high reputation by her lyric and other poems, among which was *The Distaff*. It is said that she died at the age of nineteen. Fragments of her poems may be found in Bergk's *Poetæ Lyrici Græci*.

Erin'nys (in Gr. Ἐριννύς, or Ἐρινύς), plu. **Erinnyes**: a name given to the Furies or EUMENIDES (*q. v.*).

Erioden'dron [from Gr. ἔριον, wool + δένδρον, tree]: a genus of evergreen trees of the family *Malvaceæ*, natives of tropical climates. They have large and beautiful flowers. They are sometimes called wool-trees, because the capsules inclose a fibrous woolly or cottony substance. The cotton of *Eriodendron samanna* is used in Brazil for stuffing pillows. The *Eriodendron anfractuosum*, which grows in the West Indies, has edible seeds, and is grown in greenhouses as a fine ornamental plant. The cotton produced by these trees can not be spun, but its use in paper manufacture has been proposed. Revised by CHARLES E. BESSEY.

Eritrea, ā-rēē-trā'ăă: an Italian colony on the African coast of the Red Sea, organized in 1890-91. It extends along the coast a distance of 670 miles from Cape Kasar, lat. 18° 2′ N., to the Strait of Bab-el-Mandeb in lat. 12° 30′ N. (see map of Africa, ref. 4–G). The west boundary extends to the latitude of Kassala, but does not include that town, which has been restored to Egypt. The southern boundary as fixed by the treaty concluded with Abyssinia, Oct. 26, 1896, is the river Mareb with its tributary the Belesa, and the Muna, which flows eastward; area about 88,500 sq. miles; pop. estimated at 450,000. The climate is generally tropical and water scanty in the colony proper. Little agriculture is practiced, and cattle, hides, and tallow are the chief exports. Pearl-fishing is carried on at Massowa and Dahlak. There is a telegraph line of 318 miles from Massowa, through Assab, to Perim, and a railroad, 17 miles, from Massowa to Saati. Massowa is the capital, with a population in 1893 of 7,775, of whom 600 were Europeans and 480 Asiatics. The colony is autonomous, the central government at Rome being represented by a civil governor, who is under the direction of the Minister of Foreign Affairs.

Erivân′ (in Lat. *Erivana*; Pers. *Rewân* or *Revân*): a fortified town of Russian Armenia; government of Erivan; on the river Zenga, near where it flows into the Aras; 115 miles S. by W. from Tiflis (see map of Turkey, ref. 4–J). It has a citadel on a high rock, several Armenian churches, a large bazaar, and a few mosques; also a cannon-foundry and manufactures of cotton goods, earthenware, and leather. It was stormed and taken by the Russian general Paskewitch in 1827, and was ceded to Russia by Persia in 1828. Pop. (1874) 30,000; (1897) 28,910.

Erlangen, ār'lăăng-en: a handsome town of Bavaria; on the river Regnitz and on the railway from Bamberg to Nuremberg; 11 miles N. of the latter (see map of German Empire, ref. 6–E). It is partly inclosed by the ancient walls, and is divided into the old and new town, the latter of which is very well built. Here is the University of Erlangen, which was founded in 1742, and is celebrated as a school of Protestant theology. It has a library of about 150,000 volumes, a botanical garden, and manufactures of hosiery, gloves, mirrors, plate-glass, combs, and hats. Pop. (1890) 17,565.

Erlau, ār'low (in Hung. *Eger*; Lat. *Agria*): city of Hungary; capital of the county of Heves; on the river Erlau, or Eger; about 75 miles E. N. E. of Budapest (see map of Austria-Hungary, ref. 5–H). It is inclosed by walls, and is pleasantly situated amid vine-clad hills. It has a cathedral, a bishop's palace, a gymnasium, a normal school, a lyceum, a richly endowed hospital, and manufactures of linen and woolen fabrics; also an extensive trade in red wine of superior quality, which is produced in the vicinity. Erlau is a very old town and was formerly fortified. A bishopric was founded here in the eleventh century. Pop. (1890) 22,200.

Erl′king (in Germ. *Erlkönig*; Dan. *Elverkonge*, i. e. king of the elves): in German and Scandinavian mythology, a fabulous being which, through seductive allurements, causes injury and destruction to human beings, especially to children. This tale has become widely known through the ballad of that name by Goethe.

Ermenonville, ār'me-nōṅ-veel′: a small village of France; department of Oise; 7 miles S. E. of Senlis (see map of France, ref. 3–F). Here is a beautiful château with an extensive park, which is visited in summer by many Parisians; also the tomb of J. J. Rousseau, who died here in 1778.

Erment: See HERMONTHIS.

Ermine: in heraldry, one of the furs used in blazonry. It represents the skin of the ermine, white, spotted or timbered with black. The arrangement of the spots varies with the wearer's rank. A black fur with white spots is called *contre ermine* or *ermines*.

Ermine, or **Stoat**: a species of weasel (*Putorius erminea*) inhabiting the cooler portions of Europe and Asia. Its body is about 10 inches long and the tail about 5 inches. It preys upon mice, poultry, eggs, young rabbits, etc., and like the other weasels has the power of emitting a most offensive

Ermine or stoat.

odor when irritated. In the summer the color of the upper parts is a pale reddish brown, and that of the under parts nearly white. In winter the whole of the body is covered with white fur, slightly tinged with yellow, but the tip of the tail remains black in all seasons. This change is not brought about by shedding the brown coat and growing a white one, but is caused by a change in the color of the hair itself, which turns white shortly after the first fall of snow. The fur is closer and finer in winter, and that which is obtained from Siberia, Norway, and other cold countries is one of the most valuable of furs. It is used for ladies' winter apparel and for the robes of kings and nobles. When made up the tails are inserted one to each skin, at regular distances and in the quincunx order or otherwise, according to the wearer's rank. The fur called miniver is a variety of spotted, "powdered," or "timbered," ermine. The ermine fur forms the distinctive doubling of the state robes of sovereigns and nobles, as well as of their crowns and coronets. It is also worn by judges in some countries. North America furnishes a very small part of the ermine fur of commerce, although most fur so called is simply white rabbit fur, with spots of black rabbit fur inserted.

The common stoat of Great Britain produces a fur much inferior to that of the same species in the far north. It is regarded as vermin, and is a most destructive pest among rabbits, hares, and fowl, wild and domestic. It is caught in snares or traps. It is most active by night.

Revised by F. A. LUCAS.

Erne, or **Earn** [O. Eng. *earn*, connected closely with Germ. *Aar*, eagle, Goth. *ara*, Gr. ὄρνις, bird]: a local English name for the sea-eagle (*Haliaëtus albicilla*).

Erne: a river of Ulster, Ireland; flows nearly northwestward through the county of Fermanagh, and expands into two beautiful lakes, called Upper and Lower Lough Erne. After a course of 72 miles it enters Donegal Bay. The Lower Lough is 20 miles long, 7 miles wide, and over 200 feet deep. The Upper Lough is smaller. Each incloses numerous islands. The banks of these lakes and of the river present fine scenery. The town of Enniskillen stands upon an island between the loughs. On another island is the seat of the Marquis of Ely. The loughs cover 40,000 acres, and are 140 feet above the sea. The salmon and other fisheries are very productive. The river and both loughs are deep, and have lines of steamboats, but the river has several cataracts.

Ernest, or **Ernst**: Elector of Saxony; the founder of the line called Ernestine or Ernestinian; b. Mar. 25, 1441. He succeeded his father, Frederick II., in 1464, and annexed Thuringia to his domains in 1482. "This prince loved a quiet life, and sought it by all the means in his power, at the same time permitting no man to offend him with impunity." He did much for the development of the resources of his territories. D. Mar. 22, 1486.

Ernest (Ernst) I., surnamed THE PIOUS: Duke of Saxe-Gotha; b. at the castle of Altenburg, Dec. 24, 1601; a brother of the famous Bernard of Saxe-Weimar. In the Thirty Years' war he served with distinction under Gustavus Adolphus as a colonel of horse. He completed the victory of the Swedish army at Lützen, where Gustavus was killed. He was a zealous Protestant, and a ruler of great wisdom and activity. He instituted reforms, some of which were very fruitful of good. Many of his institutions were lasting. D. in 1675.

Ernest (Ernst) IV., or **Ernest II.** of Saxe-Coburg-Gotha: Duke of Saxe-Coburg; b. at Coburg, June 21, 1818. His younger brother, Albert, married Queen Victoria of England. He succeeded his father in 1844, and sympathized with the efforts to promote the unity and nationality of the Germans. He composed operas entitled *Zaïre*, *Casilda*, *Sainte Claire*, *Diana de Solanges*, and wrote some memoirs. In 1863 he declined the crown of Greece. D. Aug. 22, 1893, at Coburg, the Duke of Edinburgh succeeding him.

Ernest Augustus: King of Hanover; b. June 5, 1771; fifth son of George III. of England. He was styled the Duke of Cumberland before he became king, and was a field-marshal in the British army. On the death of his brother, William IV., in 1837, he inherited the throne of Hanover, which was then separated from Great Britain, because it was not lawful for a woman to reign over Hanover. He was the object of intense popular dislike both in England and Germany. In the House of Lords he belonged to the extreme Tory party. In Hanover he was a tyrant, and in 1837 expelled from the University of Göttingen seven professors of liberal tendencies. In 1848 he was forced, in order to keep his throne, to grant some liberal reforms. D. Nov. 18, 1851.

Ernesti, ār'nes-tēe, August Wilhelm: philologist: b. in Thuringia, Nov. 26, 1733; a nephew of Johann August Ernesti. He became a good Latin scholar, and was Professor of Eloquence at Leipzig in 1770. He produced a good edition of Livy (3 vols., 1769) and other works, several of which were explanatory of the text of Livy's writings, and are still valued. D. July 20, 1801. See Bursian, p. 400 ff., *Allg. Biogr.*; *Allg. deut. Biogr.*, vi., pp. 235–242.

Ernesti, Johann August: a German critic and the founder of a school of theology; b. at Tennstedt, in Thuringia, Aug. 4, 1707. He was liberally educated at Wittenberg and Leipzig, and was so excellent a Latin scholar that he was called the "German Cicero." He became Professor of Ancient Literature in the University of Leipzig in 1742, and obtained the chair of Rhetoric in 1756, to which the chair of Theology was added in 1758. In theology he was liberal or rationalistic. He was the founder of the grammatico-historical exegetical school of New Testament interpretation in his *Institutio Interpretis Novi Testamenti* (Leipzig, 1761; 5th ed. by C. F. Ammon, 1809; Eng. trans. by Moses Stuart, *Elements of Interpretation*, Andover, Mass., 1822; n. e. by E. Henderson, London, 1827; 3d ed. 2 vols., 1832). He wrote other theological works, and published an excellent edition of Cicero (6 vols., 1737–39), including a *Clavis Ciceroniania*. D. in Leipzig, Sept. 11, 1781. See A. W. Ernesti, *Memoria J. A. Ernesti* (1781); J. van Voorst, *Oratio de J. A. Ernesto* (1804).

Ernst, Oswald Hubert: soldier; b. near Cincinnati, O., June 27, 1842; entered Harvard College July, 1858; graduated at the U. S. Military Academy in June, 1864, and was commissioned first lieutenant in the corps of engineers; served as assistant chief engineer of the Army of the Tennessee to the close of the Atlanta campaign; was detached to serve as astronomer with the commission sent by the U. S. Government to Spain to observe the solar eclipse of Dec., 1870; instructor of practical military engineering and military signaling and telegraphy at the U. S. Military Academy. He became assistant engineer on Western river improvements 1878–80, and afterward took charge of the river and harbor improvements in the district whose headquarters are at St. Louis, Mo. He has served since 1880 as member of various boards of engineers, and has directed various surveys and examinations of rivers; member of Mississippi river commission May, 1888; on duty in Mexico under orders of Department of State Nov.–Dec., 1888; in charge of public buildings and grounds, Washington, D. C., 1889–93; superintendent U. S. Military Academy Apr., 1893. He was breveted captain in 1865, commissioned captain of engineers in 1867, and major of engineers May 5, 1882. His principal publication is a *Manual of Practical Military Engineering* (1873). Revised by James Mercur.

E'ros (in Gr. Ἔρως, gen. Ἔρωτος): the Greek name of the god of Love, the Cupido of the Romans. In Hesiod, Eros is one of the great cosmogonic powers, but later poets represent him as a son of Aphrodite. See Cupid.

Eros: asteroid. See Asteroids.

Erosion [from Lat. *ero'sio*, deriv. of *ero'dere*; *e*, out + *ro'dere*, gnaw]: in geology, the action of a current of water, as in a river, in excavating or enlarging its channel, the gradual abrasion of strata, by rain, frost, glaciers, etc. The deep hollows occupied by most lakes and rivers are supposed to have been formed by the action of rivers or glaciers, and are called "valleys of erosion." The action of atmospheric agencies, glaciers, etc., in wearing away the general surface of a country or district is called *surface erosion*, *degradation*, or *denudation*. The changes wrought by this agency on the superficial features of the earth are much more grand and interesting than they are generally supposed to be; and it may be said that the surface configuration of the earth and the whole "aspects of nature" are the result of the antagonistic action of surface erosion and internal elevatory forces. See Geology.

Erpe'nius, or **Van Er'pe**, Thomas: Orientalist; b. at Gorkum, Holland, Sept. 7, 1584. He studied theology at Leyden, and took the degree of Master of Arts in 1608, after which he visited France, England, Italy, and Germany. In 1613 he became Professor of Arabic and other Oriental Languages (with the exception of Hebrew) at the University of Leyden. A second chair of Hebrew was founded for him in 1619. He printed a number of Arabic works with a press which he kept in his own house. He produced in 1613 an *Arabic Grammar*, the first ever written in Europe, prepared an Arabic chrestomathy, and published *Historia Saracenica*, which is an edition of Elmacin's history, with a Latin translation (1625). D. Nov. 13, 1624.

Errani, Achille: See the Appendix.

Errard, ār'raar', Charles: painter and architect; b. at Nantes, France, in 1606. He was patronized by Louis XIV., for whom he adorned the Louvre, Tuileries, and other palaces. He was one of the twelve artists who founded the Academy of Painting in Paris in 1648, and was the principal founder of the French Academy of Art in Rome (1666). D. in Rome, May 15, 1689.

Erratic Blocks, or **Erratics**: in geology, fragments of rocks on the surface of the ground which have been transported from a distance by glaciers, icebergs, etc. See Drift.

Errázuriz, Federico: Chilian statesman; b. at Santiago, Mar. 27, 1825. He graduated in law at the National University, was a successful advocate, and an author of some repute. Early elected to the Chamber of Deputies, he became a leader of the opposition to President Montt, and at one time was forced to leave the country. President Perez made him Minister of Public Instruction, Religion, and Justice (1861), and he brought about many needed reforms in the department; later he had the portfolio of War and Marine, and directed affairs during the war with Spain 1865–66. A combination of conservatives and moderate liberals elected him president to succeed Perez for the term of 1871–76. By instituting various reforms, and especially by the abolishment of ecclesiastical privileges, he sided rather with the liberals: public works and the reorganization of the army and navy were pushed forward with great vigor, but the treasury was heavily burdened. At the end of his term he retired to private life. D. at Santiago, July 20, 1877. Herbert H. Smith.

Errett, Isaac, A. M.: preacher, editor, and author; b. in New York, Jan. 2, 1820. His parents became identified with the Disciples of Christ in 1810, and in 1811 his father wrote in defense of the principles now advocated by the Disciples. Young Errett's boyhood was spent at Pittsburg, Pa., where, at the age of fourteen, he was baptized. He was thrown on his own resources at the age of ten, but diligently used every opportunity for increasing his stock of knowledge. In 1840 he began his career as a preacher, and soon won a wide reputation for his eloquence and power. After serving as pastor in Pennsylvania, Ohio, and Michigan, he became in 1851 corresponding secretary of Ohio Christian Missionary Society, resigning that work after three years' service to become corresponding secretary of the American Christian Missionary Society. On the death of Alexander Campbell, in 1866, he was elected its president. *The Christian Standard*, a weekly religious journal, was founded by him in 1866. He was president of Alliance College, Alliance, O., 1868–69, and then removed with his paper to Cincinnati, where he continued to reside until his death. He was the first president of the Foreign Christian Missionary Society, and retained that office until his death. Among his works are *Debate on Spiritualism* (Tiffany and Errett); *Walks about Jerusalem*; *Talks to Bereans*; *Letters to Young Christians*; *Evenings with the Bible*; and *Life of George Flower.* D. at Terrace Park, near Cincinnati, Dec. 19, 1888.

J. H. GARRISON.

Error, Writ of: See WRIT.

Ersch, JOHANN SAMUEL: bibliographer; b. at Gross-glogau, in Silesia, June 23, 1766. He studied at Halle, became Professor of Geography there in 1803, and published, besides other works, *Allgemeines Repertorium der Litteratur für 1785–1800* and *Handbuch der deutschen Litteratur seit der Mitte des 18. Jahrhunderts bis auf die neueste Zeit.* His chief work is the *Allgemeine Encyklopädie der Wissenschaften und Künste*, which he began conjointly with Gruber, and of which he edited seventeen volumes (1818–28). D. at Halle, Jan. 16, 1828. He is called the founder of German bibliography.

Erse: See GAELIC LANGUAGE.

Erskine, DAVID STEWART, F. R. S.: eleventh Earl of Buchan, and Lord Cardross; b. June 1, 1742; brother of Lord Chancellor Erskine; author of several antiquarian papers, *Lives and Writings of Fletcher of Saltoun and the Poet Thomson* (1792), and other works. He was a man of eccentric character. D. Apr. 19, 1829.

Erskine, EBENEZER: a Scottish preacher and the founder of the Secession Church; b. at Dryburgh, Berwickshire, June 22, 1680; educated at Edinburgh University (M. A. 1697). He preached at Portmoak, in Kinross, from 1703 to 1731, and acquired a high reputation. In 1731 he removed to Stirling, where he advocated popular rights in the settlement of ministers, and differed from the majority of the General Assembly in relation to lay patronage. He was deposed or suspended in 1733. In 1736 Erskine and his friends formally seceded and organized the Secession Church. He continued to preach in Stirling till his death there, June 2, 1754. In 1847 the Secession Church united with the Relief Church to form the United Presbyterian. Erskine's *Works* (mostly sermons) appeared in London 1799 (3 vols.; n. ed. 2 vols., 1826). See his *Life* by Donald Fraser (Edinburgh, 1831; 2d ed. 1834); cf. those by James Harper (Edinburgh, 1849) and John Ker (London, 1881).

Erskine, HENRY: lawyer; b. in Edinburgh, Nov. 1, 1746; brother of Thomas, Lord Erskine. He was a Whig in politics, became lord advocate of Scotland in 1782, and again in 1806. He was eloquent and witty, and was distinguished for tact and fascination of manner. During part of his career he was the most eminent member of the Scottish bar. D. near Midcalder, Oct. 8, 1817.

Erskine, JOHN: eleventh Earl of Mar; a Scottish Jacobite and ambitious politician; b. at Alloa in 1675. He was appointed secretary for Scotland in 1708. In Sept., 1715, he took arms for the Pretender, and obtained the command of about 12,000 insurgents. He was defeated by the Duke of Argyle at Dunblane in November of that year, and soon escaped to the Continent. D. in May, 1732.

Erskine, JOHN, of Carnock: Scottish jurist; b. in 1695; was a son of Col. John Erskine and a grandson of Lord Cardross. He was appointed Professor of Scottish Law in the University of Edinburgh in 1737, and filled that chair until 1765. He published in 1754 *Principles of the Law of Scotland*, and wrote an important standard work entitled *Institutes of the Law of Scotland* (1773). D. at Cardross, Mar. 1, 1768.

Erskine, JOHN, D. D.: divine; a son of John Erskine of Carnock; b. in Edinburgh, June 2, 1721, and educated there. He was ordained minister of Kirkintilloch, near Glasgow, in 1744, and of Culross in 1753. In 1758 he was translated to the New Grey Friars' church, Edinburgh, where he became the leader of the orthodox and popular party in the Church. He was promoted in 1767 to the Old Grey Friars' church, where he was a colleague of Dr. Robertson, who was the leader of the moderate party. Erskine wrote many theological works, which are highly esteemed. D. in Edinburgh, Jan. 19, 1803. See his *Life* by Sir H. M. Wellwood (Edinburgh, 1818).

Erskine, THOMAS, Lord: orator and lawyer; b. in Edinburgh, Jan. 10, 1750; the youngest son of Henry David, Earl of Buchan. His father, whose income was about £200 a year, could not afford to give him a liberal education for a learned profession. Young Erskine therefore entered the navy in 1764 as a midshipman, after he had attended the High School of Edinburgh. Four years later he purchased a commission in the army, and in 1770 he married a daughter of Daniel Moore, M. P. In the social circles of London he was admired for his elegant manners, conversational powers, and genial disposition. Renouncing the military profession, which he disliked, he resolved to study law, and was admitted as a student in Lincoln's Inn in Apr., 1775. In Jan., 1776, he entered Trinity College, Cambridge, as a gentleman commoner. It is said that in this part of his career he was very poor, suffered great privations, and boasted that he did not know a lord *out of his own family.* He was called to the bar in 1778, and obtained immediate and rapid success in his profession. One of his first clients was Capt. Baillie, prosecuted for a libel on Lord Sandwich, who was then a cabinet minister. He made his *début* in a court crowded with eminent men, yet when the judge interrupted him by the assertion that Lord Sandwich was not before the court, he had the courage to reply, "I know that he is not before the court, and for that reason I intend to bring him before the court." Lord Campbell expresses the opinion that Erskine's plea in this case was "the most wonderful forensic effort of which we have any account in our annals." In 1781 he defended Lord George Gordon, who was tried for treason and was acquitted. He was elected in 1783 to Parliament, in which his success was not so brilliant as in the forum. He was a Whig in politics, and was re-elected in 1790. In several political trials that occurred during the excitement of the French revolution he bravely defended the liberty of the press and the friends of reform whom the ministers prosecuted on a charge of constructive treason. He was counsel for Mr. Hardy and Horne Tooke, who were tried in 1794 and were acquitted. On the formation of a Whig ministry by Fox and Grenville in Feb., 1806, he was appointed Lord Chancellor, and was raised to the peerage as Baron Erskine of Restormel Castle. He resigned this office when the Tories came into power early in 1807. He was the author of *Armata*, a political romance, and a *View of the Causes and Consequences of the War with France*, which ran through forty-eight editions. D. Nov. 17, 1823. Many persons consider him the greatest advocate who ever practiced at the English bar. "He spoke," says Lord Campbell, "as his clients respectively would have spoken, being endowed with his genius; and those who heard him seemed to be inspired with a new ethereal existence." His printed speeches, enriched with noble thoughts, brilliant imagery, and beautiful diction, retain in a great measure their original impressiveness. See Lord Campbell, *Lives of the Lord Chancellors*; Lord Brougham, *Memoir of Erskine*, prefixed to a collection of Erskine's speeches (4 vols.).

Erwin von Steinbach: architect; b. at Strassburg about 1240. He was appointed in 1275 master of the works of the cathedral of Strassburg, then about half finished. He planned the west front and towers, and carried on the work until his death, in 1318. He designed other churches and monasteries in Alsace, and directed the work on the fortifications of Strassburg.

Erysipelas [Gr. ἐρυσίπελας (Hippocrates), of doubtful etymol.; cf. ἐρυσίβη, mildew, red blight; once popularly called *St. Anthony's fire*]: an inflammatory disease of the skin, caused by a specific micro-organism and associated with a peculiar rose-colored eruption of the skin, whence the name. The inflammation attending this disease is of a peculiar low type, which tends to extend. It may terminate favorably by resolution, less favorably by abscess (which is apt to be diffuse—i. e. not limited to a single spot—and is then very dangerous), or the termination may be in gangrene and the death of the patient. The disease is very common in military hospitals, seating itself in wounds, when it frequently proves fatal. Erysipelatous diseases sometimes present a distinctly infectious and almost an epidemic character. Puerperal fever, peritonitis, phlebitis, and a long catalogue of diseases of low type are akin to erysipelas. Its infectious character is admitted. The best treatment is a sustaining one. Pure air, a milk diet, and the use of quinia and iron, with stimulants, are in general indicated. Externally, it is safest to use only the blandest applications, carbolized lotions, etc.

Revised by WILLIAM PEPPER.

Erzeroum, or **Erzrum**, érz-room' [i. e. land of Rome, or Byzantium, so called because it was originally founded under the Eastern Roman empire]: town of Armenia, Asiatic Turkey, and capital of the Turkish vilayet of the same name; on a fertile plain on the river Kara-Su, a branch of the Euphrates; about 120 miles S. E. of Trebizond (see map of Turkey, ref. 4–I). It is 6,200 feet above the level of the sea. The streets are narrow and filthy; the houses are built mostly of mud, wood, or sun-dried bricks. The town has a large citadel, a custom-house, about forty mosques, several Armenian and Greek churches, and a number of bazaars. It has an extensive trade, carried on partly by caravans. The principal manufactures are of copper, tin, iron, and leather. The inhabitants own large sheep-farms in the mountains or keep sheep and cattle in the town, sending them out daily to mountain pastures. The climate is very severe, snow covering the ground for about six months. Pop. estimated at 60,000, mostly Turks. A town called *Theodosiopolis* was founded here in 415 A. D. In 1201 it was taken by Seljooks, who are said to have destroyed 100 churches. The capture of Erzeroum by the Russian general Paskievich, in 1829, brought to a successful close the Russian campaign in Asia. In the Russo-Turkish war of 1877–78 it again fell into the hands of the Russians, who held it from Feb. till Oct., 1878.

Erzgebirge, ārts-ge-beer'ge (i. e. ore mountains): a mountain-chain of Southern Germany; extending along the boundary between Bohemia and Saxony; it is nearly 120 miles in length and 25 miles broad. The Schwarzwald and Keilberg, the highest parts of this chain, have an altitude of about 4,000 feet, and are of granitic formation. The range is rich in minerals, among which are silver, tin, iron, and cobalt. On the southeast side it is steep, often rising in a perpendicular wall 2,000 feet high. On the northwest side it is broken by beautiful and fertile valleys, and gradually loses itself in the North German plain. On the northern foot of the mountains are two extensive coal-fields which, with the abundant water-power, have made this region the great industrial center of Saxony. Chemnitz, the chief town, is called the Manchester of Germany.

Esarhad'don [called in the cuneiform inscriptions *Asshur-aha-iddina*, Asshur has given a brother]: the Old Testament name of an Assyrian king, the son and successor of Sennacherib. He appears to have reigned from 680 to about 667 or 668 B. C. He is shown by the monuments to have been one of the most powerful of Assyrian monarchs. His rule extended northward to Armenia, on the W. it included Syria and Cyprus, while on the S. Egypt and even Ethiopia were claimed by him. He built a palace at Babylon. Among the numerous and splendid remains of his reign is the southwest palace of Nimrud.

E'sau (rough, hairy): the elder twin-brother of the patriarch Jacob (Israel), and the son of Isaac and Rebekah (Gen. xxv. 25). He took his name from his hairiness of body. The story of his marriage to two Canaanitish and an Ishmaelite woman, of his loss of birthright through the craft of Rebekah and Jacob, and of his quarrel and reconciliation with Jacob, is beautifully told in the book of Genesis. He was the progenitor of the Edomites, who dwelt in Mt. Seir, otherwise called Edom.

Esbjörn, ās'byörn, LARS P.: founder of the Swedish Lutheran Church in America; b. in Sweden, Oct. 16, 1808; educated at Upsala; pastor for fourteen years before emigrating to the U. S. in 1849; pastor at Andover, Ill., 1849–56; at Princeton, Ill., 1856–58; professor in Illinois State University, Springfield, Ill., 1858–60. In 1860 he organized the Swedish Augustana Synod, a body which in 1893 numbered over 84,000 communicants, and became president of its theological seminary. Returning to pastoral work in Sweden in 1862, he died there July 2, 1870. He published ten volumes and pamphlets, all in the Swedish language.

HENRY E. JACOBS.

Escalade, es-kă-lād' [Fr. from Span. *escalada*, from deriv. of Lat. *scala*, ladder, steps]: in war, an assault in which ladders are used in surmounting the obstacles presented by the scarp and counterscarp walls (or slopes) of a fortification in which no breach has been made; sometimes even a rapid blow directed at an unbesieged place with hope of success by surprise (e. g. the capture by the English troops of Almarez, Sept., 1812). Among the most famous escalades are those of Adrianople by the Goths; of Beauvais by Charles the Bold, in 1472; of Fécamp in 1593; of Prague in 1741. Still more remarkable was that at Corfù in 1717 by Count Schulenberg, who, reduced to extremity in the defense by the capture of the outworks, hastily prepared ladders, and by a desperate assault by escalade retook them, and thus saved the place. The second siege of Badajos (1812) presents an event unparalleled in the history of sieges. Two entire divisions of troops were at the moment of assault employed to escalade the defenses where intact, and each succeeded, while the regular assault on the breaches was repulsed with terrible slaughter. The castle was successfully scaled where the walls were 18 to 24 feet high, and "tolerably flanked"; the Bastion St. Vincente had a scarp-wall 31½ feet high, flanked by four guns, palisaded covered way, a counterscarp-wall 12 feet high, and a cunette ditch 5½ feet deep.

Escallop Shell: See SCALLOP SHELL.

Escanaba: city; capital of Delta co., Mich. (for location of county, see map of Michigan, ref. 3–G); situated on the C. and N. W. Railway and on Green Bay, 360 miles N. of Chicago. It has 9 Protestant and 2 Catholic churches, 4 public and 2 parochial schools, a hospital, lumber-factories, waterworks, gas and electric light, sewers, electric street railway, etc., and an excellent natural harbor. It ships annually 4,000,000 tons of iron ore and large quantities of coal, lumber, and fish. Pop. (1880) 3,026; (1890) 6,808; (1900) 9,549.

EDITOR OF "MIRROR."

Escape: in law, the departure of a prisoner from confinement before he has been released by process of law. Any liberty given to a prisoner not authorized by law is technically an escape. Escapes may occur either in civil or criminal cases. They are either negligent or voluntary—negligent, when the prisoner escapes without the consent of the officer having him in custody; voluntary, when such officer consents to the escape. In criminal cases an escape is a public offense, of which the prisoner may be convicted, as also the officer through whose act or neglect the escape occurs. An officer voluntarily permitting a criminal to escape is guilty of the same offense as the criminal, as he then becomes an accessory after the fact. In civil actions there is an important distinction between *mesne* and final process, the former being that which is issued between the commencement and the termination of the action; and the latter, that which is used to enforce the judgment. If the escape be voluntary, the officer is liable in either case; but if it be negligent, he will not be liable in the case of *mesne* process if the prisoner is again in his custody before an action is commenced against him for his neglect; though he will be liable in any event in the case of final process. The damages recoverable are measured by the injury sustained. In final process these would in general be the amount of the judgment. Nothing will excuse an escape but an act of God or of the public enemy or of the law.

Revised by F. STURGES ALLEN.

Escapement: the device in watches and clocks by which the rotatory motion of the wheels gives rise to or perpetuates the vibration of a pendulum or balance-wheel.

Escapements have received various forms, many of which are still in use. The earliest, introduced by Huyghens, about 1650, was called the crown-wheel or vertical escapement. The crown-wheel has its teeth not in the plane of the wheel, but in a cylindrical surface of which the axis of the wheel is the axis. In the crown-wheel of the clock or watch the teeth were acute-angled, and inclined in a common direction like saw-teeth. The axis of the pendulum, or balance, was longer than the diameter of the crown-wheel over which it extended. It carried two short arms or projections, called pallets, set in different azimuths, in such a manner that when one of them, being encountered by a tooth, was pushed out of the way by the advancing wheel, the opposite one was caught by another tooth, which pushed in the opposite direction. Thus the wheel made an intermittent progress as the teeth successively escaped from the pallets.

In a clock, when the pendulum is disturbed from the mean position, it is brought back by gravity. In the watch the same result is produced for the balance-wheel by the action of the spiral spring attached to the verge, called the hair-spring. The escapement most commonly in use for both clocks and watches is the anchor escapement, first introduced by Hooke in 1656. It is so called from its resemblance to the flukes of an anchor, the shaft of the anchor in the clock being parallel to the pendulum and connected with it. The escapement-wheel is a spur-wheel. The pallets project from the extremities of the anchor flukes, meeting the wheel at the points where tangent lines from the center of motion would touch it. When one pallet is engaged with the wheel the other is free, and *vice versa*. The extremity of the pallet is inclined in such a manner that, as the tooth escapes, it gives an impulse to the pendulum. As, after the pallet first engages a tooth, the swing continues for some time in the same direction, anchor escapements are of two kinds, according to the manner of their action upon the train during this swing. In Hooke's escapement the surfaces of the pallets are so inclined that by their pressure on the tooth they turn the train slightly backward, or cause it to *recoil*, up to the end of the swing. In the *dead-beat* escapement, invented by Graham early in the eighteenth century, the surfaces of the pallets are circular arcs having the center of motion for their center; so that during the swing the train simply stands still. Though the dead-beat escapement is now generally used in clocks, there are not wanting those who prefer the recoiling escapement. Besides the anchor dead-beat there are several other very ingenious forms, among which may be mentioned Lepaute's pin-wheel escapement, McDowall's ruby-disk escapement, and Denison's three-legged dead escapement.

The only escapement used for watches till about 1700 was the crown-wheel escapement. Graham invented the cylinder escapement, so called because a hollow cylinder of steel or ruby replaces in part the verge of the balance. This cylinder is cut away on one side for about one-fourth of the circumference, in order to allow the pallets, which are small triangular pieces of steel, to enter the interior. During the swing the pallet rests with little friction on the smooth exterior or interior surface. In entering and in escaping it gives an impulse to the balance. The pallet is not in the plane of the wheel, but stands on a short stem at right angles to this plane. Hence the cylinder must be much more extensively cut away at the point where the wheel passes, and on this account the cylinder escapement, though performing very well, is too frail to be popular in use. The duplex escapement of Lepine receives its name from having a double escapement. The escapement-wheel carries spur teeth rather widely separated, which engage at every double vibration with a notch in a cylinder forming part of the verge, and constructed of a gem. The verge itself carries also an arm which engages with a set of pins, or crown-wheel teeth, fixed in the escapement-wheel at right angles to its plane. The impulse is chiefly derived from the escapes of this arm, but proceeds to some extent from those of the spur teeth also. It takes place only in one direction, and hence the system is called by the French an escapement *à coup perdu*. The duplex escapement, though attended with little friction and running without oil, is subject to the disadvantage that a sudden jerk may check the swing of the balance and prevent the escape. If a single such failure occurs, the watch will stop.

The lever escapement is a dead-beat anchor escapement, first applied to the watch by Mudge, in 1793. The lever is attached to the anchor, generally crosswise, or at right angles to the proper position of the anchor-shaft. At one extremity it presents a notch into which a pin attached to the verge strikes at each swing in either direction. This tilts the anchor and allows a tooth to escape. Except at these moments of locking and unlocking, the balance swings entirely free. The lever carries also a pin just at the summit of the notch, which enters an indent in the verge as the lever passes. As there is no other indent, the lever can not tilt except when the verge pin strikes it.

The escapement which interferes least with the uniformity of movement of the train is the chronometer escapement, introduced into England in the eighteenth century by Earnshaw, though said to have originated in France. In this the train is locked by a tooth projecting from a light bar tangent to the escapement-wheel, which yields by bending and not by turning on a pivot, the fixed extremity being a spring. The free extremity carries another delicate spring parallel to itself and extending a little beyond it. A tooth on the verge passes this slight spring in one direction without sensible resistance. On its return the bar behind the spring prevents its bending, and so is carried along with it, unlocking the train. The train being released, a tooth of the escapement-wheel strikes a pin, or enters a notch, connected with the verge, and gives an impulse to the balance. This, like the duplex, is an escapement *à coup perdu*, and is liable like that to stop when subjected to sudden jerks. Hence chronometers carried on the person sometimes stop; but with nautical chronometers this accident hardly ever occurs.

The chronometer escapement is sometimes called a free escapement, since the balance is wholly free from contact with any other part of the work, except in the instant of unlocking and receiving the impulse. This is true also of the lever escapement; but in that the unlocking requires more force, and is attended with larger friction. See the article CLOCK.

Esceleu: See ESSELENIAN INDIANS.

Eschatology, es-kă-tol'ŏ-ji [from Gr. ἔσχατος, last + λόγος, discourse]: that section in dogmatics which treats of the second advent, the intermediate state, the resurrection, the last judgment, heaven, and hell. Upon these themes revelation does not go into minute details, while yet the salient points are strongly marked. The passages which must be relied upon to furnish the data are Matt. xxv., Luke xvi., xxiii. 43, John xiv. 23, 1 Cor. xv., 2 Cor. v., 2 Thess. i., ii., Rev. xx. and xxi. See FUTURE STATE.

Escheat' [from O. Fr. *eschete*, deriv. of *escheoir* < Lat. **excade're* for *exci'dere*, to fall to one's share]: a reverting of lands to their original owner (lord of the fee) because of some obstruction in the course of descent, either by failure of heirs or corruption of blood (now abolished) when the tenant had been convicted of treason or felony; also, the estate itself thus reverting. An escheat differs from a forfeiture in the fact that the latter is a penalty for a crime, and the property forfeited accrues to the person injured or the sovereign, while escheat depends solely on the failure of heirs, and the land reverts to the former owner (lord of the fee). In the U. S., where feudal tenure does not exist, the doctrine of escheat has a limited application; still, if an owner of land dies without heirs, it is said to escheat to the state. Incorporeal rights, such as ways and commons, do not escheat, but become extinct. The land of a corporation, in case it becomes extinct, reverts to the grantor, and not to the state. The state takes an escheat subject to any charges or encumbrances attaching to the land when its title accrued. A proprietor may prevent an escheat by conveying or devising his estate. In Great Britain, and generally in the U. S., the subject is regulated by statute.

Revised by F. STURGES ALLEN.

Eschenbach, esh'en-baăkh, WOLFRAM, von: mediæval poet and minnesinger; b. of a noble family, at Eschenbach, near Ansbach, Bavaria. In 1203 he went to the court of Hermann, landgrave of Thuringia, whose bounty he enjoyed until 1215. He died between 1218 and 1225. His principal poems are *Parcival* and *Willehalm*, which have also been translated into modern German, and are much admired. Though Wolfram possessed no learned education and was even unable to read, these epics rank among the greatest imaginative works in the German language. They display an exquisite humor, depth of feeling and thought, and great mastery of language. See Karl Lachmann, *Wolfram von Eschenbach*; G. Bötticher, *Die Wolframliteratur seit Lachmann*; K. Kant, *Scherz und Humor* in *Wolfram von Eschenbach*.

Revised by JULIUS GOEBEL.

Eschenmayer, esh'en-mī-er, ADAM KARL AUGUST: a German philosopher and mystic; b. at Neuenberg, Würtemberg, July 4, 1768. He became Professor of Philosophy and Medicine at Tübingen in 1811, and obtained the chair of Practical Philosophy there in 1818; removed to Kirchheim 1836, and there died Nov. 17, 1852. He wrote, besides other works, *Religionsphilosophie* (The Philosophy of Religion, 3 vols., Tübingen, 1818–24).

Eschscholt'zia califor'nica: a plant of the poppy family (*Papaveraceæ*), a native of California. It is cultivated for the beauty of its flowers, which are yellow. The calyx separates from the flower-stalk when the flower expands, and resembles the extinguisher of a candle. This genus was named in honor of J. F. Eschscholtz (1795–1831), a German botanist.

Revised by CHARLES E. BESSEY.

Eschwege, esh'vā-ge: a town of Prussia; province of Hesse-Nassau; on railway and on the river Werra; 28 miles E. S. E. of Cassel (see map of German Empire, ref. 4–E). It has a castle, a Realschule, and manufactures of linen and woolen goods. Pop. (1890) 9,787.

Eschweiler, esh'vī-ler: town of Rhenish Prussia; on railway from Cologne to Aix-la-Chapelle; 8 miles E. N. E. of the latter (see map of German Empire, ref. 5–C); has extensive manufactures of ribbons, canvas, needles, glass, machinery, and woolen goods. There are mines of coal, zinc, and lead in the vicinity. Pop. (1890) 18,119.

Esclot, BERNAT: See D'ESCLOT.

Escobar y Mendoza, es-kō-baar'ee-men-dō'thaa, ANTONIO: Spanish Jesuit and casuist: b. at Valladolid in 1589. He wrote *Liber Theologiæ Moralis* (1646); *Summula Casuum Conscientiæ* (1626); and other works. The lax morality of his writings was censured by Pascal in some of his *Provincial Letters*. D. July 4, 1669.

Escobedo, -bā'dō, MARIANO: Mexican general; b. in Galeana, Nueva Leon, Jan. 12, 1827; in early life a trader on the frontier. He served as a soldier in the war with the U. S. 1847–48; was prominent in the "reform war" 1858–61, and in the resistance to the French invasion 1862–63; and held out with Juarez until 1864, when he retired to Texas. In Nov., 1865, he inaugurated a new republican campaign in the north by capturing Monterey; advancing in a series of victories, he defeated Miramon at San Jacinto, Feb. 1, 1867, besieged the Emperor Maximilian in Querétaro, and took him prisoner May 14; he ratified the decree of the court martial which condemned Maximilian to death. Promoted to general of division, he was made commander-in-chief of the republican armies. In Aug., 1876, President Lerdo made him Minister of War; on Lerdo's deposition, Nov. 6, 1876, he went into banishment. In Feb., 1878, he tried to enter Mexico, was captured, tried, but exonerated, and in 1880 he again took office under the Government. Since 1883 he has lived in retirement. HERBERT H. SMITH.

Escosura, -soo'raa, PATRICIO, de la: statesman and author; b. in Madrid, Nov. 5, 1807; studied mathematics in Valladolid. In 1824 he was exiled for his connection with the society of the Numantinos, and then studied in Paris and London. On his return to Spain two years later he entered a regiment of artillery, where he was soon promoted to the rank of officer. Twice banished as a partisan of the Carlists (in 1834 and in 1836), he returned to his country in 1846, and became Under Secretary of State in the following year. In 1855 he was sent as especial envoy to Portugal, after which he was Minister of the Interior, and from 1872 to 1874 Spanish ambassador to the German empire. For a long time Escosura was one of the most prominent editors of the *Revista de España*, in which he published a number of articles bearing on Spanish literature and art. He has written several historical works, such as the *Historia Constitucional de Ingleterra* (1859); dramas, such as *Corte del Buen Retiro* (represented in 1837); *Las Mocedades de Hernan Cortés* (represented in 1844); *Roger de Flor, ó los Españoles en Oriente*, an historical tragedy represented in 1846, and published in 1877; and historical novels, such as *Ni Rey ni Roque* (1835) and *El Patriarca del Valle* (1846). D. Jan. 22, 1878. HENRY R. LANG.

Escrow [O. Fr. *escroe*, scrap, shred, loan-word from German; cf. O. H. Germ. *scrōt*, scrap]: a deed or other instrument importing a legal obligation deposited by the grantor or party executing it with a third person, to be delivered to the grantee or obligee on the fulfillment of a certain condition. Until the condition is fulfilled a deed in escrow has no effect as a deed, and the title of the estate remains in the grantor. An escrow takes effect, in general, from the time of the fulfillment of the condition or of the second delivery; and where the second delivery is expressly made necessary to give it effect the delivery will be enforced by a court of equity. In certain cases, where the ends of justice require it, and no injustice will be done, the instrument may, by a fiction of law termed "relation," be referred for its validity back to the first delivery. Revised by F. STURGES ALLEN.

Escuintla, es-kweent'laa: a southern department of Guatemala; bounded N. by Chimaltenango, Zacatepequez, and Amatitlan, E. by Santa Rosa, S. by the Pacific, and W. by Suchitepequez and Solola. Area, 1,950 sq. miles. The northern part is hilly or mountainous, the coast regions generally low; the soil is very fertile, and there are many large sugar and cacao plantations. The department has extensive forests yielding cabinet woods; at Guaymango and Santa Lucia there are interesting Indian antiquities. Pop. (1892) 31,302.—ESCUINTLA, the capital, on the Central Railroad, is important as a central point between Guatemala, San José, Antigua, and Amatitlan; its trade with the surrounding district is large. From December to March it is much frequented by wealthy Guatemalans. Pop. about 6,000.
HERBERT H. SMITH.

Escu'rial, or **Esco'rial** [deriv. of Span. *escoria*, a heap of rubbish from a mine: Ital. *scoria*: Fr. *scorie* < Lat. *scoria*, slag]: a monastery and royal palace near Madrid, in Spain, built by Philip II., and dedicated to St. Lawrence on occasion of the victory of St. Quentin in 1557, on that saint's day. According to the somewhat doubtful tradition, it was built in the form of the gridiron on which that saint is said to have been broiled alive. The work was begun by Juan Bautista de Toledo in 1563, and completed by his pupil, Juan de Herrara, in 1584. The cross-bars of the gridiron are represented by ranges of buildings separated by intervening courts. They were formerly inhabited by monks and ecclesiastics. The main portion of the building is 706 feet long and 550 feet wide. The projection which forms the royal palace is 460 feet in length. The height of the edifice is about 60 feet, and at each angle is a square tower 200 feet high. It is one of the largest and perhaps one of the most tasteless buildings in Europe, though grand from its size. The church in the center of this enormous mass of stone is very large and rich. The Pantheon, a repository beneath the church, is the place of interment for the royal family, whose remains are deposited in tombs of marble placed in niches, one above another. The richest part of this edifice, however, was that which contained pictures by Rubens, Titian, Raphael, Velasquez, and other great masters—the best collection that any place in Europe displayed. The French, when in possession of the Escurial, removed many of these works. The most valuable treasures of the Escurial constitute the collection of ancient manuscripts preserved in the library, especially those of the Arabian writers.

Escutcheon [O. Fr. *escusson*, from deriv. of Lat. *scu'tum*, shield]: in heraldry, a surface, usually shield-shaped, on which heraldic bearings are charged, and which makes up the larger part of the *achievement*. An escutcheon of pretense is the shield on which a man carries the arms of his wife, if she is an heiress and has children. It is placed in the center of his own shield, and is mostly of the same form. An escutcheon is sometimes used as a bearing. See HERALDRY.

Escutcheon, or **The Milk Mirror**: in the Guénon method of selecting milch cows, the shield-like outline upon the back of the cow's udder and the adjacent parts, formed by the upward growth of the hair. Some writers call the whole outline the "mirror," and the upper part only the "escutcheon." The size and perfection of these marks afford valuable means of judging the milking qualities of cows, though much experience is required to make the estimate.

Esdrae'lon, in the apocryphal book of Judith, **Esdrelom** [from the Gr. Ἐσδραήλων, a corruption of the Hebrew *Jezreel*]: the most picturesque, most fertile, and historically most important plain in Palestine, "lying between Tabor and Carmel, and between the hills of Galilee on the north and those of Samaria on the south." In Scripture it is twice (2 Chron. xxxv. 22; Zech. xii. 11) called "the valley (plain) of Megiddo." Jezreel is properly the southeastern part of it, although this name is sometimes given to the whole. It is triangular in form, the length of its southeastern side being about 15 miles, its southwestern about 18 miles, and its northern about 12 miles. Its surface, whose elevation is about 400 feet above the Mediterranean, is slightly undulating. It sends off toward the Jordan three great arms or branches, which are separated from one another by the mountains of Gilboa and Little Hermon. Only one of these arms, however (the middle one), declines eastward. The greater part of the plain is drained by the Kishon, which empties into the Mediterranean near Acre. This great plain has been the scene of several important battles, and with it are associated the names of Barak, Gideon, Saul, Josiah, the crusaders, and Napoleon. See Edward Robinson, *Physical Geography of the Holy Land* (1865).

Es'dras, Books of: certain books of the Old Testament and of the Apocrypha ascribed to Ezra, whose name is Græcized into *Esdras*, following the Septuagint. The canonical books of Ezra and Nehemiah (as they are called in the Authorized English Version) are denominated in the Vulgate and in the Thirty-nine Articles of the Anglican Church the first and second books of Esdras, while the apocryphal books, now generally known as the first and second of Esdras, are there called the third and fourth of Esdras. The Geneva Bible (1560) first adopted the present nomenclature, calling the two apocryphal books first and second Esdras.

The first (apocryphal) book of Esdras was written in very good Greek, but whether in Palestine or in Egypt, and at what time, can not be determined. It has some historical value, and is for the most part a history of the restoration of the Jews after the Babylonian captivity. It is not received into the canon of either Jews or Christians.

The second apocryphal book of Esdras is purely pseudepigraphic, being a record of pretended revelations made to Ezra for the encouragement of the suffering Jews. Many interpolations have been made in it by some overzealous Christian. The original is believed to have been written by a Jew of Egypt in the Greek tongue, either just before or soon after the Christian era. The original Greek is lost, but Latin, Ethiopic, and Arabic versions exist. It is canonical in the Abyssinian Church. English versions are the authorized, from the Latin, Ockley's, from the Arabic (1711), and Laurence's, from the Ethiopic (1820). See these books in Dr. Bissell's volume on the Apocrypha, in the American Lange series. Revised by Willis J. Beecher.

Esk: a small river of Scotland, in the county of Dumfries; flows southward through Eskdale Muir, and enters Solway Firth. Length, about 40 miles. Its valley is noted for picturesque scenery. Another river Esk is formed by the union of the North and South Esk, which meet in Dalkeith Park, Edinburghshire. It enters the Firth of Forth at Musselburgh.

Eskilstuna, es-kil-stoo'naă: town of Sweden; 55 miles W. of Stockholm (see map of Norway and Sweden, ref. 11-F). It is the principal place in the kingdom for the manufacture of the better sorts of iron. Pop. (1895) 12,064.

Eskimauan (es-ki-mō'an) **Indians**: the Eskimos: a linguistic stock occupying the northern coasts of America from Labrador to Mt. St. Elias, also Baffin Land and the shores of Greenland. In their own tongue they are called Inuit, a word meaning "men," while the word Eskimo is said to be an Algonkin term of reproach, meaning "eaters of raw meat." In color they are lighter than their Indian neighbors, and a trifle shorter in stature. Their skulls are hypsicephalic, inclining to dolichocephalic, the hair black and scanty on the body, the hands and feet small, and the faces flat and oval.

The activities and arts of the Eskimo have been evoked by their arctic environment, by the sources of material, by the climate and the movement of game, and by the changing of seasons. Their winter houses are subterranean, built, in the west, of puncheons and whale's bones covered with earth; and in the central region, of snow cut into blocks, and made in shape of a dome. The entrance is by means of a long, low gallery, with a succession of skin doors to exclude the cold. Lamps of stone, filled with blubber and having wicks of moss, afford light and heat, and fire for cooking. In the regions where wood may be obtained a hearth replaces the lamp. Banquettes around the apartment furnish sitting room by day and sleeping-places by night. The number to be accommodated varies with the locality, but in the absence of the strict clan system of social organization, the number of persons in a habitation is always smaller than that which occupied the "long house" of the stocks farther south. In the summer the underground abodes are deserted for tents or temporary shelters that may be easily transported.

The clothing of the Eskimo is made of the skin of such animals or birds as are abundant, from which the fur or feathers are not removed. Men and women are clad alike, in trousers of seal or deer skin, according to the season, and in loose fitting shirt or parka surmounted by a hood, very much enlarged for women with infants. Their feet are shod in sealskin boots, drawn over inner boots or socks of warmest fur. Their dress is ornamented with particolored fur in great taste. Waterproof garments are made of the intestines of seals or from the skins of fish. Tattooing is practiced, and the wearing of labrets is common in the west.

The men are employed chiefly in obtaining the means of subsistence, while the women are occupied in preparing it for use. Their dainty boats or kaiaks for a single hunter are made by stretching prepared sealskins over a frame. The owner sits in the center, and draws his seal-gut parka to the gunwale, where he lashes it in order to exclude the water. Around him on neatly constructed frames, or held in place by spider-lines, are his great harpoon with its line and float; his small harpoon and throwing stick; his paddle and dispatching spear ready at a moment's notice. In this frail bark he ventures on the open waters to hunt the aquatic mammals. A larger open boat, or umiak, is also used in moving from place to place during the summer hunt. Upon the land or over the ice-floe the means of transportation is the sledge drawn by dogs. By this conveyance he takes long journeys, transports his effects from place to place, and brings to his family huge loads of food and furs.

The Eskimo bows are made of bits of horn or antler lashed together, or of brittle wood strengthened with sinew cord laid on in the most ingenious manner to convert a breaking into a columnar strain.

Fishing is done with lines and nets, or with fish-spears. Frequently the nets are set under the ice. The fishing hooks are marvels of workmanship, with their compound barbs, ivory spreaders, and particolored sinkers of stone and ivory. The fish-spears have prongs in form of a double clasp, which are driven upon both sides of the game to secure it.

In manufactures the Eskimos are ingenious. During the long winter days, when they must stay indoors, men carve from ivory, antler, horn and wood objects of use as well as ornament. Buttons and toggles for clothing and harness, harpoon heads, barbs for darts, arrows, and fish-spears, and conveniences for the manipulation of ice and snow and water for household use, are marvels of sagacity. Women spend their time in making garments and tents. Both men and women cover everything which they manufacture with etchings and carvings or embroidery. Among them barbaric art may be seen in full bloom. For these reasons the manufactures of this people have furnished the best explanations for thousands of objects of use and adornment found in remains of ancient peoples in Europe. Between the tribes of each typical area constant intercourse and traffic are maintained, and long journeys are taken to secure wood or soapstone, or harder materials for their implements.

The amusements of the Eskimo are athletic sports and dramatic entertainments, in some of which they excel. Children at their sports mimic the occupations of their elders. Trials of skill and gambling are universal, and an intricate game of dominoes has been developed by them.

The language of the Eskimo is of the polysynthetic type common to all other American stocks.

The social structure of the Eskimo is not sufficiently made out; but the clan system, such as that of the Athapascans or Iroquois, seems not to exist among them. Each fjord or hunting-center is the seat of the village, and frequently a number of these villages are sufficiently near to give rise to a tribe. In each communal house there is a group of families, and often one of the older men is obeyed as a leader. In the winter the community becomes more compact, but in summer it spreads out in groups over the area visited by game and flocks of migratory birds.

The religion of the Eskimo is animistic. All things are ensouled, and spirits innumerable are everywhere. The medium of communication between the laity and the spirit world is the angakok, corresponding to the shaman of Northern Asia and the medicine man of the Indian. He can see into the land of spirits, can summon the powers to consult with him, and even compel them to heal disease and perform other services at his bidding. With myths innumerable, the Eskimo explains the phenomena of the universe. His worship is dramatic, and takes place in a large snow hut or underground casino, erected for the purpose.

O. T. Mason.

Eskimos: See Eskimauan Indians.

Eski Sagra, es'kēe-saa'graă: a town of European Turkey; province of Adrianople; on the south slope of the Balkan Mountains; 70 miles N. W. of Adrianople (see map of Turkey, ref. 3-D). It has manufactures of carpets, coarse linen, and leather. Here are several mineral springs. Great barbarities were perpetrated on the Christian inhabitants here in 1877. Pop. estimated at 20,000.

Eslaba, Sebastian, de: Spanish general; b. at Eguillor, Feb., 1698. He early entered the army, distinguished himself in the service of Philip V., and attained the rank of lieutenant-general in 1738. From 1740 to 1744 he was Viceroy of New Granada, and his term was memorable for his

brilliant defense of Cartagena against the English, Mar.–May, 1741; the fortifications which he constructed in expectation of the English attack were of great strength, and long made Cartagena invulnerable. After his return to Spain Eslaba was made captain-general, and for some years was Minister of War. D. in Madrid, Jan., 1759.
HERBERT H. SMITH.

Eslen: See ESSELENIAN INDIANS.

Esmann, GUSTAV FREDRIK: Danish journalist and dramatic writer; b. in Copenhagen, Aug. 17, 1860. In 1885 he published two short stories (*Gammel Gjæld*), but since that time he has written chiefly plays. Of his dramas may be mentioned *I Provinsen*; *Før Bryllupet*; *Enkemænd*; *Den Kære Familie*; *Magdalene*.

Esmarch, FRIEDRICH: surgeon; b. at Tönnig, Schleswig-Holstein, Jan. 9, 1823: studied at Kiel and Göttingen, and afterward served in the hospital at Kiel. He was active in the Schleswig-Holstein war 1848–50, and in the latter year was made physician superior; in 1857 director of the surgical clinic at Kiel, and in 1860 professor and director of the Kiel hospital. In the war of 1864 he distinguished himself by his excellent work in the hospitals, and when war broke out between France and Germany he was nominated physician-general and consulting surgeon to the army. After the war he resumed his work at Kiel. He has married twice, his second wife being the Princess Henrietta of Schleswig-Holstein. Esmarch's work both as a practitioner and as a medical authority has been remarkable. He discovered and applied with success the method of performing operations upon injured limbs without loss of blood. Among his many important contributions to medical literature may be mentioned *Ueber Resektionen nach Schusswunden* (1851); *Ueber chronische Gelenkentzündung* (1867); *Ueber den Kampf der Humanität gegen die Schrecken des Kriegs* (1869); *Der erste Verband auf dem Schlachtfeld* (1870); *Verband Platz und Feldlazarett* (1871); *Handbuch der Kriegschirurgischen Technik* (1885–86).

Esmeraldas, es-mā-raal'daas: the northwesternmost province of Ecuador; bounded N. E. by Colombia, S. E. by Carchi, Imbabura, and Pichincha, S. W. by Manabi, and W. by the Pacific. Area, 5,364 sq. miles. The surface is hilly rather than mountainous, the highest peaks attaining hardly 2,500 feet; the rivers Esmeraldas and Cayápas, with their branches, form extensive valleys in which the land is open and adapted for grazing; the hills are covered with luxuriant forest. The climate is warm, but exceptionally healthy for the coast region. With great natural advantages, the province is in a very backward condition. Cattle-raising, farming on a small scale, and a little gold-washing are the only industries. Pop. (1892) about 15,000.—ESMERALDAS, the capital, at the mouth of the Esmeraldas river, has about 3,000 inhabitants. See Wolf, *Memoria sobre la geografía y geología de la provincia de Esmeraldas* (Guayaquil, 1879).
HERBERT H. SMITH.

Es'neh, or **Isné** (anc. *Latopolis*): a town of Upper Egypt; on the left bank of the Nile; about 30 miles above Thebes. It has manufactures of blue cotton and pottery; also an active trade with Sennaar and Abyssinia. Here are the ruins of the populous ancient city of *Latopolis*, so called from the worship of the *latus* fish. Among them is a well-preserved portico of a grand temple, with twenty-four beautiful columns standing, and a zodiac on the ceiling like that at Denderah. All the rest of the temple is literally buried, the houses of the modern town standing even upon its roof. In visiting the portico, one goes down as into a deep vault. It was cleared of rubbish by order of Mohammed Ali in 1842. An older temple appears to have been built at Esneh by Thothmes III. of the eighteenth dynasty, but the present edifice dates from the time of the Cæsars. On the river-bank are the remains of a Roman quay. Pop. about 12,000.

Esoc'idæ [deriv. of *Esox*, the typical genus; from Lat. *esox* (*isox*), name of a fish found in the Rhine, probably the pike]: a family of fishes of the order *Haplomi*, containing the true pikes. The body is elongated, with the back and abdomen nearly straight and parallel; the scales are cycloid and of small size, and cover the whole of the body and more or less of the head; the head is oblong, and produced into a broad, depressed, and flattened snout; the mouth is large, and has a deep lateral cleft; the teeth are developed on the jaws, vomer, palatine, and hyoid bones; on the jaws they are enlarged and sharp; the dorsal and anal fins are situated far behind, opposite each other, and higher than long; the skeleton has numerous vertebræ, and the abdominal ones are much more numerous than the caudal (e. g. D. 41–43 + C. 20–21). The family is entirely confined to the northern hemisphere. It is chiefly represented in America, where about five species are known, while in Europe only a single species—and that also common to the two continents—is found. All the members of the family are very voracious, and by the nature of their dentition well adapted for making havoc among their cohabitants of the water. The most notable species of the U. S. are the *Esox masquinongy*, or true mascalonge, which is pre-eminent among the species of the family for the delicacy of its flesh; the *E. lucius*, which is the same as the common pike of Europe; and the *E. reticulatus*, or ordinary pickerel, of the Middle and Eastern States. In Great Britain the name pike is bestowed on the *Esox lucius* as a specific term, as well as a designation implying maturity, while the name pickerel is restricted to the young. In the U. S., however, both these appellations are very diversely applied. See PIKE and PICKEREL. Revised by DAVID S. JORDAN.

Esox lucius.

Esop: See ÆSOP.

Esoteric, es-o-ter'ik [from Gr. ἐσωτερικός, inner, deriv. of εἴσω, ἔσω, within]: designating or pertaining to those doctrines which are designed for the initiated only. The ancient philosophers are supposed to have had a set of mysterious doctrines, which they imparted to their more enlightened and intimate disciples, and other doctrines, more popular, for the benefit of the multitude; the latter are designated as exoteric.

E'sox: a genus of fishes which includes the pikes, and the type of the family of the *Esocidæ* (*q. v.*).

Española: See SANTO DOMINGO.

Espartero, es-paar-tā'rō, BALDAMERO: Duke of Vittoria; b. at Granatula, La Mancha, Spain, Feb. 27, 1792. He was the youngest son of a common cartwright, and on account of feeble health was destined for the Church; but in 1808 he enlisted in the army, became an officer, fought with great distinction in South America 1815–25, and put down the Carlist insurrection (1833–40) by a series of brilliant exploits, for which he was made a general, grandee of Spain, and duke. In 1841 he took the place of the Dowager-Queen Christina as regent during the minority of Queen Isabella, but in 1843 a revolution declared Isabella of age, and Espartero was banished. He took up his residence in England until 1847, when the law of exile was canceled and he returned. From 1854 to 1856 he was Prime Minister, and after the revolution of 1868 he was twice mentioned as a candidate for the vacant throne. D. at Logroño, Jan. 9, 1879.

Espar'to [Span. *esparto*: Fr. *épart* < Lat. *spartum* = Gr. σπάρτος, broom]: a species of grass (*Stipa tenacissima*) growing in Spain, Barbary, etc. It has a very strong fiber, which is used by the Spaniards for making cordage, mats, nets, etc. Large amounts are used in Great Britain in the manufacture of paper. Its culture in the U. S. has been recommended. Esparto, the *halfa* of Algiers, was first used for paper by an Englishman named Routledge, whose patent was issued in 1856. The paper produced is generally of good quality. See FIBER.

Espinasse, de-les'pi-naas', CLAIRE FRANÇOISE, or JULIE JEANNE ÉLÉONORE, de l': conversationalist and letter-writer; b. at Lyons, France, in Nov., 1732; distinguished for her wit and sensibility. In 1752 she went to live in Paris as companion to Madame du Deffand, in whose house she remained nearly ten years. She gained the affection of d'Alembert, and became about 1762 mistress of a *salon* which was frequented by a brilliant literary coterie. D. in Paris, May 23, 1776. Her published letters (1809, 1887) are much admired.

Espinel', VINCENTE: poet and novelist; b. at Ronda, Andalusia, Spain, between 1544–51. Little is known of his life. He left his home very early, living for some years in Italy, and serving later as a Spanish soldier in the Netherlands. In 1591, when, having returned to his native place, he was the incumbent of a benefice, he published a volume of lyric poems (*Diversas Rimas*, Madrid, 1591) in Castilian and Italian meters. His principal work, however, is the romance entitled *Relación de la Vida y Aventuras del Escudero Marcos de Obregon* (1618), the best representative of that type of works of fiction in the seventeenth century which arose from the combination of the picaresque romance with the Italian novel. It is well known that Le Sage borrowed from Espinel's work a number of incidents of his novel *Gil Blas*. D. in Madrid, Feb. 4, 1624.

HENRY R. LANG.

Espinhaço, es-peen-yaa'sō, SERRA DO: a chain of mountains in Eastern Brazil, properly a branch of the Serra da Mantiqueira, and forming part of the great coast-range system. It lies E. of and parallel to the river São Francisco, extending from lat. 20° S. to about lat. 10° S., the trend being a little E. of N. The highest peaks are Caraço, near Ouro Preto (5,750 feet), Itacolumí, Piedade, and Itambé, from 4,800 to 5,200 feet. H. H. S.

Espinosa, GASPAR, de: Spanish lawyer and soldier; b. at Medina del Campo about 1475. In 1514 he went to America with Pedrarias as *alguazil mayor* or chief justice of the Darien colony. The charges against Balboa were tried before him, and later he presided over the court at Acla, where Balboa was condemned to death. He refused to pass sentence until ordered to do so by Pedrarias. Espinosa led many expeditions in search of gold and Indian slaves, notably one in the Nombre de Dios region (1516), when he recovered a large amount of treasure taken from Gonzalo de Badajos by the Indians. Espinosa treated the Indians with great cruelty. In 1518, acting for Pedrarias, he founded Panama. Returning to Spain some years later, he was appointed to take the *residencia* of the auditors of Santo Domingo, where it appears he afterward lived, though he frequently visited Panama. He was the real financial partner in Pizarro's second expedition to Peru (1526), though the priest Luque appeared for him. When Pizarro called for aid against the uprising of the Indians under Manco, Espinosa hurried to Lima with 250 soldiers. When he arrived Pizarro and Almagro were preparing for war on each other. Hoping to reconcile them, Espinosa went to Cuzco to see Almagro, but died a few days after his arrival (Aug. or Sept., 1537). HERBERT H. SMITH.

Espirito-Santo: a state of Southeastern Brazil; bounded N. by Bahia, E. by the Atlantic, S. by Rio de Janeiro, and W. by Minas Geraes. Area, 17,310 sq. miles. Except Sergipe, it is the smallest of the Brazilian states. It lies almost entirely in the region of the Brazilian coast range, but the mountains are not so high as those of the neighboring province of Rio de Janeiro. They take various local names, as the Serra dos Puris in the S., and in the northern part the Serra dos Aymorés, which appears to be the culminating group. The rivers Doce, Mucury, Guarapary, and others are bordered by lower and often very fertile land, and along the coast there are regions of swamps and small lakes. The greater portion of the surface is still covered with heavy forest, and the cutting and export of rosewood and other cabinet woods form one of the principal industries. The most important agricultural products are coffee and sugar. Espirito-Santo was one of the original Portuguese captaincies ceded to Fernandes Coutinho, and settled by him in 1535. It progressed slowly owing to the poverty or lack of enterprise of the early governors, and it is still one of the most backward regions in Brazil. Estimated pop. (1893) 132,092. The capital and principal port is Victoria; São Matheus, Guarapary, and Itapemirim are small towns. See Hartt, *Geology and Physical Geography of Brazil* (1870), chap. ii.; Bazilio Carvalho Daemon, *Provincia do Espirito-Santo* (1879). HERBERT H. SMITH.

Esprits Forts [Fr., bold spirits]: a school of advanced thinkers in France, numbering among them Voltaire, Diderot, d'Alembert, and Helvétius. They opposed the doctrines and practices of the Church, and wished to substitute the worship of reason. See FREE-THINKERS.

Espronceda, es-prōn-thā'daa, JOSÉ, de: poet; b. in Estremadura, Spain, in 1810; perhaps the best representative of Byronic romanticism in that country. His restless life began with imprisonment at the age of fourteen for belonging to a revolutionary society, Los Numantinos. After his release from the convent where he was confined he found it wise to leave Spain, and so wandered to Lisbon, London, and Paris. In Paris he fought at the barricades in 1830. He enrolled himself among the volunteers to free Poland from Russia. Returning to Spain, he lived in the midst of republican and revolutionary plots until his premature death, May 23, 1842. He left behind him portions of two narrative poems, *Pelayo* and *El diablo mundo*; a novel, *Sancho Soldaña*; and a limited number of lyric poems of great power and beauty. See his *Obras poeticas* (Paris, 1870); *Páginas olvidadas* (Madrid, 1882). A. R. MARSH.

Es'py, JAMES POLLARD: meteorologist, sometimes styled the "storm-king"; b. in Washington co., Pa., May 9, 1785; graduated at Transylvania University in 1808, subsequently studied law and practiced for four years in Xenia, O. In 1817 he removed to Philadelphia to take charge of the classical department of the Franklin Institute. He was the author of a theory of storms which excited some controversy, and which he published in 1841, in systematic form, under the title *The Philosophy of Storms* (Boston and London, 1841). According to this theory, every great atmospheric disturbance commences with the uprising of a body of air which has been rarefied by heat. The heavier air, flowing in beneath, creates currents converging from all directions to the central point. The rising mass dilates as it rises, in consequence of diminished pressure, and its temperature falls, in consequence of this dilatation, down to the dew-point and below, precipitating its contained vapor in the form of cloud. The latent heat of elasticity thus liberated dilates the air still more, and disturbs the equilibrium anew, so that the rising continues to go on, till the moisture in the air forming the upward current is practically exhausted. As the heavier air flowing in beneath finds a diminished pressure above it, this air also rises, causing still greater draughts upon the surrounding air, and establishing permanent converging currents, which meet in the center and rush upward, with constantly increasing violence. The vast amount of aqueous vapor precipitated during this atmospheric commotion gives rise to heavy rains. Espy's theory found many adherents. The physical principles on which it rests are sound, and it is so far supported by observation. It received also the approval of the French Academy of Sciences in a formal report. But his views as to the mechanics of storms are untenable, and are contrary to observed facts. Converging currents invariably produce rotation, and hence, though storms doubtless often originate in the causes assigned by him, their characteristic action is rotatory or spiral. The rotatory theory is now generally accepted, and has given to meteorology the familiar term *cyclone*.

Espy entertained a sanguine belief that rains could be brought on at any time by means of great fires, kept up long enough and over a sufficiently large surface to initiate a powerful upward movement, relying on natural causes to maintain the current when once started. He even supposed that it might be possible in this way to maintain the navigation of the upper Ohio river through the dry season. He therefore petitioned Congress and the Legislature of Pennsylvania to make a sufficient appropriation to enable him to try the experiment, but without success. He received, however, an appointment as meteorological observer under the Government; and while holding this position he made arrangements, in accordance with a judicious suggestion of the Hon. A. H. Stephens of Georgia, with the press and with the various lines of telegraph converging to the capital, to publish daily bulletins of the state of the weather in different and distant localities. These were doubtless the first weather-telegrams ever regularly made public. The system, discontinued during the civil war, was subsequently revived and largely extended. D. in Cincinnati, Jan. 24, 1860.

Esquimault, or **Esquimalt**: a harbor and British naval station on the southeast end of Vancouver Island; 3 miles W. of Victoria, capital of British Columbia (see map of Canada, ref. 8–D). It is strongly fortified, is a naval arsenal, and is connected by rail with the coal mines of Nanaimo. It is a safe and excellent anchorage for ships of any size, has a fine graving dock, and is the rendezvous of British warships on the Pacific coast of North America. M. W. H.

Esquimaux: the ESKIMAUAN INDIANS (*q. v.*).

Esquirol, es'kēē'rol', JEAN ÉTIENNE DOMINIQUE, M. D.: physician and philanthropist; b. at Toulouse, France, Jan. 4, 1772. He founded at Paris in 1799 an asylum for the insane, which was a model institution, and he initiated a reform in the treatment of the insane. In 1817 he began a course of clinical lectures for mental maladies, on which he wrote a valuable work, *Des Maladies Mentales* (2 vols., 1838). He became in 1826 chief physician of the asylum at Charenton. D. Dec. 12, 1840.

Esquiros, es'kee'rōs, HENRI ALPHONSE: a poet and novelist; b. in Paris, France, in 1814. On account of his work, *L'Évangile du Peuple* (The Gospel of the People), he was in 1840 sentenced to eight months' imprisonment, during which time he became an intimate friend of Lamennais. After the revolution of 1848 he was elected a member of the Legislative Assembly, in which he belonged to the Extreme Left. In consequence of the *coup d'état* of 1851, he had to leave France, and lived in England until 1869, when the amnesty proclaimed by Napoleon allowed him to return. Soon after he was elected a member of the legislative body. After the overthrow of the empire, in Sept., 1870, the provisional government sent him as administrator-general of the department of Rhône to Marseilles, where he succeeded in suppressing anarchical tendencies. He favored the separation of the south of France from the north, and for a while refused to recognize the decree of Gambetta which suspended him, but finally resigned in Nov., 1870, in order to avoid a civil war. In Feb., 1871, he was elected a member of the National Assembly, and took his seat with the Extreme Left. He published, besides other works, *Le Magicien* (1837); *Charlotte Corday*, a novel (1840); *L'Évangile du Peuple* (1840); *L'Histoire des Montagnards* (1847); *La Morale Universelle* (1859); *L'Angleterre et la vie anglaise* (5 vols., 1859–70); and in the English language, *Religious Life in England* (London, 1867). D. at Versailles, May 10, 1876.

Esquivel, es-kē̆e-vel', JUAN, de: Spanish soldier, conqueror of Jamaica; b. about 1470. He went to Hispaniola with Ovando in 1502, and commanded the Spanish troops in the province of Higuay during the struggle with Cotabanama, 1504–05. In 1509 Diego Columbus sent him to conquer and colonize Jamaica; he easily reduced the Indians to submission, founded a colony, and governed it with wisdom and success. D. in Jamaica about 1519. H. H. S.

Ess, LEANDER (his convent name, properly JOHANN HEINRICH), van: Roman Catholic theologian; distinguished at once for his learning and his liberality of opinion, especially with respect to the circulation of the Scriptures: b. at Warburg, in Westphalia, Germany, Feb. 15, 1772. In 1790 he entered the Benedictine monastery of Marienmünster in Paderborn, in 1796 became priest, and his monastery being secularized in 1802, pastor at Schwalenberg, and from 1813 till 1822 was Professor Extraordinary of Theology at Marburg. He aided his cousin, Karl van Ess (1770–1824), in publishing a German translation of the New Testament (1807), and in 1840, without assistance from his cousin, who had meanwhile given up his liberal opinions, published also a translation of the Old Testament. His edition of the Vulgate appeared in 1822, and his edition of the Septuagint in 1824. He lived in literary seclusion for several years, and died at Affolderbach, Oct. 13, 1847. His library, rich in Bibles, patristic, mediæval, and Reformation literature, and comprising over 13,000 volumes, now belongs to the Union Theological Seminary in New York city.

Es'segg, or **Es'sek** (anc. *Mur'sia* or *Mur'sa*): a strongly fortified town of the Austro-Hungarian monarchy; capital of Slavonia; on the river Drave, 13 miles from its entrance into the Danube, and 150 miles S. by W. from Budapest (see map of Austria-Hungary, ref. 8–G). It has a prosperous trade, facilitated by the steam-navigation of the river, and contains an arsenal, a town-house, and a normal school. Pop. (1890) 19,600.

Essele'nian Indians: a distinct linguistic stock of North American Indians, comprising only the Eslen (Escelen, Eclemach, etc.) tribe formerly inhabiting a narrow strip along the coast of California, from Monterey Bay southward to the vicinity of Santa Lucia Peak. Their habits and customs differed somewhat from those of the tribes of Costanoan and Salinan stocks bounding the Esselenian territory on the north and south respectively. The distinctness of their language is sufficiently determined by what is known through investigation among the Rumsen, a Costanoan tribe with whom the Eslen intermarried, and through the study of short vocabularies gathered by Lamanon in 1786 and Galiano in 1792. The names of nineteen of the villages formerly occupied by the Eslen are known, nearly all of them having been connected with the San Carlos mission.

AUTHORITIES.—*Voyage de La Pérouse*, p. 288 (Paris, 1797); Galiano, *Relación del viage hecho por las Goletas Sutil y Mexicana* (Madrid, 1802); H. H. Bancroft, *History of California*, i–vii. (San Francisco, 1884–90); H. W. Henshaw, in *American Anthropologist* (Washington, Jan., 1890). See INDIANS OF NORTH AMERICA. F. W. HODGE.

Es'sen: a town of Rhenish Prussia; on the Cologne and Minden Railway, and near the river Ruhr; 27 miles by rail N. E. of Düsseldorf (see map of German Empire, ref. 4–C). It has a cathedral, a gymnasium, a Realschule, and an asylum for deaf-mutes; also manufactures of steam-engines, firearms, woolen cloth, paper, and iron wares. It derives its prosperity chiefly from the rich coal mines which surround it. Here are Krupp's steel-foundries, the largest in the world, employing 15,000 men. Pop. (1890) 78,723; (1900) 118,863.

Essen, HANS HENRIK, Count of: a Swedish general; b. in West Gothland in 1755. He was appointed governor of Stockholm in 1795, and obtained in 1807 the command of an army with which he defended Stralsund against the French. He was sent as ambassador to Paris by Charles XIII., who became king in 1809, and the result of the negotiation was the restoration of Pomerania to Sweden. In 1814 he was raised to the rank of field-marshal and Governor-General of Norway. D. July 28, 1824.

Essenes, es-seenz', or **Essæans**: the latest, and apparently the smallest, of the three Jewish sects in existence in the time of Christ. They are not mentioned in the New Testament. The etymology of the name is doubtful, and the history of the sect obscure. The Essenes were mystics, and most of them celibates. They are not to be confounded with the Therapeutæ, although a kindred sect. The greater part of them lived by themselves near the northwest shore of the Dead Sea, but they were also scattered in various parts of Palestine, and are supposed to have numbered in all some 4,000 or 5,000. The first distinct trace of them is about 110 B. C., and they disappear from history after the destruction of Jerusalem by the Romans. See C. D. Ginsburg, *The Essenes* (London, 1864), and the article in J. B. Lightfoot's commentary on *Colossians*, pp. 82–179. See also JEWISH SECTS.

Essential Oils [so called because they were formerly supposed to contain the essence or active principle of the plant or substance from which they are extracted], called also **Volatile Oils**: a large class of compounds, mostly of vegetable origin, though some are derived from animal sources. They mostly exist already formed in plants. With a few exceptions they are colorless, and have in most cases a powerful odor and pungent taste, resembling that of the plant whence they are derived. A large number of them are isomeric (or identical in composition) with oil of turpentine and with caoutchouc. These are called terpenes ($C_{10}H_{16}$); others are aldehydes; still others appear to be compounds of alcohol radicals with organic acids, etc. A very few contain sulphur. Most of them are obtained by distillation with water, others by pressure. They are in many cases changed by time and exposure into resins, or resolved into several distinct substances.

Essequibo, es-se-kee'bō: the largest river of British Guiana, rising in the Acaraí Mountains, 41 miles N. of the equator, and flowing, in general, northerly to the Caribbean Sea; length, about 625 miles. Except in the last 50 miles of its course it is much obstructed by rapids and falls. The mouth is an estuary 15 miles broad, but dangerous for navigation owing to numerous islands and sand bars. The lower Essequibo was originally bordered by forests, now largely cleared for sugar-cane plantations; all the middle course is still lined with heavy forest growth, but the upper river flows through open land. The Rupununi, a western branch of the Essequibo, is 220 miles long. Venezuela claims the Essequibo as her eastern boundary, but a large region W. of the river is in the possession of the British.

HERBERT H. SMITH.

Essex (East Saxons): a county of England; bounded E. by the North Sea and S. by the estuary of the Thames. Area, 1,542 sq. miles, of which nine-tenths are arable. It is drained partly by the Stour, the Lea, and the Chelmer rivers. The surface is pleasantly diversified, except the flat marshy land near the sea. The soil is mostly a fertile loam, which produces wheat, barley, oats, beans, hops, potatoes, etc. Essex is an agricultural county, with few manufactures. Many sheep are raised. The chief towns are Chelmsford (the capital), Colchester, Harwich, and Maldon. Essex was a kingdom of the Anglo-Saxon heptarchy, which comprised Essex and parts of Middlesex, Hertford, and Bedford. Pop. (1901) 816,524.

Essex: town; Middlesex co., Conn. (for location of county, see map of Connecticut, ref. 11–I); on railway and on the Connecticut river, 7 miles from its mouth, and about 17 miles W. of New London. It has manufactures of carriages and soap. Pop. of township (1880) 1,855; (1890) 2,035; (1900) 2,530.

Essex: town (incorporated in 1889); Essex co., Ontario, Canada (for location of county, see map of Ontario, ref. 6–A); on railway; 15 miles S. E. of Windsor. It has five churches, high school, creameries, sawmills, cooperage, cabinet-works, and manufactures of engines, boilers, and agricultural implements. Pop. (1881) 800; (1891) 1,709.

EDITOR OF "FREE PRESS."

Essex, ROBERT DEVEREUX, Second Earl of: English courtier; b. near Bromyard, Herefordshire, Nov. 10, 1567; eldest son of Walter, the first Earl of Essex. He was educated at Cambridge; graduated in 1581, and was one of the most learned noblemen of the age. He served with distinction at the battle of Zutphen. In 1587 he was made master of the horse, and after the death of Leicester, in 1588, he became the declared favorite of Queen Elizabeth. He had a handsome person, agreeable manners, and possessed the art of ingratiating himself. He married, in 1590, Sir Philip Sidney's widow, who was a daughter of Sir Francis Walsingham. He commanded the land forces of the expedition which took Cadiz in 1596, and was made earl-marshal of England in 1597. He was appointed Lord-Lieutenant of Ireland, and was sent in 1599 to subdue a revolt of the Irish, but was not successful. He was removed from office, deprived of all the honors the queen formerly had showered upon him, and ordered not to leave his house. In despair, he made an attempt to excite the population of London to rise in his favor, but the attempt failed utterly. In the straits caused by these acts, Bacon acted as his friend, but, nevertheless, Essex was tried for treason, and beheaded Feb. 25, 1601. He was brave and generous, but impetuous and imprudent.

Essex, THOMAS CROMWELL, Earl of: See CROMWELL.

Essex Junto, The: a name first applied by John Hancock about 1781 to a group of political leaders who lived in Essex co., Mass., or had business connections there. The interests of this section were commercial, so that the Essex Junto became the personification of the desire of the commercial interest for a stronger federal union. Prominent members of the Junto were George Cabot, the Lowells, Timothy Pickering, Theophilus Parsons, Stephen Higginson, and Benjamin Goodhue, while Fisher Ames sympathized with them strongly. The Junto naturally joined the Federalists and became the extreme wing of that party. On the succession of Adams the members of the Junto followed Hamilton. On two occasions the faction attracted special notice. At the time trouble was threatened with France, President Adams tried to throw upon the Essex Junto the responsibility for the "war scare," and denounced them as a British faction. When opposition to the "restrictive system" (see EMBARGO) arose in New England, the name "Essex Junto" became a synonym for New England federalism. It was vaguely but wrongfully believed that behind this lurked a spirit of disloyalty, of which the alleged intention to secede in 1808, the Hartford convention, etc., were supposed manifestations. C. K. ADAMS.

Essipoff, ANNETTE: See the Appendix.

Ess'ling: village of Austria: on the Danube; 7 miles E. of Vienna; the scene of an indecisive battle between Napoleon and the Austrians in May, 1809. See ASPERN.

Es'slingen: town of Würtemberg; on the river Neckar; 9 miles by rail E. S. E. of Stuttgart (see map of German Empire, ref. 7–D). It is on the railway which connects Stuttgart with Ulm, is still partly surrounded by walls, and has an old castle. It has a splendid Gothic church, built in 1440, with a spire 246 feet high, a handsome town-hall, and a richly endowed hospital. Here are important manufactures of machinery, cotton and woolen stuffs, paper, silverware, and wine. Esslingen was founded in the eighth century, and became in 1209 a free city of the German empire, and in 1802 a part of the duchy of Würtemberg. Pop. (1890) 22,156; (1895) 24,031.

Essonite (cinnamon-stone): See GARNET.

Estado Oriental: See URUGUAY.

Estaing, des'tăn', CHARLES HECTOR, Count d'; naval officer; b. in Auvergne, France, in 1729. He served in the army in India, 1757, and was appointed lieutenant-general of the naval forces in 1763. But the hostility excited among naval officers whose hopes were destroyed or whose pride was stung by the appointment to such high rank of one who was educated for the land service placed him in an unfortunate position, which his want of discretion rendered still worse. He commanded as vice-admiral a fleet sent in 1778 to fight for the U. S. His fleet was damaged by a storm near Newport in August of that year. He soon repaired his ships, and sailed to the West Indies, where he captured Grenada in 1779, displaying great bravery in the attack. In September of that year he attacked the British at Savannah, without success. He returned to France in 1780, and afterward devoted himself to politics. In the Revolution he supported the king and queen with a fidelity and zeal that finally cost him his life. He was guillotined Apr. 28, 1794.

Estate [from O. Fr. *estat* (> Mod. Fr. *état*): Ital. *stato*: Span. *estado* < Lat. *status*, condition, state]: a word sometimes used to indicate property generally, whether real or personal. Sometimes it includes land alone. In law it denotes the interest which one may have in property. It means the time during which ownership exists, as for a year, or for life, or forever. Under the common law, estates in land are divided, as regards the *quantity* of interest, into two general divisions, freehold estates and estates less than freehold.

A *freehold* is an estate which may last for life or longer. An estate which is circumscribed within a certain number of years, or one in which the possessor has no fixed right of enjoyment, is less than freehold, and although, in fact, it may endure longer than the life of its first possessor, still the law regards it as a lower estate than a freehold; it is in the eye of the law personal property, and does not descend to heirs, though it may pass to executors or administrators.

Freehold estates are divided into estates of inheritance, which pass to heirs, and estates not of inheritance; the former are again divided into estates in fee simple and estates in fee tail. A fee simple is the most extensive and highest interest a man can have in land. If not aliened or devised, it passes to heirs generally. A fee tail, on the other hand, is an estate which is limited to certain particular heirs or to a certain class of heirs, to the exclusion of the others, as to the heirs of one's body, which excludes collateral heirs, or to the heirs male of one's body, which excludes females. Fee tails have had only a limited existence in this country, and are now, in general, abolished. In New York, by the law of 1782, they were changed into estates in fee simple.

Freeholds not of inheritance are for life only, either for the life of the tenant or of some other person or persons, when the estate is called an estate *pur autre vie*. Life estates are created by the act of the parties or by operation of law. An example of the former is where A conveys land to B for the term of his natural life, or where A conveys land to B without expressing the duration of the term. Here, under the common law, B would take only a life estate, but by statute in New York and many other States a grant or devise of real estate passes all the interest of the grantor or testator, unless the intent to pass a less estate or interest appears in express terms or by necessary implication. Curtesy and dower are life estates created by act or operation of law. When a man marries a woman seized at any time during the coverture of an estate of inheritance, and has issue born alive during the life of the wife, which might possibly inherit from the mother, the husband on the death of the wife has an estate for his life in her land, which is termed curtesy. In many of the U. S. a wife may alien or devise her land so as to defeat this estate, and in some it is altogether abolished. When a husband dies, the wife has a life estate in a third of all the land in which at any time during coverture he had an estate of inheritance. This estate of the wife is termed dower. In some of the States, by statute, a wife is entitled to dower only in the land of which her husband died seized, and in most of the States the interest which a wife takes in the land of her deceased husband has been a matter of statutory regulation.

Estates less than Freehold.—These are divided into estates for years, at will, and by sufferance. An estate for years is an estate for a determinate period, whether it be for a longer number of years than a human life, or for only a portion of one year. An estate at will is where one man lets land to another to hold at his will, as well as that of the lessee. Such an estate is terminated by either party on due notice. Out of estates at will a class of estates has grown up called estates from year to year, which can be terminated only by six months' notice, expiring at the end of the year. An important element in creating this estate is the payment of rent. An estate by sufferance arises when one comes into the possession of land by agreement, and holds over after his original estate has expired, and without any agreement, express or implied, by which it is continued. The landlord has a right to enter at any time, and dispossess the occupant without notice.

These estates may be created upon condition—that is, their existence may depend on the happening or not happening of some event whereby the estate may be created, enlarged, or defeated. A fee, a freehold, or a term for years may thus be upon condition. The condition must either be precedent—that is, must happen before the estate can vest or be enlarged—or subsequent, when it will defeat an estate already vested.

Estates may also be legal or equitable. They are called "equitable" when the formal ownership is in one person and the beneficial ownership is in another. Another form of expression is that a trust is created. This distinction does not affect the nature of the estate. Thus a trust estate may be a life estate or a fee, and in the latter case is transmissible to heirs as though it were a strict legal estate.

In regard to the time of enjoyment, estates are divided into estates in possession and estates in expectancy. An estate in possession is one in which there is a present right of enjoyment. Estates in expectancy are those which give either a vested or contingent right of future enjoyment. They are subdivided into remainders, which are created by the express words of the parties, as where one gives a life estate in land to A, and the remainder to B; and reversions, which arise by operation of law, as where one gives an estate for life to A; here, on the death of A, the estate reverts to the grantor or his heirs, who, until the termination of A's estate, are said to have a reversion in the land. Besides these, there are future estates introduced into the law by the doctrine of uses (see USES) which are not governed by the technical rules applicable to remainders. They are called "springing and shifting uses." Similar provisions in a will are termed "executory devises."

In regard to the number of owners, estates are divided into estates in severalty, in joint tenancy, in common, and in coparcenary. An estate in severalty is one which has only a single owner. An estate in joint tenancy is an estate owned jointly by two or more persons, whose title is created by the same instrument. The distinguishing characteristic is the right of survivorship. On the death of any tenant his interest is extinguished, and the estate goes to the survivors. By the common law, where an estate is conveyed to two or more persons without indicating how it is to be held, it is understood to be in joint tenancy. But in most States of the U. S. this rule has been changed by statute, and persons to whom an estate is conveyed or given take as tenants in common, unless they hold as trustees. An estate in common is where separate and distinct but undivided interests in land are held by two or more persons. Each tenant is considered as solely seized of his share, which on his death descends to his heirs. An estate in coparcenary is the estate which female heirs take in the land of an intestate ancestor. In the U. S. this estate is essentially extinguished, and heirs take as tenants in common.

The English classification of estates in land has been much modified by statute in the U. S., but it forms the basis of the law of real estate everywhere, except in Louisiana, where the civil law prevails. T. W. DWIGHT.

Estates, The Three, or the **Estates of the Realm**: the three classes of feudal society: 1, the nobles; 2, the clergy; and 3, the commons, including the bourgeois or middle class of towns and the peasantry. The term "estates of the realm" was used in Scotland before the Union (1707) as synonymous with Parliament. It consisted of lords spiritual (or mitered clergy), lords temporal (including the nobles and the commissioners of shires and stewartries), and the representatives, called burgesses or commissioners, of royal burghs. They met in one assembly, and usually voted in a body. The "States General" of France were rarely convened after the fourteenth century, and had little or no legislative power. One of the exciting causes of the French Revolution was the dispute which arose in 1789 between the "third estate" (*tiers état*), or bourgeois, and the nobles and clergy, as to whether the third estate had a right to sit with the first and second. In Sweden there were four estates—nobles, clergy, bourgeois (middle class), and peasants, each sitting in a separate house; but since 1865 there are but two legislative houses, both representative. A convention of the States General was long (1580–1795) the supreme power in the Dutch republic.

Es'te (anc. *Ates'te*): a town of Italy; in the province of Padua; picturesquely situated on the slope of the Euganean Hills; 18 miles by rail S. S. W. of Padua (see map of Italy, ref. 3–D). Here is a fine feudal castle, or *Rocca*, belonging to the noble family of Este; also an interesting Romanesque church with a leaning tower. Este has manufactures of silk goods, hats, and earthenware. Pop. 9,000.

Este: an ancient sovereign family of Italy, from which the monarchs of Great Britain are descended. Among the first princes of this family was Oberto I., who married a daughter of Otho, King of Italy, and died about 927 A. D., leaving a son, Oberto II. The family received several districts and towns to be held as fiefs of the German empire. Albertazzo II., who succeeded Oberto II. about 1020, married a German princess of the house of Guelph or Welf. Their son, Guelph IV., received in 1071 the investiture of the duchy of Bavaria. He was the ancestor of the houses of Brunswick and Hanover.

Estella, es-tel'yăă: city of Spain; province of Navarre; 22 miles S. W. of Pamplona (see map of Spain, ref. 12–G). It is well built, and has a church with a lofty tower, a college, and a hospital; also manufactures of linen and woolen fabrics, brandy, and earthenware. Pop. (1887) 5,974.

Estepa, es-tā'păă (anc. *Astepa*): town of Spain; province of Seville; 60 miles E. S. E. of Seville (see map of Spain, ref. 19–D). It has a church which is a noble specimen of Gothic architecture, and a fine palace; also manufactures of baize, oil, etc. Marble is quarried in the vicinity. Pop. (1887) 9,059.

Estepo'na: town of Spain; province of Malaga; on the Mediterranean; 25 miles N. E. of Gibraltar (see map of Spain, ref. 20–D). It has an old Roman castle, is well built, and has extensive sardine-fisheries. Pop. (1887) 9,771.

Esterhazy de Galantha, es-ter-haa'zē-dă-găă-laan'tăă, NICHOLAS, Prince: Austrian diplomatist; b. Dec. 12, 1765; obtained the military rank of field-marshal. He was employed as ambassador to Paris, London, and St. Petersburg between 1801 and 1816. He owned an immense fortune, and founded a rich collection of paintings in Vienna. D. at Como, Nov. 25, 1833.

Esterhazy de Galantha, PAUL, Prince: general; b. Sept. 8, 1635; became a field-marshal in the Austrian army before the age of thirty, and was chosen Palatine of Hungary in 1681. In 1686 he took Buda from the Turks, and in 1687 was created a prince of the empire. D. Mar. 26, 1713.

Esterhazy de Galantha, PAUL ANTONY, Prince: diplomatist; b. Mar. 10, 1786; son of Nicholas Esterhazy de Galantha; was ambassador from Austria to London in 1815–18, and again in 1830–38. In Mar., 1848, he became Minister of Foreign Affairs in the liberal ministry of Hungary, but he resigned about the time the war broke out, and took no part in the conflict. He owned more land than any other subject of the Austrian empire, and had a fine palace at Eisenstadt. D. May 21, 1866.

Esther, es'ter (star), the Persian name of **Hadas'sah** (myrtle): a beautiful Jewish maiden who became the queen of Xerxes, King of Persia (B. C. 486–465). She was a cousin and foster-daughter of Mordecai, the Benjamite, who became prime minister of Persia in place of Haman the Amalekite.

Esther, Book of: one of the latest of the canonical books of the Old Testament, consisting of ten chapters, and relating events which gave rise to the Jewish feast of Purim. The Jews call it emphatically *Megillah*, the Roll. The whole of it is read in Jewish synagogues every year at the feast whose origin it explains; and still, in many synagogues, with noisy demonstrations, such as hissing, and clapping of hands, and stamping of feet at the mention of Haman's name. The inspiration of the book and its right to a place in the canon have been sharply questioned. Much account is made of the singular fact that the name of God does not once occur; that, although fasting is spoken of, no mention is made of prayer; and that the religious tone of the book throughout is low. On the other side, it is urged that the providence of God is magnified; that we have a vivid picture of manners and morals at the Persian court; and, above all, a most valuable exemplification of the unspiritual character of that portion of the Hebrew people who chose not to return to the Holy Land. Its author is unknown. See the commentaries by the Lowell Hebrew Club (ed. Haley, Andover, 1885); by Paulus Cassell (Eng. trans. Edinburgh, 1888); and by Oettli in Strack u. Zöckler's *Kgf. Kommentar z. d. heil. Schriften A. u. N. Test.* (Munich, 1889).

Esther, Apocryphal Book of: the ten canonical chapters of the book of Esther, with interpolations here and there, and the addition of six chapters at the end. These additions are found in the Septuagint, and in versions made from it, but not in the Hebrew. For this reason Jerome placed them together at the end of Esther, but Luther was the first to place them in the Apocrypha. The object of the unknown author was to give a more religious tone to the book of Esther than it originally possessed. Though considered spurious by all Protestant churches, the Greek, Armenian, and Roman Catholic Churches accept these additions as canonical.

Es′therville: city; capital of Emmet co., Ia. (for location, see map of Iowa, ref. 2–E); pleasantly situated on the east branch of the Des Moines river, and Burlington, Cedar Rapids and Northern Railroad. It has superior educational advantages, a fine school-house, a machine-shop, two large flouring-mills, flax-mill, etc. Principal business, farming and stock-raising. Pop. (1880) 138; (1890) 1,475; (1900) 3,237.

EDITOR OF "EMMET COUNTY REPUBLICAN."

Estho′nia (Germ. *Esthland*): a government of Russia, and one of the Baltic provinces; bounded N. by the Gulf of Finland, E. by St. Petersburg, S. by Livonia, and W. by the Baltic Sea. Area, 7,817 sq. miles. The surface is generally flat, and extensively covered with forests of pine; the soil is sandy, and in some parts marshy. The staple products are grain, hemp, flax, tobacco, and cattle. The population of the towns and the nobility are predominantly German, while the people of the rural districts are mostly Esthonians, belonging to the Finnish race. Ninety-six per cent. of the population belong to the Lutheran Church. The language of the Esthonians is soft and melodious, comprising two dialects—the Dorpat, or Werra, and the Reval Esthonian—which differ so greatly that they can not well be treated in the same grammar. The Reval dialect is used in their literature, which consists chiefly of poems, the most important of which is the epic poem *Kalewipoeg*. The Esthonian tribe inhabits also a part of Livonia, with an aggregate population of about 600,000. Esthonia was conquered from the Swedes by Peter the Great in 1710. Capital, Reval. Pop. (1889) 392,738; (1897) 413,724.

Estivation [from Lat. *æstiva're*, pass the summer]: the summer sleeping of animals which, like the African mudfish (*Protopterus*) and some mollusks, lie dormant during hot weather; contrasted with *hibernation*. F. A. L.

Estop′pel [from O. Fr. *estoupail*, deriv. of *estouper* (> Mod. Fr. *étouper*), to stop up, calk, *estoupe* (> Mod. Fr. *étoupe*), tow, oakum: Ital. *stoppa*: Span. *estopa* < Lat. *stuppa*, tow, oakum]: a principle of law whereby one is bound by his previous admission or declaration—not on the ground that it is true, but because to dispute it is regarded as contrary to sound policy, or as subversive of the ends of justice. Estoppels are of record, of deed, and *in pais*.

Estoppel of Record.—By record is here meant the record of a tribunal of a judicial character. No one is permitted in a legal proceeding to contradict an admission made by him in his pleading. So the judgment of a court of competent jurisdiction is in most instances absolutely unimpeachable. If the judgment is *in rem*.—that is, if it determines the status of a person or thing—it is binding on all persons, whether rendered by a domestic or a foreign tribunal. If the judgment is *in personam*, it is conclusive if rendered by a domestic court, and the better opinion is that the same rule applies to a foreign judgment, unless it be shown in either case that the court which pronounced it did not acquire jurisdiction, or that the judgment was obtained by fraud. This respect for the decisions of foreign tribunals is based on the comity which nations show each other, and on the necessities of commerce. The Constitution of the U. S. provides that full faith and credit shall be given in each State to the public acts, records, and judicial proceedings of every other State. Under this provision the judgments of the courts in one State are binding on the tribunals of another State, without reference to the doctrine of the comity of nations. But a judgment *in personam* has no binding force except as to the parties to the action in which it is rendered, and those who claim under them, who are technically said to be in privity with them. The doctrine of estoppel by record does not prevent one injured by a judgment from taking direct proceedings to attack it, and judgments are often set aside on application to the court in which they are rendered. In certain cases courts of equity interfere by injunction to stay proceedings on judgments obtained in courts of law.

Estoppel by Deed.—A party to an instrument under seal is bound by the statements contained in it to those who have acted upon such statements, or, as Lord Mansfield puts it, no man is allowed to dispute his own solemn deed. The estoppel applies to recitals as well as to direct averments. To create an estoppel the recital must be clear and of a material fact, and consistent with the general scope of the deed. As a general rule, estoppels of this class are reciprocal. Thus in the case of a lease, while the tenant can not dispute the title of the landlord, the latter can not deny the right of the tenant. There is also an estoppel by deed of a more technical nature. This grows out of a covenant of warranty. Thus should a person having no title to land convey with covenant of warranty, and afterward acquire the title, he would be estopped by his covenant from asserting his claim to the land. The object of this rule is to avoid "circuity of action."

Estoppel in Pais.—In the time of Lord Coke this division of the principle was applied only to certain acts relative to the title of real estate which the law regarded as possessing equal solemnity and notoriety with a deed. Since then the principle has been greatly extended, and now presents a twofold aspect. In the first place, it is rigorously applied, from motives of general policy, to certain classes of cases. A bailee in general can not dispute the title of his bailor, neither is the indorser or acceptor of negotiable paper allowed to deny the genuineness of any of the preceding names to the paper. In the second place, it is applied when good conscience requires that one should not be allowed to insist on his strict legal rights. The rule which governs its application here may be thus stated: Where one has made a representation or an admission by his words, his action, or, in cases where it is his duty to speak, by his silence, with the intent or expectation, or reasonable grounds for expectation, that others should rely and act thereon, he shall not be permitted to prove that the representation or admission was untrue, if thereby injury would result to one who has in good faith acted upon it. It was at one time supposed that *fraud* was an essential element to constitute an estoppel *in pais*. The better opinion is that no fraudulent design is necessary. It is enough if the party claiming the benefit of the estoppel has acted upon the representations as before stated. The principle, thus limited and applied, is free from the technicalities and harshness which for a long time caused the doctrine of estoppel to be regarded with suspicion by the courts: it is constantly invoked for the prevention of fraud and injustice, and has become one of the most effective agencies of the law. A few instances of its practical application may be cited: A principal may by his conduct be estopped to deny that a certain person is his agent; one who has permitted himself to be held out as a member of a mercantile firm may be estopped as to creditors from denying his membership; a man who has held out a woman as his wife may be estopped from proving that she is not as to tradesmen who have in good faith supplied her with the necessaries of life on his credit; a statement in a bill of lading that the goods were received in good order can not be contradicted as against a person who has made advances relying on the truth of that statement; a bank may be estopped by the act of its cashier in certifying a check. The principle has been extended to the law of real estate. An owner of land who has induced another to incur heavy expenditure on the representation that the latter was owner would be estopped from asserting his own title.

T. W. DWIGHT.

Esto′vers [from O. Fr. *estover*, *estovoir*, subst. of vb. *estovoir*, to be necessary. Various attempts have been made to find a Lat. original, none of them entirely satisfactory]: necessaries or supplies allowed to a person out of an estate; especially the wood which a tenant is allowed to take from the demised premises for fuel, fences, and general agricultural purposes. This right may be claimed by any tenant, whether for life, for years, or at will, unless forbidden in his lease. But only a reasonable amount of wood can be taken; the tenant must not commit waste by destroying the timber, or doing permanent injury to the inheritance. See WASTE. Revised by F. STURGES ALLEN.

Estrades, GODEFROI, Comte d': marshal and diplomatist; b. at Agen, France, in 1607. He negotiated the cession of Dunkirk to France in 1662, and rendered important military services in Holland between 1672 and 1675. He represented France at the congress of Nymwegen, 1678. D. Feb. 26, 1686.

Estray' [from O. Fr. *estraier*, to stray, deriv. of *estrée*, road, street: Ital. *strada* < Lat. *strata* (sc. *via*), paved way]: in law, a domestic animal (the owner of which is unknown) found wandering outside the pasture or other inclosure where it belongs. In England the owner has a year and a day in which to claim such cattle, and the proprietor of the inclosure where they are found must make due proclamation in a church and in the two market-towns next adjoining. When these conditions are fulfilled and the cattle are unclaimed they belong to the sovereign, or now usually, by special grant from the crown, to the proprietor of the inclosure where they are found. The law of estrays varies in different States of the U. S. In general, estrays may be impounded (in a public or a private pound), and after being duly held and advertised may be sold to pay damages and expenses. Revised by F. STURGES ALLEN.

Estremadu'ra: province of Portugal; bounded N. by Beira, E. and S. by Alemtejo, and W. by the Atlantic, and intersected by the river Tagus. Area, 6,876 sq. miles. The surface is mostly hilly; the soil is partly fertile and partly sterile. It is subject to frequent earthquakes. Among the minerals are granite, marble, and coal. The staple productions are wine, oil, cork, fruits, and grain. Pop. about 925,000. Capital, Lisbon.

Estremadura: a former province of Spain; bounded N. by Leon, E. by New Castile, S. by Andalusia, and W. by Portugal; intersected by the rivers Tagus and Guadiana. Between these rivers a long chain of mountains extends nearly E. and W. The northern and southern parts are also mountainous. The soil is fertile, but not cultivated to much extent. Large flocks of sheep are pastured on it. This province contains mines of copper, lead, silver, and coal, which are neglected. It is comprised in the present provinces of Badajoz and Cáceres. Pop. about 750,000.

Estremoz, es-trā-mōz': town of Portugal; province of Alemtejo; about 23 miles N. E. of Evora and 82 miles E. of Lisbon (see map of Spain, ref. 17–B). It has a strong castle on a hill, around the base of which the town is built. Estremoz is noted for manufactures of porous jars which have the property of keeping water cool. Pop. 7,600.

Es'tuary [from Lat. *aestua'rium*, tidal water; deriv. of *aestus*, flood, streaming water, ebb and flow of tide]: the widening mouth of a river of moderate depth where the tides run in from the sea. An estuary is generally formed by the moderate submergence of the lower part of a valley, after which it may be widened by wave and tidal action on its shores and shoaled by deposition of land waste brought in by rivers and tidal currents. Estuaries are therefore frequently of difficult navigation from their shifting bars of sand and mud. The tides of estuaries exhibit a rapid rise and a slow fall, thus making the period of flood and ebb unequal. The rise of flood tide is sometimes so rapid as to form a wall of water advancing up stream. This is known as a bore in the estuary of the Severn, England, as a *mascaret* in the lower Seine, as a *pororóca* at the mouth of the Amazon. Typical estuaries are seen in the lower course of the Delaware and Potomac in the U. S., the Thames and the Firths of Forth and Clyde in Great Britain, and the Elbe and Gironde in continental Europe. W. M. DAVIS.

Étah: a district (and town) of Agra, Northwest Provinces, British India; on the right bank of the Ganges, between the parallels 27° 30' and 28° 1'. Area, 1,739 sq. miles. It is an elevated alluvial plateau, with dry uplands in the W. and occasional saline efflorescence in the cultivated plains nearer the Ganges. Extensive canals are used to irrigate the western portion. The principal products are wheat, cotton, sugar-cane, indigo, and opium. The climate is dry and healthful, but sand and dust storms are common. Étah town is on the Grand Trunk Railway, in lat. 27° 34' N., lon. 78° 42' E. (see map of N. India, ref. 5–E). It has about 10,000 inhabitants. Pop. of district nearly 800,000, nine-tenths Hindus. M. W. HARRINGTON.

Étampes, ā'taàñp', formerly **Estampes** (anc. *Stam'pæ*): town of France; department of Seine-et-Oise; on the Paris and Orleans Railway; 31 miles by rail S. S. W. of Paris (see map of France, ref. 3–F). It has three churches, a castle, and many flouring-mills; also manufactures of hosiery, linen thread, counterpanes, and soap. Pop. (1896) 8,637.

Etawah, e-taa'wăă: a district (and city) of Agra, Northwest Provinces, British India; on the left bank of the Jumna; between the parallels 26° 20' and 27° N. Area, 1,694 sq. miles. It is on the great alluvial plain between the Ganges and Jumna, and in general requires irrigation. About one-half of the district is cultivated. The East Indian Railway runs through the district. Etawah city is on the Jumna, 70 miles S. E. of Agra. The town (see map of N. India, ref. 6–E) is intersected by ravines, crossed by broad bridges, and has about 35,000 inhabitants. Pop. of district about 750,000, of whom about 95 per cent. are Hindus. M. W. HARRINGTON.

Etchemins: See ALGONQUIAN INDIANS.

Etching: See ENGRAVING.

Ete'ocles (in Gr. Ἐτεοκλῆς): a mythical king of Thebes (in Bœotia) and a son of Œdipus. He and his brother Polynices agreed to reign alternately over Thebes, but Eteocles usurped the throne when his brother's turn to reign came. The famous expedition of the Seven against Thebes was undertaken to restore Polynices, who killed Eteocles in single combat.

Ete'sian Winds [*etesian* is from Gr. ἐτησίαι, ἐτησίαι ἄνεμοι, periodic winds; ἔτος, year]; northerly and northeasterly winds which prevail in summer throughout a great part of Europe and in Northern Africa. The name occurs in its Greek form in several ancient writers, and is now occasionally seen in meteorological works. These winds arise in a great degree from the heat of the African Sahara.

Étex, ā'teks', ANTOINE: sculptor, painter, engraver, architect, and author; b. in Paris, Mar. 20, 1806; educated there and in Rome, and achieved distinction in all the departments to which he gave attention. He published an *Essai sur le Beau* (1851); *Cours élémentaire de Dessin* (1859); and *J. Pradier, Ary Scheffer: Études* (1859). D. July 17, 1888.

Eth'elbert: King of Kent; ascended the throne in 560 A. D. He became the most powerful prince (bretwalda) of the heptarchy about 590. His wife, Bertha, a daughter of the King of Paris, was a Christian, and induced Ethelbert and his subjects to profess Christianity in 597 A. D. St. Augustine was instrumental in their conversion. Ethelbert gave to the Anglo-Saxons their first written code of laws. D. Feb. 23, 616 A. D.

Eth'elred (or **Æthelred**) **I.**: Anglo-Saxon King of England; succeeded his brother Ethelbert in 866 A. D. In the first year of his reign the island was invaded by Danes, who conquered a large part of his kingdom. His brother Alfred defeated the Danes in 870. Ethelred was killed in battle with the Danes in 871 A. D., and was succeeded by Alfred the Great.

Ethelred II., surnamed THE UNREADY: Anglo-Saxon King of England; a son of Edgar; b. in 968 A. D. His mother was Elfrida, notorious for her crimes. He succeeded his half-brother, Edward the Martyr, in 978. In his disastrous and inglorious reign the kingdom was invaded and ravaged by the Danes, to whom he paid large sums of money to purchase peace, but they soon renewed their piratical incursions. The Danish king Sweyn took London in 1014, and Ethelred fled to the court of the Duke of Normandy, who was his wife's brother. He died in 1016, leaving two sons—Edmund Ironside and Edward the Confessor.

Eth'elwolf: Anglo-Saxon King of England; the eldest son of Egbert, whom he succeeded in 836 A. D. His kingdom was harassed by several incursions of the Danes, who pillaged London in 851. He defeated these invaders at Okely in that year. He married in 856 Judith, a daughter of Charles the Bald, King of France. D. in 858 A. D. He left four sons—Ethelbald, Ethelbert, Ethelred, and Alfred the Great.

E'ther [Lat. *aether* = Gr. αἰθήρ, clear sky, upper regions of air; cf. αἴθρη, fair weather; αἴθειν, burn, glow]: a hypothetical medium which is assumed to pervade all space, and is regarded as possessing extreme tenuity and elasticity, and as being the medium of the transmission of light and heat, these forces being transmitted by vibrations or undulations of this ether.

Ether: a general name applied to two classes of compounds which are sometimes called *simple ethers* and *compound ethers*, though now, more commonly, *ethers* and *ethereal salts*. They are usually volatile fragrant substances. *Ordinary ether*, often called *sulphuric ether* because sulphuric acid is used in its preparation, is the best-known ether. It is formed from ordinary alcohol by the action of sulphuric acid, and it has been shown to be the oxide of the radical ethyl, C_2H_5, as alcohol is the hydroxide of the same radical. The relation between them is the same as that between potassium hydroxide and potassium oxide, as indicated by the formulæ—

KOH Potassium hydroxide.	K_2O Potassium oxide.
$C_2H_5.OH$ Ethyl hydroxide. (Alcohol.)	$(C_2H_5)_2O$ Ethyl oxide. (Ether.)

Other ethers bear the same relation to corresponding alcohols. Common ether, or ethyl ether, is a colorless, transparent, and highly mobile liquid of characteristic odor and taste. Its specific gravity is 0·736, and it boils at 95°. When its vapor is mixed with air the mixture is extremely explosive. It is a good solvent for resins, fats, alkaloids, and many other classes of carbon compounds. Ether is much used in medicine and surgery as a diffusible stimulant, and is one of the most widely used and safest of anæsthetics. It was introduced by Dr. Morton, of Boston, Mass., and was probably the first complete anæsthetic ever employed. See ANÆSTHETICS.

Ethereal salts, or compound ethers, are analogous to metallic salts (see SALTS), and are formed by the action of an acid on an alcohol, the two reacting in the same way that an acid acts upon an ordinary base. Thus acetic acid acts upon potassium hydroxide and upon ordinary alcohol, as represented in the following equations:

1. $C_2H_3O.OH + KOH = C_2H_3O.OK + H_2O$;
2. $C_2H_3O.OH + C_2H_5.OH = C_2H_3O.OC_2H_5 + H_2O$.

The principal product of the first reaction is potassium acetate, a salt; while the principal product of the second reaction is ethyl acetate, an ethereal salt, or compound ether. This product is also called acetic ether. It is an exceedingly fragrant stimulant and anti-spasmodic. Among other well-known compounds belonging to the same class the following may be mentioned:

Butyric ether (ethyl butyrate, $C_2H_5.C_4H_7O_2$), used in preparing artificial pineapple sirup; pelargonic ether (ethyl pelargonate), for making artificial quince flavor; amyl acetate, for making jargonelle pear essence, extensively used in confections, besides an immense number of other ethers and mixtures used in artificial flavoring; iodic ether (ethyl iodide), used in medicine; nitrous ether (ethyl nitrite, $C_2H_5.NO_2$), used in making sweet spirits of niter. FATS (*q. v.*) belong to the same class of compounds.

Revised by IRA REMSEN.

Eth'erege, or **Etheridge**, Sir GEORGE: English dramatist: b. about 1636. He wrote *She Would if She Could* (1668); *The Man of Mode* (1676); and other successful comedies. He was sent as ambassador to Ratisbon in 1685. D., probably in Paris, about 1694.

Etherion: See the Appendix.

Ethics: See MORAL PHILOSOPHY.

Ethio'pia [Lat. *Aethiopia*, Gr. **Αἰθιοπία**, popularly understood to mean land of the burnt-faces, *αἴθειν*, burn + ὤψ, face]: a name given by ancient geographers to the regions situated S. of Egypt and Libya. The name Ethiopians was originally applied by the Greeks to all the peoples who lived in the southern parts of the known world, including the dark-colored natives of India. As the ancient Greeks and Romans had but little intercourse with the Ethiopians, the accounts which they have transmitted to us are very defective and uncertain. They supposed Ethiopia to be inhabited by several races called Troglodytes, Pygmies, Macrobii, and Blemmyes. According to some traditions, the Egyptians derived their civilization or came themselves from Ethiopia. The connection between Egypt and Ethiopia was at all periods intimate, but the belief has become more prevalent that civilization ascended the Nile instead of descending it. In its extended sense, Ethiopia corresponded to the modern Nubia, Sennaar, Kordofan, and Northern Abyssinia. The population of this vaguely defined region was a mixture of Arabian and Libyan races with the genuine Ethiopians. The latter had well-formed limbs, and a facial outline resembling the Caucasian in all but its inclination to prominent lips and a somewhat sloping forehead. Their language was Semitic. The Nubians and Shangallas of the present time are probably their descendants.

The term Ethiopia proper was restricted to the kingdom of Meroë. The high civilization of Ethiopia, as attested by historians and confirmed by monuments, was confined to the island of Meroë and *Aethiopia Aegypti*. The capital of this region was Napata, on the Nile. It became one of the most powerful and civilized nations of the world as early as 1000 B. C. The government was a sacerdotal monarchy, the priests being the ruling class, as in Egypt. The military power of the Ethiopians was celebrated by Isaiah (xx. 5) and other Hebrew prophets, and the sacred history records their invasion of Palestine. In the eighth century B. C. an Ethiopian dynasty (the twenty-fifth of Egypt) reigned in Lower Egypt. The first king of this dynasty was Sabaco, whose son and successor, Sebichus (the So or Seva of the Bible), was an ally of Hoshea, King of Israel, in 722 B. C. It is stated that in the reign of the Egyptian King Psammetichus (630 B. C.) the military caste, numbering 240,000, migrated into Ethiopia. It was invaded by the army of Cambyses, King of Persia, in 530 B. C. According to Josephus, he conquered Meroë. In the reign of Augustus Cæsar, Candace, Queen of Ethiopia, waged war against the Romans. Having been defeated, she sued for peace, and became tributary to him in 22 B. C., but the Roman tenure of Ethiopia was always precarious. Early in the fourth century many Christian churches were planted in Ethiopia. See Hopkins, *Travels in Ethiopia* (1835). See ABYSSINIA.

Revised by C. K. ADAMS.

Ethiopic Language: the language of the Geez or Ag'âzi (i. e. those who have traveled, or the free). Modern philologists use Geez as the more accurate, in preference to Ethiopic language, the more general term, for it has nothing in common with the language of the race called by the ancients Æthiopes (the Cushites of the Bible); and in the large empire of Abyssinia, which was called Ethiopia in the Middle Ages, there were and are still many other languages. The Geez were one of the Semitic tribes, who had emigrated from Arabia to Abyssinia, and had settled in Tigre and its capital, Aksum. In the large Abyssinian empire which grew up around Aksum, and which was gradually Christianized after the fourth century, this Geez language became the official and the Church language, beside which the dialects and languages of the different native tribes still continued to exist, but were not used as written languages. In this ruling position as the official language of the empire it continued to maintain itself until the middle of the thirteenth century, when, in consequence of a change of dynasty, the Amharic language gradually gained the ascendency at the imperial court, and entirely superseded the Geez as the official language. But its position as the language of the Church and of the scholars of Christian Abyssinia it did not lose in consequence of this political revolution. The clergy and literary men were for centuries compelled to have a knowledge of it, and understood it even well enough to write books; and the old Geez books continued to be copied. During the last 300 years books of all kinds have been prepared in the AMHARIC LANGUAGE (*q. v.*), which is more familiar to the people, and even the Bible or parts of it have been translated, especially at the instance of the Protestant missionaries, into the modern languages of Abyssinia, in particular into the Amharic and Tigre, without diminishing, however, the influence of the old Geez translations. As a popular language the Geez has died out even in Tigre, its original home, or rather it has been modified in the mouths of the people into dialects. Among these descendants of the Geez language two principal dialects are distinguished: the Tigre, which is closely allied to the Geez, and which is spoken by nomadic tribes in the extreme north, in the regions bordering on Nubia and Sennaar, which for a long time have been cut loose from Abyssinia; and the Tigriña, which is spoken in the old province of Tigre and the neighboring districts, and which has degenerated more than the other in sounds, forms, and fullness of words, and is largely mixed with Amharic words. A grammar of this language has been published by Prætorius, *Grammatik der Tigriñasprache* (1872).

The Geez is a purely Semitic language, but still, in its way, is very peculiar, and is justly regarded as a special branch of the Semitic family. Its relation to the language of the Himyaritic monuments (i. e. the Sabean) can hardly be said to be nearer than its relation to the Arabic as now written. It has, however, much in common with the entire Arabic group of languages, not only in regard to the stock of words, but also in regard to the system of sounds and the formation of words; and although it has never attained the fullness of forms of the Arabic, it has developed some Semitic peculiarities, even more consistently than the written Arabic. But in many words, roots, forms, and even in many syntactic forms, it agrees more with the northern Semitic languages, especially with the Hebrew, but also with the Aramaic and the Assyrian. It must therefore be assumed that the Geez, after its branching off from the northern Semitic, continued to develop itself in connection with the southern Semitic (Arabic) languages, but separated itself very early from these, and continued to go along its own path. For this reason it has still many peculiarities of the ancient Semitic languages—peculiarities which have been abandoned even in the Arabic; and in some respects has retained the most ancient forms (e. g. it has no article). Other forms it has developed in a peculiar manner, contrary to the method of all other Semitic languages (e. g. most of the prepositions and conjunctions). Especially in the method of construction it has formations which are hardly to be found in the other Semitic languages, and has acquired a flexibility of syntax which distinguishes it favorably from all the other languages related to it. On the other hand, besides many ancient and peculiar forms in the Geez, there are met, strange to say, many forms which the other Semitic languages only reached in their latest stages of development (e. g. the disappearance of the inner passive and of the participial form, the dropping of short vowels, etc.); and it may be inferred from this that the Geez, as it is presented in the Abyssinian books, has already passed through a long stage of development. From this it is seen that the study of the Geez is very important and instructive to the Semitic philologist.

The Geez has never been grammatically treated by native (Abyssinian) scholars. In Europe, after several very incomplete attempts in the sixteenth and seventeenth centuries, it was treated of in a grammatical and lexicographical exposition, which for its time was excellent, by Hiob Ludolf (*Grammar and Lexicon*, 1661; 2d ed., *Lexicon*, 1699, *Grammar*, 1702). In accordance with the demand of modern linguistics, and on the basis of a much fuller knowledge of Ethiopic literature, the language has also been treated of by A. Dillmann (*Grammar*, 1857; *Lexikon*, 1865), and in shorter form by F. Prætorius (grammar, with chrestomathy and glossary, 1886, one of the volumes of the *Porta Linguarum Orientalium*). See also E. Schrader (comparison between Ethiopic and the cognate languages, 1860); B. Stade (on the quadriliterals, 1871); and E. König (on script, pronunciation, and forms, 1877).

The Geez is written with peculiar characters, which originally were identical with the Himyaritic and old Arabic characters found in the inscriptions of Syria and Assyria, and were afterward only slightly modified. It is written from left to right, and is also remarkable in that it separates the single words by two dots (:), and that the writing of vowels by means of little lines and hooks, which are attached to the consonants, is uniformly carried out. These characters were subsequently used in Abyssinia for the other dialects and languages also, especially for the Amharic and the Tigriña, but enriched by several new characters, so that they can be said to have become the universal alphabet of Abyssinia. AUGUST DILLMANN. Revised by C. H. TOY.

Ethiopic Literature: the literary monuments in the ETHIOPIC LANGUAGE (*q. v.*). The oldest monuments of the Ethiopic characters and language which are known at present do not date beyond the first centuries of the Christian era. They are coins and inscriptions; among the latter especially the large inscriptions of Axoom, which have been made known to the world by Rüppel in the account of his travels. They mostly show an archaic mode of writing the consonants, and the vowel-signs are only in their infancy. An Ethiopic literature came into existence after the introduction of Christianity into Abyssinia (in the fourth century), and has always retained a predominantly religious character. Its basis was the translation of the Bible, both the Old and New Testaments, together with the semi-biblical, apocryphal, and pseudepigraphic books belonging thereto, which in the other churches were rejected or lost (as the book of Jubilees, of Enoch, the Apocalypse of Ezra, the Ascension of Isaiah, the Shepherd of Hermas, and others). The entire translation was made from the Greek, but was afterward revised several times—the Old Testament at last even from the Hebrew; and it is necessary therefore to distinguish between the old, middle, and latest revisions of the text. The pseudepigraphic books are nearly all printed. A critical edition of the Old Testament has been begun by Prof. Dillmann, and has progressed (1893) through the second book of Kings. The Psalms and Solomon's Song have been published several times. The New Testament was printed at Rome in 1548, and was reproduced in the London Polyglot with many mistakes. The edition (now out of print) of the English Bible Society (by P. Platt, 1826) gives a mixed text, which can not be used for critical purposes. The other literature consists, for a large part, of translations of Greek and even Coptic works, and after Mohammedanism had taken root in Egypt, the mother country of the Abyssinian Church, Arabic works also were translated. The literature comprises theological and religious works of every kind, such as collections of old canons (Clementina, Didascalia, Synodus), catenæ, and homilies, exegetical and dogmatical writings (especially those of Cyril, Epiphanius, Chrysostom, and also of the Syrian Fathers, especially those of the Monophysitic Church; Haimânôta Aban (i. e. a large collection of confessions of faith of the monophysitic teachers); lectionaries for the whole year, especially for the fasts and the Passion-time; horologia, liturgies of the mass, and church-books for the other sacraments, and for burials, church discipline (Faus Manfasawi), and church law (Fetha Nagast), Acta Sanctorum (Synaxa), a large number of monastic rules and monastic writings; in sacred and profane history and chronology the works of Joseph Ben Gorion, George Ben Amid, Abushaker, and others, and even something relating to philosophy and the natural sciences.

Among the native productions of the Abyssinians themselves are dogmatic treatises, pseudonymous apocalyptical writings, numerous prayer-books and formulas, meditations, eulogies and biographies of saints, martyrs, monks, and archangels in prose and verse, mostly productions of monkish imagination and an insane belief in miracles. More important in their way are the large ancient hymn-books (Degwâ, Mawâs'et, Me'râf), with hymns and antiphonies, not only for Sundays and holidays, but for every day in the year, and containing formulas for the ceremonies in honor of all the saints of the calendar, with peculiar notes for singing, the use of which has been very imperfectly explained. Most of these works, which indicate a considerable progress in religious poetry and music, have been traced back to a certain Jared in the sixth century. Besides these there were also large works on native history, and explicit annals of the several kings (from which J. Bruce in the second volume of his travels has given extracts), which were written in a peculiar language, a mixture of the Geez and the Amharic. After the extinction of the Geez a beginning of grammatical and lexicographical work was made, and was deposited in many Ethiopic-Amharic glossaries (Savasev).

Much was also written during this period on medicine, witchcraft, exorcism, and divination for the superstitious people, either in Ethiopic-Amharic or entirely in the Amharic language. The poetry was almost entirely in the service of the Church and of religion. At all events, poems on secular affairs in the Geez language have not been preserved. Besides the peculiarly arranged hymns, only lyrical poetry was developed. The poems are divided into strophes of equal length. The construction of the strophes shows many varieties: the lines are rhymed; the syllables are neither measured nor counted. Of real poetic genius there are but few traces in these poems; many have of poetry nothing but the rhyme.

Of the entire literature there have been printed besides the Bible the *Hermas Paster* (1860); Æthiopic liturgies and prayers (1865); *Physiologus* (1877); and a number of things in the journals of the French and German Oriental societies. It is very fully represented in manuscripts in all the large libraries of Europe, especially in Rome, Paris, Oxford, London, Tübingen, Frankfort-on-the-Main, Vienna, and Berlin. Since the Abyssinian war in 1868 the collection of the British Museum has been so largely increased that it is without doubt the largest in Europe. All the older and most of the later manuscripts are written on beautiful parchment. Among the manuscripts none date further back than the fifteenth century. Catalogues have been published of the collections in St. Petersburg (1837); Würtemberg (1843); Tübingen (1847); Oxford (1858); Paris (1859); Vienna (1862); and London (1870).

AUGUST DILLMANN.
Revised by C. H. TOY.

E'thiops Mineral: the black powder obtained by triturating mercury with sulphur. It is a sulphide of mercury. The term ethiops was formerly applied to other black powders.

Ethmoid Bone [*ethmoid* is from Gr. ἠθμός, sieve + εἶδος, form]: a bone in man placed between the orbits and at the base of the nose, and receiving its name from its numerous perforations, through which pass the branches of the olfactory nerve. In comparative anatomy the term ethmoid is applied in combinations to various structures, but it belongs properly to an impaired cartilage bone developed at the union of the trabeculæ in front of the pituitary space. In man it consists of four parts—the cribriform plate, the perpendicular plate, and the two lateral masses. In the condition called "pug nose" the perpendicular plate is deficient, and in consequence the bridge of the nose is low.

J. S. KINGSLEY.

Ethnology [from Gr. ἔθνος, nation + λόγος, discourse]: in common usage, the science which treats of the division of mankind into races, their origin, distribution, and various characteristics, including the whole science of man. In a more restricted sense, it is the science by which men are classified into races or groups distinguished by physical characteristics, as the color of the skin, the structure of the hair, the attitude of the eyes, the form of the skull, the proportions of the skeleton, etc.; but this use has not largely prevailed. The tendency at the present time is to apply the word to that science which treats of the culture of the tribes and nations of mankind, or the origin, development, and condition of industrial and decorative arts and the arts of amusement; the arts of society; the arts of language; the arts of literature; the fine arts; natural religions; and, finally, the opinions of mankind. These subjects give rise to a series of sciences which will now be mentioned in the order above indicated.

Technology.—This term is sometimes used to denote the science of industrial arts. Perhaps it is well to extend its signification so as to include also the science of the arts of decoration and of the arts of amusement. Modern investigation has demonstrated that all industrial arts have had a lowly beginning among savage tribes, who first learned to re-enforce the labor of their hands with rude tools and implements made of stone, bone, horn, shell, wood, sinew, skin, animal and vegetable fiber, and various other substances. The rude tools and implements of this earliest stage of culture are found everywhere throughout the habitable globe, as vestiges and evidences of the lowly condition of primeval man. It is customary to speak of man while in this condition of culture as existing in the "stone age"; but this stone age was not a synchronous period throughout the habitable earth. It seems to have begun earlier in some regions than in others, and it certainly extended much later in some lands than in others. The term stone age is commonly used as one of a series, namely, stone age, bronze age, and iron age. These particular ages, or, more properly, stages of culture, are not well established over all parts of the earth, but are rather applied to stages of culture in Europe and in some smaller portions of Asia and Africa. Another method of seriating the stages of culture is of wider application and of greater significance, viz.: first, the hunter stage; second, the shepherd stage; third, the artisan stage; fourth, the inventor stage. In the first stage man derived his food from nature, by hunting, fishing, and harvesting the fruits and roots of the forest and plain. In the second stage man cultivated the soil to some extent, and domesticated animals, and from them derived his food and clothing, all men generally being engaged in the same occupation. In the third stage, marked especially by the growth of "city states," men were engaged in various trades and occupations, using tools made of the metals and various other materials. Thus arose a division of labor, one man producing articles for the use of others, and obtaining from them in exchange the many things needed by himself. In the fourth stage, which is the modern period of highest culture, such trades and handicrafts are to a greater or less extent superseded; the powers of nature are employed to drive machinery, which men operate in such a manner as to multiply products with great economy of human strength.

The *arts of decoration and amusement* have not been satisfactorily seriated, or classified in stages.

Sociology is the science of institutions or the arts of society. These arts or institutions are usually grouped in three great classes, viz.: economics, or political economy; civics, or the science of government; and ethics, or the science of morality.

Four stages of economic culture may be quite clearly discerned, but, like all such stages, well-defined planes of demarkation are not found, as lower stages develop gradually into higher. Among the lowest tribes a stage of communal property is found, when much the larger part of all the property is owned by the clan, the gens, or the tribe. In this stage only a few articles become the property of individuals, and such property is usually destroyed on the death of the owner. The second is the barter stage, when property is exchanged for property to supply the wants and desires of the exchanging parties. In the third stage a measure of value and medium of exchange is provided by the invention of money; and this stage is approximately coeval with the artisan stage of industries. The fourth stage is the credit stage, when business is transacted through banks and clearing-houses by an exchange of credits.

The civic or governmental stages of culture are most fundamentally characterized as two. The first and lowest is the tribal stage, where the organization of the body politic is a *societas* organized on the basis of actual or theoretical kinship. The second and higher stage is national, where the body politic is organized on a territorial basis, giving the *civitas*.

Savagery and Barbarism.—Tribal society may be divided into two stages. The first and lowest may be called the clan stage, or savagery, in which kinship is primarily reckoned through the female line in such a manner that the children belong to the clan of the mother. Clans thus reckoned by kinship in the female line are grouped into tribes by kinship in the male line and by intermarriage; so that kinship through females, kinship through males, and kinship by marriage are alike recognized. Barbarism is gentile society, in which kinship in the gens—which corresponds to the clan in savagery—is reckoned in the male line. A number of such groups, or gentes, are organized into a tribe. In the gens only kinship through males is recognized; in the tribe, kinship through females and kinship by intermarriage are recognized.

Patriarchies are forms of government peculiar to barbarism, or the gentile structure of tribes. In them the elder man becomes chief of the gens, and in some cases holds despotic sway over a large group of descendants composed of his own family and the families of his younger brothers. The property of the clan is communal, but is to a greater or less degree under the control of the patriarch.

Exogamy and Endogamy.—An attempt has been made by some writers to show that two systems of marriage have widely prevailed in the world, one called exogamy and the other endogamy, but it is now known that, in the case of American tribes at least, these are only two aspects of the same form of marriage. In tribal society the people are exogamous in relation to one group—that is, they must marry outside the clan or gens; but they are endogamous in relation to another and higher group, for they must marry within the tribe.

Feudalism is a transitional stage between tribal society and national society. By the institution of feudalism tribes are fused under the authority of great leaders, who are often landholders on an extensive scale. Their retainers render them service, especially in war, and are under the protection of their lords, who stand between them and the crown.

Perhaps national society may be best seriated in two stages, imperial sovereignty and popular sovereignty. In the first the state is theoretically, and sometimes actually and wholly, under the authority of the ruler, and property is held in trust or by the grace of the ruler. In the second stage the citizen is the sovereign, from whom the ruler derives his authority through constitutional law, and the authority of the ruler over the property of the subject theoretically extends only so far as may be necessary to collect taxes for public purposes.

The subject of ethics not only involves a consideration of the development of human culture, but is also related on the one hand to philosophy and on the other to religion.

Philology or *linguistics* is the science of languages. Attempts have often been made to classify languages by grammatical structure, but no such system of classification has received universal or even general acceptance. An attempt has been made to classify languages genetically by throwing together those having a common origin. To a large extent this classification is based upon vocabularies, and to a slight degree upon grammatic characteristics. This classification is yet incomplete. Many families or stocks of languages are now recognized, but there are numbers of languages outside of the recognized stocks that have not yet been studied to such an extent as to reveal their proper affinities and indicate the groups to which they belong. The work of classifying languages is one of vast extent, requiring long and painstaking research, and it must be many years before the task is completed.

Formerly it was expected that linguistic research would reduce the families of languages to a very small number, and by some it was even supposed that all would be traced to a common primeval speech; but these expectations have not been realized, though many languages so diverse as not to be mutually understood by the speakers have been traced to common origins. On the other hand, research has brought to light a greater number of distinct families or stocks of languages. With the progress of culture languages of the same stock have differentiated, while the lower tribes of mankind appear to have a great number of languages belonging to totally distinct stocks; so that, while there has been some differentiation of languages within the same family, the general progress has been toward their unification. As culture progresses fewer tongues are spoken, and a single tongue is common to an ever-increasing body of people. Often distinct languages of the same stock are formed by amalgamating with languages of other stocks, so that independent tongues disappear and are found only as integral elements in stocks that are preserved. All evidence goes to show that in savage society a vast number of wholly independent languages are developed, and that these languages coalesce to some extent and many become extinct.

Literature.—The lower tribes of mankind who have not developed written languages are always possessed of a great body of myths, folk-lore, and legends, which are handed down orally from generation to generation. In it the superstitions of the people are almost inextricably confounded with their history. Whenever such a people in the progress of its culture becomes possessed of the art of writing, more or less of this oral literature is permanently recorded, especially in songs and tales; such is everywhere the root of literature. With the more advanced peoples poetry, romance, and drama are abundantly developed, until gradually a literature of science springs up.

The æsthetic or fine arts also belong to the subject of ethnology. For this science the term *æsthetology* has been proposed. It treats of the origin, development, and characteristics of the fine arts. Authors are not wholly agreed as to what are the fine arts. Some would include poetry, romance, and drama in the fine arts; others classify these arts as literary. All agree that sculpture, painting, and music belong to the fine arts, and by most authors architecture is considered one of the fine arts, though perhaps with less substantial reasons. When the term architecture was applied to the construction of temples and great public works, and especially when these works were highly symbolic, the inclusion of architecture in the fine arts could be supported with cogent reasons, but in modern times the term architecture is applied to the construction of all classes of buildings. To an overwhelming extent the art is applied to industrial structures. For this reason architecture may be included among the industrial arts, its chief motive being the production of the economically useful.

Sculpture has a very lowly beginning with primeval man, for the lowest tribes of which there is knowledge carved images of men and animals in stone, bone, wood, and other materials, chiefly to develop the paraphernalia of religious worship. This art attained a very high degree of development in early civilization, especially among the Greeks, whose works are renowned for beauty and artistic expression.

Painting also begins in the lowest known stage of culture, when rude pictures are formed of human beings, the lower animals, and various inanimate objects. The purpose of these crude pictures seems to be in the main mnemonic, and they are known as picture-writings. Such graphic art is rude and conventional, but it steadily develops through savagery, barbarism, and civilization along two distinct lines. On one hand the picture-writings become more and more conventional, until ideographic writing is produced, then syllabarics, and finally alphabets. On the other hand, picture-writing develops into modern painting, and becomes properly an æsthetic or fine art. The stages of this development may in a general way be characterized as the flat stage, the relief stage, the perspective stage, and the chiaroscuro stage. In the first the picture-writings are mainly flat representations of objects, without relief or perspective, and are often found as monochromes. The picture-writings of the North American Indians are chiefly of this character. In the second stage skill in the representation of relief is developed. Most of the known graphic art of Egypt is of this character. In the third stage the power to represent objects as related in perspective is developed. The struggle of art through the stages of perspective drawing is well illustrated in Chinese and Japanese art, where imperfect perspective and conventional forms are often found. The fourth stage is represented by modern graphic art, where to relief and perspective is added aërial perspective, with a nice gradation of lights and shades and a high appreciation of the values of the constituent parts in developing the central thought of a work of art.

Music is born of the dance, and the earliest is purely rhythmic, its purpose being to mark time for terpsichorean performances. The music of the American Indians is largely of this character, though a slight development of melody is discovered. The second stage is the melodic, in which themes are repeated with variations. The third stage is the harmonic, which is a union of coexistent melodies. The fourth stage is the symphonic, when music is a succession of harmonies with varying themes. Often the æsthetic arts are combined in song, music, and poetry; while in the opera, music, poetry, drama or histrionic art, and even painting, are combined.

Religions, as naturally developed, are usually included in the subject of ethnology, while the subject of revealed religion, or theology, is excluded therefrom. The subject of natural religion is presented under two heads: mythologies, as theories of supernatural beings and their relation to mankind and the universe; and worship—to which the term religion is sometimes exclusively applied—which deals with the methods of propitiating and otherwise influencing such beings. It will thus be seen that the whole subject of mythology is logically included in the science of opinions, and the term religion should then be applied only to worship, but the more common usage makes it include mythology and worship. Religions are many. In tribal society every tribe has its own religion, consisting of a pantheon of superhuman beings and a system of worship. Each tribe recognizes the religion of other tribes, and cultivates its own religion for a variety of purposes: to preserve health, to cure disease, to bring abundant harvest, to prevent storms, floods, and droughts, and in general to avert all the evils to which mankind is subject, as well as for the purpose of exalting its own deities and obtaining their assistance in thwarting the deities of hostile tribes. In these natural religions four stages of philosophy or theology are discovered. The first has been characterized by Tylor as *animism*, in which inanimate things are supposed to have supernatural powers, and to be endowed with life and mind; mountains, rivers, trees, stones, and other inanimate things are held to be of equal power with the animate world, the lower animals and man. The second stage may be styled *zoötheism*, in which the distinction between the animate and inanimate is made; spirits of mountains, rivers, and other great geographic features there are still, but these are usually supposed to have animal forms. The pantheon is chiefly made up of beings with animal forms—wonderful mammals, birds, reptiles, and fishes, and mythic articulates, mollusks, and radiates. The people do not worship the live animals, but only mythic animals, to which are attributed many powers, and which are supposed to have a supernatural existence, and to have been the progenitors or prototypes of the existing animals. In this stage, too, the sun, moon, stars, and other heavenly bodies and phenomena are worshiped as gods, and they are supposed to have the forms of the lower animals, though sometimes, but rarely, of men. The third stage may be characterized as *physitheism*, in which the heavenly bodies and the great powers and phenomena of nature are personified and deified. The fourth stage may be denominated *psychotheism*. Gradually the natural gods, as powers, assume especial psychic characteristics and come to preside over realms of life, passion, and human interests: thus there is a god of war, a god of love, a god of revenge, a god of agriculture, etc.

The methods of worship can, in a general way, be characterized in stages, though the series of stages necessarily coalesce as the lower is developed into the higher. Of the worship attending that stage of theology known as animism, little is known. In zoötheism the principal form of worship may be called terpsichorean. The gods are mainly influenced by dancing and music, but to this a variety of crude ceremonies is added. In the third stage terpsichorean worship still remains, but to it is added a vast system of sacrificial worship, where wine, fruits, animals, and men are offered to placate or otherwise influence the mythic gods. In this stage terpsichorean worship is developed into dramaturgy, and ceremonies are highly dramatic and thaumaturgic, or wonder-working. In the fourth stage terpsichorean worship wanes; sacrificial worship with dramatic performances still remains, but to it is added an important element of what may be called fiducial worship, which is characterized by profound belief in the gods, faith in their powers, and reliance on them for all the good of life. This new form of worship is especially characteristic of psychotheism.

Opinions.—It has been proposed to designate the science of opinions by the term *sophiology*. This science derives an important part of its material from the history of the growth of concepts as they are expressed in parts of speech. Another great source of material is discovered in the history of literature, in which the opinions of mankind are recorded. Mythologies, which are very numerous, and of diverse characters, afford a wealth of material upon the same subject. Finally, the history of the sciences contributes its materials. Two great systems of opinions have existed side by side throughout the entire history of human culture, which may be designated as mythological opinions and scientific opinions. In the earlier history of mankind the mythic basis prevailed; in the later, the scientific; so that development has been from myth to science. J. W. POWELL.

Ethyl Butyrate: See BUTYRIC ETHER.

Ethylene, Olefiant Gas, or **Bicarbureted Hydrogen**: a gas (C_2H_4) produced by heating alcohol with strong sulphuric acid or boric anhydride; also by the dry distillation of many organic bodies, as fats, resins, wood, coal, many salts of organic acids, etc. It is an important constituent of coal gas, the illuminating power of which is largely due to its presence. It is colorless, and has a faint ethereal odor, which is attributed to a slight contamination with ether vapor. Its specific gravity is 0·9784. By pressure and cold it may be condensed to a limpid liquid. It burns in the air with a bright white flame, which is very luminous. It is a diatomic radical, uniting with two atoms of Cl, Br, Cy, and other monatomic radicals, and with one atom of O, S, and other diatomic radicals. By replacing hydrogen in two or more molecules of ammonia, it produces diamines, triamines, etc. Its compound with chlorine ($C_2H_4Cl_2$) has long been known as "Dutch liquid."

Étienne: See STEPHANUS.

Etiolation [from Fr. *étioler*, be blighted; cf. O. Fr. *esteule*: Ital. *stoppia* < Lat. *sti'pula*, *stu'pula*, stubble, straw]: the state of a plant which is deprived of green color by the exclusion of light. When it is obtained by keeping plants in the dark in order to render them tender and less acrid, it is called *blanching*, as in the case of celery. In this process the chlorophyll pigment disappears from the chloroplasts in the cells, leaving them colorless.

Revised by CHARLES E. BESSEY.

Et'ive, Loch: a salt-water lake or inlet of the sea in the county of Argyle, Scotland. It is 20 miles long, and varies in width from half a mile to 3 miles. It receives the river Awe, and communicates with the Firth of Lorn. Grand and romantic scenery occurs along its banks.

Etna (in Gr. Αἴτνη; Lat. *Æt'na*; Sicilian, *Mongibel'lo*): a volcanic mountain of Sicily; in the northeast part of the island, adjacent to the sea and very near to the city of Catania. It is an isolated mass of conical form, having no connection with the other Sicilian mountains, from which it is separated by the valley of the river Alcantara. It has an altitude of 10,935 feet above the level of the sea, and its base is about 90 miles in circumference. The volcanic phenomena, which it presents on a greater scale than is elsewhere seen in Europe, early attracted the attention of the ancients, and were described by Pindar, who mentions the rivers of fiery lava rolling down its side into the sea. Thucydides states that an eruption occurred in 425 B. C. It is recorded that four violent eruptions occurred in a period of twenty years—viz., 140, 135, 126, and 121 B. C. The city of Catania has repeatedly been nearly ruined by the eruptions and earthquakes.

The form of the mountain leads to the belief that it was once more lofty than now, the upper part of its cone having

Etna.

probably been blown into the air by a stupendous explosion. The crater thus produced has been filled up by subsequent eruptions, and a new cone built over it. A terrace, or shoulder, high up on the slope separates the new cone from the surviving part of the old. The Val del Bove, a great valley on the east slope, probably marks the scene of another explosion. It is partly filled by later lavas. The eruptions of modern times have usually issued from fissures on the flanks instead of from the summit, and all the slopes, including the Val del Bove, are characterized by numerous cinder cones, marking the positions of subsidiary vents.

The lower part of the mountain, up to an elevation of 2,300 feet, is densely inhabited and very carefully cultivated. The soil, consisting of decomposed lava, is exceedingly fertile, and all the ordinary Sicilian products are raised there with ease and to perfection. At a height of 2,300 feet a forest belt begins, and extends to an elevation of about 6,300 feet. Above 6,300 feet the desert region—vast wastes of black sand, ashes, lava, etc.—begins, and extends to the summit. It is covered with snow for about eight months in the year, and snow may be found in certain rifts near the summit in midsummer. The Casa Inglesi, a house of lava built by the English officers stationed in Sicily in 1811, stands at an elevation of 9,652 feet. Revised by G. K. GILBERT.

E'ton: a town of Buckinghamshire, England; on the Thames, opposite Windsor; 22 miles W. of London (see map of England, ref. 12–J); pop. (1891) 2,499. It is the site of Eton College, one of the most famous educational institutions of England, founded and richly endowed in 1440 by Henry VI., although the buildings were not completed until 1523. It is a favorite school of preliminary instruction for the sons of the nobility and gentry. Many scholars are at the age of seventeen elected to valuable scholarships at King's College, Cambridge. Eton is governed by a provost and seven fellows. The main portion of the establishment, numbering nearly 900, consists of the *oppidans*, who live outside of the college, and for whose tuition the same price is paid as for that of the *collegers* or scholars. The number of the latter is limited to seventy.

Etru'ria, or **Tuscia**: an important country of ancient Italy; called **Tyrrhenia** (Τυρρηνία, or Τυρσηνία) by the Greeks. It was bounded N. by the Apennines, E. by the Tiber, and W. by the Mediterranean or Tyrrhenian Sea. The inhabitants were called Etruscans (*Etrusci*) and Tuscans (*Tusci*) by the classic Latin writers. Their national name in the Etruscan language was *Rasena*. The chief rulers bore the general title of *lucumo*. The cities which composed the league of Etruria proper are universally reckoned as twelve in number, but these can not all be identified, as no ancient writer has preserved a list of their names. Among the most important were Tarquinii, Veii, Clusium, Volsinii, Cortona, Cære, Perusia, Arretium. The early traditions mention several Etruscan kings, as Porsena, King of Clusium, but during the greater part of the historic period the political constitution was an aristocracy.

Origin and History.—The question of the origin and affinities of the Etruscans has long exercised the ingenuity of scholars and antiquaries, but it still remains undecided. The opinion generally adopted by Roman writers ascribed to them a Lydian origin. The earliest authority for this tradition is Herodotus, who states that he received it from the Lydians. This opinion was rejected by Hellanicus, who represents the Etruscans as Pelasgians, and by Dionysius of Halicarnassus, who considered them indigenous (*autochthones*), and states that in his time they were very distinct from every other people in language as well as in manners and customs. Niebuhr maintained that they were a mixture of Pelasgians and Umbrians with a race of northern invaders (*Rasena*), who conquered them at an unknown date. He believed that the Rasena or Etruscan nobility came originally from the Rhætian Alps. Knowledge of the history of the Etruscans, even during the period of their greatest power and prosperity, is very vague and imperfect. The Etruscan language is thought to be Indo-European in its grammatical construction, though its vocabulary, so far as ascertained, can not be with any certainty affiliated. There is no Etruscan literature extant, and no bilingual inscriptions of any length have been found. There were three Etrurian centers of occupation: (1) from the Tiber northward to Pisa, where the Etruscans seem to have been limited by the Ligurians; (2) the settlement on the Po, of which Bologna, Verona, and Mantua were the principal cities; the Etrurian population is shown by inscriptions to have extended northward as far as the Rhætian Alps; (3) that in the Phlegræan plains surrounding Capua and Nola, which are regarded as Etruscan cities. Livy states that before the Romans became the dominant people of Italy the power of the Tuscans was widely extended both by sea and land. Several Greek writers attest the facts that they were bold and enterprising navigators, and fitted out large fleets for naval warfare. In 538 B. C. they fought a naval battle against the Phocæans at Corsica. The Tuscans and Carthaginians were allies on this occasion, and in other battles against the Greek colonies of Italy. Besides the twelve cities of Etruria proper, these people possessed another state or confederacy on the northern side of the Apennines. According to the Roman traditions, the Tuscans were a powerful nation before the foundation of Rome, 753 B. C. It probably attained its greatest power about 150 years later. The Tuscan cities of Clusium and Veii were involved in several wars against the rising power of Rome. Tradition indicates the establishment of an Etruscan dynasty at Rome under the later kings, the two Tarquins, and assigns to this period of Etruscan domination the construction of the Cloaca Maxima and the Capitol. About 508 B. C., Porsena, King of Clusium, marched against Rome, and, as the best critics believe, captured it. Hostilities continued, with occasional intervals, between the Romans and the Veientes from 483 B. C. to 396 B. C., when Veii was captured by Camillus and destroyed. It does not appear that the other Tuscan cities gave any aid to Veii during this period. This apparent neutrality may be explained by the fact that their northern frontier was then infested by predatory hordes of Gauls, whom they were scarcely able to repel. In the subsequent wars it was sometimes Tarquinii and sometimes Volsinii that fought against Rome. About 309 B. C. the combined forces of several Etruscan cities were defeated by Fabius Maximus in a battle which gave the first decisive blow to their power. The conquest was completed by a victory which the Romans gained at the Vadimonian Lake in 283 B. C. The Etruscans, however, retained long after this event their own language, customs, religious rites, and nationality. They were admitted to the Roman franchise in 89 B. C.

Arts and Civilization.—Ancient writers concur in representing the Etruscans as the most cultivated and refined people of ancient Italy, and as especially skillful in ornamental and useful arts, in which the ideas and patterns used singularly resemble those of Egypt. The Romans derived from them many arts and inventions that conduce to the comfort of life. The genius of the Etruscans appears to have been practical rather than speculative. They excelled in agriculture, navigation, engineering, and in useful public works. They had made great progress in architecture, sculpture, and painting, and especially in bronze-work and gold jewelry; but their artistic ability was far inferior to that of the Greeks. The so-called Tuscan order of architecture is a Roman, and more especially a Renaissance modification of the Doric. The Cloaca Maxima at Rome proves that they were acquainted with the true principle of the arch, and exemplifies their skill in the construction of sewers. Of their temples, theaters, and amphitheaters no considerable remains have been preserved. Among the existing monuments of their massive and cyclopæan masonry are fragments of walls which defended the cities of Cortona, Fæsulæ, Clusium, and Volaterræ. Their tombs are in some cases chambers hewed in a cliff or solid rock, and adorned outside with façades like those of temples. The interior walls are decorated with paintings, and the tombs contain vast numbers of vases, tripods, urns, etc. The Etruscans excelled in several branches of plastic art, especially in the fabrication of bronze articles and pottery. Bronze statues and utensils were exported from Etruria in immense numbers. Among the extant specimens of their bronze-work are probably the figure of a she-wolf in the Capitol of Rome, of which group, however, the two children are modern, and the Chimæra in the Museum of Florence. The painted vases called Etruscan, which have been found in great numbers, especially at Chiusi (Clusium) and Vulci, are Greek in design and workmanship. The metallic specula or mirrors, adorned with figures on one side, a peculiarly Etruscan manufacture, are prized as illustrative of customs, mythology, etc.

Etruscans: See ETRURIA, and ITALIC LANGUAGES.

Ett'müller, ERNST MORITZ LUDWIG: philologist and antiquary; b. at Gersdorf, near Löbau, Saxony, Oct. 5, 1802; studied at Leipzig and Jena. He became Professor of German at Zurich in 1833, and gained distinction by his researches in mediæval German literature. He produced an epic poem called *Deutsche Stammkönige* (1844), and *Lexicon anglo-saxonicum* (1852). He also edited the works of several old German poets. D. in Zurich, Apr. 15, 1877.

Et'trick: a pastoral vale in Selkirkshire, Scotland; extends along the Ettrick river, which, after a course of 28 miles, enters the Tweed 2 miles below Selkirk. It is remarkable for beautiful scenery. Ettrick Forest, a royal hunting tract, included all Selkirkshire. It is nearly divested of trees. JAMES HOGG (*q. v.*), the poet, called the "Ettrick Shepherd," was born in the vale and parish of Ettrick, which was also the haunt and residence of the famous freebooter Adam Scott, the King of the Border.

Etty, WILLIAM: figure-painter; b. in York, England, Mar. 10, 1787; pupil of Royal Academy, London, and of Sir Thomas Lawrence; Royal Academician 1828. He painted the nude successfully. His pictures are agreeable in color. *Head of a Cardinal* (1844) is in the South Kensington Museum; four works, including *Bather* (1844), National Gallery, London. D. in York, Nov. 13, 1849. W. A. C.

Etymology [from Gr. *ἐτυμολογία*: *ἔτυμον*, the true or original sense of a word (*ἔτυμος*, true) + *λόγος*, discourse]: that department of scientific grammar which concerns itself with the history of individual words both as to form and signification. In the common usage of the ordinary descriptive grammar, however, the term is applied to that part of the grammar which deals with modifications in the form of words, i. e. with inflexion and derivation. The etymology of scientific grammar seeks to reconstruct the primitive form and meaning of words by tracing their earlier forms and values and by comparison of cognate languages or dialects, or at least in case of later formations to determine their connection as derivatives or compounds with primitive word-forms or with groups of word-forms united severally in the possession of a common element known as the root. The tracing of earlier recorded forms includes the many cases in which a word can be followed into the territory of another language from which it has been borrowed.

Prior to the establishment in the nineteenth century of the science of comparative philology, etymology was little better than learned guesswork. It relied merely upon striking resemblances of form or meaning, and lacked entirely the restraints of definite critical tests. With the progress of the science the tendency has been to apply with increasing rigidity the tests of phonetic law, which seems to offer the only safe basis for estimating the correctness of an etymology.

The natural tendency of the mind to associate resemblance of signification with resemblance of form in words produces the manifold phenomena of folk-etymology. This association betrays itself most commonly in changes of form, accommodating the word to its presumed etymon, as *female* for *femele* (cf. *male*), *sparrow-grass* for *asparagus*, but also in mental groupings, such as *cutlet* with *cut*; cf. Palmer, *Dictionary of Folk-etymology*; Andresen, *Deutsche Volksetymologie.*

The etymology of a word even when certainly known is not directly applicable in determining the form or use of that word in current speech. The earlier meaning of the word is no "truer" than the later. Etymology is not, as the ancients thought and as its name implies, a search for the "true" meaning, but for the *history* of meaning and use as well as form. The information conveyed by an etymology is therefore to be historically and not directly applied. It shows how a word has come to be what it is, and makes it intelligible in its historical relations and according to the creative conditions of its existence.

English etymology is specially treated in the etymological dictionaries of Skeat and Müller, and excellent etymological notes are found in Murray's and Webster's (*International*) English dictionaries. For a list of etymological dictionaries, see DICTIONARY. BENJ. IDE WHEELER.

Eu, ö (Lat. *Au'ga*, or *Augium*): town of France; department of Seine-Inférieure; 17 miles E. N. E. of Dieppe and 2 miles from the sea (see map of France, ref. 2–E). It has a fine Gothic church, and manufactures of lace, silk, and soap. Here is the château d'Eu, which was owned by King Louis Philippe, and is surrounded by a large and beautiful park. It contains a portrait-gallery, which is said to be the finest collection of historical portraits in France. Pop. (1896) 4,818.

Eu, PRINCE LOUIS PHILIPPE MARIE FERDINAND GASTON D'ORLÉANS, Comte d': general; b. at the château of Neuilly, Apr. 28, 1842; the eldest son of the Duc de Nemours, and a grandson of Louis Philippe, King of the French. In 1864 he married Isabella, daughter of Dom Pedro II., Emperor of Brazil. As marshal of the empire he took command of the allied forces operating against Paraguay, and Mar. 1, 1870, the war was ended by the death of the dictator Lopez, who was killed in a battle at Aquidubon. He was commander-general of the Brazilian artillery from 1865 to 1889, but when the revolution of the latter year deposed Dom Pedro, Comte d'Eu accompanied him to Europe, and afterward resided at Versailles, France.

Eubœ'a, or **Negropont** (in Gr. Εὔβοια; Fr. *Eubée*; Turkish, *Egripo*, or *Egripos*; Ital. *Negro'ponte*): a Greek island; the largest island in the Ægean Sea. It is about 90 miles long, and the greatest breadth is about 30 miles. Area, 1,574 sq. miles; with the Sporades islands (forming a nomarchy of the kingdom of Greece), 2,216 sq. miles. It is separated from the northeast coast of Attica and Bœotia by the narrow channels of Egripo (*Euri'pus*) and Talanta. It is connected with the mainland of Bœotia by a bridge across the channel at Chalcis. The surface is mountainous. Mt. Delphi, near the middle of the island, is said to be 7,266 feet high. It is of limestone formation. The soil of the valleys is fertile, and produces cotton, wheat, grapes, etc. Among the exports are wool, hides, and oil. The chief towns are Chalcis and Carystus. In ancient times Eubœa belonged to the Athenian republic. Pop. of nomarchy (1896) 115,515.

Eubu'lides (in Gr. Εὐβουλίδης): a Greek philosopher of the Megaric school; flourished about 350 B. C. He was a native of Miletus, a disciple of Euclid, and an opponent of Aristotle.

Eubu'lus (in Gr. Εὔβουλος): an Athenian comic poet of the middle comedy; flourished about 375 B. C. He wrote numerous comedies on mythological subjects, of which only small fragments are extant. Fragments in Meineke's and Kock's collections.

Eucalyp'tus [from Gr. εὖ, well + καλυπτός, covered]: a genus of trees of the family *Myrtaceæ*, comprising 100 or more species, mostly natives of Australia. As a common name the plural is eucalypti. They form a characteristic feature of the peculiar vegetation of Australia, having entire leathery leaves, of which one edge is directed toward the sky, so that both surfaces are equally exposed to the light. The eucalypti are called gum-trees, because they abound in resinous exudations. The timber is excellent, and is used for ship-building and other purposes. The *Eucalyptus obliqua*, called stringy bark, attains a height of 150 to 250 feet, and is said to reach occasionally 400 to 500 feet, but this needs confirmation. The bark of several species abounds in tannin, and is used for tanning leather. The *Eucalyptus resinifera*, which grows to a great height, yields a red astringent gum, which is called "Botany Bay kino," and is used in medicine as a substitute for kino. An exudation resembling manna in medicinal properties is obtained from the leaves of *Eucalyptus viminalis* and *dumosa.* The blue gum (*Eucalyptus globosa*) produces ship-timber of the best quality. It is said to furnish a febrifuge principle surpassing quinia in efficiency. Several species of eucalyptus have been successfully introduced into California and Europe. See VICTORIA (*Flora and Fauna*).

Eucharist [from Gr. εὐχαριστία, thanksgiving; εὖ, well + χάρις, favor, thanks]: the sacrament of the Holy Communion, or the feast of the Lord's Supper; so called in allusion to the blessing and thanksgiving with which the last supper of our Saviour with his disciples began and ended. This solemn festival has been kept in all Christian churches from the time of the resurrection, in commemoration of the passion and death of our Lord, and in obedience to his own divine institution. Among the earliest disciples in Judæa, the Lord's Supper seems to have been a regular meal, probably the principal meal of the day in each family, into which the commemorative breaking of bread and partaking of the cup of blessing were introduced as a part. Subsequently the disciples of many families came together and held a festival in common—a practice in which originated the ἀγάπη, or love-feast, in the course of which the brethren saluted each other with a holy kiss. The abuses which grew out of this, and which are severely rebuked by St. Paul in the First Epistle to the Corinthians, led to a separation of the two institutions; and the commemorative observance has since been celebrated, with a solemnity in harmony with its character, by itself.

No part of the Christian practice and doctrine has given rise to larger diversities of opinion or to a more voluminous polemical literature than the sacrament of the Eucharist. Irenæus (*Hæres.*, iv. 18, 5) indeed says that the bread after the Epiclesis is no longer common bread but eucharistia, consisting of two parts, an earthly and a heavenly. But to be wise above what is written was not the temper of the early Church. There was no attempt to explain what has since been called the "real, spiritual presence" of the Lord in the consecrated elements of bread and wine. And so with Justin Martyr. Writing of the Holy Communion, he expresses simply, and in words such as might be used to-day, the view of this great mystery which he in common with those of his day believed: "This food is called among us *Eucaristia*. . . . For not as common bread and common drink do we receive these; but in like manner as Jesus Christ our Saviour, having been made flesh by the word of God, had both flesh and blood for our salvation, so likewise have we been taught that the food which is blessed by the prayer of his word, and from which our blood and flesh by transmutation are nourished, is the flesh and blood of that Jesus who was made flesh" (2 *Apol.* lxvi.). The metaphysical controversies on this subject were not known to the Church during its first eight or nine centuries. It seems entirely just to believe that, during all this early period, the visible elements employed in the celebration, the consecrated bread and wine, were regarded chiefly as symbols and emblems of the body and blood of Christ given for our redemption; inasmuch as the expression of an opinion or doctrine different from this appears to have been first publicly made in the year 831 by a monk, subsequently abbot of Corbey, in France, named Pascasius Radbert, who maintained the two following propositions, which he declared to be the true doctrine of the Church, but which were received with loud and general remonstrance; viz., first, that, "after the consecration of the bread and wine in the Lord's Supper, nothing remains but the outward figure, under which the body and blood of Christ are really and locally present"—that is to say, the doctrine more recently known under the name of *transubstantiation*; and secondly, that "the body of Christ thus present in the Eucharist is the same body that was born of the Virgin, that suffered on the cross, and that was raised from the dead." The excitement which followed this announcement was such that the Emperor of Germany, Charles II. (I. of France, called "the Bald"), directed counter-expositions to be prepared by Johannes Scotus and Ratramn (otherwise called Bertramn). The work of Scotus, though often cited in subsequent centuries, has perished; that of Ratramn is still extant. Both held that the consecrated bread and wine in the Eucharist are only signs or symbols, and not the veritable body and blood of Christ; but in the work of Ratramn there are some things said on this point which are ambiguous or obscure, while Scotus, on the other hand, is said to have been perspicuous, distinct, and intelligible. Out of this dispute arose some extraordinary and repulsive secondary controversies, as to the natural consequences of taking into the stomach and digesting the consecrated elements, whatever view be taken of their nature, for which those who desire to understand them must refer to the ecclesiastical histories.

The doctrine of Pascasius, or at least his first proposition, found no small number of adherents, but the struggle, though warm, was a struggle of private opinions, and not of opinions with authority. The Church set forth no definition of her own views on the subject, and the excitement after a time abated. About two centuries later, however, the controversy was renewed in a manner which presently led to the interposition of the Roman pontiffs, and subsequently of councils of the Church. The first incident in this renewal was a declaration, in 1004, by Leutheric, Archbishop of Sens, to the effect that none but the sincerely pious receive the body of Christ in the Holy Communion. It is easy to see what questions may arise out of a doctrine like this, especially with those who hold the certainty of the real presence. Later, in 1045, the celebrated Berengarius, at that time Archdeacon of Angers, taking the work of Johannes Scotus, above mentioned, as his text and guide, attacked with vehemence the doctrine of the real presence. He was met by Bruno, his own bishop (of Angers), and also by Hugh of Langres and Adelman of Bresse. But his most powerful and most dangerous antagonist was the pope, Leo IX., who assembled two councils in 1050—one at Rome and one at Vercelli—where he caused the writings of Berengarius to be condemned and burned, and excommunicated their author. Retiring into Normandy, Berengarius sought the support of William (afterwards "the conqueror" of England), but this prince having convened an assembly of the principal prelates and theologians of his province, the unfortunate polemist was again condemned; and in the Council of Paris, called by Henry I. in the same year (1050), he was not only condemned still a third time, but deprived of his benefices. The subsequent history of Berengarius is a painful one. On three different occasions, under three different successive popes, Victor II., Nicholas II., and Gregory VII., he was compelled by threats and intimidation to renounce his opinions; and on two of these occasions to subscribe to declarations drawn up for him by his enemies. The first of these declarations, made at what may be called his second trial, under Nicholas II., was to the effect that "the bread and wine after consecration are not only a sacrament, but also the real body and blood of Jesus Christ; and that this body and blood are handled by the priests and consumed by the faithful, and not in a sacramental sense, but in reality and truth, as other sensible objects are." He was not only forced to subscribe to this declaration, but also to confirm it with an oath; but hardly had he returned to France before he abjured it utterly, and resumed the teaching of his former views. He was accordingly arraigned a third time, and this arraignment took place under Gregory VII. (Hildebrand), who seems himself not to have partaken of the extreme views of Berengarius's relentless persecutors, yet to have felt compelled to oblige him to renounce his own. The unfortunate man constrained himself consequently to subscribe to his belief of the following proposition, and to confirm this declaration by an oath—viz., that "the bread laid on the altar becomes, after consecration, the true body of Christ, which was born of the Virgin, suffered on the cross, and now sits at the right hand of the Father; and the wine placed on the altar becomes, after consecration, the true blood which flowed from the side of Christ." There was affirmed to be an ambiguity in this declaration, perhaps growing out of the construction to be put upon the words "laid, or placed, upon the altar." At any rate, it did not satisfy the enemies of Berengarius, and he was therefore subjected to the humiliation of subscribing and making oath to still another confession of faith, in the following words—viz., that "the bread and wine are, by the mysterious influence of the holy prayer and the words of our Redeemer, substantially changed into the true, proper, and vivifying body and blood of Jesus Christ"; to which was added, that "the bread and wine are, after consecration, converted into the real body and blood of Christ, not only in quality of external signs and sacramental representations, but in their essential properties and substantial reality." This form of submission having been fully completed, Pope Gregory dismissed the humble prelate with many marks of personal esteem, and visible and liberal evidences of his friendship. Notwithstanding which, no sooner was Berengarius in his own country again, than he retracted this last declaration, as he had done all the former, and prepared an elaborate refutation of the doctrines to which he had just subscribed. The pope took no notice of this retractation, whence the inference has been drawn that Gregory himself was personally not far from entertaining the same opinions as Berengarius. The evening of the days of this greatly tried champion of the right to freedom of opinion where the Church has not spoken was passed in acts of penance and mortification, to which he subjected himself in expiation of the guilt of his dissimulation and perjury at Rome.

It was not till the assembling of the fourth Lateran Council by Innocent III., in the year 1215, that the voice of the Roman Church was authoritatively uttered as to the true doctrine of the Eucharist. That pope, through a decree of that council, declared the true faith to be that the elements of bread and wine are really and truly, after consecration, the body and blood of Jesus Christ in actual substance, remaining bread and wine only to outward appearance; and he himself invented and introduced the term "transubstantiation," by which this doctrine has been ever since known and recognized as a doctrine of the Roman Church. It was a natural consequence of the admission of this doctrine as an established dogma that that view of the Eucharist which regards the ceremonial consecration and placing upon the altar of the elements as a *sacrifice*, in which the original great sacrifice upon Calvary is perpetually renewed, found easy acceptance; and other consequences have been the worship of the consecrated elements, as being a worship directly paid to Christ himself; the elevation of the Host in the celebration of mass, that it may be seen and reverenced by the people; and the custom, prevalent in Roman Catholic countries, of carrying this consecrated bread about in solemn processions through the public streets, to be administered to the sick and dying.

Another controversy in regard to the Eucharist arose in the sixteenth century, which continues still to divide opinions, the Church not having formally declared on either side. It was (and is) held by the Jesuits and Dominicans, that the sacraments have in themselves an instrumental and efficient power by virtue of which they work in the soul, independently of any previous preparation or state of the propensities, a disposition to receive the divine grace; and this they call the *opus operatum*. Thus, according to their view, neither knowledge, nor wisdom, nor humility, nor faith, nor devotion is necessary to the efficacy of the sacraments, whose prevailing energy nothing but a mortal sin can resist. Hence, therefore, according to them, priests may give immediate absolution to all who confess their misdeeds and evil thoughts and wicked sentiments and propensities, and admit them directly to the use of the sacraments. This view was resisted by the Jansenists, and is rejected by all in the Roman communion who have the progress of vital and practical religion truly at heart. These demand that none shall be admitted to the sacrament of the Holy Communion who do not give evidence of true penitence, and of an intent henceforth to lead a new life, following the commandments of God, and walking in his holy ways.

The same century saw the great uprising against the abuses which had gradually crept into the Church of Rome, commonly called the Reformation, inaugurated by the monk Martin Luther. It soon appeared that, upon some essential points of doctrine, there was as little harmony of doctrine in the ranks of the Reformers as there had been in those of the Church. In regard to the Eucharist, the difference between Luther and Zwingli, if not quite so wide, was at least as irreconcilable as that between the Jesuits and the Jansenists, or that of the ninth century between Radbert and Scotus. Luther maintained that the body and blood of Christ are really, though in a manner far beyond human comprehension, present in the Eucharist, and are exhibited together with the bread and wine. This is the doctrine since known as "consubstantiation." Zwingli, on the other hand, regarded the bread and wine as being only symbols present, and typifying the body and blood of Christ, which themselves are absent. Numbers of zealous and able men enrolled themselves in this controversy, on both sides, and the consequent danger to the common cause of Protestantism was such that Philip, Margrave of Hesse, whose devotion to this cause was deep and sincere, appointed a conference to be held at Marburg, between Luther, Zwingli, and other doctors of both parties. The result, so far as the main point is concerned, was a failure. The two great leaders separated without either having been able to convince the other, and without having been able to agree upon any statement of doctrine in regard to Christ's presence in the Eucharist which both could accept.

The doctrine of the Anglican Church, which is that of the Protestant Episcopal Church in the United States on this subject, is briefly set forth in the catechism, where, after defining a sacrament to be an outward and visible *sign* of an inward and spiritual grace, and affirming the object for which the sacrament of the Lord's Supper was ordained to have been "for the continual remembrance of the sacrifice of the death of Christ, and of the benefits which we receive thereby," it is declared that in this sacrament the outward and visible part or sign is the "bread and wine which the Lord hath commanded to be received," and that the thing signified is "the body and blood of Christ, which are spiritually taken and received by the faithful in the Lord's Supper." And in the "Articles of Religion, as established by the bishops, clergy, and laity of the Protestant Episcopal Church in the United States of America, in convention, on the 12th day of September, in the year of our Lord 1801," which are, with some alterations of minor importance, identical with the Thirty-nine Articles of the Church of England, it is declared (in "Art. xxviii.; of the Lord's Supper") that "transubstantiation (or the change of the substance of the bread and wine) in the supper of our Lord can not be proved by Holy Writ; but is repugnant to the plain words of Scripture, overthroweth the nature of a sacrament, and hath given occasion to many superstitions." And further, "that the body of Christ is given, taken, and eaten in the Supper, only after an heavenly and spiritual manner. And the mean whereby the body of Christ is received and eaten in the Supper is faith." For the Roman Catholic doctrine on Eucharist, see MASS. Revised by W. S. PERRY.

Euchee: See UCHEAN INDIANS.

Euchlorine [from Gr. εὖ, well + χλωρός, green + suffix *-ine*]: a green gas liberated when potassic chlorate is acted upon by hydrochloric or sulphuric acid. It possesses bleaching properties. It is prepared by heating gently a mixture of two parts of sulphuric acid, two of water, and one of chlorate of potash. It has been shown to be a mixture of chlorine dioxide, ClO_2, and chlorine.

Revised by IRA REMSEN.

Euchre [orig. spelled *uker* or *yuker*; etymology unknown]: a game at cards played with a pack containing only the aces, kings, queens, knaves, tens, nines, eights, and sevens. These rank in the order named, except that in the trump suit the knave, called *right bower*, is highest, while the knave of the *next* suit (i. e. the one like the trump suit in color), called *left bower*, is considered as belonging to the trump suit instead of its own, and ranks there next below the right bower and next above the ace. Ordinarily, four persons play, partners sitting opposite each other. After shuffling and cutting five cards are dealt each player, from left to right, two the first time round and three the second, or *vice versa*, and the next card is turned face up. Then the eldest hand (i. e. the player at the dealer's left) either *orders up* this card or *passes*. By ordering it up he makes the suit trump, and the dealer must take the card in exchange for one in his hand. If he passes instead, the next player (the dealer's partner) has the same option, and so on until, if the card has not been ordered up, the dealer himself has the option of taking it up, thus making it trump, or of turning it down, in which case the players, in the same order, exercise the option of again passing or of naming as trump any suit except that of the card thus turned down. If no one is willing to make trump the hand is thrown up and the deal passes on to the next player to the left, just as it would if the hand were played. An apparent exception to the above is that the dealer's partner is always said to *assist* instead of ordering up. The player making the trump, if he announces his intention to do so before a card is led, may *play alone*, i. e. without the aid of his partner, who in this case turns his cards face down and remains silent while the other three play out the hand. If the person who makes trump does not play alone, the privilege may be exercised only by the partner of the eldest hand when the latter makes the trump, and by the dealer when his partner makes it.

When the trump has been made the eldest hand leads a card, and each other player in turn plays one to it. The four cards constitute a trick, which is taken by the highest card of the suit led, unless it contains one or more trumps, when it is taken by the highest of these. The winner of one trick leads for the next. A player must always follow suit if he has it; otherwise he may play any card he chooses. The game is won by the side first scoring five points. The side making trump scores two points by taking all five tricks (a *march*), or one point by taking either three or four. If they take less than three tricks they are *euchred*, and the opposing side scores two points. A player who plays alone scores for his side in like manner, except that a march counts four; if he is euchred the opposite side scores two.

Euchre is played by two persons just as by four, with the omission of the features distinctive of the latter, as the difference in scoring when a hand is played alone. When three play, in each hand the person making trump plays against the other two, each of whom scores two if they secure a euchre; a march counts three. With modifications as regards selecting trump and scoring, five or even six persons may play. There are many popular variations even in the game for four: quite commonly the eights and sevens are omitted from the pack; sometimes a blank card is included and stands as the highest trump of any suit; with some a person playing alone takes his partner's strongest card in exchange for one of his own; but these and other modifications are made only by previous agreement. S. A. T.

Euclase [from Gr. εὖ, well + κλάσις, fracture, deriv. of κλάειν, to break]: an exceedingly rare variety of silicate of beryllium found in Brazil and the Ural Mountains, occasionally used as a gem.

Euclid (in Gr. Εὐκλείδης) OF ALEXANDRIA: a Greek mathematician, called the "father of geometry." He was born in Alexandria in Egypt, and lived about 300 B. C., and is said to have belonged to the Platonic school of philosophy. The events of his life are mostly unknown, except that he taught mathematics in the reign of Ptolemy I. (Soter), who died about 282 B. C. He made important discoveries in geometry, and surpassed all preceding geometers in the rigorous method and arrangement of his demonstrations. When Ptolemy I. asked him if geometry could not be mastered by an easier process than the ordinary one, he returned the celebrated answer, "There is no royal road to geometry." His *Elements of Geometry* presents the most ancient system of that science that is extant, and has been considered an excellent standard work for 2,000 years. See Smith's *Dictionary of Greek and Roman Biography.*

Euclid OF MEGARA: a Greek disciple of Socrates; flourished about 400 B. C. He is said to have witnessed the death of Socrates (399 B. C.), after which he founded at Megara a school called the Megaric or Dialectic. His system was based on or partly derived from the principles of the Eleatic school, to which he added the ethics of Socrates.

Eude'mus (in Gr. Εὔδημος) OF RHODES: a disciple of Aristotle and author or editor of the *Eudemian Ethics* in seven books, published among Aristotle's works. Fragments of his other writings in Mullach, *Fragmenta Philosophorum Græcorum*, vol. iii., pp. 222–292. B. L. G.

Eudiom'eter [from Gr. εὔδιος, clear, fair (weather) + μέτρον, measure]: an instrument originally intended for ascertaining the proportion of oxygen in the air, with a view of judging of its purity or impurity; but it is also employed to test the composition of any mixed gases. Many forms have been used, but one of the best consists of a graduated glass tube having two platinum electrodes within it, the tube closed at one end. To test the composition of air, for example, the carbon dioxide (carbonic acid) of the air within the tube is removed by strong liquor potassæ over a mercury bath, when the rise of the mercury within the tube indicates the proportion of carbon dioxide in the atmosphere. A large but determinate proportion of hydrogen is then introduced and exploded by means of the electrodes. After cooling, one-third of the loss of gas by explosion is the volume of free oxygen in the tube. Allowing for the hydrogen unconsumed, the volume of nitrogen is readily seen. The results are then reduced to a percentage of volumes.

Eudo'cia (in Gr. Εὐδοκία; Fr. *Eudocie*), sometimes called **Eudoxia**: the wife of Theodosius II.; b. in Athens about 393. She was a daughter of the sophist Leontius, and her name before she was converted to Christianity was Athenaïs. She was very carefully educated and thoroughly conversant with Greek literature and philosophy; she had even studied the sciences. A quarrel with her brothers about the inheritance after her father's death brought her to Constantinople, where she wished to lay her case before the emperor. Theodosius was completely captivated by her beauty and her accomplishments, and in 421 he married her, she having in the meantime embraced Christianity. In 438 she made a pilgrimage to the Holy Land, imitating, in a rather ostentatious manner, the Empress Helena, the mother of Constantine the Great, and distributing enormous sums as alms and donations for pious purposes. Shortly after her return an estrangement took place between her and her husband, some imprudence upon her side having aroused his jealousy, and in 449 she was banished from the court. She settled in Jerusalem, and devoted herself entirely to the study of Christian theology and to religious exercises. She died there in 460. She wrote paraphrases in heroic verse of the Octateuch, Daniel, and Zechariah, and a poem on the martyrdom of Cyprian, etc. See F. Gregorovius, *Athenais* (1882).

Eudox'us (in Gr. Εὔδοξος): a Greek astronomer; b. at Cnidos in Caria; flourished about 366 B. C. He was a pupil of Archytas and of Plato, and he opened a school at Athens or Cnidos. Cicero called him the prince of astronomers. Eudoxus computed the length of the year to be 365¼ days, and appears to have originated the doctrine of concentric solid crystalline spheres, by which he explained the apparent motions of the sun, moon, and planets. He is frequently referred to by ancient writers.

Eufaula, yu-faw'la: city and railway junction; Barbour co., Ala. (for location of county, see map of Alabama, ref. 6–E); 80 miles E. S. E. of Montgomery; on the right bank of the Chattahoochee river, which is navigable to this point for its largest boats at all seasons. The city is a winter health resort, and has a college for young women, a school for colored people, a bagging-factory, several cotton-warehouses, a fair-ground, water-works, etc. Over 50,000 bales of cotton are sold here annually. Pop. (1880) 3,836; (1900) 4,532.

Eugene: city; capital of Lane co., Ore. (for location of county, see map of Oregon, ref. 4–B); 71 miles S. of Salem; on railway and on the west bank of the Willamette river, which is navigable for steamboats during several months of the year. It is the business center of the upper Willamette valley, and the educational center of the State. It contains the University of Oregon, located here by act of the Legislature in 1872, a fine Masonic temple, a large flouring-mill, steam saw and planing mills, furniture-manufactory, and a woolen-mill. Pop. (1880) 1,117; (1900) 3,236.

EDITOR OF "OREGON STATE JOURNAL."

Eugene, yu-jeen' (in Fr. *Eugène*; Germ. *Eugen*), PRINCE, or, more fully, **François Eugène de Savoie**: general; b. in Paris, Oct. 18, 1663. He was a son of Eugène Maurice, Count of Soissons, and Olympia Mancini, a niece of Cardinal Mazarin. Having been offended by Louis XIV.'s refusal to grant him a commission in the army, he entered the service of the Emperor of Austria in 1683. He served with distinction in the war against the Turks, and was rapidly promoted. In 1691 he obtained command of the imperial army in Piedmont, where he fought against the French. Louis XIV. afterward offered him a marshal's bâton if he would enter the French service, but he declined. Having been appointed commander of the Austrian army in Hungary, he gained a decisive victory over the Turks at Zenta Sept. 11, 1697. In the great European war of the Spanish succession, which broke out in 1701, Eugene first commanded in Italy, where he was opposed by the able French marshal Catinat, and afterward by Villeroi, whom he surprised at Cremona and took prisoner in Jan., 1702. An indecisive battle was fought at Luzara in Aug., 1702, by Prince Eugene and the Duke of Vendôme. About the end of that year he was appointed president of the council of war in Vienna. He commanded the imperial army which co-operated in Germany with the English army under the Duke of Marlborough. These allies defeated the French and Bavarians at the great battle of Blenheim, Aug. 13, 1704. In 1705 he took command of the army in Italy, and was defeated by the Duke of Vendôme at Cassano in August of that year. He gained a victory over the Duke of Orleans at Turin in Sept., 1706, expelled the French from Italy, and returned to Vienna in 1707. The seat of war was next transferred to Flanders, where Prince Eugene was associated with the Duke of Marlborough in the command of the combined armies. They defeated the French at Oudenarde (1708), and claimed the victory at the great battle of Malplaquet (Sept. 11, 1709), where they remained masters of the field but lost about 25,000 men. In 1712 he was sent to London on a diplomatic mission, the object of which was to persuade the English to continue the war and to restore Marlborough to the command, but he was not successful. A victory which Marshal Villars gained over the Dutch allies of Prince Eugene at Denain in July, 1712, induced Austria to negotiate for peace. In Mar., 1714, he signed a treaty of peace at Rastadt. He defeated a large Turkish army at Peterwardein Aug. 5, 1716, and took Belgrade from the same enemy in 1717. After the end of this war, in 1718, he rendered important services as a statesman, and enjoyed the confidence of the Emperor of Germany. D. in Vienna, Apr. 21, 1736. See John Campbell, *Military History of Prince Eugene and Marlborough* (2 vols., 1736), and Von Sybel, *Prinz Eugen von Savoyen* (London, 1868).

Euge'nia: a genus of trees and shrubs of the family *Myrtaceæ*, nearly related to the myrtle. It comprises numerous species, which are natives of tropical and subtropical countries, and some of them produce delicious fruits remarkable for their pleasant balsamic odors. The fruit is a berry of one or two cells, with one seed in each cell. The *Eugenia malaccensis*, a native of the Malayan Archipelago, is a small tree which bears a red fruit nearly as large as an apple, with a juicy pulp and an agreeable odor like that of a rose; hence it is called rose apple. The last name is also applied to the fruit of the *Eugenia jambos*, an East Indian tree, now cultivated extensively in many tropical countries. Florida has five or more unimportant species.

Eugénie, ö'zhā'nee', or **Eugénie Marie de Montijo**, de-mōṅ'tee'zhō: ex-Empress of the French; b. in Granada, Spain, May 5, 1826. Her father was the Spanish Count de Montijo, and her mother was Maria Manuela Kirkpatrick, who was of Scottish extraction. Eugénie was styled the Countess of Teba in her youth. She was married to Napoleon III., Jan. 30, 1853, and bore a son Mar. 16, 1856. As a zealous Roman Catholic she used her influence to promote the power of the pope. She acted as regent in 1859 when Napoleon was in Italy, in 1865 during his Algerian tour, and again in the interval between his departure for the seat of war, July 23, 1870, and the proclamation of a republic by the people of Paris, Sept. 4, 1870. She then escaped to England under the protection of M. de Lesseps, and resided at Chiselhurst, afterward removing to Farnborough. The constant litigation to which her claims against the French Government gave rise, and her frequent visits to the Continent, kept her name before the public. The latter years of her life have been greatly saddened by the death of the young prince imperial, June 1, 1879. Eugénie is the author of *Some Recollections from My Life* (1885).

Euge'nius: Bishop of Toledo from 646–57; a writer of Latin poems on a great variety of subjects in various measures, including some acrostics and telestichs. (See DRACONTIUS.) The poems were edited by Sirmond (Paris, 1619), and by Migne in vol. lxxxvii. of the *Patrologia Latina*. A new ed. by R. Peiper is promised for the Vienna Corpus SS. eccl. lat.

M. W.

Eugenius I.: pope; consecrated Aug. 10, 654 A. D., as the successor to Martin I., who was banished by the Emperor Constans. D. June 1, 657.

Eugenius II.: a native of Rome; succeeded Pascal I. as pope in June, 824 A. D. He called a council, which met at Rome in 826 for the reformation of the clergy. D. Aug. 27, 827, and was succeeded by Valentinus.

Eugenius III. (BERNARD PAGANELLI): a native of Pisa; was chosen pope Feb. 15, 1145, in place of Lucius II. The Romans, excited by the preaching of Arnaldo da Brescia, had revolted against Pope Lucius. Eugenius, being unable to enforce his authority, retired to France and held a council at Rheims in 1148. He also promoted the second crusade. D. July 8, 1153, and was succeeded by Anastasius IV.

Eugenius IV. (Gabriele Condolmiere): pope; b. in Venice, 1383; was crowned pope Mar. 3, 1431, as successor of Martin V., who had convoked a council at Basel. This council refused to recognize the supremacy of the pope. Eugenius therefore issued a bull proclaiming that the Council of Basel was or must be dissolved, and he called another council at Ferrara in 1438. The Council of Basel in 1438 deposed the pope, and elected as his successor Amadeus of Savoy, who assumed the name of Felix V. The result of this election was a schism in the Church, for Eugenius continued to act as pope in Rome, and was recognized by several powers. In 1439 the sessions of the council were transferred to Florence. Eugenius and John Palæologus signed in 1439 a convention for the union of the Greek and Latin churches, but this convention had no permanent effect. D. in Rome, Feb. 23, 1447.

Eugip'pius: abbot of Lucullanum, near Naples; b. at Carthage about 450; educated at Rome; in the beginning of sixth century made a collection of excerpts from the works of St. Augustine, and composed in 511 an admirable life of St. Severinus, which is very valuable for the light which it throws upon the customs and life of the Germans of that period. The best edition is by P. Knoell (2 vols., Vienna, 1885–86). M. W.

Eugraph'ius: a Latin grammarian, probably of the sixth century, whose commentary on the plays of Terence is extant, and may be found with the commentary of Donatus in Klotz ed. of Terence (2 vols., Leipzig, 1838–40). See H. Gerstenberg, *De Eugraphio Terentii interprete* (Jena, 1886). M. W.

Eugu'bian Tables: certain bronze tablets found near Gubbio (the ancient *Iguvium*) in 1444. Five of the inscriptions are in Etruscan and Umbrian characters, the other two in Latin. They were published by Lepsius in his *Inscriptiones Umbricæ et Oscæ* (1841), and contain the acts of a corporation of priests.

Euhe'merus: a Greek philosopher of the third century B. C.; the founder of Euhemerism, or that principle of interpreting the pagan mythology according to which each myth is supposed to have originated from some simple historical event. This method of interpretation, which earned for the author the surname "Atheist," was introduced into Rome by Ennius, and eagerly employed by the Fathers of the Church to discredit pagan mythology. The works of Euhemerus have perished.

Eulachon: See Oulachan.

Eulenburg, oi'len-boorkh, Friedrich Albrecht, Graf von: Prussian statesman; b. June 25, 1815; went in 1859 as envoy to China, Japan, and Siam; concluded a treaty of amity and navigation with Japan, Jan. 1, 1861, and in September of the same year another with China; became in 1862 Minister of the Interior. D. near Berlin, June 2, 1881.

Eu'ler (Germ. pron. oi'ler), Leonard: geometer; b. at Basel, Switzerland, Apr. 15, 1707. He was educated at the university of that city, and went to St. Petersburg with his friend Daniel Bernoulli. In 1733 he became Professor of Mathematics in the Academy of St. Petersburg. He displayed great fecundity and inventive genius by the composition of a multitude of treatises on mathematics. It is said that he wrote more than half of the forty-six quarto volumes published by the Academy between 1727 and 1783. Having been invited by Frederick the Great, he removed to Berlin in 1741. He improved the integral calculus and the science of mechanics. Among his numerous works are *Mechanics, or the Science of Motion analytically explained* (in Latin, 2 vols., 1736–42); a *Treatise on Naval Science* (1749); *Institutiones Calculi Integralis* (Treatise on Integral Calculus, 1768); *Letters to a German Princess* (in French, 1768); a *Treatise on Dioptrics* (1771); and *Theory of the Moon's Motion* (1772). He became blind about 1767, after which he resided in St. Petersburg until his death, Sept. 7, 1783. Condorcet, who wrote a eulogy on him, says, "He multiplied his productions marvelously, and yet was original in each."

Eu'menes (in Gr. Εὐμένης): a favorite officer of Alexander the Great; b. at Cardia, in Thrace, about 360 B. C. He had a high command in the army which Alexander conducted against Persia in 334 B. C., and gained the confidence of that prince. On the death of Alexander, Eumenes became governor of Cappadocia and Pontus. As an ally of Perdiccas he defeated Craterus in the year 321, soon after which Antigonus and Antipater formed a coalition against him. Eumenes was captured and put to death by Antigonus in 317 or 316 B. C. See Plutarch, *Life of Eumenes.*

Eumen'ides [in Gr. Εὐμενίδες; εὖ, good + μένος, mind, disposition—i. e. the gracious ones, so called for the sake of propitiating them], or **Erinnyes**: the Greek name of the Furies, whom the Romans called Furiæ or Diræ. They were supposed to be goddesses who punished crimes and pursued the guilty with burning torches. According to the later tradition, there were three Furies—namely, Tisiphone, Alecto, and Megæra. The Cave of the Eumenides is at the N. E. angle of the Areopagus, at Athens, immediately below the seats of the judges.

Eumol'pus (in Gr. Εὔμολπος): in the Greek mythology, a Thracian bard, son of Neptune, and the founder of the Eleusinian mysteries. Musæus is said to have had a son named Eumolpus, who was an instructor of Hercules.

Euna'pius (in Gr. Εὐνάπιος): a sophist and physician; b. at Sardis, in Lydia, about 348 A. D. He was a Neoplatonist, an opponent of Christianity, and a partisan of Julian the Apostate. He lived at Athens, and wrote in Greek *The Lives of Philosophers and Sophists*, which is interesting and important for the view which it gives of the intellectual life of the times. Ed. by Boissonade in 1822. D. about 420.

Euno'mius (in Gr. Εὐνόμιος): the founder of an Arian sect called Eunomians; b. at Dacora, in Cappadocia, in the early part of the fourth century. He was appointed Bishop of Cyzicus in 360 A. D. by Eudoxius, Bishop of Antioch, who four years afterward deposed him for heresy. Eunomius was a man of superior abilities, and maintained the extreme Arian doctrines. For him Christ was neither of the same nor like substance with the Father, but essentially and substantially different. This was his peculiar teaching, for which he was several times banished. D. at Dacora soon after 392 A. D. His followers, the Eunomians, were for some time very numerous, but the sect died out in the fifth century. Revised by J. W. Chadwick.

Eunuch [from Gr. εὐνοῦχος, chamberlain; εὐνή, bed + ἔχειν, hold, keep]: originally, a servant who had the care of bedchambers; hence, from the custom of placing women's apartments under the care of castrated persons, any castrated male of the human species. Castration was a very ancient practice, and was especially frequent in Syria and the East. It is a natural consequence of the system of polygamy. In Greece it was not common until the Byzantine period. In Rome under the emperors many eunuchs were kept. It is asserted that they existed in considerable numbers in mediæval Europe. In Italy they were much esteemed for their fine soprano singing. Leo XIII. is said to have effected their banishment from the papal choir, where they were employed long after they had disappeared from the operatic stage. At present they are chiefly found in Mohammedan countries, and are said to come mostly from Northeastern Africa. The operation is highly dangerous, the mortality being enormous. At Moscow there is a community of eunuchs who are jewelers by profession, and who add to their numbers by the purchase and mutilation of children. Eunuchs as a class are small, beardless, and weak, of a jealous and intriguing character; yet some, like Bagoas, the Persian minister, Philetærus, King of Pergama, and Narses, the Byzantine general, have possessed energy and ability. As used in the Bible and the classics, the word often means simply a chamberlain. There is a Russian sect, known as Skopzi, which practices castration.

Euon'ymus [Lat. form of Gr. εὐώνυμος, fortunate, propitious; εὖ, well + ὄνομα, name; so called by euphemism because it is poisonous]: a genus of shrubs of the family *Celastraceæ*, natives of Europe and the U. S. The fruit is a capsule, with seeds inclosed in a red aril. The flowers, foliage, and fruit of some of the species are poisonous. The wood of the *Euonymus europæus*, an ornamental shrub, is strong, compact, and yellow, and is applied to various useful purposes. The *Euonymus atropurpureus* (burning bush, or wahoo), a native of the U. S., is an ornamental shrub, with crimson fruit drooping on long peduncles. The bark is used as a remedy for dropsy, and as a hepatic stimulant and laxative, and has active properties. The *Euonymus americanus*, or strawberry bush, is often cultivated for ornament.

Eupato'ria (formerly **Koslof**): a seaport of Russia; government of Taurida; on the Black Sea, and on the west coast of the Crimea; 38 miles W. N. W. of Simferopol (see map of Russia, ref. 11–C). It has a shallow harbor, a custom-house, a hospital, and a handsome Tartar mosque. Grain, wool, hides, and salt are exported from this place. The English and French armies landed here in Sept., 1854, and the Russians were repulsed here in Feb., 1855. Pop. 14,000.

Eupato′rium [said to have been so named from Mithridates Eupator, King of Pontus (d. 63 B. C.)]: a genus of plants of the family *Compositæ*, having the florets all tubular and perfect. It comprises many species of perennial herbs, mostly American. The *Eupatorium perfoliatum*, called boneset and thoroughwort, is a native of the U. S., and is used in medicine as a tonic, stimulant, and sudorific. The leaves, as the specific name denotes, are connate-perfoliate—i. e. united at the base around the stem. The hemp agrimony (*Eupatorium cannabinum*), which grows wild in England, has been used in medicine. The *Eupatorium purpureum* and several other American species appear to have valuable diuretic properties.

Eupen, oi′pen (in Fr. *Néau*): town of Rhenish Prussia; on the Vesdre; in a beautiful valley 10 miles by rail S. S. W. of Aix-la-Chapelle (see map of German Empire, ref. 5–C). It is well built and flourishing, and derives its prosperity chiefly from its manufactures of woolen goods (broadcloths and cassimeres). It has fourteen woolen-mills, dye-works, and manufactures of machinery. Down to the Peace of Luneville (1801) Eupen belonged to the duchy of Limburg, and consequently to the Austrian crown. Pop. (1890) 15,-445.

Euphemism [from Gr. εὐφημισμός, deriv. of εὔφημος, uttering words of good omen, abstaining from inauspicious words; εὖ, well + φάναι, speak]: a figure in rhetoric by which an unpleasant idea is expressed by indirect and milder terms. The euphemisms of the ancients generally originated in a desire to deprecate the ill-will of malevolent powers by attributing to them characteristics opposite to those which really belonged to them. Thus the Furies were by the Greeks termed Eumenides, "gracious."

Euphor′bia [named in honor of *Euphorbus*, physician to Juba, King of Mauritania]: a genus of plants of the family *Euphorbiaceæ*, or SPURGEWORTS (*q. v.*), having an acrid milky juice and monœcious flowers, included in a cup-shaped four to five lobed involucre resembling a calyx. More than 100 species of this genus are natives of the U. S. The seeds of "caper spurge" (*Euphorbia lathyris*) of Europe and the U. S. yield the fixed oil known as oil of euphorbia, a powerful cathartic. Some African euphorbias are large trees. Some species are quite cactus-like in appearance, and are popularly classed with them, e. g. *Euphorbia splendens*, a fleshy, prickly plant of the greenhouses; *Euphorbia meloformis*, from South Africa, closely resembles a melon cactus. *Euphorbia pilulifera* is a drug valuable in the treatment of asthma. See EUPHORBIUM.

Euphorbium: an acrid and inodorous gum-resin produced by the *Euphorbia officinarum* of Southern Africa and some other species, including *Euphorbia canariensis* of Western Africa, and *Euphorbia antiquarum* of the Levant. It is a violent emetic and purgative, and is sometimes used in the composition of plasters and in veterinary medicine.

Euphorion: a Greek poet and grammarian; b. at Chalcis in Eubœa; flourished about 250–220 B. C. He became librarian to Antiochus the Great, and produced epic poems and elegies besides several prose works, all of which have perished. He was learned to obscurity like Callimachus and Lycophron, and like these had his admirers and students, among them the Roman poet Gallus. Fragments of his writings may be found in Meineke's *Analecta Alexandrina*, p. 3.

Euphra′nor (in Gr. Εὐφράνωρ): Greek painter and sculptor; b. at Corinth: flourished about 350 B. C., a contemporary of Apelles. He excelled both in painting and in sculpture. Among his works, which are highly praised by Pliny and Plutarch, was a painting of Ulysses in his feigned insanity.

Eu′phrasy [from Gr. εὐφρασία, cheerfulness, deriv. of εὐφραίνεσθαι, to be happy; εὖ, well + φρήν, mind], or **Eyebright**: a plant of the family *Scrophulariaceæ*, the *Euphrasia officinalis*, a small annual herb from 2 to 8 inches high, a native of Asia, Europe, and North America. Milton in his *Paradise Lost* speaks of its virtues in clearing the eyesight. It is probably somewhat useful in inflammation of the eyes, from its astringent character. Some varieties are said to have in their blossoms a spot or "signature" resembling the eye, and this spot caused, or at least strengthened, the popular faith in its powers.

Euphra′tes (in Gr. Εὐφράτης; Turk. *El-Frat*): a large river of Western Asia, celebrated in all periods of history for the important events which have occurred on its banks and the magnificence of the cities whose walls it washed. It rises in Armenia, in the Anti-Taurus Mountains, by two branches—the Moorad and Kara-Soo—which unite near lat. 39° N. and lon. 39° E. The stream formed by this junction flows first southwestward, effects a passage through a defile of Mt. Taurus, and forms the boundary between ancient Syria and Mesopotamia. Near the town of Bir it approaches within 100 miles of the Mediterranean. After crossing the 36th parallel of N. latitude it pursues a general southeastern direction, flows through the extensive alluvial plains of Babylonia and Chaldæa, and enters the Persian Gulf at its northwestern extremity. Its total length, says Guyot, is 1,750 miles, and the area of its drainage is 255,000 sq. miles. It is with difficulty navigable down stream for about 700 miles above the site of Babylon, but many rapids impede up-stream boating. From Babylon to the sea, 450 miles, it is navigable. Its principal affluent, the Tigris, is nearly as large as the Euphrates itself. It receives no large tributary from the right hand. The width in some places is nearly 600 yards, but below Hillah its volume and width are reduced by numerous canals cut for irrigation. The name Shatt-el-Arab is given by the natives to that part of the river below the mouth of the Tigris. The melted snows of the mountains of the Taurus and Anti-Taurus cause a periodical inundation of the Euphrates in the spring. The water is highest in May and June. In ancient times the chief city on its banks was Babylon.

Euphros′yne [Gr. Εὐφροσύνη; εὖ, well + φρήν, mind]: one of the three Graces in Greek mythology; a personification of the genius of mirth or joy. See GRACES.

Eu′phuism [from Gr. εὐφυής, well-endowed; εὖ, well + φυή, natural growth]: an affected style of speaking and writing which became a fashion in the reign of Queen Elizabeth. The term originated in the title of a pedantic romance called *Euphues* (1580), written by John Lilly (Lyly) and abounding in antithesis, alliteration, and illustrations drawn from a fabulous natural history.

Euplexop′tera [Mod. Lat. from Gr. εὖ, well + Lat. *plexus*, a folding + Gr. πτερόν, wing]: an order of insects. See ENTOMOLOGY and FORFICULIDÆ.

Eu′polis (in Gr. Εὔπολις): Greek comic poet of the fifth century B. C.; in wit and grace second only to Aristophanes, if second even to him. A friend and collaborator of his great contemporary, he took part in the composition of the *Knights*, but the poets soon quarreled and accused each other of plagiarism. Alcibiades was one of the chief targets of his satire, and it was fabled that he took vengeance on the poet for his *Dunkards* [Gr. Βάπται] by drowning him. The origin of the story was doubtless the fact that Eupolis perished in a naval engagement 411 B. C., in consequence of which disaster the Athenians are said to have exempted poets from service. No less than seven of his pieces out of no more than seventeen received the first prize. The fragments may be found in Meineke's and Kock's collections.

B. L. GILDERSLEEVE.

Eurasia: the continent comprising Europe and Asia, which are themselves more usually termed continents.

Eura′sians [formed from *Europe* + *Asia*], or **Half-castes**: the offspring of European fathers and Asiatic mothers. The term is properly restricted to East India, where persons of this class are especially numerous in the large cities, as Calcutta, Madras, and Bombay. They generally receive a European education, but although they speak English grammatically they have a peculiarly disagreeable pronunciation. The girls are sometimes very beautiful, and often marry British officers; while the young men enter the Government offices or serve as clerks with merchants. They are very useful in this position, but as soon as they become rich, or advance to higher offices, they generally become insolent and wild. The Europeans, who also call them "Vepery Brahmins," do not hold them in high estimation. The natives call them "Cheechee."

Eure (Fr. pron. ēr): a department in the northern part of France; a part of the old province of Normandy. It is bounded N. by Seine-Inférieure, E. by Oise and Seine-et-Oise, S. by Eure-et-Loir, and W. by Orne and Calvados. Area, 2,301 sq. miles. It is intersected by the rivers Seine and Eure, and is bounded on the N. W. by the estuary of the former. The surface is mostly level; the soil is fertile. The staple productions are grain, hemp, flax, apples, and pears. Good horses, cattle, and sheep are reared here. Eure has important manufactures of cotton and woolen stuffs, paper, glass, stoneware, and copper-ware. Pop. (1896) 340,652. Capital, Evreux.

Eure-et-Loir (Fr. pron. ėr'ā-lwaar'): a department in the northwest part of France; bounded N. by Eure, E. by Seine-et-Oise and Loiret, S. by Loir-et-Cher, and W. by Sarthe and Orne. Area, 2,268 sq. miles. It is drained by the rivers Eure and Loir. The surface is partly level, and is in some parts diversified by hills and valleys. The soil is very fertile, and produces large crops of wheat. Good cavalry horses are raised here. This department is traversed by a railway connecting Paris with Chartres and Le Mans. Pop. (1896) 280,469. Capital, Chartres.

Eureka: city; capital of Humboldt co., Cal. (for location of county, see map of California, ref. 3–A); situated on Humboldt Bay, 7 miles from the ocean and 225 miles N. N. W. of San Francisco. It has excellent educational facilities, a $170,000 court-house, twenty-six lumber-mills, several tanneries, and a safe and commodious harbor on which improvements by means of jetties have been made by the Government. Eureka is one of the chief shipping-points for redwood lumber. Pop. (1880) 2,639; (1890) 4,858; (1900) 7,327.

Eureka: village and railway junction (incorporated in 1856); Woodford co., Ill. (for location of county, see map of Illinois, ref. 4–E); 19 miles E. of Peoria; in a fine agricultural district. It is the seat of Eureka College, connected with which is a normal school and a biblical school of the Disciples of Christ. The village also has an excellent high school and a very large manufactory of tile and pressed brick. Pop. (1880) 1,185; (1890) 1,481; (1900) 1,661.

EDITOR OF "JOURNAL."

Eureka: city and railway junction; capital of Greenwood co., Kan. (for location of county, see map of Kansas, ref. 7–I); 110 miles S. S. W. of Topeka. It has an academy, and is the trade center of an agricultural and stock-raising region. Pop. (1880) 1,127; (1890) 2,259; (1900) 2,091.

Eureka: town; capital of Eureka co., Nev. (for location of county, see map of Nevada, ref. 5–I); situated midway between Salt Lake and San Francisco, and 90 miles S. of the Southern Pacific Railway, with which the town is connected at Palisade by the Eureka and Palisade Railway. Eureka is the third town of importance in the State. The principal business is mining, and large quantities of lead and silver ore are produced. Pop. (1880) 4,207; (1890) 1,609; not returned separately in 1900.

Eureka: town; Juab co., Utah (for location of county, see map of Utah, ref. 5–L); on the Union Pacific and the Rio Grande Western railways; 66 miles S. of Salt Lake City. It is an important center for agriculture and mining. Pop. (1880) 122; (1890) 1,733; (1900) 3,085.

Eureka Springs: city (founded in 1879); capital of Carroll co., Ark. (for location of county, see map of Arkansas, ref. 1–B); situated 1,800 feet above sea-level in the Ozark Mountains and on Eureka Springs Railway; 8 miles S. of north line of the State, and 18 miles E. by S. of Seligman, Mo. It has seven churches and a summer normal school, and is chiefly noted for its medicinal springs and mild, bracing climate. The city has street railways and is lighted by gas; water-works in course of construction in 1893. Pop. (1880) 3,984; (1890) 3,706; (1900) 3,572.

EDITOR OF "TIMES-ECHO."

Eurhipidura, yu-rip-i-dyu'ra [Gr. εὖ, well + ῥιπίς (-ίδος), a fan + οὐρά, tail]: a term used by Gill to designate those birds having a small number of tail-vertebræ, the last of which are fused into a pygostyle, and having the tail feathers arranged in the shape of a fan. A few of the birds included in this group, like the ostrich and grebe, have no external tail, but this is due to degeneration. The group, or subclass, includes all existing birds and is opposed to *Saururæ*, fossil birds with a considerable number of long tail-vertebræ, having a pair of feathers attached to each vertebra. It is the equivalent of the *Ornithuræ* of Fürbinger.

F. A. LUCAS.

Euric: King of the West Goths; b. about 420, gained possession of the crown by killing his brother, Theodoric, 466. He consolidated the West Gothic empire in Gaul by subjugating the whole region between the Rhône, the Loire, the ocean, and the Pyrenees. He then sent Gotheric into Spain, and in a very short time the Romans were expelled and the whole peninsula was brought under the sway of the West Goths, with the exception of the small Suevic kingdom in Lusitania, which remained independent. The West Goths were Arians, and Euric is said to have persecuted the orthodox. D. at Arles, in 484.

Eurip'ides: one of the three great tragic poets of Greece; son of Mnesarchides and Cleito; according to tradition, b. on Salamis the night of the great battle, 480 B. C.; according to the Parian chronicle, four years later. A malicious story was current that his mother was an herb-seller, but certain it is that he received a careful education. In his boyhood he took part in religious festivals as a dancer and a torch-bearer. In his youth the future declaimer against athletes was himself an athlete. We read also of his essays in painting, but while yet a young man he devoted himself to dramatic art, and his first piece was acted in 455, receiving the third prize only. From this time on he worked steadily for the stage through evil report and good report. He was not only a tragic poet, but also a thinker and a scholar. He had a valuable library, of which he made diligent use, living as he did withdrawn from the world, and though he could not be called the disciple of a philosophical school, he was in close contact with the philosophic thought of his day, with such men as Anaxagoras, Protagoras, and Prodicus, and he could not have been a stranger to the Socratic circle. He was the apostle of enlightenment, and the faith in the gods that dominated Æschylus and sustained Sophocles gives way in Euripides to a rationalistic spirit, and when it returns it comes in a questionable shape. Unlike Æschylus, he did battle for no political cause; unlike Sophocles, he held no office, but he was for all that an ardent Athenian. Twice married, the infidelity of both his wives is said to have made him a woman-hater, but, rightly read, his tragedies show a profound appreciation of all the higher qualities of womanhood. He had three sons, one of whom, Euripides the younger, put on the stage the posthumous tragedies of his father. The close of his life was spent at the court of Archelaus of Macedon, the great patron of letters, and there he died in 406, torn in pieces by hounds, according to a doubtful tradition. Of ninety-two dramas or twenty-three tetralogies ascribed to Euripides, nineteen plays have been preserved, among them one satyr-drama, *Cyclops*, and one tragedy of doubtful genuineness, *Rhesus*. Several of the extant plays held high rank in antiquity, but of the remainder some are undoubtedly inferior to others that are lost, so that Euripides is not known exclusively by his best work. The chronological order of his plays is so hard to determine that Nauck has arranged them alphabetically—a safe plan. *Alcestis* (438), strictly speaking not a tragedy but a substitute for a satyr-drama, transcribed by Browning in *Balaustion's Adventure*; *Andromache*; *Bacchæ*, a posthumous play, considered a sort of poetical deathbed repentance (translated by Milman); *Cyclops*; *Electra*; *Hecuba*, once a great favorite of editors; *Helena*; *Heracleidæ*; *Hercules Furens* (translated by Browning in *Aristophanes's Apology*); *Hippolytus* (428), emulated by Racine in his *Phèdre*; *Ion*; *Iphigenia in Aulis*; *Iphigenia among the Taurians*, made additionally famous by Goethe's *Iphigenie*; *Medea* (431), which with the *Hippolytus* forms the double summit of Euripidean art; *Orestes*; *Phœnissæ*, a remarkable accumulation of tragic scenes; *Rhesus*; *Supplices*; *Troades*.

Euripides found less favor with the Athenian people than did Æschylus and Sophocles. He did not win his first victory until 441, and received the first prize only five times. After the beginning of the Peloponnesian war he seems to have struck the right vein, and to have become the favorite of Young Athens by virtue of his allusions to politics and his sympathy with the spirit of the times. The more popular he became with Young Athens the more virulently was he attacked by the comic poets, who were sworn foes of enlightenment and detested new-fangled notions of art. Even the grave did not hide Euripides from the persecution of Aristophanes, otherwise not an ungenerous enemy, and the *Frogs*, acted soon after the death of Euripides, is a formal indictment of the poet's art, as well as of the poet's moral teaching. But rhetoric and rationalism, point and pathos, won posterity for the poet of humanity, and "Euripides, the human, with his droppings of warm tears," ruled the stage from his death down to the present century, and while most scholars nowadays see in him a departure from the Hellenic standard, which from the Hellenic point of view must be called a decline, all recognize the greatness of the genius who opened to the world a new realm of dramatic art. His language may lack the large utterance of Æschylus, and the variety of its tones may produce an inharmonious effect. His meters and rhythm may mark a departure from the high standard of a severer art and display too much laxness here, too much mechanical uniformity there; and his sensational monodies and trivial melodies may deserve all the censure so freely dealt out by critics ancient and modern. His plots may lack the subtle articulation that makes the plays of Sophocles as inevitable as is life itself; the choruses, exquisitely beautiful sometimes in themselves, may show too plainly that they are adornments and not instruments of the drama; the dialogue may degenerate into dialectic digladiation; there may be too much moralizing and too much paradox; but Euripides is a great poet, not merely a great preacher; and both as poet and preacher he still retains his hold on those whose judgment is not swayed by critical cant. Editions of separate plays are too numerous to mention. Important editions of the text have been put forth by Kirchhoff (1855), and by Nauck in the Teubner series, an edition with notes in English by F. A. Paley. There are valuable selections, with notes, by Wecklein and by Weil. Especially noteworthy are von Wilamowitz-Möllendorff's various contributions to Euripidean study. See the introduction to his *Herakles* (1889). Of English renderings, Potter's translation in verse is out of date. A new translation in prose by E. P. Coleridge is in progress (1893). Fitzgerald's *Hippolytus* and Webster's *Medea* may be added to the translations incidentally mentioned above. See also W. C. Lawton, *Three Dramas of Euripides* (Boston, 1889).

B. L. Gildersleeve.

Euroc'lydon [Gr. εὐροκλύδων, corrupt reading Acts xxvii. 14 for εὐρακύλων = Lat. *euraquilo*, northeast wind]: a violent wind of the Mediterranean mentioned in Acts xxvii. 14. The Vulgate renders it *euro-aquilo*, i. e. northeast wind. But in some of the best manuscripts (Sinaitic, Vatican, and Alexandrian) εὐρακύλων, east northeast wind, is the reading, instead of εὐροκλύδων, northeast wind; and this reading is adopted by the best recent editors. The wind in question is said to be half a point N. of E. N. E. See Smith's *Voyage and Shipwreck of St. Paul* (1856; 3d ed. 1866).

Euro'pa (Gr. Εὐρώπη): in classic mythology, a daughter of Agenor, King of Phœnicia, and a sister of Cadmus. According to a poetic legend, Jupiter, in the form of a bull, carried her on his back to Crete, where he assumed human form and won her love. She bore by him Minos, Sarpedon, and Rhadamanthus.

Europe, yu'rup [Lat. *Euro'pa*, so named by the Asiatic Greeks, either from its wide coast or from the Phœnician Princess Europa]: one of the four great continents, and historically the most notable; occupies an area of about 3,781,647 sq. miles; bounded N. by the Arctic Ocean, E. by Asia, S. E. by the Caspian, S. by Asia, the Black Sea, and the Mediterranean, and W. by the Atlantic. The boundaries are well defined except on the E. and S. E., where the Ural and Caucasus Mountains do not exactly coincide with the frontiers of European and Asiatic Russia; Caucasia especially is variously classified and mapped as in Europe or Asia. Its greatest breadth is about 3,400 miles, and its extent from N. to S. 2,400 miles at the extreme points. Its territory has been more carefully mapped out than any other part of the earth's surface. Great Britain and Ireland, although distinct islands, always rank as a part of Europe, having been separated from the continent at no very remote period. In the N., Iceland and Nova Zembla, and in the Mediterranean, Corsica, Sardinia, Sicily, Malta, Crete, the Ionian and the Balearic islands also belong to Europe. Europe is only about one-quarter as large as either Asia or America, and is more populous in proportion to area than any other continent, having about a hundred inhabitants to the square mile. The length of coast-line is about 20,000 miles, 8,000 of this being on the Atlantic, 3,600 on the Arctic Ocean, and 7,800 on the Mediterranean and Black Seas, giving unequaled advantages for commerce. Its three great southern peninsulas—Italy, the Græco-Balkan Peninsula, and the Iberian Peninsula of Spain and Portugal—form very marked features of its topography.

Geology.—The great Mediterranean basin is the geological feature of Southern Europe, having its north limit at the chains of mountains known as the Cévennes, the Jura, etc. The prevailing rocks are plutonic and metamorphic, of which the Alps are composed, and which are found in France, Germany, Scandinavia, etc. In Spain the Silurian rocks are found. Other Palæozoic rocks—the Devonian, Carboniferous, and Permian—occupy large areas in Russia, the British islands, etc. Germany, France, and England have extensive strata of the Secondary formations, and the Tertiary are still more widely distributed. Cretaceous rocks abound in Denmark, Greece, and Southern Russia, besides forming a large part of the Paris basin and the basin of the lower Rhine. Mineral wealth abounds. Mines of iron ore, lead, copper, coal, and salt are extensively worked, while for gold and silver Europe is mainly dependent on other countries. Europe abounds in mineral springs of great variety and chemical virtue.

Mountains and Plains.—The leading physical features are the mountainous region in the S. and the low district in the N. and E. The central mountain system is the Alps, which extend in a great arc of about 700 miles along the frontiers of Italy and France, through Switzerland and western portions of the Austrian empire, and along the border of Southern Germany. They culminate in Mont Blanc, 15,779 feet in height, the highest point in Europe (if we exclude the Caucasus), but inferior to the chief summits of Asia, Africa, North and South America. N. and E. of the Alps are the Jura, Vosges, Black Forest, Sudetic Mountains, Carpathians, and other ranges of Central Europe. Westward the Cévennes and other mountains of Southern France form connecting links between the central highland region and the Pyrenees. This latter range extends in an almost uniform wall along the border of France and Spain, and reaches a height of over 11,000 feet. All of the southern peninsulas are in general mountainous or elevated. The Græco-Balkan Peninsula has the Balkans, Pindus, and various groups of Greece; Italy is traversed by the Apennines, whose principal peak is over 9,000 feet high; and Spain is a table-land crossed by chains whose southernmost, the Sierra Nevada, has about the elevation of the Pyrenees. The lowlands comprise considerable portions of Western and Northern France, Belgium, Netherlands, Denmark, Northern Germany, Galicia, and Russia. Scandinavia is traversed by mountains, while the British islands are undulating, hilly, and in places mountainous.

Rivers.—The principal rivers are the Danube, Volga, Ural, Dnieper, Don, Neva, Petchora, the two Dwinas, Niemen, Oder, Rhine, Elbe, Vistula, Tagus, Duero, Ebro, Guadalquivir, Loire, Garonne, Rhône, Seine, Thames, Severn, Humber, Po, etc. The Volga drains 500,000 sq. miles of Russian territory, and the Danube has a basin estimated at 300,000 sq. miles. The flow of some of these is very irregular, and the Danube, the Elbe, the Loire, and others are subject to serious floods. Extensive engineering works to promote navigation and diminish the dangers of floods have been executed. The rivers penetrate the whole continent, fertilizing the soil and rendering great natural facilities to commerce. No European river has a great waterfall. The famous Staubbach fall is a mere rill, although the whole descent is about 1,000 feet.

Lakes.—Europe abounds in lakes, Lake Ladoga in Russia being the largest. Minor lakes, celebrated for their beauty, are found in the mountainous regions, as Lakes Geneva, Maggiore, Garda, Como, Neufchâtel, Constance, Zurich, Lucerne, etc.

Climate.—The numerous small lakes of Europe increase the area of evaporation, and tend to make the climate far more moist than that of America or Asia. This is further increased by the Mediterranean, and the large water surface penetrating and hemming in the continent has a powerful tendency to ameliorate the climate; and this tendency is greatly strengthened by the proximity of the Gulf Stream to the western coast of Europe. The temperature of any given parallel of latitude in the greater part of Europe is several degrees warmer than the regions of the same latitude in America. Russia, however, has a continental climate. The whole of Europe belongs to the north temperate zone, except the small portion extending into the north frigid zone. While no part of the continent touches the tropics, the south portion is marked by the dryness of the summer peculiar to the sub-tropical zone. The rainfall occurs most largely in the winter in Southern Italy and Spain; autumn and spring are the rainy seasons in Northern Spain

and Italy and in Southern France. Summer brings a rainy season to Switzerland, Germany, Austria, Prussia, and Sweden. The British islands have their maximum rainfall in winter. Meteorological statistics show the maximum rainfall at Skye and in the West of England, with 101 to 189 inches of annual rainfall, while that of Salamanca in Spain is only 9 inches, and the average in Sweden and Russia and parts of Germany is as low as 15 to 21 inches per annum. Western Europe has heavier rains than Eastern, and the most prevalent wind is the southwest. In Southeastern Europe the prevailing winds are from the N. and E., the latter in fall and winter. The snow-line in the mountains varies from 8,000 to 10,000 feet above the sea among the Alps, while in Norway the snow-line comes down to the altitude of 2,360 feet.

Soil and Productions.—The climate of Europe has such variety as to favor the growth of the richest products of the vegetable kingdom. The regions of the Mediterranean, where ages of fertility have produced both vernal and autumnal growths, and the south of Spain, where almost tropical luxuriance bears fruits every month, contrast strongly with the Arctic regions with their short period of vegetation. Of the cereal crops wheat is heavily grown in Russia, Austria, France, England, Germany, and the countries of the Danube. Barley is an almost universal crop, as are rye and oats in Central and Northern Europe. Maize or Indian corn is largely cultivated in the south; the potato has spread over Central and Northern Europe. Beans, pease, clover, lucerne, sainfoin, hemp, flax, etc., are grown profusely. The cultivation of the vine is of prodigious extent (being profitably grown as far north as 50°), and forms a vast industry in France, Italy, Austria, and Spain. The olive flourishes in Italy, Greece, Spain, and Portugal, growing two crops annually. Tobacco is grown all the way from Sicily north to Sweden. The beet is cultivated in Central Europe for the manufacture of sugar. Among fruits and nuts there are the orange, fig, almond, citron, pomegranate, pistachio, apples, pears, cherries, plums, and date-palms. The timber trees, though greatly depleted by centuries of consumption, still furnish forest products for fuel and the arts. Northern Europe has a large timber trade. Among the trees are the oak, chestnut, beech, ash, alder, birch, pine, elm, maple, poplar, hemlock, and fir.

Zoölogy.—According to Wallace, Europe belongs to the palæarctic region. While wild animals are by no means so numerous as on other continents, the domestic animals are reared in large numbers and in great perfection. The larger varieties of Carnivora are few. Among the characteristic animals are the reindeer, bear, wolf, fox, weasel, badger, hedgehog, chamois, hare, rabbit, squirrel, marten, etc. The birds number 247 genera and 531 species, but of these only two or three are peculiar to this continent. There are the thrush, warbler, magpie, jackdaw, linnet, sparrow, shrike, kingfisher, vulture, quail, eagle, hawk, kite, buzzard, owl, swallow, lark, nightingale, blackbird, etc. The waters, both coastwise and inland, are well stocked with fish, among which the salmon holds a chief place, while the herring, cod, sardine, sprat, perch, tunny, anchovy, etc., abound. Oysters are found all along the Atlantic coast, and their artificial culture is widely extending, though in quality they are inferior to the American oyster. The sponge and the coral fisheries are actively pursued on the Mediterranean. Among reptiles the tortoise, turtle, chameleon, lizard, adder, viper, frog, and toad are the principal. Insects are not so numerous nor so annoying in Europe as in the warmer regions of the globe.

Population.—The inhabitants of Europe embrace many composite races, the characteristics of which have been greatly changed and modified in successive ages by migrations, intermarriages, and conquests. Modern archæologists have found evidence of human inhabitants in Europe as early as the Pleistocene period. Remains of these races, called the men of the Old Stone Age (and distinguished by some as the cave-dwellers and the inhabitants of the river-beds), are found in England, Belgium, France, Germany, and Switzerland. At a later but still prehistoric period came the Neolithic people, still of the Stone Age. The great Aryan race, still predominant in Europe, came in at an uncertain period, probably by way of Asia Minor. Writers on ethnology mark out four great Aryan detachments—viz., the Græco-Latin or southern, the Celtic or central, the Teutonic or northern, and the Slavonic or northeastern. Of the Semitic race (mainly Jews), the migration into Europe was gradual. Brachelli estimated the 287,000,000 Europeans of Aryan origin to be composed approximately as follows: German peoples (including Germans, Dutch, Flemings, British, Swedes, Norwegians, and Danes), 95,000,000; Græco-Latin peoples (including French, Italians, Spaniards, Portuguese, Greeks, Ladins, Moldavians, Wallachians, etc.), 96,400,000; Slavonic peoples (including Russians, Poles, Bohemians, Moravians, Wends, Croatians, Servians, Bosniaks, Bulgarians, Slavonians, etc.), 82,170,000; Celts, 4,100,000; Semitic peoples, 3,200,000; Lithuanians, 2,800,000; Albanians, 1,300,000; Basques, 700,000; Gipsies, 600,000; Circassians, 400,000; Armenians, 260,000. There were besides this overwhelming preponderance of Aryanized populations only about 4,000,000 Mongolians (Tartars, Turks, and Kalmucks) and 10,500,000 of Uralian peoples (Magyars and Finns). The increase in population since his estimate is most noteworthy among the Germans and Russians.

Language.—There are about sixty distinct languages now spoken in Europe; most of these are of the Aryan family, including the Hellenic, Italic, Celtic, Teutonic, Slavonic, and Lettish branches. The Semitic branch includes the Hebrew, Arabic, etc., and the Tartaric, the Turkish, Magyar, Lapponic, and many other dialects of limited area. Rapid changes are going on which appear destined to extinguish ultimately many of the minor languages in favor of those great vehicles of speech, the English, French, German, Italian, Spanish, and Russian.

Political Divisions.—Recent changes in the political map of Europe have left its principal divisions as follows: 4 empires, 12 kingdoms, 4 republics, 4 principalities, and 1 grand duchy. The areas and populations of these political divisions are as follows:

COUNTRIES.	Government.	Sq. miles.	Population.
Andorra	Republic	175	6,000
Austria-Hungary	Empire	240,942	41,358,886
Belgium	Kingdom	11,373	6,495,886
Bulgaria	Principality	37,860	3,154,375

Bosnia, Herzegovina, and Novibazar, occupied by Austria-Hungary.	Belong to Turkey.	23,570	1,504,091
Totals		3,770,438	371,999,726

The increase of population in Europe is very slow, being probably less than 1 per cent. per annum. War and emigration are the principal causes retarding its growth. The areas of densest population are near London, Paris, Milan, Naples, and Leipzig. The keeping on foot of great armies and the maintenance of costly navies constitute one of the chronic checks to the prosperity of Europe. In productions Europe (as has been estimated) raises annually less food than its population consumes, and for clothing it is dependent upon other countries for all its cotton and for much of its wool and silk, the raw materials. Europe, however, more than makes up by its labor and skill for all it lacks in materials; its industries are so vast that it may be called one great workshop, supplying with its manufactures not only its own wants, but a large share of the wants of other divisions of the world. See Europe in the Appendix.

Education.—The condition of Europe exhibits a great advance in education during the nineteenth century. In every country (even including Turkey) laws exist for maintaining primary schools, and education is compulsory in almost all the nations (Russia, Turkey, Belgium, and the Netherlands are the chief exceptions); but in Italy, Spain, and others of the southern countries the compulsory law is not strictly enforced. Switzerland and Prussia hold the highest rank in the universal diffusion of education.

Religion.—Paganism has but little foothold in Europe, which is pre-eminently Christian. There are three grand divisions—the Roman Catholic Church, the Greek or Eastern Church, and the Protestant Church. Roman Catholicism has much the largest number of adherents, especially in Austria, France, Italy, Belgium, Spain, and Portugal. A comparison of the adherents of the leading religions, compiled from the latest data, gives in round numbers:

COUNTRIES.	Roman Catholics.	Protestants.	Greek Orthodox.	Jews.
Great Britain and Ireland.	5,200,000	27,400,000	....	100,000
Germany	17,600,000	31,000,000	....	500,000
France....................	30,000,000	700,000	....	50,000

Norway....................	....	2,000,000	....	....
Roumania	100,000	....	4,500,000	300,000
Servia	....	....	2,000,000	....
Bulgaria..................	....	....	2,500,000	....
Greece....................	....	....	2,100,000	....
Totals, about	154,100,000	80,760,000	85,600,000	6,750,000

There are several millions of Mohammedans, mostly in Turkey, Russia, and Bulgaria. There are also several millions in Austria-Hungary belonging to the Greek-Oriental Church, and in France about 7,000,000 who refuse to make a statement of religious belief.

History.—The authentic annals of Europe commence with the Greeks. Greece founded colonies, but her people were not given to conquest, while the history of Rome, which soon supplanted Greece as a political power, is one of continued aggression and territorial acquisition. Before the Christian era Rome had successively conquered Sicily, Spain, Greece, and Gaul. In the time of Augustus the Roman rule covered the whole region now embracing France, Belgium, Spain, Portugal, Western Germany, Switzerland, Italy, much of the Austrian empire, Servia, Turkey, and Greece. When Constantine established the seat of government at Byzantium (now Constantinople) and made Christianity the religion of his empire, his territorial outlines were nearly the same, with the addition of Britain. The prominent facts of the third and following centuries are the migrations of the peoples, Huns, Teutonic races, and others, their assaults on the empire, and the empire's internal decay, with the spread of Christianity. In A. D. 395 came the division of this great empire into Eastern and Western, the latter embracing much the larger territory and population. The Western Empire, which formally ended in 476, was temporarily revived by Charlemagne in 800; the idea of a world-empire was seen in the Holy Roman Empire of the German nation, established in the tenth century, important through mediæval times, and lingering with power and prestige greatly diminished down to 1806. Gradually the German race became ascendant. Angle, Saxon, and Jutish kingdoms were established in England; a West Gothic kingdom was founded in Spain; the Franks and Burgundians formed monarchies in France and Central Europe; the East Goths, and after them the Lombards, ruled in Italy. Somewhat later came the great Slavic influx into Southeastern and Eastern Europe. The Saracens appeared in the south, and held a great part of Spain for several centuries.

Numerous conquests and changes mark the map of the Middle Ages. The great institutions of feudalism and chivalry are developed. The papal power of Rome becomes dominant in the politics of many nations, and the Eastern and Western Churches are separated. France and England struggle for possessions on the Continent; Western and Central Europe sends forth a crusade for the recovery of Christ's sepulcher, and the advance of the Ottoman power ends in the overthrow of the Eastern empire by the Turks in 1453. The close of the Middle Ages is signalized by the revival of learning and art known as the Renaissance, and by the development of parliamentary institutions in England. In the fifteenth century a tendency toward absolutism and centralization exists, together with a spirit of discovery and exploration; the new trade routes lead to the decline of such powers as the Hanse cities, Venice, etc., and the rise of Spain and Portugal. The sixteenth century is marked by the Reformation, and by the vast extension of the empire of Charles V. over the Netherlands, Spain, Naples, and the German states, leading to wars and rivalries which lasted for generations. The religious wars in France between the Catholics and Huguenots resulted in the final triumph of the former, while Germany was desolated by the politico-religious Thirty Years' war of 1618–48. In the seventeenth century a prolonged struggle in England ended in favor of constitutional government; the same period on the Continent saw Spain displaced by France as the great military power. In the eighteenth century Russia and Prussia rise to the rank of great powers, and Sweden sinks from that position; England and France carry on a rivalry for expansion; Poland disappears from the map, and Turkey ceases to be threatening. The century closes with the great crash of the French Revolution.

From 1789–1815 war again broke up the political frontiers through nearly all Europe, ending in a temporary triumph of absolute government, followed by many more or less successful revolutions, which gave constitutional or representative government to most of the nations. A revolutionary wave in 1830 caused various changes; Belgium became a separate constitutional kingdom, France placed Louis Philippe, a constitutional king, on the throne, and about this time the independence of Greece was secured. In 1848 a revolutionary storm swept over Europe; Rome expelled the pope, and Sicily the Bourbons; France became temporarily a republic, and the King of Prussia was forced to grant a constitution and a representative government to the people. A reaction set in, however, which carried back the tide of political reform. In 1854–56 the Crimean war was fought, Great Britain, France, and Sardinia maintaining the integrity of Turkey against Russia. Great changes soon followed in Italy, whose chief separate states consolidated under one constitutional king in 1861, though the complete unity of Italy was not effected until 1870. Germany and Austria wrested Schleswig-Holstein from Denmark in 1864, and in 1866 the jealousies of Prussia and Austria led to the victory of the former and the establishment of the North German Confederation; 1870 saw the great Franco-Prussian war, which lasted less than a year, ending in the firm establishment of the French republic and the crowning of the Prussian king as emperor of the new German empire. In 1877 Russia declared war against Turkey, and but for the intervention of Great Britain and other powers would have swept her from the rank of a European nation. Turkey has recognized the independence of Roumania and Servia, now kingdoms, while the principality of Bulgaria, lately increased by Eastern Roumelia, is practically independent. In the early part of 1897 the Christian population of Crete declared in favor of annexation to Greece, and a Greek army was landed at the request of the insurgents. The great powers, however, intervened and blockaded the Cretan coasts. Autonomy was promised, but this did not satisfy either the Cretans or the Greeks. In the war which ensued, Greece was beaten by the Turks at almost every point, and instead of winning Crete, lost a few small areas along her northern frontier.

Of the six great powers of Europe, Germany, Austria-Hungary, Italy, France, Russia, and Great Britain, the first three form the Triple Alliance which profoundly influences Continental politics; opposed to this league is the looser bond of union between France and Russia.

To maintain what is called the "balance of power" in Europe has cost a long succession of bloody wars, a sacrifice of countless lives, and a squandering of vast treasure. There is a tendency to adopt arbitration instead of war, and the present so-called "concert" of the great powers professes to have for its object the maintenance of the peace of Europe.

Revised by EDMUND KIMBALL ALDEN.

Euryd'ice (in Gr. Εὐρυδίκη): the wife of ORPHEUS (*q. v.*). She died in consequence of the sting of a serpent, and, according to the poetic legend, Orpheus descended to the infernal regions, and persuaded Pluto to restore her to him on condition that she should walk behind Orpheus, and that he should not look back until they had reached the upper world. But he was tempted to look back, and finally lost her. (See Vergil's *Georgics*, book iv., 454.) There are seven other mythical persons bearing the name Eurydice, but the wife of Orpheus is the most celebrated of them.

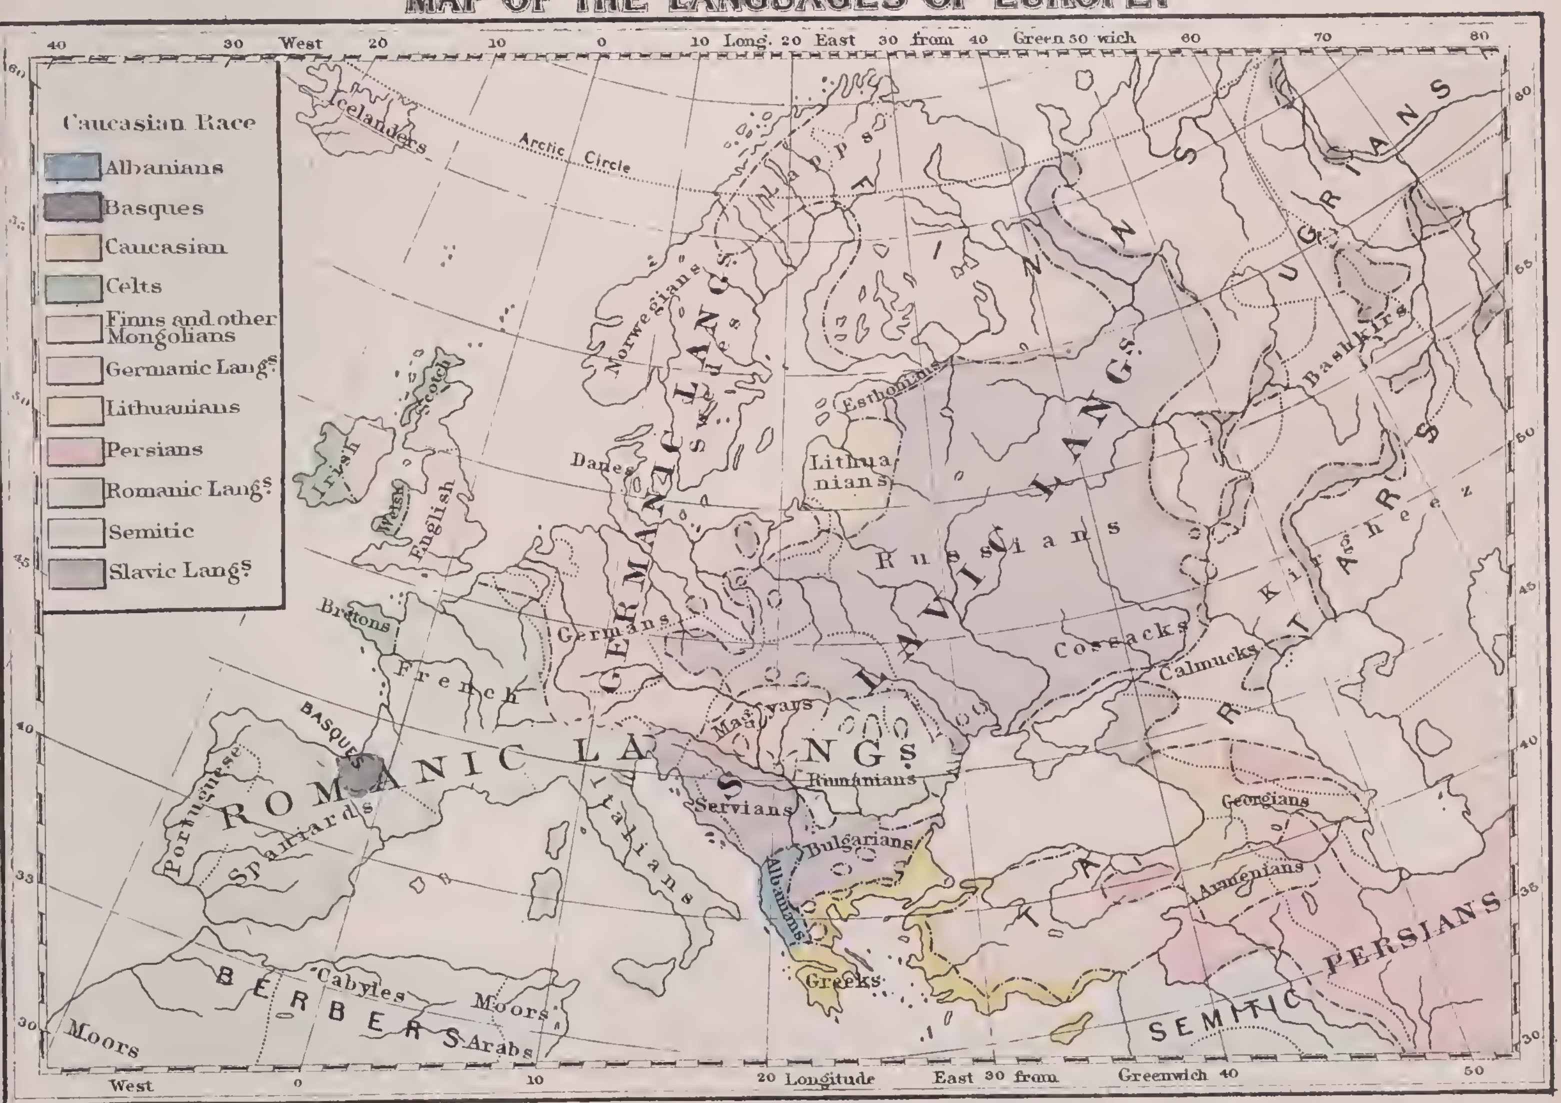
Euryp'terus [from Gr. εὐρύς, broad + πτερόν, wing]: a genus of Arthropods occurring fossil in Silurian and Devonian rocks, which bears resemblances to both scorpions and *Limulus*. It has a square cephalothorax bearing five pairs of feet (one of which terminates in a large pincer), and a

EUROPE UNDER THE ROMANS (2nd CENTURY).

EUROPE UNDER THE CARLOVINGIANS (9th CENTURY).

EUROPE UNDER NAPOLEON I. (1810-1812).

MAP OF THE LANGUAGES OF EUROPE.



long tapering abdomen (twelve-jointed) terminating in a spine like that of the horseshoe crab. It belongs to the *Merostomata.* J. S. K.

Euse'bius Pam'phili: Bishop of Cæsarea, theologian and writer of ecclesiastical history; b. in Palestine about 260 A. D. He assumed the surname PAMPHILI in honor of his friend Pamphilus the martyr. He became Bishop of Cæsarea in 314 or 315 A. D., and took a prominent part in the Council of Nice (325 A. D.). The Emperor Constantine the Great, who was his friend, selected him to open this council by an oration. Eusebius was inclined to moderation and peace, used his influence to reinstate Arius, and was a leader of the Semi-Arians. He was one of the bishops who censured Athanasius at the Council of Tyre (334). He was very eminent for learning, as well as for talents. He wrote in Greek, besides several works that are lost, an *Ecclesiastical History from the Christian Era to 324 A. D.*, which is of the greatest value; a *Life of Constantine the Great*; *Gospel Preparation* (*Præparatio Evangelica*); a *Universal History or Chronicle*; and a work *On the Proof or Demonstration of the Gospel* (*De Demonstratione Evangelica*). D. about 340 A. D. Complete editions of his works have been published by Migne in his *Patrologia Græca* (XIX.–XXIV., 6 vols., 1856–57), and by Dindorf (1865, *seq.*). A new critical edition of his historical works has been published by F. A. Heinichen (3 vols., Leipzig, 1868–70). Eng. trans. of the *History* by A. C. McGiffert, with elaborate notes, and of the *Life of Constantine the Great, Constantine's Oration to the Assembly of the Saints,* and *Oration in Praise of Constantine*, by E. C. Richardson (New York, 1890). There is a partial English translation of his *Præparatio* by H. Street, *Leaves from Eusebius* (London, 1842); a complete translation of his *History of the Martyrs in Palestine* by W. Cureton (London, 1861); of his *Theophania* by S. Lees (Cambridge, 1843). See the *Life of Eusebius* by Stein (Würzburg, 1859), and by V. Hély (Paris, 1877).
Revised by S. M. JACKSON.

Eusta'chian Tube [named after its discoverer, Bartolomeo Eustachi, an Italian anatomist (d. 1574)]: in anatomy, the canal leading from the middle ear to the pharynx. It is developed from the first (spiracular) gill cleft of the embryo; and in the amphibia, reptiles, birds, and mammals it enters into close connection with the auditory organ proper. Its function is to equalize the pressure of the air on either side of the tympanic membrane, and when it becomes closed by disease the hearing is impaired. J. S. K.

Eusta'thius (in Gr. Εὐστάθιος): Greek scholar; Archbishop of Thessalonica from 1175 A. D.; author of a wordy commentary on the *Iliad* and *Odyssey*, which is still consulted, though it has lost much of its consideration since the discovery of the Homeric scholia. It was reprinted from the original Roman ed. by Weigel (1825, *sqq.*). B. L. G.

Eustis, HENRY LAWRENCE: U. S. army officer and engineer; b. at Fort Independence, Boston, Mass., Feb. 1, 1819; studied at Harvard, and graduated at West Point in 1842; served as lieutenant of engineers in the construction of fortifications, etc., and assistant professor at the Military Academy till he resigned (Nov. 30, 1849) to become Professor of Engineering in Lawrence Scientific School of Harvard University. In the civil war he was colonel of the Tenth Massachusetts Volunteers, serving at Williamsport, Fredericksburg, Marye's Heights, Salem, Gettysburg, Rappahannock Station, Mine Run, Wilderness, Spottsylvania, Cold Harbor, and many minor actions; and became brigadier-general of volunteers in 1863, but resigned June 27, 1864, to resume his professorship at Cambridge, Mass. D. Jan. 11, 1885.

Eustis, JAMES BIDDLE: See the Appendix.

Eustis, WILLIAM, LL. D.: physician; b. in Cambridge, Mass., June 10, 1753. He served as a surgeon in the war of Independence, after which he practiced medicine in Boston, and was a member of Congress 1801–05 and 1820–23. He was Secretary of War from 1807 to 1813, resigning after Hull's surrender, and was minister to Holland from 1814 to 1818. In 1823 he was elected Governor of Massachusetts. D. in Boston, Feb. 6, 1825.

Eutaw: town (founded in 1839); capital of Greene co., Ala. (for location of county, see map of Alabama, ref. 4–B); on railway; 96 miles S. W. of Birmingham. It has 7 churches (4 for whites), 6 schools, a women's college, a saw-mill, 2 grist-mills, and 2 ginneries. Agriculture is the chief industry. Pop. (1900) 884.

Eutaw Indians: See SIOUAN INDIANS.

Eutheria [from Gr. εὖ, well + θηρίον, beast; i. e. the true beasts or mammals]: a term proposed by Gill for the viviparous mammals as opposed to the *Prototheria*, or egg-laying mammals, such as the ECHIDNA and ORNITHORHYNCHIDÆ (*qq. v.*). By Huxley and Flower the term is restricted to the placental mammals, or *Monodelphia*, the marsupials, or *Didelphia*, being placed apart as the *Metatheria.* F. A. L.

Euthyneu'ra [from Gr. εὐθύς, straight + νεῦρον, nerve]: a name given by Spengel to that group of gasteropod molluscs which includes the Opisthobranchs and Pulmonata, in allusion to the fact that the visceral nerves in these forms do not partake of the torsion of the body explained in the article GASTEROPODA (*q. v.*). J. S. K.

Eutro'pius, or **Flavius Eutropius**: a Latin historian who flourished about 350–370 A. D. The events of his life are mostly unknown, except that he was secretary under Constantine, and accompanied Julian in his expedition against the Persians. He wrote in ten books an *Epitome of Roman History* from the foundation of Rome to the time of Valens (*Breviarium ab Urbe Condita*), which became very popular, was translated into Greek, and has been extensively used as a school-book in modern times. His Latinity is pure and his style simple. The best editions are by Droysen (Berlin, 1879) and F. Rühl (Leipzig, 1887). M. W.

Eu'tyches (in Gr. Εὐτύχης): an aged superior of a monastery near Constantinople. He was a zealous opponent of the doctrines of the Nestorians, and was charged with teaching that there is in Christ only one nature—that is, the divine. He was condemned by the Council of Constantinople in 448 A. D., but this decision was reversed by the Council of Ephesus in 449. This triumph was obtained by the violent and disorderly acts of the soldiery and monks. The doctrines of Eutyches were again condemned as heretical by the general Council of Chalcedon in 451 A. D., soon after which he died. He was then above seventy years of age. The Eutychians were often called *Monophysites.* See MONOPHYSITES, JACOBITES, and CHRISTOLOGY.

Eutyches: Latin grammarian of the sixth century; pupil of Priscian. His treatise on the verb in two books is printed in vol. v. of Keil's edition of the *Grammatici Latini.*

Eutychianism: the doctrine with regard to the nature of Christ held by the followers of EUTYCHES (*q. v.*).

Euxine Sea: See BLACK SEA.

Evag'oras (in Gr. Εὐαγόρας): King of Salamis in Cyprus; was descended from Teucer, a famous hero. He began to reign in 410 B. C., and as an ally of the Athenians and Egyptians waged a long war against the King of Persia, who invaded Cyprus. He was assassinated in 374 B. C., and was succeeded by his son Nicocles.

Eva'grius: a Church historian; b. in Epiphania, on the Orontes, Cœla Syria, about 536; was at first a lawyer in Antioch, and defended the patriarch Gregory of Antioch before the Synod of Constantinople (589) from the charge of incest so well that he was appointed city questor by Tiberius Constantius and master of the rolls and prefect by the Emperor Mauricius. He continued the Church histories of Socrates and Theodoret in six books from 431–594. His Church history is compiled with great care and impartiality. The best edition was published by Reading (Cambridge, 1720). Eng. trans. in Bohn's Ecclesiastical Library.

Evangelical Alliance: a voluntary association of evangelical Christians from different churches and countries for the purpose of promoting religious liberty, Christian union, and co-operation in every good work. It owes its origin to a widespread and growing desire for a closer union among Protestants, both for its own sake and for a more successful conflict with infidelity on the one hand and superstition on the other. Its object is not to create a union, but to acknowledge, exhibit, and strengthen that spiritual union which has always existed among true Christians as members of Christ's body, but which is sadly marred and obstructed by the many divisions and rivalries of Protestant denominations and sects. It aims not at an organic union, nor at a confederation of churches as such, but simply at a free Christian union of individual members from different churches who hold essentially the same faith; although such a union will naturally tend to bring gradually the churches themselves into closer fellowship and mutual recognition. It claims no official and legislative authority that might in any way interfere with the internal affairs of the denominational organizations or the loyalty of its members to their particular communion. It relies solely on the moral power of truth and love. After a number of preparatory meetings and conferences, the Alliance was founded in a remarkable and enthusiastic meeting held in Freemasons' Hall, in London, Aug. 19–23, 1846, composed of some 800 Christians—Episcopalians, Presbyterians, Independents, Methodists, Baptists, Lutherans, Reformed, Moravians, and others, and including many of the most distinguished divines, preachers, and philanthropists from England, Scotland, Ireland, Germany, France, Switzerland, the U. S., and other countries. Sir Culling Eardly, Bart., presided, and became the first president of the British branch. Nine doctrinal articles were adopted; not, however, as a binding creed or confession, but simply as an expression of the essential consensus of evangelical Christians whom it seemed desirable to embrace in the Alliance. These articles are as follows:

1. The divine inspiration, authority, and sufficiency of the Holy Scriptures.
2. The right and duty of private judgment in the interpretation of the Holy Scriptures.
3. The Unity of the Godhead, and the Trinity of the persons therein.
4. The utter depravity of human nature in consequence of the Fall.
5. The incarnation of the Son of God, his work of atonement for the sins of mankind, and his mediatorial intercession and reign.
6. The justification of the sinner by faith alone.
7. The work of the Holy Spirit in the conversion and sanctification of the sinner.
8. The immortality of the soul, the resurrection of the body, the judgment of the world by our Lord Jesus Christ, with the eternal blessedness of the righteous and the eternal punishment of the wicked.
9. The divine institution of the Christian ministry, and the obligation and perpetuity of the ordinances of baptism and the Lord's Supper.

Some regard this doctrinal statement as too liberal, others as too narrow (especially on account of Art. 9, which excludes the Quakers, and Art. 8, which excludes the Universalists), while still others would have preferred no creed, or only the Apostles' Creed, the simplest and most generally accepted of all creeds. Nevertheless, it has answered a good purpose, and maintained the positive evangelical character of the Alliance. The American branch, at its organization (1867), adopted the nine London articles, with the following important explanatory and qualifying preamble:

Resolved, That in forming an Evangelical Alliance for the U. S. in co-operative union with other branches of the Alliance, we have no intention to give rise to a new denomination; or to effect an amalgamation of churches, except in the way of facilitating personal Christian intercourse and a mutual good understanding; or to interfere in any way whatever with the internal affairs of the various denominations; but simply to bring individual Christians into closer fellowship and co-operation, on the basis of the spiritual union which already exists in the vital relation of Christ to the members of his body in all ages and countries.

Resolved, That in the same spirit we propose no new creed; but, taking broad, historical, and evangelical catholic ground, we solemnly reaffirm and profess our faith in all the doctrines of the inspired word of God, and in the *consensus* of doctrines as held by all true Christians from the beginning. And we do more especially affirm our belief in the *divine-human person and atoning work of our Lord and Saviour Jesus Christ*, as the only and sufficient source of salvation, as the heart and soul of Christianity, and as the center of all true Christian union and fellowship.

Resolved, That, with this explanation, and in the spirit of a just Christian liberality in regard to the minor differences of theological schools and religious denominations, we also adopt, as a summary of the *consensus* of the various Evangelical Confessions of Faith, the Articles and Explanatory Statement set forth and agreed on by the Evangelical Alliance at its formation in London, 1846, and approved by the separate European organizations; which articles are as follows, etc.

The Evangelical Alliance thus auspiciously organized soon spread throughout the Protestant world. Branch Alliances were formed in Great Britain, Germany, France, Switzerland, Sweden, and even among the missionaries in Turkey and East India; also in Australia, in Brazil, and among the Protestant missionaries in Japan (Dec., 1873). There is no central organization with any controlling authority, and the General Alliance appears in active operation only from time to time when it meets in general conference, which has assumed the character of a Protestant œcumenical council, but differs from the œcumenical councils of the Greek and Roman Churches in claiming only moral and spiritual power. The various national branches are related to each other as members of a confederation with equal rights. The British branch, the oldest and largest, has the most complete organization, with a house in London; the continental branches are more elastic, and confine themselves to occasional work; the American branch, which was organized at the Bible House, New York, in 1867 (a previous attempt having failed on account of the anti-slavery agitation before the civil war), in a short time became the most vigorous and popular.

The Alliance assumed from the beginning that freedom of conscience and Christian union, far from being inconsistent with each other, are one and inseparable; that freedom is the basis of union, and union the result and support of freedom; that a union without freedom is only a dead mechanical uniformity; that true union implies variety and distinction, and a full recognition of the rights and peculiar gifts and mission of other members and branches of Christ's kingdom. The united efforts of the different branches of the Alliance, through the press and by deputations, have had a considerable moral influence in bringing about those remarkable changes in favor of religious liberty which have taken place among the Latin races and in Turkey. The Alliance aided in inducing the Sultan of Turkey to abolish the death penalty for apostasy from Mohammedanism in his dominions. It interceded for the Methodists and Baptists in Sweden, which has since abrogated the penal laws against Roman Catholics and Protestants not belonging to the Lutheran Confession. It sent in 1871 a large deputation, in which prominent citizens of the U. S. took the leading part, to the Czar of Russia to plead for the oppressed Lutherans in the Baltic Provinces. It sent a similar deputation to the embassy from Japan, when they visited the U. S. and the courts of Europe in 1872, to remonstrate against the persecution of Christians, mostly Roman Catholics, in that empire, and not long thereafter the persecution ceased.

As regards the cause of *Christian union*, the other great object of the Alliance, it is promoted mainly by means of general conferences of an international and inter-denominational character, which are arranged from time to time in different capitals by the branch in whose bounds it meets, with the co-operation of the sister branches. These meetings last from ten to twelve days, and are spent in prayer and praise, brotherly communion, and discussions of the most important religious questions of the age. Nine general conferences have been held so far. The first general conference took place in London in 1851, the year of the great exhibition of the works of industry of all nations in the British metropolis; the second in Paris, 1855; the third in Berlin, 1857; the fourth in Geneva, 1861; the fifth in Amsterdam, 1867; the sixth in New York, 1873; the seventh at Basel, Switzerland, 1879; the eighth at Copenhagen, Denmark, 1884; the ninth at Florence, Italy, 1891. The U. S. branch held a national conference, the tenth, in connection with the Columbian Exposition at Chicago, in Oct., 1893. PHILIP SCHAFF.

Evangelical Association, popularly but incorrectly known as the **German Methodist Church**: a body of American Christians, chiefly of German descent, organized by the Rev. Jacob Albright, a native of Eastern Pennsylvania. Regarding the doctrines and morals that prevailed in the German churches of that part of Pennsylvania as corrupt, Albright undertook about 1790 a work of reform among them. At a meeting of his converts in 1800, called for the purpose of deliberating on the measures best suited for advancing the new religious movement, Albright was unanimously elected pastor or bishop, and authorized to exercise all the functions of the ministerial office over the members of the organization. In the course of time annual conferences were established, and in 1816 the first general conference was held in Union co., Pa., consisting of all the elders in the ministry. Since 1843 the general conference, consisting of delegates from the annual conferences, has regularly met once every fourth year. During the first thirty years of its existence the Evangelical Association met with violent opposition, but since then it has quietly and rapidly advanced. As the Church repeatedly took action on the slavery question and sided with the anti-slavery churches, its progress was for many years wholly within the Northern States; but it now (1893) is represented in the South, though no conference has been established there. Differences of long standing led to a division in the Church in Oct., 1891.

In doctrine and theology the Evangelical Association is Arminian; with regard to sanctification, Wesleyan; in the form of government and mode of worship it generally agrees with the Methodist Episcopal Church (of which Albright, prior to beginning his reformatory labors in the German churches, was a member). The ministers, who, like the Methodists, practice itineracy, are divided into deacons and elders; the bishops and presiding elders are elected for a term of only four years—the former by the general conference, the latter by the individual conferences. The general conference is the highest legislative and judicial authority in the Church; the transactions of the annual and quarterly conferences are mostly of an executive and practical nature. A charitable society for the support of the widows and orphans of poor itinerant preachers was established in 1835, and a missionary society in 1838. There is, moreover, a Sunday-school and tract society, and church-building societies have been established in several conferences. A denominational publishing-house at Cleveland, O., publishes six periodicals—three in German and three in English; besides, two periodicals are published in Germany. The literary institutions of the Church are the Northwestern College, in Naperville, Ill.; the Union Seminary, in New Berlin, Pa.; the Blairstown Seminary, Blairstown, Ia.; and the Ebenezer Orphan Institution, at Flat Rock, O. In 1893 the Church had twenty-two annual conferences, inclusive of those of Canada and Germany; 1,864 ministers; 2,043 churches; and 148,506 members. See the history of the association, by W. Orwig.

Evangelical Church Conference: one of the periodical meetings of the Protestant state churches of Germany. The idea of these meetings originated with King William of Würtemberg in 1815. The first conference, held at Berlin in 1846, had representatives from almost every German state. At the second conference, held in 1852 at Eisenach, an official central organ was established at Stuttgart (*Allgemeine Kirchenblatt für das evangel. Deutschland*). The conferences are held at Eisenach every two years.

Evangelical Churches: those bodies of Christians which accept the Bible as the only rule of faith and practice, and believe in the divinity of Christ, in the necessity of his atonement, and in personal repentance and faith as essential to salvation.

"Evangelische Kirche" (Evangelical Church) is the official title of the Established Church of Prussia, formed in 1817 by the union of the Lutheran and the Reformed Churches. The Lutherans and Reformed (Calvinistic) Churches of Baden, Würtemberg, and other German states have been similarly united.

The "evangelical party" in the Church of England is that section of the Church which attaches especial importance to the teachings of the New Testament, and is charged with neglecting or slighting Church authority and underrating the efficacy of the sacraments.

Evangelical Counsels (Lat. *consilia evangelica*), or **Counsels of Perfection**: such directions or admonitions in the Roman Catholic Church as are not in themselves obligatory upon any one, but are recommended by the Church to some persons as highly advantageous to spiritual excellence. The chief evangelical counsels are voluntary celibacy, poverty, and obedience to monastic rules. Some writers reckon as evangelical counsels the scriptural recommendation to turn the left cheek to the man who has struck one's right cheek, to go two miles with a person who desires one's company for one mile, etc. There are reckoned twelve of these counsels.

Evangelical Union: a body of Scotch Independents, called **Morisonians**, from Rev. James Morison, their original leader. In 1843 they left the United Secession Church, and soon were joined by some Congregational churches of Scotland and England. They reject a part of the Calvinistic doctrines, and have a theological school at Glasgow. The three propositions for which Morison was deposed and on which the union was formed were that faith is one's belief in Christ's dying for him; that the "Spirit is poured out upon all flesh" and strives with all unbelievers; and that the atonement was universal. In 1889 the union embraced ninety-three churches. See Fergus Ferguson's *History of the Evangelical Union* (Glasgow, 1876).

Ev'ans, Arthur John: See the Appendix.

Evans, Augusta Jane (since 1868 *Mrs. L. M. Wilson*): novelist; b. near Columbus, Ga., May 8, 1835; removed in childhood, with her father, to Texas, and in 1849 removed to Mobile. She has published *Inez, a Tale of the Alamo* (New York, 1856); *Beulah* (1859); *Macaria* (1864); *St. Elmo* (1866); *Vashti* (1869); and *At the Mercy of Tiberius* (1887).

Evans, Sir De Lacy, D. C. L.: a British general; b. at Moig, Ireland, in 1787; served at Baltimore (1814), New Orleans (1815), and Waterloo (1815). He was a Liberal member of Parliament from 1831 to 1841. In 1835 he was appointed commander of a legion of 10,000 men raised in Great Britain to fight for the Queen of Spain. He defeated the Carlists at several places in 1836 and 1837. He represented Westminster in Parliament for many years, beginning in 1846. He became lieutenant-general, and commanded a division at the battle of the Alma and at Sebastopol in Oct., 1854. D. Jan. 9, 1870.

Evans, De Scott: See the Appendix.

Evans, Frederick William: lecturer and writer; b. in Leominster, England, June 9, 1808; removed in 1820 to the U. S. with his father. He became in theory a socialist, and studied the works of Owen, Fourier, and other leaders in the various projects for social reform. He visited England, and after his return went to visit the community of the United Society of Believers (Shakers) at Mt. Lebanon, N. Y., which he joined in 1830, and subsequently became the recognized leader of the Shakers in the U. S. His teachings added new dogmas and considerably modified the former doctrines of the Shakers. He was author of *Compendium of Principles, Rules, Doctrines, and Government of Shakers* (New York, 1859); *Autobiography of a Shaker* and *Tests of Divine Revelation* (1869); *Shaker Communism* (London, 1871); *Religious Communism* (1872); *Second Appearing of Christ* (1873); and other works. D. in Mt. Lebanon, N. Y., Mar. 6, 1893.

Evans, Sir John: See the Appendix.

Evans, Llewelyn Ioan, D. D., LL. D.: Welsh Presbyterian minister; b. at Treuddyn, near Mold, North Wales, June 27, 1833. His literary education was obtained at the Presbyterian College in Bala, North Wales, and at Racine College, Wisconsin, and Lane Theological Seminary, Cincinnati. He was a member of the Wisconsin Legislature 1856–57; pastor of the Seminary church, Cincinnati, 1860; Professor of Church History in Lane Seminary in 1863; of Biblical Literature and Exegesis in 1867; of New Testament Greek and Exegesis in 1875. In 1892 he returned to Wales as principal of the college at Bala. Besides publishing many sermons, pamphlets, and articles, he translated and edited *Zöckler's Commentary on Job*, in the American Lange series, 1874. D. at Bala, Wales, July 25, 1892. Willis J. Beecher.

Evans, Mary Ann, or Marian: See Eliot, George.

Evans, Oliver: inventor; b. in 1755 at Newport, Del. He invented the automatic flour-mill, the high-pressure steam-engine, a machine for making card-teeth, a steam dredge, and the boiler known as the "Cornish boiler." These important inventions brought him small pecuniary return, and his means were insufficient for the prosecution of his mechanical experiments. He wrote *The Young Engineer's Guide* (Philadelphia, 1805; French translation, Paris, 1821); *Miller and Millwright's Guide* (Philadelphia, 1797; Paris, 1830). D. in New York, Apr. 25, 1819.

Evans, Robley D.: See the Appendix.

Evanson, Edward: clergyman; b. at Warrington, Lancashire, Apr. 21, 1731. He studied theology at Cambridge, and became a minister of the Church of England, but was tried for heresy in 1775 in the consistorial court of Gloucester. He omitted or altered such phrases in the church service as seemed to him to be untrue; he corrected in accordance with his own views the authorized translation of the Scriptures; he contravened the creeds and the divinity of Christ, etc. The case was carried on appeal to the court of arches, and there it was buried, 1777. But in 1792 Evanson, who was now universally regarded as an unbeliever and practically out of the pale of the Church, published his *Dissonance of the Four Generally Received Evangelists*, in which he rejected most of the books of the New Testament as mere forgeries. He was answered by Thomas Falconer. D. at Colford, Gloucestershire, Sept. 25, 1805.

Evanston: town; Cook co., Ill. (for location of county, see map of Illinois, ref. 2–C); on railway, and on Lake Michigan; 12 miles N. of Chicago. It is a very handsome suburban town, the seat of NORTHWESTERN UNIVERSITY (*q. v.*) and the Garrett Biblical Institute, and has numerous churches. Pop. (1880) 6,703; (1890) 13,059; (1900) 19,259.
EDITOR OF "INDEX."

Evanston: town (founded in 1868); capital of Uintah co., Wyoming (for location of county, see map of Wyoming, ref. 12–F); situated on Bear river and on the Union Pacific Railway, 76 miles E. of Ogden. It is the seat of the State Asylum for the Insane, and has six churches, a high school, railway machine-shops (employing 200 men), a steam saw-mill, and a large flouring-mill. It is the center of a large region devoted to agriculture and stock-raising; in the vicinity are also valuable coal mines. Pop. (1880) 1,277; (1890) 1,995; (1900) 2,110. EDITOR OF "NEWS."

Evansville: city, railway center, and port of entry (incorporated in 1847); capital of Vanderburg co., Ind. (for location of county, see map of Indiana, ref. 11–B); pleasantly situated on a high bank on the Ohio river, 185 miles below Louisville and 192 miles above Cairo. It is the terminus of the E. and T. H., Peoria, Decatur and E., and Ohio Valley railways, and is 161 miles E. S. E. of St. Louis by the St. Louis and Southern Division of the L. and N. Railroad. It has 15 public schools, besides private and parochial schools, a fine U. S. custom-house and post-office, a U. S. marine hospital, one of the finest temperance halls in the country, 5 national banks, 2 savings banks, 8 flour-mills, foundries, machine-shops, and industries in wool, leather, etc. The census of the U. S. for 1890 shows 375 manufactories, with a capital of $8,432,384, giving employment to 6,766 persons, at an annual wage of $2,876,398. The cost of materials was $6,386,368; the value of product $11,788,672. Evansville is the principal shipping-point of Southwestern Indiana, and in commercial importance is one of the first cities in the State. Pop. (1880) 29,280; (1890) 50,756; (1900) 59,007. EDITOR OF "JOURNAL."

Evansville: village; Rock co., Wis. (for location, see map of Wisconsin, ref. 7–E); on Chi. and N. W. R. R.; 22 miles S. by E. of Madison. It has 5 churches, a seminary, a high school, 2 extensive tobacco warehouses, an iron-foundry, and a large windmill-factory. Pop. (1880) 1,068; (1890) 1,523; (1900) 1,864. EDITOR OF "REVIEW."

Evaporation [from Lat. *evapora'tio*, deriv. of *evapora're*, give forth steam; *e*, out + *vapor*, steam]: the passage of a substance from the liquid or solid state to the condition of vapor; especially such a change at a temperature below the boiling-point. Evaporation takes place in a vacuum more rapidly than in the air. It has been shown by Dalton that the elastic force of all vapors is the same, whether mixed with gas or air, or not; and that air is never truly saturated with vapor unless it contains an amount sufficient to saturate a vacuum of the same extent.

Evaporation is caused by heat which is absorbed when vapor is formed, and the most intense degree of cold known is caused by the evaporation of volatile liquids. The lowest point yet artificially produced, about −220° C., has been obtained by the evaporation in vacuo of liquid oxygen.

Ev'art: village; Osceola co., Mich. (for location, see map of Michigan, ref. 5–H); situated in the heart of a great lumber country; on the Flint and Pere Marquette Ry.; 60 miles E. of Ludington. It has saw and shingle mills, foundry and machine-shop, and is supplied with water-power. Pop. (1880) 1,302; (1890) 1,269; (1900) 1,360.

Evarts, WILLIAM MAXWELL, LL. D.: lawyer; b. in Boston, Mass., Feb. 6, 1818; graduated at Yale College in 1837; studied law, and in 1840 was admitted to the bar in the city of New York, where he practiced with great distinction. He was the leading counsel employed for the defense of President Johnson in his trial before the Senate in Apr. and May, 1868; Attorney-General of the U. S. from July, 1868, to Mar. 4, 1869; one of three lawyers appointed by President Grant in 1871 to defend the interests of citizens of the U. S. before the tribunal of arbitrators who met at Geneva to settle the Alabama claims; appointed Secretary of State by President Hayes Mar. 7, 1877; elected U. S. senator for New York Jan. 21, 1885. Among his public addresses are his eulogy on Chief Justice Chase (1873); Centennial Oration, in Philadelphia (1876); and the oration at the unveiling of Bartholdi's statue of Liberty. D. Feb. 29, 1901.

Eve, PAUL FITZSIMONS, M. D.: physician; b. near Augusta, Ga., June 27, 1806; graduated at the University of Georgia in 1826; graduated as M. D. at the University of Pennsylvania in 1828; studied several years in Europe; was a surgeon in the Polish revolution of 1831, and received the Golden Cross of Honor of Poland in that year; became Professor of Surgery in the Medical College of Georgia in 1832; in Louisville University (Kentucky) in 1849; in Nashville University (Tennessee) in 1850; and in Missouri Medical College, St. Louis, in 1868. In 1870 he became Professor of Operative and Clinical Surgery in the University of Nashville. Prof. Eve was president of the American Medical Association in 1857. He served as a surgeon in the Confederate army. He was editorially connected with professional journalism for many years, and was the author of very numerous monographs upon surgery, etc. D. in Nashville, Tenn., Nov. 3, 1877.

Evection [from Lat. *evectio*, act of carrying out; *e*, out + *ve'here*, *vec'tum*, carry]: an inequality of the moon's motion, depending on the position of the transverse axis of the moon's orbit, as compared with the earth's radius vector. The eccentricity of the lunar orbit varies with the relative position of these lines. It is maximum when they are coincident, and minimum when they are perpendicular to each other.

Evelyn, JOHN: author; b. at Wotton, Surrey, Oct. 31, 1620; educated at Baliol College, Oxford; traveled abroad from 1641 to 1652; enjoyed great favor at the court after the Restoration, and held various positions of honor and trust, but no office. He was a very prolific writer, and published *Sylva*, an elaborate treatise on arboriculture; *Navigation and Commerce, their Origin and Progress*; an introduction to a history of the Dutch war, which he began, but never finished; *A Parallel of Ancient and Modern Architecture*, etc. But his most important and most interesting work is his *Diary*, written without any idea of publication and containing numerous contributions to the history of the time. The sixth edition, with his *Life* prefixed, was published in 1879. D. in London, Feb. 27, 1706.

Evelyn College: an institution for the education of young women, situated at Princeton, N. J. It was established in 1887; legally incorporated in 1889, and formally authorized to confer degrees. In the same year resolutions were passed by the board of trustees of Princeton University granting to the students of Evelyn all necessary use of the Princeton libraries and museums. In 1890 the increased number of students made it necessary to secure a second building. The board of trustees consists principally of professors and trustees of Princeton University and Theological Seminary. The classes are mainly in charge of the professors in Princeton University and their assistants, and any course of study given at Princeton can be made available for the students of Evelyn. There is no co-educational element, and the work is wholly separate from that of Princeton University. There is a preparatory school in connection with the institution. The students in residence are divided into families of from fifteen to twenty each, in order to secure healthful home influences.

Evening Schools: institutions established in many of the larger towns of Great Britain and Ireland, and in the most of the cities of the U. S., for the instruction of artisans and others who have been unable to receive education in childhood. In some instances such schools are maintained by private benevolence, but they are generally established and maintained by local or municipal authorities. See EDUCATION, MANUAL TRAINING, and SCHOOLS.

Everest, HARVEY W.: preacher, teacher, and author; b. at North Hudson, Essex co., N. Y., May 10, 1831; educated at Geauga Seminary, Ohio, the Western Reserve Eclectic Institute, Bethany College, and Oberlin; president of Eureka College, professor in Kentucky University, president of Butler University, and chancellor of Garfield University. His work, *The Divine Demonstration—a Text-book of Christian Evidence*, is used in many colleges. He is pastor of the Christian church (Disciples) at Hutchinson, Kan.
J. H. GARRISON.

Ev'erest, Mount: the highest mountain of the earth; in the eastern range of the Himalayas, in Northern Nepaul; lat. 27° 59′ 12″ N., lon. 86° 58′ 6″ E. According to the measurement of Waugh in 1856, the altitude is 29,002 feet.

Everett: city (incorporated 1893): Middlesex co., Mass. (for location of county, see map of Massachusetts, ref. 2–H);

on the Eastern Division and Saugus Branch of the Boston and Maine Railroad; adjoining Boston, Chelsea, and Malden, of which last it formed part until incorporated as a town in 1870. It has 7 churches, 7 schools, a high school with a library of 8,000 volumes, large chemical works, and a number of small manufactories. Pop. (1880) 4,159; (1890) 11,068; (1900) 24,336. EDITOR OF "FREE PRESS."

Everett: borough; Bedford co., Pa. (for location of county, see map of Pennsylvania, ref. 6–D); on railway; 100 miles E. S. E. of Pittsburg. It has 8 churches, 2 public schools, an iron-furnace, glass-works, 2 tanneries, a flouring-mill, and 3 planing-mills. Pop. (1880) 1,247; (1890) 1,679; (1900) 1,864. EDITORS OF "PRESS."

Everett, ALEXANDER HILL, LL. D.: a scholar and diplomatist; b. in Boston, Mar. 19, 1792; a brother of Edward Everett; graduated at Harvard in 1806, and studied law in the office of John Q. Adams, with whom he went to Russia as secretary of legation in 1809. He was *chargé d'affaires* at The Hague for nearly six years (1818–24), and published in 1821 an able work entitled *Europe, or a General Survey of the Principal Powers*, etc. In 1825 he was appointed minister to the court of Spain by President Adams. During his residence at Madrid he wrote *America, or a General Survey of the Political Situation of the Several Powers of the Western Continent* (1827). He returned in 1829, and became editor of the *North American Review*, to which he contributed many articles. In 1845 he was appointed commissioner to China. D. at Canton, June 29, 1847.

Everett, CHARLES CARROLL, D. D.: philosopher; b. in Brunswick, Me., June 19, 1829; graduated at Bowdoin College in 1850; studied at Harvard Divinity School and at the University of Berlin; librarian, tutor, and Professor of Modern Languages at Bowdoin from 1853 till 1857; after graduating at Harvard Divinity School, in 1859, settled over a Unitarian church in Bangor; in 1869 became Professor of Theology at Harvard, and in 1878 dean of the divinity school; published *The Science of Thought* (Boston, 1869); *Religions before Christianity* (Boston, 1883); *Fichte's Science of Knowledge* (Chicago, 1884); *Poetry, Comedy, and Duty* (Boston, 1888); *Ethics for Young People* (Boston, 1891); *The Gospel of St. Paul* (1892). His philosophy is deeply tinged with that of Hegel, but without sacrifice of his individual quality, and is much enforced and illustrated from his scientific studies. D. Oct. 17, 1900.

Everett, EDWARD, LL. D., D. C. L.: orator and statesman; b. in Dorchester, Mass., Apr. 11, 1794; a son of Rev. Oliver Everett, who died in 1802. He was twice a Franklin medal scholar of the Boston public schools, and for a few months a pupil of the Phillips Exeter Academy. In 1811 he graduated at Harvard College with the highest honors of his class, being then little more than seventeen years of age. In 1812 he was appointed a tutor at Harvard while pursuing theological studies, and in 1814 he was ordained as pastor of the Brattle Street (Unitarian) Church in Boston. In Mar., 1815, he accepted the Eliot professorship of Greek literature at Harvard, the duties of which he assumed in 1819, after a course of study at Göttingen and extensive travels in Europe and the East. A brilliant course of lectures on ancient Greece and its architecture inaugurated his accession to the professorial chair, which he held until 1825. His fame as a secular orator was increased by a Phi Beta Kappa oration, delivered at Cambridge in 1824, in the presence of Lafayette, and an oration on the Pilgrim Fathers, delivered at Plymouth, on Dec. 22 of that year. Mr. Everett represented the district of Middlesex in Congress from 1825 to 1835; he was elected Governor of Massachusetts, and was annually re-elected until 1840, when he was defeated by a single vote out of more than a hundred thousand. He returned to Europe in 1840 and settled in Florence in order to devote himself to the writing of history, but in about a year was appointed minister plenipotentiary of the U. S. to Great Britain. He entered upon that mission in 1841 at a moment when questions of the greatest delicacy were pending between the two nations. Returning home in 1845, he was offered the presidency of Harvard College, which he accepted and held for three years. He then re-established himself in Boston, for the purpose of resuming literary work. The death of Mr. Webster in Nov., 1852, left a vacancy in the Department of State at Washington, which Mr. Everett was immediately summoned to fill; and on the expiration of his brief term as Secretary of State, by the termination of President Fillmore's administration in 1853, he was elected by the Legislature of Massachusetts a Senator in Congress. He held that place but a single year, when, owing to ill-health, he retired. In 1860 he accepted a nomination for the vice-presidency of the U. S., but failed of an election; and the last ten years of his life were spent in the exercise of his oratorical powers in behalf of some charitable institution, or in commemorating some historical event, or in eulogizing some illustrious person. During the first half of these last ten years his topics were within the common range of occasional discourses. To this period also belongs the memorable and patriotic pilgrimage made for the purpose of rescuing Mt. Vernon from the danger of falling into the hands of speculators, and of securing it as a national possession. His address on *The Character of Washington* was delivered in all quarters of the Union, and Mr. Everett paid over about $60,000 to the treasurer of the fund as the product of his eloquence. The opening of the civil war gave a new field to the labors of his pen and of his tongue, and from *The Flag-raising in Chester Square* (Boston), on Apr. 27, 1861, to his last utterance for *The Relief of Savannah*, in Faneuil Hall, on Jan. 9, 1865, his thoughts, his time, and almost all his numerous addresses, filling nearly 350 pages of an octavo volume, were given to the support of the Union cause. He received the highest literary honors from Cambridge and Oxford, and the Institute of France enrolled him as a corresponding member. At home he enjoyed the life-long intimacy and confidence of Daniel Webster, whose collected works he edited and published in 1851 in six volumes with a carefully written biography in the first volume. In 1822 he married Miss Charlotte Gray, daughter of the Hon. Peter Chardon Brooks, a distinguished merchant of Boston, of whom he prepared an elaborate memoir, which is included in the third volume of his *Orations and Speeches*. Two sons and a daughter survived him. D. in Boston, Jan. 15, 1865.

Revised by C. K. ADAMS.

Everett, WILLIAM, Ph. D.: author and teacher; youngest son of Edward Everett; b. in Watertown, Mass., Oct. 10, 1839; graduated at Harvard College in 1859 and at Trinity College (England) in 1863; was assistant Professor of Latin at Harvard 1872–77; became master of Adams Academy, Quincy, Mass., in 1878, and member of Congress in 1893. He has published *On the Cam* (lectures, 1865); *Changing Base* (1868); *Hesione* (poem, 1869); *Double Play* (1870); and *School Sermons* (1881).

Everglades: an extensive marshy region in Southern Florida, S. of Lake Okeechobee, consisting of a great shallow lake, in which are many low islands, varying in size from a few square yards to hundreds of acres, and covered with a dense jungle of pines, palmettoes, vines, and tropical trees. The water between the islands is from 1 to 6 feet deep. This region is a recently raised sea-bottom whose drainage is as yet imperfectly developed. As the streams gradually sink their channels into the level tract it will become drained, as is the case with the pine-land plains of New Jersey.

Evergreen: town; capital of Conecuh co., Ala. (for location of county, see map of Alabama, ref. 6–C); 97 miles N. E. of Mobile. The principal industry is truck farming. The town has medicinal springs, and is a place of winter resort, visited yearly by large numbers of Northern tourists. Pop. (1880) 985; (1890) 1,783; (1900) 1,277. EDITOR OF "STAR."

Evergreens: plants which hold their leaves throughout the winter. Horticulturists usually speak of two classes of evergreen plants, the broad-leaved, like the laurels and mahonias, and the narrow-leaved, or coniferous, including the pines and spruces, but many of the conifers, which are commonly considered evergreens, have deciduous leaves, as the larches and bald cypress. The leaves of some evergreen plants persist little more than a year, but they do not fall until new ones have appeared. The leaves of pines and spruces fall when from two to six or even more years old.

L. H. BAILEY.

Everlasting Flowers: the common name of several genera of the order *Compositæ*, having flowers which if dried and preserved retain their form and color many years. They are often called immortelles.

Evesham: town of Worcestershire, England; on the navigable river Avon, here crossed by a stone bridge of eight arches, and in the beautiful Vale of Evesham, 15 miles S. E. of Worcester (see map of England, ref. 11–G). It has remains of an abbey built about 700 A. D. Most of the surrounding country is occupied by market-gardens. Here Edward, Prince of Wales, afterward Edward I., defeated Simon de Montfort and the barons on Aug. 4, 1265. Pop. (1891) 5,836.

Eviction [from Lat. *evin'cere*, to triumph, to get control by dispossessing; *e*, out + *vincere, victum*, conquer]: in law, the act of dispossessing one of lands or tenements, as when a landlord ejects a tenant who is in arrears in his rent, or when a third person dispossesses a tenant by means of a title superior to that of the landlord, or a vendee by a title superior to that of the vendor. Originally eviction, as a legal term, was applied only to a dispossession by judgment of law, but it is now used to denote a dispossession under paramount title, or claim of paramount title, as well as many acts done by the landlord to impair the enjoyment of the premises which in intendment of law amount to a dispossession of the tenant and justify him in leaving them. In such cases, however, he must actually leave, or otherwise he can not claim to have been evicted. When the grantee of premises, with a covenant of warranty, is evicted, the damages recoverable are, in general, the consideration-money, with interest. In case of a lessee, however, as the rent ceases on eviction, he can, as a general rule, recover only the expenses of defending his possession. When the eviction is only from a part of the premises, the rent or damages is in many cases apportioned.

Evidence [viâ Fr. from Lat. *eviden'tia*, clear view, clearness; *e*, out, fully + *vide're*, see]: in law, the means of establishing an allegation made in a court of justice. In an action the respective parties make written statements of their cause of action and defense. The matter thus in dispute between them is called an issue. The object of evidence is to establish or disprove the propositions alleged. The result of the evidence is called proof. Evidence may be considered under a number of divisions: 1. Its nature and the doctrine of presumptions; 2. The rules that govern in the production and exclusion of testimony; 3. Its effect; 4. The instruments of evidence, including witnesses, and the mode of making use of them as well as writings.

1. *Its Nature, etc.*—The object of evidence is to establish a fact. It presupposes a disposition in the mind of a listener to believe upon sufficient grounds. Belief on the part of mankind is instinctive, yet this instinct is modified by the results of observation and reflection. When evidence is offered in a court of justice, it is assumed to be addressed to minds competent to give it such weight as its quality justifies. It may be either *direct* or *circumstantial.* It is said to be direct when it is offered simply to establish the fact which it concerns; it is circumstantial when its object is to lead the mind of the hearer to *deduce* or *infer* some other fact from it. In the case of circumstantial evidence the minds of the jury or judge, as the case may be, go through a process of reasoning to arrive at the principal fact in dispute. It must be resorted to with caution, in order that the conclusion arrived at may be sound and logical.

Reference may now be made to the subject of presumptions. These are of two kinds—of law and of fact. Presumptions of law are either conclusive or disputable. A conclusive presumption of law takes place when a legal conclusion is arrived at which no evidence is admissible to rebut. This doctrine is based largely on public policy, and leads to a series of artificial and arbitrary subordinate rules. An illustration is that a child under seven years of age can not commit a felonious crime. The doctrine of estoppel is another illustration. When evidence can be offered to rebut a presumption of law, it is said to be disputable. An instance is the ordinary rule in criminal law that one charged with crime is presumed to be innocent until he is proved to be guilty, or that one having possession of stolen goods immediately after a theft became possessed of them unlawfully. Under this theory, when a state of facts is once established, it is presumed to exist until there is some evidence to the contrary. Thus a man engaged in trade is assumed to follow the ordinary course of business, or the incumbent of a public office to perform its duties in the usual manner. Life is presumed to continue unless there is evidence of death, or sanity until evidence is offered to establish insanity. A presumption of fact is not a rule of law which can be announced to a jury as binding upon them, but in each case must be found by them as a matter of fact, though the court may direct their attention to the propriety of forming the conclusion. An illustration is the testimony of an accomplice, which is generally deemed to be untrustworthy without corroboration from other and trustworthy sources, and an observation to that effect may be made by the judge. Still the jury has the legal power to find a verdict upon the uncorroborated testimony of an accomplice.

2. *The Rules which prevail as to the Production of Evidence.*—The leading rules are the following: Rule 1. Certain matters may be judicially taken notice of without proof; Rule 2. Evidence must correspond with the allegations in the pleadings, and be confined to the points in issue; Rule 3. Only the substance of the issue need be proved; Rule 4. The burden of proof is with him who holds the affirmative; Rule 5. The best evidence must be produced of which the nature of the case admits; Rule 6. Hearsay evidence is in general inadmissible; Rule 7. Testimony should in general concern matters of knowledge as distinguished from opinion (though to this rule there are well-established exceptions); Rule 8. Certain evidence, otherwise admissible, is excluded on grounds of public policy; Rule 9. In certain cases, principally by statute law, written evidence must be resorted to rather than oral; Rule 10. Oral contemporaneous evidence is not admissible to vary the terms of a written instrument. These rules require some explanation. It should be premised, however, that on a trial, with or without a jury, it rests with a judge to determine whether the evidence is admissible under these rules. Whichever way he may decide, the opposing party may except, and make his exception the subject of an appeal.

Rule 1. There are certain facts of general knowledge in respect to which it is not worth while to take up time to adduce evidence, such as the recurrence of the seasons. The same rule applies to the existence of foreign nations recognized by the executive power of the nation, and to general statutes of the legislature. Of such facts a court is said to take judicial notice, and, if necessary, may resort for information to books and other sources of knowledge.

Rule 2. The second rule excludes all immaterial evidence, and confines the trial to matters in issue. Immaterial allegations in the pleadings can not be proved. For example, evidence of the intent of a party would not be admissible unless intent was material; and the same remark may be applied to evidence of good or bad character. In an action to recover money loaned, evidence of the bad intent of the debtor in delaying payment, or of the creditor's bad character, would be plainly inadmissible, while in an action for slander the plaintiff's character would be to a certain extent in issue.

Rule 3. This rule means that the minor and unimportant allegations relating to the issue need not be established as stated. They are such as the statements respecting the time or place where an event occurred, or the value of an item of property. Still, even allegations in their nature unimportant may become material by the mode in which they are stated, as if they are made descriptive. In such a case a difference between the pleadings and the evidence, called a variance, may be fatal. The effect of this stringent rule has in a number of the States of the U. S. been greatly modified as to civil actions by statutes of amendments. The criminal law is still disfigured by extreme technicality in this respect, and needs the hand of a discreet reformer to subserve the interests of the public by removing all useless impediments to the due administration of justice.

Rule 4. Under this rule he who makes an allegation which is disputed, so as to be at issue, must establish it by evidence. The burden of proof is usually with the plaintiff, though in some instances it devolves upon the defendant, as where he admits the plaintiff's case, but seeks to avoid its effect by new allegations—as, for example, infancy. The person who has the burden of proof has the right to open the case and close it. This in jury trials is often deemed to be a matter of much importance, so that each of the respective parties insists on an adjudication that the burden of proof belongs to him.

Rule 5. Under this rule evidence is divided into primary and secondary. If the primary evidence is accessible, it must in general be produced; if it be lost or destroyed, resort may be had to that which is secondary. Thus where the law requires a contract to be reduced to writing, or where the parties have written out a contract which might have been oral, the written instrument must itself be produced if it can be obtained. The rule is relaxed in certain cases where public convenience may require it. For this reason a public record may be proved by an authorized copy, without the production of the record itself.

Rule 6. The word hearsay is infelicitous, including not only what is said, but what is written, or even acted. The rule means that evidence must be given in by one who is personally cognizant of the fact to be proved, and not by one who may have gained his knowledge at second hand, from the act or narration of another. Bentham distinguished between a "perceiving" and a "narrating" witness with the same general view. The reasons for excluding hearsay evidence are obvious. Great care must be taken in distinguishing between hearsay evidence and that which is original. Thus when the very subject of inquiry is whether a certain thing was or was not said by a person, evidence that it was said is clearly admissible. So when a statement forms a part of the transaction, or, in technical language, *res gestæ*, evidence of it is not hearsay. Where the testimony is clearly hearsay, there are certain exceptional instances in which it is admissible, as in matters of public or general interest, or of ancient possessions, or of dying declarations in cases of homicide. It should be added that the admissions or confessions, when voluntary, of a party to an action are received in evidence against him on mixed grounds, partly as a substitute for more regular methods of proof, and partly as a branch of the law of *res gestæ*.

Rule 7. Under this rule a witness must in general testify only to facts of which he is personally cognizant, without giving his opinion as to their effect. There is a class of witnesses, termed experts, who are allowed to give their opinions upon facts of which they have no personal knowledge. For example, the testimony of persons acquainted with the facts may be read over to the expert, and his opinion asked as to the conclusion which should be drawn from it; or a hypothetical question, embracing the facts assumed to be established, may be put to him. An expert is one skilled in a particular trade, art, or profession. An instance is the superintendent of an asylum for the insane as to matters connected with the subject of insanity. There are a few instances in which persons who are not experts are from the necessity of the case, or by a special rule of law, allowed to testify as to their opinions.

Rule 8. This rule shuts out evidence in a number of cases where strong reasons of a public nature demand that it should be excluded. A leading instance is that of confidential communications between an attorney and client, and similar communications between husband and wife. It also prevents a judicial inquiry into secrets of state, and, to a certain extent, into the deliberations of judges in forming a judgment or of juries in arriving at a verdict.

Rule 9. There is a great statute in the English law, termed the statute of frauds, requiring certain transactions to be evidenced by writing, such as conveyances or leases of land, wills of land, and some executory contracts, as, for example, contracts to convey land or to be answerable for the debt of another. These are but instances of a more extended class of cases. Without the writing as evidence these contracts or transactions can not be established. It should, however, be added, that if such contracts, etc., have once been written and can not be produced, their contents may be proved by oral evidence.

Rule 10. This is an inflexible rule, applicable to contracts, wills, etc. Even if a contract need not have been written, yet if the parties choose to have it so, no contemporaneous oral evidence can be offered to show different or additional terms. There is a conclusive presumption of law that the parties intended to merge all anterior and contemporaneous propositions in the writing. That is the sole repository of their intention; the rule, from the nature of the case, does not preclude oral proof of a subsequent modification of the contract, nor does it prevent the introduction of oral evidence to explain the writing. Thus the meaning of technical words may be shown by the testimony of experts, and oral evidence may be used to show the circumstances surrounding the transaction, so as to place the court in the position of the parties. This is a rule of interpretation. It assumes that the instrument is valid. When the validity of the instrument itself comes in question the rule has no application. Oral evidence may accordingly be offered to show that the instrument is void. So if a clause has been omitted or inserted by mistake, a court of equity will, on sufficient oral evidence, rectify the instrument, or, in technical language, reform it, and give it the form intended by the parties.

3. *The Effect of Evidence.*—In general, evidence is to be weighed by the jury or judge, as the case may be, and a decision to be rendered in view of all the circumstances of the case. In some instances its effect is governed by technical rules. This remark is particularly applicable to matters embraced under the head of ESTOPPEL (*q. v.*). The evidence in this class of cases is conclusive. The most important instance of the application of this principle is that of a judgment recovered in a court of justice. Judgments are of two general classes—*in rem* and *in personam*. In the one case the action or proceeding is instituted against a thing, such as a ship or article of merchandise, to fix its ownership, or to establish the status of a person, as to have an adjudication that he is a lunatic, and the judgment is conclusive evidence against all as to the matters adjudicated upon. An action *in personam* is brought against a person to obtain a judicial declaration or sentence concerning his duty or obligation, as in an action for damages for a breach of contract. A judgment in this class of cases is conclusive evidence only when given upon the merits, and as to matters expressly or by necessary implication involved in the issue, and as to these only between the parties to the action and those claiming under them.

It should be added that in some cases the law gives to certain acts the force of *primâ facie* evidence, which, as the phrase implies, is liable to be rebutted. Thus a promissory note is presumptively made upon a valuable consideration. Statute law frequently declares that a particular transaction shall have this force. The rules of evidence are under the control of the legislature so long as they do not impair vested rights or violate in any manner constitutional law in its letter or spirit.

4. *The Instruments of Evidence.*—These are either witnesses or writings. (1) *Witnesses.*—A witness, when within the jurisdiction of the court, must in general attend in person. He can be compelled to attend by a writ termed a subpœna, and in the same way to bring writings which are required. When beyond the jurisdiction, his testimony is taken under a commission issuing from the court in which the case is pending. This matter is in some respects governed by statute, though in some of the courts, as in equity and admiralty, there is an inherent power to issue commissions. The testimony, when taken in the foreign country, is returned to the court, subject to any objections which may properly be taken to it. Certain classes of persons are excluded from testifying. The rules upon this subject are to some extent arbitrary. They have been modified in recent times by statute. Thus parties to the action were at one time wholly excluded in the courts of common law. They are now by statutes generally admitted. The same remarks may be made as to persons having a pecuniary interest in the event of the litigation. Persons are still incompetent who have a defect of understanding, or who are supposed to be insensible to the obligations of an oath. Thus persons convicted of an infamous crime are excluded from testifying in the courts of the State where the conviction took place. The tendency of modern law is to allow as wide a range as possible, and to permit objections to witnesses which were formerly grounds of exclusion to be only urged as affecting the value of their testimony. In technical language the objection does not go "to the competency, but to the credibility of the witness." The examination of witnesses is governed by rules which are to some extent discretionary, and in other respects absolutely binding. The principal rules are these: *a.* Leading questions are not, in general, to be asked on the direct examination. *b.* The party calling the witness can not attack his character, though he may show by independent testimony that his version of the facts is not correct. *c.* The range of cross-examination is much wider than the direct, and leading questions are permissible. A witness can not on cross-examination be asked a collateral question for the purpose of contradicting him in case his answer should be untrue. He may, however, be asked, under proper limitations, with a view to contradiction and the discredit of his testimony, if he has not given out of court a different version of the facts from that to which he now testifies, and in the same way as to expressions of hostility toward the party against whom the testimony is given. *d.* A witness is privileged from answering a question if such answer would tend to convict him of a crime or to subject him to a penalty or a forfeiture, though this rule would not extend to the case where he might simply be made liable in a civil action for a debt, etc. How far he can refuse to answer a question which if answered would tend to degrade him in the estimation of his fellows is not fully settled. *e.* The character

of a witness may be attacked by the opposing party, either by direct evidence of his bad character, or rather reputation, or by showing that he has from time to time given different versions of the facts. *f.* A cross-examination is to be confined to the matters brought out on the direct examination, and the same remark is applicable to the redirect and subsequent examinations. (2) *Writings* for the purposes of the law of evidence are either public or private. Public writings are either judicial or not judicial. The law provides compulsory modes of producing public writings for the purposes of testimony. Copies are in general resorted to, on grounds of public convenience. The officer having the document in custody has, in general, the power to give a certified copy, which is admissible in evidence. Copies of judicial records are of three varieties: exemplified (a copy either under the great seal of state or under the seal of the court), office (certified by the clerk or other custodian), or sworn. A sworn copy is authenticated by the testimony of a witness who has compared the original with the copy. An act of Congress, authorized by the U. S. Constitution, provides a convenient mode of authenticating a judgment or decree of the courts of record of one State to be used in the courts of another State. Should a record be destroyed, its contents may be proved by oral evidence. A private writing is proved by the production of the writing itself, and its existence established by the testimony of a witness. Where the writing can not be produced, secondary evidence of its contents may be given. In the special case where it is in the possession of the opposite party reasonable notice should be given to him to produce it at the trial. If he fails to produce it, secondary evidence may be given as before. When a private writing is executed in the presence of a witness subscribing his name at the request of the maker of it, this witness, called a "subscribing witness," is the proper person to prove it. If he be dead, or for any sufficient reason can not be produced, his handwriting may be proved, with some evidence to identify the party to the action as being the person who executed the instrument. When there is no subscribing witness, the proper course is to call a witness acquainted with the handwriting of the maker of the instrument to testify that in his opinion the instrument or the signature is in the handwriting of the party. Though this is matter of opinion, it is admitted from the necessity of the case. Knowledge of the handwriting may be acquired in various modes, usually by seeing the person write or by having transactions or correspondence with him. The testimony of experts as to handwriting is in some cases admitted, though the law as to the extent to which they may be examined varies in different States. In some of the States there are convenient statutory modes of proving private writings. A single instance may be cited from the law of New York, which allows nearly every contract, if acknowledged by the maker before an authorized officer, such as a notary public, to be put in evidence without other testimony by way of authentication

The final remark may be made that the rules of evidence, though positive and in some respects arbitrary, are largely based upon public convenience, and are adapted to the wants and habits of the community. T. W. DWIGHT.

Evidences of Christianity, The: proofs of the divine origin of the religion founded by Jesus Christ. The evidences of Christianity, by the very fact of their existence, afford a strong presumption in its favor. They place it before the world as at least claiming to be founded in truth and suited to the reason of man. Had it made its way by mere force and policy, or did it now require assent without testimony and argument, there would be no need even to investigate its merits. It might be classed at once with the false religions which are confessedly without reasonable evidence, if not beneath discussion. But in distinction from all other systems it possesses a recognized body of proof which has been accumulating for eighteen centuries under the most varied and searching criticism, and which, when examined, is found to be all that the case admits or that an intelligent inquirer could demand. Such an inquirer may therefore be challenged at the threshold to acquaint himself with the history of the Christian evidences before he proceeds to judge them in detail.

History of the Christian Evidences.—The history of Christianity is, in one view, but the history of its evidences. Externally, at least, its course through the world has been marked by successive crises, when it encountered various forms of incredulity which it became necessary to repel with suitable evidence; and out of every such conflict it has emerged with a triumphant vindication of its claims and a fresh contribution of proof to later generations.

Its first conflict was with Judaism. On its native soil and at its very origin it excited the bitter unbelief of the Jewish rulers and people, who repudiated it as an impious caricature of their own ancient religion, stigmatized its author as an impostor or false Messiah, and at length compelled him by the death of the cross to become the first great martyr to its truth. Judaism, as a distinct system, from that moment declined into a mere dead tradition, and has since, by its own predicted fate, served but as an unwilling witness for that Christianity which has been spreading over the globe and becoming the common heritage of all nations and races. The life and death of our Lord, including his discourses, parables, and miracles, as recorded in the four Gospels, constitute the evidences of Christianity afforded at its origin.

Its next conflict was with paganism. No sooner had it been proclaimed outside of Judæa as a gospel to the nations than it encountered the decaying religions of Greece and Rome, which desperately rallied against it as a common enemy. But its course from city to city was marked with crowds of converts, as well as with persecutions and conflicts, everywhere accelerating the decline of those old mythologies, which now figure only in the classic literature made tributary to its own defense and illustration. The planting and training of the Church, as narrated in the Acts and Epistles of the apostles, together with the Apologies of Justin, Tatian, Athenagoras, and Theophilus, yield the evidences belonging to this period.

Its next conflict was with philosophy. So long as it was contending with mere Jewish and heathen superstitions the learned class could treat it with disdainful silence, such great writers as Plutarch, Seneca, and Tacitus alluding to it only in the most distant manner; but as its exclusive claims gradually became known, its advance was met by an infidel wing of the Neoplatonic school, led by Celsus, Porphyry, and Hierocles, who assailed it as a vulgar imposture, and at length provoked the series of bloody persecutions which filled the cities of the empire with Christian martyrs. Its apparent defeat, however, was followed by a victory almost ruinous. It had already won from the very ranks of Plato its first great apologist, Justin Martyr, and it now wrested so much of philosophy itself as could be wrought into its own theology; and at length appeared upon the throne of Constantine as the visible head of a new Christian civilization. Besides these worldly trophies, its direct evidences for this period are to be found in the testimony of the martyrs and the apologetical writings of Tertullian, Clement, Origen, Eusebius, Cyril, Arnobius, Lactantius, and Augustine.

Its next conflict was with barbarism. In the Dark Ages following the barbarian conquest and the wreck of the Roman empire, though it was now deprived of all earthly aid, it subdued the rude religions of the North as it had already vanquished the classic mythologies of the South, and treasured up from the civilization of the past all that was valuable for that of the future. While contending with such savage foes it could have no other evidences than such as appeared practically in the Germanic missions and in the great Christian schools of the Middle Ages.

Its next conflict was with Mohammedanism. The Saracen was invading its domains with the sword and the Koran from the East to the shores of Spain; but the fierce Goths whom it had trained into Christian knights now by successive crusades battled for the tomb of the Saviour, until Europe was delivered from the infidel. Its evidences for this epoch were all that could be expected—the exploits of Christian chivalry, the prizes wrested from Arabian learning, and the apologetical writings of the Schoolmen against the Jews and Mohammedans in Moorish Spain.

Its next conflict was with modern rationalism. Divided at the Reformation into Catholicism and Protestantism, it encountered a treacherous foe which for several centuries, under various guises, has been subjecting its divine revelations to the test of mere human reason. But hitherto the strength of its evidences has only been proved by each successive assault. The Italian naturalists of the sixteenth century, such as Pomponatius, Cæsalpin, and Cremoninus, who held Aristotelian opinions subversive of revealed religion at the very court of Rome and under feigned respect to the Church, wrought their own defeat by their shameless hypocrisy and vice. The English deists of the seventeenth century (such as Herbert, Hobbes, and Toland) and of the eighteenth century (such as Collins, Tyndal, and Bolingbroke), who professed mere natural religion as essential Christianity, were so completely repulsed by the great apologists, Cudworth, Bentley, Berkeley, and Butler, that their very works have become obsolete or linger only as brilliant names in literature. The French atheists of the eighteenth century, such as Helvetius, Diderot, and d'Holbach, who assailed Christian morality itself with a sensual fatalism, only precipitated that terrible revolution which made them infamous as enemies of civilization, no less than of religion. The German pantheists of the nineteenth century, such as Strauss, Bauer, and Feuerbach, who had been striving to resolve Christianity into mere mythology, were routed upon their own ground and with their own weapons by such learned and acute writers as Neander, Ebrard, and Ullmann. And it is safe to predict that the sciolists who are opposing it with science falsely so called are but insuring a like failure and defeat.

But the still remaining and perhaps final conflict is to be with modern heathenism. Having developed for itself in the Western nations of Europe and America a civilization the highest the world has yet ever seen, it would be strange if it could not cope with those Eastern nations of Asia and Africa which meanwhile have remained stationary or relapsed to a savage state. And accordingly it has been slowly enveloping the globe with a network of missions, which, in connection with advancing science, commerce, and diplomacy, already betokens the ultimate triumph of Christian civilization over heathen barbarism throughout the earth.

Classification of the Christian Evidences.—Much ingenuity has been exercised in digesting and arranging the evidences which have thus been accumulating during this exciting history, but the most common and serviceable classification is that by which they are divided as *external* and *internal*, with suitable subdivisions.

The external evidences are such as relate to the fact or existence of Christianity, rather than to its nature or system —the mere credentials of revelation as distinguished from its contents. They naturally distribute themselves into the following groups: 1, *Prophecies*, which have been fulfilled in the course of ancient empires, in the coming of Messiah, in the fortunes and fate of the Jews, and in the progress of the Christian Church; 2, *Miracles*, which were wrought by prophets and apostles in attestation of their divine commission as teachers, disclosed in the life and death of Christ, the Son of God, and confirmed by the supernatural success of Christianity in the first age; 3, *Historical Testimonies* to the authenticity and genuineness of the sacred writings, afforded not only by undesigned coincidences among them, but by contemporaneous heathen literature and by modern antiquarian research. Collections of the first kind of evidence may be found in the works of Newton and Keith; of the second, in those of Watson, Sherlock, Lesley, and Campbell in reply to Gibbon, Hume, and Paine; and of the third, in those of Lardner, Paley, Norton, Greenleaf, and Rawlinson.

The internal evidences are such as appear in Christianity itself, in the purport of the revelation which has been so miraculously attested. An argument for its divine excellence may be traced in all that distinguishes it from other mere human systems: 1, in its *doctrines*, transcending the highest philosophy, such as the existence, perfections, and policy of the Creator, the origin of the world, the scheme of redemption, the state and destiny of man; 2, in its *precepts*, surpassing the purest ethics, such as the Ten Commandments, the Sermon on the Mount, the counsels of the apostles; 3, in its *examples*, unapproached by worldly heroes, such as those of evangelists, saints, and martyrs, and, above all, the immaculate Jesus himself; 4, in its *effects*, not only upon the welfare of individuals, but upon the interests of society, as seen in works of charity and philanthropy, in the arts of peace, in humane laws and free institutions, and in the entire civilization which for centuries it has been unfolding. Specimens of such arguments may be found in the treatises of Jenyns and Warburton, of Archibald Alexander, Hopkins, and McIlvaine, and of Luthardt and Delitzsch.

Still further classes of evidence are of a mixed nature, partly external and partly internal, and serve to show the connection and consistency of Christianity with other facts and truths. They also may be indicated under several heads: 1, *Experimental* evidences, acquired by those who have personally tested in their own faith and practice the doctrines, precepts, and promises of the Gospel, and thus offer new and original testimony; 2, *Scientific* evidences, collected from the sciences which illustrate the existence and attributes of the Deity, and confirm the incidental allusions of Scripture to physical, mental, and moral phenomena; 3, *Philosophical* evidences, derived from right reason and large experience as to the probable existence of a Divine government, a future state, a supernatural revelation, and a scheme of redemption, such as are found in the Scriptures, and also from the view of religion and nature as but consistent parts of one system, having the same author. Examples of such high orders of evidence may be seen in the works of Locke, Browne, Butler, Paley, the Bridgewater Treatises, and the Bampton Lectures.

These various classes of evidence, when grouped together in one view, tend to produce a conviction which has been well likened by Bishop Butler to what is called the *effect* in architecture or other works of art. Examined separately, they may excite as little emotion as scattered stones upon a plain, but when combined, as they have been by this great architectonic genius, in one compact, cumulative argument, their resulting impression is like that of the same materials after they have been chiseled and fashioned into a magnificent building.

Logic of the Christian Evidences.—A far more important question than the mere classification of these evidences is that of their logical nature and value. Viewed from this point, they must ever take rank as the highest branch of applied logic, as well for the difficult problems which they involve as for the kinds of reasoning employed. And the practical bearing of the inquiry is shown by the fact that different apologists, in treating of the evidences, have more or less consciously exaggerated one class of them at the expense of the other, until, like a divided army wrangling in the face of an enemy, they have allowed infidels to involve both of them in doubt and suspicion. Of the two evidential schools which have thus taken opposite grounds, the one would render Christianity reasonable, the other present it as simply credible; the one would claim for it demonstrative evidence carrying full conviction, the other seek only probable evidence accumulating toward certainty; the one would dwell upon the internal philosophical proof, the other upon the external historical testimony; and at length the one ends in testing the whole content of revelation by mere reason, while the other virtually destroys all rational conditions of faith. The former method has been successively pursued to its extreme by Descartes, Clarke, and Wolf, and the latter by Butler, Chalmers, and Mansel.

It is enough here to assert the validity of both methods within the limits they impose upon each other. Each has had its value at different times and for different minds. The primitive apologists needed the external evidence for the Jews, who required a sign, as well as the internal evidence for the Greeks, who sought wisdom. And from that day till the present there have been infidels who were won by the doctrine and example of Jesus before they could admit his miracles, as there have been believers who ceased to find difficulties in Scripture after they had accepted it as an attested revelation. The simple truth is that neither kind of proof can be spared from the high argument, and that both must be combined in order to insure full conviction.

At this point the logical question considered begins to involve an ethical or moral element. It should be carefully observed that the apparent deficiency in the Christian evidences neither necessitates unbelief nor releases from obligation. On the contrary, the inquirer simply becomes accountable in proportion to the evidence perceived and the interests at stake. He is still to be tested and judged by the light which he has. Moreover, his incredulity may be his own fault. It is certain that the Christian evidences have hitherto proved sufficient for the greatest minds of the race.

Progress of the Christian Evidences.—A distinguished mathematician of the seventeenth century, John Craig, professed to calculate, on the hypothesis that the suspicions against historical evidence increase with the square of the time, that the evidence of Christianity will become extinct about the year 3150, when the Son of Man will come and no longer find faith on the earth. And a school of modern skeptics, including poets as well as philosophers, is already sighing over the decay of Christianity as but the last of the world's mythologies, destined to be superseded by the perfect religion of the future. If all that is meant by such writers is the decay of their own Christian faith, it need not be denied that many restless, speculative minds are breaking away from their moorings in false creeds and corrupt systems claiming to be Christian; but if the apprehension is that Christianity itself is dying out or losing its hold upon the world, such forebodings are to be no more seriously treated than the outcries of men losing their anchorage who fancy it is the immovable shore and not their own little vessel that is drifting away. Christianity has in fact lost nothing of the evidence which it has been accumulating since the time when first its miracles were wrought and its prophecies spoken. Not only does the testimony to those miracles remain unimpeached, not only is the fulfillment of those prophecies still going on, but the human sciences since then unfolded are yielding it a new class of evidences, affording it fresh confirmation and illustration, and commending it to the highest intellect and culture of the time; and the reasonable presumption is that, one after another, they will yet corroborate all revealed facts and doctrines, until everywhere there shall be an intelligible triumph of the Divine through the human reason over all earthly error and sin.

That such an increase of evidence in this quarter is probable may be argued from the very nature of science and revelation as complementary factors of knowledge. It is inconceivable that the word of God should contradict his works, or that human reason could supersede a divine revelation; and when any discrepancies appear between nature and Scripture, we must simply assume that there has been some wrong induction from either or both of them, and that ultimately, after the whole truth is known, they will confirm and illustrate each other. This has, in fact, been the result of past conflicts between the scientific and religious parties. Geography, in the early Church, repudiated the idea of an inhabited globe as contrary to the Scriptures, but ships now carry the same Scriptures to the antipodes. Astronomy, during the Middle Ages, described the heavens as huge crystal spheres revolving about our earth, but the very same heavens, as devoutly interpreted by Kepler, Newton, and Herschel, still declare the glory of God. Geology has seemed inconsistent with the long-received interpretation of Genesis, but the story of the earth itself, as read by Miller, Hitchcock, and Guyot, still tells how it was made in six days. Anthropology is full of conflicting theories, some of which menace the Scripture doctrine of the first Adam, but he must simply prejudge the whole question against all precedent who asserts that man was not made in the image of God. And in the region of the mental, moral, and social sciences, where the need and fact of a revelation are so much more obvious, the likelihood increases that there will hereafter be still higher and grander illustrations of Christian doctrine.

It is an encouraging sign of progress in the evidences of Christianity that so many organized efforts are on foot for their promotion, and some of them in the interest of true science as well as of religion. The Royal Society itself was founded by philosophers and divines who vindicated the consistency of natural with supernatural knowledge. Other institutions have followed, expressly designed for the defense of the Christian religion, such as the Boyle Lectures, the Bampton Lectures, the Bridgewater Treatises, the Burnet Essays in Great Britain, and the Lowell, Graham, and Ely Lectures in the U. S., together with more permanent educational appliances, such as chairs of Christian apologetics in divinity schools and of science and religion in our colleges. And the literature which has grown up in connection with these institutions, and by other independent efforts, is already of surprising extent and richness. Notices of this literature may be found in the appendix to Farrar's *Critical History of Free Thought*, and the Abbé Migne has published a series of twenty volumes, 4to, entitled *Demonstrations Evangéliques*, containing a full collection of the principal evidential treatises, of all schools in all ages, chronologically arranged. CHARLES W. SHIELDS.

Evil: the total or partial absence or negation of good, and the presence of imperfection, suffering, or sin. The question of the origin of evil has in every age attracted the attention of thoughtful minds. The Zoroastrians and Gnostics tried to solve it by the dualistic theory of the opposition of a good and an evil principle. Others have maintained that evil is a necessary part of the Divine economy, and that under the superintendence of Infinite Wisdom evil will result in the highest possible good. It seems certain that moral freedom itself implies at least the possibility of an evil choice, so that evil must potentially exist where goodness exists. See PESSIMISM.

Evil Eye: the mysterious power of injury which in former ages was generally ascribed to the look of a malevolent person. The Greek and Roman classics contain numerous references to this belief, which was also very common in the Middle Ages in Europe. In Mohammedan and uncivilized countries this superstition is still almost universal, and it is by no means extinct among the peasantry of more civilized lands. It especially prevails in Western Africa. It is perhaps based upon the supposed powers of fascination possessed by serpents, of which much exaggerated stories were told and believed. Charms were much worn to prevent the mischief which it was believed could be done by the evil eye, which was considered especially dangerous to young children.

Ev′olute (see EVOLUTION): in mathematics, a curve, plane or otherwise, around which, if a flexible and inextensible string be wrapped, and then unwrapped under tension, there result other parallel curves called *involutes*, one of which is described by every point of the tense string in unwinding. Every plane curve has its plane evolute, besides an infinite number of helical evolutes lying in the curved surface of the solid generated by the motion of the given plane curve parallel to itself. The common cycloid, the epicycloids, and the hypocycloids have plane evolutes exactly similar to themselves, but inverted in position. The logarithmic spiral is the only curve having all its evolutes similar to itself.

Evolution [from Lat. *evol′vere, evolutum*, unroll, open up]: the act of unfolding, development; in algebra and arithmetic, the extraction of roots; in other words, the inverse operation to involution. The object of evolution, therefore, is to ascertain the quantity which multiplied by itself a stated number of times yields a given result. In a wider sense, evolution may be regarded as synonymous with the solution of a binomial equation, for it is obvious that the n^{th} root of any number a satisfies or is a root of the equation $x^n - a = 0$. This root is indicated by the symbol $\sqrt[n]{a}$ or $a^{\frac{1}{n}}$.

Evolution: primarily, an unrolling or an unfolding; so with respect to the living world it was used to designate the growth of the germ within the egg, under the belief that the organism existed there fully formed and that incubation was but the increase in size and unfolding of the minute germ. Later, the term ontogeny has been used for the development of the egg into the adult, while the term evolution has been restricted, in biological language, to denoting that continuous progress from the simple to the complex, from the homogeneous to the heterogeneous, which, in the judgment of naturalists, has been the method of origin of the varied animals and plants which now exist or which have existed. In the limited space available here only the barest outline of this organic evolution can be attempted.

The world is occupied by an enormous number of animals and plants—hundreds of thousands of species, myriads of individuals. Further, there are found in the rocks—those records of past ages—an almost equally great assemblage of forms, some of which are closely similar to living species, while others are greatly different from anything in the same region or even in the world. Further, all these forms, both living and extinct, show a wonderful range of adaptations to their functions and surroundings, and like adaptation of parts to the purposes they have to perform. The question for solution is this: How did all these forms come into existence? for the evidence is ample that there was a beginning. Several answers have been attempted, only two of which obtain much acceptance. The one predicates the existence of an Omnipotent Being who created them as we find them; the other does not deal with the question of the origin of life, but claims that given one or a few original forms of life all other forms must have come from them by the accumulative effects of innumerable small variations correlated with the action of heredity. This latter is the theory of organic evolution, a theory which has given rise to an enormous literature, and which is accepted by every naturalist the world over, with the exception of a very few who were already old men when, in 1859, Darwin first placed the idea before the world in a systematic form. The questions under discussion are merely those of detail; and in every investigation the law of descent is made the touchstone of the truth or falsity of each and every discovery.

The three great factors of evolution are (1) variation, (2) heredity, (3) struggle for existence, with survival of the fittest.

Variation.—According to the one idea species are immutable. There is, indeed, variation, but the extent of variation is always limited by specific boundaries. The great difficulty at this point comes in the definition of a species. Linnæus, who is frequently regarded as the father of zoölogy, said: *Tot sunt species quot ab initio creavit infinitum Ens* (There are as many species as an infinite being created at the beginning)—a test which is absolutely incapable of scientific application—while the older Agassiz, writing at the very time when Darwin was bringing out his epoch-making volume, *The Origin of Species*, maintained that species were actual things, capable of almost mathematical valuation and definition. However, the various tests for species have proved weak and faulty, that of the fertility of hybrids having no more value than other supposed tests. As a rule, crosses between what are regarded as distinct species prove infertile, but frequently these hybrids can reproduce their kind. On the other hand, according to the anti-evolutionist's view, descendants from a common ancestor must belong to the same species, and yet the rabbits of Porto Santo (descendants from the European stock of nearly 500 years ago) will no longer breed with their continental cousins. In short, there is no test for species, specific lines are as intangible as those between heat and cold, and the very idea of a species is a concept of the human brain without a corresponding object in nature.

The existence of variation is indisputable. The children of the same parent almost always differ in features as well as in mental characteristics; the leaves upon the same tree vary in size, shape, venation, and color. A clear realization of the nature and extent of this divergence is necessary for appreciation of the theory of evolution. Those variations which occur in domesticated forms are most widely known, and one has but to recall the thousands of varieties of apples, which vary in every conceivable character, and the varieties of cattle (Jerseys, Alderneys, Holsteins, muleys, Durhams), and of the barnyard fowl, to see something of the range of variation which can take place in a few years without excessive change of conditions. Possibly most striking of all are the differences between the different breeds of domesticated pigeons, all of which are descended from the common rock pigeon (*Columba livia*) of Europe. In the wild state this bird is a slaty blue, with a dark band across the end of the tail, two black cross bands on the wings, while the tail feathers, as in all wild pigeons, are twelve in number. From this type, by cumulative variation, have descended all the many recognized breeds, in which scarcely a feature has been left unaltered. Some are pure white, others pure black; the pouters have developed an expansible crop, the fantails have increased the tail feathers in some cases to forty, the tumblers have adopted the strange habit of turning back-somersaults, while the short-faced tumblers have shortened the skull, and the carriers have lengthened it. Thus every portion of the body is capable of variation, and in every direction.

It may be said that domesticated animals and plants are living under abnormal conditions; but the same variation, differing only in degree, is noticeable everywhere in nature, and from the standpoint of the evolutionist it would be as prominent there were it not for the principle of panmixia, to be mentioned below. Variation is seen everywhere, and a little careful study will show that its extent is far greater than is ordinarily supposed. Thus the studies of Dr. Joel A. Allen on the birds of the Eastern U. S. have often been quoted. He shows that in a large series belonging to the same "species" the variation will amount to from 15 to 20 per cent.; and further, that every part of the bird varies with regard to the others. Thus the feathers of wing and tail will vary among themselves, giving these organs different contours; the colors and color patterns will change to such an extent that had one only the extremes of the series there would be no hesitation in classing them as distinct species. Habits are constantly changing. The nests of many birds are far different now from what they were years ago; but possibly the most striking instance is the change in diet of the kea-parrot of Australia. This formerly fed on insects and honey. Since the advent of the whites it has become carnivorous, and it will now attack living sheep, burrowing great holes into the backs of these animals.

Variations in mental characters are less evident in wild animals because of the difficulty of observation, yet every one has noticed the variations in timidity, the differences in intelligence, presented by individuals belonging to the same brood.

Several causes of variation have been described, but all are not of equal importance. All, however, are alike in that they can admit of no limit to the extent to which variation can proceed in successive generations.

First come mechanical causes. Use and disuse of parts may produce variations in a manner easily understood. Thus the blacksmith by continual use of his arm increases its size to far beyond the normal. Pickpockets are said, by continual pulling at the index finger, to make it equal the second finger in length, a matter of no slight importance to them. The German soldiers, by frequent and prolonged drilling, induce the formation of a bone in the skin of the hand (*Exercierknochen*) where it comes in contact with the lock of the gun. On the other hand, disuse of a part causes a deterioration in size and in functional capacity. The leg, enveloped in a plaster bandage, shrinks in size, and this merely from disuse, not from any compression of the nourishing blood-vessels. The Stylites of religious fanaticism completely lost the use of certain members.

Closely allied to variation by use or disuse is the modification by change of function so strongly insisted upon by Cope and Spencer as a factor in evolution.

That these mechanical causes can produce modification of structure is beyond dispute, but the part that such modifications play in the evolution of new forms is still in dispute. According to Lamarck and to the Neo-Lamarckians, as they call themselves, variations acquired in this manner are all-important, because liable to become hereditary. The other school, the Neo-Darwinians, deny that they are to be considered at all. (See *infra*, and also the article HEREDITY.)

There is also a marked connection between the environment and variation, but whether environment stands in a causal relation is not certain. Possibly as striking an instance as any is that described by Schmankewitsch. He found that a certain Phyllopod Crustacean (*Artemia salina*), occurring in the brine of the salt vats of Southern Russia, when the brine was weakened produced a distinct species (*Artemia mülhauseni*). He went further, and by gradually freshening the water the changes became more marked, and when it was quite fresh, after several generations, the antennæ had altered their form, a joint had been lost from the abdomen, and other changes had occurred of so great an extent that a distinct genus—*Branchipus*—had been evolved. Here also are to be noticed the observations made by Dr. Joel A. Allen on the relations between climate and color. This student finds that in the same species of North American birds and mammals, as one goes from north to south, or from a dry climate to a humid one, the colors become more intense; and further, that the alterations in color are correlated with variations in absolute size and in the relative proportions of parts. It is, however, possible to explain these and other similar cases without considering them as the *direct* result of the action of the environment upon the organism.

Were all variation induced by external causes, like those already indicated, it would in all cases show a more or less evident adaptive character. One finds, however, numerous instances where there is, so far as can be seen, no relation between the variation and the surrounding conditions. Such, for instance, are the variations in the individuals of the same brood, or from the same lot of seeds. Hence one may distinguish sharply between two classes of variation: (1) those produced by the operation of external agencies, which Weismann calls acquired characters; and (2) those the causes of which are to be sought within the organism itself. These latter—congenital variations—proceed from alterations in the germ-cells themselves. How these modifications are produced is not certain. (See HEREDITY.) The most plausible theory is that which connects them with the modifications and diminutions which the germinal substance undergoes in its maturation, and then the union of these modified and diminished germs.

In this field of the causes of variation the most suggestive discoveries may be expected. The important point is that variations occur, and that they may appear in all portions of the organism, and may have any conceivable direction.

Heredity.—The second factor of organic evolution is heredity. By this word is meant not only that law of nature whereby individual peculiarities may be repeated in a second generation, but that principle which insures perpetuity, which is expressed by the breeder as "like begets like." We notice the reappearance of individual peculiarities by inheritance—that a six-toed cat will have six-toed kittens—but one is apt to lose sight of that more wonderful fact, that a cat will invariably have kittens, not puppies or whales. Of the universality of this law none can doubt. "Blood will tell" is but a homely expression of it. In some way the parent is able to impress upon the germ-cell the capacity of reproducing not only the broader features of class and genus and species, but not infrequently the more subtle characters of the individual as well. To explain this capacity, which is common to both animals and plants, various hypotheses have been advanced (some of which are outlined in the article HEREDITY), but they need not be detailed here.

Variation and heredity are contrasting factors. Variation is constantly introducing change. Heredity as constantly tends to reproduce the old conditions. Variation introduces new features, new modifications, into each succeeding generation; heredity strives to perpetuate the generation that has gone before. Variation is progressive; heredity conservative.

As was hinted above, it is not yet certain whether all variations can be perpetuated by heredity, and according to the view taken, two schools of modern evolutionists may be differentiated. The one, the followers of Weismann—Neo-Darwinians, they are called—claim that there is no satisfactory evidence that those variations which are the result of mechanical causes (in other words, acquired variations) can be inherited; that every instance in which the effects of use and disuse, of mutilations, of prenatal influences, and the like are supposed to be shown, are capable of explanation upon another basis. The other school—that of the Neo-Lamarckians, which has its stronghold in the U. S.—maintains, on the other hand, that "acquired variations" can be transmitted from generation to generation, and that since these variations are and must be adapted to external agencies and surroundings, and hence of greater value to the individual and the race, it must needs follow that such variations are most important in the differentiation of new forms of life.

As will be seen, the line between the two views is sharply drawn, and time must elapse before the dispute is settled. The idea of the inheritance of acquired characters is the old one, and indeed it forms the whole of the evolution of Lamarck. The view of Weismann is new, but it accords so well with what is known of the constitution and phenomena of the germ-cells that it has been most favorably regarded by the majority of the embryological workers. Weismann has provided a logical theory of heredity, in good accord with what is known of the egg and sperm cells, through which inheritance must take place, and in this theory there seems no place for the transmission of acquired characters. How the dispute will end can not be predicted. It must, however, be kept in mind that the differences between the schools are upon methods; both agree that variations exist, and that some variations at least can be transmitted from generation to generation.

Heredity furnishes some other interesting phenomena which have a bearing upon evolution. One of these is reversion. This is the reappearance in the progeny of characters or traits not seen in the immediate ancestors, but which are found in those more remote. Sometimes but a single generation is skipped, at others the number of generations omitted is enormous. When pigeons are removed from the somewhat abnormal conditions under which they exist in domestication, they exhibit a marked tendency in successive generations to revert more or less perfectly to the rock pigeon, or ancestral condition. In other cases the reversion is more marked and more remarkable. Evolution teaches that the single-toed horse has descended from the three and four toed horses of the Eocene age. Hundreds of thousands of years have elapsed since the three-toed condition was normal, and yet among modern horses polydactyle individuals occasionally occur, and this three or four toed condition must be regarded as reversional or atavistic in character. Cope has pointed out that in man the teeth of the higher races are tending back toward those of the lemurs, a reversion which is not occasional, but which is becoming the normal condition. In all cases of reversion or atavism, the more recent the change the greater are the chances of the occasional reappearance of the ancestral condition.

Another feature of heredity is the constant tendency toward reduction to the average by the action of the law which Weismann has called panmixia (or cessation of selection). A supposititious case will illustrate this: Suppose an animal appears with a neck much longer than the average in the species. It pairs with another with a normal neck. Now, other things being equal, the chances are decidedly against the reappearance of a neck of the same length in the second generation. On the contrary, it may safely be predicted that, unless some selection be active, the necks of the descendants will, in a few generations, be reduced to the normal.

Struggle for Existence.—As one ordinarily looks upon nature, the idea of a constant struggle seems absurd. An occasional bird may fall a victim to a cat; a hawk may pounce upon a snake or field-mouse, but, as a whole, nature seems quiet and peaceful. A more careful examination, however, shows that this peace is but superficial; in reality every plant and every animal is in a constant struggle for existence. The struggle is constant, omnipresent, and its effects are correspondingly great. It is a logical result of the geometrical ratio of increase of all living things. Were the progeny of a single pair, no matter how small, or how slow breeding, to go on generation after generation reproducing their kind without any check except natural death, it would require but a short time for the whole world to become too small for their accommodation. Thus Darwin, taking the elephant (possibly the slowest breeder of all animals) concludes that in 750 years the living offspring of a single pair would number nearly 19,000,000. Supposing that each egg should produce an adult, in twenty-five years the descendants of a single pair of codfish would make a mass larger than the earth. In the lower forms the reproduction is even more rapid. Maupas states that were the infusorian which he studied—itself invisible to the naked eye—to continue at its most rapid rate of division for thirty-eight days, the result would be a mass of protoplasm equaling the sun in size.

So it is with every animal and every plant. Unchecked, they increase with enormous rapidity; and yet under normal conditions there is no such increase, but rather a balance of nature. The total number of individuals remains tolerably constant, and taking several years together the number of forms in a given area shows but little change. Indeed, the world is about as full of individuals of animals and plants as it can possibly be. Such being the case, and such the natural rate of increase, there must of necessity be a constant struggle for existence, a struggle which if not outwardly apparent is none the less real; a struggle between the various species and a struggle between the individuals of the same species as well.

In the well-kept garden the plants cultivated are to a large extent removed from this competition, but when the garden is neglected the struggle begins. Weeds spring up, and in a few years they have choked out the former vegetation, and even some of the first weeds to appear have themselves disappeared. In a forest of birches there is a struggle between the individuals. Each year myriads of seeds are produced, but of these only a sufficient number grow into trees to replace those which die. If now a single beech-tree spring up in the forest, the character of the struggle changes. No longer do the birch-trees have to compete with each other; they have to struggle with the new invader. It lies between beech and birch, and ultimately, except in favored localities, the birch must succumb. Among animals it is the same. Every species is limited in numbers by the question of food as well as by the abundance of forms for which it in turn forms flesh, to say nothing of questions of climate and the like.

Usually the factors which enter into this competition are very numerous and very complex. One of the simplest instances is this: The abundance of clover in any locality is directly dependent upon the number of cats and owls in the region. The capacity of clover for reseeding itself depends upon the fertilization of its flowers, and this fertilization is accomplished chiefly by bumble-bees. Now bumble-bees form the principal food of field-mice. Hence fewer cats and owls, more field-mice, fewer bees, less seed and less clover the next year. In most cases the factors are more complex, and it is a dangerous thing for man to attempt to alter the balance of nature. Witness the ill-advised introduction of the English sparrow into the U. S., and the disastrous importation of rabbits to Australia.

Now, if there be such a struggle, what is to determine which individuals and which species shall survive? Evidently the answer must be those individuals and those species which are best fitted for their environment. Hence as a corollary to the struggle for existence follows the principle which Spencer has termed "the survival of the fittest." By this it is not implied that in every instance the best will survive, the unfit will be killed off. Nature deals with enormous numbers, and it is the great majority of which we speak. In the production of varieties of domesticated animals and of cultivated plants the breeder and the horticulturist exercise a selective action. They choose for breeding purposes those individuals which present variations in the desired line, and in the second generation a similar selection is again exercised, until the result may be quite different from the form with which the start was made. Variation, an inheritance of variations, and an artificial or human selection have produced all of the most highly prized cultivated plants and domesticated animals; selection for speed has given us our trotting horse; selection for color, our wonderful displays of tulips; selection for fruit, our peaches, apples, etc.

These are cases of artificial selection in which human intelligence plays an important part. There is an analogous selection ever operative in nature—natural selection—which insures, in the long run, that those forms best fitted for their surroundings survive and alone perpetuate their kind. This principle was ignored by Lamarck; it was first recognized by Dr. W. C. Wells, of Charleston, S. C., who, in 1813, noticed that Negroes and mulattoes are exempt from certain tropical diseases, and argued that nature, like man, exercised selection, and thus originated varieties of human beings fitted for the country they inhabit. This principle, however, remained without further public notice until 1859, when Mr. Alfred Russel Wallace and Charles Robert Darwin read essays which again brought the principle before the scientific world, supported at this time by a weight of evidence that was perfectly overwhelming.

The struggle for existence is severe, and nature stands ready to seize upon and perpetuate the slightest variation which may be of advantage to the individual, and in consequence to the race. The slightest superiority in some one particular may prove the means of life; a correspondingly slight inferiority may result in death. This difference may proceed from a change in the organism, or from modifications in its environment, or from both. It has been seen that all living beings are liable to variation, while geology teaches that the "everlasting rocks" are far from stable and that our earth is in constant change. Elevations and depressions of its surface will convert marshes into dry plains, meadows into lakes; will change the directions of ocean currents, and alter the prevailing winds. These in turn will modify the temperature and humidity of large regions, thus changing the environment of the fauna and flora. Many forms can not adapt themselves to the new conditions and hence must become extinct, while those which show greater adaptability and greater modifications will be more apt to survive. Now, since such modifications are subject to perpetuation by heredity, the result must be the formation of a new race. It is not blind chance which determines the question of life and death; it is a fixed law so determinate in its character that when the factors are known the result can with certainty be predicted.

For instance, a terrestrial animal inhabiting a marshy country is the better adapted for its surroundings when it has a broad and spreading foot which prevents it from sinking in the mire. When the region is drained, the large foot is no longer an advantage, rather an incumbrance; and, other things being equal, those species and those individuals which show a tendency toward reduction in the size of the foot will have the advantage. This is no fancy sketch. It is one which long ago was pointed out in the history of the horse. On the other hand, the struggle is not always be-between the individual and climate, etc.; it may occur between species and between individuals of the same species; or, again, the alterations produced in one animal or plant may affect its neighbors. In fact, the play of interactions is wonderfully complex. Here, too, must be mentioned that other struggle which Roux has termed the battle of the parts within the organism, the meaning of which is self-explanatory.

Every investigation goes to support the view that there is an intimate interdependence between organisms, and that probably every character which appears in the living world is or has been of distinct advantage to the race. For years no other reason was suggested for the bright colors and attractive perfumes of flowers than that they were intended for the gratification of the æsthetic tastes of man. Now it is known that this is not their end; they exist rather as attractions for insects, etc., on which depends pollination and production of seed. Every advance in knowledge clears up previous difficulties, and either shows a utilitarian adaptation in every feature or demonstrates that the organ in question is a remnant of some structure which formerly has been of use but which is now on the road to obsolescence. To this latter category belong such structures as the vermiform appendix of the human intestine. Except in the light of evolution it is absolutely inexplicable in the human being, for it subserves no function, but is a veritable death-trap. In the lower vertebrates the same organ is large, and clearly has there a digestive function. In man it is a vestigial structure derived from the ancestor and retained in its degenerate condition through the conservative action of heredity. In short, the old doctrine of final causes has had to shift its base; the new teleology accommodates itself to evolution.

To summarize the foregoing: All animals and all plants are constantly varying, and these variations may have every conceivable tendency, some being distinctly beneficial, others as distinctly injurious to the forms in which they occur. Every individual, from the moment it begins life, even while an egg, a seed, or a spore, is a partaker in an active struggle for existence; and while accident may occasionally produce a different result, those species and those individuals which are best fitted by variation for their part in the world will survive. The principle of heredity now steps in and insures the repetition of the favorable variation in the next generation, where it may serve as the basis for new variations, which in turn will undergo similar selective processes. As a logical result of these factors a sufficient length of time is alone necessary to people the earth with all its present varied fauna and flora from a single primitive type of life. Further, the apparent gaps between so-called species are but the tombstones of the unfit or less fit which have fallen by the wayside.

Proofs of Evolution.—There are two records of the history of the living world, both of which have been carefully studied, and both of which are well understood. One is embryological, the other geological, and both are in full accord with evolution.

Geology teaches that what are known as stratified rocks have been laid down as deposits at the bottom of bodies of water. Hence objects which are included in them are of the same age as the deposits themselves, while of two layers or strata the lower is the older. Hence by studying these rocks and their included fossils a clear history may be obtained of the main features of the world of life which has gone before. Were the series of rocks continuous and complete, and were all forms which have lived preserved as fossils, the testimony of geology upon the question of evolution would be absolute. Unfortunately this is not the case. There are many breaks in the series of rocks where whole ages have left no trace; and, on the other hand, there exist large numbers of forms of life, of great importance from the standpoint of the evolutionist, which have no hard parts capable of fossilization. Such being the case at present, it is inferred that such was the case in the past. Hence the geological record is faulty* in two respects; but even if faulty it should, so far as it goes (provided evolution be true), agree with the doctrine of descent. Thus we ought to find in the successive strata constant progress in life from the simple to the complex, and that the older forms should be lower and more generalized. Even with the imperfect records there ought to be found direct evidence of the transformation of one species into another, and conclusive proof that from one species two or more distinct species have been evolved.

At the very bottom of the stratified rocks are some which contain no recognizable fossils, but they show evidence of

* Darwin spoke of this imperfection of the geological record. The anti-evolutionists of 1860 made reply that the bulk of the world is already known, and that no important geological discoveries were yet to be made. Ten years later began those wonderful investigations in the Western U. S. which have revealed more than three times as many mammals as were previously known. So, too, wonderful discoveries have since been made in India, South Africa, Greece, Australia, and the Argentine Republic. And yet Africa, Asia, and Australia are unknown. Further, every new palæontological discovery has readily fallen into its proper position in the doctrine of descent; not a single fact has come to light which tends to discredit it.

alteration by intense heat, and contain graphite—a highly metamorphosed coal—which may be of vegetable and, possibly in some instances, of animal origin. In the Cambrian are found numerous forms of life, but all are extremely generalized. In the Cambrian are found generalized sharks, the lowest vertebrates possessing hard structures. In the Carboniferous the batrachians appear; the reptiles are first known in the Permian, and reach their culmination in the Cretaceous; while mammals appear as monotremes or marsupials in the Triassic, and then, after an as yet inexplicable absence from the Cretaceous, reappear in higher and more differentiated species in the Tertiaries. The birds make their appearance in the Cretaceous. Thus there is in the order of appearance exactly the same progress from the simple to the complex, from the undifferentiated to the specialized, which evolution demands.

The geological record is more detailed than this. It is possible to trace clearly, step by step, the evolution of a large number of forms. The history of the rhinoceroses, the horses, and the crocodiles is known in detail. In the successive beds can be traced the gradual modifications of the skeleton of *Prohatteria* of the Permian, which resulted in the gavials, alligators, and crocodiles. All the stages can be found which intervene between the four-toed *Eohippus* of the Lower Eocene and the three-toed *Anchitherium* (*Miohippus*) of the Miocene to the single-toed *Pliohippus* of the Pliocene and the horse and zebra. Not only the successive steps in the evolution of foot-structure are preserved, but also every phase in the development of the complicated enamel pattern of the teeth.

Neumayr and Paul have studied the fossil fresh-water shells of an old lake basin in Hungary, and Hyatt has performed a similar service for corresponding beds in Würtemberg. In both localities the successive layers afford slightly varying forms, so that in either bed can be seen the gradual evolution of the new species and the extinction of the old. In some cases the causes of extinction can be seen, and the character of the unfitness demonstrated. With this slight reference the geological record must be dismissed.

A little more detail may be pardoned in stating the character of the embryological record, since this has not so thoroughly found its way into the popular works. If the principle of heredity be true, one would expect to find in the development of animals and plants traces of the line of descent. If evolution be true, one ought to find, following back the development of the egg, just as in the geological record, that specific details would vanish and give rise to more generalized features; that the earlier the stages the more the embryos of related forms would resemble each other.

The lowest forms of animal life are the Protozoa, each individual of which is but a simple mass of protoplasm with a central differentiated spot, the nucleus. In the language of histology it is a simple cell. The egg of a frog, for instance, can be described with the same language. In other words, the egg is the representation of the protozoan stage. The protozoan can reproduce itself by dividing into two individuals, each with its nucleus. The frog's egg in its development segments in a similar way, with the same wonderful processes. In certain very low forms (*Volvox*), sometimes classed as animals, sometimes as plants, the organism consists of a hollow sphere of cells produced by the continued division of a protozoan-like germ. In the developing egg of the frog a corresponding stage with central cavity and superficial cells occurs.

In the plane above the Protozoa comes the great group of Cœlenterates, in which the body has but a single opening, connecting the external world with a two-walled sac. This opening serves at once for mouth and vent, while the internal sac serves as stomach. In the next stage of the frog's egg one side of the hollow sphere becomes pushed in, much as one might push in one side of a rubber ball, thus converting it into a double sac like the Cœlenterate. The resemblance goes further. The inner sac becomes the stomach, while the opening is converted into the vent of the adult. In the Cœlenterate the nervous system is but a portion of the outer skin, and all the sense organs are differentiations of that layer. In the frog's embryo there is a stage when the brain and sense organs—eyes, ears, and nose—are differentiated from the outer layer of the sac.

Next, the frog's egg passes through what may be called the annelid stage. On either side of the body are formed little blocks of muscle which correspond to the segments (rings) of the earthworm, for every vertebrate is as plainly made up of a series of segments as is any worm or arthropod. A central circulatory apparatus forms, in both frog and worm, on the side of the intestine opposite the nervous system, and further, in both, branches run from this central tube between the blocks of muscle. Some of these in the frog, as in the fish and shark, form the gill arteries, and they unite above in these forms, as in the earthworm, to form a dorsal aorta.

In the following stage the developing frog leaves the invertebrate behind, and takes on true vertebrate features. The mouth becomes open, as in the shark, while the gill-slits are formed, from which gill filaments soon protrude. Somewhat earlier, in both frog and shark, the digestive tract forms a cartilaginous rod on its dorsal surface (the notochord), about which the vertebræ later appear. In the frog can be seen a shark-like stage in the development of the skull—the same formation of cartilage rods and sense capsules, the same formation of a cartilaginous case for the brain. Here the frog leaves the shark behind, and developing true bone, a complicated skeleton for the limbs, lungs for respiratory purposes, becomes a true frog.

The foregoing is but one of thousands of series of correspondences which every naturalist can furnish, in each case there being the closest parallel between the geological and embryological records, and in both there is the same sequence, the same conditions which the theory of evolution demands. A few coincidences might be explained as accidental, but they are so numerous, so universal, that one is fully warranted in the aphorism that the history of the individual (i. e. embryology) is a recapitulation of that of the race. So firmly has this principle been established that it is used as the chief factor in tracing relationships and pedigrees of both animals and plants, especially in those groups where there are no hard parts for preservation as fossils, and where, consequently, the geological record can not be consulted.

There is also much corroborative evidence of varying character. Here is to be enumerated the evidence of atavism or reversion already referred to. The occasional occurrence of well-defined and regular banding on horses indicates a former zebra-like ancestor, while the occasional occurrence of three-toed horses points clearly to the three-toed progenitor of the Eocene.

Here, too, one must refer to the geographical distribution of both plants and animals. Those forms which, both from embryology and geology, are known to be extremely old have a very wide range, and at the same time are poor in species. Thus the scorpions, dating from the Silurian, are found, with slight variations in form, in all quarters of the globe. The horseshoe crab, which has existed in a scarcely modified condition since the Carboniferous, is found in both the Atlantic and Pacific Oceans. Phyllopods, which appear in the Cambrian, are found all over the world to-day. The primitive Dipnoi, or lungfishes, with but four living species, range from South America to Africa and Australia, and one genus (*Ceratodus*) has existed since the Triassic. *Lingula*, a brachiopod which occurs in the Cambrian rocks, is found in the seas of the Carolinas and of Japan. The marsupials, already referred to as among the oldest of mammals, are living in America and Australia. In all of these, and hundreds of other instances, these old forms are found widely separated and few in species. When, however, one studies the fossils, he finds them distributed through all the intervening regions, and is forced to the conclusion that the existing representatives of these groups are the survivors of a formerly widely distributed fauna and flora which is all but extinct.

Coming to the newer forms, one finds that there is a close connection between the past and present fauna and flora of certain regions; that these newer forms have their centers of origin, and have not yet become distributed far from it. Thus South America was the former home of the edentate mammals, and in the same region flourish the sloths and armadillos of the present epoch. In Australia all the mammals* at the time of the discovery belonged either to the monotremes or marsupials. In the same island continent is found a rich fossil fauna, but not a single representative of the placental mammals. The conclusion is that since this region was first peopled by the then existing highest mammalia, it has been protected from immigration of the higher groups which have arisen in other parts of the world. On the other hand, evolution has not been idle here, for in Australia the marsupials have evolved a range of

*** Excepting the dingo, or native dog, probably introduced by man.**

forms which strikingly imitates, in all but method of reproduction, the forms which have arisen in other parts of the world. One needs but to mention the strange kangaroos, the rodent-like wombat, the cat-like dasyures, the insect-eating bandicoots, and the sugar squirrels, so like the flying squirrels of North America, resembling in general habits and many points of structure the forms they have been compared with, and yet all bound together by the pouch for the reception of the immature young.

The Evolution of Man.—If the theory of evolution be true, man, like all other living forms, must be the result of its laws. He must show variation and heredity, and, like all other organisms, must be subject to the law of survival of the fittest. Further, there should be in both geology and embryology undisputable traces of his past history.

In the embryonic history of man there are certain peculiarities which, upon the idea of special creation, are perfectly inexplicable; in the light of evolution they are exactly what one ought to expect. The egg of man, in its earlier phases, passes through stages which are capable of exact comparison with those of the frog, described above. The egg divides, forms the germ layers, nervous system, notochord, and muscle plates in exactly the same way. Then comes the same formation of heart and blood-vessels. In man, as in the fish, the heart is at first two-chambered; then it becomes three-chambered, as in the lower reptiles; and later it develops the four-chambered condition, which it retains through life. In the blood-vessels are the same gill arteries as in the frog or shark, running in the same direction and uniting to form the same dorsal aorta. There is the same tendency to form gill-slits upon the sides of the neck, and in exactly the same manner, as outgrowths from the throat toward the external skin. Later the blood-vessels change, the gill-slits close up, all except the first, which persists as the Eustachian tube, connecting the throat with the middle ear.

After a time the distinctively mammalian features become more prominent, and there comes a time when no one can decide between two embryos which is that of a dog and which that of man. Later the two can be distinguished, but still that of man and that of a monkey show no differences, that of man presents so many monkey-like features. A few of the monkey-like characters of the human embryo may be suggestive. At one stage there is a true tail extending considerably beyond the legs and containing several more vertebræ than can be traced in the coccyx of the adult. The convolutions of the brain at the seventh month almost exactly parallel those of the baboon, and the great toe, instead of being longer than and parallel to the others, is shorter and extends at right angles to the axis of the foot, just as it does in the foot of monkey or ape. At the seventh month the whole body, except the palms of the hands and soles of the feet, is, like that of the ape, covered with hair. Even after birth the monkey-like characters have not entirely disappeared. The young orang-utan clings with its hands to the hair on the mother's breast, and the newly born infant, so weak in other respects, will cling to any hairy surface with sufficient grip to support its weight.

In structure the differences between man and the nearest mammals are extremely slight. His superiority in the struggle for existence lies in the development of the intellect, and, transposed to this plane, the struggle is the same as before, differing only in degree. Excepting articulate speech and a spiritual nature there is nothing in man which can not be traced, less developed, in the brute creation. Every owner of a horse or dog knows that these animals possess intelligence, and have as clear ideas of right and wrong as have many human beings. Mr. Romanes has given us accounts of monkeys and higher apes which show that these animals, as would be expected from their nearer structural relationship to man, are far more intelligent than the horse or the dog, while no one who has read Sir John Lubbock's charming works can doubt that animals even so low as bees and ants, if not possessed of articulate speech, possess other means of communicating with each other.

It may be objected that man can form abstract ideas, while brutes can not. This is true of only the higher races of man, but of the lower to no greater extent than of many brutes. Many tribes have words for white stone, black stone, red stone, but none for stone; for elm-tree, oak-tree, and the like, but none for tree. Is it difficult to believe that a dog does not form as clear an abstract idea of tree as do these people? In short, the intellect must be regarded as subject to the same laws as the physical structure, and it must be concluded that those differences upon which such stress is laid are not those of kind, but of degree, while their extent presents no insuperable obstacle to evolution.

Man is varying and changing. His intellect has removed him from many consequences of the law of the survival of the (structurally) fittest and made him subject to another lot. He is consequently undergoing a structural degeneration at the same time that he is becoming more intellectual. Thus the teeth of the higher races are reverting to those of the lemurs, while the wisdom-tooth is on the road to entire disappearance. The eyes are becoming weaker and less perfect, the eighth rib is losing its connection with the sternum, the lower jaw is becoming smaller and its muscles weaker, while a joint is disappearing from the fifth toe. On the other hand, the skull is increasing in size and its sutures are disappearing in the adult. The muscles of the hand are undergoing differentiation and improvement, and the arms are changing more rapidly than the legs.

Man further possesses many structures of no possible present use, which can not be explained upon any hypothesis as yet advanced, except upon that of his descent (or ascent) from lower forms, where they are of distinct value. Here are to be enumerated the vermiform appendix, already alluded to, the rudimentary muscles to move the ear, those muscles in the skin which in lower animals serve to erect the hair, and which in man have no other function than to cause the "goose flesh" of fear or cold, the tonsils, the pineal organ, the pituitary body, and the like.

The geological evidence in regard to man is as yet extremely scanty, but such as exists is in full harmony with the theory. The skulls of Cro-magnon and the Neanderthal indicate an intelligence far below that of any existing races, while that of Table Mountain in California shows that one must go back at least as far as the Pliocene age to find the time when the ancestors of man and of the existing monkeys separated. The almost entire absence of traces of primitive man is paralleled by the great scarcity of fossils of the anthropoid apes. It is possibly to be explained by supposing with Sclater that his primitive home was in the lost continent "Lemuria," which may have once occupied the site of the Indian Ocean, or with Wallace, that it was in the tableland of Asia, the geology of which is not yet understood. When the wonderful discoveries made in the Western U. S. are recalled one may be pardoned for believing that the future explorations in the cradle of the race may afford conclusive evidence of the descent of the human race, through the anthropoid apes, from the lemur-like forms, just as America has supplied the history connecting the Eohippus of the Eocene with the Equus of to-day.

Objections to the Theory of Evolution.—A theory so subversive of preconceived ideas as was that of evolution has naturally aroused no little antagonism, but it is a fact of great significance that as yet there has not been produced a single new argument against the theory. On the other hand, many of the so-called objections have been shown to be without force, and indeed in many instances to be strong supports of the theory. As a result the whole scientific world has accepted evolution, and it is a serious task to attempt to find any real argument against it. A somewhat extensive reading of critiques, etc., reveals but one stock objection: that no one has yet seen one species change into another. The answer to the objection in its first form is easy. Given a satisfactory definition of a species, and every naturalist can show myriads of instances of the evolution of new forms. The trouble is the anti-evolutionist begs the whole question when he assumes that a species is something fixed and immutable, and at the same time claims that all forms which can be traced back to one parent must belong to the same species. The other type of objection, the demand that the transformation be shown of the highest alga into the lowest zoöphyte, would not be worth a moment's attention were it not advanced by persons whose names bear weight in other lines of thought. It does not admit of serious reply, as it betrays such ignorance of the theory as should prevent entrance into scientific discussion. It is in effect a demand that a person transform himself into his cousin, a procedure only to be expected in the case of Dr. Jekyll and Mr. Hyde. See the next article.

The literature of evolution has become enormous, and reference can be made to only a few of the works in English which deal with various phases of the subject. Darwin, *Origin of Species*; *Descent of Man*; *Variation of Animals and Plants under Domestication*; *Fertilization of Orchids*; *Different Forms of Flowers on Plants of the same*

J. S. Kingsley.

Evolution (as related to biological and geological questions): In the use of the term evolution it will always be necessary to discriminate between its different meanings. Literally, it is the act of unrolling; the primary idea being that of the unfolding of the leaves of a bud, hence the similar unfolding and extension of the germ in a seed, and the development of the embryo-cell of an egg into an animal. In a more general sense it is applied to any process by which a thing rudimentary or apparently homogeneous passes into a more heterogeneous condition in which it displays more or less complexity or distinction of parts or organs. We may for the present neglect, as exceptional, cases of retrograde development in which complex structures become more simple. In a hypothetical sense the term is applied to any supposed change or series of changes whereby organic and living bodies may pass from simple to more complex states, or whereby one species or kind of plant or animal may be transformed into another, usually of more complicated structure.

The present article is intended to refer more especially to the hypothetical employment of the term evolution in certain modern philosophical discussions, and will allude to the ordinary or matter-of-fact uses of it, chiefly in illustration of these, and in order to inquire what basis there may be in nature for the philosophical conceptions of evolution of organic beings held by Darwin and his followers.

There are certain data essential to this question which are not usually sufficiently considered, and which should therefore be stated in the first instance.

1. Evolution itself is not and can not be an efficient cause of anything. It is merely a development of things previously existing in embryo or potentiality, and is thus a process having its beginning and its stages, but dependent altogether on previous arrangements and on contemporaneous conditions or efficient causes. This is seen in the development of an egg. It must have an embryo-cell potentially representing the chick, and pabulum appropriate and available for its nourishment. To produce the evolution of these into a bird there must be the warmth of incubation. It would be absurd to expect by any process to hatch a bird from a pebble, and an egg kept in an ice-house would be equally incapable of development. In every case of evolution there must be (1) something to be evolved; (2) the development of this according to what may have been potentially in it; (3) the causes or conditions of the development. In other words, whenever anything is said to be evolved, three things must be considered: (1) potentiality, (2) development, (3) causation. Unfortunately there is too great a tendency to confine attention altogether to the second of these and to take the first and third for granted.

2. It follows from the previous statement that evolution, even if all the component parts above described are included in it, can not explain the origin of anything. It must presuppose something having at least potentially present all that is to be evolved. In other words, it has to take for granted all that is to be produced. It is certain that every feather of the chick must be potentially present in the embryo in the egg, and to explain the origin of this is therefore quite as difficult as to explain the origin of the complete bird. When therefore evolution pretends to explain origins it becomes a process of reasoning in a circle, and the question resolves itself into that old one, whether owls preceded eggs or eggs preceded owls. This is admitted in terms by Darwin and his followers, but they constantly overlook it. The title of Darwin's famous book *The Origin of Species* is an example. It really says nothing of the origin of species, but only of transmutations of species already in existence.

3. Taking for granted, as Darwin had to do, the existence of living organisms with all their powers and properties, and referring to their development with reference to cause and effect, four kinds of this may be recognized, to any of which may be given the name evolution, but they are quite distinct from each other. The first of these is the *direct* development of structures previously prepared and subjected to the operation of adequate causes, as heat, moisture, etc. Of this kind is the development of seeds and eggs into adult plants and animals. A second kind is *indirect* development, or that which takes place in adult organisms under the power and guidance of an external will. Such is the artificial production by men of varieties of plants and animals by processes of culture, selection, and isolation. A third kind would be a *fortuitous* or natural series of changes, by which varieties or even species might arise in nature, under the influence of external conditions. This has been termed variation under natural selection, but in this expression a fallacy is involved, unless an intelligent selector and varieties to be selected from are assumed, in which case it becomes the same with the second, except as carried on by some power distinct from man. A fourth kind which has been imagined, but is altogether unknown to science, is the *spontaneous* evolution of life and organization from that which is dead and unorganized. This, however, can not be realized in its causes and methods unless a creative power be assumed, and this acting in a way different from anything within the sphere of human observation.

These considerations, which do not seem liable to any doubt, closely restrict the sphere of organic evolution of the nature of phylogeny, or the development of new species from forms previously existing; and when we eliminate ordinary variation, in which varietal forms still capable of reproduction with each other and also capable of reversion to the original type are produced, it can scarcely be affirmed that there is any fact open to observation justifying the assertion that any case of the production of a distinct species in this way is known. Darwin's illustration taken from the domestic pigeon is a case in point. This bird, the original of which is believed to be the rock pigeon of Europe (*Columba livia*), has varied under domestication to such an extent that some of its breeds, if found wild, would be regarded as distinct specifically, or even generically, from each other. Yet all breed together freely, and all show reversion to the forms and colors of the wild stock. In this case also there is an indirect development dependent on human agency, and Darwin himself has ably proved that it could not occur in wild nature. This case, therefore, shows that the utmost efforts of artificial selection, acting for thousands of years on a creature easily domesticated and of plastic organization, have failed to develop a specific type. Obviously one is here at an infinite distance from any explanation of the origin of the rock pigeon itself, and there is no reason to believe that any treatment or lapse of time would suffice to separate it into distinct species.

Facts in support of the evolution of species being thus wanting, its advocates fall back on two kinds of evidence—(1) that of analogy between the evolution or ontogeny of the individual, and the phylogeny or evolution of the race; and (2) the succession of animals and plants in geological time. The first of these is liable to the objection, taken in the earlier part of this article, to the confounding of distinct kinds of evolution. It is not logical to establish an analogy between the evolution of a germ through various stages into an animal, whose parts were potentially present in the germ, and the evolution of an adult animal into an animal of another kind. Nor is it logical to allege an evolution taking place under special conditions of parental origin, incubation, etc., to prove the possibility of an evolution in regard to which all these preparatory conditions and efficient causes are absent. The only possible use of the argument from analogy is that suggested by Weismann, namely, that causes may so affect the germinal matter in an animal or a plant that the resulting germ to be developed shall not represent potentially the parent, but something else. This supposition accords with experience in the production of certain varietal forms, but is not known to produce new species, and if it could do this it would effectually overthrow the Darwinian idea of slow changes under natural selection, and the Lamarckian idea of similar slow changes under the influence of adaptation to environment. It would, in short, be a production of forms *per saltum*, and not by gradual evolution. The evidence of palæontology is equally unsatisfactory. It is not difficult to obtain, by selecting series out of the known fossil animals of successive periods, chains of forms which may be supposed to have produced each other; but the gaps are enormous in structure, in time, and in place, and there is no evidence of genetic connection, while the apparently abrupt and widespread introduction of new forms at certain periods of geological time, and their subsequent gradual decadence, seem to indicate the incoming of new dynasties of animals and plants in successive waves rather than by a gradual and imperceptible rise.

While the ordinary theories of evolution seem to be thus destitute of proof, there are certain arguments tending to show the imperfect and partial character of all the current doctrines of this kind, which merit careful consideration. (1) Current hypotheses of evolution are partial and imperfect in their tendency to refer numerous and complex phenomena to one cause or to few causes only, when all trustworthy analogy would indicate that they must result from many concurrent forces and determinations of force. This is especially evident when we consider the necessity of the co-existence of several distinct and unconnected things to produce the observed effect, and also the marvelous balance and correlation of the parts in the individual animal or plant, and the wide range of correlation of certain animals and plants with each other. The relations of nectaries in flowers and the suctorial organs of certain insects furnish a case in point. One must imagine flowers to develop useless and wasteful honey-glands or insects to part with their masticating organs to their own injury, or else imagine infinitely complex, simultaneous, yet independent, changes to occur in a manner altogether inconceivable. Asa Gray might well deny that insects could produce flowers, and he may have ventured too far when he admitted that they might perhaps modify them. (2) They are also partial and imperfect in their tendency to follow out supposed modifications of single organs without considering the correlations of these, and the balancing of parts which gives coherence to them as components in a complex whole. Nothing can more clearly indicate this than the delicacy and instability of constitution induced by breeders in the races of animals modified by artificial treatment and selection. Instances of this will occur to every one acquainted with domestic animals. (3) The ordinary theories of evolution are partial and imperfect in their tendency to think only of the continuous operation of physical forces and laws, and to leave out of sight the distinction between life and organization and dead matter, between mere force and the correlation and determination of forces, between the merely physical and material and the unseen and spiritual. This bald materialistic tendency is everywhere conspicuous, and seems almost to be essential to evolutionary speculations. (4) Such speculations are partial because they fall short of origins and final causes. They have to take for granted the existence either potentially or actually of all they propose to evolve, and this not in the mind and purpose of an eternal Creator, but in mere brute insensate matter. Even in assuming the existence of matter and energy they are begging the whole question of origins.

It is interesting to observe in all these respects the essentially unscientific character of evolution as ordinarily advocated, its violations of the inductive method, its tendency to assume that which has to be proved, and to found the structure of the universe on one speculative doctrine, and to pursue this in a vicious circle. In all these respects it has more affinity with those philosophical speculations which prevailed before the rise of experimental and inductive science, and its affinity in this respect is greatest with the least complete of these ancient systems. It has a nearer relationship to the atomism of Democritus than to the loftier idealism of Plato, while it seeks to string the whole of the precious gems of modern science on the slender and brittle thread of a specious but baseless speculation. Such philosophies have often dazzled the world. Originating with some powerful and persuasive mind, they have carried all before them for a time. Then, falling into the hands of feebler men, they have disintegrated into opposing schools and warring sects, which have destroyed one another. The Darwinian evolution, more short-lived than some of its predecessors, has already entered into this phase.

The diverse schools of evolution now contending with each other may perhaps be best considered in connection with the difficulties which have met the original Darwinian conception, and the various attempts to turn or overcome these which have led later speculators to diverge from the path of the great apostle of the creed.

One arises from the fact that most of the leading types can be traced so far back that they seem to constitute parallel rather than diverging lines, and show no certain evidence of branching. The continuance of the *Lingula* and other Brachiopods, and of the siliceous sponges and the Foraminifera, from the Cambrian to the modern, and more lately the history of the oysters, which have continued from the Carboniferous age to the present, and that of the scorpions, which have continued from the Silurian—in both cases with scarcely any more differences than their living successors present—may be taken as examples. With this must be connected the further fact that nearly all the early types of life seem very long ago to have reached stages so definite and fixed that they became apparently incapable of further development, constituting what have been called "terminal forms."*

A further difficulty arises from the failure to find satisfactory examples of the almost infinite alleged connecting links which must have occurred in a gradual development. This, it may be said, proceeds from the imperfection of the record; but when there are abundance of examples of the young and old of many fossil species, which can be traced through their ordinary embryonic development, why should not examples be found of the links which bound the species together? An additional difficulty is caused by the fact that in most types one finds a great number of kinds in their earlier geological history, and that they dwindle rather than increase as they go onward. This fact, established in so many cases as to constitute an actual law of palæontology, is altogether independent of the alleged "imperfection of the record."

Objections of this kind appear to be fatal to the Darwinian idea of slow modifications, proceeding throughout geological ages, and to throw us back on a doctrine of sudden appearance of new forms, occurring at certain portions of geological time rather than at others, and in the earlier history of animal and vegetable types rather than in their later history, and in early geological times rather than in those more recent. This doctrine, however, of critical or spasmodic evolution is essentially different from Darwinism, and approaches to that which has been called mediate creation, or creation under natural law.

With respect to the origin of man himself, which is no doubt the most important point, these difficulties are enormous. Man can be traced only a little way back in geological history, not further than the Pleistocene period, and the earliest men are still men in all essential points, and separated from other animals, recent and fossil, by a gap as wide as that which exists now. Further, if from the Pleistocene to the modern period man has continued essentially the same, this, on the principle of gradual development, would remove his first appearance not only far beyond the existence of any remains of man or his works, but beyond the time when any animals nearly approaching to him are known to have existed. This is independent altogether of the further difficulties which attend the spontaneous origin of the mental and moral nature of the human species. It would seem, then, that man must have been introduced, not by a process of gradual development, but in some abrupt and sudden way. Even Wallace, who has all along adhered to the doctrine of natural selection in its integrity, while he agrees with Darwin that man must be a descendant of apes as to his bodily frame,† maintains that his higher mental and moral faculties must have had another origin.

These considerations have led many of the more logical and thoughtful of the followers of Darwin to the position of supposing not a gradual, but an intermittent and sudden development, and this, in the main, in the earliest periods of the history of living beings. In a very able essay by Dr. Alpheus Hyatt, in the *Proceedings* of the Boston Society of Natural History, this view is very fully stated in its application to animals. On the one hand, Hyatt holds that the biological facts and the geological evidence as it has been stated by Marcou, Le Conte, Barrande, Davidson, and by the writer,‡ precludes the idea of slow and uniform change proceeding throughout geological time, and he holds justly that the idea of what he calls "a concentrated and accelerated process of evolution," in early geological times, brings

* Clelland, *Journal of Anatomy and Physiology.*
† *Darwinism*, p. 461.
‡ *Modern Ideas of Evolution* (6th ed. London, 1891).

the doctrine of development nearer to the position of those great naturalists like Cuvier, Louis Agassiz, and Gegenbauer, who have denied any genetic connection between the leading animal types. He quotes Cope and Packard in support of his view on this point. Cope has, in a series of brilliant essays,* endeavored to illustrate what he terms "causes of the origin of the fittest." Of this kind are growth-force modified by retardation or acceleration of development produced by unfavorable or favoring conditions, the effects of use and disuse on modifying structures, the law of correlation of parts and the effects of animal intelligence. All of these causes are ignored by the genuine Darwinian. Nevertheless they exist in nature, though rather as causes of mere adaptive variation than of specific difference.

Another modification of orthodox Darwinism is that of Romanes, who may almost be regarded as Darwin's most prominent successor. He has introduced the idea of physiological selection—that is, of the occurrence accidentally or from unknown causes of reproductive changes which render certain individuals of a species infertile with others. The effect of this would be an isolation amounting to the erection of two forms not reproductive with each other; or, in other words, of two species not gradually differentiated, but distinct from the first. This is really an inversion of Darwin's theory, in which the initial stage of Romanes is necessarily the culmination of the development. It differs also essentially in eliminating the idea of use and adaptation to change implied in the theory of natural selection.

Romanes even goes so far as to stigmatize the adherence to natural selection pure and simple as "Wallaceism," in contradistinction to Darwinism, while he admits that Wallace has a good right to adhere to this view, as having in some sense antedated Darwin in asserting the dominant influence of natural selection. It is fair to say, with regard to Romanes, that while advocating the importance of physiological selection, he claims that Darwin admitted, or would have admitted, this factor, since he believed that in the absence of infertility to prevent intercrossing, natural selection would fail to produce new species. It is worthy of remark here that both Romanes and Wallace seem to be aware that this admission might be fatal to the doctrine of natural selection, unless they can show some other cause capable of producing infertility.

In the meantime, Weismann in Germany has, in the name of what has been called pure Darwinism, introduced into the discussion facts and considerations as destructive to the usual doctrine as Puritanism would be to High Churchism. He contends that all evidence is against the perpetuation by heredity of characters acquired by the individual. Only characters born with him can be perpetuated. For example, a man born with six fingers on his hand may have six-fingered children, but a man who acquires in his lifetime manual dexterity, or who loses a finger by accident, will not transmit either peculiarity. Weismann has undoubtedly made out a strong case in favor of this contention, which would at once overthrow the Lamarckian theory of evolution, and would remove one of the subsidiary props of Darwinism, throwing it back entirely on the natural selection of fortuitous congenital variations. Purified in this way, and reduced to chance variation, perpetuated by accidental action of favoring circumstances, Darwinism would, according to some of its adherents, evaporate without leaving any residuum. Nor has it escaped notice that the theory of Weismann implies profound and far-reaching considerations respecting the independence of the germinal matter of animals of individual peculiarities, and its constancy to the ideal plan of the species, which would help to account for the wonderful permanence of types in geological time, while it would oppose change, except when this arises from causes directly affecting the reproductive function.

Another important point involved in Weismann's results is the probability that, while asexual reproduction, as, for instance, that of budding, tends to perpetuate individual peculiarities, whether of advance or retrogression, ordinary reproduction tends to eliminate all variations, whether produced by habit and use or by obscure causes affecting the individual in its lifetime. Thus there is a strong barrier set up, especially in the higher organisms, against either degradation or elevation. Advantage has been taken of this by some speculators to suggest that new species may have originated by parthenogenesis, that is to say, by what theologians would call miraculous conception, and this idea has by some of them been connected even with the nativity of our Lord on the earth. But such speculations are very far removed from even the borders of science.

A curious point, little thought of by most evolutionists, but deserving consideration here, is that to which Herbert Spencer has given the name "direct equilibration," or the balance of parts and forces within the organism itself. The body of an animal, for example, is a very complex machine, and if its parts have been put together by chance, and are drifting onward on the path of evolution, there must necessarily be a continual struggle going on between the different organs and functions of the body, each tending to swallow up the other, and each struggling for its own existence. This resolution of the body of any animal into a house divided against itself, is at first sight so revolting to common sense, and so hideous to right feeling, that few like to contemplate it; but it has been brought into prominence by Roux and other recent writers, especially in Germany, and it is no doubt a necessary outcome of the evolutionary idea. For why should not the struggle of species against species extend to the individuals and the parts of the individual? On this view, the mechanism of an animal ceases even to be a machine, and becomes a mere mass of conflicting parts thrown together at random, and depending for its continued existence on a chance balance of external forces. Fortunately, geological history completely negatives this idea, by showing the extreme permanence of many forms of life which have continued to propagate themselves through almost immeasurable ages and great changes of environment, without material variation, and the apparent fixity of these in their final forms.

Viewed rightly, the direct equilibration of the parts of animals and plants is so perfect and so stable, and such great evils arise from the slightest disturbance of it by the selective agency of man, that it becomes one of the strongest arguments against the production of new species by variation. This has been well shown by T. Warren O'Neill,* who adduces a great number of facts, detailed by Darwin himself, to show that when the stability of an organism is artificially altered by man in his attempt to establish new breeds, infertility and death of these varieties or breeds results; and if this happens under the fortuitous selection supposed to occur in nature, any considerable variation would result either in speedy return to the original type or in speedy extinction. In other words, so beautifully balanced is the organism that an excess or deficiency in any of its parts, when artificially or accidentally introduced, soon proves fatal to its existence as a species; so that, unless nature is a vastly more skillful breeder and fancier than man, the production of new species by natural selection is an impossibility.

Two remarkable books by two of the ablest exponents of the Darwinian theory of evolution have appeared, which may be taken as specimens of the evolutionary method, and may be commended to those who desire to know this theory as defended and extended by its friends.† One of these works is by Alfred Wallace, who may be truly said to have anticipated Darwin in the theory of natural selection—the other by Dr. Romanes, Darwin's successor. Both claim to be orthodox Darwinians, though each accuses the other of some heresy. Wallace's book may, however, be accepted as the best English exposition of Darwinism in general, that of Romanes as the ablest attempt to explain on this theory the evolution of the higher faculties of man. Neither professes to explain the origin of life, but both profess, life and species of animals being given, to explain their development as high as man himself, though they differ materially as to this highest stage of evolution, and also as to the omnipotence of natural selection. The judicious reader will, however, observe that both take for granted what should be proved; in other words, reason constantly in a narrow circle, and constantly use such formulæ as "we may well suppose" instead of argument.

Take as a specimen from Wallace the history of evolution of the water-ouzel or dipper. It may serve as an example of the questions which are raised by the Darwinian evolution, and which, if they have no other advantage, tend to promote the minute observation of nature, of which Wallace's book shows many interesting examples. It serves, at the same time, to illustrate that peculiar style of reasoning in a circle which is characteristic of this school of thought. This special illustration from Wallace has been chosen be-

* *Origin of the Fittest*, in *American Naturalist*.

* *Refutation of Darwin* (Philadelphia, 1880).

† *Darwinism*, by Wallace; *Mental Evolution in Man*, by Romanes.

cause it is one in which the idea of adaptation to fill a vacant space—an idea as much Lamarckian as Darwinian—is introduced.

"An excellent example of how a limited group of species has been able to maintain itself by adaptation to one of these 'vacant places' in nature is afforded by the curious little birds called dippers or water-ouzels, forming the genus *Cinclus* of the family *Cinclidæ* of naturalists. These birds are something like small thrushes, with very short wings and tail and very dense plumage. They frequent, exclusively, mountain-torrents in the northern hemisphere, and obtain their food entirely in the water, consisting, as it does, of water-beetles, caddis-worms, and other insect larvæ, as well as numerous small fresh-water shells. These birds, although not far removed in structure from thrushes and wrens, have the extraordinary power of flying under water; for such, according to the best observers, is their process of diving in search of their prey, their dense and somewhat fibrous plumage retaining so much air that the water is prevented from touching their bodies, or even from wetting their feathers to any great extent. Their powerful feet and long curved claws enable them to hold on to stones at the bottom, and thus retain their position while picking up insects, shells, etc. As they frequent chiefly the most rapid and boisterous torrents, among rocks, waterfalls, and huge bowlders, the water is never frozen over, and they are thus able to live during the severest winters. Only a very few species of dipper are known, all those of the Old World being so closely allied to our British bird that some ornithologists consider them to be merely local races of one species; while in North America and the Northern Andes there are two other species.

"Here, then, we have a bird, which, in its whole structure, shows a close affinity to the smaller typical perching birds, but which has departed from all its allies in its habits and mode of life, and has secured for itself a place in nature where it has few competitors and few enemies. We may well suppose that, at some remote period, a bird which was perhaps the common and more generalized ancestor of most of our thrushes, warblers, wrens, etc., had spread widely over the great northern continent, and had given rise to numerous varieties adapted to special conditions of life. Among these some took to feeding on the borders of clear streams, picking out such larvæ and mollusks as they could reach in shallow water. When food became scarce they would attempt to pick them out of deeper and deeper water, and while doing this in cold weather many would become frozen and starved. But any which possessed denser and more heavy plumage than usual, which was able to keep out the water, would survive; and thus a race would be formed which would depend more and more on this kind of food. Then, following up the frozen streams into the mountains, they would be able to live there during winter; and as such places afforded them much protection from enemies and ample shelter for their nests and young, further adaptations would occur, till the wonderful power of diving and flying under water was acquired by a true land bird."*

Here it will be seen that a bird, distinctly marked off by important structures and habits from others, is supposed to have originated from a different species at some remote period, by efforts to obtain food in what, to it, must have been an unnatural way; and the sole proof of this is the expression, "we may well suppose." Why may one not as well suppose that all the perching birds were at first like water-ouzels, which would accord with the early appearance of aquatic birds, and that they gained their diverse forms by availing themselves of the better circumstances and more varied food to be found in the woods and fields, so that the water-ouzel may be a survival of a primitive type? Neither theory can be proved, and the one is as likely as the other, perhaps the latter, of the two, the more likely, and neither actually explains anything. It is to be observed, also, as already hinted, that the kind of evolution in this, as in some other cases supposed by Wallace, is rather Lamarckian than Darwinian.

It is interesting to note that, though wedded to that strange mode of reasoning of which the extract above given furnishes an example, Wallace frankly and fully admits three of the great breaks in the continuity of evolution. First, he admits that the introduction of life at first can not be accounted for, because no way is known in which mere chemical combination can produce living protoplasm. Here, he says, "we have indications of a new power at work which we may call Vitality." Secondly, he sees no cause in the continuous evolution for the introduction of animal sensation and consciousness. No attempt at explanation by any modification of protoplasm can here "afford any mental satisfaction, or help us in any way to a solution of the mystery." He sees a similar break of continuity in the introduction of the higher faculties of man. "These faculties could not have been developed by means of the same laws which have determined the progressive development of the organic world in general and also of man's physical organism." These he refers to an unseen universe—to a world of spirit to which the world of matter is altogether subordinate. If one refers these three great steps to a spiritual Creator, and eliminates on the other side, the known development of varietal forms, the field for the Darwinian evolution becomes greatly narrowed.

Romanes, the author of the other work, will listen to no such compromises; but, on the other hand, is willing to admit a union of the Darwinian and Lamarckian doctrines, besides sexual selection and other factors, which are admitted also by Spencer. His latest work is devoted to the bridging over the third of the gaps above mentioned, as in a previous work he had dealt with the second. He does not affirm that he has fully succeeded, but that, by considering the case of savages and of prehistoric man, we "are brought far on the way toward bridging the psychological distance which separates the gorilla from the gentleman." It is one thing, however, to be on the way to a chasm, and another to be assured that there is a good bridge over it. If one succeeds in crossing with him from instinct to animal intelligence, from this to rational thought, from this to ethical judgments and to the belief in God and immortality, and along with all this to speech, there is the following reward in regard to one step of the progress: "I believe that this most interesting creature (speechless man) lived for an inconceivably long time before his faculty of articulate sign-making had developed sufficiently far to begin to starve out the more primitive and more natural systems; and I believe that even after this starving-out process did begin, another inconceivable lapse of time must have been required to have eventually transformed *Homo alalus* into *Homo sapiens*." A process which thus requires two eternities in which to pass through two of its stages may well stagger the credulity of ordinary specimens of *Homo sapiens*, and may surely be dismissed as itself "inconceivable."

While however, the conclusions of Romanes are thus somewhat unsatisfactory, his book contains much that is valuable, more especially with reference to the perfectly legitimate questions relating to the development of civilization, and of new ideas and inventions in human history. Man is not confined, like the lower animals, within the range of unvarying instinct. He is gifted with inventive and progressive powers, and in the study of the progress of these there is scope for much psychological inquiry and discussion, though it is evident that human progress is not of the nature of a slow and gradual evolution, but rather by sudden leaps under the influence of superior genius and mental power, and it is all within the specific limits of man, and in no respect tends to the production of a new species.

The modern hypotheses of evolution present themselves to the Christian under two aspects—the theistic and the atheistic or agnostic, for the two last are practically the same. The theistic evolutionist holds that God creates, but that created things may have powers of spontaneous evolution, under laws whereby they may pass into new and higher forms. The atheist and the agnostic eliminate the idea of a Creator, and reduce everything to the action of atoms and forces supposed to be practically and inherently omnipotent. They thus make of these atoms and forces a supreme God, attributing to them the same powers assigned by the theist to the Creator. It is obvious, however, that many adherents of evolution have no clear perception of the distinction between these phases, or find it convenient to overlook its existence, since they often hover in thought between the one and the other, or occupy one or the other position indifferently, as the exigencies of debate may require.

It is also to be observed that either of these phases of evolution may admit of modifications. One of the most important of these arises from the distinction between the idea of slow and uniform development maintained by Darwin and others, and that of sudden or intermittent evolution advocated by such evolutionists as Mivart and Le Conte.

* *Darwinism*, pp. 116, 117.

Viewing the matter in this light, it is evident that neither the theological idea of creation nor the evolutionist notion, in either of its phases, can have any close dependence on biological and geological science, which studies the nature and succession of organic forms without ascertaining their origin; either hypothesis may, however, appeal to scientific facts as more or less according with the consequences which might be expected to follow from the origins supposed. It is further evident that, should evolutionists be driven by natural facts to admit the sudden apparition of organic forms rather than their gradual development, there may be no apparent difference, as to matter of fact, between such sudden apparition and creation, so that science may become absolutely silent on the question.

Palæontology has indeed tended to bring the matter into this position, as Barrande and others have well shown. The writer has elsewhere adduced the advent of the Cambrian trilobites, of the Silurian cephalopods, of the Devonian fishes, of the Carboniferous batrachians, land snails and myriapods, of the marsupial mammals of the Mesozoic and the placental mammals of the Eocene, and of the Palæozoic and modern floras, as illustrations of the sudden swarming in of forms of life over the world, in a manner indicating flows and ebbs of the creative action, inconsistent with Darwinian uniformity, and perhaps unfavorable to any form of evolution ordinarily held.*

This neutral attitude of science has been strongly insisted on by Dr. Wigand † in his elaborate work *Darwinismus*, in which he holds that this doctrine does not represent a definite and consistent scientific effort and result, but merely an "indefinite and confused movement of the mind of the age," and that science may ultimately prove its most dangerous foe. In like manner the veteran German physiologist Virchow, in an able address before the Assembly of German Naturalists at Munich,‡ taking the spontaneous generation of organisms and the descent of man from apelike ancestors as test questions, argues in the most conclusive manner that neither can be held as a result of scientific investigation, but that both must be regarded as problems as yet unsolved.

But in the face of such opinions as these, one is struck with the fact that eminent men of science in England and America assert that science demands belief in the theory of evolution, and this in its atheistic as well as its theistic phase. When, however, reasons are asked for this demand, those who make it are themselves obliged to admit the absence of a scientific basis for the doctrine. For example, reference may be made to the able and elaborate address delivered before the American Association by its president, Prof. Marsh. He says: "I need offer no argument for evolution, since to doubt evolution is to doubt science, and science is only another name for truth." In the sequel of the address he limits himself to the evolution of the vertebrate animals, admitting that he knows nothing of the absolute origin of the first of them, and basing his conclusions mainly on the succession, in distant times, and often in distant places, of forms allied to each other, and advancing in the scale of complexity. Such succession obviously falls far short of scientific proof of evolution; and other than this no evidence is offered for the strong assertion above quoted. In the conclusion of the address he asserts that life may be a form of some other force, presumably physical force: but admits in the same breath that we are ignorant of its origin; and finally he makes an appeal, not to facts, but to faith: "Possibly the great mystery of life may thus be solved; but whether it be or not, a true faith in science knows no limit to its search for truth."

Another eminent apostle of evolution, Prof. Tyndall, asserts, in a public address, that "it is now very generally admitted that the man of to-day is the child and product of incalculable antecedent time. His physical and intellectual textures have been woven for him through phases of history and forms of existence which lead the mind back to an abysmal past." But, however generally this may be "admitted," it is nevertheless true that the oldest known men are as truly human in their structures as those now living, and that no link between them and lower animals is known. In a previous address he had gone further back still, and affirmed that in material atoms reside the "promise and potency of life"; yet in his capacity of physicist he has by rigid experiments in his laboratory done as much as any man living to convince us that science knows no possibility of producing the phenomena of life from dead matter.

The man who in a popular address or in a text-book introduces the "descent of species" as a proved result of science, to be used in framing classifications and in constructing theories, is leaving the firm ground of nature and taking up a position which exposes him to the suspicion of being a dupe or a charlatan.* He is uttering counterfeits of nature's currency. It should not be left to theologians to expose him, for it is as much the interest of the honest worker in science to do this as it is that of the banker or merchant to expose the impostor who has forged another's signature. In the true interests of science one is called on to follow the weighty advice of Virchow: "Whoever speaks or writes for the public ought, in my opinion, doubly to examine just now how much of that which he says is objective truth. He ought to try as much as possible to have all inductive extensions which he makes, all conclusions arrived at by the laws of analogy, however probable they may seem, printed in small type under the general text, and to put into the latter only that which is objective truth." To practice such teaching may require much self-denial, akin to that which the preacher must exercise who makes up his mind to forego his own thoughts, and, like Paul, to know nothing among men but God's truth in its simplicity. The mischief which may be done to science by an opposite course is precisely similar to that which is done to religion by sensational preaching founded on distortions of scriptural truth, or on fragments of texts taken out of their connection and used as mottoes for streams of imaginative declamation.

To render such evils impossible, there must be a more general and truthful teaching of science. It is a great mistake here to suppose that a little knowledge is dangerous; every grain of pure truth is precious, and will bear precious fruit. The danger lies in misusing the little knowledge for purposes which it can not serve; and this is most likely to take place when facts are not known at all, or imperfectly comprehended, or so taught as to cause a part of the truth to be taken for the whole. Let the structures of animals and plants in some of their more prominent forms be well known, along with their history in geological time, and the attempt to explain their origin by any crude and simple hypotheses like those now current will become unreal as a dream.

It may be useful in conclusion to say a few words on the application of the doctrine of evolution to other lines of investigation than that of organic development. Here it is scarcely necessary to remark that when one speaks of the evolution of the physical universe from disseminated atoms, of chemical elements from one original substance, of continents and mountain-chains in geological time, or, on the other hand, of the arts and languages and history of men, new and diverse fields are entered, in which the developments which may occur are altogether different in their nature and dependent on different causes; in which consequently the term evolution must in each case have a distinct and peculiar meaning, unless indeed the reader is prepared to use it to designate any mode of doing anything, in which case it loses all distinctive significance.

In the case of the physical universe one must assume space and time, matter and energy, with all their laws and potencies, and has then before him the question of the possible interactions of these in time, their possible determination in a given direction, with or without a planning creative mind, and in the things developed one has to deal with the inorganic and the dead, altogether destitute of the plastic and progressive vital energies of the organic world. Evolution in this sense is merely the movement of a machine, the original construction of which no theory of evolution can *per se* explain. When, on the other hand, the evolution of human history or human art is discussed, an entirely different plane is reached. Here a planning intelligent mind deals with external objects and molds them to its will. Here also the new factor of genius appears as a sudden inspiration from time to time, giving at once a great

* In England, Davidson, Jeffreys, Williamson, Carruthers, and other eminent naturalists have strongly insisted on the tendency of palæontological facts to prove permanence of type and intermittent introduction of new forms, as distinguished from descent with gradual modification.

‡ On the *Liberty of Science* (1877).

* Huxley, in the preface to the *Manual of the Anatomy of the Invertebrated Animals* (1878), has taken this ground. He says: "I have abstained from discussing questions of ætiology, not because I underestimate their importance, or am insensible to the interest of the great problem of evolution, but because, in my mind, the growing tendency to mix up ætiological speculations with morphological generalizations will, if unchecked, throw biology into confusion."

and rapid impulse. All history shows that in this way, and by great bounds, advance has been secured, and not by any slow and gradual process of mere struggle and survival. Here also the subject becomes infinitely complicated with the varieties of human taste, feeling, and reason, and with the infinite interaction of interests and opportunities.

The vague and indefinite application of the term evolution to all these modes of development and to their innumerable and complicated causes and determinations has perhaps more than anything else tended to disgust men of common sense with this protean and intangible philosophy, and to divorce it more and more from the alliance of rigid science. On the other hand, its vague and shadowy character, and the pretension to explain all things by one dominant idea have great charms for the unwary and enthusiastic crowd, and it gives a cheap and easy way of appearing learned and philosophical, which has a peculiar attraction for an age characterized by a superficial and confused expansion of thought and discussion, and by an intense craving for the exciting and sensational. These elements of the thought of the age must for some time longer give currency to the abundant coinage of a mint which so easily converts the base metal of speculation into the semblance of scientific conclusions. J. WILLIAM DAWSON.

Evolutions, Military: the movements by which troops change the order, position, and direction of their primary formation. All such movements as marching, countermarching, changing front, forming line, facing, wheeling, defiling, deploying, etc., come under the general head of evolutions. All evolutions are performed according to a regulated system, which differs in its details in the armies of different nations.

Ev′ora (anc. *Ebora* and *Liberalitas Juliæ*): town of Portugal; capital of the province of Alemtejo; pleasantly situated about 73 miles by rail E. by S. from Lisbon (see map of Spain, ref. 17–B). It has two ruined forts, a large Gothic cathedral founded in 1186, several convents, a library, manufactures of cotton, cloth, and hats, and a trade in wine. It has been an archbishop's see since 1541. Ebora was taken by Sertorius about 80 B. C. Here are Roman antiquities which are more interesting than any others in Portugal. Among them are an aqueduct said to have been built by Sertorious; a temple of Diana with beautiful Corinthian columns; and a brick tower adorned with columns of the Ionic order. Pop. about 14,000.

Évremond, *āv′r′mōṅ′*, CHARLES DE SAINT-DÉNIS: seigneur de Saint-Évremond; a French courtier and *littérateur*; b. near Coutances, in Normandy, Apr. 1, 1613. He was witty and accomplished, a perfect specimen of an Epicurean of that time, squandering his life in the pursuit of frivolous pleasures, and ready to give it up at any moment for the sake of a bon-mot. He entered the army about 1629, and became a friend of Turenne and the Prince of Condé. Having given offense to Louis XIV. by his raillery and sarcastic wit, he took refuge in England in 1662. He gained the favor of Charles II., who granted him a pension of £300, and he never returned to France. He wrote dramas, essays, and letters, of which his *Comédie des Académistes pour la Réformation de la Langue François* is an exceedingly witty, elegant, and entertaining production. His *Sir Politics*, which he wrote in company with Buckingham, is very weak. D. Sept. 20, 1703.

Évreux, *ā′vrö′* (anc. *Mediolanum*, afterward *Eburovices*): city of France; capital of the department of Eure; pleasantly situated on the Iton; about 67 miles by rail W. N. W. of Paris, with which it is connected by railway (see map of France, ref. 3–E). It is a bishop's see, and has a fine old cathedral, an episcopal palace, a theater, a clock-tower built in 1417, and a botanic garden. Here are manufactures of cotton and woolen fabrics, leather, etc. Évreux has sustained numerous sieges. It was taken and pillaged by Rollo the Norman in 892 A. D., and was burned by Henry I. of England in 1119. Pop. (1896) 17,766.

Ewald, *ā vaalt*, GEORG HEINRICH AUGUST, von: Orientalist and biblical critic; b. at Göttingen, Germany, Nov. 16, 1803. He became Professor of Philosophy in the University of Göttingen in 1831, and Professor of Oriental Languages in 1835. In 1837 he was removed on account of his liberal political opinions, he and five other professors, among whom were Gervinus and Grimm, solemnly protesting against the abolition of the free constitution which the Hanoverian king had felt himself compelled to give during the revolutionary commotions in 1830. He went to Tübingen as professor in 1838 (first in the philosophical and then in the theological faculty), but became involved in conflicts with Catholics, Pietists, and Hegelians (F. C. Baur and the Tübingen school), and could not be contented in his new home. He was reinstated in his chair at Göttingen in 1848, and was elected a member of the North German Parliament in 1869, where he was a bitter opponent of Prussia. In 1874 he was found guilty of a libel on Prince Bismarck, and was sentenced to three weeks' imprisonment. His critical judgment was not equal to his learning, and his character was marred by excessive arrogance; but his influence on his generation was enormous. He wrote grammars of Hebrew and Arabic, numerous commentaries on the Old and New Testaments, a history of Israel, a work on biblical theology, and numerous articles touching almost every point of Semitic learning in his *Year-books of Biblical Science* (1849–65). D. in Göttingen, May 4, 1875.

Revised by C. H. TOY.

Ewald, *ā′vaald*, HERMAN FREDERIK: Danish novelist; b. in Copenhagen, Dec. 13, 1821. After writing several stories of modern life, he turned his attention to the historical romance, with which he has been very successful. Of his books may be mentioned *Valdemar Krones Ungdomshistorie* (The Story of Valdemar Krone's Youth, his first publication, 1860); *Familien Nordby* (The Nordby Family, 1862); *Johannes Falk* (1865); *Svenskerne paa Kronborg* (The Swedes at Kronborg, 1867); *Agathe* (1873); *Knud Gyldenstjerne* (1875); *Niels Brahe* (1877); *Anna Hardenberg* (1880); *Dronningens Jomfruer* (The Queen's Maidens, 1885); and *Griffenfeld* (1888). G. L. KITTREDGE.

Ewald, JOHANNES: Danish poet; b. in Copenhagen, Nov. 18, 1743. He gave early evidence of that fickleness and weakness of will that caused most of his subsequent misfortunes, running away to join the Prussian army in 1759, and then almost immediately deserting to the Austrians. After some six months' soldiering he returned home and studied theology. His literary activity, which continued till his death, began in 1765 with an unsuccessful didactic poem. Four years later his drama *Adam og Eva* (Adam and Eve) was published and gained him immediate recognition. He was at this time dominated by Klopstock and his school. In 1770 appeared his prose tragedy *Rolf Krage*, which is chiefly of interest as indicating the direction in which the Romantic school of the next century was to turn for material. It exhibits him as still under the influence of Klopstock. *Balder's Død* (The Death of Balder), a tragedy in iambic pentameters, marks a distinct advance in independence of his models and in poetic power. Its influence on OEHLENSCHLÄGER (*q. v.*) makes its appearance in 1773 an important date in Danish literature. Between *Rolf Krage* and *Balder's Død* Ewald had written various lyrics and occasional poems; an essay, *Om Pebersvende* (On Bachelors), remarkable for its humor and elegance; and three comedies in the manner of Holberg: *De brutale Klappare* (The Brutal Clappers), *Pebersvendene* (The Bachelors), and *Harlequin Patriot*. He spent 1773–77 in the country in poverty and ill-health, induced in part by his drinking habits. From this time dates one of his most admired poems, *Rungsteds Lyksaligheder* (The Blessings of Rungsted). In 1777 he returned to Copenhagen, where he lived in improved circumstances till his death, Mar. 17, 1781. In Copenhagen he became the idol of the literary society known as the "Danish Club," which upheld German models in opposition to Wessel's "Norwegian Club," which looked to France for instruction. He had, however, freed himself from Klopstockism. His best work, the comedy of *The Fishers* (*Fiskerne*), was written in 1778. All Ewald's writings possess an historical interest, but it is as a lyric poet that he is chiefly remembered. In this department of poetry he ranks among the greatest names of modern Scandinavian literature. His two best songs, *Kong Kristian stod ved høien Mast* (King Christian stood by the High Mast) and *Liden Gunvor* (Little Gunvor), which occur in *The Fishers*, are among the most popular of Danish lyrics. A careful edition of Ewald's works (*Johannes Ewald's Samlede Skrifter*, 8 vols.) by F. L. Liebenberg appeared 1850–55. See also A. D. Jørgensen, *Johannes Ewald* (1888).

G. L. KITTREDGE.

Ewell, *yu′el*, BENJAMIN STODDERT, LL. D.: soldier and educator; son of Dr. Thomas Ewell and Elizabeth Stoddert; b. in the District of Columbia, June 10, 1810; graduated at West Point, 1832; served while lieutenant Fourth Artillery as assistant professor at the U. S. Military Academy 1832–36; resigned, 1836; civil engineer 1836–39; Professor of Mathematics and Natural Philosophy at Hampden-Sydney College 1839–46; Professor of Mathematics and Military Science at Washington College 1846–48; acting president and Professor of Mathematics, College of William and Mary, 1848–49; Professor of Mathematics and Natural Science 1849–61; president 1854–88. He served in the Confederate army in command of the Thirty-second Regiment Virginia Volunteers 1861–62, and as adjutant-general, with the rank of colonel, to Gen. Joseph E. Johnston, while commanding the departments of Tennessee and Mississippi 1862–64. In 1874 he received the degree of LL. D. from Hobart College, N. Y. D. in James City, Va., June 19, 1894.

Ewell, Richard Stoddert: son of Dr. Thomas Ewell and Elizabeth Stoddert; b. in the District of Columbia, Feb. 8, 1817; graduated at West Point in 1840; served with distinction on the frontier and in the Mexican war as lieutenant and captain in the First Regiment of Dragoons 1840–61; resigned and served with the Confederates as lieutenant-colonel, colonel, brigadier-general, major-general, and lieutenant-general 1861–65, participating in the battles of first and second Manassas, in the latter of which he lost a leg, Front Royal, Cross Keys, Port Republic, and Cedar Mountain; assigned, on the death of Jackson, to the command of his, the Second, corps of Lee's army, which he led at the capture of Winchester, at Gettysburg, Wilderness, and Spottsylvania Court-house; relieved from duty in the field because of physical inability, and ordered to take charge of the department of Richmond; captured, on Lee's retreat, at Sailor's Creek; moved after the war to Tennessee. D. in Springfield, Tenn., Jan. 25, 1872.

Ewer, yu'er, Ferdinand Cartwright: clergyman; b. at Nantucket, Mass., May 22, 1826; graduated at Harvard, 1848; was ordained a minister in San Francisco, 1858; came to New York in 1860; became assistant minister of St. Ann's; in 1862 rector of Christ Church; but developing ritualistic tendencies he resigned, and his friends formed for him the new Church of St. Ignatius, 1871, in the same city, and he was its rector till his death. He made a great stir by his *Sermons on the Failure of Protestantism* (New York, 1869). Died while on a visit to Montreal, Oct. 10, 1883.

Ewing, yu'ing, Finis: one of the fathers of the Cumberland Presbyterian Church; b. in Bedford co., Va., June 10, 1773, of Scotch-Irish stock; is said to have studied for a time in college. He removed to a place near Nashville, Tenn., and in 1823 married a daughter of Gen. William Davidson; joined a Presbyterian church, and soon after removed to Kentucky. Awakened in 1800 to a new religious life, he was licensed to preach, and in 1803 was ordained by the Cumberland presbytery. His ordination not being recognized by the Kentucky synod, the presbytery being dissolved, and the action of the synod being sustained by the General Assembly, he with two others in 1810 formed the germ of the new Cumberland Presbyterian Church. In 1820 he removed to Missouri. D. July 4, 1841.

Ewing, James Alfred, B. Sc., F. R. S.: Professor of Engineering and writer on electro-technics, especially in the domain of magnetism; b. in Dundee, Scotland, Mar. 27, 1855; educated at the High School of Dundee and at Edinburgh University, where he graduated in science; was assistant to Sir William Thomson in telegraph engineering, then Professor of Engineering at the University of Tokio 1878–83. Since 1883 he has been Professor of Engineering in University College, Dundee. Professor Ewing is the author of an important work, *Magnetic Induction in Iron and other Metals* (1892); also of many important papers on electricity and magnetism, and upon the measurement of earthquake motion, a subject to which he gave much attention while in Japan.

Ewing, Gen. Thomas: See the Appendix.

Ewing, Thomas, LL. D.: statesman; b. near West Liberty, Ohio co., Va., Dec. 28, 1789. In 1792 he removed with his parents to Ohio. In his youth he prepared himself for college by night study, while employed in the Kanawha salt-works. In 1815 he graduated at Ohio University at Athens, receiving the first degree of A. B. ever conferred in that State. He was called to the bar in 1816; U. S. Senator from Ohio 1831–37 and 1850–51: U. S. Secretary of the Treasury (1841) under Harrison, and Secretary of the Interior under Taylor (1849). He was the father of Gen. Thomas Ewing (b. Aug. 7, 1829; d. Jan. 21, 1896), and father-in-law of Gen. W. T. Sherman. D. at Lancaster, O., Oct. 26, 1871.

Exactions [from Lat. *exac'tio*, act of driving out, forcing out, a forced contribution; deriv. of *exi'gere*, exact; *ex*, out + *a'gere*, drive]: a legal term of ecclesiastical jurisprudence, used in the Middle Ages to denote such duties or contributions, demanded by the clergy of their parishioners, as were extraordinary, either because they were new and against custom or because their amount was unduly increased. They were illicit, and it was found necessary repeatedly to denounce their unlawfulness. The power of the clergy over their parishioners, or of the bishops over the subordinate clergy, was so great that it was easy for them to make the most outrageous exactions. In 589 the third Council of Toledo forbade the bishops "exactiones diocesi vel damna infligare," and the meaning of this is more exactly defined by Leo IV., who in 853 forbade the bishops to exact from the clergy and ecclesiastical institutions of their dioceses "dationes ultra statuta patrum aut super appositæ in angariis." Yet, in 1179, Alexander III. found it necessary to repeat: "Prohibemus ne ab abbatibus, vel episcopis, aliisve prælatis novi census imponantur ecclesiis, nec veteres augeantur, nec partum redituum suis usibus appropriare præsumant."

Example-books: same as Exempla-books (*q. v.*).

Exarch [from Gr. ἔξαρχος, leader, chief]: in ancient Greece, the person who conducted the dramatic chorus during the performance, as distinguished from the coryphæus and the choregos, of whom the former was the teacher of the chorus, generally the author of the play, while the latter was simply some rich citizen who supplied the costs of the outfit of the chorus. Later on the title was used in the Eastern Church to denote the highest ecclesiastical dignity, and was bestowed on the bishops of Alexandria, Antioch, Ephesus, Cæsarea, and Constantinople, but was soon exchanged in most places for that of patriarch, though it never was wholly abolished. At present it denotes a chancellor or deputy under the patriarch in the Russian Greek Church. He travels as a delegate from the patriarch through the diocese, investigating the discipline of the monasteries and the observance of the canons, and forming a kind of court of appeals in all ecclesiastical cases arising between the clergy and the people.

As a civil officer, an exarch was a viceroy intrusted with the administration of one or more provinces. The title was given especially to the prefects who from the middle of the sixth century until the middle of the eighth governed that part of Italy which was subject to the Byzantine empire. The line began with Narses, an officer of Justinian, who reconquered Italy from the Ostrogoths. They held their court at Ravenna, combining civil, military, and often ecclesiastical authority. They appointed dukes as vice-governors for several parts of Italy, and these often made themselves independent. The exarchate was finally destroyed by the Lombards in 752; three years later Pepin of France conquered Ravenna and ceded it to the pope. The title of exarch for high civil and military officers was employed in Western Europe until the twelfth century.

Excam'bion [a doublet of *exchange*, *excambium* being the Med. Lat. form of Ital. *scambio*, subst. of *scambiare* < Lat. *ex* + *cambia're*]: in the law of Scotland, an exchange of lands, or the contract by which one piece of land is exchanged for another. The term is chiefly used in laws and treatises relating to the rights of heirs possessing lands under deeds of entail. They are empowered to exchange, or excamb, certain portions of them (not amounting in value to more than one-fourth in value of the entailed estates) for other lands contiguous to, or convenient to be held with, the entailed lands. Revised by F. Sturges Allen.

Ex cath'edra [Lat., from out the chair; Lat. *cathedra* = Gr. καθέδρα, seat]: a phrase originally applied to decisions given by popes or prelates in a solemn judicial manner. Hence it is applied to every decision pronounced by any one in the exercise of his proper authority, as a judge on the bench, etc.

Excellency [from Lat. *excellentia*, superiority, deriv. of *excel'lere*, be eminent]: a title of honor given to ambassadors, governors of British colonies, and the Governor of Massachusetts. The President of the U. S. and the governors of many of the States have the same title by courtesy. In former times it was applied only to sovereign princes.

Excelmans, ek'sel'maañ', or **Exelmans**, Remi Joseph Isidore, Baron: a French marshal; b. at Bar-le-Duc, Nov. 13, 1775. He entered the army in 1791, and became aide-de-camp to Murat in 1801. He served with distinction at Austerlitz (1805), and gained the rank of general of brigade for his conduct at Eylau (1807). In the Russian campaign (1812) he commanded a division and gave proof of much skill. He directed a corps at the battle of Waterloo (1815), after which he passed four years in exile. He was restored to his title as a peer in 1831, and became a marshal of France in 1851. D. July 10, 1852.

Excelsior Springs: city; Clay co., Mo. (for location of county, see map of Missouri, ref. 3–D); on the Ch., Mil. and St. P. Railway; 30 miles N. E. of Kansas City. It is situated in an agricultural region, and is a summer resort. Pop. (1890) 2,034; (1900) 1,881.

Exchange [with restoration of Lat. prefix *ex-*, from O. Fr. *eschange* (> Mod. Fr. *échange*): Ital. *scambio* < deriv. of Lat. *ex*, out + *cambia're*, change]: (1) a place of meeting (also called a *bourse*) of traders in any given line of business, as stock exchange, produce exchange, etc.; (2) commercial paper and the transactions to which it gives rise. Bills of exchange as a method of commercial settlement are probably of nearly coincident date with the origin of commerce. De Paw says that bills of exchange were used at Athens, and were known among the Arabs. The Abbé Raynal says they were known in the East Indies when the Portuguese first arrived there. Macpherson says there is no express mention of them in any known record until the beginning of the thirteenth century, when the pope, in the plenitude of his power as sovereign of the world, offered the kingdom of Sicily and Apulia to King Henry III. on the condition that he would drive Manfred out of it. Henry accepted it for his second son, and authorized the pope to carry on the war against Manfred at the expense of England; whereupon the pope took up large sums from the Italian merchants, who were compensated by drawing bills on the English prelates and sending agents to collect them. Owing to the balance of trade or debt between any two places, either domestic or foreign, there may be a difference of value between a given quantity of gold or silver in such places respectively. This difference is called the exchange, and it is generally expressed by a percentage on the bill that is bought for remittance. The exchange is said to be at *par* when there is no such difference, or "when a given quantity of gold in one country is convertible at the market-price into such an amount of the currency of that country as will purchase a bill of exchange on the other country for such an amount of the currency of that other country as will there be convertible at the market-price into an equal quantity of gold of the same fineness." Exchange is said to be in favor of a country when a given quantity of gold purchased in it is convertible into such an amount of the currency of another country as will there be convertible into a *greater* quantity of gold of the same fineness; and it is said to be adverse, or against a country, when the proceeds of a bill of exchange will yield in the country to which it is transmitted a *smaller* quantity of gold of the same fineness. The effective limitation, therefore, to the price of a bill of exchange designed for transmission to another country is the cost of sending gold. The exchange will ordinarily rise to the height of the cost of transmitting gold, which is made up of freight, insurance, interest, and brokerage; but if there is little gold in a country, and if the sources of supply are uncertain, it may greatly exceed that cost, especially if the balance of foreign debt be adverse. The principal circumstance which determines the cost of gold in a country is the state of its foreign account. If its exports are continuously less than its imports, it must transmit gold or silver to pay the difference.

Payments of money to be transmitted from the U. S. to France or Germany are usually made with bills of exchange drawn payable in the standard money of those countries. Remittances of money payable in other foreign countries are commonly made in bills of exchange drawn on London, the chief monetary center of the world.

The act of Congress of Mar. 3, 1873, provided that the values of the standard coins of the various nations should be estimated annually by the director of the mint, and be proclaimed on the first day of January by the Secretary of the Treasury. (See Coinage.) It also provided that in all payments by or to the treasury, whether made in the U. S. or in other countries, where it becomes necessary to compute the value of the sovereign or pound sterling, it shall be deemed equal to \$4.8665; the same rate to be used in appraising merchandise imported, when the value is by invoice in sovereigns or pounds sterling. It also provided that this rate should be used in the construction of contracts payable in sovereigns or pounds sterling; that this valuation should be the par of exchange between Great Britain and the U. S.; and that all contracts made after the first day of Jan., 1874, based on an assumed par or exchange with Great Britain of 54*d.* to the dollar, or \$4.44$\frac{4}{9}$ to the sovereign or pound sterling, should be null and void.

Soon after the passage of the act the Secretary of the Treasury issued a circular, from which it appears that by a usage dating back to an early period in colonial history the dollar had been rated as equivalent to 54*d.* sterling; the pound therefore at \$4.44$\frac{4}{9}$, or £9 = \$40. The dollar, which was the original subject of comparison, was the old Spanish silver dollar, or piece of eight reals, and the computation at the time was approximately true, as compared with the British silver money. In all transactions of exchange involving the dollar and British money the par was therefore assumed at 54*d.* to the dollar, any difference from this par being represented by premium or discount.

The true par value of the pound sterling is \$4.8665, and the fictitious par, at the assumed rate of 54*d.* to the dollar, is \$4.4444. Formerly dealers selling exchange charged a nominal premium of 9$\frac{1}{2}$ per cent. on the fictitious par of \$4.444. In appearance, exchange was heavily against the U. S., when, in truth, there was neither premium nor discount, as 9$\frac{1}{2}$ per cent. on \$4.4444 gives exactly \$4.8665. Thus, through a pure fiction, retained by usage only, and not by any law, exchange with Great Britain appeared permanently *against* the U. S., whose bonds were quoted at a fixed discount of nearly 8$\frac{2}{3}$ per cent. below their real value. The remedy for such anomalies lay in the abandonment of the false par or valuation of the moneys of the U. S. in British money, and it was to this object that the law referred to was directed. In quoting exchange on foreign countries it had never been the practice, except in dealings with Great Britain, to assume a par upon which a percentage was rated. The universal rule, except in this case, was to quote the money of the U. S. against the money of other countries. Thus on France and the franc countries, exchange was quoted in francs and centimes to the dollar; on Prussia, cents to the thaler; on Frankfort, cents to the florin; and so on. In reforming practice with Great Britain the same method was adopted, and exchange on London is now quoted as so many dollars and cents to the pound sterling. Revised by A. T. Hadley.

Exchange, Bill of: See Bill of Exchange and Exchange.

Exchequer [with false use of Lat. prefix *ex-* from M. Eng. *escheker* < O. F. *escheker*, checker-board, the checkered table on which accounts were computed, a court of revenue; a deriv. of O. Fr. *eschecs*: Ital. *scacchi*, chess (Eng. *chess* from O. Fr. *eschès*, another form of same), ultim. from Pers. *shāh*, king]: a former superior British court of record, more fully designated as the *Court of Exchequer*. See Exchequer, Court of.

Exchequer Bills: negotiable interest-bearing bills issued at the Exchequer, under the authority of acts of Parliament, as security for money advanced to the Government. The receipts of the British treasury from the ordinary sources of taxation amounted in 1891–92 to £75,604,119. The mode of collecting and disbursing sums of money so large as this may greatly enhance or diminish the burden of the taxpayers, and in a corresponding degree affect the interests of the receivers. The withdrawal of any considerable portion of the revenue from the pockets of the people and placing it in the treasury as a hoard in waiting to meet the liabilities of expenditure would very seriously affect the movements of business. The policy of the exchequer-bill system very happily obviates such disturbance of the money movement of the kingdom. The investments in these bills are almost entirely drawn from the inactive capital of business people. For such service the exchequer-bills are admirably adapted. They vary but a trifle, and when they can be had are always in demand; they never enter into the currency circulation, and rarely appear in the reports of the British money market. They are issued in denominations of £100, £200, £500, and £1,000 bills, and have ten half-yearly coupons attached stating that the bearer is entitled to the interest on the sum named, but not stating the amount of the interest, as that is fixed from year to year and can never exceed 5½ per cent. per annum. It is now usually about 2¼ per cent. At the end of each twelve months the holders may claim payment of the principal sum named on the face of the bill, but at no other time. They are used as reserves of the English banks and bankers, and may be tendered during the last six months of every year in payment of customs, excise, and other duties payable to the Government. They were first brought into use by Chancellor Montague, Earl of Halifax, at the time of the great financial difficulties attendant upon the recoinage and the over-issue of the Bank of England to the Government in the earliest years of its existence. From that time on, through two centuries, they have been so useful as to have become a prominent feature of the British fiscal system. Their normal function is to anticipate the income of those taxes which are payable only at such periods as are too distant from each other to meet the daily drafts upon the treasury. The taxes of this class amount to about the half of the annual revenue of the kingdom, and in that proportion require an artificial adjustment as to the times of answering to their current disbursement. The bills are usually made redeemable about the time the incoming taxes shall reach the treasury. One of their excellent adaptations to service is in the circumstance that they furnish the funds to the common currency by the price at which they are sold to capitalists in advance of the equivalent demand made upon the taxpayers, providing the Government, at a small rate of expense, with the avails of the internal taxes, and at the same time providing beforehand the currency for payment without affecting the general volume in the service of the business community. The U. S. has never had anything corresponding to the British exchequer-bills policy. Revised by A. T. HADLEY.

Exchequer Chamber, Court of: in England, originally a court of all the judges of the three superior courts of common law, assembled for the decision of matters of law. By 1 Will. IV., c. 70, this court was constituted the proper tribunal for the trial of writs of error from the three superior courts of common law. The judges of two of these courts always formed the court of appeal, which reviewed the decisions of the third. Error lay from this court to the House of Lords. It is now abolished and its jurisdiction in appeals is transferred to the court of appeal under the Judicature Acts. See COURTS. Revised by F. STURGES ALLEN.

Exchequer, Chancellor of the: the title of the highest finance minister of the British Government. This office is from its nature necessarily intrusted to a Commoner. When the Prime Minister is a member of the House of Commons, he sometimes holds the office of Chancellor of the Exchequer. See CHANCELLOR.

Exchequer, Court of: in England, one of the three superior courts of common law which were abolished by the Judicature Acts, this court being constituted the exchequer division of the high court of justice. It was originally established for the recovery of the king's debts and ordinary revenues of the crown. The judges of this court consisted originally of the Lord Treasurer, the Chancellor of the Exchequer, and three puisne judges, which last were called barons of the exchequer. In its later shape it became, in fact, a combination of eight distinct ancient courts. It acquired concurrent jurisdiction with the other two superior courts in all personal actions by the fiction of the plaintiff being a debtor to the king—a fiction which was abolished by 2 Will. IV., c. 39. It had exclusive jurisdiction in cases in which the royal revenue was concerned, and also had an equitable jurisdiction, which was abolished by 5 Vict., c. 5, and transferred to the court of chancery. The court at the time of its abolition consisted of six judges—viz., the chief baron and five barons of exchequer. Error lay from this court to the COURT OF EXCHEQUER CHAMBER (*q. v.*); see also COURTS.

Ireland had a court of exchequer, consisting of a lord chief baron, three barons, and a master, with the necessary clerks and other inferior officers, but it was abolished as such by the Supreme Court of Judicature Act (Ireland), 1877, being constituted the exchequer division of the high court of justice in Ireland. Scotland had, until the year 1856, an exchequer court which decided questions relating to revenues and customs, and to honors, estates, forfeitures, and penalties arising to the crown. Its authority and jurisdiction was transferred to the court of session, which was declared to be the court of exchequer in Scotland. One of the lords ordinary appointed by the crown acts as a lord ordinary in exchequer cases. Revised by F. STURGES ALLEN.

Exchequer Tallies [*tally* is connected with Fr. *tailler*, to cut]: tallies of wood by means of which, up to the year 1783, the English exchequer checked its accounts. The checking was done as follows: Seasoned wands of hazel, ash, or willow were inscribed on one side with the sum for which the tally was an acknowledgment, and on the other with the Roman characters indicative of the same sum, with the date and payer's name. Notches of varied appearance stood for various amounts. The deputy chancellor then split the stick with knife and mallet in such a way that each check was divided; and when the payer presented his tally for payment, it was first matched with its corresponding tally in the exchequer office. This ancient and clumsy device was nevertheless an almost perfect protection against forged applications for money. The old tallies were stored in the Parliament House, and in 1834 Parliament ordered them to be burned. The flues became superheated in consequence, and the building itself was destroyed.

Excipient, or **Vehicle** [*excipient* is from Lat. *exci'pere*, take up, undertake; *ex*, out + *ca'pere*, take]: in pharmacy, an inert substance used to give form and consistence to solid preparations, such as pills and *dragées*, or to give palatability and the necessary qualities for administration to any medicine. The various conserves, also honey, treacle, simple sirups, glycerin, white of egg, and mucilage of acacia, are among the most useful excipients.

Excise, ek-sīz' [by folk-etym. corruption (as if meaning a cutting out) from M. Eng. *assise* < O. Fr. *asise*, *assise*, deriv. of *asseoir* < Lat. *asside're*, sit down to; *assize* is the continuance of the correct form]: a tax on goods of home production, as distinct from customs or duties on imports. The term excise is chiefly used in Great Britain, the corresponding term in the U. S. being internal revenue. The British excise system as a system dates from the Long Parliament in 1643, duties being levied to support the army against Charles I. It was continued after the Restoration, and further extended in 1733. At the beginning of the nineteenth century taxes of this kind were widespread and oppressive. Under the leadership of Sir Robert Peel, beginning about 1844, there was a gradual abolition of the excise duty upon many articles, with the most useful results to trade. In 1849 the boards of excise, stamps, and taxes were united as commissioners of inland revenue. The present revenue of the United Kingdom from taxes of this kind is upward of £25,-000,000. The chief duties of the sort in France are those upon spirits, wine and beer, on tobacco and snuff, and on gold and silver plate, while with them may be included legacy and succession duties and stamp taxes on various commercial transactions. For similar taxes in the U. S., see INTERNAL REVENUE and FINANCE. A. T. HADLEY.

Excito-motor Action: in physiology, that variety of reflex action which, arising from impressions made at the periphery (internal or external), is first transmitted by afferent nerve-filaments to a nerve center, and thence reflected without volition along motor (deferent) nerve-filaments to a muscle, which is thereby aroused to action. For example, a sudden impression of light causes the pupil of the eye to contract; the presence of a particle of food in the glottis causes intense involuntary coughing. (See REFLEX ACTION.) Excito-motor action is peculiarly active in very young children and in many of the lower animals. In some diseases (tetanus, hydrophobia, strychnia poisoning) it is immensely increased. Chloral, belladonna, curari poison, and especially the alkaloid curaria—all appear powerfully to reduce action of this kind.

Exclusion Bill: in English history, a bill which was designed to exclude the Duke of York (King James II.) from the throne, because he was a Roman Catholic. It was adopted by the House of Commons in 1679, but was rejected by the House of Lords. See CHARLES II. and JAMES II.

Excommunication [from deriv. of Eccles. Lat. *excommunica're*, put under ban; *ex*, out of + *communica're*, communicate; *commu'nis*, common, shared]: the formal expulsion of a person from privileges religious or social, inflicted by church authority upon persons accused of misconduct or heresy. The ancient Israelites excommunicated offenders by exclusion from the camp, by "cutting off from the people," and in later times by "putting out of the synagogue." This punishment, in extreme cases at least, was a social interdict of the severest kind. Excommunication in the Christian Church was established by Christ's teachings, and by the precept and example of the apostles, and was necessary both for the self-preservation of the Church and for the spiritual and moral good of the offender. In early times—as also in the Roman Catholic and in several of the Reformed Churches at present—there was a lesser and a greater excommunication; the former a virtual suspension from Church privileges, the latter a formal expulsion. The greater excommunication in the Latin Church is less severe than the anathema. Excommunication was not unfrequently employed by the popes in former times as a punishment for refractory monarchs, and even for whole nations, but in later times it has not been so employed, the so-called excommunication of Victor Emmanuel in 1860 being merely a statement of the ecclesiastical penalties which the pope might inflict upon the invaders of the pontifical domains. In Prussia and Switzerland the excommunication of the Old Catholic priests by the Catholic bishops in 1871–73 brought on severe conflicts between the state and the Church. Excommunication is rarely resorted to in modern days in any other than the Roman Communion.

Exe, eks (anc. *Isaca*): a river of England; rises in Exmoor, in Somersetshire, flows generally southward through Devonshire, and after a course of 54 miles enters the English Channel at Exmouth. The chief towns on its banks are Tiverton and Exeter.

Execution: in civil law, the formality of signing, sealing, and delivering a deed, or of signing and publishing a will; in civil actions, the carrying out the final judgment of the court, or, more strictly, the writ directing the sheriff, coroner, or marshal to carry such judgment into effect.

Under the law of England, there were three writs in constant use to enforce a judgment for the payment of money: 1, a writ of *fieri facias*, commonly called a *fi. fa.*, directing the officer to cause to be made the amount of the judgment out of the goods and chattels of the debtor; 2, a writ of *elegit*, given by statute of 13 Edw. II., directing the officer to deliver the goods and chattels of the debtor to the creditor at an appraised value, in satisfaction of the judgment, and, if these are insufficient, to put him in possession of one-half the debtor's land till the rents and profits satisfy the judgment; 3, a writ of *capias ad satisfaciendum*, commonly called a *ca. sa.*, directing the officer to arrest the debtor and keep him in confinement till he satisfies the judgment.

The English practice has been somewhat changed in the State of New York. There are two writs of execution—one against the property, and one against the person, of the debtor. The former, which resembles the *fi. fa.*, directs the sheriff to satisfy the judgment out of the personal property of the debtor within the county, and, if sufficient can not be found, then out of his real property, and to return the writ within sixty days. The latter, like the *ca. sa.*, directs the officer to arrest the debtor and keep him in jail till he pays the judgment or is discharged according to law. Since the act of 1831 abolishing imprisonment for debt this writ is allowed in comparatively few cases, as when the debt was contracted in fraud, or the debtor has attempted to remove his property, or has violated his duty in some trust relation. Under the execution against the property the sheriff sells at public auction the real and personal property of the debtor, though a variety of articles necessary for the prosecution of a business and support of a family are exempted, as also a homestead to the value of one thousand dollars, subject to certain conditions. If the judgment is for the recovery of specific real or personal property, the execution directs the sheriff to deliver such property to the plaintiff. Many other States of the Union have closely followed the New York practice.

Although these proceedings are instituted by the party in whose favor the judgment is rendered, they are considered as the acts of the law, and the officer intrusted with their performance is responsible to the party aggrieved for any misconduct or neglect of duty.

Executive Department, The: in the U. S. Government, the branch of the public service which attends to the execution of the laws of the General Government. This department is under the direct control of the President, who is the principal executive officer. The duties of the Executive Department are the most extensive of all. It makes all civil, naval, and military appointments, and manages the army and navy, collects customs and internal revenue, sells public lands, and pays all appropriations authorized by Congress. The Secretary of State, of the Treasury, of the Interior, of War, of the Navy, the Postmaster-General, the Attorney-General, and the Secretary of Agriculture take rank next the President as officers of the Executive Department; they together constitute the cabinet, which, by usage, has become a consulting or advisory council to the President. See UNITED STATES.

Executor [Lat. *exsecu'tor*, one who carries into effect, deriv. of *ex'sequi, exsecu'tum*; *ex*, out + *se'qui*, follow]: one to whom a testator commits the execution of his last will. The will is the source of the executor's title, and the probate (or proof) of the will is merely evidence of it. As a general rule, any one capable of making a contract can be an executor. In England, an infant may be appointed executor, but can not act as such during minority. In many of the U. S. it is provided by statute that no person under twenty-one is competent to act as executor. The chief duties of an executor are to bury the deceased in a manner suitable to the estate which he leaves, to prove the will, make an inventory of his goods, collect the assets, and pay the debts and legacies. An executor has general control over the personal estate, and possesses the same property in it as the testator had when living, and the same remedies to recover it. He has no power over the real estate, unless it is given to him by the will, or unless the local law gives it to him when the personal property is insufficient to pay the debts. When he has authority given to him in a will to control the real estate, he is not deemed to act as an executor, but either as a trustee or the grantee of a power, according to the nature of the authority conferred upon him.

An executor *de son tort* is one who interferes with the goods of a deceased person without lawful authority. He has the trouble of an executor without the advantages. He may be sued as executor if any assets have come into his hands, but can not bring an action as executor.

In some States, executors are required to give bonds for the faithful discharge of their duties, and in others the probate court has a right to require them to furnish security if there is any doubt of their solvency.

Exege'sis, or **Exeget'ical Theology** [*exegesis* is Gr. ἐξήγησις, interpretation, deriv. of ἐξηγεῖσθαι, lead the way, prescribe, tell at length, explain; ἐξ, out + ἡγεῖσθαι, lead]: the first and most important part of theological science, covering the whole field of biblical literature, or all that pertains to the learned explanation of the Old and New Testaments. It originated among the Jewish rabbis, but was afterward far more extensively cultivated among the Christian Fathers, the Reformers, and the divines of all ages, and is now engaging more attention than ever before. It has received much impulse from Oriental discoveries (in Egypt, Palestine, Babylon, and Assyria) and from the advances in the knowledge of the classical and Semitic languages. It is taught as a science and practiced as an art in all theological institutions, and its results are applied from every pulpit throughout the Christian world.

I. *Kinds of Exegesis.*—(1) *Philological* or grammatico-historical exegesis is the basis on which all other interpretation and application must rest. It aims simply at the meaning of the writer according to the recognized laws of language and the *usus loquendi* at the time of composition, and according to the historical situation of the writer, irrespective of any doctrinal or sectarian bias. It implies a thorough knowledge of Greek and Hebrew, and familiarity with contemporary literature. (2) *Theological* exegesis develops the doctrinal and ethical ideas of the writer in organic connection with the whole teaching of the Scriptures and according to the analogy of faith. (3) *Practical* or *Homiletical* exegesis is the application of the well-ascertained results of grammatical and theological interpretation to the wants of the Christian congregation, and belongs properly to the pulpit, the Bible class, and the Sunday-school.

II. *Auxiliary and Supplementary Branches.*—(1) *Sacred Philology*, the science of the languages in which the Bible was originally written—viz., the Hebrew in the Old Testament (with a few sections in the cognate Semitic dialect called Chaldee or biblical Aramaic), and the Greek in the New Testament. The latter is not the classical Greek, but the Macedonian or Alexandrian dialect, with a strong Hebrew coloring (hence called the Hellenistic, because spoken by the Hellenists, i. e. the Greek Jews) and the infusion of the spirit of Christianity, which created new words or inspired a deeper meaning into old words. The New Testament Greek requires, therefore, a particular study, special grammars (i. e. Winer, Buttmann, Jr.), and special dictionaries (Wahl, Bretschneider, Wilke, Grimm, Cremer, Robinson, Thayer).

(2) *Biblical Archæology* or *Antiquities*—i. e. a systematic description of the external and internal condition of the nations among which, and the countries in which, the Bible was composed. This includes, again, the geography and natural history of Palestine and adjacent countries, the topography of Jerusalem, an account of the domestic habits, social institutions, agriculture, arts and science, religious rites, and ceremonies of the Hebrews. The material of Jewish antiquities is derived mostly from the Bible itself, but also from Philo and Josephus, the Talmud, the monumental remains from Egypt, Assyria, Babylon, and the accounts of modern explorers down to the labors of the Palestine Exploration Societies of England, Germany, and the U. S.

(3) *Biblical Criticism* is twofold—textual (also called lower) and literary (also called higher). *Textual* criticism deals with the form or letter of the Bible, and aims at the approximate restoration of the original text as it came from the hands of the authors. The autographs being lost, recourse must be had to the oldest uncial manuscripts, which date from the fourth and fifth centuries. Besides, we have partial and secondary sources of the Greek text in the very numerous Scripture quotations of the Christian Fathers (Origen, Irenæus, Eusebius, Chrysostom, Ambrose, Jerome, etc.), and the old translations (especially the Syriac Peshitta, the Latin Itala, and the improved Vulgate of Jerome). Textual criticism includes a discussion of the merits of the received text (*textus receptus*, derived from Erasmus, Stephens, Beza, and Elzevir), the principles for ascertaining the oldest and purest text, the classification of manuscripts and different readings, and a history of the printed text from Erasmus and the Complutensian Polyglot down to Lachmann, Tischendorf, Tregelles, Westcott and Hort. There is a gradual approach to an agreement among the best critics, and the conviction of the essential integrity of the primitive text has been greatly strengthened by the latest discoveries (e. g. the *Codex Sinaiticus*), the full publication of the *Codex Sinaiticus* (St. Petersburg, 1863), and the *Codex Vaticanus* (in fac-simile, 1889), and the investigations of the leading critical editors. *Literary* or historical criticism deals with the contents of the Bible and investigates the questions of authorship, and all the historical surroundings of the several books as also their collection into a collective body or canon.

(4) *Historico-critical Introduction to the Books of the Old and New Testaments* is a literary history of the Bible, and includes all the introductory information necessary for the proper understanding of its contents, as the question of the genuineness and integrity of the book, the persons addressed, the place and time of composition, the object and aim of the writer. It gives also a history of the canon or collection of the several books of the Bible into one authoritative code, distinct from all other books, and recognized as a rule (**κανών**) of faith and morals by those who receive them. The principal works on introduction are by De Wette, Hug, Bleek, Reuss, Weiss, Holtzmann, Godet, Horne, Davidson, Haverniek, Keil, Ewald, Wellhausen, Driver, Cornill. Compare also the *Bible Dictionaries* of Kitto (3d ed. by William L. Alexander, 3 vols.), William Smith (ed. with improvements by Hackett and Abbot, in 4 vols.; revised English ed., 1893, *sqq.*), Fairbairn, Winer, Schenkel, Riehm, Schaff.

(5) *Biblical Hermeneutics*—i. e. the science of the principles of interpretation, and the necessary qualifications for an expounder of the Scriptures. These qualifications are partly intellectual (familiarity with the general laws of thought and speech, knowledge of the particular languages of the Bible, sound judgment) and partly moral (freedom from prejudice, readiness to do justice to the author, sympathy with his spirit and ideas). Works by Fairbairn, Immer, Terry, Diestel, Farrar.

(6) *Biblical Theology of the Old and New Testaments* is a summing up of the results of exegesis in systematic order, and presents a full view of the teaching of the Scriptures, irrespective of the subsequent systems of denominational dogmatics and ethics derived from them. This branch of exegetical theology is of recent growth, and has thus far been mostly cultivated by continental scholars. There are also special treatises on the theology of Christ, the theology of Paul, John, and Peter. Each of the apostles, as he has his own peculiar style, represents also a special aspect of the Christian system; yet all harmonize and exhibit together the fullness of the Gospel. Compare the works of Schmid, Baur, Weiss, and Van Oosterzee on New Testament Theology; Ewald, Schultz, and Oehler on Old Testament Theology; and Wendt on the teaching of Jesus (1892).

III. *History of Exegesis and Principal Commentaries.*—(1) *Jewish* exegesis, confined to the Old Testament. It began soon after the close of the canon. It was especially devoted to the Law (the Thorah), i. e. the Pentateuch, and derived from it minute rules for the individual, social, and ecclesiastical relations. The body of these interpretations is called *Midrash*. The prevailing method of exegesis was the rabbinical or literal; it excluded all foreign ideas, and was subservient to the strict legalism of the Pharisees. But among the Hellenist (Greek-speaking) Jews, especially in Alexandria, the allegorizing method obtained favor, especially through Philo (d. about 40 A. D.), who endeavored to combine the Mosaic religion with Platonic philosophy, and prepared the way for the allegorizing exegesis of Clement and Origen of Alexandria. The Jewish rabbins of the Middle Ages cultivated grammatical exegesis at a time when the knowledge of Hebrew had died out in the Christian Church. The most distinguished among them are Ibn Ezra (d. 1167), R. Sal. Isaak or Raschi (d. 1105), David Kimchi (d. 1190), Moses Maimonides (d. 1204). Their commentaries are printed separately, and also in the so-called Rabbinical Bibles e. g. of Buxtorf (3 vols., Basel, 1618).

(2) *Patristic Exegesis.*—The first use made of the Bible in the Church was practical and homiletical. It was to the early Christians what it still is to the great mass of believers, and will be to the end of time—a book of life, of spiritual instruction and edification, of hope and comfort. Scientific or learned exegesis began when the Bible was perverted by heretics and made to serve all sorts of errors. The Greek Church took the lead. Origen (180–254), the greatest scholar of his age, a man of genius and iron industry, is the father of critical exegesis. He is full of suggestive ideas, but far from being sound. His theory of hermeneutics is untenable, and opens the way for the most fanciful and arbitrary expositions or impositions. He distinguishes three senses in the Bible, corresponding to the three parts of man: (*a*) a literal or bodily sense; (*b*) a moral or psychic sense; (*c*) an allegorical or mystic, spiritual sense. Where the literal sense is offensive, he escaped the difficulty by adopting a purely spiritual sense. The greatest commentators of the Greek Church are Chrysostom (d. 407), who in his *Homilies* explained the principal books of the Old and New Testaments, Theodore of Mopsuestia (d. 429), Theodoret of Cyros (d. 457). Among the Latin Fathers, Augustine (d. 430) is the profoundest and most spiritual, Jerome (d. 419) the most learned and critical, expounder. The latter achieved the highest merit by his improved Latin version of the Bible (the Vulgate), which remains to this day the standard version of the Roman Church. The Council of Trent forbade the interpretation of Scriptures except according to "the unanimous consent of the Fathers." But this rule, strictly carried out, would prevent all progress in theology; and besides, such a "unanimous consent" does not exist except in the most fundamental doctrines.

(3) *Mediæval exegesis* was purely traditional, and consisted of brief glosses (*glossaria*) or of extracts from the Fathers (called *catenæ Patrum*). The original languages of the Bible were almost unknown in the West, and even the first among the scholastics depended upon Jerome's version for their knowledge of God's word. The prevailing method distinguished four senses of the Scriptures: (*a*) the literal or historical; (*b*) the spiritual or mystic, corresponding to faith, teaching what to believe (*credenda*); (*c*) the moral or tropological, which corresponds to love or charity, and teaches what to do (*agenda*); (*d*) the anagogical, which refers to hope (*speranda*). The principal patristic compilations are (*a*) in the Greek Church, those of Œcumenius (d. 990), Theophylactus (d. 1007), Euthymius Zigabenus (d. 1118), and Nicephorus (fourteenth century); (*b*) in the Latin Church, Wallafried Strabo (d. 849), Thomas Aquinas (d. 1274). The *Catena aurea in Evangelia* of Thomas Aquinas has been reproduced in a scholarly English translation by Pusey, Keble, and Newman. Among the more independent biblical scholars of the Middle Ages who prepared the way for the Reformation must be mentioned Nicolaus à Lyra (d. 1340: "*Si Lyra non lyrasset, Lutherus non saltasset*"), and Laurentius Valla (d. 1465), the pioneer of biblical and historical criticism.

(4) The exegesis of the *Protestant Reformers* of the sixteenth century marks a new epoch. It is full of enthusiasm for the word of God in the Bible as the only rule of Christian faith and practice, and free from the slavery of ecclesiastical tradition. It went directly to the original Greek and Hebrew Scriptures, and furnished the best translations

for the benefit of the people, while Romanism regards the Bible as a book for the priesthood, and discourages or prohibits efforts for its general circulation without note or comments. All the Reformers wrote commentaries more or less extensive on various books of the Bible—Luther (d. 1546), Melanchthon (d. 1560), Zwingli (d. 1531), Œcolampadius (d. 1531)—but the ablest of them are Calvin (d. 1564), and his pupil Beza (d. 1605). Calvin combines all the qualifications of an expounder in rare harmony, and his commentaries on Genesis, the Psalms, the Prophets, and all the books of the New Testament (except Revelation) are valuable to this day.

(5) Protestant commentaries of the seventeenth and eighteenth centuries by Hugo Grotius (d. 1645, Arminian), Vitringa (d. 1722, Dutch Calvinist), Hammond (d. 1660, Church of England), Mathew Poole (Presbyterian, d. 1679, *Annotations upon the Whole Bible*, an English synopsis from his Latin synopsis). Matthew Henry (Presbyterian, d. 1714, the best homiletical commentator of England), John Gill (Baptist, d. 1771), Philip Doddridge (Independent, d. 1751, author of *Family Expositor*), Calovius (Lutheran, d. 1686, *Biblia Illustrata*, versus Grotius), J. A. Bengel (Lutheran, d. 1752, author of the *Gnomon of the New Testament*, in Latin, twice translated into English, an admirable specimen of *multum in parvo*). Collective works: *Critici Sacri* (London, 1660, 9 tom.; Amsterdam, 1698–1732, in 13 vols. compiled from the principal commentators as an appendix to Walton's *Polyglot*, under the direction of Bishop Pearson and others); Poole's *Synopsis Criticorum aliorumque S. Scripturæ interpretum* (London, 1669–76, 4 vols. in 5 fol., a very useful abridgment from the *Critici Sacri* and other commentators).

(6) Modern commentaries, chiefly German, English, and American: (*a*) On the whole Bible: Lange's *Bibelwerk* (Bielefeld and Leipzig, 1857, *sqq.*), a threefold commentary, critical, doctrinal, and homiletical, prepared by a number of continental, mostly German, divines, for the use of ministers and students; the same in English, with large improvements and additions by more than forty Americans scholars of all denominations, under the editorial care of Philip Schaff (25 vols., New York and Edinburgh, 1864–80; new ed. 1884, *sqq.*); *The Speaker's Commentary*, suggested by the Speaker of the House of Commons, ed. by Canon F. C. Cook, aided by a number of bishops and presbyters of the Church of England (10 vols., London and New York, 1871–82); Strack and Zöckler, *Kurzgefasster Commentar zum A. und N. Test.* (including the Apocrypha, Nördlingen, 1886, *sqq.*); other commentaries on the whole Bible by Reuss; Bishop Chr. Wordsworth; Jameson, Fausset, and Brown; Ellicott; the *Expositor's Bible*; the *Pulpit Commentary*; Butler's *Bible Work*; *The Cambridge Bible for Schools*; and Methodist and Baptist Commentaries (popular). (*b*) On the Old Testament: Keil and Delitzsch (orthodox); the *Exeget. Handbuch zum A. T.*, by Dillmann and others (critical), several editions. (*c*) On the New Testament: Olshausen, De Wette, and especially Meyer (the first philological commentator; d. 1874; continued by Weiss and others), Holtzmann, Lipsius, and others, among the Germans; Alford among the English—all for critical students. Of popular commentaries of the New Testament, Barnes has had by far the widest circulation in America and England, but is now replaced by others edited by Bishop Ellicott, Dr. Schaff (*International Commentary on the N. T.*, illustrated, New York, 4 vols.), etc. The nineteenth century has also produced a large number of exegetical works of the first order on separate books of the Bible, which it would be impossible here to enumerate. Among recent commentators on one or more books of the Old Testament, Gesenius, Ewald, Hupfeld, Hitzig, Hengstenberg, Delitzsch, Dillmann, Schlottmann, Moses Stuart, Joseph A. Alexander, Perowne, occupy the first rank. Of New Testament commentators must be mentioned Winer, Fritzsche, Tholuck, Lücke, Bleek, Harless, Heinrici, Godet, Stuart, Hodge, Stanley, Jowett, Ellicott, Westcott, Milligan, Brown, Beet, Edwards, Lightfoot, and M. R. Vincent. Among these, again, Tholuck on Romans and the Sermon on the Mount, Lücke on the Writings of St. John, Harless on Ephesians, Hodge on Romans, Ellicott on Galatians, Ephesians, Thessalonians, and Pastoral Epistles (republished in Andover), Lightfoot on Galatians, Philippians, and Colossians, Westcott on the Gospel and Epistles of John and on Hebrews, Godet on Luke, John, Romans, and Corinthians, are most useful for the critical study of the Greek Testament.

PHILIP SCHAFF.

Exempla-books [from Lat. *exem'plum*, orig., that which is taken out as a sample; from *exi'mere*, to take out, *ex-*, out + *emere*, buy, take]: collections made in mediæval times of stories introduced into sermons (usually at the close) to illustrate some precept or to arouse the attention of the congregation. The technical word employed in mediæval literature to denote a story used for such a purpose was *exemplum*. Gregory the Great used legends in this way in his homilies (before 604), but the practice did not become common until the end of the twelfth or the beginning of the thirteenth century, when the foundation of the Franciscan and Dominican orders gave a great impulse to preaching, and entirely changed its character. It became necessary to interest and amuse the common people who had gradually become accustomed to an entertaining literature more and more secular in its nature, and who possessed, moreover, an innate love for tales. St. Dominic himself, we are told, abounded in stories, and almost all who played an important part in the use of *exempta*, either by employing them in their sermons or by collecting them for other preachers, were Dominicans. The most notable exception to this rule was the eminent prelate Jacques de Vitry, Bishop of Acre, later cardinal and historian of the crusades, the date of whose death is uncertain (about 1240). He was the author of several collections of sermons (only the *Sermones in Epistolas et Evangelia Dominicatia totius anni* have been printed, Antwerp, 1575) in one of which, the *Sermones vulgares* (written probably late in life), he employed *exempla* to such an extent that henceforth their use in sermons addressed to the people became customary.

The fame of Jacques de Vitry as a preacher, and the attractive character of his illustrative stories, early led to a demand for some convenient edition of the *exempta* alone. Probably the first form was a collection of *exempta* accompanying the sermons (such an edition of the fourteenth century is in the National Library at Paris), and then of the *exempla* alone (there are a number of such independent collections as early as the thirteenth century). Subsequent preachers employed *exempla* more or less frequently, and the practice naturally led to abuses which are mentioned by Dante (*Paradise*, xxix. 103–120), and against which various councils of the Church directed edicts.

The demand for *exempta* soon led to the preparation of collections varying in size and contents. The chief sources of these collections were the *Vitæ Patrum*, the *Diatogues* of Gregory, the *Diatogus Miracutorum* of Cæsar of Heisterbach, the legends of the Church, Valerius Maximus, and the *exempta* already used by Jacques de Vitry and others. The form of these collections is usually alphabetical, and they are all anonymous. One of the most interesting is the *Alphabetum narrationum* (the anthor of this happens to be known: he was Étienne de Besançon, general of the Dominican order, d. 1294), which was never printed, although a Catalan translation of the fifteenth century was published at Barcelona in 1881, under the title *Recull de eximptis e miracles, gestes e faules e altres ligendes ordenades, per A. B. C.* With the invention of printing the numerous older manuscript collections were replaced by a few printed ones, which enjoyed enormous popularity. These were fresh compilations and not reprints of the earlier manuscript ones. Their sources were the same, and they may be divided into two classes: those containing *exempla* pure and simple, and those containing *exempla* with an application or moral appended (moralized natural history, etc.). The best of this class is the *Speculum Exemptorum*, an anonymous work first printed at Deventer in 1481, and revised in 1603 by Johannes Major, a Jesuit of Douay, who added 160 *exempta* to the 1,215 of the original work, and arranged the whole in alphabetical order, placing at the end of each *exemptum* the source from which it was taken. Besides such independent collections, several preachers took the trouble to append to their collected sermons a *promptuarium* or repository of *exempla*, the object of which was partly to enable the user of the sermons to vary the stories contained in them, and partly to afford preachers in general a magazine of illustrations. The most famous *Promptuarium* is that of John Herolt, a Dominican monk of Basel, who flourished during the first half of the fifteenth century. The arrangement is the usual alphabetical one by topics, and the work contains 114 chapters, under 20 letters, embracing 917 *exempla*, of which 283 are found in the sermons and only referred to in the *Promptuarium*.

These collections were soon imitated, and vast compilations of historical and local anecdotes arose, the most important of which are the *Promptuarium Exemplorum* of Andreas Hondorff (d. 1572), and the *Fleurs des Exemples ou Catéchisme historical* of Antoine d'Averoult, a Jesuit who died in 1614. It is interesting to note that the use of stories in sermons is still frequent enough to call for modern collections, and that a number of such, one bearing the time-honored name of *Promptuary*, have been published.

The second class of exempla-books mentioned above contains stories to which have been appended a moral conclusion or an explanation of the hidden or allegorical meaning of the story. For this class fables and parables were extensively used, as well as the symbolical interpretation of natural history. To this class belong such works as the fables of Odo of Cheriton, the *Moralizationes* of Robert Holkot, an English Dominican, the *Gesta Romanorum*, and the *Scala Celi* of Johannes Junior (his surname was Gobii, and he was from Alais, in the south of France). Of the collections devoted especially to moralized natural history may be mentioned the *Bonum universale de apibus* of Thomas of Cantimpré, a Belgian Dominican, written between 1245 and 1263, in which the peculiarities of bees are explained in an allegorical manner; and the *Formicarius* of John Nyder (d. 1458), a Dominican of Swabia, in which the ant plays the part of the bee in the work just mentioned above. Similar works by Neckam, John of Sangeminiano and Bartholomew, incorrectly called Glanville (a Franciscan, born probably in England, who lived in France and flourished between 1226 and 1248), enjoyed great popularity and are often cited in sermons.

Besides the above collections of *exempla*, with or without moralizations, there are certain systematic treatises for the use of preachers which contain large numbers of *exempla*. The earliest and most interesting is the work of Étienne de Bourbon, a Dominican of the thirteenth century, whose work, usually known as the *Liber de septem donis Spiritus Sancti*, has been partially edited by A. Lecoy de la Marche for the Société de l'histoire de France. Other works of this class are the *Liber de abundantia exemplorum*, attributed without reason to Albert the Great; the *Summa virtutum ac vitiorum*, by William Perrault, who died about 1475; Holkot's treatise on the wisdom of Solomon (*Opus super Sapientiam Salomonis*); and the most extensive and important work of this class, the *Summa Prædicantium* of John Bromyard, an English Dominican who died in 1418.

The influence of the above-mentioned collections of Latin *exempla* had a profound influence upon the vernacular literatures: some of the Latin collections were translated in their entirety, as was the case with Étienne de Bourbon, already cited, but generally the similar works in the modern languages of Europe are imitations and not translations. The most extensive of these are the Spanish *Libro de los Enxemplos* (beginning of the fifteenth century), published in the *Biblioteca de Autores Españoles*, an alphabetical collection, probably a translation, although the original has not yet been discovered, and the Catalan collection mentioned above. There are brief collections in Portuguese, Italian, French, and English, which can not be mentioned in detail here.

The collections above described contain an immense amount of material of all kinds, historical anecdotes, fables, apologues, legends, jests, popular tales, etc. Their value consists partly in the light they throw upon the history of mediæval culture, but more especially in the important part they played in the diffusion of popular tales (fables, jests, etc.). The Oriental elements brought from Syria by Jacques de Vitry and others were spread throughout Europe by the host of preachers who incorporated them into their sermons.

A full account of the use of *exempla* in sermons and of the collections for the use of preachers, as well as the imitations in the various modern languages of Europe, may be found in the introduction to *The Exempla or Illustrative Stories from the Sermones vulgares of Jacques de Vitry* (London, 1890, Folk-lore Society), by the writer of this article. T. F. CRANE.

Exemplary Damages: See DAMAGES, MEASURE OF.

Exequa'tur: See CONSUL.

Exercise [viâ Fr. from Lat. *exerci'tium*, from *exerce're*, *exer'citum*, to drive along, to busy]: activity of any part of the body having for its essential object the attainment or maintenance of a healthy degree of activity of the vital processes. So important is it to the development, growth, and sustenance of bodily and mental vigor that it is instinctively sought, and from time immemorial various games, sports, and similar measures, together with a vast number of mechanical devices, have been devised to provide it. It is a curious circumstance that there are comparatively few pleasures which do not necessarily involve activity either of body or of mind.

Exercise may be active or passive: active, when directly due to volitional effort; passive, when neither mind nor body takes active part, as when obtained by massage, electricity, or similar means practiced by another individual or by purely mechanical devices. The various forms are differently directed: some to the mind, as study, composition, chess, etc.; others to the body, as dumb-bells, Indian clubs, rowing, walking, etc.; and others both to mind and body, as in games such as lawn tennis, cricket, etc., which demand mental and physical decision and skill. Its importance to the healthy development and maintenance of both mind and body is becoming more and more appreciated, especially in respect to systematic physical exercise by those whose time is largely spent in mental labor; and instruction of this character is fast assuming a necessary part of the curricula of the leading schools, colleges, and universities. The old idea that a man can not be an athlete both in mind and body can no longer be accepted, while, on the other hand, it can not be denied that the vigor of the mind is increased by greater vigor of the body. Exercise to afford the most benefit should be conducted systematically; it should last for short periods at first, and then gradually be increased from day to day; it should be directed to those parts of the organism that most need it, and it should not be persisted in beyond a stage of slight fatigue. It is perhaps needless to state that the brain worker needs physical exercise and the bodily worker mental exercise, but it must not be forgotten that the former rarely uses all of his faculties in his labor, and that in the work of the latter only a few parts of the body may be involved. The cardinal principles in the adoption of any form of exercise are to select those which are specially directed to such parts as are, because of peculiar vocations, but little or rarely used, or to portions of the system which for some reason are illy developed, and to choose those which, other things being equal, are most agreeable to us, and which by experience yield the most good.

Where certain groups of muscles or individual muscles are weak the Swedish system of gymnastics will be found especially available. By this method the muscles are exercised systematically by compelling them to work against proper forms of resistance. Massage and electricity are also of great benefit in these cases, particularly the former, in which the muscles are pressed, pounded, kneaded, rubbed, or stroked. Such exercise favors the supply of blood to the parts, stimulating them to healthy activity and carrying away effete and detrimental waste products that tend to accumulate when the tissues are sluggish.

Nearly all forms of exercise are more beneficial if procured in the open air, and especially when the body is free from unnatural restraint by clothing. In all forms of physical exercise women should avoid wearing corsets or other articles of apparel that restrain free movements of the body or hinder in any way absolute freedom of the circulation.

Parts of the body long subjected to disuse become enfeebled, degenerated, and finally functionless. Fish kept in caves from which light is excluded soon lose their power of vision, successive generations are born blind, and after a time the offspring are born with very imperfect or even rudimentary eyes.

See PHYSICAL EDUCATION, SPORTS, ROWING, BASEBALL, FOOTBALL, LAWN TENNIS, etc. EDWARD T. REICHERT.

Exeter (in Lat. *Isca* or *Exonia*): city and seaport; capital of Devonshire, England; on the river Exe, about 10 miles from the sea, and 170 miles W. S. W. of London, with which it is connected by railway (see map of England, ref. 14–E). It is pleasantly situated on the sides and summit of an acclivity, and is well built, well paved, and liberally supplied with water. It was the *Isca Damnoniorum* of the Romans, and the coins, pottery, sepulchral urns, etc., which have been found there show that it was a place of some importance. At the time of the Saxon conquest it was not deserted by the British. When Athelstan arrived there, in 926, he found it occupied by Britons and Saxons in common. William the Conqueror appeared before the city in 1068; he founded the castle of Rougemont. Exeter is the see of a bishop, and has a magnificent cathedral, which was commenced in 1280; it is 408 feet long, and has two Norman towers 145 feet high. The W. front is richly decorated, and presents a façade which is one of the most beautiful in England. In one of the towers is the Great Tom of Exeter, or Peter's bell, which weighs 12,500 lb. Exeter contains a theater, twenty-four Episcopal churches and chapels, and an asylum for lunatics. It returns one member to Parliament. Vessels of 400 tons can ascend the Exe to this place, from which dairy produce, fruits, and other articles are exported. Exeter has several nurseries, and was at one time the center of a considerable woolen trade. In the middle of the eighteenth century the value of its annual export of woolen goods amounted to half a million dollars, and was exceeded only by that of Leeds. Its trade, though still flourishing, is now of a miscellaneous description. Pop. (1901) 47,180.

Exeter: town (founded by Rev. John Wheelwright in 1638); one of the capitals of Rockingham co., N. H. (for location of county, see map of New Hampshire, ref. 10–G); on the Squamscott river and on the Boston and Maine Railroad; 50 miles N. of Boston. It has 8 churches, the Phillips Exeter Academy (a richly endowed institution founded in 1781), the Robinson Female Seminary, 9 schools, a high school, a large cotton-mill, a machine-shop, one of the largest shoe-factories in New England, and manufactures of shoemaking-machinery, grist-mill supplies, pottery, lumber, castings, and carriages. During the American Revolution Exeter was the capital of the State and a center of military operations. Pop. of township (1880) 3,569; (1890) 4,284; (1900) 4,922. EDITOR OF "NEWS-LETTER."

Exile [from Lat. *exsi'lium*, *exi'lium*, deriv. of *exsul*, *exul*, an exile; etym. uncertain]: the condition of a person who either voluntarily or by penal sentence absents himself from his own country in order to escape the consequences to life, liberty, or property that residence at home would bring with it; also, the person who so absents himself. The Greeks in their usages and legislation were familiar with voluntary exile on account of involuntary homicide, with ostracism, a political contrivance, especially at Athens, in order to get rid of a powerful party-leader, and with exile especially for life. In the two former cases a man retained his property, and return to his native land was allowed; in the last, besides lifelong absence, he suffered the ills of confiscation of his goods. At Rome, while the republic lasted, a person, before sentence for crime, could go to a foreign country; and there were even treaties with certain states by virtue of which Romans, and *vice versa* citizens of such states, had a liberty conceded to them of living in exile in each other's country. Verres and Milo, with many others, thus left the Roman dominions to escape a sentence. Exile was also a penalty for certain crimes, or, as in the case of Cicero, was decreed by vote of the comitia. It was called *aquæ et ignis interdictio*—i. e. prohibition from the use of fire and water within certain limits. Under the empire the forms of exile in use went by the names of *relegatio* and *deportatio*. Relegation either excluded the person affected by it from a particular place or territory, or it required him to reside at a particular place or within a particular country, without depriving him of property, citizenship, or a father's power, and did not necessarily prevent his return. Deportation, called also deportation to an island, was introduced under the emperors, and involved loss of citizenship and of property. The poet Ovid was relegated, under Augustus and by an edict, to Tomi in Lower Mœsia, where he died after ten years of exile.

Exile is as a punishment unknown to English law, unless it be in the form of transportation by act of Parliament, or as a condition of release by the executive from a capital or other severe punishment.

Free countries, unless overawed by superior power, have generally given refuge to political exiles, and seldom have they delivered them up on demand from the exile's country. (See ASYLUM.) This was the boast of Athens, which Demosthenes calls the common place of refuge for Greece; he also pronounces it to be the common usage of all men to give shelter to an exile. The connection of the exile with his native land of course ceases. The jurisdiction over him depends on the laws of the land where he is domiciled. If, as sometimes happens, he engages in plots with accomplices in his native country, he is amenable to the law of his domicile for any criminal acts he may commit within its jurisdiction. Such a person is sometimes demanded by the authorities of his original home, in order to be proceeded against by its laws and modes of trial. But a free country will refuse to surrender its territorial rights in such cases. See EXTRADITION.

Exmoor Forest: a district of England, partly in Devonshire and partly in Somersetshire; mostly uncultivated, and occupied by dark ranges of hills and lonely valleys. The surface rocks are Devonian slate and new red sandstone. The highest point of the hills is 1,668 feet. Exmoor is partly covered with heath, and contains considerable meadow-land. It gave name to a breed of sheep, now nearly extinct. Area, 19,270 acres. Ponies are bred extensively, and iron is mined.

Exmouth: a town and watering-place of Devonshire, England; on the English Channel at the mouth of the Exe; 10 miles S. E. of Exeter (see map of England, ref. 14–E). The mildness of the climate and the beauty of its scenery render it a favorite place of resort. The fisheries and lace-making are the principal industries. Here Sueno the Dane landed in 1003. Pop. (1891) 8,097.

Exmouth, EDWARD PELLEW, Viscount: admiral; b. at Dover, England, Apr. 19, 1757. He served with distinction at the battle of Lake Champlain in Oct., 1776, and became a post-captain in 1782. In 1804 he obtained the rank of rear-admiral, and in 1808 that of vice-admiral of the blue. He was created Baron Exmouth in 1814, and was raised to the rank of admiral. He commanded a fleet which in 1816 was sent to enforce a treaty which the Dey of Algiers had violated. This fleet, aided by a Dutch fleet, bombarded Algiers in August of that year, and reduced the dey to submission. Exmouth received the title of viscount in Dec., 1816. D. Jan. 23, 1833. The title is extant, and in the Pellew family.

Ex'ner, FRANZ: philosopher; b. in Vienna, Aug. 28, 1802; became in 1831 Professor of Philosophy in the University of Prague, and was appointed counselor in the Austrian Ministry of Public Education in 1848. He wrote, among other works, *Die Psychologie der Hegel'schen Schule* (1842–44) and *Ueber die Lehre von der Einheit des Denkens und Seins* (1845). D. in Padua, June 21, 1853.

Exodus [from Gr. ἔξοδος, a going out; ἐξ, out + ὁδός, way]: the migration, whether by compulsion or otherwise, of any considerable body of people, as of the Moors from Spain in 1492, of the Huguenots from France after the Revocation of the Edict of Nantes in 1685, or of the Irish to the U. S. since 1847. The term is commonly applied, however, almost exclusively to the departure of the Israelites from Egypt under the leadership of Moses. The 400 years of the affliction in Egypt (Gen. xv. 13, Acts vii. 6) is doubtless a general expression, equivalent to the more specific 430 years of Ex. xii. 40, 41. But did this 430 years begin when Jacob went into Egypt, or was some other well-known event, Abraham's migration to Canaan, for instance, taken as the starting-point? The latter would be quite consonant with the Bible usage in other passages—e. g. Jud. xiv. 17, cf. 14; Num. xiv. 33, cf. Deut. ii. 14. The Septuagint translators (Ex. xii. 40, 41), the apostle Paul (Gal. iii. 17), and Josephus (*Ant.* ii. xv. 2, cf. ii. ix. 1, and *Wars* v. ix. 4) all interpret the 430 years as beginning with the migration, thus making the time of the actual sojourn 215 years. This is confirmed by Gen. xv. 16: "In the fourth generation shall they come hither again." The coming hither would be after the forty years of the exodus, added to the period of the sojourn. According to the Bible genealogies, the sons of Moses or Aaron who entered Canaan were of the fourth generation from the grandchildren of Jacob who came to Egypt (Ex. vi. 18, *seq.*). Bezalel's sons were of the seventh generation (1 Chron. ii. 3–20), and the daughters of Zelophehad of the sixth (Num. xxvi. 28–33), and the sons of Joshua, the son of Nun, of the tenth or eleventh (1 Chron. vii. 22–27), though there is here some uncertainty as to the meaning. All these are consistent with the idea of a period of 255 years, and inconsistent with that of a period of 470 years. Against this it is urged that 215 years is too short a time for the Israelites to have become so numerous as they were at the exodus. But the Bible does not represent that they were all lineal descendants of Jacob. It mentions by name "seventy souls" (Gen. xlvi. 7–27), but intimates that, in addition, those who came with Jacob were a great multitude (Gen. xii. 5, xiv. 14, xxvi. 16, xxxvi. 7, etc.). These were all participants in the covenant of circumcision (Gen. xvii. 12, etc.), and others might become so (Ex. xii. 48). Further, as Malthus says, it has been constantly remarked that all new colonies, settled in healthy countries, where room and food were abundant, have constantly made a rapid progress in population. Egypt, it is well known, was famous among the nations of antiquity not only for its animal fecundity, but also for the fertility of its human occupants. And yet the rapid increase of the Israelites in Egypt is emphasized in the history, and referred to afterward (Ps. cv. 23, 24), as something extraordinary. On the whole, it seems to be well established that the period of 430 years dates from the migration, though this is doubtless contrary to the opinions now most prevalent.

As to the points of contact between Egyptian and Hebrew history, the time has not yet come for final conclusions. Egyptian history itself is undergoing reconstruction. It may be regarded as settled that the Pharaohs of the exodus were those of the nineteenth dynasty, and that the Pharaoh of Abraham was one of the shepherd kings. It is now generally assumed that the Pharaoh of Joseph was Apophis, the last of the shepherd kings, but this is certainly at variance with Gen. xlvi. 34, xlvii. 22, xli. 45, etc. Probably the shepherd kings had lost their supremacy as early as Isaac's time (Gen. xxvi. 2). Jacob's Pharaoh may have been Thothmes III. or some other king of the eighteenth dynasty.

The Israelites dwelt principally in the Delta. Several biblical sites have been identified there by recent explorers. Opinions differ as to whether they crossed the Red Sea near the present site of Suez, or further north, near the Bitter Lakes. From Suez to Sinai the distance is about 150 miles. Their route to Sinai was probably through the Wadi Feiran. Kadesh Barnea, the point at which they first touched the borders of Palestine, and to which, after thirty-eight years of penal wandering, they returned, has been identified on the west side of the desert. If the Israelites were to be civilized by contact with another people, no better place could have been found, and on the whole no safer, than Egypt. The miracles by which they were delivered, and which attended them all the way through the desert until they were finally planted in their former home, made a profound impression upon the national character.

The date of the exodus, in years of the Christian era, is a matter of conjecture. Usher places it about 1490 B. C. A more correct computation from the Bible numerals might make it some decades earlier. The date now most commonly received is about 1320 B. C., but this is in conflict with the Bible statements, and is based on really very slight evidence. WILLIS J. BEECHER.

Exodus, The Book of: the second book of the Old Testament; so named by the Alexandrian translators of the Old Testament. The Hebrews of Palestine designated it by its opening words, *Elleh Shemoth*, "These are the words." It consists of two distinct portions; the former (chaps. i.–xviii.) describing the deliverance of the Israelites from Egypt; the latter (chaps. xix.–xl.) describing the giving of the law. Its Mosaic authorship is affirmed by tradition and attested by evidence, but denied by many eminent scholars. See HEXATEUCH. Revised by WILLIS J. BEECHER.

Exogamy: See ETHNOLOGY.

Exogenous (eks-oj'ĕe-nŭs) **Plants**, or **Ex'ogens** [from Gr. ἔξω, without + root γεν-, become, grow]: plants in which the growth of the stem is in concentric layers between the pith and the bark. See DICOTYLEDONS.

Exophthalmic Goitre: See BASEDOW'S DISEASE.

Ex'orcism [from Gr. ἐξορκισμός, deriv. of ἐξορκίζειν, to administer an oath, (in Eccles. Gr.) to drive out by adjuration; ἐξ, out, + ὅρκος, oath]: a ceremony designed to expel demons or evil spirits from persons, places, or things. Exorcisms of various kinds have been practiced from remote antiquity in nearly all nations and races. The ancient Jews, according to Josephus, the Talmud, and the New Testament, had a class of persons professing to be skilled in casting out devils. In the early ages of the Church a separate class of exorcists arose who claimed special powers of controlling evil spirits. Many ceremonies were instituted by them, and their powers were exerted not only over those possessed by the devil, but over all candidates for baptism, over the baptismal water, and other sacred things and places. In the Church of Rome there is a special order of exorcists—one of the four orders of the minor clergy. All persons in superior orders must pass through this degree. In the Greek Church a similar order exists. Exorcism is obsolete in all Protestant denominations, though formerly recognized in several.

Exosmose: See LIQUID DIFFUSION.

Exoteric: See ESOTERIC.

Exosto'sis [Gr. ἐξόστωσις, a diseased excrescence on the bone; ἐξ, out + ὀστέον, bone]: an abnormal outgrowth from one of the bones of the skeleton. In man the disease especially seats itself upon the femur or on some of the bones of the skull. In the latter case it sometimes assumes a peculiar ivory-like character (eburnized exostosis), from the presence of an excess of calcium phosphate. It is usually developed from an inflammatory exudate, and is ordinarily formed with the exact structure of true bone. The disease is commonly painless. Some classes arise from a syphilitic taint, others from a rheumatic or gouty diathesis, others from various forms of irritation.

Some writers include bony outgrowths among the tumors, but it is best to regard as tumors only the apparently causeless bony masses that occur about bones or elsewhere. Ordinarily the only cure is in ablation.

Revised by WILLIAM PEPPER.

Expansion [from Lat. *expan'dere*, *expan'sum*, spread out]: a spreading out; an increase of bulk or extent, especially under the action of internal forces. In physics the term is sometimes applied to mere increase in length (more properly, elongation or dilatation), sometimes to superficial expansion, but most frequently to increase of volume. An important cause of expansion is rise of temperature, although there are important exceptions to the law, as in the case of vulcanized rubber, of iodide of silver, of water between 0° and 4° C., of the oxide of copper and the diamond at low temperatures, and of iron above a red heat. Elongation per unit of length, when a body is heated one degree centigrade, is its coefficient of *linear* expansion; increase of bulk per unit of volume, when a body is heated one degree, is the coefficient of *cubical* expansion. The observed expansion of a liquid or gas within a containing vessel, on heating or cooling, is termed its *apparent* expansion. The *true* expansion of the fluid is obtained by correcting for the changed expansion of the vessel.

In the case of homogeneous bodies, heated uniformly, expansion takes place in all directions equally. The result is change of volume without change of form. In crystals other than of the "regular" system, and in all bodies or systems not homogeneous, expansion will not be the same in all directions, and change of form will accompany every change of temperature. The expansion of wood, for example, is greater across the grain than with it. In extreme cases (where two materials of very different coefficients are rigidly combined) the deformation on heating and cooling or under change of pressure may be so marked as to afford a means of measuring temperature or pressure. See THERMOMETER; also BAROMETER (aneroid). E. L. NICHOLS.

Expatriation [from Lat. *ex*, out of + *patria*, native country]: the voluntary abandonment of one's native country with the intention of becoming a citizen of another state. The right of a person to throw off the obligation of allegiance has been denied by eminent writers and some governments. The true view would seem to be that the power to determine when the allegiance of the citizen may cease belongs to the state of which he is a member, rather than to himself. At the same time the freedom of intercourse between nations in modern times and the interests of civilization require that the various nations should provide liberal rules by which at proper times the relation of the citizen to the state may cease, and the individual, freed from the ties of burdensome allegiance, may assume another citizenship if he so desire. In this spirit may now be found statutory declarations by leading states on this subject, as well as treaty stipulations. In the act of the U. S. Congress of July 27, 1868, § 1, it is recited that the act of expatriation is a natural and inherent right of all people, and it is enacted that any declaration or instruction or decision of any officer of the government which denies, restricts, or questions the right of expatriation is inconsistent with the fundamental principle of the government. In the United Kingdom, by 33 Vict. ch. 14, § 6, subjects in general cease to be such upon becoming naturalized in a foreign state. The laws of the various nations upon this subject are collected under the direction of the U. S. Government in a publication entitled *Opinions of the Principal Officers of the Executive Departments, and other Papers, relating to Expatriation, Naturalization, and Change of Allegiance* (Washington, 1873).

If the right of expatriation be admitted except in certain cases, such as where the person holds a public trust, or is liable to do military service, or is charged with crime, a question of practical difficulty remains as to the mode in which his election to abandon his citizenship shall be evidenced. In some countries—e. g. France and Prussia—it may be shown by the fact that the person has taken his domicile in a foreign country in such a sense that he has abandoned all intent to return to his former home. This rule is not very satisfactory, for questions of domicile are frequently very difficult of solution, as they depend upon a judicial inquiry into the intent of the party, and this in turn depends upon an examination into a great variety of circumstances, often ranging over many years. A much more convenient test is that of the British statute already cited. This provides that naturalization in a foreign country shall be evidence of an intent to renounce British citizenship. Should the former subject wish at any time to resume his relations with the United Kingdom, he can be naturalized under the laws of that country. The subject of expatriation is not so important in the domain of private law as it was formerly, when aliens were subject to serious disabilities. See ALIEN, NATURALIZATION, INTERNATIONAL LAW, and CITIZEN.

Expectorant [from Lat. *ex*, out of + *pec'tus, -oris*, breast; Lat. *expectora're* is used only in sense of banish from the mind]: a medicine which facilitates or causes the discharge of mucous secretions from the air-passages within the chest. Many balms, gums, and nauseating medicines, as well as demulcents and other drugs, are reputed to have expectorant properties. Some medicines not usually considered expectorant appear to stimulate the secretions of mucus in the air-passages, as ammonium chloride (sal-ammoniac) and potassium hypophosphite. Among the most useful expectorants are ipecac, squill, lobelia, and blood-root. These are also emetics, sedatives, and diaphoretics.

Expectoration: the act of expelling fluid or semifluid matters from the lungs and air-passages by coughing and spitting; also, the matters so expelled. The characters of the expectoration are of great importance to the physician in discriminating between various diseases. The general appearances of the sputum have lost somewhat in value as indications of different diseases, since the science of physical diagnosis and microscopic examination have made possible much more accurate means of diagnosis, but in ordinary practice the physician is still to a large extent guided by the nature of the expectoration. In ordinary "colds," or bronchitis, there is usually a somewhat frothy, mucous expectoration, becoming more yellow and purulent toward the end, but at no time of absolutely distinctive character. In the early stages of pneumonia, when the lungs are engorged with blood, small hæmorrhages are apt to occur and give to the sputum a quite distinctive "rusty" appearance. Sometimes in similar conditions of congestion of the lungs, not pneumonic, rusty sputum may occur, but in the great majority of cases pneumonia is indicated. In consumption a variety of appearances may be presented according as the disease takes one form or another; but in slow, chronic cases, and less constantly in other forms, a peculiar kind of sputum is seen. In this form occur rounded masses of yellow, purulent appearance, which do not break up, but remain as clumps when received into water, and from the peculiar appearance the name "numular," or coin-like, has been applied. In gangrene of the lungs the sputum is peculiarly offensive; in abscess it is composed of pure pus. The latter condition may also occur when abscesses in other localities, as the liver, spleen, pleural cavities, etc., break through the lung to be discharged.

The expectoration when lying in the bronchial tubes acts as an irritant, thereby causing cough and its own discharge. It is therefore not usually advisable to employ medicines to check cough, but rather to so alter the character of the secretions as to make expectoration easy. If, from the irritable condition of the bronchial mucous membrane or other cause, excessive cough be provoked, it may become necessary to apply remedies to lessen the cough. This is especially desirable when, as in old persons or the debilitated, the strength is being exhausted by constant effort.

The microscopical examination of the sputum has become of very great importance, since the means of discovering the bacillus of tuberculosis and other micro-organisms have made it possible to reach a positive diagnosis in this way. Sometimes, indeed, an incipient case of consumption may be detected before any auscultatory signs or general symptoms would indicate the onset of the disease. At the same time, the occurrence of the bacilli in the expectoration, and a knowledge of the contagiousness of consumption, point out one of the means of dissemination of the disease, and indicate, as a means of prevention, the destruction of the germs in the sputum by receiving this at once into antiseptic solutions, and, above all, preventing expectoration upon floors or carpets where the sputum may be subsequently dried and spread in the air as dust. Another micro-organism now recognized as the cause of disease, and readily demonstrated in the sputum, is the pneumococcus, or the germ of pneumonia; but its recognition is of much less practical value than that of the tubercle bacillus. WILLIAM PEPPER.

Expert Testimony and **Expert Witnesses**: See the Appendix.

Expiration [from Lat. *exspira'tio*, deriv. of *exspira're*; *ex*, out + *spira're*, breathe]: in physiology, the operation or movement by which the air that has been changed by the respiratory process is expelled from the lungs. This movement is effected partly by the elastic contraction of the lungs and the walls of the chest, which were dilated by the act of inspiration, but the resiliency of the chest-walls is greatly assisted by the action of numerous muscles, especially in forcible expiration. See RESPIRATION.

Exploits, River of: a river of Newfoundland; traverses nearly the whole breadth of the island from S. W. to N. E. It is navigable for steamers 12 miles to the rapids, and above these small boats can go to within 50 miles of the southwest coast. Its valley is level, well timbered, and abounds in game and fish, but has few inhabitants. This valley is known to contain much arable land.

Explosion [from Lat. *explo'sio*, deriv. of *explo'dere*, *explo'sum*, drive off the stage by clapping or making a noise; *ex*, out + *plau'dere*, clap the hands, stamp the feet]: a bursting with a loud report; in physics, the sudden and violent expansion of the parts of a body, caused by heat or chemical affinity. Explosions are often caused by the elastic force of steam confined in boilers, etc. The explosion of gunpowder is the result of the sudden formation and expansion of gases, into which the powder is converted by chemical agency. This term is also applied to the violent eruption or discharge of a volcano. Humboldt heard the explosion of Cotopaxi at the distance of 130 miles.

Explosives: compounds practically available in war, in mining, and in general use for the sudden development of immense force. They may be classified conveniently as nitrate mixtures, of which gunpowder is the familiar type; nitro-compounds, including guncotton and nitroglycerin, together with their very numerous derivatives; chlorate mixtures; picrate mixtures; and, lastly, the class of fulminates—chiefly useful as detonators.

Gunpowder, which was first employed in war about the year 1350, is the oldest and most generally useful of these agents. It is a mechanical mixture of potassium nitrate, carbon, and sulphur, in proportions usually varying but little from 75, 13, and 12 respectively. Purity is essential to excellence. The operations of its manufacture consist, in general terms, in very finely pulverizing the ingredients, thoroughly incorporating them, compressing them into a cake, granulating it, separating the different sizes of grain by sieves, glazing, drying, and finally removing all dust by the use of fine sieves.

In the storage of gunpowder special precautions against fire and moisture are needed. A spark, friction between hard bodies, or a temperature raised suddenly to 572° F., determines an explosion; while slight moisture, which may readily be absorbed from damp air, produces caking and deterioration. A wetting is permanently destructive to the compound. Frost produces no injurious effects, either temporary or permanent.

As gunpowder is a simple mechanical mixture, its properties may readily be varied to suit the requirements of a quick-burning or a slow-burning explosive. Its expansive power is due to two distinct causes—the sudden transformation from a solid to a gaseous form of vastly greater volume, and the heat developed by the chemical change, which induces enormous tension. It is apparent therefore that a variation in the relative proportions and condition of the ingredients, by changing the chemical products of the explosion, must affect the expansive force; and also that a similar result may be obtained by mechanical means directed to modifying the duration of the time required for combustion.

It is to a skillful application of the last method that some important improvements in gunpowder designed for heavy ordnance are due. Gen. Rodman, of the U. S. army, inaugurated a series of experiments directed to this end in 1856, and from the results of his labors the U. S. was provided in advance of European nations with an explosive suited to modern cannon. His mammoth and perforated-cake powders—the former consisting of large irregular grains, tested by two standard sieves of six-tenths and nine-tenths of an inch respectively, and the latter of hexagonal or cylindrical cakes perforated by holes—have been copied in the English pebble and pellet, and the Russian prismatic powders, by the aid of which some important improvements in artillery have been rendered possible. Pebble powder is simply pressed cake, broken into large irregular pieces and glazed. Pellet powder consists of mealed powder compressed into small blocks, of regular and sometimes indented forms, and of dimensions varying for different calibers. Prismatic powder consists of mealed powder compressed into flat, perforated cakes of hexagonal form, about an inch thick and an inch and a half on the longest diagonal. This subject is still undergoing investigation; the facts having been developed that the time of burning, and hence the strain upon the gun for a given initial velocity in the projectile, may be modified by varying the size and form of the grains, their density and hardness, and the mechanical condition of the exterior.

The next advance in the development of gunpowder was made by modifying the carbon ingredient. By replacing one-third of it by uncarbonized peat, Gen. Oliver, in 1874, was manufacturing in the U. S. a variety which when well rammed gave a higher initial velocity, with less recoil and less smoke, than the older grades, by reason of its slower rate of burning. Its color was a clear brown. Following the same line of research, brown prismatic or cocoa powder was introduced in Germany in 1882, and it soon attracted widespread attention. The carbon consisted of slightly carbonized straw; the rate of burning was much less than with black powder, giving a lower initial but a longer sustained pressure. Cocoa powder is manufactured in the U. S., the carbon consisting of about two parts of baked wood, retaining its fibrous structure, and one part of a carbohydrate, as sugar. The proportions are varied according to the grade desired. The rate of combustion at first is slow, but it increases as the grains break up, thus tending to equalize pressure throughout the bore of the gun. For further information on this subject see GUNPOWDER.

The maximum pressure of exploded gunpowder, unrelieved by expansion, has been investigated by various parties, whose results range from 7 tons to 662 tons to the square inch, the latest authorities indicating about 40 tons.

The difficulty of obtaining saltpeter in large quantities, and hence its cost, has induced many attempts to replace it by other nitrates, such as those of sodium, lead, and barium; but although good blasting powders have been thus prepared, none suited to propelling purposes have been obtained. Mixtures containing ammonium nitrate, however, have attracted attention; in part because, although objectionable from its deliquescent tendency, this salt yields only gaseous products, and hence may form the basis of a class of "smokeless" powders of which Chilworth special is the best-known type. In combination with di- or trinitrobenzole and other ingredients, it also forms bellite, roburite, and securite, which have been used in shells and commercially. They are claimed to be "flameless," and hence specially suited for use in mines dangerous from fire-damp.

Guncotton.—In 1832 Braconnet discovered that by dissolving starch in nitric acid, and adding water, a white explosive substance was precipitated, to which the name xyloidin was given. A little later, Pelouse obtained a similar compound by treating paper, or cotton or linen fabrics, with nitric acid, and named it pyroxilin. These were the precursors of guncotton, which was discovered by Schönbein in 1846, and at once excited much attention as a possible substitute for gunpowder. Adverse official reports, however, were soon made in France, the U. S., Germany, England, and Austria, and the explosive fell into general disfavor on account of its liability to spontaneous explosion, its corroding residua, and its excessively violent and irregular character, all of which unfitted it for most military uses. Baron von Lenk, a member of the Austrian commission, was not so readily discouraged. He continued a series of experiments for several years, which ultimately led to so great improvements in manufacture that in 1853 he was able to construct a successful twelve-pounder battery employing guncotton. This led to its temporary introduction into the Austrian military service, and again attracted the attention of foreign nations to the new explosive.

Baron von Lenk's system consisted in cleansing the long-staple variety of raw cotton in an alkaline wash, followed by one in pure water; thoroughly drying it; steeping it for forty-eight hours in a cold mixture of strong nitric and sulphuric acids—one part of the former to three parts of the latter by weight; freeing the resulting trinitrocellulose from the acids by a centrifugal machine, by thorough rinsing, and finally by the action of running water for a period of six or eight weeks, alternated with a boiling potash bath and hand-washing; air-drying it; rinsing it in a hot solution of potassium silicate to retard the rapidity of combustion; and, lastly, again washing and thoroughly drying it. He partially regulated the suddenness of explosion by twisting the guncotton into ropes or weaving it into cloth to secure a more uniform density. Musket cartridges were formed by wrapping the thread around wooden plugs, to prevent unequal ramming. An admixture of a certain proportion of ordinary cotton was also employed to reduce the violence of action.

In 1863 Mr. Abel, as a member of a committee appointed by the British War Office, undertook an experimental investigation into the merits of this system, and succeeded in materially improving it. Instead of the costly long-staple cotton, he employs ordinary cotton waste, which is treated with the mixed acids, one part of nitric to three of sulphuric by weight, without any preliminary process except careful drying. It is then rinsed in a large volume of water, and dried by a centrifugal apparatus three or four times. Next it is placed in a pulping engine, like those commonly used in the manufacture of paper, and reduced to a state of fine subdivision. It is then transferred, in quantities of at least 10 cwt., to a poaching-engine, where it is beaten for about forty-eight hours until it remains uniformly suspended in a large volume of warm water, continually renewed, and finally rendered slightly alkaline. It is then dried in a centrifugal machine, and molded into disks of the desired form and dimensions, which receive a pressure ranging from 4 to 6 tons per sq. inch. Up to this point the guncotton has been in a damp, and consequently entirely safe, state, and if desired it may be so stored for an indefinite period of time without losing its peculiar properties. To prepare it for use it is dried upon hot plates, freely open on every side to the air. This system of manufacture is the best known, and yields a product both uniform and safe.

In appearance, Abel guncotton consists of regular cylinders, of dimensions varying with the use proposed. It is white in color, hard to the touch, and sinks readily in water. Ignited, unconfined, by a flame, it burns with a strong blaze. Fired by a detonating fuse, or raised to a temperature of about 340° F. in a strong case, it explodes with great violence, a single ounce being sufficient to indent a plate of iron or disrupt a thin slab of stone upon which it is loosely laid. The character of the detonation varies with the fulminate employed, being most sudden with fulminating mercury. Even in a damp state, containing 20 per cent. of moisture—it may be exploded without much loss of power by a disk of dry guncotton in contact. It is believed, upon good grounds, to be free from danger of spontaneous explosion. Several governments have adopted it as the explosive best suited to submarine warfare, and have accumulated large quantities in store.

Guncotton produces little smoke, and leaves a very small residuum of solid matter, the chief products of combustion being carbonic oxide, carbonic acid, water, and nitrogen. It is unalterable in water, no matter how long submerged. It contains about 2 per cent. of moisture in its normal condition, and even when exposed to ordinary damp air it absorbs but little more—a property which gives it a great advantage over gunpowder. Chemically, the purest guncotton may be regarded as cellulose, in which three atoms of hydrogen are replaced by three molecules of peroxide of nitrogen. Thus constituted, it is insoluble in mixtures of ether and alcohol. If, however, great care has not been observed in the manufacture, less simple compounds are formed, which may readily be dissolved in these mixtures, forming collodion, much used in photography and the arts.

Guncotton does not contain sufficient oxygen to consume its carbon completely, hence some nitrate is often added to supply the deficiency. In mining this is beneficial, for the further reason that it tends to lessen the formation of a poisonous gas, carbonic oxide.

In the studies to produce a "smokeless powder" much attention has been given to nitrocotton. Trinitrocellulose treated with acetone or certain other solvents, either in a liquid or gaseous form according to the object in view, becomes plastic, and may then be either strongly compressed into sheets or plates or be forced through dies to form cords; and thus be subdivided into grains of the size required. After the evaporation of the solvent the organic structure seems to have been destroyed, leaving a dense amorphous mass incapable of detonation and exploding with but little smoky residue. Munroe's new smokeless powder, which is meeting with favor in the U. S. navy, contains trinitrocellulose as an important ingredient.

Schultze Powder.—The conversion of lignin or wood-fiber into an explosive similar to guncotton was attempted soon after the discovery of that compound, especially by Capt. Schultze, acting for the Prussian Government. His method consisted in soaking the wood—preferably alder—in water, to give it toughness, cutting it by fine saws into a kind of cross-grained veneering, and subsequently punching it into small cubes, of which the size varied with the use for which the powder was designed. The grains thus produced were boiled in a solution of soda, and afterward alternately exposed to steam and washed in a solution of chlorine to free them from resins, etc. They were next treated for several hours with mixed nitric and sulphuric acids, kept cool by constant stirring, and afterward were thoroughly washed and dried. In this state the powder is but slightly explosive, and it may be kept in store indefinitely. For use the grains must be submerged for about twenty minutes in a solution of nitrate of potassa and baryta, and then carefully dried and sifted. The necessary oxygen having been now supplied, the powder has a high explosive power. It burns with but little solid residuum or smoke, and is said to be both cheaper and stronger than common gunpowder, weight for weight. It, however, readily attracts moisture, is liable to form dust by attrition, and is more bulky than gunpowder, in the proportion of 3 to 1.

Nitroglycerin, or *glonoin oil*, was discovered in 1847 by Ascagne Sobrero, but remained unapplied to practical uses until 1864, when Alfred Nobel, a Swedish engineer, began to develop its industrial value. Since then it has been largely employed upon the continents of Europe and America. It is prepared by the action of a mixture of concentrated nitric and sulphuric acids upon glycerin introduced drop by drop. At ordinary temperatures it is an oily liquid, usually colorless if made from good glycerin, but sometimes discolored by causes not well understood. It has no odor, and is of a sweet and slightly pungent taste. It is highly poisonous, even short contact with the skin being sufficient to produce severe headache. Its specific gravity is 1·6. When first made it has a milky appearance, which ultimately disappears. Nitroglycerin incompletely freed from the acids undergoes spontaneous decomposition, is dangerous to handle, and ultimately may lose its explosive properties. When pure it congeals, as a rule, at about 40° F., and is then very insensitive to blows or detonation. At 212° F. it begins to decompose; at 365° F. it throws off yellow or reddish fumes; at 423° F. it deflagrates violently. When uncongealed, nitroglycerin may readily be exploded by concussion, which renders it quite unfit for transportation in that state. In store it should be kept in a cool place, under pure water, in open vessels, and, if practicable, in a frozen condition. For use it should be thawed very gradually by placing the can in warm water raised to a temperature not exceeding blood heat. Any leakage should be carefully avoided at all times, and emptied cans should be destroyed. Flame applied to small quantities of nitroglycerin causes it to burn with difficulty like ordinary oil, but a fulminate exploded in contact with it produces a tremendous detonation. To develop its full effect, fulminating mercury, in quantities not less than 15 troy grains, and confined in a strong copper capsule, is recommended. Its advantages as an explosive consist in its instantaneous development of force, due to the fact that, pound for pound, it produces at least three and a half times as much gas, and twice as much heat, as gunpowder; its high specific gravity, which permits the use of small drill holes; its admitting of water, or loose clay, or even air, tamping; and, finally, the facility with which it can be made upon the spot for immediate use. Its disadvantages are the severe headaches it causes to those not habituated to its use, its liability to spontaneous explosion, the dangers sure to attend its careless handling, and, especially for military uses, its unfitness for being kept long on hand, unless prepared and treated with a degree of care not readily to be secured. To these may be added the fact that its rate of explosion is not under control, which restricts its economical use to blasting in hard rock or under water. In soft rock or clay its service at equal cost is inferior to that of common gunpowder, because its action is akin to a sudden blow rather than to a continued push.

Dynamite, now the generic name of a class of explosives, was invented in 1866–67 by Nobel. It first consisted of nitroglycerin absorbed by a porous, inert solid. The percentage of the former is, of course, limited by the capacity of the absorbent. The best material is a siliceous infusorial earth found in Hanover, Germany, and known as *kieselguhr*. It is when dried a white, impalpable powder, showing under the microscope a cellular structure. It will absorb and safely retain three times its weight of nitroglycerin. Many experiments were made in Paris during the siege of 1870–71 to discover the most suitable substitute there available. Finally, a residue from the gas-works was adopted, which would take up and retain a little more than its own weight of nitroglycerin. The use of a very absorbent kind of charcoal, made by carbonizing cork, has been patented, giving an explosive named carbo-dynamite, which it is claimed will retain nine times its weight of nitroglycerin and even resist wetting. With ordinary bases water causes a separation of the ingredients.

Dynamite made from kieselguhr has the appearance and consistence of heavy brown sugar. It possesses most of the virtues of the parent nitroglycerin, with some peculiar to itself; of which the chief are exemption from liability to spontaneous explosion and to detonation from moderate shocks, both of which result from the exceedingly fine granulation of the nitroglycerin. It was formerly largely used in the U. S., especially in California, and these important advantages are now generally admitted. Kieselguhr dynamite possesses another advantage over nitroglycerin. If kept in the state of loose powder without compression into cartridges, it may be exposed to any natural temperature without losing its explosive properties when subjected to the action of a primer charged with 15 grains of fulminating mercury; and this, too, without becoming more sensitive to ordinary shocks and handling. In the form of compressed cartridges it is as inexplosive when thoroughly frozen as nitroglycerin itself. Saturated with water it loses only a very small percentage of its explosive power, but requires a primer much more powerful than those ordinarily used. Ignited by a flame, and unconfined, it burns quietly without detonation. Experiment indicates that its explosive force is not quite so instantaneous as that of pure nitroglycerin; hence in certain kinds of resisting media, where a sustained pressure is required, the mechanical work performed by three-quarters of a pound of nitroglycerin in the form of dynamite may largely exceed that produced by a full pound of the unabsorbed material. This apparent paradox actually occurs in the submarine mines usually called torpedoes. For rock-blasting dynamite should be pressed firmly home and tamped with sand.

Dynamite possesses another merit. By modifying its ingredients in judicious percentages, a certain control can be exerted over the quickness of its action, and a classification similar to that of the different grades of gunpowder, but more restricted in range, may be made. The milder grades of such explosives, whatever be their specific names, are usually designated by the prefix No. 2, the stronger being known as No. 1. The tendency in the U. S. is to use the cheaper low grades in the larger drill-holes which they entail; in Europe, the higher grades and smaller holes are preferred.

Various have been the attempts to increase the strength of dynamite by replacing its inert base with different explosive materials. Measurements have established that neither the strength nor the economic value of a dynamite is proportional simply to the percentage of nitroglycerin it contains. An explosive base, properly selected, may add enormously to the energy developed. Moreover, for each base an economic loss occurs from increasing the percentage of nitroglycerin above a certain point. Of such compounds, glyoxaline, lithofracteur, and dualin were the earlier types.

Glyoxaline was invented by Abel shortly after the introduction of dynamite. It consisted of a mixture of guncotton pulp and potassium nitrate, saturated with nitroglycerin, and was made both in a granular and a cake form. It proved to be less troublesome in handling, owing to the granules being coated with an impermeable material which reduced the tendency to produce headache, but it was never largely introduced into practical use.

Lithofracteur was devised about the same time by Prof. Engels, of Cologne. Its precise composition was not made public, further than that it consists of 525 parts of nitroglycerin, 225 parts of silica, and 250 parts of mineral bodies; and analyses of different samples have exhibited varying results. One authority (Trauzl) reports 52 parts of nitroglycerin, 30 parts of kieselguhr, 12 parts of coal, 4 parts of sodium nitrate, and 2 parts of sulphur. Others place the proportion of sodium nitrate as high as 25 per cent.; others add guncotton. Lithofracteur is a pasty substance of dark color. Like the other compounds of nitroglycerin, it burns quietly when ignited by a flame, and explodes violently when fired by a detonating fuse. Water dissolves the sodium nitrate, and thus sets free a certain part of the nitroglycerin—of course a decided disadvantage. The compound exhibits explosive properties similar to dynamite, and offers equal security against concussion. Its use heretofore has been restricted chiefly to Germany and Belgium, although it has been experimentally tried in England, and was employed by the Germans in the war with France in 1870–71. In the U. S. the type is represented by Judson powder, which is very largely used. The lowest grade contains only 5 per cent. of nitroglycerin, and its function seems to be simply a detonator of the special variety of gunpowder which forms its base. Its intensity may exceed 40 per cent. of dynamite No. 1.

Dualin was invented by Dittmar shortly after dynamite, and its use has been chiefly restricted to Germany and the U. S. The patent describes it as consisting of "cellulose, nitrocellulose, nitrostarch, nitromannite, and nitroglycerin, mixed in different combinations, depending on the degree of strength which it is desired the powder should possess in adapting its use to various purposes." A sample supplied by the inventor for trial at the Hoosac Tunnel was found by analysis to consist of 60 per cent. of nitroglycerin and 40 per cent. of washed sawdust, not treated with nitric and sulphuric acids. Trauzl reports it as consisting of 50 parts of nitroglycerin, 30 parts of fine sawdust, and 20 parts of potassium nitrate. The best variety ever manufactured is believed to be cellulose derived from poplar pulp, treated with nitric and sulphuric acids, and saturated with nitroglycerin.

Having a less specific gravity than dynamite, dualin is slightly inferior to it, bulk for bulk, in explosive energy. When thoroughly soaked in water, it can be exploded only by a very violent detonation, much exceeding that of the ordinary fuse, and even then it loses more than half its power. It congeals at about 45° F., and in this state readily explodes, becoming so sensitive to friction as to make it dangerous to tamp in cold weather. In other respects its properties resemble those of dynamite.

Nitrogelatin.—In 1876 Nobel patented a new and important nitroglycerin compound, variously known as nitrogelatin, blasting gelatin or explosive gelatin. It consists essentially of nitroglycerin solidified to a stiff jelly by the addition of from 5 to 8 per cent. of carefully prepared nitrocellulose usually of the soluble form. A temperature of about 100° F., or the addition of a volatile solvent, is required in the manufacture. As nitroglycerin contains an excess, and nitrocotton a deficiency, of the oxygen needed for complete combustion, the resulting explosive should be more powerful than either ingredient, and experiment proves this to be the case to a marked degree. In appearance nitrogelatin is an elastic translucent jelly of a pale-yellow color, having a specific gravity of 1·6. Moderate confinement is necessary to develop its power of transmitting a wave of detonation. Unlike dynamite, its sensitiveness is increased by cold, so that when frozen special care in handling is demanded. It is wholly unaffected by water, and it may be handled without producing headache. In the manufacture extreme care is needed in purifying the ingredients to avoid a tendency to decomposition or liquefaction, but this result has been attained in practice, and the explosive is recognized as both stable and safe. The addition of from 3 to 5 per cent. of camphor forms *gelatine explosive de guerre*, and materially reduces sensitiveness to high temperatures, or to shocks even as severe as the impact of a musket ball, which in the uncamphorated form usually determines ignition, if not explosion. Strong detonators are required to develop full power. Even without camphor the range of sympathetic explosion under water is very much less than with dynamite. The Austrian explosive, ecrasite, which is claimed to have given remarkable results as a charge for shells, is believed to be a modified blasting gelatin. By the addition of nitrates, with or without carbon, gelatin dynamites of various grades are formed for use when reduced intensity of action will suffice.

When the proportion of nitrocellulose is increased to about 50 per cent., and of camphor to about 10 per cent., a horn-like substance is produced, known as Nobel's C. 189, or ballistite. Rolled into sheets and suitably subdivided, this is claimed to be one of the best "smokeless" powders now known, giving good results both in small arms and in cannon. It has been officially adopted by Italy, and is largely experimented with in Germany and elsewhere. Cordite, which also has a high reputation as a "smokeless" powder, belongs to this class; as does also leonard powder, which has recently done excellent work at Sandy Hook proving ground.

Forcite.—This is the American representative of the class of gelatinized nitrocompounds to which nitrogelatin belongs. It is manufactured on a large scale in New Jersey, and has been considerably used. Several grades are in the market. The strongest contains 95 parts by weight of nitroglycerin and 5 parts of a prepared cellulose of a special kind. It resembles blasting gelatin so much in appearance and properties that no further description is necessary here. By the addition of nitrates in varying proportions forcite dynamites are formed. They contain from 75 per cent. to 30 per cent. of nitroglycerin.

Terrorite or Perunite.—This nitrocompound, the invention of Prof. Mendeleff, is one of the latest of its class. It consists of 80 parts by volume of nitroglycerin, 10 parts of nitroethyl, and 10 parts of nitromethyl, and is a colorless volatile liquid, having a specific gravity of about 1·4. By dissolving in it from 8 per cent. to 24 per cent. of pyroxilin it becomes a semi-fluid paste of progressively increasing thickness, but never attaining the consistency of a solid jelly. Official trials have shown its strength to be phenomenal, exceeding that of nitrogelatin itself by upward of one-third as roughly measured. Its fluidity and volatile ingredients are serious objections.

The Chlorates.—The violent action of potassium chlorate upon readily oxidizable substances has given rise to many attempts to employ it in the preparation of substitutes for gunpowder. Under the names of white gunpowder and German gunpowder a mixture of this salt with potassium ferro- and ferri-cyanide and sugar has long been known. Mixed with nut-galls, resins, and other vegetable substances, it has been repeatedly introduced to temporary use as Horsley's powder, Ehrhardt's powder, etc. The form best known in the U. S. consists of potassium chlorate, potassium nitrate, and crude gamboge, which, under the name of Oriental powder, or safety compound of the Oriental Powder Company, was at one time considerably employed in the oil-wells of Pennsylvania and for other blasting purposes. Its dangerous sensibility to friction, and the consolidating effect of heat upon the gum, have prevented its general use. With some of these chlorate compounds sulphur enters as an ingredient, which intensifies the chief objection against them—their liability to explode from slight friction or percussion. As a class, they have many times the explosive intensity of gunpowder, but are also more dangerous to handle. For special purposes they are extremely useful—for instance, a mixture of potassium chlorate and sulphur, formed into a paste, and dried to fit small cartridge-cases of lead, has been found to be terribly effective as a charge for explosive bullets. They may be fired with safety from a musket, but explode with great violence, even in penetrating flesh.

It is in chlorate mixtures that the most important practical application of the researches of Dr. Herman Sprengel has been made. In 1873 he published a noteworthy paper indicating a new class of explosives, formed by mixing just before use an oxidizing and a combustible ingredient, each of which by itself is non-explosive. The proportions were adjusted to cause "their mutual oxidation and deoxidation to be thoroughly complete." Solids and liquids were both discussed. Hellhoffite (nitric acid and metadinitrobenzole) is one variety of the Sprengel class; Gruson introduced it for use in shells. Turpin brought these explosives forward in France, under the name of panclastites. In the U. S. Divine patented rackarock (potassium chlorate and nitrobenzole), which constituted the bulk of the charge at the destruction of Flood Rock, New York harbor, in 1885 (107 tons to 19 tons of dynamite). This explosive, being composed of a liquid and a solid, is not dangerously sensitive to friction when fresh, and before mixing is absolutely safe to handle, transport, or store in any quantities. At Flood Rock accident revealed another merit. Water leaked into some of the cans after they were in drill holes sloping downward. With dynamite this would have dropped free nitroglycerin on the floor of the headings, and men passing would probably have caused a premature explosion. The nitrobenzole was not only harmless, but by its well-known smell attracted attention and by its color pointed out the defective holes. It was found in the investigations preceding this great blast that (*a*) in rackarock the nitrobenzole should constitute 21 per cent. of the whole weight; (*b*) that dampness in the potassium chlorate largely reduced the intensity of action, 6 per cent., 4 per cent., and 2 per cent. of water causing losses of 19, 10, and 5 per cent. respectively; (*c*) that full detonation in moderate charges was secured by two fuses each containing 24 grains of mercuric fulminate, but that in the long drill-holes relay primings were desirable; and (*d*) that the explosive as supplied was very uniform, and possessed an intensity of action about 8 per cent. greater than dynamite No. 1.

The Picrates.—Picric acid was discovered in 1788 by Haussman while treating indigo with concentrated nitric acid. Chemists have derived it from other substances, especially from carbolic acid. It has been called *amer d'indigo*, *amer de Welter*, carbonitric acid, nitropicric acid, carbazotic acid, and trinitrocarbolic acid. It is a crystalline body of a brilliant golden yellow, very bitter to the taste, and is largely used as a dye. When heated to 600° F. it detonates with violence.

The salts obtained by treating many of the bases with picric acid possess its characteristic properties; that best known is the potassium picrate. This forms golden crystals having a metallic reflection. Insoluble in alcohol, and but slightly soluble in water, it detonates violently at 600° F. Its action is akin to that of the fulminates in suddenness; and to regulate this property, Designolle has mixed it with charcoal and potassium nitrate, thus forming a compound similar to, but more powerful than, ordinary gunpowder. To obtain the maximum explosive energy, he employs equal parts of potassium nitrate and potassium picrate. For use in rifles from 12 to 20 per cent. of potassium picrate is used, with a small amount of charcoal. For cannon only from 8 to 12 per cent. of potassium picrate is employed. Under the name of *poudre Designolle* this compound has been considerably manufactured in France for military purposes, both for large guns and for torpedoes.

Brugière powder consists of an admixture of ammonium picrate and saltpeter. It is comparatively a slow powder, less liable to attract moisture than ordinary gunpowder, and yielding but little smoke. In England, Abel has experimented with a similar compound, to which he has given the name of picric powder, and which he considers especially suited for use in shells, because, although little liable to explode from concussion or friction—the great objection to the potassium picrate compounds—its effects when strongly confined are more violent than those of gunpowder.

To the class of picrates belongs mélinite, although neither its original composition (said to be fused picric acid and nitrocellulose dissolved in ether) nor its successive modifications are certainly known. It has been adopted in France as a charge for shells, and according to report has been thus fired with safety in charges exceeding 100 lb. in weight. According to the latest reports, cresilite is combined with mélinite for this purpose, in the proportion of about 3 to 1 by bulk. Lyddite, which has received considerable attention in Great Britain, is similar in composition to the original mélinite.

In the U. S. the class is represented by emmensite—the invention of Dr. S. H. Emmens. Experiments by the Government have shown it to possess decided merits, especially for use in shells. The highest grade consists of eacid and nitrate of ammonia. For the trade three grades are manufactured. The first, for ordinary blasting, consists of picric acid, sodium nitrate, and ammonium nitrate. The second for military uses in shells, etc., is composed of picric acid and dinitrobenzene, with sodium nitrate and ammonium nitrate. The third, for projectile uses, consists of picric acid, sodium nitrate, and charcoal or flour. The grade for shells has been tested by the Government with promising results. It is of a pale yellow color, and the odor of nitrobenzole is strong. It is singularly insensitive to shocks, and in intensity of action it takes rank with guncotton; but taking into account its superior density when solidly compacted it is stronger than that explosive in the ratio of about 5·5 to 3·2.

The picrate class has not been neglected in efforts to obtain a "smokeless" powder. France has led the way in this direction, but so much secrecy has been observed that few details are known. Poudre B or Vieille powder, formerly used in the Lebel rifle, is believed to contain picric acid as an important ingredient. The latest modification is known as BN powder.

The Fulminates.—The violent action and dangerous sensitiveness of explosives of this class restrict their use to a limited field. By far the most important among them is mercuric fulminate, which is the best agent known for inducing detonation in all high explosives, and which in consequence is now largely used for that purpose, either alone or mixed with potassium chlorate. Commercially, it is supplied in long copper capsules of eight grades, according to strength. They are called "detonators," and contain from 0·3 to 2 grammes of explosive. Trebles (0·54 gramme) are usually employed with low grades of dynamite, but for less sensitive explosives heavier charges are more economical even when not absolutely necessary.

Fulminate of silver is used in minute quantities in toy fireworks. Fulminate of copper is excessively sensitive to frictional electricity, being readily fired by sparks far beyond the cognizance of the sense of touch. It was formerly much used as a fuse-priming in blasting, but many accidents resulting from oversensitiveness have now banished such fuses from the market. HENRY L. ABBOT.

Exponent [from pres. partic. of Lat. *expo'nere*, set forth, expound]: in algebra, a number or symbol representing a number which, when written above and at the right hand of any symbol of quantity, indicates a corresponding power of that quantity. Thus a^3 denotes the *third power of a*, and 3 is said to be the *exponent* or index of that power; usually, though less correctly, it is called the exponent of a. Thus a^3 is merely an abbreviation of aaa, and from the definition of an exponent it follows at once that $a^{m+n} = a^m a^n$. The notation of exponents was introduced by Descartes, and being very convenient was soon extended. The convention on which the extension is based is the general truth of the above equation. Thus if the meaning of a negative or fractional exponent is asked for, on the hypothesis that the above equation shall hold for all values of m and n, it is found that since $a^m = a^{m+0} = a^m a^0$, a^0 must be a symbol for 1, no matter what a represents.

Exponential Equation: an equation involving terms wherein the unknown quantity is an exponent or constituent of an exponent. The simplest form of such an equation is $a^x = b$; one of its solutions is the logarithm of b to the base a, or, what is the same thing, the ratio of the logarithm of b to that of a, the bases being the same, but arbitrary. This is one solution only; the equation has many other imaginary roots, and is consequently transcendental. A curve in whose equation the co-ordinates appear as exponents is also called an exponential curve. The logarithmic curve is an example.

Exposition, Cotton States: See the Appendix.

Expositions, International and **Universal**: a name applied to the great public exhibitions which have been held, since the middle of the nineteenth century, in various countries, of the products of the industry and of the evidences of culture, intellectual and æsthetic, of all nations; notably, to those of London in 1851 and 1862; to those of Paris in 1855, 1867, 1889, and 1900; to that of Vienna, which was held in 1873; to that of Philadelphia, which was held in 1876; and to that of Chicago in 1893. These grand displays may be regarded as the development on the largest scale of an idea which, for the preceding fifty or sixty years, had had many less imposing manifestations—the idea that, in order to the improvement of the arts of industry, the first requisite and the most effectual incitement is to be found in acquainting a people with the actual state of those arts as they exist. These expositions, therefore, though nominally universal, comprehended in their first conception and in their earliest practical illustrations only what are called the useful arts, in contradistinction to the liberal and the fine arts; and they furthermore omitted from their scheme the evidences of that kind of moral activity which aims to ameliorate the condition of the human race by repressing vice and crime, by relieving distress, by diminishing the amount of disease, by the improvement of prison discipline, by softening the horrors of war, and by other means analogous to these; all of which have been kept more or less in view in the later. The early international expositions, moreover, omitted to provide, or at least provided only on a limited scale, for the display of animals useful to man, or of living and growing vegetables, plants, and flowers, or for illustrating the operations of the garden, the field, the farm, and the dairy. The later have given to these objects a very large portion of their space.

Public exhibitions of the products of industry were in the first instance held as marts or fairs. (See FAIR.) The earliest held not for commercial purposes, but strictly for the promotion of improvements in the useful arts, were instituted by the Society of Arts of London. This society has held such exhibitions annually since 1760. The first properly national exhibition of this kind, the first, that is to say, organized under government direction, took place in France in 1798. Since that time the French Government has given a similar exhibition every four or five years. The effect has been greatly to improve the quality and to enlarge the quantity of production in all the departments of industry throughout France.

In the U. S. exhibitions for the encouragement of agricultural or mechanical industry have long been annually held under State and county organizations, with partial aid from the State governments, in some States of the Union, and more recently in many. The Franklin Institute, founded in 1824, in Philadelphia, the American Institute established four years later in New York, and many less conspicuous though perhaps not less useful associations organized for promoting industrial improvement, have relied on public exhibitions as among the most effectual means of accomplishing their objects.
