Dr. Stimpson argues that many of those reported as cured by conservative methods, may not have been penetrating wounds, and should not be placed in that category. That seems to me, however, begging the question. Those records come from the hands of skilled and experienced surgeons; who inasmuch as they scarcely thought of operative interference when they made their diagnosis, were not swayed by any bias. The impartial observer must acknowledge that Prof. Stimpson's essay, gives no good ground for encouragement, for the future. Nothing is offered, or is demonstrated to show how the attendant dangers of laparotomy can be obviated.

Dr. Stimpson in closing his monograph, in ques-

tion gives cold comfort to those of us who look for a hopeful future, for laparotomy. He says, "In the present state of our knowledge, it cannot be said that interference or non-interference should be the rule, in practice, and the surgeon may be guided by his own convictions, and feelings, whether they lead him to seek as much good, or only as little harm as possible."

This short paragraph epitomizes the whole subject. Hence, when we are called on to deal with those terribly serious cases, we should proceed slowly and cautiously; never to advise or perform any sort of exploratory-incision in penetrating wounds of the abdomen, which may put our patient's life in further peril, and perhaps remove his only hope of escape from death, without the advice and assistance of the most skilled and experienced consultants; for it has, in more than one case, within the past few years, been a question for juries to decide, whether the deceased came to his death in consequence of a murderous assault alone, or whether surgical interference, did not deprive the victim of his only chance of recovery.

Let us hope that after another decade of years; with greater experience and extended knowledge of the pathology of those lesions, with a better appreciation of the therapeutic requirements, our results may be more encouraging.

THE PATHOLOGICAL SURGERY OF THE PERITONEUM AND ITS ENCLOSED VISCERA.

Although I have had considerable experience with traumatic lesions within the abdomen, and did the third successful laparotomy for penetrating and perforating gun-shot wound, involving the intestine in the city of New York, yet owing to a sort of traditional impression, and I believed a sound knowledge of the pathology of derangements in this region, I was loath to take up the scalpel, until I was convinced that other remedial measures, local and constitutional, were powerless, and the efforts of nature were futile. But within a year, several circumstances conspired to induce me, to take a somewhat different view of the matter. Abbé, of New York, had devised the catgut-ring, and reported successful cases of operations requiring intestinal anastomosis on the human subject.

I had the pleasure of listening to the almost unanswerable argument of Dr. J. A. Baldy, of Philadelphia, at our late convention in Newport, on the "Surgical treatment of peritonitis." Added to this my medical friends, were sending me cases, for the express purpose of having laparotomy performed.

The contagion was spreading, and I was being consulted outside of the hospital, for obscure abdominal lesions.

With the rather unanimous accord on the question of abdominal section, I began to feel that after

all, my conservatism, had gone too far, so I decided to give the next case which came under my observation, the benefit of this catching innovation. I did not have long to wait, as the very day after my arrival home from Newport a woman came to me to have laparotomy done, if necessary.

Case 1.—Patient a well nourished person, 35 years old. She had steady pain over the liver and had noticed her abdomen greatly enlarged. Dr. Hoffeimer who brought her to me suspected malignant disease of the liver. That was my conclusion after examination. Inasmuch as I could not give an absolute opinion, and she was desirous of making most any sacrifice to know, a few days later in the Harlem Hospital, I did a laparotomy, and found the liver, one solid cancerous mass. She rallied well, from the operation, which was a very simple one, but died on the evening of the second day from prostration.

Case 2.—Dr. A. C. Cox sent a man to Harlem Hospital, who had obstruction of the bowels for eight days. The fellow's general condition was good when I saw him, except for some fecal vomiting. As the doctor had exhausted the usual remedies, and sent the case to the hospital for a laparotomy, I did not have much discretion, in the matter, and went on and did an abdominal section. I found a short loop of the small intestine nipped by a thin constricting band and presuming it to be gangrenous, I cut it away, and did a circular enterorrhaphy. There was no peritonitis present. Result: patient never rallied, dying early the following morning from exhaustion.

Case 3.—A man was brought into my ward in the hospital with general-peritonitis; transferred to me, from the medical division. His general condition was very bad. On opening through the right semilunaris a perforation of the caudal appendage was discovered; but it had formed firm adhesions with the caput-coli. Everything within the abdomen was pus-soaked. Pockets of pus were found in every direction; all the viscera being bound together in one compressed mass. Recent adhesions were broken up, the abdominal cavity flushed and drained. The patient felt rather better after the operation, but died on the following day.

Case 4.—Strangulated inguinal hernia; man 52 years old. One yard one and one-half inch resected for gangrene. The man rallied well from the operation and gave every promise of recovery, but died rather suddenly on the evening of the third day. At an autopsy a leakage was found in the line of suture near the mesenteric insertion.

Case 5.—A young man having been run over by an ice wagon was brought to Harlem Hospital complaining of severe pains over the right hypochondriac region. The usual topical appli-

cations were applied. On the eighth day he was up and about and desirous of leaving the hospital. But the visiting physician thought it well for him, to remain a day or two longer. On that evening he secretly induced the orderly to give him an enema. The next day, and day following he was in great distress, from an enormously disturbed abdomen. I opened the belly on the right of the rectus abdominalis muscle and more than two gallons of bile flowed away. We found a rupture of the ductus communis choledicus near the junction of the pancreatic tube. Old adhesions were found about the seat of leakage. It was evident that nature was doing the work of repair when the strain of the large rectal injection tore up, the walling, in which nature had provided, with the result described. A cholecystotomy or a cholecystectomy was altogether out of the question, as everything was welded together by adhesive inflammation, besides, the flagging pulse warned us to desist from further manipulations. He died thirty hours after laparotomy.

Case 6.—An aged physician who had strayed away from his regular brethren, into the homœopathic camp had ailed for some time. At first he fell to treating himself with electricity,—with which he believed he could cure anything—with great diligence and regularity until his wife a most estimable and observing lady, seeing that it rather aggravated his condition made him desist, when his homœopathic *confidres* took him in hand. After a time, I was requested to assume charge of the case, when I recommended Prof. Gerster for consultation, and to operate if necessary. An exploratory incision was performed. To say it was done by Prof. Gerster is enough to warrant that no antiseptic precaution was omitted. The doctor never rallied, and died thirty hours after. On post-mortem cancer of liver was found. I should state, that at the time of operation, the gall-bladder was found greatly distended, from which nearly a hundred gall-stones were removed, of various sizes.

Case 7.—The patient was a man 30 years old; was brought in by the ambulance, for operation, for treatment of a strangulated hernia. The intestine nipped was discovered to be gangrenous in patches. Ten inches were cut away and lateral anastomosis performed with the Abbé ring. The operation was rapidly performed though it was somewhat complicated; as the splacelus involving the bowel, extended up close to the immoveable cæcum, and I was obliged to open freely the lateral abdominal wall, to make space for manipulation, and for the return of the gut, with the catgut apparatus, which was of considerable size, making a bulky, awkward mass to handle. Our man nearly sank on the table, but after his return to bed recuperated fairly well, though never fully regained consciousness, and

died the following night. On post-mortem sound union was found, over the seat of anastomosis. Not the slightest trace of septic peritonitis was present.

With this mortality record, in seven consecutive cases, it is scarcely a matter of wonder, that I am very skeptical, when I hear it proclaimed, that no delay should be made, in making an ocular inspection of the abdominal contents, in that class of cases, wherein, diagnosis is obscure, or difficult; in those, whose pathological condition, is invariably fatal, by its very nature; and especially in female diseases, which usually will yield to hygienic and constitutional measures.

It may be contended that all of my cases of last year, were surely fatal, any way. I will admit this of cases Nos. 3, 4, and 7, but not of Nos. 1, 2, 5 and 6.

Since last June I have had two cases of obstruction of the bowel, in my own practice, one of six days' and one of nine days' standing; one woman and one man, treated by non-interference, with good results, and was called in consultation in two others; one being Dr. Jas. Moran's and one being Dr. A. J. Fitzgerald's patients; one of five days, and the other, nine days; obstruction in the latter, acute peritonitis; I advised against operation and both recovered.

With our patient who died after operation for internal strangulation, the constricting band gave way very readily under the finger nail, and I am not sure that the bowel excised might not have been safely returned to the cavity of the abdomen.

In Case 5, though the gall-duct was ruptured, I do not see, why the effusion of bile, if drained away with the canula should in itself compromise life. Varoise has proved by his case that this is possible.

The peritoneum in woman, in fair health, will tolerate most any sort or degree, of mutilation in the removal of morbid growths and accumulations. But even if they do survive the operation, let us not close our eyes to the state of things which follow as a sequence, bearing in mind the proneness of the peritoneum to take on adhesive inflammation on irritation of the most trifling description, much less the violent and protracted, bruising and tearing, which is often done in the operations on the female. That this is no exaggeration is settled beyond question, by the present indications; by the collapse of the laparotomy boom, the craze which was gaining a mischievous prominence, but which is now condemned by many of its former, and most brilliant advocates. A grand future seemed to have opened for intestinal surgery; but its application to the human subject, has a very limited range.

In reporting my last fatal case of resection of the intestines, in the Academy of Medicine, I said that I had never heard of a case, in a male, in

which the patient survived an operation which entailed the resection of the gangrenous gut, in strangulated hernia. Dr. H. C. Dalton, of St. Louis, who was present, stated that Dr. Prewitt, of St. Louis, has such a case with recovery, but that it had not been reported. Since then Dr. Dalton very kindly sent me Dr. Prewitt's notes on the case. Dr. Prewitt performed the operation on November 20, 1888, removing ten inches of the intestine, and his patient left the St. Louis Hospital three weeks after the operation a well man. The doctor says "he disappeared after the operation, going on to Indianapolis, where he has done hard work constantly since with the pick and shovel, now nearly two years, and has not worn a truss."

NON-OPERATIVE METHOD OF TREATING ABDOMINAL DISEASES.

No one, I am sure, will deny, that of late, we have been going too far with operative interference in those pathological conditions peculiar to woman, neither am I satisfied that the new nomenclature of these maladies has tended to a clearer elucidation of their real pathology.

Modern authors tell us that pelvic cellulitis is a misnomer; that a localized collection of pus is not phlegmon; besides, they have given to a very simple and common variety of affections, designations, of a most complex, unpronounceable and meaningless character; to give their Greek or Latin derivations, I am sure, some who use them most frequently, could not do. But they are novel, catching, and mysterious to the simple, and unsophisticated. As a matter of fact, exclusive of those conditions, dependent on a malignant nature, and ovarian cysts of great volume, there are few diseases occasioned by pathological mutations within the peritoneum, which are not amenable to medical treatment.

Those congestive, inflammatory, and suppurative processes encountered here, can, in the vast majority of cases, be successfully managed, I believe, without the use of the scalpel. I certainly do not mean to imply that there are not cases, which may demand surgical aid, or that there are not often afflictions when this may be resorted to for temporary relief, and in shortening the course of a painful, chronic malady, but what I do insist on, is that cases within this category are very rare. If we had much doubt about this we might simply examine into what threatens to be the next panacea, which will do in woman's pelvis, what it cannot elsewhere; which will soon displace laparotomy, and which we all know, exclusive of its psychological effects, possesses little utility. However, we must admit that electricity, in some respects, has been a real Godsend, in the way of diminishing the practice of laparotomy, in those cases which rapidly cure themselves if left alone.

These being my impressions, on what I regard as the essential difference between the treatment of pathological lesions, by surgical and constitutional measures; here as in traumatism, an operation, involving the division of the perineum, should never be performed, until all ordinary remedies fail, and never without a consultation. The patient herself should also be fully informed of its immediate dangers and remote results.

CONCLUSIONS.

1. Enough has been considered in this article, to admonish us, to proceed with caution when we contemplate an operation, which involves an abdominal section.

2. The melancholy statistics, of interference in gunshot or penetrating wounds of the abdomen, must not be unheeded, and operators should proceed slowly with exploratory incisions, until the art of diagnosing and localizing lesions within the peritoneum has reached greater perfection, than at present, obtains.

3. The varied modern tests of intestinal laceration having been proven to possess no substantial value, as we are yet without means of determining whether or not the intestinal tube is wounded; where, or to what extent, and hence we are unable, to intelligently direct, remedial measures.

4. Though anæsthesia and antiseptics have been a precious boon to mankind, and have lent their aid in the entire revolution of surgery, still it does seem that our progress to-day, in dealing with serious abdominal wounds, or lesions, is but a little in advance of the eighteenth century; and this must be so, while we are in doubt, as to the nature and extent of the lesion, and have no way of estimating the degree of shock, which sundry individuals possess.

5. While in penetrating wounds of the intestine, the indications for treatment from a mechanical standpoint, are clear, to fulfil those, without compromising life, is the difficulty, which yet remains.

With the limited time allotted me and the manifold and varied pathological mutations within the peritoneum, I have been able to, but touch on a few of the most common here, situated.

I have endeavored to demonstrate that very many acute affections may be safely limited to medical treatment, without any surgical aid; though I do not ignore the fact, that in the hands of the skilled and experienced operator, many of those grave cases are the safest; and that there are not a few in which the surgeon's aid is imperatively demanded. What I wished to combat, was, that surgical should not be the only treatment, and the prevailing impression that abdominal operations are not always serious. I wished to strongly emphasize what has lately occupied my attention, viz.: that a recovery from an operation was not a cure, in any sense.

I have regarded very many of our modern operations as not only reckless mutilations but an interference, vicious, and unnecessary; which are invariably followed by most serious consequences, to the patient. I am not aware that Christian or civil law authorizes, or justifies us, in unsexing a woman, unless her life is in positive peril, or without her own and nearest relations' full consent.

It is incontestable that in these days, when the contest for bread is close; and with our profession which gives gratuitously more in the way of free service than any other, the temptation to do those operations, which pay large fees, is very great; especially when the contingent fee is always in hand, whether the case goes ill or well.

The most valuable operations are the simplest. But after all, the mere manual part, in my mind, is the inferior; as the real art, lies in knowing and recognizing when the time comes, that nature is powerless and the scalpel must be taken in hand.

A NEW ANTERIOR CHAMBER SYRINGE.

Read in the Section of Ophthalmology at the Forty-first Annual Meeting of the American Medical Association, Nashville, Tenn., May, 1890.

BY J. A. LIPPINCOTT, M. D.,
OF PITTSBURGH, PA.

At the last meeting of the American Ophthalmological Society, in a paper on "Irrigation of the Anterior Chamber," I described a syringe which I had employed in fifteen cases of cataract extraction and in two cases of hypopyon. Since that meeting I have continued this method of cleansing the anterior chamber in the two classes of cases referred to, with what I am inclined to think very favorable results.

A large majority of the cases of hypopyon which we see in Pittsburgh, judging at least from my own experience, arise in connection with cor-

neal wounds produced by pieces of coal. Whether owing to some malignant quality in this substance, or to malnutrition incident to the occupation of the miner, hypopyon thus originating is a very serious affection, and its tendency is to destroy the function and even the appearance of the eye. Notwithstanding the most conscientious application of the usual remedies, viz.: bichloride of mercury, atropine or eserine or both, hot water, the actual cautery, and incision of the cornea, the morbid process is apt to lead to large anterior synechiæ, abolition of the anterior chamber, and more or less flattening of the globe. In these cases there is nearly always plastic iritis with the formation of masses of degenerated lymph, mixed with pus, which adhere with great tenacity to the intraocular tissues, and require for their dislodgment the introduction of some form of instrument into the eye.

These accumulations are removed by the syringe in a very satisfactory manner. I am in the habit of introducing the nozzle through a moderately large corneal incision, and then letting the current run steadily until the chamber is perfectly cleared, in the meantime moving the nozzle about in various directions, especially directing the stream against that part of the inner corneal surface which is opposite the area of ulceration, and even rubbing this surface with the smooth tip of the nozzle. At the same time I do not hesitate to break up by means of the nozzle all iris adhesions which do not seem very resistant. After the anterior chamber is thus thoroughly cleansed, the ulcerated surface is well cauterized, and the usual treatment instituted. Surprisingly little reaction follows the operation, and the results are better than I formerly ventured to hope for in the form of hypopyon in question.

I am strongly inclined to believe that the introduction, or rather reintroduction, by McKeown and Wicherkiewicz, of the practice of washing cortical remains out of the anterior chamber in the operation for cataract, marks a distinct advance in ophthalmic surgery. During the past year and a half I have made use of this procedure in forty-nine out of fifty-two extractions; and, although my statistics are not yet ready for publication, I may say that the results obtained appear to fully justify the adoption of the measure. In the whole series there was no serious case of inflammation following the operation, certainly none that militated against a good result. There was one case of failure due to escape of fluid vitreous produced by the violent restlessness of the patient, who was withal extremely deaf. But even in this case there was no reaction, and at the end of a week all the external appearances were those of a perfectly successful operation. The healing process in the other cases was so uniformly smooth as to scarcely cause me an anxious thought.

The visual acuity obtained was, from the standpoint of my own experience at least, unusually good, and this without the necessity of resorting (except in a few cases) to a secondary operation on the capsule. For example, $\frac{2}{30}$ and better was reached in about 50 per cent. of the cases without subsequent discission. In a large proportion of those with visual acuity less than $\frac{2}{30}$, the defective sight was not due to opacity of the capsule, but to opacities of cornea and vitreous, and various pathological conditions in the fundus, such as atrophy of the optic nerve, choroidal disease, etc., all of which could be as accurately studied as if the lens had been removed in its capsule.

While it is true that good instruments are not the only requisites for a good operation, it is also emphatically true that, in ophthalmic surgery at least, good instruments are essential to the accomplishment of the best work, and the matter of irrigation forms no exception to the rule. I may be permitted to quote from the article referred to the following passage giving the tests to which a good syringe should respond: "1. It should be easily made aseptic and kept so. 2. It should always be ready for use or capable of being quickly made so. 3. It should be easily handled, and its movements readily and absolutely controlled with one hand alone, the other being free for other purposes. 4. Its ejecting force ought to be capable of being accurately estimated and regulated. 5. It should not throw bubbles of air into the eye."

These requirements I venture to think are met by the syringe which I present for your inspection to-day, and very imperfectly by any other instrument which I have seen described. Piston syringes (used by McKeown) are not easily kept aseptic, are often out of order, are not easily and safely manipulated, especially with one hand, and their ejecting force cannot be accurately gauged. Syringes made on the principle of the *compte-gouttes*, like De Wecker's, are not easily kept aseptic, the force of the current is not fully under control, it is easy with them to inject air, and moreover, as pointed out by Wicherkiewicz, they may exercise suction on the intraocular tissues. In my judgment, one of the best syringes is that of the last named author, and was described at the Heidelberg Congress in 1887. It consists of a pretty large glass bulb with a nozzle attached. The liquid is forced out by condensing the air over it by means of two rubber bags arranged exactly as in the double hand-ball atomizer for producing continuous spray. The only objections I make to this syringe are that it must be awkward to manipulate, and the force of the current must be an unknown quantity.

The syringe which I have used during the past year is a modification of that described in the paper referred to the beginning of this article. A small reservoir is fixed by a metal framework to

the upper end of a hollow hard rubber handle, through which runs a piece of rubber tubing attached at its upper end to the reservoir, while the lower is armed with a curved gold nozzle which fits firmly into the lower end of the handle and is removable at pleasure. The current, whose force depends on the height of the column of liquid, is retarded or stopped by pressing a short metal piston down upon the tubing with the index finger. The length of the whole apparatus is about eleven inches. In using the instrument no assistant is required, and for washing out cortical remains, the current is as strong as is consistent with safety. In hypopyon cases, however, we may require, and it is perfectly safe to use, a much stronger current; and for them I use the original form of the instrument with a longer bit of tubing and a larger reservoir, the latter being held by an assistant, or attached by a sliding clasp or ring to an upright post. It is safer to have two distinct instruments, one for cataract and the other for hypopyon cases.

Actual Size.

THE PRIX BÉHIER.—The Faculty of Medicine of Paris have authorized the acceptance of 30,000 francs, a legacy from Madame Béhier, the income of which is to go to furnish a biennial prize to be known as *Prix Béhier*, for work in medical pathology.

FEEDING THE YOUNG.

Read in the Section of Diseases of Children at the Forty-first Annual Meeting of the American Medical Association, at Nashville, Tenn., May, 1890.

BY O. H. PHELPS, M.D.,
OF BLOCKSBURY, CAL.

It goes without saying that a large majority of the children who die under the age of 5 years perish from diseases of the alimentary canal, and in large cities the rate of mortality is such that even Maltheus would doubtless call a halt. That other causes than bad feeding come in for a share in the work of fatality we will not deny, neither will we discuss them in this paper. That bad feeding is the principal cause is fully borne out by the writer's observation and experience.

What is bad feeding? Mother's milk when the mother is herself badly fed all through the period of gestation and lactation; when her alimentary canal contains more or less fermenting material from excess of undigested hydrocarbons; and her whole dietary lacks tissue building material to fairly support her own body, much less that of her child. A hungry man is quarrelsome and discontented—see the Irish people fed on potatoes. An under-fed mother is weak, nervous and fretful, and the effect of this alone is often disastrous to her child. The writer recalls a case where the child several times nearly perished in convulsions caused by an explosion of anger in the mother who was badly fed, weak, and nervous. He advised weaning the child and the trouble ceased.

We will not discuss the proper feeding of the mother here, but would refer to a little book by Dr. E. Cutter, of New York, "Food in Motherhood," which we heartily commend for its treatment of this important subject.

A very common practice prevails among all classes of people of feeding solid food to infants 2 months old and upward. Sometimes they commence younger. That the digestive organs are not sufficiently developed to digest solid food is indicated by the lack of teeth to masticate with. And this may be taken as a safe guide as to the proper time to commence giving solid food. And if the child is bottle fed, sugar is usually added to the milk to assist in the alcoholic and acetic acid fermentation, and as a logical sequence of such outrageous feeding nature throws up the sponge and the doctor is called who often has to follow suit. Emaciation, colic, acrid dejections passing through the bowels, a burning seething liquid mass, only a little less irritating than molten lead.

How shall we feed to avoid all this?

First, don't give mother's milk, if it is bad milk. Don't ruin the child's digestion by persistent nursing when it is evident the mother cannot furnish good milk. Don't give impure cow's milk, and good or bad don't put sugar in it.

Don't put starchy food into the child's—shall I say yeast pan?—unless you want more yeast, more colic, more cholera infantum, more dead babies.

Pure cow's milk sterilized will usually be well borne, if the digestion has not previously been ruined. This failing give beef essence and pepsin.

The writer has usually had indifferent success with the so-called infant foods of the shops. A child that can digest the best of them can as well or better digest a gruel, made of milk slightly thickened with meal made from twice baked bread. The bread made of entire wheat flour, is best when it comes with the advantage of cheapness and known purity, which cannot always be said of commercially prepared infant foods. There are some nice formulas for taking out a portion of the caseine from cow's milk and otherwise making it as near like mother's milk as possible; all of which are good on paper, but often very impracticable to be carried out, among the majority of the clientele of the busy practitioner. Some cases from practice will illustrate some of the results of bad feeding and their treatment.

Case 1.—Hattie C., *æt.* 2 years. I was called February, 1878. Was met with a diagnosis from the mother, "Doctor, my little girl has worms and we want some medicine to remove them, our remedies have failed." Child anæmic, bowels bloated and constipated, weak, nervous and fretful; sleepless and occasional slight convulsions; breath sour and tongue coated. "What does she eat?" "Appetite poor, but eats of everything the family has: potato, turnip, of which she is especially fond, bread, coffee, etc." Treatment, a mild cathartic to unload the bowels. All solid food strictly prohibited, and lime water and milk *ad libitum*. Child improved rapidly and mother rejoiced at so rapid recovery. At a subsequent visit mother inquired when she could let the child eat everything. "Not till she is 5 years old." Counseled her to keep her on milk.

Was called again in April. Child in same condition as at first, and with a woeful face the mother declared the worms were at work again, and while relating the sad tale the little subject came in from the kitchen with the worms in both her hands—cold cooked turnip which she was eating with a zest. The former course was repeated, and the child made a good recovery.

Case 2.—Mrs. H., brought her infant of 3 months on a pillow from her home twenty miles away. At first sight it seemed almost moribund, and had hardly strength to make its pitiful wail audible. It was a bottle-fed baby, and plenty of sugar had been added to the milk and oatmeal gruel that it was fed on. The child was emaciated almost to the last degree, and in constant pain. Took the bottle often and would be quiet

for a while after feeding, or as long as the carbonic acid from the fermentation acted as a soporific. Bowels very loose, discharges green, foaming and acrid, making surface raw wherever in contact. Took away all food for eighteen hours and gave warm water and salicylate of soda, then gave sterilized milk from which most of the caseine had been removed, and lime water. On the fourth day gave in addition a little beef extract. In ten days the child was taken home much improved, and was soon able to digest plain milk. Sugar was prohibited. Child made rapid recovery, and when last seen, five months ago, was a fine vigorous boy.

Case 3.—Willie M., *æt.* 2 years. March, 1888, child pale and anæmic, tongue coated, breath sour, bowels loose with green, acrid discharges; had constant cough. Parents alarmed, thinking it had consumption. Could not take milk; was fed on oatmeal and sugar, potatoes and bacon, in fact anything its vitiated appetite craved. Treatment: positively prohibited all starchy foods; gave beef essence and pepsin for a week, then added sterilized milk and lime water. Cough soon ceased. Bowels became natural and digestion improved. Made rapid recovery.

These will suffice to illustrate some of the conditions brought on by bad feeding. Very little medicine is needed in most cases. When indicated pepsin and salicin may be given. It is also desirable to flush the colon with warm water frequently.

The proper food is milk up to 2 or 3 years of age, after that bread made from entire wheat flour (fine wheat flour is deprived of most of the tissue building material contained in wheat), milk, eggs, lean beef and mutton, fruit without sugar; in fact sugar not at all.

Such a course will give less work to the undertaker, dentist and doctor.

CLINICAL OBSERATIONS ON VAGINAL TOTAL EXTIRPATION OF THE UTERUS FOR CANCER.

Abstract of a paper read at the Forty-first Annual Meeting of the American Medical Association, Nashville, Tenn., May, 1890.

BY CHAS. A. L. REED, M.D.,
OF CINCINNATI, O.

In presenting this paper I desire to avoid all controversial questions as to the justifiability of vaginal extirpation of the uterus for cancer, but I shall proceed upon the presumption that, by a consensus of advanced professional opinion, it is looked upon as a fixed operation in surgical practice. It shall be my future purpose to discuss some clinical features of the cases requiring this operation, and to call attention to some features of technique.

My observations are based upon an experience

in eleven cases—nine recoveries and two deaths—but one of which can justly be called primary. The first case was operated upon Nov. 27, 1887, the last, April 28, 1890. There has been recurrence but in two cases; one that of a woman 48, who was operated upon Jan. 11, 1888, after sixteen months' previous duration of the disease, had recurrence after twenty months; the other, that of a woman aged 40, who was operated upon only six weeks ago, after six and a half months' previous duration of the disease, and in whom lateral infiltration of the broad ligaments was discovered only after the operation was begun. This case can not be justly called one of recurrence but an incomplete removal of the disease.

It has been my experience that one of the chief difficulties encountered in the successful management of these cases is the failure to get them for operation early. All of my cases have been above 32 years of age, and in nearly all of them I have discovered that delay in consulting a physician has occurred in consequence of the belief of the patient that her "irregularity of menstruation" as she generally calls it, implies only "change of life." When she finally consults a physician and is informed of the nature of the disease, she repels the suggestion with the remark that it can't be true because she has never suffered pain; and in many instances the physician himself is disconcerted by the observation. The idea that pain is an essential symptom of cancer of the uterus is promulgated in many of our text books and is firmly rooted in the general profession. The result is that in the absence of any complaint of pain medical men are often induced to indulge in fatal delay before making the examination which is necessary to establish the diagnosis. These cases, when examined are generally so easily made out, particularly when the aid of the microscope is invoked, that failure to diagnose them in time for successful operation can hardly occur.

The attainment of the highest success with this operation must come from early interference, a mastery of refined technique, and careful attention to the details of after treatment. A moment's thought can with propriety be given to the question of early operation. It is unnecessary to dwell at length upon the imperative importance of interference before the peri-uterine structures become involved, for I believe all operators recognize the fatality of the operation after the disease has passed beyond the limits of the uterine tissues proper. There is another consideration, however, which is not generally taken into account, viz., the induced anæmia. This state of the blood occurs from two causes, viz.: 1. Direct drain by uterine hæmorrhage, and (2) interference with the blood making function through inhibited vaso-motor activity, the result of a persistently depressed mental state. But from what-

ever causes induced, the depleted state of the circulation puts the patient in the worst possible condition to spare the comparatively small amount of blood lost and reduces her nervous resistance to such a point as to make her an easy prey to shock. One of my fatal cases died from shock within three hours after a short and almost bloodless extirpation, and I am forced to conclude from a not very extensive research that the majority of all cases that die under the perfected operation succumb, not to hæmorrhage, as was true but a few years ago, but to shock.

The preparatory treatment to which I subject my patients is designed chiefly to overcome this very condition. I endeavor to arrest the waste by the use of the vinegar douche or the vinegar tampon, and sometimes by curretting to the extent of removing the bleeding soft tissue. I at the same time keep the bowels gently open, and force the diet. This course persisted in for from a few days to a week or two places my patient in a reasonably good condition for the operation.

The operation itself requires but few instruments. The one that I particularly value is the Jones' speculum, a self-retaining perineal retractor, which enables one to operate with the patient in the much desired lithotomy position. A strong vulsellum forcep, a pair of pointed scissors slightly curved on the flat, and four ordinary Wells' large forceps complete the essential outfit. I also have at hand some silk and a pair of Hagedorn needles.

The best anæsthetic in these cases is chloroform, which is less likely than ether to cause vomiting and consequent extrusion of omentum and bowel.

The patient is now placed in the lithotomy position, the perineal retractor inserted, and the vagina carefully washed out with a 1 to 1,000 bichloride solution. The cervix is now seized with the vulsella and drawn well down, care being taken to note the vesical margin. With the scissors a dissection is rapidly made around the cervix, but only through the mucous membrane. This dissection is then carried into the peritoneal cavity anteriorly the tissues being generally separated by the finger. If the peritoneum persists in receding from the tip of the finger, as often happens, that membrane can be opened by a thrust of a pair of closed forceps. A similar dissection is then made posteriorly. These two dissections are now carried by the fingers to near the broad ligaments on either side. With the finger of my left hand introduced into the posterior incision and hooked over the right broad ligament that structure is drawn and clamped. I now release the uterus by dissection with the scissors on the right side, and draw it out of the vulva. The clamping of the left side is now a matter of convenience. If the appendages are within easy reach I bring them, too; if not, I leave them.

Many surgeons think it necessary to close the aperture but I think no one now endeavors to do so by sutures. In some cases in which I have feared protrusion of the bowel I have taken a small hæmostatic forcep and lifted up the posterior flap against the anterior raw surface and have packed it with antiseptic gauze. The dressing should, of course, be removed at the end of twelve hours, by which time agglutination will generally have taken place. I have consumed forty minutes in the operation and I have done it in eighteen minutes.

THE SCIENTIFIC ASPECTS OF MEDICAL HYPNOTISM, OR TREATMENT BY SUGGESTION.

Read before the Chicago Medico-Legal Society, October 4, 1890.

BY M. H. LACKERSTEEN, M.D., M.R.C.P., ETC.,
PROFESSOR OF MEDICAL PHYSICS AND ELECTRO-THERAPEUTICS;
CHICAGO POST-GRADUATE SCHOOL OF MEDICINE.

(Concluded from page 708.)

I wish now to say a few words from my own knowledge of the subject. My experience, has been very limited in regard to hypnotic therapeutics, and it is only as a therapeutic measure that I have any knowledge of hypnotism at all.

Some thirty years ago, about the termination of the Sepoy mutiny in India, I visited the mesmeric hospital which had been established in Calcutta, by Dr. Esdaile, many years before my time, and witnessed a capital operation on a native who had been put into the mesmeric trance. On the following week I repeated my visit with the surgeon in charge of the hospital, and by his kindness and courtesy, I had the opportunity of performing two operations, an amputation of the thigh, and the removal of a scrotal tumor, which was found to weigh a little above fifty pounds. Both these operations were done under mesmerism. There were four other operations put down for that day, but the mesmerizer had not been able to mesmerize the subjects. One I remember was a fracture of the upper jaw, and another was a cancer of the breast; the other two I forget now what they were. These cases I was told would be operated under chloroform. When I revisited Calcutta after ten or twelve years of service in the N. W. provinces, I learned that the mesmeric hospital had been abolished, because of the uncertainty of producing anæsthesia in all cases by mesmerism.

Dr. W. B. Carpenter who had made a study of the mesmeric condition, and had also studied Braid's cases of hypnotism, had announced at this time his "expectant attention" theory, in explanation of these phenomena, "the dominant idea" as he put it "influencing and governing all other mental operations." Liebault had now commenced his treatment by suggestion in France,

and an occasional notice of his doings appeared in some of the French medical journals. In the meantime the requirements of the service had thrown me right into the midst of a very densely populated part of upper India. I enjoyed the fullest opportunity here of acquiring a considerable knowledge not only of the Eastern languages, but also of the methods of practice prevalent among the native Indian doctors. From my knowledge and standpoint of therapeutics it was puzzling at first to understand how these men attained results in their practice, that were very little if at all inferior to my own, seeing that their remedies for the most part were the crudest rubbish imaginable. The fact was that the self limited diseases and functional disturbances which formed perhaps sixty per cent. of all cases, came round all right through the agency of that mysterious "*vis medicatrix nature*," a *vis* that was no more explainable and intelligible than hypnotism itself. The efficacy of this *vis* became still more convincing when the cures were effected by charms, amulets, and incantations without the exhibition of any drugs whatever. Truly nothing is impossible to those who believe. When the *vis* is helped by suggestion, similar and even more remarkable cures may be expected among educated and intelligent patients. Look for instance at the work going on at the present day before our very eyes. New schemes and devices are adopted by ignorant, but by no means necessarily dishonest healers of disease, who practice suggestive hypnotism without knowing it to be such, but who ascribe the good results which may happen to follow their ministrations, to the help of God obtained specially through their prayer and favored mediation. Is it not the same thing with the high potency practitioners? Surely no one with common sense, and in his proper senses, can really be persuaded to accept it as a sober fact that the weaker you make a remedy, the stronger will be the effects; and yet a great many educated persons follow this method of treatment. As a matter of fact therefore more than half of these sick folks, whether in India, Egypt or Chicago, get well under a treatment that is chiefly applied directly to the mind rather than the body, and which indirectly influences and modifies the diseased condition itself through the mind, not forgetting of course the *vis nature*.

The physician in his practice deals with his case objectively, and the patient has to realize his symptoms, feelings, and impressions subjectively. The latter experiences his malaise and distressed feelings, and proceeds to the physician to have them removed. The educated scientific physician makes his physical and clinical examination; for as a man of learning and sense, he has first to make a careful diagnosis, that is ascertain exactly what is the matter, before he can decide upon what ought to be done. In a great many cases,

unfortunately, such decisions, are of a very impotent character, for to know what ought to be done, and to be able to do it, are two very different things. Two physicians may agree both as to the nature of the disease and the indication of treatment, and yet they are very liable to differ as to the particular means and remedies to be employed that would best meet the requirements of the case. The knowledge of disease derived from a study of symptoms, and with the interpretation of symptoms, *i. e.*, a rational knowledge of the diseased condition is the *science* of medicine; but the treatment of disease is not a science at all, but an *art*. A great deal in this line evidently depends on the personal equation. The more practiced, the more perfect; the greater the experience, the greater the skill—these are axioms of art, all art, every art. The best and most successful physician, therefore, is he who combines the learning from science and the wisdom from experience. His learning explains and interprets his case, and his wisdom suggests its treatment. Now as to the patient, he is guided entirely by his feelings. He never goes near the Doctor unless he "feels bad"—pains, aches, pyrexia, nausea, insomnia, anorexia, etc. If the patient's distressing feelings were relieved, he would cease to *feel bad*, though he may not be cured; and hypnotism or hypnotic suggestion can inhibit all these subjective disagreeables at once.

Perhaps the most masterful diagnostician of the past generation, and a thorough master of the natural history of disease was Sir William Withey Gull. He was a marvel among Londoners as a successful physician, and yet not a physician of my acquaintance was less able to write a respectable prescription, or could get along better with fewer remedies in his practical working pharmacopœia. His immense practice necessitated the appointment of two lieutenants who took charge of the more important personages among his wealthy patrons, after a careful diagnosis and prognosis had been made. The treatment under which the remarkable recoveries took place were mint water, syrup of ginger, and such like remedies *with strict attention to diet and hygienic management*. The assurance of the big man that the disease would terminate in such a manner and within such time under the proper and judicious treatment of my friend Dr. A. or Dr. B., (his lieutenants) created a mental impression of perfect security. From that moment everything went well, and in due course of time the patient was convalescent. Implicit trust in the physician is the basis of the psychic treatment, and works half the cure in most functional diseases.

Now, can we possibly get along in this world without accepting a thousand and one things on trust? That shrewd, far-seeing writer, De Tocqueville, in his famous work on America puts this idea in the following impressive sentence:

"There never was a philosopher, however great, but believed in a million things on the faith of others, and accepted a great many more facts than he had verified." The mere suggestion, therefore, of a trusted physician acts like hypnotism to the simple minded, trusting patient, and he automatically obeys all that is enjoined, and realizes what is expected of him. Very susceptible patients are impressed in their waking moments, but light hypnosis or somnolence is the most convenient and suitable state for the generality of patients. Rarely is it necessary to induce the hypotaxic condition, and as to hypnotic somnambulism, I have never seen a case.

The cases in which I have found suggestion to act most satisfactorily, requiring but one or two sittings, are those in which menstrual irregularities constitute the most prominent features. I shall state one or two cases. A. B., 35 years old, married, mother of one child, had never been regular during the twenty years she had menstruated. The intervals were two weeks, six weeks, two, three or four months. She had last menstruated on June 3, 1889, when she saw me professionally on the 14th. I placed a piece of solid aluminium in her hands and requested her to look at it steadily. "Now I am going to put you to sleep and impress your nervous system, so that when you wake up you will be perfectly cured." Her imagination was taken by surprise, and before she realized her situation, I told her she was already looking sleepy, the eyelids were growing heavy and sleepiness would soon overtake her. "Yield to the influence, close your eyes, sleep," and in just one minute she was hypnotized. "Now pay attention to what I say. On the 1st of July you will be unwell at midnight, and on the 2d of July you will come to my office to tell me this, and every month on the night of the 28th or morning of the 29th day, you will regularly menstruate without fail. Do you hear what I say?" "I do." "Repeat it." She repeats. "Realize it." She is silent. "Do you realize it?" "I do." "You will feel no trouble or discomfort when you awake. Do you realize it?" "I do." "You will remember nothing when you awake." "Awake." On July 2 this American lady of education and intelligence was seated in my office awaiting my arrival. "What is it?" I ask. "Well, I came to tell you, doctor, that I have come round all right just to the month, the very first time in my life." "It is a funny thing that you should come to tell me this. If you are all right, you don't want to see a doctor. Why have you come to tell me this?" Well, she was so well pleased with what had happened that— She fumbled about somewhat embarrassed, asked me to excuse her, and left. I called her back. "Should you become irregular again, don't fail to come and tell me." She has been regular ever since. Eight other cases, almost

similar, were hypnotized more than once, but all with the same result.

C. D., unmarried, of American descent, anæmic, suffers from amenorrhœa, called with her mother on June 20, 1889. She suffered from severe pelvic pains for four months after receiving a chill, and has had very indifferent health ever since; has taken Warner's chalybeate pills three times a day for three months without improvement. With her sanction and her mother's permission she was hypnotized in six minutes, and told that she would menstruate in six days. On the 27th of June she menstruated, but she skipped the month of July and was again brought to me on the 4th of August. She was hypnotized in three minutes, and was requested to report on the 23d of August that the time had come on the day before, and she was assured that every twenty-eight or twenty-nine days thereafter she would menstruate regularly. She appeared on the 23d of August to say that she had been unwell the night before. She has been regular ever since.

Gastric troubles are very amenable to hypnotic treatment in conjunction with such remedies as neutralize the excess of acid in the secretions, or a little local electricity, and careful attention to diet; suggestion under hypnosis being well calculated to affect the subjective phenomena of the underlying neuroses, whether structural or functional, ataxic or neurasthenic.

As the dyspeptic cases were at the same time under dietetic or hygienic treatment, and as careful observance of regimen alone is calculated to produce good results in these diseases without the aid of hypnotism, I avoid entering into any particulars regarding them; but I shall mention in passing that under hypnotic suggestion the feelings of distress, pain and nausea were promptly relieved, and the sufferers made comfortable at once.

I have had three cases of dipsomania, two of which have been treated successfully so far, and one was a failure. This failure, however, was due to the fact that the patient was intoxicated during the treatment, and I am of opinion that he was not capable at the time of either fixing his attention or of receiving any suggestion.

A few cases of constipation, neuralgia, and rheumatic pains have made decided improvement under suggestive treatment.

Two or three cases of sexual impotency were very successfully treated by hypnotic suggestion. One in particular was not only remarkable but quite unique, even in the records of hypnotism. Suffice it to say that I have had an experience of nearly fifty cases, and that I have been more or less successful with them all. There is now, therefore, not the least doubt in my own mind that of all the means employed to cure disease through the effects of the imagination,² hypnotism is by far the most powerful. Hypnotism

is an established fact; but the question as to how far it is useful in therapeutics can be answered satisfactorily only after a great deal of investigation. The attitude of the profession towards the employment of this resource is not very creditable to medicine as a progressive science. Dr. August Voisin, physician to the Salpêtrière, discussed the treatment of neuroses by hypnotic suggestion at the last August meeting of the British Medical Association. He concurred with Braid that the hypnotic state originated in the nervous system of the hypnotized person; he also stated that hypnotism was in his experience useful when it was possible to make use only of suggestion. He then enumerated a number of cases of hallucinations, delusions, disturbances of special and general sensation, suicidal ideas, acute and furious mania, dipsomania and morphinomania, obstinate cases of onanism, etc., which had been treated by him and cured under hypnotic suggestion, and concluded by describing how he had completely transformed the depraved habits of thought in the young, and had brought them to love the good, whereas they had formerly loved the evil.

In the discussion which followed an objector declared that his attitude of mind towards the paper was simply one of amazement. There was something, he said, that cured mania, banished hallucinations, cured love of drink and morphia, stopped masturbation, improved the memory, made imbeciles wise, and bad folks good; moreover, it cured amenorrhœa, and the patient menstruated as directed. It resembled nothing so much as the waving of a conjuror's wand, and saying to the disease, "Begone." Moreover, in nine-tenths of the cases the cure was permanent. If all this were true, their vocation was gone, and they must seek some other profession. Dr. Voisin must not deem the English objectors as disrespectful if they were a little incredulous as to these wonderful results. It might be there was something in the vivid Gallic nature that the English did not possess, or something in Dr. Voisin's method that the English did not know, and more to the same effect, entirely discrediting Voisin's narrative of facts, and denouncing him as a fraud because the objector did not see how these things could possibly be; or to put it in the most charitable light he believed Voisin was a self-deluded enthusiast, and although sincere was entirely mistaken in reporting a pack of delusions as facts. Now is this the scientific method? Is this the way to establish the truth as to any natural phenomenon? Why this rooted disinclination

² It is not pretended "that suggestion acts directly upon the diseased organ to suppress vascular congestion, resolve inflammatory exudation, and restore the destroyed elements of the parenchyma. What drug in the materia medica is capable of creating such a direct curative activity? Diseases are cured, when they can be cured, by their natural biological evolution. . . . The therapeutic agents which we use are only functional medicaments—suggestion, also, is a powerful functional medicament."—BERNHEIM.

to accept the facts of hypnotism? And why should the knowledge of these truths excite amazement? Simply because they are new and unfamiliar? Partly, but chiefly because charlatans and quacks who have misused them for purposes of gain have surrounded them with supernatural claims which science cannot recognize. These are ridiculous objections. New things, and new ways of doing old things we find every day in these active times full of discoveries of new facts in nature, and inventions in art, but when these facts become familiar, and when these inventions are known and understood, they cease to excite amazement. That a new way in practice may alter in some manner our time-honored vocation is quite possible; but is it reasonable to oppose the recognition of a fact simply because it is likely to occasion inconvenience to us in our routine habits of business, or disturb our traditional views and opinions? "I don't like it," or "I don't believe in it," and "I won't have it," will scarcely produce an impression on the phenomena of nature. Not a single fact can be altered or modified by either belief or disbelief. The facts will continue to be facts just the same. The question simply is, "Is it a fact?" To denounce the statement of a fact without investigation and inquiry simply because one dislikes it, is the same kind of thing as to condemn a man to death without a trial simply because you hate him. Such a proceeding would in the first instance be unscientific, in the second unjust, to say the least. If you have an ardent love for the truth, you have plenty of means of searching for it; but first investigate before you opine. If you don't know, either keep silent or try and learn.

It is not so very long ago that a large section of the community were struck with amazement at two persons being able to converse one hundred miles apart, their voices being made to travel to and fro along a wire. "Why, how could such a thing be?" they asked. There is no amazement now, for every one knows the fact; though even to-day not one person in a hundred thousand can explain it understandingly to himself excepting as a something that is produced somehow by electricity. If anyone would like to understand how the "halloing" is done in a telephone, he must first study the laws of electricity, and next learn the principles on which the telephone is constructed; but he can easily satisfy himself that it can be done by going to a telephone and trying it himself. The same process is applicable to hypnotism and to every other fact. Learn the fact of hypnotism by seeing it, then try it yourself. If you want to know more, study the works of the physiologists and psychologists who have devoted their best talents to its explanation. And if you are still more curiously disposed and possess the necessary qualifications, go ahead and add as much to our information and inter-

pretation of hypnotic phenomena as you can, by making original investigations; for the field is wide enough to occupy many generations of inquirers without the least fear of exhausting the subject.

Hypnotism is a fact which is sure to be more generally appreciated the better it is known and understood, and the earnestness and ability with which it has been prosecuted give fair promise of rich results in the future. It will render great service to the *Physiologist*, perhaps, by clearing up our knowledge of the mechanism of reflex action, and inhibitory action, the extent of associated sensory and motor functioning, the influence of vaso-motor stimulation on secretion and excretion, the association of spinal with cerebral impulses, the character of automatic action, of unconscious cerebration, and a thousand other facts now more or less mysterious and unintelligible. It will render great service to the *Therapeutist* by indicating the true physiological action of drugs, and removing the associated influence of subjective phenomena as a modifying agent in the production of therapeutical effects. It will be of considerable interest to the *Pathologist* by enabling him to appreciate the changes producible in the fecundity and alterability of microorganisms by altering the character of their pabulum, an alteration which might possibly be effected through the vaso-motor system influencing nutrition. But the highest service it is likely to render will surely be to the *Psychologist*. The so-called philosopher of olden times had for many thousand years tried, and tried in vain, to study the functions of the brain by an introspective examination of his own mind. Metaphysics as a science have long ago been pronounced impossible. By hypnotic suggestion the psychologist of the future will in one single year learn more of the mind and the mechanism of its so-called faculties than the highest talent of the world had been able to ascertain in two thousand years. It is believed that it may help towards the objective study of consciousness itself, to the forming of a clear notion of mental diseases, and to the employment of a more effective method of treating the insane.

It will be noticed from all that I have said, that by hypnotism I understand the influence of suggestion on the willing and susceptible mind, whether this suggestion be offered under the names and processes of mesmerism, electrobiology, animal magnetism, or produced by hypnotism by the method of Braid. It is not even necessary that the sleeping illusion should be induced in order to evolve phenomena under suggestion. Hypnotism is therefore a great power, and is consequently capable of being abused. The forensic aspect of hypnotism where any amount of crime may be perpetrated through the agency of helpless and irresponsible victims is much too ex-

tensive and important a subject and can receive no more than just a passing mention in this sketchy paper. There are some erroneous and exaggerated notions, however, entertained regarding this danger. The fact is that no one can be hypnotized against his will, and a firm determination to oppose the influence of suggestion is the best safeguard against all susceptibility to hypnosis. Weak minded people under religious emotions can, however, be wrecked and ruined without warning by insane enthusiasts who capture the attention, and play upon the feelings of ardent devotees at religious revivals. These meetings should be prohibited by stringent legislation;³ and however valuable hypnotism may be to the psychological and scientific physician, in the hands of the ignorant and sensational exhibitor, it is calculated to do nothing but harm and mischief.

One word more and I am through. Will hypnotism ever become popular in general practice? I think not. It will always remain in the hands of specialists, and it is right that it should. A special training is necessary to make it impossible for the hypnotizer to do the least amount of harm in any case brought to him for treatment. It takes too much time to make it popular among busy and active practitioners; and it will always be felt as a serious inconvenience by patients to put themselves into the proper frame of mind, and then allow themselves to be sent to sleep in order to receive treatment for common ailments. Further, any unconscious resistance on their part will operate as an auto-suggestion against the suggestion of the operator, and in this way either prolong the sittings indefinitely before the sleep illusion is induced, or render the induction of the hypnotic state altogether impossible. It has its uses and its drawbacks; but in suitable cases and in proper hands I consider it a valuable therapeutic agent.

I feel that I have done scant justice to this important and highly interesting subject, and I am much obliged to you, gentlemen, for the patience and attention with which you have listened to this meagre outline.

(For discussion see Society Proceedings.)

DIPLOMAS IN COLORADO.—The Colorado State Board of Health, after July 1, 1893, will not accept the diplomas of any school which does not have an obligatory three years' course of instruction of five months each, in three different years.

³ The brutal practice of shocking and jarring hystero-epileptics by sudden flashes of lime-light, and the striking of gongs, should also be stopped by legislation. This kind of thing can hardly be called "therapeutical." Imagine an inhuman experimenter exhibiting toxic doses of strychnine to a case of traumatic tetanus, and making a public show of the contortions and agonies of the wretched sufferer. In both these cases we should have valuable remedies misapplied and prostituted for sensational purposes regardless of the misery inflicted on the unfortunate victims. From these cases no man of sense would form his opinion of the proper uses of hypnotism and strychnine.

REMOVAL OF TONSILLAR HYPERTROPHY BY ELECTRO-CAUTERY DISSECTION.

Read before the Chicago Medical Society, October 6, 1890.

BY EDWIN PYNCHON, M.D.,

INSTRUCTOR IN RHINOLOGY AND LARYNGOLOGY IN THE CHICAGO POST-GRADUATE MEDICAL SCHOOL, AND LECTURER ON DISEASES OF THE NOSE AND THROAT AND THEIR RELATIONSHIP TO THE TEETH AT THE U. S. DENTAL COLLEGE OF CHICAGO.

The anatomy and physiology of the tonsil I will not attempt in this paper to consider except with brevity. As to size, in the thoroughly normal condition, its presence is hardly perceptible. As usually described in treatises on anatomy it would appear that a moderate degree of hypertrophy has been accepted as the type of perfection. As far back as medical history goes allusions are to be met with concerning the enlarged tonsil, and the means adopted in the attempt at its removal.

The physiology of the tonsil is not thoroughly understood. It has been supposed to be of assistance in lubricating and guiding the bolus of food being swallowed. In civilized life it seems to be devoid of practical use and appears to be but rudimentary, and as a reminder of a something which in prehistoric days may have been required, when man lived on fruits and nuts, and barks of trees, before the art of cooking was discovered. One trite observer has remarked that "the principal use of the tonsil was to absorb poisons." While, in common with trite remarks generally, this one may possess the feature of exaggeration, still I believe it in the main to be worthy of attention. For example, but note the effect, in cases of diphtheria, when the tonsils are prominent, and the increased severity and fatality therefrom. Enlarged tonsils seem most often to result from exposure and debilitating influences, and from surroundings of unfavorable hygienic condition.

The object of this paper is to call attention to a condition of hypertrophy of the faucial tonsils with which I frequently meet both in clinical and private practice. I do not allude to the usual and well recognized enlarged tonsil of the hyperplastic variety which is so frequently seen, particularly in children, which is resistant to the touch and which, owing to its large size, occludes the faucial passage and materially interferes with both respiration and drainage. Such enlarged tonsils are, I believe, always removed by the educated physician, providing the consent of those closely related can be obtained, and the necessity for the removal of which has been generally conceded by the medical profession. On the contrary, I allude to a condition of the gland wherein it is hypertrophied, and therefore diseased, though the enlargement may be but slight; a condition wherein the hypertrophy is more of the follicles than of the gland, and wherein the tissue, while

nodular, is yielding to the touch. According to Sajous, "the increased volume of the hypertrophied tonsil may be hardly noticeable" (p. 287). By the ordinary examination with the use of the tongue depressor it may be difficult to see and, in fact, may even escape the attention of the observer, though if the tongue depressor be forced sufficiently far back, even to the touching of the epiglottis if necessary, the patient can be made to gag, when, by the contraction of the constrictors pharyngeus, these diseased tonsils will be thrown out from between the pillars, and in aggravated cases may be made to meet. When so examined the lacunæ will be observed to be large, and by slight pressure upon the bodies there will be seen to exude from these openings a cheesy secretion which is not only profuse, but is oftentimes of a disagreeable odor, and consists of cholesterin, débris from broken down follicular glands, epithelium, pus corpuscles and other waste matter. When profuse, I believe there is always a tendency towards decomposition. I have observed this secretion to be much more profuse and disagreeable in case of the small hypertrophied tonsil described in this paper than in case of the very much enlarged tonsil. When such condition of the tonsil exists as I am describing, there will be found associated therewith other conditions, some or all of which may at times be present. The saliva in the back part of the mouth is more profuse and frothy than in a normal throat. There is generally present a condition of chronic pharyngitis, and there is frequently given a history of previous attacks of quinsy, and the patient acknowledges himself to be the possessor of a throat abnormally sensitive, which is easily affected by exposure during inclement weather. Unless the patient has been accustomed to pharyngeal and laryngeal manipulations or to the use of gargles or post-nasal sprays, the fauces will be found to be more sensitive than normal, so much so that the induction of gagging previously alluded to will, in fact, be too easily attained, and in many cases, at first, the mere pointing of the tongue depressor at the opened mouth causing nausea. There will generally be given a history of post-nasal catarrh with its usual train of symptoms, including at times a diminution in acuteness of hearing. There will often be observed the coated tongue and tainted breath associated with other symptoms of indigestion. In fact, since I have had my attention particularly drawn to the described diseased condition of the tonsil, I have not seen a patient so affected whose tongue was not somewhat coated and who did not give some indication of dyspepsia. I believe that in the swallowing of catarrhal and diseased tonsillar secretions we have a frequent cause of chronic gastric catarrh.

If the patient is one who sings or who is accustomed to prolonged use of the voice as, for

example, a clergyman, a lawyer or an auctioneer, by inquiry it will be learned that after vocal exertion there comes a condition of huskiness of the voice or even pronounced hoarseness. If the patient be a vocalist and the diseased tonsils be not extremely small, it will be elicited that in the execution of the notes of high register there is a consciousness of greater muscular exertion and strain being required than would seem to be natural.

There is frequently given a history of cough with expectoration, particularly in the morning, of thick mucus from the larynx, often in the form of a small, hard globule which is of bad smell when compressed. There is generally a sensation of roughness of the throat which is in part attributable to the concomitant pharyngitis.

This condition of the tonsils has been by some medical gentlemen appreciated, and means have from time to time been employed for their eradication. Owing to their small size and the difficulty or impossibility of grasping them, the usual operation of tonsillotomy is not available. The process of igni-puncture has been suggested and is practiced by many, which operation consists of entering into the several lacunæ one after the other, and generally not more than three or four at one séance, a cold platinum cautery point and then, after heating the same, cause it to burn its way out. This process is repeated until all of the large follicles have been destroyed, the expectation being that after such partial cauterization as described the remainder of the gland will pass away by absorption. The results have been claimed to be satisfactory, though generally a very ragged and bad appearing surface remains.

From my own experience with this operation and from my observation of the experience of others, I am convinced that generally the expectation is not realized. In the case of young children, after a partial tonsillotomy the remainder of the gland is often found to absorb, but in the condition which I have in mind, and which from its nature is most often found in adults, there is a denseness of the tissue which precludes the expectation of even partial absorption. I frequently meet with cases in patients 30, 40 and even 50 years of age. While the tendency in the adult is towards the absorption of hypertrophied tonsillar tissue, I do not believe that such absorption is often complete. On theoretical grounds the further objection to electro-puncture can be made that, while the larger and more prominent follicles are destroyed, there yet remain many smaller follicles which in time may become large, and which even prior to such enlargement are constantly giving forth a secretion which cannot be otherwise than the gland itself, to wit: diseased. Another patent objection is that the ragged surface remaining is a necessary source of irritation by the arresting of particles of food being swal-

lowed, and is furthermore, owing to its roughness, an unfavorable surface for the best production of vocalized sounds.

Another means of eradicating small diseased tonsils is to grasp them with some form of vulsellum forceps, encircle them with a galvano-cautery snare and thus attempt their removal. While such operation may in certain cases prove more satisfactory than the former operation, it is nevertheless not a thorough success. Owing to the elongated and flattened shape of the diseased tissue the difficulties met with are apparent, and while a portion thereof may be so removed, we are justified in assuming, as before, that the leaving undisturbed of a considerable portion of the abnormal tissue is contra-indicated. Another of the physical objections to this mode of procedure is that in certain cases, owing to previous follicular inflammations with resulting suppurations, the projecting surface of the gland is not a favorable tissue for being so grasped as, while the base may be indurated, the surface is soft and easily torn. Another method which has been employed is the dissecting out of the offending tonsil by means of blunt-pointed and curved bistouries. While this method would seem to promise efficiency if prosecuted to a sufficient degree, it is, for obvious reasons, very seldom adopted.

Practitioners generally, even when they have recognized this condition described, have not been disposed to associate therewith the several symptoms which I have enumerated, and too often, realizing the obstacles to be met with in the removal of a gland so well imbedded and carefully surrounded, have preferred to prescribe placebo gargles or astringent applications which can only allay temporary irritation and never produce radical cure. In this condition, when the throat is in a passive state, I generally find the tonsil about flush with the pillars and often quite thoroughly adherent thereto both anteriorly and posteriorly and, furthermore, not infrequently associated with a condition of hypertrophy and infiltration of the pillars. The presence of such condition may in a pronounced case detract two or more cubic inches from the space of the mouth, which can be readily believed to have a material influence upon the voice. Furthermore, during vocalization the pillars, which are normally parallel and should so remain, are held apart at their middles by the presence of an indurated and unyielding mass which additionally fills a space which in the natural condition is an inverted trough, rendering undoubted help in the formation of certain of the voice sounds.

Believing that in such cases the indication is to thoroughly and completely remove the diseased tissue, and finding that the ways and methods heretofore known and as described were inefficient, after some thought and experiment I devised a method of securing the desired result with

safety and efficiency, and have since put it in practice on many occasions. It will afford me pleasure to describe this operation in detail, so that any of my *confrères* who may so elect can practice the same.

With the patient possessing a hypersensitive throat I first prescribe a course of treatment to reduce the sensitiveness thereof, which consists in the half-hourly employment of a gargle of potassium chloras accompanied by the frequent introduction into the mouth of the handle of a teaspoon, which is to be used alternately as a tongue depressor and as a soft palate elevator. In this way, generally in two weeks or so the quite sensitive throat becomes tolerant to the presence of instruments. At an appointed time I apply a solution of cocaine 10 per cent. with phenol 5 per cent., which produces some anæsthetic effect, and by its bitterness tends to detract the patient's attention from the pain incidental to the operation. I employ three electrode points, two being bent at right angles to the shaft, so that by reversing the electrode I can have a point bent either above, below, to the right or to the left as I may require. The third electrode point is very slightly curved and is likewise reversible. They are all made of No. 24 gauge platinum wire and will heat quickly. I use a current about 50 per cent. stronger than is required to produce a white heat of the electrode in the open air, so the most brief pressure on the contact button will thoroughly heat the point, and if left in contact for more than two seconds of time *in the open air* would probably produce fusion thereof. Such a point and current as described will, in use in the tissue, give the least pain with the best and most rapid results. During the operation the tongue depressor must be employed, and it occupies the patient's mind to have that instrument in charge. My first step is to dissect the tonsil away from its attachments to the pillars, generally entering the appropriate point cold, heating and burning out. For the upper portion of the pillars I use the point bent downwards and work in that direction. For the lower portion of the pillars I sometimes reverse the same point and work upwards. The point being entered cold and serving as a blunt tenaculum, the tonsil is lifted out and towards the median line, when the point is heated and burns its way out. Only a little is done at a time. The side attachments having been released, I next grasp the tonsil near its upper end with a suitable forceps, lift the same forward, and with the heated bent point dissect the tonsil little by little from its attachment below to the pharyngeal aponeurosis. The operation is of course somewhat tedious, and requires from fifteen minutes to possibly one hour's time. From five to twenty seconds' work is done at each attack, the remainder of the minute being lost by the patient resting. Unless the patient is restless, so that the electrode is caused to tear instead of

burn through the tissue, there is little or no hæmorrhage. I have in some cases lost less than twenty drops of blood, and in no case has the hæmorrhage probably exceeded one ounce. The most difficult part of the operation is in getting the upper end of the tonsil loosened. It is then very easy until the lower end is reached, by which time the loosened portion drops over on to the tongue, producing nausea. The principal points in the operation consist, firstly, in never operating while there is present a condition of acute inflammation; secondly, in constantly lifting the tonsil forward towards the median line while working; and lastly, in working slowly and doing but little at each stroke with a thoroughly heated point, which will always burn its way through the band of tissue engaged. I have also with satisfaction done this operation as described, for the removal of the indurated base of a tonsil remaining after a tonsillotomy. Immediately after the operation I have latterly been making a thorough application of "Eisen glycerine" (a German preparation much used in Vienna, and consisting of equal parts of tinct. ferri chlor. and glycerine), and have found it to be efficient in tending to prevent as marked inflammatory reaction as frequently occurred prior to my adopting its use. I repeat this application daily for the first week, providing the patient calls at the office.

Succeeding the operation for a few days the throat is quite sore, which condition I combat by directing the frequent use as a gargle of a saturated solution of the bicarbonate of sodium, and for the first two or three nights the employment of the wet pack about the neck. If in twenty-four hours after the operation the inflammation has become quite pronounced and annoying, I prescribe a mixture composed of tr. of iron and chlorate of potash in glycerine—one dose containing from 6 to 12 minims of the iron and about 4 grs. of the potash, every two hours, and have in some cases prescribed this at the start as a prophylactic with apparent benefit; and I might remark here incidentally that this mixture also has a beneficial influence upon the gastric catarrh, clearing the tongue and improving the appetite.

After the first few days, in place of the gargle of soda I substitute a saturated solution of potassium chloras, and have in some cases, where this was disagreeable to the patient, given instead a gargle of diluted tinct. of myrrh of the strength of about $\frac{1}{2}$ drachm of the tincture to the ounce of water. The amount of annoyance produced by the operation differs in different cases, being influenced in a measure by the size of the remaining wound, though to my mind it is more dependent upon the idiosyncrasy of the patient. In the several cases in which I have performed this operation I have not had reported any marked febrile disturbance, though in several cases the local inflammation has been considerable.

At a given séance but one tonsil should be removed, and generally about two weeks should intervene between operations. In a few cases, owing to the restlessness of the patient, the tonsil being operated upon was not completely removed at the first sitting. In such cases the operation was renewed at a later period, after the throat had become thoroughly healed. I have generally found the first operation to be of more annoyance to the patient than have been the one or more succeeding operations. As a result of this operation I have found that the post-nasal catarrh is almost invariably benefited and, also, that when in connection with the post-nasal catarrh there is a slight degree of middle ear deafness, the acuteness of hearing has been intensified. I also find the condition of pharyngitis improved, and in cases wherein there is neither stenosis of the nasal passages nor a condition of atrophic rhinitis, there follows an improvement in the dyspeptic symptoms with a general improvement of the health. In singing the voice is found to have become clearer and more powerful in the high notes, and is not succeeded by hoarseness as before. Furthermore, the possibility of future attacks of tonsillitis is averted.

While the operation is not pleasant to undergo, the general report is that the pain is not so severe as would be expected, and that the most disagreeable feature thereof is the difficulty of combating the tendency to nausea. No patient as yet, after the first operation when both glands were diseased, as is generally the case, has failed to solicit the removal of the remaining tonsil. Between operations after the first tonsil has been removed, the general report is that there is a sensation of more room and comfort on the side which has been operated upon when compared with the opposite side. While to the uninitiated this operation might seem quite heroic, it is certainly not productive of one-half the annoyance and pain that is given in following the treatment by caustics, as chromic acid or London paste, both of which have been employed.

In this or any other operation upon the tonsil, owing to its proximity to the carotids, it is wise to consider the possibility of serious hæmorrhage. The approximate distance from the tonsil to the external carotid is three-fourths of an inch, and to the internal carotid is one-half inch, which distances may be materially increased by traction on the tonsil, owing to the free supply of loose cellular tissue posterior thereto. Bleeding after tonsillotomy is more to be feared from wounding the smaller arteries in that region, particularly the tonsillar or ascending pharyngeal. I personally do not regard the danger from hæmorrhage in the operation described to be anywhere near as great as when the tonsillotome is employed, which from its nature can only be employed when the gland is pronouncedly hypertrophied and projecting.

Furthermore, in the small diseased tonsil described for the treatment of which I advise electro-cautery dissection, owing to its small size the blood supply is not so great as in case of the more hypertrophied tonsil, and the small vessels, when divided by the hot point, are sealed. The operation completed, the wound is protected by a seared surface which it would seem would be far less likely to permit of the entrance or absorption of anything pernicious, than in case of the open wound after tonsillotomy. From four to six days after the operation, as the slough begins to separate, there is a slight secondary hæmorrhage, the amount of which is largely dependent upon the vigor with which gargles have been employed.

In acute parenchymatous tonsillitis, when prompt escape is not given to the imprisoned pus, it is prone to burrow in the adjacent cellular tissue and, when neglected, has produced perforation of a large vessel, followed with profound hæmorrhage. Such a result I do not believe to be possible from the operation which I have described, as the remaining wound is large and open, insuring good drainage and precluding the possibility of such dangerous result. In healing by granulation there occurs a filling up of any small or irregular depressions resulting from the operation, so as to give an even surface, and I have never as yet seen any cicatricial contractions resulting therefrom.

703 Opera House.

MEDICAL PROGRESS.

SOME PRACTICAL POINTS IN THE TREATMENT OF SYPHILIS.—DR. R. W. TAYLOR thinks it impossible to over-estimate the great advance made in the treatment of this disease by establishing the fact that small doses given over long periods was more radically curative than the old time heroic dosage, or of the three to six months' courses. He then refers to the advantage of the hypodermic method of administration. The hope of aborting the disease gives rise to two methods,—the first, that of excision of the chancre; and the second, by active mercurial dosage during the primary period of the disease. Both methods have been found useless. He does not begin the mercurial treatment until the beginning of the secondary stage. The three systems of treating syphilis now in vogue are as follows: The expectant, or symptomatic; the continuous, or so-called tonic treatment; and the treatment by interrupted courses. He disapproves both of the expectant and the continuous treatment, and has found that the interrupted but carefully regulated courses of mercury alone at first, and of mercury and iodide of potassium later on, is the one most preferable, most satisfactory and practicable to both phy-

sician and patient, and the one by means of which we may almost positively promise a cure to any one with ordinary health who will systematically submit to and follow it up. The systematic treatment of the disease pre-supposes a careful hygiene and an orderly and well-rounded life during its continuance. The preparations of mercury he recommends are the green iodide and the tannate of mercury. He thinks that the bichloride should only be used hypodermically. The dose of the proto-iodide of mercury should be from one-fourth, or one-fifth to one-third, or half a grain. This may be given from three to five times daily. The dose of the tannate of mercury is from one-half to a grain. During the early secondary period is the most important time for giving the remedy, which should be continued from three to six months if necessary. In most cases, at the end of three months, during which the remedy should be taken quite steadily, the patient's condition will be found to be so reassuring that a stoppage of the dose may be allowed for one, two, or even three weeks. The next course may last for but two or three and a half months, when four weeks' freedom may be granted from drug taking. During the second year's treatment, iodide of potassium is combined with mercury. He prefers mercurial inunctions as an adjuvant reserve and emergency resource. The early rashes of syphilis are best treated by mercurial inunctions, both during their active and chronic stages. Thus, if the erythematous syphilide is exceptionally severe and persistent, it is well to leave off internal pill dosage and use mercurial inunctions. When the eruption has disappeared the pills are resumed, and the ointment discontinued. Inunctions should also be made over enlarged lymphatic glands, vessels, and blood-vessels when they are abnormally hyperplastic. A similar treatment is indicated in early papular syphilides. Regional inunctions are also recommended in early and late meningeal, cerebral, and cephalalgic symptoms. In cases of syphilides with much pustulation and encrustation, the common antiseptic remedies are better, for a time, than mercurial inunctions, as they are due to microbial complications. Local nodules, mucous patches, and condylomata should be cleansed and dusted with calomel. For hypodermic use a pure watery solution of the bichloride of mercury is considered the best. Solutions containing one-twelfth and one eighth of a grain dissolved in ten drops of water may be taken as standard doses. These injections will cause the rapid subsidence of specific lymphatic swellings, and of localized and regional eruptions. Cephalalgias may also be so treated. Where mercury taken by the mouth acted as a general depressant, hypodermic injections have relieved the condition. Osseous, bursal, fascial and articular lesions of syphilis, particularly the earlier ones,

are often much benefited by sublimate injections. It is well at the same time to give iodide of potassium in full and increasing doses. Fumigations are often of much use in stubborn localized and even general eruptions, particularly in the chronic scaly stage of early and late eruptions, and also in almost all cases of pustular, ulcerative, and serpiginous syphilides.—*Medical News*.

APPENDICITIS.—At a meeting of the Medico-Chirurgical Society of Montreal, DR. GEORGE ARMSTRONG read a paper upon this subject, dealing especially with the important question as to the time at which an operation should be performed. He urged upon all practitioners to bring forward and publish their cases, both successful and unsuccessful, in order that we might be placed in a position to decide upon an established procedure, and he assumed that on the following points all were agreed: 1. That the cæcum and appendix were entirely surrounded by serous membrane and were intraperitoneal. 2. Primary infiltration of cellular tissue in the right iliac fossa was unknown. 3. There was no evidence of the existence of an infiltration of the walls of the cæcum other than that caused by a catarrhal infiltration or ulceration of its mucous membrane, the most common forms of ulcer being stercoral, typhoid, tubercular, and perhaps syphilitic. 4. The symptoms of a catarrhal infiltration of the mucous membrane of the cæcum were those of a colitis rather than typhilitis, and ulceration of the cæcum did not give rise to symptoms of typhilitis unless the peritoneal covering became involved.

The reader dwelt upon the importance of early recognition of the disease, and upon the fact that every one of the symptoms might be very slight. A little pain on pressure might be the only symptom present to indicate the presence of a pint of stinking pus. A case was cited, that of a girl of 21, in whom the symptoms had been very mild and there had been apparent improvement until the fifth day of the illness, when symptoms of general peritonitis had been observed. Abdominal section had been performed. The appendix had been found to be perforated. The patient had died a few hours afterward.

In a second group of cases the inflamed appendix was completely surrounded by the products of inflammation, so that further changes in the tissue were prevented from contaminating the general peritonæum, at least for a time. In such cases the use of an exploring needle had been recommended, but the speaker had had little experience of its use. A distended gut could not be pierced with impunity. With regard to medical treatment, the amount of opium used should be the smallest quantity that would insure a fair degree of comfort to the patient, lest the symp-

oms be masked and the true condition of affairs not be rendered evident to the friends of the patient. Purgatives should be avoided. A mild enema was all that could safely be used. Under such treatment recovery might ensue. It was probable that merely a catarrhal appendicitis had been present. But apparent recovery was no certain indication that the appendix was whole, and in proof of this a case was cited where, after complete recovery, a second peritonitis had occurred. Here the abdomen had been opened and a quantity of pus removed, the patient making a complete recovery. In a third case the appendix was removed successfully during the period of quiescence. The paper was brought to a close by an earnest appeal for early operation.—*N. Y. Medical Journal*.

ACUTE ANTERIOR POLIOMYELITIS.—Opportunities for the examination of the spinal cord in recent cases of poliomyelitis are comparatively so infrequent that every advantage should be taken of them when they do arise. DR. R. T. WILLIAMSON, of the Manchester Royal Infirmary, has published (*Medical Chronicle* for September) a detailed account of such a case, where death occurred suddenly five weeks from the commencement of symptoms. The patient was a young man, twenty-two years old, who first complained of numbness in the right hand, the feeling soon extending to the right leg and the left side, and on the third day being followed by complete paralysis of arms and legs. The knee jerks were absent. There was no anæsthesia, and the sphincters were not involved. Rapid muscular atrophy then ensued; but he was commencing to regain some power when death occurred. The lesions found by Dr. Williamson in the spinal cord may be thus summarised: In the lumbar region, a patch of cell infiltration in the outer half of each anterior horn, composed of small round leucocyte bodies and large oval or round nucleated cells. At the periphery of the patch the blood-vessels were greatly distended, and their perivascular sheaths full of round cells. There were no true hæmorrhages. No nerve-cells were visible in the area which corresponded to the region of the antero-lateral, postero-lateral, and central group of ganglion cells. Such cells still existed in the inner part of the cornu, but those bordering on the patch were shrunken and deformed. The network of nerve fibres was destroyed by the infiltration, but in the white matter no degenerate fibres were seen. The contrast between the anterior and posterior nerve root was striking. In the former the fibres were scanty, separated by cells and their myelin broken up into fragments, whilst the latter exhibited very slight changes indeed. The dorsal region of the cord showed only slight cell infiltration and vascular distension in the outer part of the anterior horns, where a few

nerve cells were shrunken. In the cervical region the changes were much as in the lumbar, but less pronounced. The infiltration, however, here extended rather further in a posterior direction; and, moreover, the lesions were slightly more marked in the left than in the right half. In the filum terminale the vessels were dilated in the anterior horns, and a few nerve cells in the outer part had their processes somewhat obscured. In all parts the changes were most marked at the point of entrance of the antero-lateral artery. Microorganisms were sought for, but not found. Some degenerate fibres were found in the trunks of the ulnar and sciatic nerves.—*Lancet*.

EXTRAUTERINE PREGNANCY TWICE IN THE SAME PATIENT.—DR. LEOPOLD MEYER, of Copenhagen (*Annals of Gynecology and Pædiatry*, July, 1890), describes a suspected case, under his care. The first operation was performed at about the twentieth week, four weeks after rupture; there was tubo-abdominal pregnancy of the left side, and the left tube and ovary were removed. The patient was discharged cured in January, 1888. She menstruated regularly, but hypogastric pains set in towards the end of summer. On September 6, 1888, the pains came on after hard work; and on the next day, ten days before the period was due, she lost some very dark-coloured blood. The hæmorrhage stopped. On September 19, Dr. Meyer examined the case. On the abdominal end of the right tube, but inseparable from the ovary, a tender swelling of the size of a big walnut could be felt. Symptoms of collapse set in a few days later, with no distinct evidence of internal hæmorrhage. On October 25, severe symptoms set in after metrorrhagia; there was no doubt that bleeding was going on internally. The patient rallied, metrorrhagia continued, and on the night of October 28, she passed a membrane, which had all the characteristics of a true decidua of pregnancy. The hæmorrhage stopped on November 11. On February 19, 1889, only a small remnant of a big soft swelling, which was felt to the right and behind the uterus during the attack in October, could be detected. The patient was in good health when her case was published. The evidence that her second illness was of the same character as the first was strong. Dr. Meyer gives abstracts of nine similar cases (Lawson Tait, Kletzsch, Herman, Van Henkelom, Veit, Olshausen, and Bloch; three of the nine occurred in Veit's practice). Of these, only three were verified by abdominal section (one Olshausen, one Veit), or by post-mortem examination (Tait). The remaining six are open to doubt, as in Dr. Meyer's case.—*Brit. Med. Journal*.

RETENTION OF URINE FROM PROSTATIC OBSTRUCTION IN ELDERLY MEN.—DR. J. W. S. GOULEY says that a common cause of impedi-

ment to urination in elderly men was enlargement of the prostate, but it was only when the prostate was unequally enlarged that it so acted. The following forms of unequal enlargement obstructing the urethro-vesical orifice need in this paper be named: 1, general enlargement with excessive development of the posterior third of the lower isthmus; 2, enlargement of the posterior third of the lower isthmus without apparent increase in the rest of the prostate; 3, enlargement of one lobe which encroached upon the opposite lobe, obstructing the prostatic urethra; 4, unequal enlargement of both lobes, rendering the prostatic urethra tortuous; 5, multiple intra-urethral tumors; 6, intravesical enlargement of one lobe. The alterations of structure differed somewhat in their component elements. After discussing the symptoms, the means of diagnosis of the several forms of enlargement, especially of four, were pointed out.

Acute retention occurred among elderly men with incontinence as well as among those who had no hindrance. To temporize or rely wholly upon medicaments in its management was to place the life of the patient in great jeopardy. Select the catheter best suited to the case and introduce it. If called during the first twenty-four hours the bladder may be emptied at one sitting of three-quarters of an hour; but if on the second day, draw off only a third, and a little more than is secreted every two or three hours, emptying the viscus in a day or two. Special emphasis was placed on not drawing off too much at one sitting in older cases. The after-treatment should accord with the individual case, but never allow the bladder to again become over-distended. Irrigate the bladder once daily with warm boracic acid solution, 3 grains to the ounce, with the addition of one-fourth of peroxide of hydrogen solution. Chronic retention was also considered, and suitable catheters described.—*Medical Record*.

HYPODERMIC INJECTIONS OF CAFFEINE IN POST-PARTUM HÆMORRHAGES.—DR. MISRACHI, in the *Arch. of Obs. and Gyn.*, highly recommends hypodermic injections of caffeine in post-partum hæmorrhage, especially in such cases as require immediate aid, and after great loss of blood has taken place. It is especially useful in country practice, when perhaps, the physician has just come from a case of infectious disease, and there is not time for auto-disinfection preparatory to introducing the hand into the uterus. Caffeine acts more quickly than ergotine, and is more stimulating than ether. The formula of the fluid for hypodermic use is as follows: Benzoate of soda, 3 grams; caffeine, 2.0 to 2.5 grams; aqua destillata, 6.0 grams or *quantum sufficit* for 10 cctm. Every cctm. contains 0.25 grams of caffeine. The solution is administered warm, from

six to ten injections in the course of the day. Misrachi has witnessed such brilliant results from it that he now carries this solution regularly in his obstetrical case. Tablets of benzoate of soda and caffeine, to be dissolved in boiling water when needed, will do instead of the standard solution.—*Archives Gynecology, Obstetrics and Pediatrics*.

THE SURGICAL TREATMENT OF EMPYEMA.—DR. A. E. MORRISON reports in the *Edinburg Medical Journal*, twenty cases, the ages ranging from 8 months to forty-three years. Of these all but one, a starved infant of eight months, recovered. In five cases prior to operation pus had been expectorated. In one a cure was effected by this means alone, without operation. In one alone, after a slow and tedious convalescence, the pus was absorbed without operation. Two cases were complicated by phthisis, one of which died after cessation of discharge from the pleural cavity. In two instances excision of a portion of a rib was required.

In performing the operation the strictest antiseptic precautions were observed. The skin incision was vertical, the incision through the muscles horizontal, along the upper border of the seventh rib. Injection of the cavity was in no case employed.

The following conclusions are drawn :

1. In the diagnosis of empyema the only certain sign is obtained by the exploring needle, and this, carefully used, is perfectly safe.
2. Antiseptic incision—the wound being sufficiently large to admit a full-sized drainage-tube in the posterior axillary line, and made with the patient on his back—drainage, and careful dressing are all that are required.
3. The time for healing in uncomplicated cases should not exceed four weeks.
4. Double openings, irrigation of the pleura, and excision of the ribs are unnecessary and harmful if the case be seen before an opening has formed through the skin.—*Archives of Pediatrics*.

WHAT IS THE BEST METHOD FOR PREVENTING INFECTION OF OPERATIVE WOUNDS?—In a paper read before the Illinois State Medical Society, DR. L. M. MCARTHUR stated that one half of the primary wounds, under the present methods, are dressed aseptically at the time of operation, and then only become infected at the redressing. Operators under excitement are inclined to drop into careless habits, and proceed somewhat after the following fashion: They call for a questionable basin, and dropping into it an indefinite amount of carbolic acid, proceed to remove the dressings without any such formalities as we were satisfied were essential at first. Here is where the fallacy lies to-day. Too great carelessness at the redressing permits infection and

encourages the skeptical in the belief that there is nothing in the principles of aseptic surgery. Before the old dressing is removed a stream of 1 to 1,000 should be ready and playing on the inner layer of gauze as it is being removed, and during the time of exposure of the wound. Having rendered the parts clean, they can best be kept so by providing, in addition to the regular dressing, a heavy dressing of absorbent cotton, not with the idea of catching discharge, but with the object of filtering the atmosphere which is to gain access to the wound through the dressings.—*Medical Record*.

LEPROSY AND VACCINATION.—The September number of the *Occidental Medical Times* includes a joint article by DR. SWIFT, of Molokai, and PROFESSOR MONTGOMERY, of San Francisco, entitled "An Interesting Case of Anæsthetic Leprosy apparently following Vaccination." The details are thus given: "Peke, male Kanaka, aged 25, parents healthy. Has had two brothers and three sisters; one sister died at the Leper Settlement, a leper of the tubercular type. Peke has been a leper of the anæsthetic type for ten years, seven of which have been spent at the Leper Settlement. In 1878 he was vaccinated, and about one year after symptoms of leprosy appeared, and there is now a large anæsthetic scar at the site of this vaccination. He has during his whole life associated with lepers. Sixteen months ago he was a fine strapping-looking fellow, and was employed as policeman and gravedigger at the hospital at Kalawao." The authors further remark that "one of the most interesting points in this case is that Peke had been vaccinated one year before developing symptoms of leprosy, and that the vaccination scar became anæsthetic; might it not be that with the vaccine virus the virus of leprosy had also been inoculated?" This is a fair example of the bulk of the evidence as yet brought forward connecting leprosy with vaccination. Here is a patient living all his life in a leprosy country, and subject to all the conditions—diet, contagion, and what not—which may have causal relation with the disease; but because he happens to have developed leprosy a year after he was vaccinated, and now (eleven years subsequently) shows an anæsthetic patch at the scar, he is adduced, *post hoc ergo propter hoc*, as an instance of the probable inoculation of leprosy by vaccination. Remembering Arning's important observation of leprosy bacilli in vaccine lymph taken from a leper, it is not to be denied that such inoculation may be occasionally possible; but, in spite of the mere expressions of opinion of medical men and others in Honolulu and elsewhere, it may be said that we have at present no clear and indisputable facts proving that leprosy has been spread by means of vaccination.—*Brit. Med. Jour.*

REMARKS ON INSANITY.

There can be no greater misfortune than insanity,—disease of the highest expression of life,—that complex manifestation which for want of a more descriptive name is referred to as *mind*. It seems indeed a fortunate thing for our race that disease of the organic basis of mind is far less frequent than disease of other less important organs. It would seem as if a Divine wisdom had thrown a protective arm around the flower of all human existence, to ward off the arrows of disease and of decay, for certainly in the immense majority of cases it is preserved intact through many years of the gravest forms of bodily illness. Nevertheless this is one of the human realities and is a constant problem in the minds of all having a regard for the highest development of the race.

Perhaps no other thing furnishes more material for serious consideration respecting insanity, and its terrible ravages among all classes of people, than a visit to the wards of any large asylum, and a glance at the miserable wrecks of chronic cases with which the acute storm of insanity has filled our State institutions. This survey of whole wards of terminal dements will not only prove to all a pitiable sight, but will also impress one, as nothing else can, of the importance of early and careful treatment of acute cases, and one involuntarily thinks "can nothing be done further in the present state of our knowledge to lessen this overwhelming percentage of the chronic insane?" This question we think is one that is more strongly present than ever before in the

minds of the generous, the philanthropic, and the humane scientists of to-day. It has been the main-spring of all the so-called reforms which have been and are constantly being tried in all civilized countries to alleviate the condition of this unfortunate class. That the progress has been great all will admit, and for proof one has only to glance backward a few years, but the most sanguine will equally acknowledge that we are as yet only upon the threshold of discovery in this branch of medical science. How little is known of the real cause of the various psychoses! How far we are from any definite pathological classification of insanity! Perhaps the many difficulties in the way of brain investigation is sufficient excuse for the fact that this branch of pathology has hitherto been far behind the pathology of other less important diseases. At last, however, some definite progress has been made in this direction and with the many workers in our asylum laboratories the world over, we may justly hope for more light upon the psychical diseases. On the other hand the physiology of the mind is by no means clear, and in this connection we notice an interesting article by DR. EDWARD COWLES, superintendent of the McLean Asylum, Massachusetts, in a late number of the *American Journal of Insanity*.

Dr. Cowles' article is entitled the "Mechanism of Insanity," and the first of it is devoted entirely to a consideration of the normal elements of mind. It is a plea for a close consideration of the normal mind and is well worth reading. If this sort of knowledge was more universal it might lead to earlier diagnosis and treatment of mental diseases. Since a very insignificant proportion of the chronic cases of insanity recover,—and to verify this statement any asylum report is sufficient,—the treatment of acute cases becomes a most important subject, and demands that our fullest knowledge should be employed towards this end. Certainly the truest State economy is the most liberal expense for the investigation of the symptom-groups which are termed insanity. This feeling has inspired the liberal legislation of the last few years in many of our States, in providing State care for the insane. The wisdom and humanity of this law are apparent to all who will read of the horrors of some of the "county houses" in the States in which these reforms have been inaugurated, and the subject thoroughly venti-

lated. We sincerely hope that soon the county alms-house insane asylum will have become a thing of the past, and that all the indigent insane will receive all those advantages which a State asylum possesses over the miserably kept county houses. A brief article relating to the history of the treatment of insanity has been written by ORPHEUS EVERTS, M.D. (*American Journal of Insanity*, January 18, 1890), and concisely gives an idea of the progress which has been made. His paper is a very brief, incomplete notice of the subject, but for the general reader will convey an idea.

Notable among reformatory measures are the "cottage asylum" and the "family system," the latter of which has been in successful operation in Massachusetts; but time only will conclusively prove whether these measures will fill the wants of the growing problem of the indigent insane. Then we note special wards for acute cases, extra appliances for their treatment, and ample medical attention; all of which attest the growing popular sentiment that seeks the restoration, so far as possible, of this afflicted portion of humanity. As research and advancing science indicate the way, the men whose lives are spent with the insane have not been slow to follow.

A field which promises most for our future knowledge of insanity is that of pathology, and here the workers are multiplying, laboratories being now established in the largest asylums of this country for the special investigation of the changes of the nervous dements. An immense amount of material, which formerly passed unnoticed, is now being carefully examined and the results recorded. Surely it is reasonable to hope from this direction new light upon the treatment of the acute psychoses, and upon the almost total darkness of our understanding of even the simplest forms of mental derangement.

That the practical doctor and the alienist are gradually coming into closer relationship, as the physical basis for psychopathic disorders is being more firmly realized, cannot be doubted. We should at least congratulate ourselves that we live in an age when the insane are no longer treated as human outcasts, when the mass of the people are beginning to realize its true nature, as allied to other diseases, and that it is as much a definite disease as is typhoid fever or pneumonia. We should be thankful for the progress already made,

and for the more brilliant hopes for the future; since science is lending all her aid, and a more living human sympathy is yearly being evinced, towards the better understanding of the prophylaxis, nature, and rational treatment of insanity.

Lately there has been a discussion in the journals as to the advisability of the admission of the acute cases of insanity into general hospitals, which are suitably provided with separate apartments for their care. Anyone who has had a practical experience with such cases in a general hospital will not think this a generally advisable procedure, unless *very complete separation and isolation* for such cases can be afforded—an impossible thing in many of our city hospitals. We believe that in time separate and distinct hospitals for the treatment of the acutely insane will be provided, such as has already been done in London, and that such an arrangement is the ideal manner of caring for them. This ideal hospital of the future will have its list of attending and consulting specialists, and any advantages and appliances which science can suggest will be used to prevent the present high rate of chronic cases.

That such a plan for the indigent insane is Utopian we freely admit, but still the progress made in the past twenty-five years justifies our highest hopes for the future.

TREATMENT OF DIPHTHERIA.

That this disease is to be classified among the acute infectious disorders, dependent upon a specific infectious microorganism, is now generally believed. Whether the disease is at first a local trouble, with secondary infection of the organism, or whether it is a constitutional affection from the beginning, with local manifestations, are questions upon which the profession is still divided. Certain it is that abundant clinical experience has taught the value of antiseptic applications to the affected part. This rule has been evolved in the face of constant reiteration of the constitutional nature of the affection and the consequent valuelessness of such local treatment. We may remark in this connection that recent experimental work upon the Klebs-Löffler bacillus has shown that it is capable of producing an exceedingly poisonous albuminoid, when grown in nutrient media. This experimental fact lends additional weight to the

clinical value of local antiseptic measures in this disease.

DR. HERMAN WOLF (*Therapeutische Monatshefte*, September, 1890) has borne strong testimony regarding the antiseptic value of menthol in these cases. He proceeds according to the following method: A powder is prepared containing one part to ten or twenty of sugar, this, by means of a camel's hair pencil, is carefully applied to the false membrane and inflamed mucosa, which should have been previously cleansed from all secretions; if the nose is involved small quantities are blown into the anterior nares and post-pharyngeal space. If the process has extended to the bronchi, it may be employed in the form of a fine spray by inhalation. He claims for menthol that it is quite free from toxic properties, is pleasant in odor and taste, and has a greater antiseptic value than most of the usual gargles and sprays. Of the value of complete and early local antiseptics he has no doubt.

EDITORIAL NOTES.

DECLINE OF THE FRENCH.—The French political economists in discussing the vital statistics of their country as recently published express much apprehension. It is stated that never since 1870, has the marriage rate been so low as it was in 1889, in which year there was a decrease of 3,900 in the number of marriages compared with those that were contracted in 1888. With respect to births, the decrease last year, compared with the preceding one is put down at 2,000.

Despite the fact that the country is richer in resources than most of its neighbors, the fact remains that the number of marriages goes on decreasing, and in addition, there is a distinct purpose on the part of married couples to limit the number of children. This is more perceptible amongst the class that is called well-off than amongst those in a humbler position; but the children born to poor parents are too often sent a few days after their birth to some distant part of the country, where they soon drop out of life. There are also statistics belonging to illegitimate births based upon the ratios of the different peoples of Europe, but though the analysis may be of interest, they seem in the main to be explained on the score of obstacles to matrimony, as inadequate means or possibly parental opposition.

As it is, the individual exalts himself above all community interests or moral considerations in thwarting nature by preventive means, or a resort to abortion outright. Such crimes being secret are of course well guarded, but as every physician suspects their practice is widely spread. The penalty falls upon the race in its being displaced by a more prolific one and finally the catastrophe of utter extinction ends the history of its achievements. When the abortionists began to swarm into Rome, they also beckoned on the barbarians who made the imperial city a contemptible object of commiseration. Perhaps our late census may reveal truths equally unpleasant and the American, whose parents have so ingeniously conspired to keep out of the world may even cease to be a factor in the raging battle of races. There is much need of fellowship between the moralist and the physician. The Sybarite who drifts into all kinds of perversions, being an enemy of society, deserves at the very least, exile if not execution. Let us anyhow face the truth that there are many other sinners besides the French.

THE LATE CANON LIDDON AND THE MEDICAL FRATERNITY.—In the death of the Canon of St. Paul's, London, the medical profession has lost a sincere friend. He was the son of a physician, and near relations of his follow the same calling in the city of Taunton. He ever manifested, in his public addresses, a most sympathetic bearing and even laudatory expression towards our profession. Canon Liddon seldom let slip an occasion, in the pulpit of St. Paul's Cathedral, when he could fitly say a kindly word concerning the duties, worth and work of medical men. His was a nature, finely strung to catch the chords that vibrate under the influence of physical suffering; and he would be disposed naturally to accord his grateful sympathy to those who moved among the scenes of suffering intent on their allaying, and sparing not themselves where their labors could do good. In his early days, no doubt, he had many opportunities to get an inner view of the daily round of the responsibilities and labors of his medical relatives, and a deep and abiding impression was left which made him ever after a sympathizing ally of the healing art.

THE FRUITFUL BERLIN CONGRESS.—As one successful Congress leads inevitably to others, we have the right to expect that those that follow

the great Berlin gathering will be pregnant with immense benefits to medicine. Furthermore, Hy-men is said to have done an unusually large business at Berlin; according to one of the papers of that city, one of the results of the meeting was the publication of four hundred engagements of marriage. Any nation that desires to boom matrimony should have an International Medical Congress without delay.

DR. EDSON of New York has said: "From a sanitary standpoint the milk supply of cities is second only in importance to the water supply. The most vulnerable portion of the community to the attacks of disease are children."

It is said the Marine-Hospital Department contemplates having medical men attached to all United States Consulates, who will examine all persons desiring to emigrate to America, and ascertain their physical fitness.

ALCOHOL AND CHILDHOOD.—A Report of the Conference on "Alcohol and Childhood" held recently under the auspices of the Church of England Temperance Society (the Duke of Westminster in the chair) which excited so much attention by reason of the number of influential medical men attending it who had not hitherto identified themselves with the Temperance movement, is about to be published by the Society in a separate form.

NORTH CENTRAL ILLINOIS MEDICAL ASSOCIATION.—The seventeenth annual meeting of this Association will be held in the City Hall, Streator, on Tuesday, December 2, 1890, at 10:30 A.M. Special Reports: "Tenth International Medical Congress," by E. P. Cook, Mendota; "The Code of Ethics," by J. W. Pettit, Sheridan; "A Case of Hydrophobia, or Lysophobia," by W. A. Mansfield, Metamora; "The Use of the Obstetrical Forceps," by T. H. Steele, Paw Paw; "Management of the Newborn Infant, and the Child under the Age of two Years," by F. C. Vandevort, Bloomington.

This Association having nearly doubled its membership within the last five years, embraces a steadily widening territory and influence, and presents a most healthy growth. It seeks to promote the social and professional relations of its members; to afford an opportunity for the mutual comparison of experience and results among those

practicing within the same locality; and to stimulate and encourage the earnest medical student and practitioner in his individual effort within the field of professional progress. Its proceedings are of general interest to the profession; its discussions practical and free, and the relations of its members fraternal and unreserved. Physicians eligible to membership are cordially invited to unite therewith and contribute papers, clinical reports or professional experience, and engage in the discussion of the topics presented at its meetings. Copies of by-laws and membership blanks forwarded on application to the Secretary, Wm. O. Ensign, Rutland.

A GLASS AND METAL OPERATING TABLE.—The *N. Y. Tribune* says: French ingenuity has devised a surgical operating table, which, as a decidedly original conception in that line, has elicited much interest. The table, which measures seventy-eight inches in length by twenty-six inches in width, stands thirty-six inches from the floor, and consists exclusively of glass and nickel-plated iron. It is composed of four triangular plates of glass inclining to a common centre by a declivity of an inch and a quarter, converging at their apexes to a central opening one inch in diameter, in which is fixed a metal ring, through which fluids may pass into a rubber tube to the floor, and it is supported by four legs, connected for the sake of stability by cross-bars; it moves freely upon large castors, and though weighing 280 pounds, can be moved with ease by a single person; there are no arrangements for varying its elevation, any desired change in the attitude of the patient being accomplished at will with the use of rubber cushions. At the head of the table, where stands the assistant, swings a basin large enough to contain everything needed for anæsthesia, with ether, chloroform, also forceps, etc.; closed, it disappears under the table, but a very slight traction places directly under the anæsthetist all the articles needed. The table is also measured off into centimetres in its entire length, so that measurements may be rapidly taken.

SILENT HARMONIES.—A new medical club in Boston has been organized for the mutual cultivation of its members in music, and is known as the Physicians' Musical Culture Society. It is said that each member is in duty bound to compose some fresh air for the sick-room.

TOPICS OF THE WEEK.

THE RELATIONS BETWEEN PHYSIOLOGY AND MEDICINE.

Dr. James Andrews, in the course of the Harveian Oration delivered at the Royal College of Physicians, London, refers to this subject in words as follows:

A very common reproach cast upon our profession is that we pretend to be, and are not, scientific; that, to quote an old sarcasm, our occupation consists in putting drugs of which we know nothing into bodies of which we know less. There is just sufficient truth in such criticisms to make them somewhat unpleasant to those for whose good they are no doubt intended, but they derive the keenness of their sting from our own shortcomings and mistakes. We claim too much and do too little for medicine. We forget that our duty as medical men is twofold—to practice an art and to study and advance a science; that we are bound to make the best use we can of the knowledge within our reach, and, if possible, to add to it in the using, but this last is not our chief duty. We dare not sacrifice the interests, the life of one single patient to the advancement of science. If our conscience were to cease to forbid us to do this, then the sooner modern science deprives us once for all of such a treacherous guide the better for the world will it be. A man may be a first-rate practitioner and yet have no title whatever to be ranked among scientific physiologists, as a sailor may be a first-rate navigator without being in any proper sense of the word a scientific astronomer or mathematician or physicist. Yet, in spite of this admission, the physiologist ought to be the last to taunt us with ignorance and empiricism, for his own science would be far more imperfect than it now is were it stripped of all that it owes to the results of medical and surgical practice. One of the best, if not the best, definitions of "medicine" is that which describes it as "applied physiology." If we fail to attain to that ideal, if we are compelled daily to act upon probabilities in place of scientific certainties, then the blame must rest at least as much on the physiologist as on ourselves. He fails to supply us with the knowledge which we require and which he alone can give us. Medicine is thus but one of many instances of an art stunted by the insufficient development of the science with which it is connected and on which it rests. I do not mean insufficient in a general sense, but insufficient for certain special purposes. Permit me to anticipate a very possible criticism upon what I have just said. It may be thought that my words are an unfair attack upon physiology, and that, safe from immediate contradiction, I have sought to defend medicine by abusing the very science to which, of all sciences, we are most deeply indebted. Now, if I have, indeed, done this thing, I have been guilty of the basest ingratitude; I have ignored the splendid services which physiology has rendered to medicine, services which we believe to be but the earnest of others yet more splendid in the near future. If physiology is, as it seems to me, not yet equal to all the requirements of medicine, that is certainly not due to the indolence or weakness of those who cultivate it, but to the inherent difficulties of their task. They

have done all, and more than all, which we could have looked for. But at the sight of sickness which we cannot heal we grow impatient, unreasonable, and long for knowledge not yet within the reach of man. We even refuse to recognize the wisdom of those who decline to attempt to solve by scientific means problems not yet ripe for such solution. However, although the object matter with which we deal lends itself unwillingly to strict scientific method, although from its very nature we are unable to submit it to direct experiment, except in most imperfect fashion, it may still be studied and observed in a scientific spirit. Every case of disease may be, ought to be, looked upon as an experiment in practical physiology, an experiment carried out with transcendent skill by nature herself, but which she leaves it to us to observe, to register and to interpret.

Now, in this matter of scientific observation it cannot be denied that we fall very far short of what we might accomplish. It will do our profession no good to dwell upon the legitimate excuses which may in part explain our failure; rather let us acknowledge that failure and use our utmost efforts to remove it. Nor are leaders wanting who can teach us how this may best be done. We need not look beyond the circuit of our college to find men who can and do carry on their daily work in this scientific spirit, approving themselves herein worthy followers of the example of Harvey. Surely we cannot regard Harvey the physician as less scientific than Harvey the anatomist and physiologist, when we find him showing from certain familiar reasonings that the circulation is matter both of convenience and necessity. In his hands the physical signs of an aneurysm, the effect of extreme cold, the phenomena which attend "contagions, poisoned wounds, the bites of serpents and rabid animals, lues venerea, and the like"—all these are made to supply probable and cogent arguments for the truth of the doctrine of the circulation of the blood. Were our clinical knowledge as carefully accurate in its statement of facts, were it always used as soberly and to as good purpose as Harvey's was, then there would be, there could be, no outcry raised against us on the score of credulity or of want of scientific method. When he had arrived at a knowledge of the circulation of the blood by means of anatomical researches and vivisections, Harvey at once applied this knowledge to the explanation of clinical phenomena, up to that time inexplicable. He then used the fact that this explanation was a simple and adequate one as a new and strong argument for the truth of his discovery. That this intimate connection, this solidarity, between physiology and medicine is no longer recognized so fully as it once was is much to be regretted, for it is injurious to both lines of study, and has arisen, at least in part, from faults on both sides. But this view must not be pushed too far. We must not lose sight of the fact that the relationship between physiology and medicine has in many ways greatly changed during the last 250 years, and that such change is a necessary consequence of the progress made by physiology. In Harvey's time, in any classification of the sciences, physiology might have been regarded as a department of medicine. I need scarcely say that now

the reverse would be the case. The two deal, it is true, with the same object matter, for there is no physiological fact or law which is without some bearing upon medicine; and, again, every medical fact or generalization, even those most purely empirical, is more or less important to physiology. But their aims and methods are so different that they tend inevitably to become more and more sharply differentiated from each other. The goal of physiology is truth—*i. e.*, perfectly trustworthy knowledge of a certain class of facts and laws; and this independently of any use, good or bad, to which that knowledge may be put. The goal of medicine is power—*i. e.*, ability to manipulate certain natural forces in such fashion as to produce certain effects. No doubt theoretically the two ends coincide, and we may hope that in some remote future they will do so in reality and perfectly. For the present we must be content with having in one direction much knowledge which confers little or no power, and on another side very imperfect knowledge which yet brings with it very great power, too often ill-directed. Again their methods are different. Physiology by slow degrees has come to rely more and more on purely scientific modes and instruments of research, and to apply them by preference to matters which can be brought to the test of direct experiment. Medicine, on the other hand, has no choice but to remain, so far as it has a scientific side, a science of observation; for anything like effective investigation of the matters with which it deals by direct experiment is impossible. As physiology slowly reduces to order the apparently hopeless confusion of so-called vital actions the easiest questions are attacked and answered first, and thus those which have to be faced later in their turn are more and more difficult, more and more refractory, to scientific analysis. Now, these more difficult questions are often of vital importance to medicine, and in them lie dormant vast possibilities of increased knowledge of the nature of disease, of increased power over it. And yet from the great difficulty of subjecting them to experiment physiology may seem for a time to fail us, and the task of employing physiological results to explain clinical facts, or to form the basis of rational treatment, becomes harder than ever.—*The Lancet*.

PROFESSOR ROBERTS BARTHOLOW.

With reference to this distinguished physician and teacher we quote the following from *The Times and Register* of November 1:

"Up to the time of writing the situation at Jefferson remains unsettled. Prof. Bartholow declined to take a vacation, and the Trustees have declared his chair vacant, and will elect his successor on Monday. While Dr. Hare is most frequently spoken of as the chosen successor, many urge Drs. S. Solis-Cohen, T. J. Mays, Frank Woodbury; and Dr. Potter, of San Francisco, is also mentioned prominently. The action of the students, though prompted by the generous feeling of affection to their old instructor, was ill-advised in the extreme. Nobody has the interests of Jefferson at heart more than the Faculty and Trustees, and they may certainly be credited with having very good reasons for displacing as strong a man as Dr.

Bartholow. It is not always best for the interests of either party that these reasons should be made public; and serious injury might have resulted had the students persisted in their action. As a graduate and well-wisher of Jefferson we trust that the result will be favorable to her best interests. Of the gentlemen named, Dr. Cohen would be, perhaps, best fitted to deal with an unruly class. He has won an honorable place among Philadelphia physicians, and displayed talent as a teacher. Dr. Woodbury would bring to the chair a ripe professional scholarship, with considerable practical experience as a teacher. As a clinician he has no superior. Dr. Potter has made a very favorable impression with his book on therapeutics, which has been adopted as a text-book in many colleges."

The Lancet-Clinic, of the same date, has an exceedingly interesting editorial upon "Overstrain and Overwork," evidently prompted by the sad lesson. Sketching with a masterly hand the salient points in the life of Dr. Bartholow, the editor closes his article with these words:

"A pall of mournful sadness comes over us as we contemplate the thought of this termination of such a career as that of the indomitable, the gifted Dr. Roberts Bartholow. A lesson, a parting lesson, is hereby taught, and should be thoroughly heeded by those who feel the iron grip of an insatiable ambition that is inordinate in its character, that leads and goads the discontented to a violation of physiological laws in order to be able to accomplish some specific purpose that may be ever so laudable in motive. To some we say: *Slow up*; lest a link be weakened and the golden bowl broken."

THE INTERNATIONAL MEDICAL CONGRESS AT BERLIN.

The first volume of the *Transactions* of the International Medical Congress at Berlin is already in the press, and will be published in November. In addition to the business part of the proceedings, lists of delegates, members, etc., it will contain the report of the general meetings of the Congress. The work of editing the *Transactions* is in the hands of a committee composed of Professors Virchow, von Bergmann, and Waldeyer. The expenses incurred by the city of Berlin in connection with the recent International Medical Congress amounts to some 80,000 marks, so that, of the sum of 100,000 marks voted by the municipality, a balance of 20,000 marks (£1,000) remains in hand. The expenses included the cost of the *Festschrift* presented to members of the Congress, the banquet in the Rathhaus, the exhibition, the sanitary and other inspections, and the electric illumination.—*Brit. Med. Journal*.

PROPAGATION OF DISEASE.

M. G. Alessi has confirmed and extended the results of Grassi on the part taken by flies in the propagation of disease. Having fed flies on the matter expectorated by tubercular patients, he has detected the bacillus of tuberculosis in plenty in the intestines and in the excretions of the insects. The bacilli are alive and active, and if introduced into the tissues of animals, they multiply and produce characteristic lesions. The microbes of cholera, of typhoid fever, splenic fever, etc., are likewise swallowed by flies, and after passing through their bodies, retain all their vitality and virulence.—*Research*.

PRACTICAL NOTES.

PRESCRIPTION FOR ALOPECIA.

Dr. Morvan, in the *Union Médicale*, recommends the following salve in alopecia:

Gallic acid, grains, 45.
Essence of lavender, minims, 15.
Castor oil, drachms, 6.
Vaseline, drachms, 12.

M. This ointment should be well rubbed into the parts affected, every night.

OINTMENT FOR PIGMENT SPOTS OF PREGNANCY.

The following prescription for the treatment of cloasma of pregnancy is quoted by the *Revue de Therapeutique*.

R—Zinc oxide, 1 drachm.
White precipitate, 1½ grains.
Castor oil, 2 drachms.
Essence of rose, 10 drops.
Cocoa butter, 2 drachms. ℞

Apply morning and evening.—*Med. News*.

FOOD FOR INFANTS.

Dr. Louis Starr recommends the following as the best substitute for the mother's milk in gradual weaning of a child, say at ten months; it may also be employed to supplant the breast when the mother's milk is insufficient:

Cream, fʒss;
Milk, fʒiiss;
Sugar of milk, ʒss;
Water, fʒj.

Should this quantity fail to satisfy the child, all the ingredients except the cream may be increased until the mixture measures six, eight or twelve ounces.

TELLURATE OF POTASSIUM IN NIGHT-SWEATS.

According to *La Médecine Moderne*, October 21, 1890, tellurate of potassium has been found by Neusser to be valuable in the suppression and diminution of night-sweats. He employs one-third of a grain, in pill form.—*Medical News*.

CHRONIC OVARITIS.

Aside from the reflex physical derangements, both local and general, attending chronic ovaritis, there is usually present a greater degree of emotional disturbance than is found in disease of any of the female genital organs. This is not strange, since it is admitted that the ovaries give to woman, in a great measure, all of her characteristics of mind. When the inflammatory conditions are unfavorable for recovery, the emotional derangement is often progressive. In the early treatment counter-irritants and alteratives often give good results, especially the administration of small doses of the bichloride of mercury three times a

day. But, should the tissues of the organ become destroyed and suppuration take place, removal will alone give relief.—Godfrey, *Times and Register*.

LOCAL ANÆSTHESIA FOR SLIGHT OPERATIONS.

For operations upon small abscesses, opening fistulous tracts, or removing superficial growths, it is recommended that local anæsthesia be secured by atomization of the following solution:

R—Chloroform, 10 parts.
Sulphuric ether, 15 parts.
Menthol, 1 part. ℞

The anæsthesia which is thus obtained lasts from two to ten minutes.—*Medical News*.

FOR ACUTE PLEURISY.

R. Ext. jaborandi fl., ʒj.
Sig. Take at once, in a cup of hot water.

R. Sodii citrat., ʒij.
Sodii acetat., ʒij.
Sodii salicylat., ʒij.
Aquæ menthæ pip., q. s., ad fʒvj.

℞.—Sig. ʒss every two to four hours.

Hot flannels to chest, sprinkled with laudanum, and a towel pinned tightly around body; dry diet; rest in bed; flannel underclothing and night-dress.—Waugh.

SOLUBILITY OF NEW MEDICINES.

The following table of solubilities of some new medicines may be useful to some of our readers:

One part of	Is soluble in		
	Water.	Alcohol.	Ether.
Antifebrine	200	10	10
Antipyrin	1	1	50
Antithermin.	{ slightly soluble.	{ slightly soluble.	{ slightly soluble.
Cocaine hydrochlor.	5	10	
Iodol	5000	3	1
Paraldehyd	10		
Pyrodine	1	1	
Quinoline tartrate,	80	150	
Resorcin	1	1	
Salol		5	5
Thallin (sulphate)	7	100	
Thallin tartrate	10		
Urethane	1	0.6	

—*Pharm. Record*.

FORMULA FOR A GUAIAIC GARGLE.

To not a few of our practitioners, who have passed their meridian, guaiacum is esteemed only a little less than a specific for "sore throat," tonsillitis especially. The following is a combination for a gargle that has been very useful:

Ammoniated tincture of guaiac, 4 drachms.
Compound tincture of cinchona, 4 drachms.
Chlorate of potash, 2 drachms.
Strained honey, 4 drachms.
Powdered acacia, q. s.
Water, 2½ ounces.

To be used as a gargle, and a teaspoonful may be swallowed, every second hour.

SOCIETY PROCEEDINGS.

Chicago Medico-Legal Society.

Regular Meeting, October 4, 1890.

EDMUND J. DOERING, M.D., PRESIDENT, IN THE CHAIR.

DR. M. H. LACKERSTEEN read a paper on

THE SCIENTIFIC ASPECTS OF MEDICAL HYPNOTISM, OR TREATMENT BY SUGGESTION.

(See page 704.)

DR. ARCHIBALD CHURCH: Mr. President, as you have just stated, Dr. Hoag and myself were informally appointed by you as a sort of committee of control to coöperate with Dr. Lackersteen in such experiments as might be possible for us to make looking to the determination of the therapeutic value of hypnotism. In a conversation held on the 12th of March last we arranged that patients of a suitable sort secured by any of us should be first seen and carefully examined by Dr. Hoag or myself, and then subjected to treatment by suggestion, by Dr. Lackersteen, such treatment to be at times under our observation with every opportunity to examine and note the condition of affairs as the cases progressed. For a number of reasons we have been unable to carry out these details. To speak personally, patients coming to me in dispensary practice refused to be sent down town for hypnotic treatment, and patients in my private practice could not be sent for a number of reasons. So far as the committee have a report to make it is absolutely negative with this exception: two cases were referred to me by Dr. Lackersteen for diagnosis and examination previous to their being treated by him. One was a medical gentleman from Texas, a maniac with well pronounced delusions and hallucinations of hearing. He subsequently went to Dr. Lackersteen, but I believe the séance was a failure; shortly afterwards the man left town suddenly, pursued by his delusions of persecution. The second case was one of a young lady of well-marked hysterical make-up, presenting a large number of hysterical manifestations in her daily conduct, indications of the malady. I did not see her subsequently, but I am informed that after a number of séances she commenced teaching school and now has a responsible position, which she fills to the satisfaction of all concerned. At the time I saw her this would have been impossible.

It now remains for me to give the little personal experience I have had with hypnotism. Hypnosis is usually produced by fixing the eyes upon a bright object held at a short distance, and suggesting sleep. In my first ten experiments, as I was anxious to eliminate the personality of the hypnotizer, I did not suggest to these people that they were to be hypnotized, but had them

fix their eyes and attention upon a bright object held near the eyes and above the ordinary line of vision. They maintained an intense gaze for from five to thirty-five minutes, depending upon their good-nature. I did this with a little trepidation, because I was aware of the experiments of Drs. Dercur and Parker where, merely by having the finger tips extended and the eyes and mind fixed upon a given object for from ten to thirty minutes, serious convulsions resulted. If this could be done by the physiological strain of a set of voluntary muscles, it would apply to the convergence of the eyes; but I am glad to say that in the ten examples I have cited there were no bad results, and no results of any kind whatever.

In the next seven experiments, besides using a bright object, I told my patients that after a given time they would surely go to sleep; but no sleep was produced. The last case was that of a hysterical girl who had been bed-ridden for two years. I explained hypnotism to her as well as I could, I dilated upon what had been accomplished, interested her in it, and she was finally very anxious to be hypnotized, desiring hypnotism or any other means that would relieve her sufferings. After fixing her attention by my fingers the eyes finally closed and I thought I had her hypnotized, and I said, "You are asleep," but she giggled, and giggling and hypnotism are incompatible. So I impressed upon her that the giggling must be left out, and after a number of séances marked by great perseverance and patience on the part of both, in two instances only I was able to establish a slight degree of "drowsiness," as she expressed it. After the suggestion she would appear to be asleep, the eyes would be closed, there would be a little quivering of the lids, I could see the eyeball was turned up under the lid, and I suggested that the pain, which had been her terrible complaint for a number of years, causing lack of sleep, would upon awakening be absent, and that she would sleep well at night. But the pain neither disappeared nor did she sleep, and consequently if it was hypnotism that was produced, it was of no value in this instance. This fact should be borne in mind, that where a mesmerist goes into a small community, he first exhibits his skill upon a subject he has brought with him, and professes his ability to hypnotize any one. To see is to believe in hypnotism as in other things, so on the second night the mesmerist will get two or three subjects from the audience, and the following night maybe half a dozen. In my experiments—and I presume the same difficulty will be encountered by all—I had no subjects to act as object lessons for those I wished to experiment upon.

I should like to point out some of the alleged dangers of hypnotism, because unquestionably it is a wonderful force. The examples which have been tested and published, and verified by unquestioned

authorities, no longer leave any doubt of the existence of such a thing as hypnotism. But it is well to know that the fire can scorch before playing with it. Sir Andrew Clark, as quoted in the *Therapeutic Gazette*, states that in his opinion, "the habitual practice of what is called hypnotism, among women, is very injurious both morally and intellectually." And in the *Medical Record* of recent date, Dr. Norman Kerr, of London, among other things asserts "that only a limited number of persons are susceptible," and I may add that only a very limited number of persons are capable of being hypnotizers; which leads to the conclusion that hypnotism must be of very limited utility: "that the after-effect is a disturbance of the mental forces and dissipation of nerve energy; that frequent repetition is apt to cause deterioration of brain and nerve function, intellectual decadence and moral perversion. That hypnosis is a departure from health, a diseased state; that hypnosis is a true neurosis, embracing the lethargic, cataleptic and somnambulistic states; that the dangers of hypnotism are great. That each séance may bring the hypnotee further under the control of the hypnotizer, with complete submission of the former to the will of the latter." We must not forget that the most enthusiastic of European hypnotizers detail cases that wander around their hospital wards, leading a mere vegetative existence which has been induced by repeated hypnotic treatments; men and women who at the slamming of a door or the crash of a bit of glass instantly go into a hypnotic condition in which they are the subjects of the caprice, malice or criminality of all about them. Any one producing a condition like this must look upon it, even if he is only remotely responsible, with anything but satisfaction. The dangers of hypnotism are very pronounced, so much so that the matter has been made the subject of legislation in Russia, and public demonstrations of hypnotism are prohibited. The medical fraternity only are allowed to use it for so-called therapeutic purposes, and this only with three medical men in conjunction. In Belgium it is restricted to the use of medical men, and in no instance can it be applied to girls under 18 years of age. In France its public exhibition is prohibited and the medical department of the army and navy has been interdicted in its employ. We are to remember that in our own country, cases are on record where individuals have gone from the excitement of mesmerism into the agonies and delusions of insanity, and down through dementia into the irrecoverable depths of imbecility.

The two claims for hypnotism is that it is a therapeutic measure and that it may be an aid to psychical research. It may be admitted that in functional conditions and undeveloped aptitudes hypnotic treatment has and will have a sphere of action more or less legitimate, but to use hypno-

tism to remove a headache or a toothache is, as a German writer has put it, gunning for sparrows with heavy ordnance. Besides, hypnotism must be repeated at short intervals, and this brings in again the danger of the proceedings, because its repeated use, will lead undoubtedly to an increased susceptibility on the part of the patient, in itself a mark of mental deterioration and lack of self-control. The responsibility of the hypnotizer is of the greatest. To deprive a fellow being of his will power, be it only for a moment, and to substitute your own volition is in my estimation one of the greatest responsibilities in the whole range of human intercourse. Theologians tell us the Almighty himself has not assumed this prerogative, but has left man a free agent to work out his own salvation. The therapeutic use of hypnotism in conditions arising from gross pathological lesions is to be considered. Cases are on record where the pain of cancer has been controlled by hypnotism, of course the cancer has not been controlled, and in these cases it is comparable to the use of morphia for the control of pain. But if the disease runs a long course, I believe that mental deterioration will follow the use of hypnotic treatment, for it must be repeated daily. If hypnosis is, as some have claimed, an abnormal mental condition it is a serious question whether it will be of any value in psychological research. There are plenty of instances in which the will power has been blotted out, or the power of properly correlating ideas, and innumerable mental perversions have been studied, yet all these cases have not added very much to real knowledge of that group of diseases called psychological.

From all these considerations, and from the fact that abroad it has been found wise to control the exhibitions of hypnotism by stringent laws, I think that it is fitting for this society to adopt resolutions looking to the prevention of public exhibitions of hypnotism and to the limit of its employment to the medical profession. I do not wish to discourage hypnotizers, because I believe there is something in it of therapeutic value in proper cases, but I do believe those employing it should be protected and that those subjected to it should be thoroughly protected. A person should never be hypnotized except in the presence of reliable witnesses, and in the case of a woman, in the presence of her own sex. If these dangers I have mentioned are real the obligation upon the hypnotizer to acquaint the subject with them is as binding as in a case of laparotomy, and he should do this for his own protection. Yet if he does this as you will readily see very few will subject themselves to its influence. I desire to express my gratitude to Dr. Lackersteen for his brilliant paper, which is the best résumé of the subject with which I am familiar.

DR. J. C. HOAG: I think we are all prepared to admit that Dr. Lackersteen is an enthusiast,

and there is no doubt but that enthusiasm is necessary for the propagation of such ideas ; but whether or not we accept hypnotism in its entirety, there is nevertheless, a great lesson to be learned from the practice of the hypnotists. To my mind the successful physician must necessarily be an enthusiast. If he does not believe in the efficacy of his remedies, if he gives his doses in a doubting manner, he can hardly expect to secure their best results. I remember as a student having Stillé's "Materia Medica" recommended to me for reading. I think if I had contented myself with Stillé and never read any other author I would have concluded my medical studies there. It is a ponderous work, and one reads it through without getting any definite ideas ; and when one completes it he has nothing left which he can assert positively. So it is in our daily practice. If we look at the physicians who enjoy the greatest confidence of the community, we find they are the ones who have positive ideas and who impress their individuality upon their patients.

I have not seen any hypnotism done for a number of years, but I have seen some of it and I am prepared to believe that much of excellence lies in this method. Of course, there is always an element of danger in its practices, and the subject is still a comparative novel one, but so much am I impressed with its possibilities, that were I in Europe to-day, one of my first pilgrimages would be to Nancy.

I have never tried to hypnotize any one but I believe in the possibilities of hypnotism. I have read whatever has fallen in my way in this connection and have never yet seen anything, and presume there is nothing, that gives one a satisfactory explanation of its powers. I have read two or three brochures on the subject ; one of which was by an Englishman, Dr. Tuckey. This observer had paid visits to Liébault, Bernheim, Charcot and others in France, and had returned to England very much prepossessed with the method. He had had considerable practical experience, and he gave an explanation of hypnotism, or at least led one up to a comparative explanation by an inductive method. This writer takes well-known facts with which we are all familiar and puts them together in such a way as to gradually lead one into the realms of the unknown, with the feeling that there was still something substantial under his feet ; and he gets at the matter in some such way as this : For instance he takes the example of John Hunter, who said he could produce by will sensations in any part of his body by simply concentrating his thought upon them. Another writer said, that if twenty individuals would sit down in a room and look attentively at their little fingers a good many minutes with the idea that there might be something wrong there, most of them would have decided

sensations of pain. Tuckey gives a report of a physician with a decided mitral valve-disease of the heart, who felt no uncomfortable sensations except when he was examining patients with a cardiac lesion, during these times he experienced great discomfort simply by having his attention drawn to his own condition. We are familiar with such facts as increased secretion from the kidneys caused by emotion, and the effect of concentration of thought upon the various secretions ; for instance the flow of saliva may be retarded or increased by emotion. Again we have the effect of icterus, from violent emotion, such as hate or jealousy. Statements of this kind have long been familiar, and we know that in point of fact there is a substratum of truth in such stories. A great many cases are on record of paralysis of a functional nature of long duration which have been entirely removed and permanently cured by the powerful impression made upon the patient. Such is the case of a young lady who had been confined to her bed for a year and who, on being suddenly informed that an accident had happened to her brother, rose from her bed at once and went to him and took care of him and was afterwards in good health. Cases of sea sickness are often relieved in the same way, if the passengers believe that the ship is about to sink or are otherwise seriously alarmed for their safety.

A familiar example is that of medical students, who while they are studying the accurate description of diseases, fancy they have the ones in which they are most interested. It is a matter of common observance that medical authors very frequently die of the disease to which they have given the most attention during their lives. In regard to the effect of fancy in producing disease we have such examples as occurred recently in the illness and death of the Emperor Frederick ; there were epidemics of throat disease due entirely to fancy. Idleness is a great factor in these matters. People who have little to do keep their minds concentrated upon the functions of their bodies, and are often the victims of disease, as we see in the case of hypochondriacs. Now where perversion of function comes on in this way it is apt to lead to tissue alteration. It has been said too, that the fixation of attention upon a certain part of the body will render us conscious of functions that are usually performed in an automatic manner. Sir James Paget, says that temperature may be elevated by nervous excitement. In hysterical neurosis the temperature may rise exceedingly without apparent cause. In the same way anemia may be caused by depressing emotions, while pleasant surroundings are promotive of health.

Again, in the case of exerebration, some portions of the brain may become temporarily inhibited in their action by the activity of others, as in the familiar example of paralysis from fear, paralysis

of motion. An example is related of a burly farmer who was in perfect health and whose friends agreed to pronounce him in poor health and to impress it upon him that he looked badly. One after another they approached him in this way, until finally the man took to his bed and was actually sick. I would like to refer to one or two other cases: for example that of a Frenchman of noble birth who was condemned to death; his friends wished to save him from the ignominy of the guillotine and obtained permission from the authorities to try an experiment upon him. He was blindfolded and his arm slightly pricked with a sharp instrument and warm water allowed to trickle over his arm, and at the same time remarks were made to the effect that the man was going to bleed to death, that he was rapidly sinking, etc., until he actually died of syncope. Then there is the curious example of the fakirs in India producing an apparent suspension of vitality, so that they have been buried in the earth for weeks at a time and then taken up and restored to usual health. Colonel Townsend performed a similar feat, although he was not buried, but animation was so completely suspended that five or six professional men could discern no evidences of life.

Now the argument is that if death may be produced in this way, may we not look for cure in the same manner? If sickness and death may be produced in this way so may regeneration and health. And there is nothing fanciful in the cures of believers by pilgrimages to Mecca, to the Ganges, to the shrine of Our Lady of Lourdes, or to the shrine in Mexico of the Lady of Guadalupe. Amulets are sometimes worn with perhaps very decided benefit. In olden times in England it was customary for the king at intervals to touch the people for the "king's evil," and it is on record that cures were made in this way and that the influence was one of great good.

Again, by attention the special senses may be sharpened, as in the case of the savage, the hearing is improved and the sight becomes very keen. In people who are obliged to pass judgment upon fabrics the sense of touch becomes very acute; the same thing is seen in the case of the blind. All these are examples of what may be done by what has been called *directed consciousness*. These are the main facts to which I wish to call attention, and by passing from familiar facts like these to the unfamiliar ones of hypnotism, we can see at least a constant progression. There are statements, to be sure, that seem utterly absurd, but as we approach them more closely we find more and more in them that appeals to the reason.

As an example of what has been done even by professional men in the way of injury to patients, I may cite the case of a woman who was readily hypnotized, so much so that it was almost im-

possible to tell in what condition she was at a given time, whether in her usual health or in one of the three hypnotic stages. This patient was kept under observation so long and was so often put in the hypnotic state, that she escaped, and being pursued was recaptured and experimented upon until she was finally sent by the government to the insane asylum. Her insanity was probably inevitable, but it seems to have been hastened by the ordeal which she endured at the hands of her attendants. I wish to thank Dr. Lackersteen for his interesting paper.

DR. D. M. BROWER: I wish to thank Dr. Lackersteen for his very interesting and enthusiastic paper. My experience with hypnotism has been quite similar to that of Dr. Church, and from observations that have run through several years I have come to the conclusion that there are very few people in the United States who are susceptible to its influence. I believe that the danger from the practice of this method of cure more than covers the possible benefits. I think the benefit is limited entirely to functional diseases, and it seems to me it must be limited to diseases that we have already reached by other means that are less dangerous. I most heartily endorse the suggestion of Dr. Church, that this Society declare its thorough disapproval of public exhibitions of this art. There has been going on for the last six months in London a public exhibition of hypnotism that attracts thousands; there is a similar exhibition in New York, and I presume we will have them here. I trust that this society, while not condemning the method as a curative measure, will put out a signal of danger, and at least insist upon some sort of legislative action that will limit its use to physicians under certain restrictions, and will absolutely prohibit public exhibitions of this dangerous method.

DR. T. P. SEELEY: I have but a word to say on this subject. I happen to have had a little experience in 1849 when I was a student in college, before I attended a medical college. The subject of hypnotism attracted considerable attention and I had the curiosity to try it, and found I was capable of hypnotizing, or mesmerizing, as we called it then. In one case I hypnotized a young lady, put her in a condition of anæsthesia, in which state she had a tooth drawn without any more apparent feeling than if she had been under chloroform. I hypnotized several individuals, among them one or two clairvoyants, and I was perfectly convinced at the time that there was something in mesmerism. I have always thought that the truth should be known and that the medical profession should investigate it. There ought to come no great harm from our knowing the truth; if there is a great deal of evil in this thing, there are evil persons, who will take advantage of the want of knowl-

edge of professional men. I believe there might be some knowledge gained by scientific investigation that would be of advantage to the whole community.

I am very glad to have heard Dr. Lackersteen's statements. I have not pursued the question and gained the knowledge I might have on this subject; I have used it at times in the cure of headache and for some other purposes. I give my testimony as to facts I knew forty years ago, and I do not believe the light should be concealed but that medical men should investigate and find out what the truth is.

DR. M. H. LACKERSTEEN: I should feel disposed to suggest the appointment of a committee to examine into the uses of hypnotism; this committee is to prevent the abuse of it. That is looking at it from a forensic point of view in order to save society from the ignorant sensationalist; but I think a body of competent physicians should be appointed to investigate the subject in order to ascertain to what extent it might be used in medicine, and if there are any points of danger—which we can all imagine; we must first demonstrate and prove the conditions of danger so that harm can be avoided. As to my supposed enthusiasm in the matter, I am simply an experimental hypnotizer of only two years' standing. In my travels over this globe I have kept my eyes open, and have seen this thing going on around me; I have seen people who have denounced it, and in five minutes afterwards proved as susceptible to suggestion as possible. I recall the case of a lady who had pneumonia and sent for me. I told her that she no more had pneumonia than I had. Her nephew, who was a pretty well advanced medical student, had examined her and assured her that she was very ill with pneumonia—he had a great deal of knowledge but very little wisdom—fortunately she did not believe him. I did not give her any medicine, it was one of those self-limited diseases, and she soon improved. Any amount of medication on my part would very likely have done more mischief than good.

When I was on leave in 1865, in Cashmere, there were seventeen physicians on leave there. The cholera broke out in the Maharajah's domains. We received nominal returns of the sick, fresh cases, those who remained, and those who died. And the whole of the capital was supposed to be divided into seventeen divisions with a doctor in each division; and we volunteered our services. A large part of the district was overlooked, and in this part, controlled by native doctors, there were 50 per cent. of deaths to 50 per cent. of cures, while some of our energetic boys had only 17 per cent. of cures. In reference to diseases about which we know very little, such as cholera, and of self-limiting diseases, of which we know more, great latitude of treatment is permissible. I had a case of a boy with scarlet

fever, a lad ten years old, a spoiled boy. I was sent for in the morning and found his temperature 104°, his pulse 120, there was a scarlet rash on his face. I hypnotized him and sent him to sleep for six hours, first assuring him that he would be perfectly cool and comfortable when he awoke; and so he was. His temperature was normal, but the rash had gone down to his abdomen and as soon as he woke up he urinated to the extent of nearly a pint, and his bowels acted. I gave him as much water as he wanted to drink, hypnotized him again and sent him to sleep until the next morning, but the disease progressed all the same. This subject is very interesting and in some cases I dare say hypnotism might so affect the secretions and nutritive functions as to alter the pabulum of the microorganisms, and in that way influence their fecundity. We do not know everything, and I think we have a right and a duty to investigate and learn; but to be dogmatic about things of which we are ignorant I think is not worthy of us as a profession. As far as investigations are concerned I shall be glad to lend my aid in carrying out anything with the help of others, but I think we should try to understand this thing, there is a great deal in it to be known; and so far as knowing it but interdicting its practice is concerned, it reminds me of the inscription in the University of Egypt which says, "My son, learn magic but do not use it."

INTERNATIONAL MEDICAL CONGRESS.

On the Constant Galvanic Current in Gynecology.

(Translated from the French for THE JOURNAL.)

At the International Medical Congress at Berlin in August, Dr. Apostoli, of Paris, read a paper before the Section on Obstetrics and Gynecology, August Martin, of Berlin, President, on the use of "The Constant Galvanic Current in Gynecology," in which he arrived at the following general and summary conclusions:

1. The constant galvanic current finds its principal indication in gynecology in endometritis and fibroma; sovereign against circulatory and painful affections (amenorrhœa, dysmenorrhœa, and metrorrhagia) it is a powerful agent in arresting the evolution of benign neoplasms and in aiding in the absorption of peri uterine exudates. It exercises a very salutary resolvent action in many peri-uterine phlegmasiæ and in certain catarrhal ovaro-salpingites, but it is inefficacious and even injurious in high dose, especially if the intra-uterine pole is negative, against the suppurative phlegmasiæ of the appendages.

Its variable intolerance, which will increase with the inflammatory state of the appendages, ought to serve as a valuable means of diagnosis to enable one to determine the existence and na-

ture of unknown or merely suspected peri-uterine liquid accumulations (bloody or purulent) and ought to serve, in this case, to hasten a delayed or declined surgical intervention.

2. The effects of the constant current are polar and inter-polar—the trophic and dynamic inter-polar action, which increases as the square of the intensity developed, is superadded to the polar action; this utilizes first each pole for a different end, as Apostoli has shown, then the calorific action developed by the passage of the current (for stimulating the interstitial circulation), and finally the antiseptic action of the positive pole, of which Apostoli and Laquerrière have given a recent experimental demonstration.

3. *High galvanic applications* employed in a variable manner, above 50 milliampères, according to the tolerance of the patient, and the various clinical indications, form the fundamental basis of Apostoli's method, and find justification: *a.* First in the utilization of the *circulatory drainage*, the direct consequence of the calorific action due to the resistance to the passage of the current, and proportional to the square of the intensity; *b.* In the *antiseptic* or *microbicide* action, which increases with the intensity developed; *c.* In the *rapidity* and *efficacy* of the effects produced, which are proportional to the square of the electric energy, according to a formula analogous to that of the measure of the energy of other natural forces: $q. = \frac{1}{2} m. v^2$; *d.* In the easier *general application* of the method to obstinate cases (hard fibromata and violent sub-peritoneal endometrites), and in young women; *e.* In the *prevention of return*, which, other things being equal, will be less to be feared, as the application shall have been the more intense.

4. If the vaginal application of the galvanic current (which is the method devised by M. Chéron for fibromas only, and since applied by A. Martin, Brachet, Ménière, Onimus, Carpenter, Mundé, etc.) gives results, they are very inferior to those of the *intra-uterine* applications, which must remain the *preferable method*: *a.* Because it utilizes, before all, the maximum of the current developed and of its energy; *b.* Because it utilizes the antiseptic action of the positive pole, which is wholly local, and which is consumed in the inter-polar circuit, and at the level of the negative pole; *c.* Because it often lays under contribution the derivative and caustic action of the intra-uterine application, thus treating by the same operation, either the simple endometritis or the endometritis, which, so often, complicates both fibromata and peri-uterine phlegmasiæ, and so assuring a more rapid, more complete, and more permanent cure; *d.* Because it conduces, better than vaginal applications, to the diminution of pain and renders the employment of high doses more tolerable, and finally assures a greater efficacy in making possible an increase of the ap-

plied intensity and of the sanguineous irrigation, which it induces.

5. Vaginal galvano-punctures, made at a depth of some millimeters (from two to five), by means of a filiform gold trocar, completely insulated except at the point, form the often very salutary complement of the intra-uterine therapeutics, originated by Apostoli, in better localizing the galvanic action and in rendering more efficacious the application of small or medium doses in certain cases.

6. The innocuousness of his intra-uterine therapeutics is established, first, by the parallel innocuousness of the chemical and bloody methods of intra-uterine treatment, and especially by the numerical data of statistics collected all over the world, and in particular by his own: From July, 1882, to July, 1890, he has made 11,499 galvanic applications, which are classified as follows: 8,177 positive intra-uterine galvano-cauterizations, 2,486 negative intra-uterine galvano-cauterizations, 222 positive vaginal galvano-punctures, 614 negative vaginal galvano-punctures.

He has treated 912 patients, comprising 531 fibromata, 133 simple endometrites, and 240 endometrites complicated with peri-uterine phlegmasiæ, of which there were seen in *clinique* 313 fibromata, 70 simple endometrites, 163 endometrites complicated with peri-uterine phlegmasiæ; *in the office or city*: 218 fibromata, 63 simple endometrites, 85 complicated endometrites.

He has had three deaths attributable to operative errors (two galvano-punctures, one for sub-peritoneal fibroma and the other for an ovaro-salpingitis—and one galvano-cautery for ovarian cyst mistaken for a fibroma). He has seen thirty cases of pregnancy occur after intra-uterine galvanic applications.

BOOK REVIEWS.

A SYSTEM OF ORAL SURGERY. Being a treatise on the Diseases and Surgery of the Mouth, Jaws, Face, Teeth, etc. By JAMES E. GARRETSON, A.M., M.D., D.D.S., President of the Medico-Chirurgical Hospital and Emeritus Professor of Oral and General Clinical Surgery in the Medico-Chirurgical College; Dean of the Philadelphia Dental College; Surgeon in Charge of the Hospital of Oral Surgery; Member of the Philadelphia County Medical Society, etc. Illustrated with numerous wood cuts and steel plates. Fifth Edition, thoroughly revised, with additions. Philadelphia: J. B. Lippincott Company; London: 10 Henrietta Street, Covent Garden. 1890. Price \$9.00.

Those who have been familiar with the former editions of this treatise upon oral surgery will anticipate that in the preparation of a new edi-

tion the author will have so re-cast and extended his labors as to include the latest literature, the latest improvements and the most approved methods pertaining to oral surgery and dentistry. In this respect there will be no disappointment. The purpose of the volume is to show what dentistry is, when practiced from the stand-point of oral surgery.

The present work contains over thirteen hundred octavo pages. Through the courtesy of other authors, by cuts which are familiar, and by the help of a large number of original drawings, it is well illustrated. In appearance, it is creditable to the publishers.

The description and surgical anatomy of the head including its muscles, vessels, nerves and glands occupy the first one hundred pages. Then follow chapters upon the mouth, the teeth, and upon dentition. The lesions of first dentition and their treatment constitute a chapter of value to the general practitioner as well as to the specialist. Another hundred and more pages are devoted to second dentition, to diseases of the teeth and to their treatment. Then follow a series of chapters upon operative and prosthetic dentistry, with ample illustrations.

The writer associates with oral surgery facial and pharyngeal disease, diseases of the nose, nerve lesions, tumors of the mouth and face, etc., and concludes with a chapter upon medical diagnosis, preliminary to the study of anæsthesia and the use of anæsthetics and antiseptics. The mastery of the subjects here considered will bring the physician and the dentist into inseparable relations, upon a common ground.

MISCELLANY.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from November 8, 1890, to November 14, 1890.

Capt. Louis A. La Garde, Asst. Surgeon U. S. A., detailed as member of board for duty in connection with the World's Columbian Exposition, and will report by letter to Major Clifton Conley, Ordnance Dept., member of the Board of Control and Management of the Government exhibit to represent the War Department. Par. 1, S. O. 260, A. G. O., Washington, November 6, 1890.

Capt. William D. Crosby, Asst. Surgeon U. S. A., is granted leave of absence for four days. By direction of the Acting Secretary of War. Par. 2, S. O. 259, A. G. O., Washington, November 5, 1890.

Lieut. Col. Charles Alexander, Surgeon, and Major Johnson V. D. Middleton, Surgeon, are appointed members of a board of officers, appointed to meet at the call of the senior officer thereof, at the rooms of the Board of Engineers, Army building, New York City, to examine such officers of the Corps of Engineers as may be ordered before it with a view to determining their fitness for promotion, as contemplated by the Act of Congress approved October 1, 1890. By direction of the Secretary of War. Par. 4, S. O. 261, A. G. O., Washington, November 7, 1890.

Col. Basil Moore, Surgeon, and Major George M. Sternberg, Surgeon, are appointed members of a board of officers, appointed to meet at the call of the senior officer thereof, in San Francisco, Cal., to examine such officers of the Corps of Engineers as may be ordered before it, with a view of determining their fitness for promotion, as contemplated by the Act of Congress approved October 1, 1890. By direction of the Secretary of War. Par. 5, S. O. 261, A. G. O., Washington, November 7, 1890.

Major Henry McElderry, Surgeon, extension of leave of absence on account of sickness granted in S. O. 214, September 12, 1890, from this office, is further extended two months on surgeon's certificate of disability. By direction of the Secretary of War. Par. 28, S. O. 263, A. G. O., November 10, 1890.

Major Stevens G. Cowdrey, Surgeon, leave of absence granted in S. O. 112, Dept. of Ariz., October 24, 1890, is extended fifteen days. By direction of the Secretary of War. S. O. 263, A. G. O., Hdqrs. of the Army, Washington, November 10, 1890.

Official List of Changes in the Medical Corps of the U. S. Navy for the Week Ending November 15, 1890.

Surgeon Thomas Owens, ordered to the Museum of Hygiene at Washington, D. C.

Surgeon H. M. Martin, detached from the receiving ship "Wabash," and ordered before Retiring Board.

Surgeon P. M. Rixey, continued in charge of Naval Dispensary at Washington, D. C., until November 20, 1891.

P. A. Surgeon E. H. Green, promoted to Surgeon November 10, 1890.

Surgeon Howard Smith, placed on the Retired List November 10, 1890.

ON THE RELATIVE VALUE OF MERCURY AND IODINE COMPOUNDS IN THE TREATMENT OF SYPHILIS.

Read at the opening of the Discussion in the Section of Dermatology and Syphilology, at the Forty-first Annual Meeting of the American Medical Association, Nashville, Tenn., May, 1890.

BY L. DUNCAN BULKLEY, A.M., M.D.,
OF NEW YORK.

Syphilis is one of the most important diseases which afflict mankind, and the study of its various aspects and conditions is one of the most interesting which can engage human thought. The pathology of syphilis, in all its stages, reaches deeper than that of any other known disease, while its symptomatology may at times extend into the domain of innumerable other affections; it may stimulate in certain cases, in various organs, a great variety of diseased conditions, and may complicate a still larger number.

In opening briefly a discussion of the treatment of syphilis it is evident, therefore, that we cannot at all enter into the subject of the disease itself, nor of the treatment of all the various aspects and phases presented by the same; and, therefore, from the nature of the case it will be difficult to deal with the question before us as fully and accurately as could be desired. But, on the other hand, the indications for treatment vary so greatly at different stages of the disease and in different individuals, that any discussion of the relative value of mercury and iodine compounds in syphilis must take into consideration, to a greater or less extent, other factors than simply the existence of syphilis in the subject to be treated. In other words, "the treatment of syphilis" has two aspects: first as to the treatment of the disease itself, the nullification of the poison with which the system has become infected; and, second, as to the treatment of the diseased condition, or the particular manifestation of the action of the poison, in some special organ or part of the body at a particular time; it is upon the recognition of these two aspects of the question that a sound therapeutics of syphilis must rest.

Now as regards the treatment of the disease it-

self, the neutralization of the poison, so that it cannot be again communicated to another, or be transmitted to offspring, the opinion of modern observers agrees, I think, that mercury alone possesses the true anti-syphilitic power, while iodine and its preparations exert very little if any influence in this direction; that is, that in the acute, infectious period of syphilis the latter if used alone could not control the development of the disease, nor hinder or check its contagious properties, whereas mercury does possess this power in a striking, although not always in an absolute and perfectly satisfactory degree.

In regard, however, to the effect of iodine and its compounds upon many of the lesions of syphilis there can be no question whatever, indeed they are often absolutely indispensable in the treatment of syphilis in some of its stages or manifestations, and in many instances, especially in syphilis of the nervous system and of some of the internal organs, they alone can rescue the patient from impending death.

What, then, are the indications for the use of these two powerful remedies in syphilis, for that I believe is the direction which our discussion should take, rather than as to the *relative* value of the two drugs; both are equally valuable, each to serve their particular end, while their combination will be more often even more serviceable than either alone. We can really no more speak of the relative value of mercury and iodine in syphilis than we can of the relative value of the two portions of a pair of scissors; alone each may be of value to a certain degree, but together, when properly used, they form an instrument which will sever the Gordian knot, and solve the often difficult problem of the proper cure for certain lesions of syphilis. It will be understood that I am here arguing for the well-known *mixed treatment of syphilis*; this I think, (and see from experience in cases which have been treated by others) is far too often neglected in favor of the plan advocated by some writers, of using each remedy separately.

But, although I have just spoken, and wish to speak, strongly in favor of a mixed treatment in many cases of syphilis, especially in the later stages, I also recognize the fact that there are periods and conditions of the disease when mercury

or iodine may be best used alone; these we will briefly consider.

During the very early stages of syphilis iodine, with its compounds seems to exert very little effect, whereas the results following an active and efficient mercurial course are often most striking and satisfactory.

When by a well defined hardening, or by marked local or general adenopathy, or by an early eruption, or by confrontation or other means, the diagnosis of a primary sore, or true chancre of syphilis is determined with certainty, an active mercurial course should be at once instituted, and iodine is uncalled for, and some think it to be harmful. The simplest, and in many respects the best treatment is then by means of the grey powder of mercury and chalk, which can be conveniently administered in one grain tablets. These may be given, one every two hours, or even two at a time, until the effect of the mercury is seen, either in the rapid healing of the chancre, or in the subsidence of other symptoms, or, until a slight mercurial influence has been obtained in the mouth; the dose may then be lowered, by giving it every three or four hours. If now, the individual seems to resist the effect of the drug, the strength of the mercurial treatment can be increased by the addition of a few mercurial inunctions, or an occasional mercurial vapor bath. It is needless to say that all this should be carried far short of any actual salivation, and with the appearance of any marked tenderness of the gums or excessive flow of saliva, the doses of the mercury should be reduced to one-half, and then in a few days be slowly increased; salivation, if it be at all severe, rather hinders the treatment. Careful attention to the mouth, and the free use of chlorate of potash as a gargle and mouth wash should never be forgotten: but, on the other hand, I must enter my protest against the practice advocated by some of having the teeth carefully gone over by the dentist as a prophylactic, for I can never think it justifiable to expose another, and perhaps many through him, to contagion from the abundant and infectious mucous patches liable to be found in the mouth at this early stage of syphilis.

Mercury used locally is also of the greatest value in the early period of syphilis, and calomel freely dusted on, or black wash kept freely applied, or a mercurial plaster over the chancre will do much to hasten its disappearance, and the arrest of the disease.

There are other means of using mercury for its general effect in this early period of syphilis the merits of which I can hardly discuss here. The bringing of the system under influence of the drug can be accomplished by frequent mercurial vapor baths, also by mercurial inunctions alone; likewise by the hypodermic injections of mercury and oil, or its various salts, as has been

recommended by many: but, practically, in the majority of instances the drug can be introduced more pleasantly and quite as satisfactorily by the stomach, and my preference is decidedly for the grey powder, used as described, although the bichloride will often act kindly, though more prone to disagree with the stomach.

If now, the patient with syphilis remains faithful to this treatment, and the chancre heals soon, and other symptoms either fail to appear or are removed quickly, there is naturally no call for iodine or its preparations, although some would prefer to give a mercurial combined with iodine, the red or green iodide later in the course of the treatment; this, it will be understood, should, in accordance with the best modern views, be continued (with intermissions perhaps) for two years, or even longer, if troublesome symptoms or lesions have shown themselves.

We come now to consider the proper place for iodine and its combinations in the treatment of syphilis.

Unfortunately in but a small proportion of the cases of syphilis will the patient have had the satisfactory course alluded to above. For one reason or another, full and efficient treatment has not been carried out by the large majority of persons who have received syphilitic infection, and at varying periods in the course of the disease lesions of more or less troublesome and serious character will occur on the skin, mucous membranes in the bones, muscles, nervous system, viscera, or other portions of the body. It must be acknowledged also that in a certain number of individuals some of these graver manifestations of the disease will appear even during the course of and in spite of a thorough mercurial treatment, even quite early in the disease. If mercury is now given, and even pushed, for these more definite and serious manifestations of the disease, what is the result? They will often even increase in severity and extent, and the patient instead of being benefited is harmed in many respects by the treatment instituted and pressed ever so vigorously.

Now comes the action of iodine, which will sometimes seem almost miraculous; lesions which before had been stationary, or had even increased in severity will seem to melt away, and a disease which had before been rebellious, yields to medical skill and knowledge, and it may be that a life which before was threatened, is rescued, simply by the action of iodine or its compounds. This experience has been verified by numberless observers, and may occur to any one using the remedies properly when opportunity offers; this may, of course, very rarely happen to the general practitioner, but is not so very uncommon to the consultant or to one much occupied with syphilis.

Many writers advise the compounds of iodine to be given alone, unaccompanied by mercury, and the accounts of the enormous doses which have

been at times administered would astonish any one accustomed only to the ordinary dose of a few grains, as commonly prescribed. In certain rare and neglected cases, where grave nerve lesions from syphilis threaten life, such doses, running up into many hundred grains of the iodide of potassium daily, have undoubtedly saved life, and may be necessary; the remedy certainly should be pushed to the fullest extent possible when occasion seems to demand.

But, on the other hand, I am convinced, from not a small experience in syphilis, and from the results in my share of grave and threatening cases, that these exceedingly large doses are rarely if ever required, provided that other means are intelligently and judiciously employed; in other words, I believe that even in the latest stages of syphilis, and in its gravest manifestations, a certain amount of mercury will certainly aid in overcoming the disease and in removing the lesions. I know full well that in certain cases, and at certain times mercury will not be well borne, and the system will seem even to become lowered under its use: but there are very rare instances, and if combined with proper bitter tonics and iron, mercury can be borne and will aid in the treatment of all stages of syphilis. But, of course, it must be used carefully and judiciously in those of broken down habit, and often other remedies, mineral acids, etc., are required to secure the best results.

My more common method of treatment of the later manifestations of syphilis is by means of the old mixed treatment, where a minute dose of mercury is combined with a moderate dose of an iodide, with iron and a bitter tonic; if the symptoms do not yield, the active elements of the treatment are increased until the desired effect is produced. The mercury in the mixture is first slowly increased, $\frac{1}{32}$ of a grain of the bichloride of mercury, to $\frac{1}{24}$, $\frac{1}{18}$, $\frac{1}{12}$, or possibly more; this is especially the case in lesions occurring during the first year or two after infection. For lesions occurring later in the disease, or when others still prove rebellious, the amount of the iodide is increased, the other features of the treatment remaining the same; or possibly being also added to.

Thus, the mixed treatment being continued after each meal, a watery solution of the iodide of potassium, sodium, or ammonium, or a combination of them, is given in Vichy water, *between* the meals, beginning, say, with fifteen grains three times daily, and augmenting the dose daily, until the symptoms yield; in some instances the syrup of hydriodic acid between meals will act better, or the compound liquor iodi, or the iodide of starch may be employed.

If early in the disease, and the mercurial element seems to be required, the mixed treatment may be added to by means of occasional mercurial baths or inunctions. But, personally, I have

not been satisfied with the plan of giving a mixed treatment by means of administering the mercury and iodide entirely separate, as advised by some writers; I feel confident that better results can be obtained by combining them together in proper proportions in one dose, and then augmenting the strength of one or the other element, in the manner above described, to meet the indications of the case.

My remarks have been somewhat personal, in opening this discussion, but I trust that they will be taken as intended, as a contribution of experience and opinion to this most interesting subject. If each will contribute his personal mite it will be better than if the impersonal opinion of others was quoted.

FIVE CASES OF REMOVAL OF THE JAW FOR TUMOR.

Read in the Section of Dental and Oral Surgery, at the Forty-first Annual Meeting of the American Medical Association, at Nashville, Tenn., May, 1890.

BY WILLIAM D. HAMILTON, M.D.,
OF COLUMBUS, OHIO.

The cases that form the subject of this paper have come under the observation of the writer in his service at the Mount Carmel Hospital within the past three years. Three had to do with the superior and the remaining two with the inferior maxilla. There were four females and one male. The youngest patient was twelve, the eldest fifty-five years of age.

In conversation with the eminent surgeon, Mr. Thornley Stoker, of Dublin, last summer, it was learned that one of his patients for whom he had recently extirpated the upper jaw for sarcomatous disease was a woman eighty years old. A still more interesting fact was elicited: that she was discharged from the hospital cured in a fortnight.

Cases of epithelioma beginning in the soft parts will not be herein considered. In this department of oral surgery we are confronted with certain facts at the outset: 1. Difficulty in maintaining anæsthesia; 2. The impracticability of observing with nicety antiseptic details; 3. The tendency to hæmorrhage and shock.

It is to be hoped that rectal anæsthesia will some day be reduced to a practical method, so that an irritating fluid like ether may be prevented from entering the bowel in the liquid state, where it excites such great disturbance, or even perhaps a fatal bloody diarrhœa.

The renewal of the anæsthetic on account of the returning consciousness of a patient upon whom such an operation is being performed is a most embarrassing and pathetic necessity. It frequently means the occurrence of vomiting and the loss of invaluable time. The resort to a preliminary tracheotomy, while possessing certain advantages as a mode of administration, is by no

means free from danger to the lungs and air passages which it is intended to protect, while its performance must add materially to the shock.

Unfortunately the mouth is frequently found to be in an unwholesome condition. The irregularities of the growth, which may prevent separation and closure of the jaws, the occasional existence of a foul ulcer, that has been teased and irritated by opposing teeth, the numerous hiding places for septic matter in such a cavity—all these considerations make it a trap for filth and enhance the difficulty of preventing suppuration. It is all the more incumbent upon the surgeon, however, to aim at thorough cleanliness. There should be liberal irrigations with a harmless antiseptic lotion like boracic acid in an aqueous solution, and in this way all removable matter disposed of in the five days prior to operation.

The strict observance of extrinsic antiseptic details is as clearly imperative in this as in other surgical procedures.

As a preliminary step, with a view to preventing hæmorrhage in removing some of these growths, the common or external carotid artery has been tied. While benefit may sometimes be derived from it, preparatory deligation was not seriously contemplated in any of the cases enumerated. In dealing with the facial artery and vein, the knife was carried quickly down to the bone dividing them clean at one stroke. Their prompt seizure with hæmostatic forceps prevents the loss of much blood and simplifies the operation. Digital pressure by an assistant is available during their isolation.

With reference to shock it may be said that time is a most important element. In order to minimize the duration of the ordeal, scrupulous care should be taken to have a simple reliable armamentarium at hand consisting of strong instruments in perfect condition. For completing the division of bone, a pair of powerful straight pliers with short jaws and long handles, giving great leverage, is invaluable.

For ligating vessels, properly prepared silk is preferable. A precaution that should never be neglected is to transfix the tongue with a coarse silk thread; the ends being tied together should be held by an assistant. It is perhaps needless to observe that anæsthesia should be *very profound* before beginning.

Again it is a rule applying to all such undertakings, to postpone entering the cavity of the mouth as long as is consistent with method. Therefore the bone should be freed as extensively as may be before the mucous membrane is divided. In this way blood can often be kept outside of the throat until the operation is well-nigh completed.

Case 1.—Adeno-Sarcoma of Lower Jaw; Removal of Left Half of Bone; Recovery.

Miss N. M., sent by Dr. A. M. Dent, of Co-

shocton, Ohio, was 27 years old when first seen by the writer. In July, 1884, she ran against the edge of a door in the dark and the left side of the face was struck. Some swelling followed which never receded. From the time of the injury until September, 1888, when she was admitted to the hospital, her face grew larger. The disease first appeared in front of the left masseter muscle and the contiguous portion of bone gradually became implicated. She stated that it had grown more rapidly since October, 1887, than during the preceding two years. A slight oral hæmorrhage took place then and pain had annoyed her most of the time since. The latter was attributable to the continual bruising of the tumor by the upper teeth. A surgeon having been consulted some months previously, had incised and scraped the prominent outer surface of the jaw, and with negative results. The month preceding the second operation had been of rapid progress of the growth. Painful sores existed where the upper teeth impinged upon it. The left side of the face had a rounded appearance, the cheek being prominently bulged outward. The mouth was encroached upon both posteriorly and toward the median line, so that it could only be opened for distance of seven-eighths of an inch. The ramus was extensively involved.

Operation, September 30, 1888. Dr. F. W. Blake and Dr. A. N. Dennison assisted. The usual incision was made and extended in the line of the old cicatrix. A clear exposure of the bone being thus secured, the dissection was completed with guarded scissors, care being taken to cut *on* the tumor throughout. While detaching it from the cheek, several sub-cepts of which it was partially composed, discharged their contents into the wound, the fluid being of a yellow, viscid character. The subsequent steps of the operation including the disarticulation and the median section with the saw were readily accomplished. Hæmorrhage was tolerably free but easily controlled. Interrupted silk sutures were used in uniting the mucous lining of the cheek, and continuous gut for the outside. A rubber drain was inserted at the most dependent point and allowed to remain for several days. Shock was well-marked but yielded promptly to proper measures. Some suppuration of the wound with febrile movement ensued and retarded her recovery. She was discharged four weeks later.

Microscopical examination showed it to be an adeno-sarcoma that had probably developed centrally, expanding the plates of the bone, parts of the growth having undergone cystic degeneration.

Case 2.—Osteo-Sarcoma of Right Upper Jaw; Excision; Recovery.

P. C., æt. 16, from Johnstown, Licking Co., Ohio, was sent by Dr. C. R. Lockwood of that place. He had always enjoyed good health. In the early part of 1884, the right side of his face

was seen to be getting larger, especially in the neighborhood of a defective upper molar tooth, from which the disease seemed to emanate. The growth was gradual until early in December, 1888. He entered the hospital February 8, 1889, at which time the right cheek was the seat of a prominence, extending laterally from the molar bone to the side of the nose, and vertically from the angle of the mouth to the floor of the orbit. The latter was lifted up and the right eye slightly elevated. The hard palate was moderately depressed. There was no sign of fluctuation at any point.

Diagnosis.—A tumor of the upper jaw which had of late taken on such rapid growth that removal was deemed advisable.

Operation.—February 11, 1888. The entire right upper jaw was excised by the external flap method. An incision began opposite the inner angle of the eye, going vertically downward, encircling the wing of the nose and through the lip in the median line. Following again the natural fold between the cheek and the lower lid, it proceeded along the rim of the orbital floor as far as the molar bone. The flap could then be readily raised and the cheek was reflected from within outwards, thus securing a good exposure of the tumor. An incisor tooth was then extracted, and the saw was carried through the hard palate and the alveolus of the missing tooth, the nose being pushed out of the way. A section of the nasal process of the upper jaw and molar bone followed, the latter line of division being continuous with the speno-maxillary fissure. The bones were of ivory-like hardness, so that their division was very tedious and difficult. Large pliers were forced into the notches made by the saw, thus loosening the growth, so that the pterygoid process could be broken and the soft palate cut away. The patient believed badly under ether, a large quantity of which was required. The extreme hardness of the bones and the time consumed in dealing with them added to the delay. The wound was dusted with iodoform, and stitched with gut inside and out and no drain was used. The shock was very profound. Evidently considerable concealed hæmorrhage had occurred for the patient vomited a large amount of clots and bloody fluid. The lower extremities were elevated and injections of warm water and brandy were frequently given. Hypodermics of morphia and brandy were resorted to, dry heat was liberally applied and after two hours of persistent effort, vomiting ushered in reaction. Union was tolerably firm in 30 hours and his convalescence was uneventful.

Case 3.—*Large Round-Cellled Sarcoma of Right Upper Jaw; Excision; Recovery.*

Mrs. M. A. T., æt. 55. Residence, Napoleon, Henry Co., Ohio. In July, 1888, a swelling was first observed over the right molar bone, which

continued to grow until February 27, 1889, the date of her admission. Had had nose-bleed once, a month before. Her health had always been good, and the growth was only slightly painful. The physical alterations and the change in facial expression were about such as were seen in Case 2.

In view of the rapid development of the tumor, excision was advised and was done March 2, 1889. Aside from the fact that the incision was longer, the plan adopted was the same as that in Case 2. Much less difficulty was experienced in making the sections than in the former case, the bones being much softer. The wound having been carefully sutured, neat apposition was secured. External hæmorrhage was very slight. One-third of a pint of clotted blood was vomited after the completion of the operation. Shock was hardly appreciable and the pulse, although somewhat weak, was slow and regular. She passed a good night, and after the first week had no febrile disturbance. She was discharged March 24, three weeks after the operation.

Case 4.—*Sarcoma of Left Upper Jaw; Excision; Recovery.*

Gertrude W., æt. 12, brought by Dr. Chambers, Dentist, from Newark, Ohio. Eighteen months before, when cutting a molar tooth, she had observed that her left cheek was prominent. Two months before entering, she had had a single nose-bleed. She was in good general health. The floor of the orbit was elevated by the growth, and the left side of the nose somewhat smaller and crowded forward. The roof of the mouth was depressed on the side involved. On November 6, 1889, the external flap operation was done in the usual manner. She had no unpleasant symptoms and was discharged well in a fortnight.

Case 5.—*Recurrent (Myrtoid or Giant Cell) Sarcoma of Lower Jaw; Excision of Right Half; Recovery.*

Mrs. A. W., æt. 36. Residence Corning, Perry Co., Ohio. In 1875 she had undergone an operation for epulis of the lower jaw, in which several teeth with their alveoli were removed. Suspicions of recurrence were aroused early in November, 1889, and she entered the hospital three weeks later. A growth, central to the right maxilla had evidently started at or near the angle, causing the bony plates to spread. It was growing forward on the body and upward on the ramus. It had of late become painful, and excision was advised and done on November 30, in the usual manner. The anterior section was easily accomplished, as only the rim had been left when the epulis had been ablated. Care was observed in securing the vessels, but notwithstanding this fact, persistent and rather free secondary hæmorrhage occurred during the night following the operation, which necessitated the removal of a few stitches and reopening the wound. No vessel of appreciable size could be

found, however, and Monsell's solution was applied. An opening was left for drainage and for the escape of sloughing particles. The bleeding never recurred and the wound healed nicely by granulation. She was discharged in three weeks.

The original disease was epulis of a malignant type. The propriety of removal in cases of epulis is forcibly impressed upon us, and this had been thoroughly done by Dr. McGraw, of Detroit.

These cases and one already reported in the *New York Medical Journal* of May 10, 1887, in which a large tumor and half of the lower jaw were excised, make six in all: three of the superior and three of the inferior maxilla. If an apology be wanted for their presentation on this occasion, reference might be made to the fact that Dr. Deadrick, of Tennessee, in 1810, was the first to remove a portion of the lower jaw for tumor.

Reports of operations of the kind enumerated do not seem to be common nowadays. Whether it be on account of their infrequency, or because they are deemed unimportant, I cannot say.

While an experience such as that indicated is not sufficiently broad to justify one in dogmatizing, I suspect that the larger proportion of these cases can be successfully handled without the preliminary delegation or tracheotomy; that the best way to do them is to get *through* with them as quickly as is compatible with thoroughness.

All the patients are free from recurrence to-day.

ATYPIC HERPES ZOSTER GANGRENOSA, WITH REPORT OF TWO CASES.

Read in the Section of Dermatology and Syphilology at the Forty-first Annual Meeting of the American Medical Association, Nashville, Tenn., May, 1890.

BY BENJ. MERRILL RICKETTS, PH.D., M.D.,
VISITING SURGEON FOR SKIN AND CANCEROUS DISEASES AND
PLASTIC SURGERY TO GERMAN PROTESTANT AND CHRIST'S
HOSPITAL, AND CONSULTING DERMATOLOGIST TO
THE WOMAN'S HOSPITAL AND MED. COLLEGE.

I am somewhat at a loss to know just how to bring the subject of "Zoster" before you, in the most profitable manner, unless it be to report two cases of that form so seldom met with, even by the specialist, viz.: Herpes Zoster Gangrenosum.

This is the most intense of all forms, being characterized by the usual primary eruption following the usual premonitory symptoms which in character are also very severe.

The vesicular contents remain clear for three or four hours, gradually becoming a light wine color, then a greenish black, soon changing to a greenish brown; these color changes occur around the base of the vesicles, the area of which remains a pigmented brown color for some months.

Necrotic changes occur before the vesicles break, and crusts form immediately after their rupture; the duration of the vesicles may be from three to eight days, and the time of cicatri-

zation is in proportion to the amount of sloughing that takes place. Kaposi says that if the suspected surface be touched early with nitrate of silver or iodine, the eruption will not appear, and that in every hæmorrhagic zoster the necrotic changes begin at the base of the affected spot.

Gangrene may appear in one or more vesicles, accompanied by pain and fever, the pain being of a neuralgic form and located throughout the distribution of any nerve, but oftener over that nerve with main branch nearest to seat of lesion.

The appearance of paresis or atrophy of muscles is not infrequent, nor is atrophy of hair or teeth infrequent, especially in the tissue diseased. Paralysis and atrophy occasionally occur when the eruption is situated in the territory of the trigeminus, or in upper nerves of the throat. Oculo-motor paralysis of zoster facialis and frontalis is sometimes met with.

As to the cause of this disease, there is much doubt, however in many cases it seems to have been in the intervertebrate ganglia, while in others it seems to be a neuritis or some peripheral disturbance. Thus far observers seem to feel that no treatment will retard or shorten the courses of this disease, hence it is a self-limited one.

Case 1.—Lena W., æt. 15, white, American, a nurse girl, brown eyes, dark brown hair, teeth good, height five feet two inches, weight 135, physique good, no glandular enlargement; menstruation regular; drinks beer, wine, coffee and tea; digestion good, bowels constipated, has considerable alopecia.

Small pimples appeared on the hands at 5 years of age, but they never gave any trouble whatever, and disappeared in a few days. At ten years the first characteristic eruption appeared on the chest the size of a three cent piece, and this gradually increased to six inches in diameter; two weeks later appeared in cheek, then on forehead; appetite at this time was poor, headache was severe, vomiting frequent.

Two months later a large patch, quite extensive, appeared on the inner side of the left leg, this was healed by means of simple remedies, and a similar patch appeared in the precise spot of the right leg.

Six weeks later an extensive eruption appeared upon each instep simultaneously; these increased to two and one-half inches in diameter, and in two weeks the inner surface of right knee and ankle was affected followed very soon by a similar condition of the corresponding position of left knee and ankle.

During the succeeding six months various eruptions, slight in character, reappeared over the spots previously healed, but the whole outer surface of the left leg became involved then; and four months later the affection was equally extensive and severe upon the right leg.

At 14 years of age she entered the Home of the Friendless in Cincinnati, she previously having lived out of the city and had come for treatment; her legs were still affected; sloughing had been extensive and was still present, and the integument entirely destroyed at that point.

Up to this time the body and arms had been entirely free, excepting the slight eruption on the chest at the very beginning four years previous. In last May she entered the German Protestant Hospital under my care; there had been a reappearance and entire healing of the affected parts of legs a number of times.

On the 10th of June there appeared three groups of vesicles upon the right side of the scalp, two upon the left side, and two on the scalp anteriorly, and five upon scalp posteriorly, all resulting in the destruction of the hair follicles affected; leaving white cicatrices from the size of a dime to that of a silver half-dollar.

On July 4, the back of both hands were affected to the extent of several inches, the left being the most extensive. On the following day there reappeared a patch four inches in diameter upon the inner left leg; this was healed entirely in two months.

July 10, there appeared large vesicles covering an area three inches in diameter on back of each forearm. August 3, she began to take kali iodidi grs. 60 each day, the dose being increased 20 grs. each succeeding day until 480 grs. were taken daily, this being reached August 26. She continued this amount until September 6, eleven days; then her mouth became sore and the amount was reduced to 250 grs., with the addition of $\frac{1}{3}$ gr. bichloride.

The eruption reappeared upon the forearms September 6, and on outer angle of right elbow.

October 20, reappeared on back of left hand, and at this time iodide and bichloride were discontinued. During November, December and January, patient did not have any reappearance of the eruption, except an occasional very small patch of vesicles here and there over the cicatrices and their immediate tissues.

February 10, 1890, there reappeared a patch five by three inches upon the outer surface of right leg.

In November, all medicine was stopped and an effort made to keep the bowels open thoroughly with saline cathartics and enemas. She complains most of the time of bones aching, of obstinate constipation all of the time, sleeps well, appetite fair, never has vomiting nor chills, pain more or less in eyes.

About March 18, 1890, there appeared a group of vesicles leaving an ulceration about three inches wide and six inches long, upon the outer surface of left leg which is very slow in healing. It has an offensive odor and looks worse than any I have seen owing, perhaps, to having ap-

peared upon the seat of an old lesion. The integument upon which the eruption appeared in this case would become gangrenous with a sharply defined border extending into the cellular tissue.

The time required for separation from healthy tissue varied from ten to fifteen days, an offensive odor being present from the time of the rupture of the vesicles. She has done better during the past seven months than any time since the first appearance of the disease. Up to November, 1889, she had taken mercury, arsenic, iodide potassium, iron, quinine, strychnine and belladonna, each having been given to its limit, without any appreciable effect or benefit; on the other hand the eruption would appear more frequently, more severe, and at the time of their full administration, so that with the two cases at hand, I cannot speak favorably upon any course of treatment.

However, I would suggest, and will in all succeeding cases, adopt a systematic course of curing the diseased surface, as soon as the line of demarkation is established, that recovery may be hastened and offensiveness obviated.

Then, too, I would keep the bowels freely opened once or twice each day with warm water injections or saline cathartics.

Case 2.—Josephine M., æt. 14, German-American, a domestic, blue eyes and light hair, teeth fair, height 5 ft. and 3 in., weight 140, physique very good; no glandular enlargement, menstruation not yet established, but premonitory symptoms present, drinks beer, wine, coffee and tea; digestion good. Came to me with an irregular colored crust upon each cheek, about the size of a silver half-dollar; one upon the anterior surface of the middle third of each forearm, the size of a silver dollar, and another upon the anterior surface of middle third of each leg; all of these appeared forty-eight hours previous, within a few hours of each other. She stated that this was the third time that she had ever had any skin disease, and that the three attacks were similar in duration, location and character, and had all occurred within the past year. Pain of a burning character, tenderness in the affected parts, headache, tongue coated, constipation, hyperemia of conjunctiva, indicated the possibility of a previous fever, during the early stages of the disease.

I sent her to the German Protestant Hospital, where she improved very rapidly, and left for home at the end of a week, but was not entirely well as the gangrenous spots were not cicatrized yet. Nothing was heard of her until May 1, when she returned with another attack, upon the surfaces before attacked, with the exception of those upon the cheeks.

In each of the foregoing cases, the disease appeared long before the menstrual period; became very much worse just before, during and after the

first few menstruations, and were accompanied by hysteria, varying in degree with the severity of the disease. These are symptoms all of which Kaposi mentions as special features found in favor of the five cases in which he has made observations.

THE OCULAR SYMPTOMS OF BRIGHT'S DISEASE.

*Read before the Kings County Medical Association, Brooklyn, N. Y.
November 8, 1880.*

BY L. A. W. ALLEMAN, M.A., M.D.,
OF BROOKLYN, N. Y.

There are some diseases which always present profitable subjects for consideration; they never grow old, never uninteresting. In the light of ever varying and broadening experience, some old and familiar fact possesses a new and vital interest. Some facts, indeed, we have heard so constantly that we have grown deaf to them by their very repetition, till some emergency makes us eagerly strive to summon them from the shadowy realm of half-forgetfulness. It is, therefore, with less reluctance that I ask your attention to a subject upon which I can hope to say nothing new, nothing original.

"The Ocular Symptoms of Bright's Disease" is, it seems to me, a subject, the importance of which it is hard to overestimate. In the eye, as nowhere else in the body, a nerve, arteries and veins are exposed to our view, a lens even being kindly provided to assist us in our examination. Here it is sometimes possible to read, as in an open book, the signs of vital deterioration, as shown by the condition of the arterial system, long before any other symptom gives warning of the impending danger.

It is not an infrequent occurrence that the ophthalmoscopic examination discloses a condition of the eye ground, which tells of serious renal lesions, in patients who believed themselves to be in perfect health, and sometimes fortunately this discovery is of incalculable benefit to our patients, as it may enable us to avert, or at least delay the threatened calamity.

In no disease unless, perhaps, we except intracranial disorders, has the ophthalmoscope proved itself so valuable an aid to diagnosis as in Bright's disease. Before the discovery of the ophthalmoscope, the eye symptoms in this disease were of little value and were little observed. In Bright's book I find no mention of them, nor in Johnson's published in 1852. To-day, no author would think of treating this subject without special reference to the eye lesions, and as an example of the deserved prominence now given to these symptoms we may note that in Eehhorst

"the manifest symptoms of chronic interstitial nephritis" are said "To refer chiefly to the condition of the urine, the circulatory apparatus and ocular changes."

Before beginning the consideration of our subject proper, a word may not be amiss as to our understanding of the term Bright's disease.

In medicine, where we can have no settled authority, and where every man is more or less a law unto himself, very annoying confusion is apt to arise from the fact, that a given name of a disease will not call to the mind of any two men exactly the same complexus of symptoms. This is especially apt to be the case with the term, Bright's disease, for since the appearance of Bright's book, diseases differing most widely in cause, symptoms and pathology have been classed under this general head.

It would be quite beyond the scope of this paper to propose or adopt any classification of Bright's disease, but I think it will suffice, to prevent any misunderstanding in the present instance to say that I do not use the term, Bright's disease as synonymous with albuminuria.

It may seem to you quite unnecessary to say that I include under Bright's disease cases where no albumen can be found in the urine, yet it has not infrequently happened to me, having made a diagnosis of this disorder from an examination of the fundus of the eye, to be told by the physician in charge of the case, that there must be some mistake as no albumen could be found.

It is quite true that as a general rule, retinal affections are a late symptom of renal disease and that albumen is usually found in the urine when such retinal troubles are present. Yet I shall endeavor to show that this is by no means an invariable rule, and that examination for glasses, for example may end in the discovery of morbus Brightii.

It has been claimed, I think by Gall and Sutton, that chronic Bright's disease is a disease of the arterial system primarily, and I find that it is now quite common to use this term and chronic endarthritis as synonymous.

Mahound recognizes three stages of the disease: First, the functional stage which is limited to the condition of high arterial pressure without organic changes in either the vascular system or the kidney. Second, chronic Bright's disease without nephritis the stage of organic changes in the vascular system. Third, chronic Bright's disease with nephritis the natural but by no means invariable termination of the disease.

The studies of DaCosta and Longstreth are of great interest in this connection. They find upon investigation changes in the renal nerve plexus and cardiac ganglia.

Our knowledge of the sympathetic system is at present so limited that we must accept with caution any theory founded on any but the firmest

¹ The Medical Reports.

basis of investigation; but to quote Dr. Meigs,² "from a purely theoretical point of view it is quite as reasonable to suppose that the morbid process might begin in the nervous system as in the lining of the arteries or elsewhere," and such an explanation would well account for some of the cases of optic neuritis met with in the disease.

The first symptom of Bright's disease which we will consider is uræmic amblyopia.

This disorder must not be confounded with visual disturbances depending upon retinal changes, for it is a condition characterized by sudden, partial or complete loss of sight with no corresponding ophthalmoscopic lesion.

Since the introduction of the ophthalmoscope, amblyopia and amaurosis occupy a much less prominent position in ophthalmic diagnosis than formerly, but in all forms of renal disease, amblyopia may occur, the condition which has been humorously described as when neither the patient nor the physician can see anything. The severity of this symptom may vary all the way from transient dimness, swimming and uncertainty of vision, to absolute blindness. Total blindness, of sudden onset and transient duration, is so rarely met with as to be but seldom mentioned.

Dr. Cocks³ has reported three cases, which seem of sufficient interest to justify a brief review.

The first case was that of a boy of twelve, who was seized with what was believed to be an epileptic convulsion. He was first seen by Dr. Cocks when just arousing from the stupor following the convulsion, which was uræmic, and then complained that he could not see. The following day, a careful ophthalmoscopic examination was made. The sight was entirely gone, he could not even perceive the light thrown in the eye by the mirror of the ophthalmoscope. The pupils were widely dilated, but on the closest examination not the slightest organic lesion of the retina, choroid or nerve could be discovered. This condition continued for about thirty-six hours when light perception was noticed, and finally sight was perfectly restored, and so remained for some time, while under observation.

The second case was of a woman aged forty-five, who was suddenly taken with intense headache, complete loss of sight and finally unconsciousness. The examination of the fundus oculi was negative. The urine showed an abundance of albumen. She completely recovered, and about a year later had a similar attack, from which she also made a good recovery. The duration of the amblyopic symptoms was about ten days.

Case three is of interest as showing the not common condition of retinal œdema. Mrs. C., aged twenty, developed uræmic convulsions dur-

ing her first pregnancy, at the seventh month, and was delivered while unconscious; the following day, when she partially awoke she was found to be nearly blind, being able only to distinguish the largest objects. An ophthalmoscopic examination revealed no lesion, save a slight œdema of the retina near the nerve. Three weeks later the sight was perfect.

Uræmic amblyopia is an affection of the nerve centers rather than of the eye proper. The poison which from a defective excretion has accumulated in the blood, overwhelms the nerve centers, and their function is temporarily suspended. Should the patient live till the poison can be eliminated, or till a tolerance can be established, the visual centers again resume their functions. The slight manifestations of this amblyopia, the dimness, the momentary loss of sight are most valuable danger signals, and by carefully watching for them in cases where we fear an attack of uræmic convulsion, we may be often forewarned, and it seems to me, that in all cases of pregnancy as well as in all cases of recognized kidney disease, the patient should be on the lookout for these visual disturbances, and the importance of at once summoning medical aid should they be discovered, fully explained. In this way much valuable time, moments upon which, perhaps, hang the life or death of the patient, could be saved.

The ocular symptoms occurring during pregnancy, in nephritis gravidarum, while not differing especially in appearance from those observed in other cases of nephritis, yet from the difference in cause and prognosis deserve a separate consideration. The difference is well pointed out by Weeks,⁴ who says, "In the study of albuminuric retinitis it becomes apparent that, in regard to their etiology two classes of retinal disease are included in the present acceptance of the term.

One depends entirely on the condition of the blood brought about by an acute disease of the kidney, the kidney symptoms preceding the changes in the retina, the other depending on a general (systemic) diseased condition of the arteries, capillaries, and to a less extent, the veins, in which the ocular changes and symptoms may, and not infrequently do precede the kidney symptoms. To the first belongs the retinitis of pregnancy, scarlet fever, diphtheria, etc., and all forms of acute nephritis. The first may be termed an irritative nephritis, due to the effect of a morbid element on the kidney tissue. The latter a strangulative nephritis, in which the blood supply is cut off by arterial stenosis."

Obstetricians are by no means agreed as to the manner in which pregnancy produces renal disease, but be it due either to increased intra-abdominal pressure, to the increased arterial ten-

⁴ Archives of Oph., xvii, 3.

sion, to renal anæmia, the result of reflex vaso-motor spasm, or to any of the causes suggested, the fact remains that in Bright's disease developed by the pregnant state, there is not the same widespread degeneration present which characterizes the chronic forms of the disease, and this fact, taken with the increased recuperative power which follows pregnancy, makes the prognosis much more favorable than under other conditions.

I have at present under observation a patient who informs me that six months ago, after confinement, her vision was reduced to light perception, she has to-day nearly perfect vision ($\frac{20}{30}$ + in both eyes) and can read the finest print with ease. The ophthalmoscope shows a healthy retina with a few white patches between the macula and nerve.

Another case recently observed, showing a surprising improvement in vision was a patient of Dr. Lindsay, of Huntingdon. This patient, Dr. Lindsay informs me, had an attack of acute Bright's, resulting in miscarriage in September, 1884. For about a month previous to this accident, eye symptoms were noticed, and for some eight weeks after, while confined to her bed, the patient was so blind as not to be able in full daylight to see anyone in the room, although they were but a few feet distant. For three or four months after her vision improved and has since then remained about the same. When I saw her last August her vision was $\frac{20}{30}$ in the right, $\frac{20}{100}$ + in the left, which with + 1.25 D. glass, can be brought up to $\frac{20}{30}$. The left eye deviates outward, and has done so since childhood, and was probably amblyopic before the attack. This visual result is quite surprising in view of the condition of the fundus. Both nerves are atropic, the arteries are much reduced in size and marked retinal changes are present about the macula, and between the macula and disc in both eyes. Albumen and casts are not discoverable in the urine and the patient's general condition is fairly good.

The question of the induction of premature labor for the preservation of vision is one of interest alike to the ophthalmic surgeon and to the obstetrician. Dr. E. G. Loring was, I believe, the first to urge this procedure for the preservation of vision alone. In practice this problem is not likely to present itself, for the eye symptoms calling for active interference are usually but a part—an index, as it were, pointing to the threatened uræmic convulsion; but were they the sole danger, I can conceive of no condition more imperatively demanding our intervention.

Granting that the induction of premature labor is ever a justifiable procedure, a proposition which I think few will dispute, under what circumstances can it be more necessary, than for the preservation of vision?

The love of life is the most deeply rooted of human instincts, and when called upon to decide

in his own case, one might prefer even blindness to death; but in the case of another, where we can weigh the arguments more dispassionately, it seems to me that, except perhaps in rare instances, blindness is by far the more terrible affliction.

As the conclusion from a very interesting paper on the "Induction of Premature Labor, in Amaurosis and Amblyopia from Albuminuria in Pregnancy," Dr. Pooley says:

1. In all cases of pregnancy, not only should examinations of the urine be systematically made, but the eyes should be examined with the ophthalmoscope; since, in a large proportion of cases, where eye troubles exist, the patients make no complaint of disorders of vision. Frequently such troubles can be detected with the ophthalmoscope long before any disease of the kidney is shown in the urine.
2. In uræmic amaurosis, without changes in the eye visible to the ophthalmoscope, even should the usual accompanying symptoms, such as dizziness, nausea, and threatened convulsions, be absent, their supervention is soon to be anticipated, and the immediate induction of premature labor is indicated, without waiting until the life, as well as the sight of the patient is in danger.
3. In neuro retinitis the induction of premature labor is not only justifiable, but urgently demanded. In some instances it is called for even in the earlier months of pregnancy.
4. It is required in cases of eye trouble recurring in successive pregnancies.
5. A woman having once suffered in this way during pregnancy, the relationship of cause and effect should be fully explained, both to herself and her husband.

As an interesting example in support of the foregoing conclusions, we may cite a case reported by Fryer,⁵ of a pregnant woman in whom a typical albuminuric retinitis, without hæmorrhage, was discovered in the sixth month. The urine was loaded with albumen, but no other symptoms of kidney lesion were present. Premature labor was advised, but deferred, and vision was reduced to mere perception of light. Premature labor was, however, finally induced, and health was restored, but complete blindness followed. The retina became normal in appearance, but the nerves were atrophic.

Dr. Loring, in a paper entitled "Premature Labor for the Prevention of Blindness,"⁶ cites two cases which show the disastrous results which may follow from allowing pregnancy to proceed to full term in presence of this complication. In both cases vision was permanently injured, and in one there was nearly complete blindness. "Looking," says Loring, "at the serious results which follow non-intervention on the one hand, and the favorable results which are known to have followed an early termination of pregnancy on the other, there are cases in which it is not only justifiable, but imperative to induce premature labor for the preservation of vision."

Detachment of the retina may occur as a consequence of a Bright's disease, and is probably

⁵ Kansas City Medical Index, July, 1858.

⁶ N. Y. Med. Journal, January 20, 1883.

due, when present, to a serous effusion between the retina and choroid. Wadsworth⁷ reports such a case in a pregnant woman at the eighth month. There was extensive detachment in both eyes, with choroidal changes. The retinae became reattached and vision $\frac{1}{30}$ – $\frac{1}{2}$ followed the induction of premature labor.

Changes in the retinal vessels, unattended by nephritic retinitis, are observed in Bright's disease. It is in these cases that an ophthalmoscopic examination is of great value in arriving at a correct diagnosis. If a sclerosed condition of the retinal vessels can be seen, it is fair to infer that a like change is present in other organs, but the converse does not hold good, for in many cases of chronic endarteritis, the changes in the vessels are not sufficient to be visible by the ophthalmoscope. The ophthalmoscopic picture in this condition varies greatly. In some cases, the vessel walls are to be seen as fine white lines bounding the arteries, and again the opacity may be sufficient to entirely obscure the red blood column, and white bands replace the usual appearance of the blood currents.

Gowers mentions this condition as present in Bright's disease. Harlan⁸ cites a case presenting this condition treated in Wecker's clinic, and I remember to have seen, some time since, in the eye service of the Jefferson Hospital, a case where the retinal arteries were entirely sclerosed. If I remember correctly, in one eye no red arteries were visible, and the appearance of the white lines replacing the retinal arteries, sharply defined against the red ground of the fundus, was indeed striking, and reminded one of the branches of a tree as seen on a frosty morning.

Gowers emphasizes the importance of not confounding cases of arterial sclerosis with those cases of no pathological significance in which, "at a point where the vessels emerge from the disc, they are, the arteries especially, often surrounded by white tissue, sometimes like a cloud upon them, and from it prolongations may be traced along the chief vessels.

Aneurismal dilatation of the retinal vessels is also sometimes seen. I have at present an example of this rare condition complicating senile central choroiditis, in a gentleman, a private patient. At several places in the course of the larger retinal arteries, on or near the disc, dilatations are present, of about twice the size of the normal artery. I cannot detect any pulsation in these small aneurisms, even on pressure.

Neither albumen nor casts are present in this case, but the presence of these dilatations is of great interest as showing the possible presence of a like condition in the smaller arteries in other organs.

Two forms of aneurism are observed, according

to Gowers: First. Of some size in the primary branches of the central artery on the disc. Second. Miliary aneurisms of the arterial twigs in the retina and of the smaller capillary vessels.⁹

Retinal hæmorrhages, although by no means distinctive of Bright's disease, are sometimes met with. They differ in number and appearance in different cases. They are of most frequent occurrence in the posterior part of the eye, and vary in size from the smallest discoverable dot to several times the disc diameter. When occurring in the inner layer of the retina, they present a peculiar striated flame-shaped appearance; when in the more external portion they are more sharply defined in extent and round or irregular in shape. They are due, when present in this condition, to degeneration of the retinal vessels, general high arterial tension, from the firm support of the inelastic coats of the eye, having little effect in determining them.

None of the foregoing ocular changes are pathognomonic of Bright's disease; they may be found in other conditions as well, and may be absent in well-marked cases of kidney disease, but when found in connection with such symptoms as hypertrophy of the left ventricle, an incompressible radial artery, urine of high specific gravity with or without albumen and casts, then the diagnosis is certain beyond question.

Of the ocular symptoms of Bright's disease, nephritic retinitis, also called albuminuric retinitis, is the one most frequently observed. This affection is, as a rule, an attendant of chronic kidney disease, and is a late symptom.

As previously stated, we may for convenience divide the cases presenting retinal disease into two classes, the irritative and the strangulative nephritis. The latter class is the one by far the oftener observed and, as the points wherein the former class of cases differ from it have been already pointed out, while considering nephritis gravidarum, the following description of the retinal symptoms will apply to both.

It is difficult to say even approximately in what proportion of cases of Bright's disease retinal changes are present. It has been estimated by different observers as occurring in from 6 to 30 per cent. The frequency with which this symptom is observed, as well as the type of case presenting it, will depend largely on the class of patients examined. As seen in the wards of a general hospital, in an eye hospital or in private practice, nephritic disease will present widely differing aspects. In the first instance cases with much œdema and highly albuminous urine are most frequently observed; in the other classes the disease manifests its chief symptoms through the nervous system, and headache, dizziness, dyspeptic symptoms and frequent micturition are complained of, and the attention of the patient is not

⁷ Annual Med. Science, 1886.
⁸ Trans. Am. Oph. Soc., 1886.

⁹ Medical Ophthalmoscopy.

especially called to the condition of the kidneys. It is in such cases that the ophthalmoscope frequently discovers the renal origin of the symptoms. It is not, however, safe to say that retinal lesions are present with much greater frequency in these cases presenting few annoying symptoms, than in those in which such distressing manifestations as dropsy and dyspnoea are observed, for in the latter the severity of the other symptoms makes the patient indifferent to the condition of the eyes, and no examination of the fundus is made.

I have seen it stated by an eminent ophthalmic surgeon that in a London hospital where all cases of Bright's disease were systematically examined, 60 per cent. showed eye symptoms, but I have not been able to verify the statement. I believe that such a careful and systematic examination of a large number of cases would show retinal disease to be a surprisingly frequent complication.

Why, in Bright's disease, the retina should be so frequently and seriously involved, has never been explained to our entire satisfaction. The explanation may lie partly in the highly specialized, delicate nature of the retina, and partly in the fact that a pathological condition of the retina is more appreciable to the patient, and more easily observed by the physician than similar changes in other nervous tissue.

As to the method of production of retinal lesions, some may be explained by the altered condition of the blood. Changes in the retina corresponding to those found in other nervous tissue by Gall and Sutton have been suggested (Gowers), but the explanation most frequently adopted is, that these lesions are due to the altered condition of the retinal vessels. Dr. Carl, by a very careful study of the subject, has demonstrated a degenerated condition of the vessels in all the tissues of the eye, more especially in the retina and choroid, and affecting all the coats of the arteries save the intima. Weeks also supports this view.

"There is," says Weeks, "little or no inflammatory action involved, there is but little infiltration of leucocytes and increase of nuclei, and very little hyperplasia of connective tissue, such as we would expect to find in so chronic a condition if a true inflammation were present. Extravascular the condition usually is simply one of the escape of the blood from the vessels."

Retinal complications are not confined strictly to any period of life or to either sex. As tabulated by Schlesiinger¹⁰ the ages and sex varied as follows:

	Male.	Female.
From 1 to 10 years	1	—
" 10 " 20 "	3	8
" 20 " 30 "	5	3
" 30 " 40 "	7	2
" 50 " 70 "	12	1
Unknown	1	—
Total	29	14

being 67 per cent. males, 33 per cent. females, the majority of males being over 50, females at the age of sexual maturity. In the 103 cases presented by Bull¹¹ the age varied from 5 to 78 years and the sexes were about equally divided.

The degree to which vision is impaired ranges all the way from no noticeable loss of vision to almost complete blindness, and is sometimes surprisingly at variance with the ophthalmoscopic picture. In one of the most severe cases of neuro-retinitis I have ever seen, while I had carefully tested the vision shortly before the attack, I found V. = $\frac{2}{10}$ had been reduced but to $\frac{2}{10}$, which in a few days improved to $\frac{3}{10}$, with no corresponding improvement in the appearance of the fundus.

When the macula is damaged central vision may be lost, but this is not common. Hæmorrhages may, however, encircle the macula and cause an annular defect in the field (Gowers).

As to the symptoms observed, we may divide nephritic retinitis into two general types—the degenerative and the inflammatory.

The degenerative form is the most common, and the first changes noted are usually the appearance of small white spots in the retina, usually in the neighborhood of the macula. These white spots, caused by the degeneration of nerve fibres, are at first small and delicate, and are often arranged in a radiatory manner around the macula. As the disease progresses they may become larger and coalesce.

It may be well to observe here that care should be taken not to confound the early manifestations of nephritic retinitis with the small dots somewhat similar in appearance, but more yellow in color, which are sometimes seen in the eyes of old people and are probably due to some senile choroidal changes.

Hæmorrhages are present in the degenerative type with varying frequency. Sometimes none are observed, sometimes the smaller hæmorrhages are absorbed, leaving little or no trace, and fresh ones make their appearance. In some cases, the hæmorrhages are so conspicuous a feature of the disease as to lead to its designation as hæmorrhagic retinitis. Little or no disturbance of the nerve is noted in this type of the disease. Sometimes a slight blurring of its outline takes place, but no change presenting an inflammatory appearance.

In the inflammatory form, neuro-retinitis, the first change in the ophthalmoscopic appearance is probably an œdema of the retina—but this condition is rarely noted. When first seen, as a rule, the retina and nerve are hazy, the veins distended, and often so tortuous as to present a corkscrew appearance; the arteries are reduced in size. As the disease progresses the evidences of interference with the retinal circulation become

¹⁰ Oph. Review, iv. 334

¹¹ Trans. Am. Oph. Soc., 1886.

more marked. The nerve is swelled and the disc outlines blurred, while masses of exudation are seen in the retina; these may increase in size till they encircle the nerve with a wall, as it were, of exudation. Numerous hæmorrhages are present, and in the region of the macula, in typical cases, white shining spots are seen, radiating from the macula as a centre. The general infiltration of the nerve and retina and this peculiar arrangement of the white patches at the macula, are said to be pathognomonic of Bright's disease. In some cases the nerve is more seriously involved, presenting a papillitis with the typical woolly disc. These cases are sometimes spoken of as the neuritic type of the disease. It is not to our purpose to enter now into detail in describing the well-known ophthalmic picture of nephritic retinitis. As seen in practice the disease will present a great variety of deviations from the typical, and widely varying combination of symptoms.

As a rule, nephritic retinitis is always present in both eyes, one eye may be attacked first, but we may confidently expect its appearance in the second eye. To this rule there are some well authenticated exceptions. In Bull's cases, in ten of the 103, only one eye was involved, but he lays no stress on this fact, expecting its subsequent appearance in the other eye. Eales¹² reports a case in which a typical retinitis was present in one eye, the other being healthy. Weeks, in his paper before cited, gives a similar case, and Yvert¹³ reports a most curious case in which unilateral albuminuric retinitis was shown post-mortem to exist with the absence of the kidney on the same side as the healthy eye. The case was one, according to Yvert, of typical nephritic retinitis with hæmorrhages and concentrically arranged degenerative changes about the macula. The kidney, renal vein, artery and nerve were absent on the right side, and on the left one kidney about double the normal size was found, which presented microscopically and macroscopically the lesions of parenchymatous nephritis.

Other cases are on record of this peculiar coincidence, for I can see no reason to consider it more than a coincidence.

In cases of retinal troubles in Bright's disease albumen is frequently found in the urine; it is also frequently absent. No doubt repeated and careful examinations would discover it in the majority of cases. Grand¹⁴ presents thirteen cases in which the retinitis preceded the appearance of albumen in the urine. Delande and Trousseau each report three similar cases.

Cardiac hypertrophy is a very frequent attendant of the retinal disease—in all but three of Bull's 103 cases, it was either present or developed while under observation.

Retinal symptoms being most frequently found

in cases of granular kidney as a late symptom, the prognosis as to life is necessarily bad.

Dr. Miley¹⁵ considers the presence of such retinal changes in Bright's disease to affect the prognosis very much for the worse, the mortality in hospital cases among the affected being at least doubled, not one having lived eighteen months after the changes were observed. In Bull's cases, from which all cases due to scarlatina and pregnancy were excluded, of the 103, eighty-six had died—fifty-seven in one year, eighteen in two, six in three, four in four, one in six. Of the fifty-seven dying during the first year, thirty died in the first six months, and of the sixty-seven cases living, fourteen were seen for the first time within six months. In view of this very unfavorable prognosis as to life, the prognosis as to vision is of less importance. Vision is rarely entirely lost, and often slight improvement in the condition of the eye is noticed.

As to treatment no general proposition can be laid down. Treatment directed to the patient's general condition is indicated, and the eye symptoms should be met as they arise.

RECENT EXPERIENCE IN THE TREATMENT OF EXOPHTHALMIC GOITRE.

Read at the Meeting of the New York State Medical Association, October 23, 1890.

BY E. D. FERGUSON, M.D.,
OF TROY, N. Y.; SECRETARY OF THE ASSOCIATION.

Exophthalmic goitre is not a common disease, and yet not so rare as to render it a curiosity. Doubtless the large majority of physicians have had more or less experience in its treatment. If that experience has corresponded with my own, it would have been marked until a recent time by eminently unsatisfactory results, at least in the majority of cases. It is true that occasionally cases would be met which did not make rapid progress downward—cases in which the disease would remain stationary, or even an improvement take place—but until about two years ago it had been the conviction of the writer that but little encouragement could be given the victims of this disease, while the idea of a cure could rarely be entertained. The variety of treatment suggested and the contradictory statements of those treating on its therapeutics justified the conclusion that either the medication was eminently unsatisfactory or a variety of morbid conditions requiring differing treatment had come to be classed as exophthalmic goitre, and the therapeutical as well as the nosological differentiation remained to be made.

Though the disease is one with sufficiently well-defined characteristics to allow of ready

recognition, still errors of diagnosis may and doubtless do occur. The fact that enlargement of the thyroid body is not peculiar to this disease, and that a frequent pulse is attendant on a multitude of morbid conditions, furnishes us two-thirds of the diagnostic points as of common occurrence, and it is not unreasonable to suppose that occasionally prominence of the eyes may be added from causes not the same as the conditions determining the development of exophthalmic goitre. The conclusion that the condition is not at any rate a pathological unit has been strengthened, in the judgment of the writer, from the results of the use of digitalis, for in every instance in which he felt confident of the diagnosis, that drug not only failed to afford relief, but was apparently productive of injury. In this he found himself in accord with many to whose writings he has had access; and yet, occasionally, benefit or even a cure would be ascribed to digitalis.

Prior to 1888 his experience had been one of nearly uniform failure to relieve or benefit the patients suffering from this disease, at least so far as direct results from the agents prescribed could be fairly assumed; and this statement is made in connection with the fact that all therapeutical measures, including electricity, which had been recommended as useful, had been given thorough and persistent trial.

Being so thoroughly convinced of the inefficiency of our resources, it was with reluctance that the care of a pronounced case of the disease was undertaken in the autumn of 1887, and the husband of the patient was quite plainly given to understand that the result would probably be a failure to cure or even stay the progress of the malady.

The patient was a woman about 55 years of age, with notable exophthalmos, enlargement of the thyroid body, and a pulse from 110 to 120. She faithfully followed the treatment advised, which included tonics, aconite, belladonna, electricity in the form of the so-called central galvanization, digitalis, etc., but after several months she was so much worse as to be confined to her bed with a pulse rate of 120 to 150 and a discomfort in the cardiac region that prevented sufficient sleep, and at times seemed to reach the agony of an angina pectoris.

In deliberating on the course to be pursued in this case, it occurred to the writer that the rapid, forcible and occasionally tumultuous action of the heart, as well as the changes found in that organ in cases dead from the malady, would favor the idea of an increase in the resistance in the systemic arteries as one of the events of the disease, and as digitalis was believed to increase arterial tension it was concluded that that fact explained its failure to quiet the excited heart action.

The then new therapeutical agent, strophan-

thus, was said to lessen the resistance in the systemic circulation, and with that object in view its administration was begun. The patient at that time was in a pitiable condition. She was unable to walk; in fact, every change of position brought on exceedingly uncomfortable, generally quite painful, sensations in the pericardia, and emaciation had advanced to an extreme degree, thereby emphasizing the exophthalmos. A measure of relief was manifest soon after commencing the use of strophanthus, which was some three or four months after the case was taken in charge.

As soon as a positive degree of improvement in the rate and quality of the pulse and the general condition of the patient was manifest, all treatment aside from the administration of iron, arsenic and strophanthus was omitted, and the improvement continued, till in about six months the pulse was reduced to 80, the patient was in every way comfortable, and able to take a fair amount of exercise without inconvenience.

By one of those curious coincidences of the observation within a short interval of time of a number of rather rare cases of disease, it fell to the writer's lot to see within a few months eight cases of the disease under consideration, and thereby quite an amount of clinical material was placed at his disposal.

One of the early cases was seen in consultation, and was the first instance of the disease ever seen by the attending physician. The patient was a woman, 41 years of age, with a pulse rate of 150, and with the usual dyspnoea. She was at once put on the strophanthus treatment and the improvement was rapid. A few weeks after this case was seen, and as another curious coincidence, the same physician brought to my office another case in a man 41 years of age. In this case the pulse was 130 and the dyspnoea on exercise was troublesome, but not as extreme as in the preceding case. He was placed on the same treatment and improvement was prompt. He continued the medicine for about ten months, except a few days, when he took spartein, but returned to the strophanthus under my advice. I examined him recently and found him in good health and with a pulse rate of 76 per minute.

It is not necessary for me to give details of all the cases, it being sufficient to state that the administration of strophanthus afforded relief and allowed a return to ordinary occupations in every instance excepting one, and in that case there was associated pulmonary disease, probably of a tuberculous character, which implied an unfavorable termination aside from the exophthalmic goitre. In this instance there was no improvement in any of the symptoms, the case passed from my observation and doubtless progressed to a fatal issue, though I have been unable to trace the history. Several of the cases

are still under observation, and I consider them still under treatment, for though they have improved so as to consider themselves in some instances as cured, in my own judgment the treatment should be continued with more or less regularity for a longer period of time. I have also excluded from my report some cases recently seen, and in some cases seen only once and that failed to keep me advised of their progress.

In no instance has either the exophthalmos or the goitre been entirely removed, and so far as the goitre is concerned I should not expect its removal, for where the enlargement has existed for some time it becomes of so dense or fibrous a consistence as to exclude the idea of its complete removal. So far as I could judge, however, there was a notable degree of improvement both in the exophthalmos and in the enlargement of the thyroid body, but it is manifestly difficult or even impossible to express in mathematical terms the changes in these features of the disease as can be done in the rate of the pulse. In the case of the heart, however, and in particular in the instance of the patient first cited, I was satisfied that not only were the rate and rhythm of the contractions favorably influenced, but there undoubtedly existed a dilatation of the left ventricle, which improved so as to leave no physical or symptomatic evidence of cardiac lesion.

Though recent pathological considerations tend to place exophthalmic goitre in the category of the neuroses, and to find the locus of its origin in that specially vital region—that neuropathic switch-board—the vicinity of the floor of the fourth ventricle, still the evidence is not such as to give us any clew concerning its etiology or treatment aside from what we can gather from clinical observations, and consequently there is no explanation to offer as to the method by which strophanthus affords relief, aside from the idea that first suggested its use, and that was to relieve an apparently overtaxed heart through the lessening of the resistance in the systemic circulation, which was claimed to be its action. This explanation may not be in full harmony with the results of physiological experiments, and particularly with what is known as Marey's law, that there is an inverse ratio between the arterial or general blood pressure and the rate of the pulse, the heart apparently being hastened in its rapidity when resistance is diminished, as would be the case in an ordinary piece of machinery.

While accepting in a general way the conclusions from physiological experiments, there are some claims made relative to the dynamics of the vascular system that fail to gain my assent, or at least to stand as explanations, and the disease under consideration is an instance, for in it the action of the heart more nearly resembles that which attends and follows violent physical exercise than any other condition with which it

can be compared, and assuredly we will hardly concede that the rapid, violent and excited action of the heart in those who are climbing mountains is due to diminished arterial tone. Whether we are to consider arterial tone and systemic resistance as occasionally convertible terms is also a problem, though an intimate relationship is manifest. Incidentally it may be noted that the mystery and perplexity of some points in the physics of the circulation of the blood renders a climax in the claim made that blood-vessels may *actively dilate*, and thereby practically solve the problem of lifting oneself by the boot-straps.

If we grant the power of forcible dilation on the part of the blood-vessels, it is not difficult to understand that the range of change in vascular resistance from the tonic contraction of arteries to their active dilation, and consequent virtual suction effect, would be sufficient seriously to disturb the heart. A corresponding variation of resistance would be disastrous in a steam engine were it not for the "governor." But we are told the heart has such a "governor," and that it is located in the vicinity of that part of the medulla occupied by the restiform bodies. We will consent that physiological experiments seem to justify such a claim, though pathological observations have not so far contributed any positive evidence, and a careful sifting of the evidence will not justify positive conclusions—nothing more than the probability that in the medulla there is a centre having control over the circulation of the blood, and that strophanthus may in some way "govern" this.

Aside from any theoretical considerations as to the way in which the agent acts, the fact remains that benefit was apparently the direct result of its use, a benefit so notable as almost to justify the claim of a cure in some of the cases, but it would be wise to stop short of such a claim, for it was observed in one of the most favorable instances that while the result in a general way was eminently satisfactory, still any mental anxiety or disquietude was sufficient to raise the pulse rate from about 80 to over 100 for a period of several days.

The period of time during which the agent has been on trial is altogether too brief to justify too glowing claims for permanency of results, and the writer cannot divest himself of the fear that the improvement will not in the majority of cases remain permanently.

The only claim that is justifiable at present is that strophanthus has proved more notably beneficial in the treatment of exophthalmic goitre than any other drug or remedial measure.

A few words relative to the agent itself, or rather its preparations and dosage, may be useful. The only preparation used by the writer was the tincture, but it was observed that a notable difference existed in the taste of different specimens.

This difference related mainly to the bitterness, and upon investigation was found to be ascribed by some pharmacists to the length of time the drug was allowed to remain in the menstruum, and by others to the improper predominance of pods over the seeds in preparing the infusion. It was impossible to conclude just how the excessive bitterness was induced, but it was apparently due to an oil or oleo-resin which would render the tincture opaque on the addition of water. Several ounces of this oily material were shown to the writer by one pharmacist as having been separated in the process of manufacturing the tincture.

In some instances the presence of a large amount of this bitter principle seemed to be productive of disturbance of the stomach, which was avoided by using other samples with less bitterness, and on the other hand some instances were noted where the bitterness was not objectionable, though on the whole the impression remained that those specimens that were notably bitter did not act as favorably.

The administration was by the conventional method of three doses daily—one at each meal—the initial dose being from 8 to 10 drops, which was increased, if necessary to reduce the frequency of the pulse, to 15, 20, or even 25 drops, and in fact relief was not obtained in some cases until the large doses mentioned had been used. In no instance did unpleasant results appear to be due to the drug, aside from some nausea which was ascribed to the individual preparation used, and apparently due to an excess of the bitter principle.

There have been but few, and those brief, notices of the use of *strophanthus* in Graves, or Basedow's disease, and its use is not advised in any of the recent "year books" consulted by the writer. It had been used by him for over a year in the treatment of the disease under consideration before he saw any notice in medical literature of its prescription by others. Within a year he has seen in the medical journals a few notices of its use, and the reports have been quite uniformly favorable.

Whether its apparent utility will bear the test of time and larger experience is still problematic—at present it seems to be our most valuable therapeutic resource in exophthalmic goitre.

INFLUENZA IN DOGS.—MM. MEGNIN and VEILLON recently presented a note to the Société de Biologie, stating that of late a disease similar to influenza has raged in certain kennels. In a pack of 120, at Chantilly, the majority were attacked, and among coursing dogs, at Aveyron, and a fine pack of beagles, the disease was also prevalent. All the characteristics of human influenza were found in these dogs.

THE CLINIC.

SURGICAL CLINIC

Held at the Harlem Hospital, New York.

BY THOMAS H. MANLEY, M.D.,

OF NEW YORK.

[Reported for THE JOURNAL].

Dr. Manley opened his clinical lecture by stating that the whole of their time, on this occasion, would be occupied with their consideration, and technique, of procedures for the radical cure of hernia, in reducible and strangulated cases, and would specially call attention to the question of anæsthesia. He said he proposed to do two operations, one of which, would be performed on a young man who suffered with a reducible hernia, and the other on an elderly lady, for a strangulated hernia.

Commencing he said: I propose to first submit for operation this young man, while the nurses are preparing the female patient. He is thirty years old; was always in good health until five years ago, while pursuing his occupation of ship's carpenter, in Kinsale, Ireland, he fell a distance of about fifty feet. He was picked up in an unconscious condition, and was not able to resume his vocation for more than a month. When he started to work again he discovered that there was a small swelling in his right groin, and for the first time in his life, he was troubled from time to time with dizziness. He bought a truss which sufficed for a time to keep the hernia in position, but in turn it would slip down by it; he now purchased a stronger one, which in a short time he had to leave off, as its chafing pressure was more than he could endure, and continue with his work. In time, along with the advance in volume of the hernia, his back commenced to give him pain, and for a long while he was unable to continue steadily following his trade, and was practically invalidated. In examining the protruded part it was evident that the sac, the fascia-propria-abdominalis, etc., was very much thickened; and though the intestine and omentum, went readily upward into the abdomen, and this pouch through adhesions, formed through cellular inflammation excited by the truss, remained. The patient had a horror of taking an anæsthetic, and Dr. Manley said, that since Réclus, of Paris, had published his famous article on "Cocaine Anæsthesia;" a report of more than seven hundred consecutive operations, he had used it locally with very great satisfaction, and hence he proposed to do both of these herniotomies, for radical cure, and strangulation by cocaine anæsthesia, injecting and diffusing it after the method of Réclus. He said, he regarded this, as one of the greatest boons ever conferred on either the patient or surgeon, for, while it dispensed with the ne-

cessity of an assistant, an important matter in emergency cases in the country at night, or amongst the poor, the patient himself proved the most valuable assistant of all, rising, sitting, standing, changing or shifting his position, or even using his hands as the surgeon desired. About ten minims of a 4 per cent. solution of the subcutaneous-injection were administered and the operation begun.

The speaker said he proposed to be guided by the conditions which he encountered in doing the operation, his aim would be, however, to separate, and ligate off the sac, close the ring by partly detaching the inner pillars of it, for there was no real canal, in this case, and, clamping them together with tin plate, and shotted silver wire, leaving the metal *in situ*, till firm, solid union was complete. As the incision was carried down, it was at once seen, what is almost to be expected, to be met with, every time we do this operation. An ectopic testis was discovered which instead of having one spermatic cord, had really three, *i. e.* the artery was found coursing along the under surface of the sac, the vas deferens on one side, and an enormously varicose spermatic vein on the other. They all converged as the peritoneum was approached, and assumed some sort of normal anatomical arrangement. They were all intricately incorporated with the laminae of the peritoneal pouch, and required very delicate dissection. The cocaine anæsthetic acted admirably, and though the operation was extremely tedious, with very much tearing and lacerating of the parts, and occupying more than an hour, the analgesic-action of the alkaloid was perfect. The most rigorous antiseptic measures were observed throughout the operation.

When the female patient was brought in upon the stretcher for operation, Dr. Manley said that he wished it noted that her condition was very low, that she had had no movement from the bowels for nine days, that protracted and futile taxis had been made, before she was turned over to him for treatment; that she had faecal vomiting; in fact, was in positive collapse. He said last year, one woman in a similar condition, under etherization, had died on the table, before the operation could be completed, and a man, at about the same time, never rallied well from the anæsthetic, and died within ten hours after the herniotomy for strangulation. After satisfying himself that the local anæsthesia was complete, he permitted the House Surgeon, Dr. James Guest to operate. The hernia was a direct inguinal; of the incarcerated variety; the operation itself was a McBurney, which the speaker said, he regarded as superior to all others, in every species of strangulated herniæ; as it afforded the operator an opportunity to see precisely what he was doing, he had the hæmorrhage under perfect control and perfect drainage of the foul secretion in the sac

was complete. This operation, as in the preceding, was most gratifying as regards the cocaine anæsthesia. The difference of the patient's condition after an operation with cocaine and ether was most marked and satisfactory.

The operator said that he wished to emphasize the enormous value of this alkaloid in those cases in which, from organic, local or constitutional diseased conditions a pulmonary anæsthetic was never administered without danger. As in the present two instances; in cases of nephritic, hepatic, pulmonary or cerebral diseases; in cases of stenosis of the air-passages, idiosyncracies, and other morbid states of the system; wherein, after operation, either death speedily supervenes, or the patient's general health is deranged, the volatile anæsthetic may be blamed justly, rather than shock, loss of blood, or inflammation.

MEDICAL PROGRESS.

REPORT OF AN EXPERIMENTAL INVESTIGATION OF THE ACTION OF CHLOROFORM AND ETHER.—At the annual meeting of the British Medical Association held at Birmingham, July, 1890, DR. JOHN A. WILLIAMS presented in the Section on Medicine, a report upon this subject, and closed his paper with an extended summary of conclusions as follows, as reported in the *Brit. Med. Journal*, Oct. 25.

1. During chloroform anæsthesia the blood pressure is lowered and the heart's action is weakened.

2. Dilatation of the heart occurs to an appreciable extent, even when chloroform is administered gently, mixed with abundance of air (under 4 per cent. of chloroform vapor in the air).

3. Dilatation may occur even before the conjunctival reflex is abolished.

4. The dilatation affects all parts of the heart more or less—the left side as well as the right. It is not due to changes in the pulmonary circuit.

5. The dilatation is not due to the accompanying fall of pressure, to the diminished resistance to the ventricular systole, or to the diminished blood supply through the coronary arteries. Dilatation does not result from a similar fall of pressure brought about by means other than chloroform, for example, arterial relaxation caused by section of vasomotor nerves. Dilatation under chloroform often occurs very quickly, before there is any fall of pressure. Moreover, when the dilatation has followed a fall of pressure it is not removed by artificially raising the pressure, for example, by compression of the abdominal aorta.

6. There is no distinct change in the rate of the heart's action when dilatation occurs. A sudden

NOTE—Both patients made rapid and satisfactory recoveries.

and complete cessation of the cardiac rhythm is never caused by the inhalation of chloroform. Cardiac failure occurs by a more or less sudden enfeeblement and dilatation of the organ; not by a sudden complete cessation of rhythm.

7. The tone of the heart muscle is depressed, the cardiac walls become relaxed, and the functional efficiency of the organ is impaired.

8. When the heart becomes greatly dilated it fails to be an effective force in keeping up the circulation, while its rhythmic movement still continues—though so feebly as to be inefficient.

9. Cardiac failure sometimes occurs in this way a considerable time before the respiration stops, though generally the respiration stops before the heart has become incapacitated.

10. The failure of artificial respiration to bring about recovery (in some cases of chloroform collapse), when begun immediately after the spontaneous respiration has ceased, is in all probability due mainly to the enfeebled and distended state of the heart, which has become unable to maintain the circulation. Hence the supply of fresh air (by artificial respiration), free from chloroform, cannot be taken advantage of.

11. The depressing influence of chloroform on the heart—leading to dilatation of its cavities—is not exerted through the vagus nerves, but is a direct effect of the drug upon the cardiac mechanism. Section of both vagi does not obviate the weakening and dilating influence of chloroform upon the heart.

12. The weakening and dilatating effects of chloroform are sometimes manifested in tolerably equal degrees on both auricles and ventricles; but sometimes more readily upon the auricles, and at other times upon the ventricles.

13. A peculiar periodic depression of the ventricular action sometimes occurs during recovery from the primary effects of chloroform.

14. The contrast between the relation to the heart's action of chloroform and ether in anæsthetic doses is very marked. With chloroform, cardiac dilatation frequently occurs—and often, indeed, a very marked dilation—before the conjunctival reflex is abolished. With ether, the induction of anæsthesia with complete abolition of the conjunctival reflex has not been attended by any noteworthy dilatation: indeed, effects of a stimulating character have sometimes been observed, and the peculiar periodic ventricular depression sometimes following chloroform has been seen to be removed.

15. Under the influence of chloroform a temporary slowing of the heart's action sometimes occurs—from asphyxial conditions or from sensory stimulation during imperfect anæsthesia. This slowing is quite different in its nature and causation from the enfeebling and dilatating effect already mentioned. The slowing is not due to direct influence of chloroform on the heart, but is

indirectly brought about through vagus nerves. It does not appear to be dangerous in the healthy animal.

16. The occurrence of fibrillar contraction (*delirium cordis*) does not appear to be a primary mode of cardiac failure from the inhalation of chloroform in the healthy animal, though it may sometimes supervene when the heart has become distended and incapacitated by chloroform.

17. The fall of blood pressure under chloroform is in its earlier stages due mainly to the depressing effect of the anæsthetic on the vasomotor centre, preceded often by a slight stimulation; the later stages are associated with failure of the heart as well as of the vasomotor centre.

18. The relative occurrence of cardiac dilatation and vasomotor depression varies. Sometimes the heart begins to dilate early—before there is any fall of pressure; at other times a large fall of pressure may occur before cardiac dilatation becomes marked.

19. The lowering of the blood pressure is in a certain sense protective; it retards the access of more chloroform to the vital organs. But, on the other hand, the fall of pressure may become excessive and produce dangerous effects.

20. In certain circumstances, when chloroform is very suddenly taken in, a dangerous dose may be absorbed, and the heart may become seriously affected *before* the vasomotor centre has had time to be much depressed.

21. When a fall of carotid pressure has been brought about by the *gradual* inhalation of chloroform in the ordinary way, firm pressure applied to the abdomen causes a marked rise of pressure—very much more than can be obtained by inversion of the animal. And even when the fall of pressure is due to the *sudden* inhalation of an excess of chloroform, pressure on the abdomen commonly, but not in all cases, leads to a decided rise in the carotid pressure. The existence of cardiac failure may prevent the possibility of such a change.

22. Changes in the respiration exert a most important influence upon the effects of chloroform administration. An amount of chloroform which can be given with safety during easy breathing may speedily become dangerous during deep, rapid respiration.

23. Free dilution of chloroform with air—the restriction of the percentage of chloroform vapor to 4 or 4½ per cent.—gives no security against an overdose. A percentage that give safe anæsthesia during ordinary breathing may lead to fatal collapse if given during exaggerated respiration.

24. Changes in respiration may be excited by sensory stimulation (operative interference, too strong chloroform vapor, etc.) during imperfect anæsthesia. Rapid, gasping respiration occurring in such circumstances is usually accompanied by

a rise in the blood pressure, and, as there may be already a considerable amount of chloroform in the circulation, there occurs a combination of circumstances specially favorable for the speedy and sudden development of dangerous collapse.

ANTIPYRIN IN PNEUMONIA, CHOREA, AND RHEUMATISM.—S. H. DESSAU, M.D., in *Arch. of Paed.*, in discussing this subject, says that the only disease in which he has employed antipyrin as an antipyretic is pneumonia. In this he seldom resorts to it unless the temperature runs above 104° F. early in the attack, and there are symptoms of nervous irritation including a tendency to convulsive seizures. Besides the antipyretic effects, antipyrin allays the nervous disturbance when not given too freely. It should be given in 2½ to 5 grains, repeated every hour for four hours—once in 24 hours. He prefers to have it administered toward evening, to secure sleep, as the result of its sedative action. If sleep takes place before all the doses are given, the rest is withheld. He has had the most marked success with antipyrin in the treatment of chorea, and corroborates the evidence of Dr. H. C. Wood in regard to its value in this disease. He has used antipyrin in 7 cases of chorea, 2 being still under treatment. One was cured in 1 week, 2 in 3 weeks, 1 in 4 weeks, and 1, the most severe of all, in 6 weeks. One case had previously been treated for 2 months with arsenic, bromide of potash, iron and digitalis without improvement. The beneficial effects of antipyrin might be inferred on the grounds of the evidence of the close relationship of chorea and articular rheumatism. Antipyrin has already acquired firm recognition as a reliable remedy in the treatment of articular rheumatism. For the past two years he has depended entirely upon antipyrin in pertussis, and has seen no reason for changing his practice. There were 45 cases, two being complicated with catarrhal pneumonia. They all recovered in shorter periods, or the attacks lessened in number and severity, than cases under former plans of treatment. Urticaria, of the more persistent form, does better under antipyrin alone or in combination with rhubarb and soda, than any other treatment.

TREATMENT OF ENURESIS BY DILATING THE VESICAL SPHINCTER.—M. SAENGER (*Arch. f. Gyn.*, xxxviii, 2). The technique of the operation is as follows: After cleansing the meatus with cotton, a disinfected metal catheter, preferably a female one, is introduced five to seven centimetres in the bladder, so that its point is about at the ureteral orifices. The tip of the right index finger closes up the mouth of the catheter and holds it quietly in position. The index or middle finger of the other hand is laid upon the catheter at the meatus. This finger

then makes forcible pressure, at first downward, then alternately towards both sides. The pressure must be springy, elastic, and powerful, so that the meatus becomes widely open and some urine flows off alongside the catheter. By this pressure not only the sphincter vesicæ but the muscularis of the urethra becomes strongly stretched. In cases where it is possible to introduce a finger into the vagina, pressure can be made against the catheter. In very sensitive individuals a sound armed with cotton containing cocaine may be first introduced, or the cocaine may be injected directly. In small children a thin sound should be used instead of a catheter. The dilatation is altogether painless. From eight to twelve stretchings should be made in all three directions at a sitting. More than ten or twelve sittings are seldom necessary, at first done twice a day, then on alternate days. The patient is also instructed to gain control over the sphincter, to refrain from fluids as much as possible, and to keep the abdomen warm. The bowels should be regulated. The patient is also ordered to write down, how often she urinates. S. thinks the root of the trouble consists in a weakness or paresis of the vesical sphincter, maybe also a certain tenuity of the muscular bundles. The centre for micturition must also be implicated, but negatively, as the irritation which causes the tight closure of the sphincter has but feeble effect upon the centre. In cases where abnormal width of the vesical neck and the whole urethra exists with urethral incontinence, this method is not applicable. Here the artificial narrowing of the urethra is indicated. The involuntary expulsion of urine by multiparous women frequently is due to abnormal width of the vesical neck and urinary channel, besides insufficiency of the sphincter. When not so very extensive, dilatation of the sphincter should be beneficial.—*Am. Jour. Obstetrics.*

EXAMINATION OF THE SPUTUM FOR TUBERCLE BACILLI.—DR. H. KÜHNE, of Wiesbaden (*Centralbl. für Bakt. und Parasitenk.*, vii Band, No. 10, August 29, 1890), after referring to the fallacies and difficulties with which the search for tubercle bacilli in sputum from phthisical patients is surrounded, describes a new method of staining the bacilli. When it is difficult to spread out the sputum on a cover-glass he uses a concentrated solution of borax, to which at least an equal quantity of sputum is added. The mixture is shaken up in a suitable glass or is worked up in a mortar, after which it is easily spread in a thin layer over the cover-glass. Nummular sputa from cavities may be broken down by a watery solution of carbonate of ammonia; this has the advantage that it is partially volatilized as soon as the cover-glass is heated, and what remains is broken up by the action of the acid. An equable layer on the

cover-glass being obtained, the albumen is coagulated by careful heating over a flame, after which the specimen is stained in Ziehl's fuchsin solution for five minutes, the color is completely removed with a 30 per cent. solution of nitric or sulphuric acid, and the specimens are washed in water and dried. In order to obtain a contrast stain, 2 or 3 drops of a concentrated solution of picric acid in aniline oil may be added to a watch glass containing pure aniline oil; a drop of this, placed on the slide before the cover-glass is lowered into position, gives a sufficient yellow contrast stain to cause the red tubercle bacilli to stand out very prominently. They may be examined with a magnifying power of $\times 60$ to $\times 100$, and where they are in great number, as is the rule in "cavernous" sputa, they appear under still weaker magnifying power as particles of red dust on a yellow ground. To make a permanent preparation, Kühne recommends that the aniline oil be driven off by means of his hand blower and that the specimen be mounted in Canada balsam. By this method the tubercle bacilli only are stained.—*Brit. Medical Journal.*

ON THE TREATMENT OF CYSTITIS IN WOMEN. By THOMAS MORE MADDEN, M.D., F.R.C.S.—Of all the diseases which come before us in gynecological practice there is none more frequently met with, more distressing in its effects, or more intractable to the means generally relied on for its relief, than cystitis in women. I therefore desire to bring under the notice of the International Medical Congress a method of treatment which I have found, by clinical experience, to be generally successful in the rapid curative treatment of this condition. The measures most commonly employed in such cases are merely palliative, and may relieve, but *per se* can never cure well-established cystitis in women. Nor am I aware of any method by which that can be accomplished save by giving the bladder absolute physiological rest. For this purpose Dr. Emmet's operation, *i. e.*, the establishment of an artificial vesico-vaginal fistula, may be successfully employed in some instances, but the practical objections to it are so great and obvious that for several years past I have abandoned this procedure in favor of another which I have found more generally effectual, and quite free from the disadvantages of the operation referred to. The plan which I have now employed in a very large number of cases of cystitis in the gynecological wards of the Mater Misericordiae Hospital, Dublin, consists firstly in the full dilatation of the urethral canal with the instrument exhibited, so as to paralyze the contractility of the sphincter vesicæ and canal, and thus produce a temporary incontinence of urine; and secondly, in the direct application through the same instrument of glycerine of carbolic acid to the diseased endo-vesical

mucous membrane. I may add that any pain thus caused may be prevented by the previous topical application of a solution of cocaine, and that the procedure seldom requires to be repeated more than once or twice at intervals of a week or ten days; and combined with the internal use of boric acid, rarely fails to effect a rapid cure in any ordinary case of female cystitis.

DIAGNOSIS OF STRICTURE OF THE RECTUM IN CHILDREN. (*Rev. Mens. des Mal. de l'Enf.*, February, 1890.)—The history of stricture of the rectum in children is of recent date. The condition is somewhat rare at this period of life, for children are not exposed to the many causes which produce it in adults. Also it is latent in its evolution, and the few functional symptoms which it provokes constitute a reason why, in congenital cases, it may remain undiscovered until puberty has been passed. An attack of rectitis may form the first intimation of its presence. Gosselin's definition of stricture of the rectum is a condition in which there is a diminution in the lumen of the organ caused by a transformation of the extensible tissue of its walls into inextensible tissue. This definition would not apply to all cases of stricture in children, for in some of them the valvular narrowing does not render the wall of the rectum inextensible, at least at the beginning. In all cases, as Trelat and Delens have said, there is a thickening or transformation of the walls of the rectum. Trollin mentions four causes apart from syphilis for this condition,—traumatism of whatever character, inflammation, habitual constipation, and the presence of foreign bodies. In all cases, according to Reyquier, the extent of the thickening in children is slight, but in a case reported by the author it was extensive, the rectum being converted into a long fibrous cylinder. The practical point of the paper is that in view of the possible latency of this condition and the complications which are possible, one should know the condition of the rectum by examination even in very young children.—*Archives of Pediatrics.*

MALARIAL GERMS.—DR. F. NEELSEN, in the *Centralblatt für klinische Medicin*, quoting from the writings of Camillo Golgi, in the *Archivio per le scienze*, says that two distinct types of bacilli have been demonstrated as causing the tertian and quartan malarial fevers. Biologically, the tertian germ completes its development in two days and the quartan in three, and the amœboid movements of the tertian type are much more marked than those of the quartan. Clinically, the destruction of the hæmoglobin in the red corpuscles is much more rapid in the tertian than in the quartan. Morphologically, the difference is to be seen in the first stages of development; the amœba of the tertian has a more delicate

mass of protoplasm and a sharper contour than those of the quartan, while the pigment granule and bacillus of the quartan are larger and coarser. Finally, segmentation takes place in a less regular manner in the tertian than in the quartan organism.—*N. Y. Medical Journal.*

ARISTOL IN DISEASES OF WOMEN.—SWIĘCICKI and GAUDIN (*Amer. Journ. Med. Sciences*, October, 1890), speak favorably of aristol in diseases of women. Swięcicki reports twenty cases of endometritis and pelvic exudation in which he used the drug. The discharge diminished and the local pain was relieved. The aristol was introduced in the form of vaginal suppositories, or a 10 per cent. solution was employed for the saturation of vaginal plugs. Dr. Gaudin finds the compound most useful in cervical erosion and endometritis, where it acts most favorably. It is a powerful disinfectant and deodorizer in cervical cancer, and Dr. Gaudin states that it promotes rapid cicatrization. It may be applied to the cervix in the form of powder, in solution, or in suppositories. After the curette has been used, the uterine cavity may be packed with strips of gauze saturated with a 10 per cent. ethereal solution of aristol. When the pure drug is taken or administered hypodermically, no trace of iodine can be detected in the urine. Hence, unlike iodoform, there is no danger of toxic effects when aristol is applied to large raw surfaces; moreover, it has no unpleasant odor.—*Brit. Med. Journal.*

THE ELIMINATION OF POTASSIUM IODIDE.—At the thermal baths at Bagnières-de-Luchon, M. GEORGES DOUX had several times during the past year occasion to determine the amount of potassium iodide in the urine of a patient ordered to take eight grams of the salt daily. The analysis showed the eliminated quantity to be so large and constant that M. Doux considered that further investigation of the subject would be of interest on account of the wide limits assigned to the size of a dose in treatment with this remedy. He therefore conducted a series of experiments upon himself, taking two 3-gram doses of the iodide daily for twenty consecutive days, and determining the amount of iodide and urea present in the total quantity of urine passed every twenty-four hours. The salt could be detected in the urine thirteen minutes after ingestion of the first dose, and the daily elimination after the second day remained a nearly constant quantity, being about 90 per cent. of the dose taken, whilst no traces could be detected seventy-five hours after the last dose. At the same time, the normal amount of urea present in the urine was diminished by about one-fifth. The experiments were repeated on two occasions, at two months' interval, with the same results, but it was observed that the quantity of iodide eliminated did not ex-

ceed 60 per cent. if a little absinthe had been taken on the previous day. M. Doux further states that he was prevented from extending his field of research by the attacks of coryza, epiphora, and maxillary pains that accompanied the daily ingestion of doses varying from one to five grams of iodide, whereas no ill effects were observed to follow a dose of six grams, which might have been expected to increase the severity of the symptoms.

THE DRY TREATMENT OF CHANCROIDS.—It is generally conceded that if chancroid ulcers can be kept perfectly dry a great step has been taken towards their rapid healing. In this view, the following procedure has been used to some extent on the surgical divisions at Bellevue Hospital, New York: A small roll of absorbent cotton about $\frac{1}{2}$ in. in diameter and long enough to surround the penis just behind the corona, is put in that position after the prepuce has been well retracted. A rubber thread-band is slipped over this ring of cotton in order to hold it in its place. By this means the sulcus behind the glans is obliterated, which is especially liable to retain the secretions, and the prepuce is held back from contact with the ulcerated surfaces. The cotton absorbs the exudation from those surfaces almost as soon as formed. The dressing is light, is easily handled, and may be renewed as often as needed to keep the parts in a dry condition. In addition to chancroids, herpes preputialis and venereal warts have been found to heal rapidly under the use of this dressing; sometimes no other treatment has been found necessary for these local lesions.

ACETANILID AS A HYPNOTIC FOR CHILDREN.—Amongst the many hypnotics which at present are being so liberally supplied by the chemists to the medical profession, it is well not to lose sight of the value of acetanilid in certain groups of cases. Although the drug suggests more that its action is to hinder the development of febrile condition, or, when that condition exists, to lower the temperature, still in many cases in my practice it has proved a valuable hypnotic and analgesic.

Its value has been most evident in cases of broncho-pneumonia, croupous pneumonia, and bronchitis, and that more especially in cases where children have been the sufferers. The marked relief which has frequently followed its administration has in many cases been extremely gratifying. Cases of fretful insomnia of the young, possibly partially caused by pain, fever, or general *malaise*, have been speedily relieved by the drug, and from six to eight hours of refreshing sleep have been induced. After sleep the awakening was natural, there being no excitement or confusion of thought. There was

no period of excitement observed before the drug took effect. Along with the onset of sleep there was a fall of temperature, frequently a copious perspiration, at the same time the respiratory acts were slowed and the pulse-rate diminished. In no case have any evil effects been noticed, although the success of the drug induced its employment in a large number of cases.

The need of a safe hypnotic for children, such as antifebrin, will, I think, be readily appreciated, the number of cases where it is required being unfortunately very large. It is still further enhanced as a serviceable drug for children by the fact that it is comparatively tasteless, and also by the smallness of its dose; the dose being from two to five grains, depending of course on the age of the child. A useful way of prescribing it, I have found, is to place the powder on the dorsum of the tongue either alone or mixed with a little powdered sugar. It might also be given in the form of a mixture—the drug being insoluble in a watery menstruum—suspended by the aid of mucilage and sweetened by any of the various flavoring syrups. There is yet another important advantage in hospital and general practice over many recently introduced hypnotics, in the comparative cheapness of the drug.—*Brit. Med. Jour.*

GALVANO-CAUTERY IN PURULENT OPHTHALMIA.—DARIER reports excellent results (*Le Progrès Médical*) in the treatment of two patients in the clinic of Dr. Abadie. In both of these cases there was a deplorable condition, the lids were enormously swollen, with great inflammation and marked involvement of the corneæ. They had resisted all other forms of treatment, including nitrate of silver. Antiseptic douches, with the instillation of iodoform followed each cauterization.

UNNA'S TREATMENT OF ULCER OF THE LEG.—DR. HILLEBRAND, of Cologne, has obtained excellent results with Unna's treatment. This consists in thorough cleansing of the leg with soap and water and application in a thick layer of the following paste to the parts, excepting the site of the ulcer:

R. Zinci oxidi,
Gelatin puris, āā 10.00.
Glycerini,
Aq. destillat, āā 40.00.

The ulcer is then sprinkled with iodoform, and covered with a layer of cotton and sublimate or iodoform gauze. Over this is applied tightly a doubled headed wet mull bandage, the ends crossing in front of the leg. The bandage should extend at least from the middle of the foot to the calf, and is supplemented by a second one similarly applied. The dressings are changed in from two to four or even eight days, according to the amount of discharge. The effect of this method

of treatment is to stretch the healthy skin over the ulcerated surface, the integument being prevented from retracting by the application of the paste. The free escape of cutaneous secretions is not prevented by the paste, as in the case of the adhesive plaster treatment. Hillebrand has obtained a complete cure in twenty-five cases where he employed this method. In all of them there was a rapid improvement in the local and general conditions, and the patients were able to work after application of the dressings. Equally good results were obtained in a case of chronic ulcer of the arm.—*Medicinische Monatsschrift.*

THE USES OF CODEINE.—The rush of new analgesics and hypnotics has almost completely overshadowed the long-known drug, codeine, and in this country, at least, its merits have been overlooked, and but little employment has been found for it. Dr. M. Loewenmeyer, in *Deutsch. Med. Wochenschr.*, gives a summary of the various conditions in which he has found it useful. The dose which he has used is from $\frac{1}{3}$ to $\frac{2}{3}$ of a grain; where the latter dose did not prove effectual, larger doses also generally failed. It was generally given in powder form, also in mixtures; latterly also in the form of suppositories. The results were favorable and highly satisfactory in the majority of cases of the following diseases: Painful conditions of the abdominal and pelvic organs (gastralgiæ, colics, visceral neuralgiæ), ulcer and carcinoma of the stomach, carcinomata of the liver, of the intestine, and of the peritoneum, and pain arising from disease in the genito-urinary system, for example, in ovarian pains (this latter differs from the observations made by Freund). Codeine rendered excellent service in diseases of the thoracic organs: phthisis, bronchial catarrhs, pleurisy, pneumonias, and cases of asthina. It also seemed to act favorably in diseases of the heart, as in conditions of stenosis. Loewenmeyer highly prizes the hypnotic powers of codeine, and there is no doubt that this property of the drug is very much underestimated. The hypnotic results were not so satisfactory in the different varieties of mental and nervous diseases.—*Weekly Medical Review.*

AMMONIUM ACETATE IN THE TREATMENT OF SCARLATINA.—VIDAL recommends large doses of ammonium acetate in the treatment of scarlatina, and believes that it will also be found useful in the treatment of other exanthemata. In three children suffering from scarlatina to whom he gave the drug in daily amounts of from 35 to 90 grains, the temperature rapidly fell and desquamation was established within four days. In the author's experience the earlier in the course of the disease that the ammonium acetate is given the better are the results.—*Wiener medicinische Presse*, October 5, 1890.

SATURDAY, NOVEMBER 29, 1890.

QUINIA USELESS IN NON-MALARIAL DISEASES.

DR. JOAQUIN L. DUENAS, of Havana, has published in a medical journal of that city, the results of nine years' study of uses and futilities of quinia, in 3,961 patients. The greater number of his observations were within the city limits, and he declares it as his opinion, although contrary to what might be expected, that Havana is, for the most part, free from malarial infection, and that it is only in those parts of the town where the pavements are imperfect, and where there is much decomposing organic matter that true malarial fever is met with. He thus confirms the views of LAVERAN, ROUX, COLLIN and others to the effect that malaria is not an urban infection and that the country is its home; that large cities in their growth and sanitary development gradually crowd out the elements that foster paludal disorders. Dr. Duenas classified his patients into febrile 2,267, and non-febrile 1,694. Of the pyretic affections, seventy cases only were classed as malarial, and these were freely treated by quinia; 704 cases were infectious in character, inclusive of small-pox, scarlet-fever, yellow fever, measles, varicella miliary tuberculosis, septicæmia, erysipelas and typhoid fever. Of these the last two alone treated to any considerable extent with quinia. This use was dictated by the desire to reduce high fever and to administer a cardiac and vascular tonic. After a short experience with the drug in typhoid fever and septicæmic conditions the writer abandoned its use in regard to them. He did not long per-

sist in the employment of quinia in malarial disorders of the adynamic type; in the few cases of pernicious fever, in which quinia was used as the chief remedy, death was the invariable consequence, but whether the fatal issue was due to the disease or to the medicine, the writer could not determine. Remittent fever appeared to be benefited by quinia, but in those forms where the typhoid symptoms become prominent, and which are by many called typho-malarial fevers, the uselessness of the drug was manifest, not only for the reason that it appeared to reduce the systemic resistance, to predispose the patient to attacks of syncope, to favor the degeneration of the cardiac muscular fibre—a frequent mode of death—but also by its local action to protract the period of recovery by its irritation of the gastrointestinal mucous membrane. The drug was found to be useless in diphtheria, dysentery and all forms of septicæmia, especially those having their origin in the puerperal condition; in erysipelas and acute articular rheumatism the remedy was serviceable. In the fever of syphilis quinia was useless; this was also true in regard to the fever of dentition and in chlorotic and hysterical subjects. In regard to catarrhal affections, having more or less pyrexia, the drug was often harmful, such as laryngitis, bronchitis and acute broncho-pneumonia; in these affections, the use of quinia was never followed by any significant reduction of the temperature. The same results obtained in regard to the treatment of catarrhal disorders of the digestive organs, of the bladder and other pelvic organs. It was observed, as a probable result, in several cases that the drug was harmful in prolonging the febrile stage and the duration of the disease. In cases of broncho-pneumonia in infants, it even appeared to hasten death.

In all, Dr. Duenas treated not far from one thousand cases of non-malarial febrile disorders and diseases of the various mucous membranes, with the general verdict of useless or harmful. Quinia was found useful in certain congestive conditions in hæmorrhages, apyretic rheumatic attacks, neuralgia, migraine, asthma, pertussis, cardiac depression and in some other disorders which, although not depending on any known malarial agency, frequently assume the intermittent type. Of all these diseases, neuralgia was the most frequent, and it yielded most

happily to the influence of quinia; of 228 cases successfully treated by that drug only two were regarded by the writer as having been due to a distinct malarial poisoning.

KOCH'S WISDOM.

For three month's the world has waited with impatience for a revelation of the reported cure for tuberculosis. The announcement that the illustrious KOCH had discovered a cure for the disease whose cause he had revealed ten years ago, was welcomed with a confidence that would have been bestowed upon no other discoverer in the medical profession. And now the world is filled with amazement at the remarkable results which are reported to have followed the use of this remedy—amazement mingled with disappointment that the nature of the remedy has yet been withheld. The blessing of the public is like that of Saxe on the man who first invented sleep.

If the telegraphic translations of Koch's article in the last issue of the *Berliner Klinische Wochenschrift* are to be relied upon, the discoverer is satisfied with the results of his experiments, but deems it prudent to withhold for the present the nature of the remedy from all but a few of his most eminent associates. Those to whom he has revealed it are said to be filled with enthusiasm. PROF. NOTHNAGEL is quoted as saying, "we face one of the greatest intellectual achievements in the province of medicine for centuries past. Prof. Koch's discovery has a far wider scope than Jenner's and is, perhaps, the grandest feat in the history of our science. . . . The present moment is among the most sublime that humanity has known."

The lymph which possesses the remarkable property of destroying tuberculosis is described as a brownish, translucent liquid. It is administered hypodermatically through the skin of the back. The dose is from .01 cc. to .25 cc., rapidly increasing, except in cases of advanced pulmonary tuberculosis, when only .001 or .002 cc. are at first injected. Koch's experiments have been conducted upon healthy individuals, including himself, upon patients suffering from various forms of tuberculosis, bone, lymphatic, pulmonary and cutaneous, and upon lower animals. Its action on man is many times more pronounced than

that on animals. The effect of an injection in a healthy individual begins in three or four hours after it is made. The first symptoms are lassitude, muscular rigidity in the lower limbs, dyspnoea and cough. An hour later the individual has a severe chill, lasting about an hour, accompanied with nausea and sometimes vomiting. The temperature rises to 36.6° C. (103.25° F.) or higher. These symptoms for the most part continue twelve hours, then subside; but the lassitude frequently continues several days. In the tubercular subject the same symptoms are present, but are more intense. There is a chill, elevation of temperature reaching from 39° to 41° C. (103° to 105.8° F.), extreme prostration, and usually nausea and vomiting, sometimes a slight icterus or a macular eruption (resembling measles) on the chest and neck.

The local effect on lupus is even more interesting. Within a few hours after the injection, we are told, the sores become of a dark red color; as the fever increases a rapid necrosis of the lupus tissue occurs, the color deepening to a dark brown or black. After the acute manifestations subside, repair speedily occurs. Recovery has repeatedly followed a single injection. The reaction in cases of bone, lung and lymph-node tuberculosis is not so striking because not open to ocular examination, but it is apparently similar in character. Koch believes that the remedy is a cure for incipient tuberculosis of the lung, but has not yet established the fact of its being a permanent cure. In regard to advanced tuberculosis he fears that it will not be more than beneficial.

The action of the new remedy is said to be exerted not upon the bacilli, but upon living tubercular tissue. It causes rapid necrosis of all tubercular new-formations. Its action is final, and it has no power over dead tubercle. Hence the dose administered may be rapidly increased, its action diminishing with the destruction of the tissue.

The only admitted defect of the treatment is the possibility of living bacilli being retained in the necrotic mass to infect the system at some later time. Occasional repetitions of the injections are, however, believed to be a safeguard against such infection, or, at least, a cure in case it does occur.

There might be a question of the possibility of

septic infection arising from the production of so great an amount of necrotic tissue in the organism; but we are told that the discharge from the necrotic masses is not purulent in character. The expectoration from tubercular lungs becomes non-purulent.

In nothing is Prof. Koch's wisdom more clearly displayed than in his reservation of the nature of his remedy until further observations of its action have been made. He has thus, no doubt, prevented a repetition of the absurdities which followed the announcement of BROWN-SÉQUARD'S alleged discovery. Whatever of good there is in the remedy will thus surely be secured to humanity. Long live the illustrious Koch!

DISHEARTENED CHILDREN.

Do not crowd the children! The school duties should be measured out to them in proportion to their nervous vigor. It is manifest to every discriminating observer that there are causes at work, in city life especially, that will compel a further reduction in the duration of the school attendance and in the pressure on the highly evolved nervous organizations of the present day. The hours and pressure are already much less than was considered perfectly legitimate in your and our boyhood days. The penalties then liberally administered, "for the good of the rising generation," are not tolerated for a moment now. Correctional measures of discipline have now to be administered sparingly and judiciously; you must spare the rod sometimes, or you will spoil the child. Many parents of our acquaintance view with annoyance and chagrin the apparent incapacity of their offspring, in the fact that the latter cannot undertake as many branches of study as were in vogue when they themselves were children. The only comforting assurance that we can give them is that the times are changing, and are destined to change.

EDITORIAL NOTES.

REMOVAL OF THE PANCREAS FOR CANCER.—The *Press and Circular* states that a case of removal of the pancreas for cancer has been reported by Rügge, in an Italian medical journal, name not given. The case was that of a woman, aged 50, who came under treatment for gastric symptoms, loss of appetite, constipation, and pain ra-

diating from the epigastrium in all directions. On examination, there was found a tumor between the umbilicus and hypochondrium, hard, resistant and somewhat movable. The diagnosis was arrived at of a retro-peritoneal sarcoma. Laparotomy was performed and the removal of the tumor undertaken, a procedure that was by no means easy, owing to the numerous adhesions which had formed. The growth was found to be the pancreas, the seat of primary carcinoma. The patient made a rapid recovery.

OFFICERS ELECTED.—At the annual meeting of the Washington Obstetrical and Gynecological Society the following officers were elected for the ensuing term: W. W. Johnston, M.D., President; D. W. Prentiss, M.D., H. L. E. Johnson, M.D., Vice-Presidents; H. B. Deale, M.D., Recording Secretary; Geo. Byrd Harrison, M.D., Treasurer; and G. Wythe Cook, M.D., Corresponding Secretary.

THE KOCH METHOD.—The associated press reports, under date of November 17, referring to this method has the following report from Berlin: Professor Bergmann delivered a lecture last night at the Berlin Clinical Hospital on the thirty-nine cases treated by him according to the Koch method. The patients were suffering from various tubercular affections of the joints, bones, skius, glands, throat and mouth. One of them was suffering from a tumor of the larynx, and it was doubtful whether the affection was a tubercular or cancerous one. He was treated in the manner laid down by Professor Koch, and, as there was no constitutional reaction Professor Bergmann was led to express the opinion that the tumor was of cancerous formation. Professor Bergmann illustrated the value of the Koch method as an aid in diagnosis. Professor Koch's indisposition was the result of an injection of the curative lymph. It was only very slight, and has now passed off. Professor Bergmann also demonstrated the Koch cure last night before Dr. von Gossler, Prussian Minister of Ecclesiastical Affairs, Instruction and Municipal Affairs, and many noted physicians, including the celebrated Dr. Kerschesteiner, of Munich. A visitor to the consulting rooms of Dr. Cornet writes to the *Vossische Zeitung* as follows: "Imagine a dark corridor scarcely four and a half feet wide thronged with a motley assemblage of men and

women, and in a small adjacent ante-room thirty persons coughing in a close atmosphere anxiously awaiting their turn for examination and treatment. One patient who appeared to be in an advanced stage of the disease had to be carried into the consulting room. In this room there were three assistants at work by a little table; one patient seated in a chair undressed and undergoing examination and three other patients partially undressed and awaiting their turn. Dr. Cornet in the meantime made his way through the throng calming the impatient, and seeing that every one took his or her proper place. A workingman who seemed to be suffering greatly pleaded that he was the father of four children and asked that his case might be taken without delay. He was told that he would be admitted as soon as a vacancy occurred. Similar answers were given to others who were importunate. The stream of applications for treatment has grown into a perfect avalanche." The writer in conclusion says that the municipal authorities ought immediately to erect temporary hospitals for the treatment of patients with tuberculosis.

THE ORTON PRIZE.—Dr. J. G. Orton, as President of the New York State Medical Association, has offered a prize of \$100 for the best short popular essay on some subject connected with practical sanitation, under the following conditions:

1. Competition to be open to all.
2. Essays to be forwarded to the Secretary of the Association, Dr. E. D. Ferguson, Troy, N. Y., not later than August 1, 1891, accompanied by the name of the author under separate seal.
3. Examination and award to be made by a committee appointed by the Council of the Association.
4. The successful essay to be read at the next annual meeting of the Association, and, if approved by the Council, to be offered for publication in the secular press, and issued in tract form or otherwise for general circulation.
5. Authors of essays, unsuccessful as far as the prize is concerned, but found worthy of special commendation, to receive intimation as to a proper disposition to be made of them.

DEATH OF DR. G. MONOD.—The death of this surgeon, well known in Paris from twenty-five to thirty years ago, is announced at the ripe age of eighty-seven. Dr. Monod was for many years on

the surgical staff of several Paris hospitals in succession, and had also served his seven years as assistant professor at the Paris Faculty. He was an able surgeon of a school now fast dying out, and enjoyed a large practice, especially amongst the Huguenot or French Protestant body, of which he was a prominent member. He was the father of Dr. Charles Monod, surgeon to the hospital of St. Antoine.

UNIVERSITY OF PENNSYLVANIA.—The compulsory course for the medical degree in this University has been lengthened to four years.

THE SUCCESSOR OF PROF. BARTHOLOW.—So far as we know the one to succeed Dr. Bartholow in Jefferson College has not been named. If, as in former times, the custom shall prevail to invite to that institution at every third vacancy a Western man, we think the West is now to be represented. If so, as yet, no one has been so prominently named as Dr. Samuel O. L. Potter, of San Francisco. His work has already rendered his name familiar, especially to medical students, and the college would gain an added strength if, in naming him to that position, it should also honor one of its alumni.

KOCH'S EARLY DAYS.—Mr. Arnold Koch, President of the Redheffer and Koch Art Company, of St. Louis, a younger brother of Dr. Robert Koch, of Berlin, says that "Robert is the third of thirteen children, the first nine of whom were boys. While the rest of us went fishing and hunting, Robert devoted his hours to study and observation. One of his favorite pastimes was the microscopical study of lichens and mosses. At 17 he had completed his course in the High School at Clansthal, Hanover, but was unable to enter the University of Göttingen until he was 18. At the University he wrote a prize essay in his second year. His course as a physician at Posen, where he first began the study of bacteria, his service during the Franco-Prussian war, and his investigation of the cholera germ, are all matters of record."

HYGIENIC INSTRUCTION IN SCHOOLS.—The French Minister of Instruction has directed that twelve lectures on Hygiene are to be given to the more advanced pupils in all *Lycées*.

DR. W. L. SCIENCK has removed from Osage City to Topeka, Kan.

TOPICS OF THE WEEK.

A STUDY OF DR. KOCH'S DISCOVERIES.

The result of Prof. Koch's discoveries, so far as we are able to understand them on this side of the Atlantic, promises to revolutionize the practice of medicine, at least in the treatment of diseases depending upon the presence of a microorganism. Notwithstanding that these investigations have been going on for some time, no one outside of his immediate associates seem to have any very definite ideas as to the method pursued in the preparation of the medicaments used. From the report which he has just published, nothing can be learned as to his secret, and for the present all liquids for inoculation will have to be obtained from Berlin. While this may be useful as a precautionary measure, and may serve to prevent the illegitimate uses which followed the announcement of Bergeon's gas, and Brown Séquard's fluid, it is not at all to the liking of many scientific men in this country. Still, we are scarcely warranted in entering a complaint against the discoverer, because the establishment of the correct principles upon which the cures depend is more to be desired than the immediate and wholesale practice which would follow the exact announcement of the methods.

So far as we can judge from the reports, the results in the practice of quite a number of physicians in Berlin would lead us to believe that a specific has been found which will arrest the progress of consumption, and that for all practical purposes those submitting to this treatment, even in advanced stages of the disease, may expect to be relieved from the immediate consequences of the affection. Whether it will be a guard against an attack at some future time the promoters are not prepared to say; but from our knowledge of the etiology, and the relations which the bacilli bear to it, there is no assurance that it will enact the role of vaccination as practiced for the prevention of small-pox. The remedy merely presents to the affected tissues a poison, probably in the shape of a ferment, which has a fatal effect upon the bacilli; the result of this action is that the diseased structures undergo a retrograde metamorphosis, necrosis takes place, and that portion which is not eliminated by expectoration is rapidly absorbed and thrown off through the usual channels. Where the disease affects joints, for instance, massage is recommended for the purpose of assisting nature in getting these objectionable products into the blood-current.

In the treatment of lupus and lupoid ulcerations the action of the remedy may be observed from day to day, and in this disease the descriptions are exceedingly interesting, and will be useful in enabling us to estimate the peculiar powers which it possesses. No physician can study the account published by Prof. Koch without a feeling of wonder and admiration, owing to the clearness of the evidence, the multiplicity of facts adduced, together with the well-known scientific character of the work previously performed by this celebrated *savant*.

It would be idle to speculate upon the character of Prof. Koch's medicament, but it will not be out of place

to call attention to some investigations which have preceded his, and which appear to throw some light upon this occult subject. In the *British Medical Journal* for last October, Mr. E. H. Hankin gave an account of the methods he had pursued for the purpose of rendering mice insusceptible to anthrax, by means of the subcutaneous use of an albumose obtained from cultures of the anthrax bacillus. Dr. Sidney Martin communicated an account of his researches in the same line on May 22, 1889, to the Royal Society. He succeeded in obtaining two albumoses, an alkaloid leucin, tyrosin and a peptone from cultures of this bacillus. These albumoses were strongly alkaline, and upon this condition, Dr. Martin assumed, their toxicity depended. When introduced into the living tissues, the toxic property of the albumose was similar to that of the alkaloid, only less rapid in its action. The symptoms correspond in the main with the effects which are said to attend the injection of Koch's liquid. The alkaloid used in this manner quickly produces death in mice, another factor going to show the close resemblance between the poison of Martin and the liquid medicament of Koch, which is used in what might be termed infinitesimal doses. Whether his inoculation liquid is prepared in like manner from the bacillus tuberculosis, remains to be seen. And if this assumption be correct, it is but a question of time when all disease dependent upon a germ for its progress will become amenable to similar treatment. This statement, however, does not indicate that I am committed to the belief in theory of the bacillus tuberculosis being the first cause of tubercular phthisis, as will appear from the study of other investigations referred to later on in this paper.

Mr. Rankin also reported to the Royal Society last year, that he had been able to obtain from cells that are, or can become phagocytes, a substance which is fatal to bacteria, thus confirming the doctrine of phagocytosis. In May of this year the *British Medical Journal*, commenting upon these discoveries, said: "It is obvious that this discovery throws a new light on Metschnikoff's phagocyte theory, and points to the *rationale* of pus-formation. Apparently we are dealing with a natural antiseptic—a substance produced by the organism to protect itself against microbes, and the question arises whether its administration can have an effect in modifying the course of the disease." The indications are that Prof. Koch has demonstrated the applicability of this principle in the treatment of tuberculosis, just as Martin and Hankin have shown its efficiency in arresting the progress of anthrax in mice. The weapons of the disease are the poisonous proteids, and nature meets them with weapons of a like character. The resistance of the organism is an inherent property, one of the normal functions of life; when this function has become impaired, or is temporarily suppressed, the disease-poison gains the upper hand, and if the condition is maintained for a sufficient length of time, the foundations of health are undermined, but never before have we had such a practical demonstration as in the case of the arrest of tuberculosis.

The investigations of Roussy (Experimental Researches.

on the Pathology of Fever, Acad. de Med., February 12 and March 12, 1889,) seem to shed some light upon a subject intimately related to this line of study. In the course of his experiments Roussy found that certain diastases penetrating the blood became pyretogenous. By the injection of invertin into the blood, he produced in animals violent attacks of fever. Now, we know that the intestinal juice possesses the power of inverting cane-sugar; saccharose is transformed into invert sugar, and it is not unreasonable to assume that frequently occult febrile conditions may be due solely to intestinal derangements which permit or favor the absorption of invertin. The regulation of the diet in health, therefore, becomes a matter of paramount importance, and with attention to diet, and a knowledge of the principles underlying Koch's discovery, we are apparently on the threshold of a new era in the practice of Medicine.—Dr. John Auide, *Medical Summary*.

THE STRUCTURE OF BACTERIA.

To give an account of the structure of bodies so small as those that belong to the bacteria would seem to exceed the powers of the best microscopist armed with lenses of the deepest focus, yet it has been essayed by Bütschli, the accomplished Professor of Zoology in Heidelberg. He has taken as the subjects of his examinations two large and well-known forms, which were recognized by Ehrenberg, and belong to the peculiar group of sulphur bacteria—one of these was named "Monas Okenii" by Ehrenberg, "Beggiatoa" by Zopf, and "Chromatium" by Perty—the *Ophidomonas jenensis*. These bacteria grow only in soil water impregnated with hydrogen sulphide; without that gas they dwindle and die, with it they have an active and vigorous life, and grow and multiply. They possess the remarkable power of decomposing sodium sulphate and fixing the sulphur. In their interior may be seen a variable number of dark, highly refracting granules or droplets, the accumulation of which sometimes renders the animal quite opaque. These granules are composed of soft sulphur, which dissolves readily in alcohol and reappears on evaporation of the alcohol. The droplets disappear in the course of twenty-four hours when digested in artificial gastric juice or in a 10 per cent. solution of soda. The *Chromatium Okenii* contains a red coloring matter, named by Prof. Ray Lankester "Bacterio-purpurin." Its form when seen on the side resembles that of a bean, but on transverse section is circular. The maximum length is 0.14 mm. The majority move rapidly forwards or backwards by means of a whip-like cilium. Each organism is provided with a thick, firm, colorless investing membrane, presenting net-like markings on the surface, which seems to be continuous with the flagellum. This membrane does not give the reactions either of cellulose with iodine or of albumen with Millon's reagent, but it stains well with hæmatoxylin and other staining agents. On pressure being carefully applied, the outer tunic bursts, and the body of the animal flows out in a manner that shows it to be of soft consistence, with an external reddish layer which is retiform, and an internal colorless one which contains all the sulphur granules. The addition of alco-

hol quickly dissolves out the red coloring matter, but leaves the plasma green; Bütschli therefore admits the presence of a red and a green coloring matter. The former is deposited in red rhombic laminae on evaporation of the alcohol. When the crystals are treated with diluted sulphuric acid they become blue; when with diluted nitric acid, grass-green. The central mass of the organism stains more deeply with coloring agents than the cortical, and, like the cortical, shows a kind of retiform or felt-like arrangement. The sulphur droplets are connected with the web, and not with the enclosed plasma, and are situated at the points of intersection of the web. Bütschli finds a very similar structure to that above described in spermatozoa. He recommends that the light, under which they are examined, should not be too strong.—*Lancet*.

SOME OBSTACLES TO MARRIAGE.

The leading statisticians of France are still much occupied with facts and figures concerning depopulation and its remedies. About 74 out of every 100 illegitimate children die in France before the age of 21. As one means of increasing marriage and adding to the population, it has been proposed to legalize and encourage the marriage of priests. M. Lagneau gravely reminds the Academie de Médecine that in the fifth century Sidonius Apollinaris, though a husband and father, was Bishop of Clermont-Ferrand, but, he added, "Now this would not be tolerated." Dowries are much more universally expected and guarded for marriageable daughters in France than elsewhere. This seems to interfere with the survival of the fittest. The suppression of dowries, it is suggested, would have the advantage of giving the preference over rich girls to handsome and strong young women, capable of producing beautiful and vigorous children. There is, too, it seems, too great a number of administrative and official posts, and this brings the rural population into great cities such as Paris, where they have fewer children and weaker. In Paris, the centre of administration, 11.6 per cent. of the residents are living alone, while in France in general there are only 4.25. Even these are not able to pay for bringing up their families. Scholarships and special payments by the State for this purpose cost, in 1887, £125,000. The want of provision for medical relief to the poor in the provinces also drives them into the great cities. Last year "nuptiality" and "natality" again fell off by some thousands as compared with the previous year, the marriage rate being only 7.1 per 1,000 and the birth rate 23.04 per 1,000; so that the demographic conditions are far from being satisfactory.—*Brit. Med. Jour.*

STATUE TO LIEBIG.

At Giessen there was on July 23 unveiled, in the presence of a large assemblage, a monument to this distinguished chemist. The statue is greater than life size, and allegoric figures representing Science and Culture are on two sides of the monument, which is of white marble and is described as a magnificent work of art.—*Pharm. Record*.

PRACTICAL NOTES.

KERATIN.

Drs. Unna and Beiersdorff recommend that pills coated with keratin, or capsules made of this substance, should be employed when drugs are prescribed which irritate the gastric mucous membrane, and the administration of which is liable to induce vomiting—such as preparations of digitalis and squills, salicylic acid, or iodide of iron; also when substances are given which neutralize the acidity of the stomach, or which in any way impair its activity—such as acetate of lead, tannin, nitrate of silver, alkalis, etc. An outer coating of keratin is also desirable when prescribing drugs that are required to act on the intestinal mucous membrane without affecting that of the stomach, such as extract of logwood, tannin, or the salts of aluminium. Finally, keratin is most valuable when substances are given with the object of destroying worms, but which if introduced in the ordinary way into the stomach undergo absorption to such an extent that they are liable to set up alarming symptoms, while at the same time their germicidal action is reduced. Keratin is obtained by treating shavings of buffalo horn with ether, alcohol, and an acid. Its special property is that it is insoluble in the contents of the stomach, but readily so in those of the intestine after the pancreatic juice has entered.—*The Lancet*.

INDICATIONS FOR THE USE OF GLYCERIN INJECTIONS AND SUPPOSITORIES.

The observation of the effects of glycerin injections and suppositories in a large number of patients has led Dr. Polubinski (*Deutsche Medicinal-Zeitung*, June 19, 1890) to the following conclusions:

There is no doubt that glycerin irritates the mucous membrane of the rectum. This is shown both subjectively in the burning produced by it, and objectively by the ascending of the mercurial column of the thermometer, if pushed deep enough within the intestine.

The increase of temperature and the desire to defecate are of but short duration, and the latter may often be overcome voluntarily by the patient. The irritation of the mucous membrane produces no local secretion, since the feces, evacuated as a consequence of injections of glycerin, are only covered with glycerin. The author obtained the best results when the rectum and sigmoid flexure are filled with scybala. If feces collect in the upper parts of the intestinal tract, glycerin is then inefficacious. According to the author, therefore, the cases in which glycerin enemata and suppositories are indicated are,—*first*, when the fecal masses are already in the rectum; *second*,

when they are in the parts of the large intestine immediately above, as occurs so often in lying-in women; *third*, in diseases of physiological conditions which produce mechanical pressure on the rectum or sigmoid flexure, such, for example, as new formations in the pelvis, pregnancy, etc.; *fourth*, in scrofulous children; *fifth*, in persons who, although they may daily succeed in having evacuations of the bowels, yet in whom the act of defecation is only accomplished with difficulty and accompanied by pain, and in whom in general the feces are of excessive density.—*Thera. Gazette*.

ARISTOL IN OZÆNA.

Iodide of thymol—or aristol, as it is called—is strongly recommended by Dr. Löwenstein, of Elberfeld, in ozæna. He gives in the *Internationale Klinische Rundschau* several cases in which this remedy proved more efficacious than any other. In one case, the patient, who had previously been treated with iodoform, would have been discharged from his employment on account of the smell of the drug; aristol was then employed with the most satisfactory results, the fetor vanishing, the ulcerations healing, and the scabby crusts ceasing to form. Dr. Löwenstein makes use of insufflations, which answer very well, as aristol is a fine powder. He also paints ulcerated spots with a mixture of 1 part of aristol in 10 parts of flexile collodion. It is necessary to keep aristol in a dark-glass bottle, as it is easily acted on by light. It may be remarked that it has a very slight but not unpleasant odor, and that it is remarkably cheap.—*The Lancet*.

GLYCERINE CLYSTERS IN INFANTILE DIARRHŒA.

Two-drachm glycerine clysters have been found of great value in infantile diarrhœa. They act promptly, and do not cause discomfort.

TREATMENT OF CARBUNCLE.

Dr. J. L. Napier, of Blenheim, S. C., uses pure carbolic acid locally in the treatment of carbuncles. He paints the whole carbuncular mass with pure carbolic acid three times a day, until the mass begins to lessen and the slough is detached. If the carbuncle is seen before suppuration has begun, in three or four days it will abort. If suppuration has started, in seven to ten days the whole carbuncular mass can be removed with the forceps, leaving a healthy, granulating ulcer. The treatment, as above described, reduces the time of treatment from weeks to days; and besides that, the acid being a local anæsthetic, adds very much to the comfort of the patient by relieving the pain,—so much so that, after the first application, very little anodyne is needed.—*North Carolina Medical Journal*.

SOCIETY PROCEEDINGS.

Southern Surgical and Gynecological Association.

Third Annual Meeting, held in Atlanta, Ga., November 11, 12 and 13, 1890.

FIRST DAY—MORNING SESSION.

The Association convened in Concordia Hall, and was called to order by the President, Dr. George J. Engelmann, of St. Louis, Mo., at 9:30 A.M.

MAYOR GLENN delivered an *Address of Welcome*, the response to which was made by Dr. R. B. Maury, of Memphis, Tenn.

DR. R. B. MAURY, of Memphis, then contributed a paper entitled:

HOW SHALL WE TREAT OUR CASES OF PELVIC INFLAMMATION?

The paper gave a comprehensive *résumé* of the pathology of chronic pelvic inflammation as it has been clearly demonstrated by Bernutz, by Polk, Coe and others, and by the results of abdominal section. This pathology is that of pelvic peritonitis dependent upon tubal disease—not cellulitis. The author declared the term chronic cellulitis a misnomer—a pathological condition which existed only in the imagination of the physician, a term which had been productive of pernicious results in practice and which should no longer be used in connection with non-obstetric pelvic inflammation.

When the pathology rests upon such abundant and positive evidence, the question might be asked, Why reopen a discussion upon it now? Because it is evident from our society proceedings and hospital reports, that great confusion exists in the medical mind to-day in regard to it. Dr. Byrnes' case, discussed in the New York Obstetrical Society during the present year, was taken as an illustration. In speaking of such cases the great tendency to relapses in chronic pelvic inflammation was illustrated by two cases in which pus tubes were found five and seven years after attacks of peritonitis, and when it was supposed the patients were entirely restored to health. Upon the subject of treatment, the writer admitted that by non-surgical therapeutic measures large intra-peritoneal exudations are often absorbed, and even some tubal and ovarian inflammations entirely disappear and recovery seems complete. But this is the exception and by no means the rule. For the radical cure of chronic pelvic inflammation non-surgical treatment fails in a majority of the cases. A great many women suffering to a moderate degree, continue to do so in spite of the best directed non-surgical measures, and perhaps wisely elect not to undergo operation.

As a rule, the only radical and permanent relief

is afforded by removal of the diseased appendages. The treatment of pus collections of course requires abdominal section.

DR. JOSEPH PRICE, of Philadelphia, followed with a paper on

THE MOTIVE AND METHOD OF PELVIC SURGERY, in which he said pelvic surgery must be considered apart from abdominal surgery. It is distinct from it, both in the nature of the lesions dealt with, in the difficulties it presents, and in the complications and embarrassments to routine technique.

Nowhere as much as in pelvic surgery does the distinction between the general surgeon and the specialist in pelvic disease stand out so clearly. Pelvic adhesions in appendicitis, for instance, Mr. Treves would deal with by the knife. If this is feasible, why not put the knife to ovarian and tubal abscesses, to all intestinal fixation by inflammatory processes and the like? The very suggestion of such method to the mind of the specialist accustomed to deal with all the complexities of pelvic surgery is fraught with evil, and this mere suggestion only makes it clear that general surgeons, in so far as they are entirely wedded to the knife in removing disease, fall short of the demonstrated harmfulness of its application in pelvic work.

Relative to electricity, Dr. Price said that electricians yet talked learnedly of the undetermined place of electricity in the treatment of ovarian cysts, but tar water and tractors have gone to their long rest. The time must yet come when the claims made for electricity as an universal panacea must be exploded, and its real, limited, and narrow horizon of usefulness be well defined. The pernicious effects of so-called cures of reported complicated cases, adhesions, inflammations and the like, by men without training, who look only at the ampèremeter while they adjust a clay pad or introduce a galvanic sound, is not to be overestimated. He had repeatedly shown, by exhibited specimens, the fallacy of the claim of exact diagnosis made by these men, and the arguments are irrefutable. He believed that the only position assumed by the electricians that has the slightest foundation in fact, is that electricity will sometimes control hæmorrhage and relieve pain. That it cures either is not proven.

In dealing with adhesions, the first point to be sought after is to find a crease or crevice, into which some progress can be made. In separating intestinal adhesions, they should be broken as far from the bowel as possible. The farther away the less liable they will be to bleed, and the absence of hæmorrhage is a great comfort in these cases. The strings of adhesions may be dealt with according to their size, it sometimes being best to remove them, at others there is no necessity for this. In doubtful cases their removal is

the better surgery. All bowel adhesions should be carefully examined after their separation. By so doing, fæcal fistulæ will often be avoided by the careful placing of an intestinal suture. It hence is apparent that no pelvic surgery should be attempted until the operator is competent to deal with intestinal wounds even to resection and anastomosis. Once the adherent mass is removed the ligature should be applied close up to the cornu uteri. The ligature should not be so heavy as to resist knotting nor so light as to break easily. The ordinary surgical knot is the safest of all knots with which to tie the pedicle. It constricts more evenly and certainly, and will slip less readily. The leaving of sufficient button is of the greatest importance to prevent slipping of the ligature.

In the treatment of extra-uterine pregnancy his urgent advice is, to operate without delay when the symptoms point to the disease, with the assurance that delay will only complicate matters and sacrifice the life of the mother.

The field of pelvic surgery, said Dr. Price, is not one of experiment or palliation; that it strives in all cases to remove the offending body in order to conserve the rest of the economy; that its tenets are founded on philosophy and fact, not fiction; and that its worth lies in its proven results. The surgery that plucks out the eye or casts aside the limb, to save the eye or the limb or the life, is greater, better and wiser, than a sentiment that preserves a shell to inclose a ruin.

FIRST DAY—AFTERNOON SESSION.

DR. W. H. H. COBB, of Goldsboro, N. C., read a paper on

SUPRA-PUBIC CYSTOTOMY IN A CASE OF ENLARGED PROSTATE.

The patient, a farmer, married, aged 49 years, rheumatic diathesis, dated his troubles back to 1881; while attending to the duties of Register of Deeds, he carelessly allowed over-distension of his bladder, and had suffered more or less since that time. In 1882 he had an attack of nephritic colic and passed a small calculus, similar in size and shape to a grain of wheat. On three different occasions he passed dark, gritty deposits. In 1883 he suffered much inconvenience and some pains in urinating. In 1887 he passed a dark, gristly, bloody substance about the size of a corn pea, accompanied by much pain and bloody urine. For the past three years he has suffered much with cystitis in a very aggravated form, with great pain and difficulty in defecation, urine containing much blood, pus and mucus. The patient's efforts to relieve his bladder and bowels were tormenting, and night after night was spent walking over his premises with groanings so severe as to disturb his neighbors. The patient consulted Dr. Cobb June 15th last, and from the

history of the case he suspected vesical calculus, but failed on examination with sound to detect any stone. A digital examination, however, per rectum, disclosed the right lobe of prostate greatly enlarged, rough, indurated, exceedingly tender and sensitive. After consultation by letter with Hunter McGuire, he decided upon supra-pubic cystotomy as the only hope of permanent relief, which was done after the method of Dr. McGuire on June 23. At the expiration of two months (August 23) he found the prostate perfectly normal with no symptoms of cystitis and withdrew the plug, allowing the fistula to unite, which it did in about ten days. His patient performs the act of urination and defecation without the slightest trouble, and expressed himself as entirely relieved, and is at present following his usual vocation.

INFLAMMATION IN AND ABOUT THE HEAD OF THE COLON.

DR. MCMURTRY, of Louisville, read a paper on this subject. He said the teachings to be found in systematic treatises on surgery and practical medicine, upon inflammation and its results in and about the *caput coli*, are not only worthless, but positively misleading. This is true not only as to pathology and treatment, but even as to the anatomy and relations of the cæcum and its appendix.

It is well known that inflammatory changes in the vermiform appendix are in almost every case the origin and seat of the inflammatory diseases about the *caput coli*. Inflammation of the cæcum is very rare, yet the testimony of surgeons and pathologists is abundant that in a certain proportion of cases cæcitis, with perforation, occurs without involvement of the appendix. Regnier, in 1886, operated in a case presenting symptoms of intestinal obstruction with peritonitis, doing an abdominal section. At the autopsy cæcitis with perforation was discovered. In 1888, the speaker operated in a case of perforative cæcitis and sutured two perforations in the cæcum. His patient recovered and was present in the Surgical Section of the American Medical Association in May of that year.

Fæcal impaction has been mentioned by surgical writers as a cause of inflammation about the head of the colon. Pain over the cæcum, with a fæcal mass perceptible on pressure often occurs, but rarely, if ever, associated with peritonitis. A few weeks since Dr. McMurtry saw a case in conjunction with Dr. H. H. Grant, of Louisville, in which a localized peritonitis existed in the right iliac fossa, with a well defined firm tumor. Abdominal section was done, and instead of appendicitis, they found the disease to be cancer of the *caput coli*. Irrigation and drainage rescued the patient from the immediate danger begotten by active peritonitis. The patient was a woman

of middle age, and the engrafted peritonitis presented the symptoms of an acute condition. Malignant disease of the cæcum has not, so far as the writer is aware, been mentioned by writers upon this subject as a probable condition in the diagnosis of deep-seated inflammations of the right iliac fossa.

The decision to operate should be determined more by the grade of the inflammation than by the time it has existed. When a diagnosis has been made, and three days have elapsed without subsidence of pulse and temperature, operation should be done.

Dr. McMurtry submitted the following conclusions:

1. Inflammation about the *caput coli* is, as a rule, inflammation of the appendix.
2. A certain proportion of cases will recover spontaneously by resolution. With these recurrence of the disease is common.
3. In the larger proportion the disease will endanger life, and may at any moment assume a condition practically hopeless.
4. Early operative interference involves less danger than delay, and should be resorted to in all cases in which a high grade of inflammation is persistent.
5. The essentials of the operative technique are brief anæsthesia, quick and thorough work, removal of the appendix, irrigation and drainage. The lateral incision is preferable to the median.

FIRST DAY—EVENING SESSION.

PRESIDENT ENGELMANN delivered an address entitled

THE CAUSES OF ILL HEALTH IN AMERICAN GIRLS, AND THE IMPORTANCE OF FEMALE HYGIENE.

He showed that the health of the American girl is threatened and impaired by causes more or less avoidable, as they are due to the methods of life, our methods of training and education; that the physique of this girl, most favorably situated amid auspicious possibilities, is imperfect; her brain over-worked, her nerve power exhausted, her function impaired, and reproduction endangered, all by reason of the susceptibility of her peculiar organization, and the increased impressionability of the sensitive system during the years of development, in which it is subjected to the most severe strain.

The remedy is attention to woman's peculiar organization and the cyclical waves of her dominant function; or, in other words, harmonious development and occupation of nerve and muscle; diminished brain work and nerve stimulation with increased and coördinate physical exercise; increased protection and diminished compression of dress; self-knowledge and individual care during periods of heightened susceptibility. Changes are necessary in custom and fashion, in

methods of labor and education. A harmonious co-education of mind and body should be approximated with coincident maintenance of proper hygienic condition.

Dr. Engelmann closed with a plea for the self-care of the American girl and her proper physiological instruction by the mother, which, alone will mitigate or remove the initial cause of many of her ailments. Upon the mother he would impress that the perfect development of the female function, and the maintenance of this function, once developed, in a healthy condition, is essential to the perfect health of the girl and the perfect health of the woman; that self-care, a well-regulated female hygiene, is the foundation of her well being.

SECOND DAY—MORNING SESSION.

DR. C. A. L. REED, of Cincinnati, Ohio, read a paper entitled

INDICATIONS FOR OPERATION IN ECTOPIC GESTATION.

The paper starts out with the assumption that the only proper treatment of ectopic gestation is by laparotomy, or, more properly, coeliotomy. While the profession has become practically unanimous that this is the proper line of treatment, the indications for operation have been less definitely decided upon. This conviction is forced upon the observer, not only by a study of the literature of the subject, but by encountering cases which have been advised against operation by their attending physician, until hæmorrhage within the pelvis has threatened a fatality which is but too frequently realized. The most legitimate excuse for this dilatory practice, is to be found in the confusion which has arisen with regard to the supposed uniform causal relationship of ruptured ectopic gestation to pelvic hæmatocele, and the division of the latter into "primary" and "secondary" rupture. These terms are unfortunate, and, as used in this connection, may be entirely arbitrary. Primary rupture is made to mean rupture beneath the peritoneum, instead of *first* rupture as the etymology of the word would imply, while *secondary* rupture is made to mean rupture within the peritoneum, instead of "second" rupture. Whereas, an intra-peritoneal rupture may be, and frequently is a primary rupture, when spoken of with reference to the sequence of events in ectopic gestation. There would be no serious confusion even here if we were not also taught to leave extra-peritoneal hæmatocèles alone to be taken care of by absorption, and if we did not add that as these hæmatocèles are generally caused by ruptured ectopic gestation sacs, we are to relegate these cases also to the expectant plan of treatment. This conclusion is without warrant, and is responsible for hundreds of deaths annually from this one cause.

The treatment of ectopic gestation premises the diagnosis of this condition. This is obviously difficult, and in the majority of instances cannot be arrived at at all, or, if at all, only presumptively; but in all these cases conditions can be found in the pelvis, which if not conclusively of extra-uterine pregnancy, yet constitute conclusive indications for exploratory operation. The presumption of ectopic pregnancy can be arrived at before rupture, chiefly by a history of previous sterility, by a previous amenorrhœa, followed after a few weeks by irregular hæmorrhage, by increased tumefaction to either side or back of the uterus, and by the existence of false decidua within the uterus. The latter fact may be safely determined by the judicious use of the Emmet curette forceps. The diagnosis after rupture is essentially the diagnosis of internal hæmorrhage. Time wasted either to determine the cause of that hæmorrhage, or to find out if it be primary or secondary, is criminal. The thing to do is to cut down and operate. The position has been taken that time should be taken for the patient to rally from the shock. One of Dr. Reed's own cases died simply because he waited twelve hours for reaction—a lesson which taught him the fallacy of the old teaching, and which has since saved lives at his hands. The best way to overcome shock from internal hæmorrhage is to stimulate the patient by giving ether, stop the drain by ligating the bleeding vessels, and rouse the nervous system by washing out the belly with hot water.

Dr. Reed's conclusions are:

1. The only proper treatment of ectopic gestation is that by abdominal section.
2. The operation should be done in cases before rupture so soon as the condition can be presumptively diagnosed.
3. The operation should be done in cases after rupture so soon as the evidences of internal hæmorrhage become apparent.
4. In cases in which the viability has already been reached without rupture, pregnancy should be allowed to advance to term before operation, but only under the closest possible vigilance.
5. In all cases the appendages from both sides should be removed providing the condition of the patient will justify the extension of the operation.

DR. BEDFORD BROWN, of Alexandria, Virginia, followed with a paper entitled

THE LOCAL AND GENERAL TREATMENT OF GANGRENOUS WOUNDS AND DISEASES.

Many years ago, previous to the late war, Dr. Brown determined to institute a series of experiments to ascertain the capability of local and general treatment of all gangrenous wounds and diseases that came under his care, either for their prevention or arrest. The object was to find local agents possessing active properties as stimu-

lants of vital action in the affected parts, also as means of disinfecting and deodorizing gangrenous sloughs, hastening their final separation and for the establishment of a healthy basis for granulation. In cases coming under his care he found that the deodorizer failed to accomplish these objects. He then employed a solution (almost saturated) of sulphate of zinc and dilute sulphuric acid as a local application, which seemed to meet all the requirements. The first case in which it was applied was according to the following formula:

R. Zinci sulphatis, ʒj.
Aque, Oj.
Acidi sulph. dil. ʒss. ℥.

After the free application of hot water at 110° the solution was applied every three hours on bats of raw cotton. In the course of two days the sloughs separated rapidly, leaving a perfectly clean, healthy basis for granulation. This solution evidently possesses active antiseptic properties. It is an admirable deodorizer; it is clean and cleanses the parts effectually.

In cases of great loss of sensation in the parts, weak circulation, reduction of vital action, and depressed vitality, he knows of no agents better calculated to arouse nervous action and stagnant circulation, for as soon as the living basement is exposed it gives rise to intolerable pain. He has used this solution in all forms of gangrenous wounds and diseases, some limited, others extensive, and associated with septicæmia, with benefit.

Dr. Brown cited the history of several cases of different varieties of gangrenous wounds and diseases treated by various methods.

DR. HENRY F. CAMPBELL, of Augusta, Georgia, made some impromptu remarks on *Vesico-Vaginal Fistula*.

DR. W. L. ROBINSON, of Danville, Va., read a paper on

THE TREATMENT OF GENERAL SEPTIC PERITONITIS,

in which he called attention to those cases which tended, by absence of pain and a seemingly improved condition after chill and fever, to mislead as to the necessity of operating, and instanced two cases of recent date seen in consultation in which septic peritonitis and secondary abscess existed in spite of the seemingly favorable condition of the patient. He says that often there is an utter disproportion between the pathological condition and the amount of pain and tenderness,—a condition so often seen in puerperal peritonitis.

He states that traumatic abdominal injuries, appendicitis and pelvic inflammations, are the chief causes of septic peritonitis, while of course any internal or external influence which produces suppuration may be the indirect cause.

He agrees with Dr. G. Frank Lydston, of Chicago, that in children, falls, blows, etc., are the causes generally of peritonitis, and that because

of the age of children in directing attention to the seat of injury we often diagnose the disease too late. Dr. Robinson takes the stand that gonorrhoea is a frequent cause of septic peritonitis and the reason why it did not always produce it was, that it did not invariably invade the uterus, and even when it entered the tubes, the adhesions to the ovary rendered it self-limiting. He holds that section, irrigation and drainage is the treatment, and that where adhesions are extensive that salines should follow the operation in order that the peristaltic action of the bowel would prevent re-formation. Cases occur which, when seen by the surgeon, are too prostrated to undergo a complete operation, and the proper plan is to rapidly do what one can by section, irrigation and drainage. Dr. Robinson instanced a case of recent date in which the patient was saved when seen only *in extremis*. He urges the surgeon to go prepared to resect, anastomose, etc., as complications may indicate. Where conditions are diagnosed which will most likely terminate in septic peritonitis, such as recurring appendicitis, that preventive measures should be undertaken; and where great tympanites exists he would adopt Dr. Davis' mode of opening the bowel and flushing it out with hot water.

DR. JOHN D. S. DAVIS, of Birmingham, Ala., contributed a paper entitled *The Clinical History of the Episcystic Surgical Fistula, with Cases.*
(To be concluded.)

DOMESTIC CORRESPONDENCE.

LETTER FROM NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Official Report on the Execution of Kemmler—New York County Medical Association—Academy of Medicine—Sig. Giovanni Succi—Miscellaneous Notes.

Dr. Carlos F. MacDonald, Chairman of the State Commission in Lunacy, who was at the head of the corps of medical witnesses present at the execution of Kemmler by electricity in August last, has only recently made his official report of that event to the Governor. Some of the newspapers, by the way, have objected to the publication of this report, on the ground that it is itself a violation of the new law, which expressly forbids that any accounts of executions conducted under its provisions shall be published. After giving the particulars of the execution and describing the post-mortem examination of Kemmler's body, Dr. MacDonald, in his report, goes on to say:

"Notwithstanding the wide publication of the execution of Kemmler, and the efforts which have been made to proclaim it a failure, and to invest

it with an air of repulsion, brutality and horror, it is confidently believed that, when all the facts in the case are rightly understood, the first execution by electricity will be regarded as a successful experiment, and that in time due credit will be accorded to those whose duty required them to act as principals in carrying out the law, the establishment of which is destined, in the not distant future, to be regarded as a step in the direction of a higher civilization. As might have been expected at the first execution by this method, there were certain defects of a minor character in the arrangement and operation of the apparatus which those in charge of the next execution, guided by present experience, will be able to avoid or overcome. But, in spite of these defects, the important fact remains that unconsciousness was instantly effected, and death was painless. When this is understood, together with the additional fact that less than four minutes elapsed from the time the first contact of the current was made to the time the last one was discontinued, and Kemmler was absolutely dead, it will be conceded by all fair-minded persons that the object to be attained, as far as relates to the individual, in the execution of a criminal, namely: sudden and painless death, was fully realized in Kemmler's case. And had the first contact of the current been maintained for full twenty seconds, as first suggested, in all probability there would have been no reflex movement after it was broken, and no unfavorable criticism of the result could then have truthfully been made. The reflex movements referred to were similar to those which have occasionally been observed, for a short time, in animals experimentally killed by electricity, after the current was too quickly interrupted; the animal, however, not recovering consciousness or life. Hence they may properly be regarded as involuntary muscular movements of a reflex character, following the interruption of the current, and in no sense a resumption of normal respiration, however much they may appear to be so to a superficial observer, or to one not familiar with the phenomena in animals above referred to."

At the end of his report Dr. MacDonald makes several suggestions for amendments to the present law, which will secure a more satisfactory regulation of execution by electricity in the future, and among these are the following: That there shall be only one place in the State for executions by electricity, instead of three, as at present; that a separate building shall be constructed for such executions, with suitable cells for the accommodation of criminals awaiting the death penalty; that the dynamo shall be in immediate communication with the execution room, and not a thousand feet distant, as was the case at Auburn; and that the dynamo employed for executions shall be capable of generating an electrical force of 3,000 volts.

At the November meeting of the Society of Medical Jurisprudence and State Medicine, the paper of the evening was a report on the execution of Kemmler by Dr. E. C. Spitzka, who was also one of the witnesses of the execution. He described the scene in detail, and stated that while he was not an advocate of execution by electricity, the guillotine being his preference as a means of inflicting capital punishment, he regarded the evils of that method as much less than the evils of hanging. In Kemmler's case, he said, the Warden was greatly aided by the coolness and pluck of the prisoner in all of the many steps preliminary to the turning on of the electric current. He thought, however, that many of the preliminary steps taken in this instance were unnecessary and should be omitted in future executions.

Among the criticisms that he made of the Auburn execution was that the voltmeter did not work at the time of the execution; so that there was no way by which the medical witnesses present were able to tell the voltage of the current. He believed, in fact, that the voltmeter was not expected to work; and, as far as he could make out, the strength of the current used on Kemmler was probably about 700 volts. In his opinion, the man was dead within an infinitesimal part of a second after the current was turned on. It was true that convulsive movements followed the introduction of the current into his body, but he had pronounced him dead after the current had been turned on for about seventeen seconds, and he felt perfectly confident that he was correct in doing so. Dr. Spitzka said he was now satisfied that he had made a mistake in ordering the current turned on a second time; but the muscular convulsions and emissions of air by the body threw the spectators into a state bordering on a panic, so that demoralization nearly prevailed in the room.

A phenomenon which is usually regarded as a sign of life Dr. Spitzka observed in Kemmler's body not only shortly after the withdrawal of the current but also several hours afterward, when the autopsy had been made and the brain, heart and other organs had been entirely removed, viz.: the marking of the flesh by pressure with the finger and the subsequent obliteration of the marks thus produced.

Like Dr. MacDonald, Dr. Spitzka favored the amendment of the electrical execution act so that it will provide for the establishment of but a single plant in the State; where all executions shall be carried out under the direction of a competent electrician appointed for the purpose. He agreed with him also that the engine and dynamos used should be especially constructed for the execution of criminals, and that the dynamos should be capable of generating a current of a strength of at least 3,000 volts. He thought that the contact of the current should be made preferably at the back of the neck, and that a collar could be so construct-

ed as to hold the most violent individual steady. The method used in Kemmler's case, he said, was unnecessarily trying to the nerves of the prisoner, and it involved the cutting away of portions of the latter's clothing in order to get at the base of the spine. Should it ever happen that the person to be executed was a woman, this procedure would be attended with much difficulty and embarrassment.

In conclusion he remarked: "The execution of Kemmler was a more decent and dignified execution of the law than any other I have ever seen. That the admission to the chamber of death of persons who had never before seen an execution, and knew nothing whatever of the effect of electricity on the human body, led to many extravagant and erroneous statements, I really believe. There was no warrant in law for the presence of such persons."

Among those who were present at the meeting and discussed Dr. Spitzka's paper was Dr. MacDonald, who stated that the physicians who were summoned to the execution as witnesses were not consulted about any of the arrangements, and they were not permitted to see the source of the current. During the interval between the first and second applications of the current to Kemmler he happened to go into the dynamo room, and was promptly ejected. He agreed with Dr. Spitzka that if the first application had been continued a few seconds longer, no such convulsive movements as were observed would have occurred.

The testimony of two expert witnesses such as Drs. MacDonald and Spitzka, as to the painlessness and instantaneousness of Kemmler's death, is certainly of great importance, especially in view of the fact that in the case of two or three other criminals who are now waiting the death penalty, the most strenuous efforts are being made in the courts to have their sentences set aside on the ground of the cruelty of electrical execution as exemplified in the case of Kemmler.

The recent meeting of the New York State Medical Association, a synopsis of the proceedings of which, as well as the President's able address, have already been published in *THE JOURNAL* was held for the first time in the newly enlarged Mott Memorial building, where the library of the Association has now been established. The separate papers read were on a great variety of subjects, and as a rule valuable contributions; but the chief interest naturally centered in the formal discussions which have always proved so attractive a feature of these annual meetings. The President elect, the well-known surgeon Dr. Stephen Smith, is the third incumbent of the presidential chair to be chosen from this city, his New York predecessors having been the late Dr. Isaac E. Taylor and Dr. Wm. T. Lusk.

The New York County Medical Association still continues to increase in prosperity. Each

month large accessions are made to its membership and this now amounts to over 550. At the November meeting Dr. J. Lewis Smith read one of his carefully prepared and exhaustive papers, his subject being "Appendicitis, typhlitis, and peri-typhlitis in Children."

The Academy of Medicine is now established in its handsome and commodious building on West 43d street. At the first meeting in November the reports of the delegates to the International Medical Congress, in regard to various departments of medicine and surgery, were read; and at the second November meeting, when the new building was dedicated, the anniversary of the Academy was celebrated with appropriate addresses and much festivity.

Signor Giovanni Succi, the Italian who has distinguished himself by a number of extended fasts in Europe, and whose last achievement in that line has been a reputed fast of forty days recently in London, has entered upon the task of fasting for forty-five days in this city, under the surveillance of a committee of physicians assisted by a corps of medical students. He is 38 years of age, and at the commencement of the fast weighed 147 pounds. His chest, abdominal and limb measurements were also carefully taken at that time. During his fast he allows himself a certain amount of water and also takes as occasion requires a few drops of an anodyne elixir to allay gastric or abdominal pain. He sleeps whenever he feels inclined, and during the rest of the time converses, reads, smokes, plays the piano, and even indulges in such active exercise as fencing. On the second day of the fast he was very nervous and irritable, but in excellent general condition, with a temperature of 98.9, pulse 78 and respiration 23. Tongue clear and steady. During the day he drank fifteen ounces of water and smoked two cigars. His weight had diminished to 138 $\frac{3}{4}$ pounds.

On the fifth day his weight was 134 pounds, temperature, 68.4, pulse 60; respiration 20; and he drank 13 ounces of water. On the sixth day his weight was 134 pounds, and he drank 12 ounces of ordinary water and 6 ounces of an alkaline water. On the seventh day he was unusually irritable, but he said he was not hungry. On this day he drank 16 ounces of croton water, and 8 ounces of alkaline water. His weight was 131 pounds; temperature 98°; pulse 84, respiration 22. His tongue was clear, moist and steady, and his muscles still firm.

P. B. P.

MISCELLANY.

THE AMERICAN ACADEMY OF MEDICINE.—The Annual Meeting of the Academy will be held at the College of Physicians, Philadelphia, on Wednesday and Thurs-

day, December 3 and 4, 1890. Papers will be read by Dr. Traill Green, Easton, Pa., on "The Profession's call for a better Preliminary Education of its members;" Dr. Herman B. Allyn, Philadelphia, on "Paralysis following Measles;" Dr. Henry E. Dwight, Philadelphia, on "The Influence of the German Universities upon our Profession;" Dr. W. B. Dewees, Salina, Kansas, "Medical Education that Wins;" Dr. H. O. Marcy, Boston, Mass., "The Coroner System of the United States;" Dr. E. Jackson, Philadelphia, "What can be done to Save the Eyes during School Life?" Dr. Benjamin Lee, Philadelphia, "A Statistical Study of Influenza;" Dr. J. Cheston Morris, Philadelphia, "A Pathological Study of Influenza," also "Interference of Molecular Vibrations as Explanatory of the Phenomena of Zymotic Diseases and Diseases of Nutrition." Papers (titles not yet given) will also be read by Dr. J. E. Davis, of Wisconsin State University, and Dr. David S. Jordan, President Indiana State University, and others. A Report will also be presented by the Secretary, Dr. Richard J. Dunglison, on "Laws Regulating the Practice of Medicine."

Dr. Samuel J. Jones, of Chicago, is President of the Academy, and will deliver his Address at the afternoon session Wednesday, December 3.

The Annual Collation will take place on Tuesday evening.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from November 15, 1890, to November 21, 1890.

- First Lieut. Freeman V. Walker, Asst. Surgeon U. S. A. (Ft. D. A. Russell, Wyo.), is granted leave of absence for one month, to take effect on or about the 15th inst. Par. 3, S. O. 85, Dept. Platte, November 11, 1890.
- Capt. Chas. M. Gandy, Asst. Surgeon U. S. A. (Ft. Clark, Texas), is granted leave of absence for three months. By direction of the Secretary of War. Par. 10, S. O. 266, A. G. O., Hdqrs. of the Army, November 13, 1890.
- Capt. Henry Johnson, Medical Storekeeper, is granted leave of absence from January 1 to March 24, 1891, inclusive, with permission to go beyond sea. By direction of the Acting Secretary of War. Par. 18, S. O. 268, A. G. O., Washington, November 15, 1890.
- Capt. John L. Phillips, Asst. Surgeon, is relieved from further duty at Ft. Crawford, Col., to take effect on his relinquishing the unexpired portion of his present leave of absence, and will report in person to the commanding officer at Camp Guthrie, Oklahoma Ter., for duty at that station, reporting by letter to the commanding General, Dept. of the Missouri. By direction of the Acting Secretary of War. Par. 7, S. O. 269, A. G. O., Washington, November 17, 1890.
- Capt. Henry G. Burton, Asst. Surgeon, is granted leave of absence for six months on surgeon's certificate of disability, with permission to go beyond sea. By direction of the Acting Secretary of War. Par. 9, S. O. 269, A. G. O., Hdqrs. of the Army, November 17, 1890.
- Capt. Edward B. Moseley, Asst. Surgeon U. S. A., is granted leave of absence for one month. S. O. 100, Dept. Texas, November 17, 1890.

Official List of Changes in the Medical Corps of the U. S. Navy for the Week Ending November 22, 1890.

- Surgeon J. G. Ayers, ordered to the U. S. receiving ship "Wabash."
- Sheldon Guthrie Evans, commissioned an Asst. Surgeon in the U. S. Navy.
- Medical Director N. L. Bates, ordered as President of Naval Medical Examining Board at Mare Island, Cal.
- Surgeon A. M. Moore, ordered as member of Naval Medical Examining Board at Mare Island, Cal.

HAS PROGRESS BEEN MADE IN THE
MEDICINAL TREATMENT OF
TYPHOID FEVER?

*Read in the Section of Practice of Medicine, Materia Medica and
Physiology, at the Forty-first Annual Meeting of the American
Medical Association, at Nashville, Tenn., May, 1890.*

BY T. J. HAPPEL, A.M. M.D.,

OF TRENTON, TENN.

EX-PRESIDENT TENNESSEE MEDICAL SOCIETY.

Almost semi-annually the medical public is treated to announcements of new remedies that are either infallible cures for, or at least very largely diminish the death-rate in many diseases, most notably, continued fevers. At once the enthusiasts rush into the field of experience and soon medical journals teem with reports of successes, beyond expectation from every quarter. These reports grow less and less favorable. The roseate hue disappears, and soon opposite reports begin to fill the pages of the same journals and finally the pendulum swings to its furthest point and begins to return.

The result is a few advocates of the theory remain; but the large majority, disappointed, return to their old modes of treatment. The question naturally arises: *Cui bono?* Does good result from such experimental work? I answer promptly, "Yes." Again and again a new and plausible theory is advanced to take the same course just outlined, with the same result. Well, if there is good, in what does it consist? Finding that failure so often attends the use of new systems and modes of treating diseases, the physician begins to investigate his cases more closely, finds that frequently the proposed mode of treatment cures some cases, but they are not typical cases of the disease under consideration. In fact, a careful diagnosis would show that those cases cured were not cases of typhoid fever, but were cases of some of the types of so-called malarial fevers. I would suggest then at the very outset of what I may have to say, that everything depends as to cures and curative measures upon a careful diagnosis of all cases treated. Too often the physician falls into a routine diagnosis, as well as a routine way of making a diagnosis. One physi-

cian diagnoses all cases of fever as "typhoid fever" which do not respond to his usual remedies of quinine and calomel for remittent fever; another—one in my circle of friends, a gentleman of high professional standing, asserts that when he has given 20 grs. of quinine night and morning for several consecutive days and fails to arrest the fever he is sure that he has to deal with a case of typhoid fever.

In my limited experience, I have seen a number of such cases under such circumstances,—cases which refused to respond to either ordinary or heroic doses of quinine—yet the progress of those cases through a siege of from three to eight weeks, proved conclusively that they were not cases of typhoid fever. There was but one point of resemblance to typhoid fever throughout their whole course, and that was their duration. Rarely are post-mortem examinations to be had in such cases, but in the few made, none of the typical lesions of typhoid fever have ever been found, showing that they were not cases of typhoid fever.

Before, then, entering upon a discussion of the treatment of these fevers, and especially of typhoid fever, a careful and painstaking examination and investigation of their clinical history must be made with a view to diagnosis between typhoid and continued remittent fevers. When we are certain as to the nature of the disease with which we have to contend, then and then only are we ready to discuss the treatment. In the continued remittent fevers, many cases of which have been met with in the last few years in West Tennessee, where the whole history of the attack can be gotten from a careful observer, no difficulty in diagnosis can be experienced, but otherwise, it is very difficult.

In an article on "Typho-Malarial Fever, so-called," read by me before the State Medical Society of Tennessee in 1886, (See Transactions of that year, pages 85 and 86) I reported the only two cases of this form of continued fever which I had seen or treated up to that time: since then I have met with a number of such cases, the duration of which, and their resistance to the action of quinine in large and small doses would have led one to infer that they were cases of typhoid fever, but when the clinical history of the cases were taken, there was no longer any ground upon which to

found a belief that they were typhoid. The diagnostic features of that disease were wanting. In the majority of the cases, there was no tympanitic distention, except from occasional errors of diet, no gurgling, no rose colored spots, no hæmorrhages from the bowels, no epistaxis, no low muttering delirium, such as is so often met with in typhoid fever; and above all, the temperature chart in all cases showed too great a morning and evening variation.

Another marked peculiarity of the cases was the tendency towards prolonged cold stages in the third, fourth, and fifth week of the disease, with no proportionate febrile reaction—the stages—the paroxysms, being usually an indication of a change in the character of the fever from a remittent, to an intermittent type and the beginning of a rapid improvement. There was shown a disposition to relapse in some of the cases. The prognosis was favorable. I met with but one fatal case in my own practice, and death in that case resulted from congestion of the lungs due to imprudent exposure in an algid condition.

As stated previously, a careful review of the whole clinical history of those cases satisfied an impartial observer that they were not cases of typhoid fever, and I can find no better name for them than that of continued remittent fever.

In a paper read before the West Tennessee Medical Society by one of its members, he reported a large number of cases of typhoid fever treated by him in and around Martin, Tenn., and cured by administering to them early in the disease calomel in full doses, followed by quinine in 30 gr. doses night and morning for several days. Not a case terminated fatally, but the fever rapidly yielded—was aborted—cured by the calomel and quinine treatment.

A physician living in a neighboring town in discussing the paper stated that his practice overlapped that of Dr. —, and that *he* had seen scarcely a case of genuine typhoid fever that season, but had met with a number of cases of remittent fever that had resisted ordinary methods and had been protracted to three or four weeks or more, and that these cases were among the very ones denominated "typhoid" by the author of the paper. The surroundings of the town were such as to give rise to cases of continued remittent fever, the adjacent country and the town itself being almost one large saw mill. Sawdust lay around decomposing in every direction, whilst, it being a new place, there was little or no animal matter to pollute the water supply or poison the air.

Now with the statements made, and proof adduced, I think we are ready to briefly review some of the different methods of treating typhoid fever and compare the results obtained thereby, carefully excluding cases of continued remittent fever.

In the early days of West Tennessee there were

no cases of typhoid fever. In the memory of some of the older practitioners, the impression made upon them, by the first cases of that type of fever with which they came in contact, are very vivid. It was a disease of which they had read, but with which they had no experience and the treatment of those cases by calomel and jalap followed by active purgatives, bleeding, and quinine, generally produced fatal results. That was the course then pursued with the malarial fevers which they treated. The failure of remedies that they considered infallible, led them to investigate more closely their cases, and they soon found that they had a distinct fever, to treat different in many respects from what they were pleased to call their bilious fevers.

The lancet, calomel, and quinine were soon recognized as failures, the mortality being high, nearly fifty per cent. of the cases so treated dying. The lancet was with reluctance discarded and still the cases died. Active purgatives were abandoned. Later on we were taught that mercury given in some form, and continued long enough to produce slight ptialism was highly recommended. In connection with this treatment we were taught that inasmuch as the disease was a self-limited one, and inclined to continue for a long time, the *general* abstraction of blood was to be avoided, but local bleedings were highly commended. Leeches and cups were to be used over painful tender spots. Attention was called to alimentation, and proper forms of food were discussed. Conjoined with this plan of treatment, turpentine was directed as an agent to stimulate the healing of the ulcerated glands and for the relief of gas, etc.

The mortality tables show an improvement—the percentage of death was still high and the specific was not yet found. Prof. Wood asserted in his work on "Practice," edition 1860, that all cases recovered where the remedy was begun with early and continued without cessation throughout the disease, but such was not the success of others—the mortality reaching from ten per cent. to thirty per cent.

It would be a work of supererogation to refer to all the different modes of treatment, heralded to the world as specifics for typhoid fever.

The acid treatment was recommended by high authorities as the most rational mode of procedure and statistics were adduced to prove that it was the best of all. But as in the case of other remedies, other users of it did not obtain the same happy results.

We were taught that the high temperature was an important factor in producing fatal results, and cold or tepid spongings; the packing process, veratrum veride, aconite, and other remedies were strongly advocated by some in high positions in the medical profession, but they too met the same fate as the others already named.

One set of statistics proved that the percentage of fatal cases was reduced, whilst another, satisfactorily established the other side of the case.

Salicylate of soda was to work miracles in curing cases of typhoid fever, by virtue of the many properties that it possessed, not existing in any other one remedy. But alas, many of us found to our sorrow that cases where it was persistently used terminated more frequently in hæmorrhage from the bowels, than where any other remedies had been tried. So that, in the opinion of the writer, the remedy proved to be a step backward.

Again, the fatal results in typhoid fever were claimed by some authorities to be due to the accumulation of effete, septic material thrown off into the alimentary canal by the ulcerating patches and glands, and that the remedy for this condition was to keep the bowels moving loosely several times a day. Hence small doses of magnesia sulphate or of soda bitartrate were recommended; or, if there were reasons for avoiding a purgative, the daily use of the syringe. But the death-rate did not, to put it mildly, decrease.

Another process more recently pressed as an agent capable of reducing the death-rate to 3 per cent. or even less, is that of cold bathing as recommended by Brandt. This cold bathing of Brandt must not be confounded with sponging, cold-packing, or other forms of cold bathing. To accomplish the results claimed for it, all the minutæ of the plan must be attended to, the tub must be brought to the bedside and filled two-thirds full of water. The bathing must be begun early, *even before a diagnosis can possibly be made*. I would suggest just at this point that the longer before a diagnosis can be made, the bathing is begun, the greater the per cent., *me judice* of cures, because the greater the number of febriculæ and simple continued fever cases you are apt to have to treat.

At a recent meeting in New York City of the Section on Practice of the Academy of Medicine, Dr. Simon Baruch read a review of the many discussions of the treatment of typhoid fever, and closed with an earnest appeal for the adoption of the cold-water treatment as recommended by Brandt. According to Dr. Baruch the cold bath works wonders. It reduces temperature, strengthens the action of the heart, deepens respiration, increases the action of the kidneys and skin, and improves digestion, and creates a desire for solid food. All of which brightens and strengthens the patient and *post hoc, ergo propter hoc*, must prevent the accumulation of effete material in the system.

Dr. Baruch gave an elaborate description of what constituted a cold bath *a la* Brandt, as contra-distinguished from the wet pack, cold sponging, cold effusions, and the various methods in vogue of applying either tepid or cold water to fever patients. For a description of this method, reference is made to the *Medical and Surgical Re-*

porter of March 29, 1890, page 380. The mode of using is a complicated one requiring the aid of at least four helpers, two for day and two for night service. The plan could be carried out only in a well regulated and thoroughly equipped city hospital, and hence would avail but little to the general practitioner in private practice outside of a city. But while the rationale sounds well, and the best results have been reported by Brandt, Vogt, and Bouveret, a mortality of less than 3 per cent. being reported, we are forced to admit with all the evidence before us, that the case is not proven.

There is not a practitioner here present, who, if he will make it a rule to treat *every* case of fever with systematic bathing conjoined with quinine, could not make equally as favorable an exhibit. Stress is laid upon the commencement of the bathing process before a diagnosis can be made. This is an important point. If we wait until we are fully satisfied that we have a case of typhoid fever to treat, we will find that Brandt's method will offer no advantages over former methods of treatment when the great inconvenience attending the use of it is considered. Its advocates must at least admit that it is, as yet, *sub judice*.

The only way in which reliable statistics can be obtained in regard to curative measures in the treatment of typhoid fever is to exclude all cases classed as doubtful from our calculations.

As intimated in the early part of this paper, it is strange how two practitioners of medicine having fever cases in the same neighborhood will meet with such different types of disease. One will denominate all of his cases typhoid because they refuse to yield promptly to ordinary treatment, and the other reports his as obstinate cases of remittent fever. One or the other is mistaken, and where the surroundings all favor the development of the malarial fevers, I would be inclined to regard all of those cases as of the continued remittent type.

Instead of the practitioner establishing the fact that he has discovered a new method of curing typhoid fever by large doses of quinine and calomel he simply proves his inability to diagnose the disease he is treating. There is always an inducement to call a protracted case of fever "typhoid;" that explains why it does not recover promptly; but call it "continued remittent fever," and the family expects the disease cured at once, because "any physician ought to be able to cure bilious fever."

The Brandt bath is claimed to be "not a nervous sedative," but a "refreshing measure by which the depressing effect of the typhoid poison is counteracted." That the impact of the cold water on the surface causes deeper inspirations, inhaling in consequence more oxygen and giving off more carbonic oxide, sending a refreshing im-

pulse to the nerve centres supplying the heart and stomach—thus imparting tone to the one, and stimulating into activity the secretions of the other.

It seems to me that if this is the *rationale* of the tedious, tiresome, and frequent bathings of the Brandt system, we have other agents that can accomplish as much without any more danger, with far less inconvenience, and as much certainty.

I enter a protest that the mortality in typhoid fever cannot be reduced to from 1 to 3 per cent. by any such procedure, but that the errors in diagnosis account for the vast discrepancy.

I agree with Dr. Joseph Jones, of New Orleans, who in a paper read in April, 1889, before the State Medical Association of Louisiana, took the position that, "allowing due weight to the effects upon the rate of mortality in different modes of treatment, of the variations of climate, condition and degree of severity, it must be admitted that the rate of mortality in the great class of febrile diseases has steadily diminished during the past thirty years."

"With reference to typhoid fever, which may be selected as a type of these acute febrile diseases, which are self-limiting and show a tendency to spontaneous recovery, the search after remedies which may subdue or modify the febrile movements have met with at least partial success."

Instead of the tedious and oftentimes impossible bath of the Brandt system, we can reduce the temperature of our patients without any more danger than experience and further use will prove to be present when the system is more extensively used, by the judicious administration of antifebrin or phenacetin. I use the term "judicious" advisedly, because remedies that are so powerful for good, must be equally capacitated for evil, when used carelessly. Antifebrin given in such doses as the patient is found to bear, will accomplish in one hour what is effected by the Brandt system in three times that length of time. The pulse will be reduced in frequency and its tonicity improved; the temperature will rapidly approximate the normal point, and there will be produced the same good effect upon the appetite by it, that is found in cases of the bath. In proportion as the temperature is kept near the normal point will the heart be strengthened, and the stomach stimulated, and *vice versa*, with the high temperature. The control of the fever is a most important element in the treatment of typhoid fever, and in the class of remedies at the head of which stands antifebrin, we have agents superior to any heretofore in use with which to keep the heat within bounds. I do not deem it necessary to discuss the uses and action of antifebrin on the system. A most important feature in its action is in the decided increase of the general euphory of the patient. There is a greater desire for, and a greater power to assimilate food and drink. There is a decided

decrease in temperature, and a reduction in the frequency, with a corresponding increase in the strength of the pulse—just those points that are claimed for the Brandt bath, but in addition we have as another effect, an increase in the amount of urine voided.

To this extent, if no other, could we successfully assert that progress had been made in the treatment of typhoid fever; but we can go a step further, and I trust show that in the phenol remedies we can present agents which have more claims to merit in the treatment of typhoid fever, as well as the continued malarial fevers, than any other medicines hitherto used.

In the last three years every case of typhoid fever, and my continued remittent fever cases, have been early treated with carbolic acid, either alone or combined with iodine, and in that time I have not had a single death from typhoid fever where the stomach of the patient could tolerate the remedy. I have thought that where iodine and carbolic acid could be administered together, I obtained more satisfactory results. One case of typhoid fever terminated fatally, where neither of the remedies were borne for any length of time. During the first three weeks of the disease an occasional dose was tolerated of the mixture, and with the aid of not more than 5 grs. of antifebrin in twenty-four hours, the temperature never rose above 102.5°, but at the end of that period, the stomach no longer tolerated them, and the patient died in the sixth week of the disease.

I have seen in the last year three fatal cases of typhoid fever in consultation, treated with turpentine and the acids. Death in these cases was caused by hæmorrhage from the bowels.

If the experiments of Pasteur and others have proved that many, if not all diseases are due to the presence and active development of living germs in the system, then certainly specifics—curative agents for those diseases must be remedies to destroy those germs—bacilli.

Dr. W. F. Glenn, of Nashville, Tenn., in an able paper read before the Tennessee State Medical Society at its last meeting, April, 1890, upon the "Phenique Compounds in Germ Diseases," discussed the fermentation question, as applied to zymotic diseases, showing how, when the specific microbe is introduced into the blood, it begins to multiply, and in proportion to this multiplication of disease cells, how the temperature rises.

He agrees that the fermentation process in the wine vat is not exactly analogous to that which takes place in the human system because, in the first place, only inert matter is to be dealt with, whilst in the latter living cells possessing catalytic powers, and that these cells are able to resist to a great extent the fermentation process. That "the greater the resisting power of the living cells, the milder the disease, on account of a less degree of fermentation." Now then, if typhoid fever be a zy-

motie disease, it is plain that in order to arrest it, it is but necessary to stop the so-called fermentation, or development in the blood of these microbes.

Dr. Glenn asserts that the experiments of Dr. Calvert prove that "the salts of quinine in solution will destroy all vegetable fermentation; salts of mercury in solution, all animal fermentation; and a pure solution of carbolic (phenique) acid, both."

If, then, enough carbolic acid can, in safety, be introduced into the blood of our patient, to destroy these germs, we will cure the disease, and if only enough is introduced to modify the fermentation process—that is, to destroy a portion only of the germs, or to impart to the living human cells power to resist the action of these germs; then the temperature is proportionately reduced, and the patient put into a condition to resist with greater success the disease, which, being self-limited, will run its course without danger to life.

Dr. Glenn contends that with the pure carbolic acid preparations this can be done; that enough can be given to destroy the germs and thus cure the disease; that the poisonous effects of the carbolic acid result from, and are due to the presence of impurities in the acid.

He states that for the last ten years he has employed phenique acid in the treatment of typhoid and malarial fevers as well as the eruptive ones, and in typhoid fever he "never had a diarrhœa, a hæmorrhage, never a serious tympanitis, never a death."

He believes that with antifebrin to reduce the high temperatures, when needed, and with phenique acid as a curative agent, "we possess the treatment *par excellence* of all zymotic diseases."

Dr. Glenn's experience in the use of carbolic acid, agrees exactly with my own in the same direction, though, as I stated, I usually combined iodine with the acid. I have thus referred to most of the important "forms" or "phases" of treatment of typhoid fever, without any reference to the varied complications that must be met as they are presented; nor have I touched upon the questions of nutrition and hygienic surroundings, etc., all of which must be closely attended to, but I have directed attention solely to medicinal agents that were given with a view to curing the disease, by shortening its duration and hastening the repair of all the lesions developing in the course of the disease. Time would be lacking to discuss forms and modes of nutrition, quieting delirium, etc. Now as to the mortality under the different forms of treatment:

1. Under bleeding and free purgatives we have no reliable data; but reports place the death-rate at 50 per cent.

2. When bleeding was abandoned but purgatives still continued, the mortality was reported to be from 30 to 40 per cent.

3. Under the turpentine treatment conjoined with careful feeding, we find reports showing a death-rate varying from 10 to 30 per cent.

4. Under the acid treatment, taking the tables furnished by several eminent physicians, we find the deaths to be below 10 per cent.

Thus I might continue to note the rates of mortality shown under the different modes of treatment, but most of you have access to more sources of information on those points than I have, and can read for yourselves.

To sum it up, I will only add that, allowing due weight to the reports on the Brandt method of the treatment of typhoid fever, this shows a further improvement in the prognosis of the disease, but owing to the want of accuracy in the diagnosis of cases treated by that method, we can only say that the rate of mortality is lessened not through any specific effect of the treatment *per se*, but as a sequence of keeping the patient in such a condition as to enable him to resist the attacks of the typhoid germs.

But in the last mentioned plan of treatment, viz.: antifebrin or phenacetin to keep the temperature at or below 102°, and thus place your patient in the same condition that the Brandt system does; and the phenique preparations, either alone or combined with iodine or ammonia, to destroy the bacillus typhoides, we have a rational mode of procedure that offers to the medical profession some hope in the near future of being able to say that typhoid fever can be cured; not that it is a self-limited disease, and that this or that plan of treatment enables you to sustain your patient till the disease has run its course and pabulum is no longer furnished upon which the germs thrive; that this pabulum is destroyed and hence the bacillus dies, or that the bacillus is itself destroyed.

In concluding this article I desire to call your attention to two effects of the carbolic acid treatment, which Dr. Glenn notes, and which my experience also substantiates, namely: the tendency to constipation, and in a slight degree to render the blood less fluid. The judicious use of mild laxatives, or the syringe will be needed to relieve the first, and the second can be met by administering ammonia in combination with phenique acid, in the form of ammonia phenate.

The use of the phenique preparations will be found also to lessen the temperature, and hence there will be less demand for antipyretics. So long as the temperature does not go beyond 102° I do not use antifebrin, but depend upon sponging with cold or tepid water, whichever I find to be most pleasing to the patient.

In regard to the question of ventilation and disinfection of the sick apartment, and the disposal of all the discharges of the typhoid fever patients, I deem them as matters no longer *sub judice*; they have been settled.

THE TREATMENT OF FIBROID TUMORS OF THE UTERUS.

Read before the Medical and Surgical Faculty of Maryland, November 12, 1890.

BY GEORGE H. ROHÉ, M.D.,

PROFESSOR OF OBSTETRICS AND HYGIENE IN THE COLLEGE OF PHYSICIANS AND SURGEONS, BALTIMORE; GYNECOLOGIST TO ST. JOSEPH'S HOSPITAL.

The object of this paper is to advocate a rational discrimination in the treatment of fibroid tumors of the uterus.

Uterine fibroids differ greatly in size, situation, structure and character of the symptoms to which they give rise. The treatment demanded by these differences likewise varies.

In structure, fibroid tumors are homologous with the tissue of the organ in which they are found. They are composed of muscular and fibrous tissue in varying proportions usually encapsulated by a connective-tissue capsule, in which large vessels ramify. In some cases, the growth is made up principally of muscular tissue, in others almost exclusively of white fibrous tissue. In the majority of cases, however, the growths are composed of varying proportions of these two tissues, sometimes the muscular, at another the fibrous predominating.

Most fibroid tumors, especially if of moderate size, are firm and solid, but the larger growths frequently have cysts or cavities filled with a lymphoid fluid. These fibro-cystic tumors often cause no little difficulty in diagnosis, being sometimes mistaken for ovarian cysts, at others confounded with pregnancy. It must not be forgotten that pregnancy and fibroid tumors may co-exist, although happily this combination is not very frequent.

Fibroid growths may occupy any portion of the uterus. Their site of predilection appears to be the fundus and posterior wall of the corpus uteri. Schroeder found 92 per cent. in the body of the uterus and only 8 per cent. in the cervix.

With reference to their situation in the uterine walls, fibroids are usually classified into sub-mucous, subserous and interstitial.

The submucous project into the uterine cavity, the subserous toward the cavity of the abdomen, and the interstitial occupy a more or less intermediate position between the inner and outer walls of the uterus. As a matter of fact, most large fibroid tumors begin as interstitial or intramural growths, and become submucous or subserous in consequence of the contractions they excite in the muscular walls which forces them either inward or outward.

Fibroid tumors may undergo fatty degeneration and be absorbed, they may slough and be cast off through the genital canal, they may undergo calcareous change and become encysted, and be thus carried through life, or may slough out in

the form of concretions which have received the name of uterine stones. Finally they may undergo sarcomatous degeneration and become malignant. All of these terminations are, however, exceptional. Generally the tumor continues growing until or after, the menopause, and gives rise to symptoms more or less troublesome, and in many cases sufficiently serious to demand active measures of relief.

The most pronounced symptoms of fibroid tumors of the uterus are pain, hæmorrhage, and interference with the functions of other organs by pressure. They may also produce great discomfort by their weight. Occasionally the sub-mucous variety undergo sloughing, when they may cause the death of the patient by septicæmia.

The pain produced by uterine fibroids is sometimes so severe as to be alone a sufficient reason for medical or surgical interference. It usually manifests itself at the menstrual periods as dysmenorrhœa, but may be constantly present as severe backache, bearing down simulating labor pains, especially in the submucous variety, or neuralgia of the sciatic nerves. Sometimes there is persistent pain in the uterus itself, or more probably in its peritoneal covering which is subjected to irritation or inflammation.

Comparatively small fibroids situated low down in the uterine walls or in the cervix may cause severe irritation of the bladder by pressure. There is often vesical tenesmus with frequent micturition, causing the most intense suffering.

The pressure upon the rectum may also give rise to constipation and great pain on going to stool. Hæmorrhoids and œdema of the lower extremities are not infrequent complications due to interference with the venous circulation. During the menstrual periods these pressure symptoms are generally increased in severity. Intra-pelvic or intra-abdominal pressure may also cause ascites, and in some cases localized peritonitic processes.

Hæmorrhage is in most cases the symptom that urgently demands remedy. It is most frequent and gravest in the sub-mucous tumors, but may be an accompaniment of any variety. It may be alarming in cases where the tumors are so small as to be detected with difficulty on bi-manual palpation. The bleeding usually occurs at the menstrual periods which are prolonged and more profuse than normal. The menstrual interval may be normal in duration, but in many cases is shortened, so that the bleeding recurs in two or three weeks. The blood is frequently discharged in large clots. Indeed the discharge of clots at the menstrual period is an absolute indication of something abnormal, and should always invite attention to the condition of the uterus. In a very large proportion of cases it will be found to be an outward sign of fibroid growths.

A definite relation exists between uterine fibroids and sterility. Whether the sterility is a cause or a consequence of the morbid growths is not positively determined. Statistical compilations show that above seventy-five per cent. of the women having fibroid tumors have never borne children. This may be regarded as fortunate, for in cases of labor complicated with uterine fibroids over half of the mothers and nearly two-thirds of the children die.

The treatment of fibroid tumors of the uterus is preëminently surgical. Even the administration of ergot and savine may be looked upon as a surgical method of treatment, for the effect striven after in the use of these remedies is the extrusion, or partial extrusion of the growths, whose removal is completed by surgical means. While the deaths directly due to the use of ergot are probably few, most writers discountenance the treatment for these reasons: the ergot treatment is tedious, painful, often ineffective and even at times dangerous. When the tumor is forced into the uterine cavity, or through the cervix by the contractions induced by the medicine, the practitioner must be ready to interfere surgically, otherwise sloughing and sepsis are imminent.

The ideal operation for a fibromatous tumor is the removal of the tumor, leaving the uterus intact. Unfortunately in many cases this result cannot be attained. Nevertheless this should be striven for wherever possible. The marvelous success of Schroeder and Martin in enucleating fibroids and thus preserving the uterus should encourage us to an imitation of their work. The enucleation of fibroids whether by the genital canal, or by laparotomy is in the true line of conservative surgery.

When a submucous tumor projects into the uterine cavity or the vagina, its attachment is usually by a pedicle of greater or less thickness. When the pedicle is thin the tumor may be twisted off. The torsion seems to arrest all hæmorrhage at the same time from the highly vascular mucous membrane covering the pedicle. When the latter is thick, attachment may be severed with scissors, *ecraseur*, or galvano-caustic wire. I prefer the latter method as less dangerous, cleaner, more rapid and thoroughly aseptic.

When the tumor is attached by a sessile base, the mucous membrane and capsule over it may be split with a knife after carefully dilating the cervix under antiseptic precautions, and then enucleating the tumor from its base. To arrest hæmorrhage a tampon of iodoform or creolin gauze may be packed against the bleeding surface. Great care is requisite, however, not to allow the tampon to remain too long, as the secretions may be backed up through the tubes and cause salpingitis or other inflammatory dis-

turbances in the pelvic cavity. I am sure I produced a pelvic peritonitis in one case by the improper use of a tampon to arrest hæmorrhage after amputation of the cervix.¹

Sloughing of a submucous fibroid is not necessarily fatal, as careful disinfection of the genital canal before and after operation will often avert sepsis.

Vaginal enucleation of subserous tumors of the cervix may sometimes be practiced. The operation was first done by Czerny. An incision is made through the vaginal fornix, avoiding the large vessels on the sides of the cervix, and the tumor enucleated from the tissue of the cervix and the pelvic connective tissue.

Tumors of considerable size may be delivered by intra-uterine and vaginal enucleation. If the growth is too large to remove entire it may be diminished in size by subdividing it with scissors, saws specially devised for the purpose, or the galvano-caustic wire. The operation should always be completed at one sitting, for to allow part of the tumor to remain is an invitation to septic absorption. Judgment and experience are required, however, to decide when the growth has reached a size that does not permit its safe removal by way of the vagina.

The enucleation of fibroids through an incision in the abdominal wall—laparo-myomectomy—is indicated in certain cases where the tumor cannot be removed by the vagina. It is at once a graver operation than the latter, and accompanied by a considerable mortality. If the tumor is subserous and attached by a thin pedicle, its removal after section of the abdominal walls is not difficult. The pedicle may be transfixed by a double ligature and tied tightly, the tumor cut off above the ligature, the peritoneum stitched over the end of the stump, and the external wound closed. Unfortunately the tissues of the pedicle often shrink after the tumor is removed, and hæmorrhage may take place from the stump. To avert this accident various measures have been adopted by different operators. Some remove a wedge-shaped plug from the face of the stump and sew the opposing raw surfaces firmly together by deep and shallow sutures, lastly bringing the peritoneum together over all. This is usually efficient, but consumes valuable time. Other operators clamp the stump in a wire-snare (Koeberle's *serre-neud*) or a constrictor of parallel steel bars (Keith's clamp), and bring it outside of the abdominal wound, where the constricted portion of the stump mummifies or sloughs off. The peritoneal covering of the sides of the stump is stitched to the parietal peritoneum, and so

¹ In reference to this point Sir Spencer Wells says: "I have occasionally put on one or two prs. of pressure forceps to a pedicle, either before cutting away the polypus, or when bleeding occurred after cutting away, and have left the forceps hanging out of the vagina for several hours; and I prefer this method to the more common one of applying perchloride of iron and plugging the vagina."

closes the peritoneal cavity against any discharges from the end of the stump. This method gives better results than the intraperitoneal method, but leaves much to be desired in the way of surgical neatness and rapidity of healing. It is also at times attended by other inconveniences and dangers, especially if the pedicle and uterus are much put upon the stretch.

When the growth of the tumor is sessile and directly under the peritoneum, or covered by a very thin layer of uterine tissue, it may be enucleated by making a bold incision over the tumor, and shelling it out of its base.

To guard against excessive bleeding an elastic ligature—a piece of rubber tubing—may be tied around the cervix, including within the ligature the arteries supplying the uterus and appendages. Even large growths may be removed in this way. If the cavity left in the uterine tissue is too large to get good coaptation between its walls, it may be packed with iodoform gauze as practiced by Fritsch, and the edges stitched to the abdominal incision, in order to secure free drainage and make the cavity accessible to external treatment.

Deep intra-mural, or even submucous tumors may be treated by this method, but the results are less and less favorable the more the uterine cavity is opened.

Sometimes the uterine walls are so occupied by the new growths that their total removal can only be accomplished by the excision of the entire uterus, or at least that portion above the cervix. This operation is one of the gravest in surgery, and gives, in the hands of nearly all operators, a high mortality. The total extirpation of the uterus including the cervix by way of abdominal section has not been very often done, but with present methods should give more favorable results than supra-vaginal hysterectomy.

In the latter operation the stump very often gives trouble, either from hæmorrhage or sepsis.

Complete removal of the uterus at the vaginal junction, approaches the conditions of vaginal hysterectomy, and should give very little higher mortality than the latter. However, at best, the complete or partial extirpation of the uterus is an operation of great gravity and should only be resorted to when all other means promising success have been tried.²

Tait has called especial attention to the soft œdematous myo-fibroma, which often gives the impression on examination, of containing cysts. This tumor frequently fluctuates in size, being now larger, now smaller, without any apparent cause. These, as well as fibro-cystic growths of the uterus are particularly suitable for complete extirpation by abdominal section. No other op-

eration or method of treatment seems to control their growth or arrest the hæmorrhage which is a frequent accompaniment.

In 1872, Lawson Tait, of Birmingham, and Alfred Hegar, of Freiburg, almost simultaneously devised the operation of removal of the uterine appendages—ovaries and fallopian tubes—with the view of artificially inducing the menopause, and thus arresting the growth of fibroid tumors by cutting off the principal source of blood-supply to the growth. This operation has now probably been done over one thousand times with very satisfactory results. Tait's own results as shown in a statement recently furnished by him³ are extremely favorable. In 426 cases 16 died, a mortality of 3.75 per cent. Tait also declares that 95 per cent. of the cases of fibroid operated by removal of the uterine appendages are cured, that is to say, the bleeding is arrested and a large proportion of the tumors diminished in size, some disappearing altogether. These effects have been established by many observers especially when the cases have been properly selected. As above pointed out, in the soft œdematous growths the arrest of the bleeding does not seem to follow so regularly as in the hard, nodular fibroids.

The cause of the arrest of the hæmorrhages after removal of the appendages is probably due, as suggested by Mr. Knowsley Thornton,⁴ to cutting off the blood-supply by ligature of the large vessels in the broad ligaments, and not merely to removal of the ovaries and Fallopian tubes. As a matter of fact the mere extirpation of the ovaries alone often fails in producing the expected results.

The high mortality of the abdominal hysteromyomectomy, and the opposition on many sides to the removal of the ovaries which it was claimed by many, unsexed the woman,⁵ led Dr. George Apostoli, of Paris, about 1882, to experiment with the galvanic current in the treatment of uterine fibroids. It is true, Cutter, Kimball, and perhaps others had used galvanism successfully for this purpose before, but Apostoli developed a method by which the application of electricity is reduced to scientific exactness. The improvements in the instruments for generating, measuring, and applying electricity now permit the physician to administer this remedy with as much exactness in dosing, as any other therapeutic agent at his command. It would take too much time here to describe the apparatus or the methods in use. For a full description I refer to pages 327-350 of "Practical Electricity in Medicine and Surgery," by Liebig and Rohé, and to Dr. G. Betton Massey's excellent little book on "Electricity in Diseases of Women,"

² Several American surgeons have done complete extirpation of the uterus successfully, and A. Martin reports eleven recoveries out of sixteen operations, a pretty high mortality. Fritsch's mortality in all cases of hystero myomectomy, including enucleations is 25 per cent. Bantock's 22 per cent.

³ MacNaughton Jones, Diseases of Women, 4th Ed., p. 340.

⁴ Am. Gynecol. Trans., 1882.

⁵ This objection is not tenable as the "unsexing" consists merely in anticipating the menopause, which is one of the natural characteristics of the human female.

both published by F. A. Davis, Philadelphia.

In 1887 Dr. Apostoli reported 278 cases treated by this method with a successful result (arrest of hæmorrhage, diminution in size, disappearance of pain and pressure symptoms) in 95 per cent. The average number of applications was fifteen in each case. In August, 1889, Dr. Thomas Keith and his son, Dr. Skene Keith, published a detailed record,⁶ without commentary, of 106 cases treated according to the method of Apostoli. The average number of applications in the cases treated to a termination was twenty-eight. Three of the cases died during or shortly after the discontinuance of the treatment, but in neither case was the fatal result attributable to the applications. Admitting, however, for the sake of argument, that the electricity was the cause of death, a mortality of 3 per cent. cannot yet be claimed by any operator in hysterectomy, and even in the comparatively safe operation of removal of the appendages, very few operators can show as favorable results as Keith has obtained with electricity.

I have carefully gone over the record of the cases reported by Keith and have been surprised at the almost uniform improvement noted. Diminution in size of the tumor, arrest of hæmorrhage, relief of pain, and general improvement in the nutrition and spirit of the patient are recorded in nearly every case.

August Martin, the greatest living gynecological surgeon of Germany, has very recently⁷ referred to ten cases treated by him, in the following words: "The results in those ten cases show that hæmorrhage, the most troublesome and dangerous symptom of myomata, may usually indeed, be controlled, in fact, in those large multiple tumors, which apparently were situated intramurally, and included the fundus, hæmorrhage ceased nearly entirely. Several small tumors were not influenced in the same manner, and the hæmorrhages continued unchanged in spite of very frequent sittings, so that here the result must be regarded as a very doubtful one. One patient, who had a myoma of the size of an ostrich egg, had such violent pains after seven sittings, that she insisted upon being operated. The operation was performed and the patient recovered. A second symptom, often so frequently complained of, is the phenomena of pressure. These disappeared in all of nine cases, so that in this respect the result is very satisfactory. An essential decrease in size has, up to now, not been obtained in any case."

This is not very enthusiastic, but Dr. Martin admits that the symptoms for the relief of which hysterectomy is at all justifiable, were relieved in his cases. He states that he shall continue "making experiments with the procedure."

Numerous other competent observers in France, Germany, England and in this country have had successful experience with this method, and although there is still a good deal of sneering at the method as being useless, and withal dangerous, and those who use and advocate it are denounced as quacks and "low-down, no-account sort o' pussons" generally, electricity in the treatment of fibroid tumors of the uterus has come to stay, and demands investigation. Ridicule and denunciation are no answers to plain records of facts submitted by Apostoli, Zweifel, Martin, Keith and many others, less eminent perhaps, but still of some account in the world.

Some of those who use the electrolytic method, apply it in office or dispensary practice allowing the patients to walk or ride considerable distances after the application. This I regard as imprudent, and likely to cause trouble. All the cases in which serious symptoms or a fatal result followed after the use of electricity were such as had imprudently exposed themselves. I regard it as important that several hours at least of perfect rest should follow each application. To allow this course to be pursued it is requisite that the patient should be treated at her own home, or in a properly fitted institution.

It goes without saying that careful asepsis of the genital canal should be maintained during the electrical treatment as well as in the gravest and most delicate surgical operations.

Laparo-hysterectomy puts the woman in jeopardy of her life and keeps her a helpless invalid for at least one month. The electrolytic treatment keeps the patient under moderate restraint for a period of two or three months, does not endanger her life, and leaves her generally in such a condition of comfort and health that she is satisfied to live her allotted days, even though she is obliged to carry her tumor with her to the grave.

I would not advocate the exclusive use of the electrical method in the treatment of uterine fibroids. As stated in the beginning of this paper a rational discrimination is demanded of those who treat this condition. Many cases are readily relieved by vaginal or intra-uterine division of the pedicle by scissors, *ecraseur* or galvano-cantery wire; others are best treated by vaginal, intra-uterine or abdominal enucleation. Large œdematous tumors or fibro-cysts should be treated by laparo-hysterectomy; bleeding fibroids of not too great size, are proper cases for removal of the appendages, and most large chronic, immovable tumors, choking up the pelvis, causing pain, pressure-symptoms and hæmorrhage yield to the proper, patient employment of the galvanic current after the method of Apostoli.

TENTH INTERNATIONAL MEDICAL CONGRESS.

*Read before the Cambridge Society for Medical Improvement,
October 27, 1890.*

BY AUGUSTUS P. CLARKE, A.M., M.D.,
OF CAMBRIDGE, MASS.

Your Secretary has requested me to report what proved of interest to me during my recent trip to the Tenth International Medical Congress. In accepting this invitation I am not unaware that much has been written in regard to the Congress, but the interest manifested at Berlin in the healing art was so great, I am sure that any observation or information, though from a point somewhat remotely connected, would not be unacceptable. Before reaching Berlin I was enabled to attend as a delegate the meeting of the British Medical Association which opened on July 29, being one week earlier than usual so as not to interfere with the International meeting.

The meeting at Birmingham was instructive and full of interest, and I have no doubt was a fair exponent of the views and practice which prevail in Great Britain. There was, however, a noticeable absence from this meeting of many of the great lights of London. In striking contrast to what we in our country consider to be essential in regard to biological and bacteriological investigations, and in the study and attainment of other languages beside our own, was the studied and carefully prepared address of Mr. Lawson Tait, delivered before a large and sympathetic audience. I am confident, had his address been delivered before an audience on this side of the ocean, his trenchant but dreary periods would not have elicited such generous applause. Mr. Tait was evidently able to discern the temper of his hearers, and also to judge to what heights of ecstasy they could be carried.

The dinner of the British Medical Association, which took place on Thursday evening, was an enjoyable occasion, and was rendered more so on account of the presence of Surgeon T. H. Parke, A.M.S., who had accompanied Mr. Stanley while making his exploration of the "Dark Continent," and who had the high honor of receiving at that meeting the Association's decoration of honor (a gold medal) for distinguished merit while in service with his chief, accomplishing those great results which must ever redound to the honor and glory of England.

I did not leave the meeting until near the close of the week, but fortunately, though delayed somewhat by the trains, arrived in Berlin Sunday, August 3, the day before the opening of the Congress. The plan of registration was a simple but most excellent one. The membership cards and ladies' cards, on presentation of the proper credentials, were obtained at S.W. Leipziger strasse 75. Other cards were obtained at the Bureau in

the Landes Ausstellungs-Park railroad viaducts, 18-22. August 4 the first general meeting of the Congress took place in the Circus Rentz, an amphitheatre in many respects like a Roman Coliseum. It was a grand sight indeed, when we beheld that magnificent building, gracefully decked with the flags of all nations, and filled with so many distinguished of our profession with their ladies from all parts of the globe. The gay uniforms and decorations worn by many of the members who had gained recognition in military and Imperial service, together with the State representatives from the various Sections of the German Empire, dignified the occasion and rendered indescribably grand the formal opening of the Tenth International Medical Congress.

The meetings of the Congress were divided into eighteen Sections. The Section for which I had preference was that of Obstetrics and Gynecology. This Section was admirably managed by its accomplished President, Dr. August Martin, of Berlin. Subjects proposed by the organization of the Committee.

ANTISEPSIS IN MIDWIFERY.

Those who were especially selected for the discussion of this theme, were Galabin, London; Slawjanski, St. Petersburg; Stadfeldt, Copenhagen; and Fritsch, Breslau. The speakers favored the use of a sublimate solution for the hands of the medical attendant and of the nurses. All clothes and whatever else came in contact with the patient should be made as aseptic as possible. The methods of treatment were greatly simplified, and much of the useless ceremony heretofore carried out was dispensed with. The consensus of opinion coming from almost every country was in favor of such use of antiseptics. A mortality of 15 to nearly 20 per cent. in puerperal epidemics, which had heretofore prevailed, had been reduced by the use of antiseptics to about 1 per cent. The results of the discussion were favorable to the general adoption of the methods for private practice. Abdominal palpation instead of early resort to digital examination was touched upon, and received the approval of the participants in the discussion.

Another subject for discussion was

EXTIRPATIO UTERI VAGINALIS.

I well remember the results of the discussion on that subject which took place in the meeting of the Ninth International Medical Congress at Washington in 1887. Dr. A. Martin, of Berlin, who was at that meeting, presented a most able paper, and discussion on the importance of total extirpation of the uterus in certain stages of cancerous disease. At that meeting such operative methods were opposed by Dr. A. Reeves Jackson, of Chicago, who contended that the statistics furnished by Dr. Martin failed to show that the operation advocated by Dr. Martin and the other Ger-

man surgeons was a justifiable one. Since that date, the treatment of cancerous disease in Berlin and in other places by the surgical method in the extirpation of the uterus has been more extensively carried out. Statistics now presented are still more encouraging. Kaltenbach, of Halle, reported eighty-two cases of total extirpation with only two deaths. Reports from Russia are also more favorable for the same method of practice. The participants for the discussion were Williams, London; Schanta, Prag; Pozzi, Paris; Olshausen, Berlin; Landau and Martin, of Berlin; Sajajtzky, Moscow; Kaltenbach, Halle; Czerny, Heidelberg. The discussion brought out on

ARTIFICIAL PREMATURE LABOR, ITS INDICATIONS AND METHODS,

was highly interesting. Dr. Parvin's opening paper on the subject was a masterly one. Deformity of the pelvis proved by far to be the chief indication for resort to the induction of premature labor. Out of 988 cases collected, 870 were for deformity of the pelvis. The other occasional indications for the resort to the operation are uncontrollable vomiting of pregnancy, cardiac disease, eclampsia, certain diseases of the lungs and brain. The choice in the methods evoked by the discussion was in the use of the soft or flexible bougie previously made aseptic, the employment of hydrostatic dilators for the uterine cervix, and hot water douches. On the choice in the operation for premature delivery and that of Cæsarean section the discussion continued at some length. The result, however, showed that each method of delivery has under certain peculiar conditions its own appropriateness. The Cæsarean section, when undertaken with all the more recent precautions, proved the more hazardous alike to the mother and the child.

In the discussion of the subject in

MYOMATA,

the appearance of Apostoli before the Section was regarded with much interest. It appears that in many cases in which there is profuse uterine hæmorrhage at irregular periods, Apostoli has resort to electrolysis instead of the curette and other strictly surgical measures. He instituted, as he had done in his previous publications, many precautions for the employment in cases of peri-uterine inflammation. Our associate, Dr. E. Cutter, appeared as the originator of electrolysis in uterine myomata. He evidently desired a share of the glory for the discovery. He certainly is deserving of much praise for his perseverance in his early work, considering the prejudice and the obstacles he had to overcome.

Four hundred and fifty members registered in this Section. One hundred and fifty papers were read, beside the discussions on them. Fifteen meetings were held. For members to avail themselves of the opportunities offered it will ap-

pear that they had at all times to be on the alert, especially when it is remembered that there were three general meetings in the Circus Rentz; five grand balls given; a social meeting in the Ausstellings Park N. W. for the members of the Congress and their ladies; the reception at the Rathaus; the abschiedsfest (farewell parting) in the Königsplatz (Kroll's Garden) also given to the members and their ladies by the physicians of Berlin; the Court reception; the dinners of the several Sections; visits to the many hospitals, besides attendance on private entertainments, scientific and social, all of which had to be accomplished in six days.

Though I registered as member of the Section of Obstetrics and Gynecology, I was able to attend several of the meetings in other Sections, especially in that of Surgery. The boldness and brilliancy of Oppenheim's achievements will be appreciated when it is known that a patient from whom he had removed successfully a sarcoma of the brain some three months before, had within a short time given birth to a healthy and well developed child.

I visited Professor Glück's Policlinik in Zeiglestrasse, where I saw in use the articulated ivory pegs about which so much has been told. These were used in cases of excision of the knee and other important joints. The pegs were introduced into and along the medulla of both bones so as to give support and motion to the joint.

The dinner at the Central Hotel, given by the Surgical Section, was a most enjoyable occasion. There were some seven hundred invitations. It was presided over by von Bergmann, Court Surgeon, who had charge of the late Emperor during his last illness. At the President's table sat some of the most renowned surgeons of the world. Among the number were Prince Carl Ludwig, Sir James Paget, Sir Joseph Lister, Sir William MacCormac, von Es-march and Billroth. At the President's table I am happy to be able to bear witness that our own countryman, Dr. Billings, of Washington, also had a seat of honor.

In the Section of Neurology and Psychiatry, Victor Horsley, of London, was the fortunate recipient of the highest honor. Erb maintained that our knowledge of localization of lesions of the brain is as yet quite imperfect, that trephining had been done for a supposed lesion which had not existed, that in cases of thrombi ligature of the carotids cannot be of service in arresting cerebral hæmorrhage. He deprecated the frequent resort to surgical measures. Notwithstanding all he had to say, it was apparent that the number of advocates for surgery of the brain was far in the ascendancy.

In the Section of Obstetrics and Gynecology Prof. Barbour, of Edinburgh, presented a paper upon "Frozen Sections from the Eighth Month of Pregnancy, the First and Second Stages of

Labor and immediately after Delivery." At Birmingham I had the good fortune to make that author's acquaintance and to hear him give before the British Medical Association the results of his long and careful investigation.

Time would fail me to give the briefest mention of the leading points of the other most important papers presented. I would state, however, that the American representatives were everywhere well received; that respectful attention was given to the reading and discussion of their papers. The respect for Americans was well shown by a hearty applause, even on the first day, when it was announced before the General Session that 630 representatives from the United States had registered. This was the largest number from any country except Germany herself.

After the close of the Congress, accompanied by my wife and two daughters, I resumed my travels through the great centres for medical education, observation and training through other parts of Germany, through Austria, Italy, Switzerland, France, Belgium and Holland. I found that Rome in the early part of September was most delightful, the city was well governed. During our stay in Rome there was scarcely any rain, the weather was not uncomfortably warm. I was reliably informed that very little sickness prevails there at that time. I cannot regret the time required and expenses incurred incident to my attendance on the Congress. I already look forward with much pleasure to the meeting of the next Congress, which is to take place in Rome in October, 1893. I have full confidence that Bacelli will not prove an unworthy successor to the renowned Virchow, should the mantle of the high office fall upon him. However that may be, my great desire shall be to be counted among the representatives worthy and able to attend the next Congress in the Eternal City.

THE TONSILS AS PATHOLOGICAL PRODUCTS.

Read by Title at the Annual Meeting of the Mississippi Valley Medical Society.

BY GREEN V. WOOLEN, M.D.,

PROFESSOR OF RHINOLOGY AND LARYNGOLOGY, CENTRAL COLLEGE PHYSICIANS AND SURGEONS, AND LARYNGOLOGIST IN THE CITY HOSPITAL, INDIANAPOLIS, IND.

It doubtless has been observed by others engaged in throat work that but few people, old or young, have tonsils. It doubtless has been observed further, that when seen, they have always been associated with present or preëxisting catarrhal disease of the naso-pharynx.

It, therefore, soon became a question with the writer, if they were a true anatomical structure and organ, or a pathological product. As is well known, they are described by anatomical writers

as the former, but with no fixed idea as to size and character of function. Gray probably gives a more correct description than his predecessors, and says: "The tonsils are two glandular organs situated on each side of the fauces, between the anterior and posterior pillars of the soft palate. They are of a rounded form, and vary considerably in size in different individuals. . . . Their inner surfaces present from twelve to fifteen orifices leading into small recesses, from which numerous follicles branch out into the substance of the glands. These follicles are lined by a continuation of the mucous membrane of the pharynx, covered with epithelium, their walls being formed by a layer of closed capsules imbedded in the submucous tissue. These capsules are analogous to those of Peyer's glands. They contain a thick, grayish secretion."

But this description, it would seem, embraces tonsils which "vary considerably in size in different individuals." Now, this cannot occur except by hypertrophy or hyperplasia. We do not find this variation in size in Peyer's glands, except in disease. They both are an aggregation of solitary lymphoid glands. The mechanism of deglutition demands some such aid in the fauces, that the muscles comprising the pillars of the fauces may freely act, and the bolus to be swallowed may be coated, so as to be bolted without friction.

The difficulty has originated in describing diseased for healthy tonsils. The size of any tonsil, however large, and not inflamed or increased by the growth of a new formation, is due to the enlargement and distension of the glandular structures, or hypertrophy of the stroma—usually more or less of both—and it is invariably caused, as I believe, by chronic inflammation from former or existing catarrhal disease of contiguous parts; simply an undue increase of normal elements—hypernutrition and consequent perversion of function.

It is not difficult, in those persons who have no tonsils, to spread the faucial pillars apart and, inserting a probe into these follicles, to raise separately each gland, which is loosely attached to its associates. Any attempt to assign enlargement to different genetic sources, seems unnecessary, since hyperæmia and consequent hypernutrition from preëxisting catarrhal disease, can easily be traced. The drainage of the naso-pharynx, so admirably described by Leffert, shows how easily the unhealthy discharges from above must necessarily deposit a sufficient source of irritation in the follicles and folds of the normal mucous membrane in this region, to awaken the diseased processes.

Barring such explanations, however, the fact remains, that in healthy fauces nothing but a loose aggregation of from twelve to fifteen solitary glands, forming spongy tufts of mucous membrane, exist between the pillars of the fauces. If

the proposition is made that want of development or atrophy has occurred, then we must conclude that nature has made a great mistake, as the larger portion of mankind are thus constructed, at least in the earlier and later stages of life. But one who is closely observant will not fail to see that it is such cases that furnish the peculiar glairy mucus that is so helpful in deglutition and phonation, and that in the hypertrophic form of enlargement, the follicles or crypts are often filled with degenerated cheesy secretions, and accompanied with a granular pharynx, while in the hyperplastic condition, the follicles are closed and no secretion is furnished at all; that these enlargements become hurtful from mechanical disturbances of deglutition, respiration and phonation; that these enlarged follicles (crypts) become the frequent seat of disease, in which diphtheria and scarlatina are conspicuous; that submaxillary and cervical glandular disease is often a result of this local infection, with, as I believe, much constitutional sepsis, often regarded incorrectly as of malarial, scorbutic or scrofulous origin. And, furthermore, that the greater number of those who do have tonsils, lose them by atrophy on arrival at mature life, and are then without their aid, if they are normal organs and have functions.

This being the case, that tonsils are always a pathological product, we are brought to the practical part of the subject, What shall be done with them? It would seem that the long-established operation for removal was legitimate. But the cry against it is like Banquo's ghost. Such excrescences elsewhere producing such direful results, would unquestionably receive surgical attention. Why this want of agreement as to the tonsils? We answer because,

1. There is a general belief that an organ is being destroyed, and with it, some useful function such as virility, voice production, an aid in hæmatisis, etc. But, if the contention of this paper is correct, the tonsil is not an organ, and the function of the glands involved in the pathological process is already destroyed.

2. It is claimed they, the tonsils, will be reproduced and the operation will need to be repeated. This is partially true as it has been heretofore performed. The very name "tonsil" conveys an incorrect idea, *i. e.*, meaning something to be clipped. Nothing should be left through fear, conservatism, or the impression that the remnant left will subsequently atrophy. Often the crypts are laid bare even more freely than before, so that infection is more possible; and the broad base will also keep the pillars apart, and thus interfere with faucial action, much as before—especially phonation—which result will ever after be used by many as an argument that the operation produced it.

3. Medication is still advocated with a hope of shrinking, and otherwise aiding in alleviating the

distress incident to the enlargement. This is so tedious and unsatisfactory that, except in acute affections, it is fast falling into deserved disrepute by those of largest experience, and needs only to be mentioned to be condemned.

4. Fear of hæmorrhage deters many who would otherwise remove these excrescences. It is doubtless safe to say that no other operation in surgery, so often made, has been attended with less serious trouble in this respect. In a somewhat extensive practice in this line, based upon a belief in the doctrines herein advocated, the writer has never had but two unpleasant results—one from bleeding of a vessel at the lower border of the cut, the blood escaping into the stomach unobserved, until syncope and vomiting called attention to it; the other from injudicious use of stimulants, bringing on the trouble the third day after removal of the tonsil. In fact, the loss of blood to a considerable degree, in conjunction with the operation, is helpful in relieving the engorged contiguous tissues, and thus expediting the cure of the associated pharyngitis. Ablation then would probably be a better term than excision, as describing the proper operation, and never that of clipping.

Mathieus' tonsillotome is perfectly adapted to accomplish this, provided the barbs are removed from the fork, which facilitates puncture of the mass without displacement, and thus allows removal of the exact amount desired. With Elsborg's applicator for pressure, and application of Mackenzie's tano-gallic acid paste, no one need fear in controlling any hæmorrhage which may occur, unless a large blood-vessel should be cut because of abnormal distribution. This, however, is practically impossible if the proper instrument is skilfully used. The fork should always be adjusted for each individual case, so as to retract, after puncture, sufficiently to raise the tonsil enough for its removal, without drawing in the contiguous parts. This is to be done by carefully estimating the size of the tonsil prior to application of the instrument. The pharyngeal fascia, as is known, separates the mass from the superior constrictor muscle and adjacent blood-vessels, and if this care is exercised, the tonsil will generally be removed as if peeled off from it, so that one may introduce a probe into the crypts of the tonsil without its passing through. When removed in this manner, it has seemed to the writer, less hæmorrhage has occurred than when a part has been left. If, by any misfortune, any part of the tonsil has been left, or because of follicular disease and insufficient size for removal with the tonsillotome, then the vulsellum and curved scissors should be used, and the diseased parts removed. The writer has three tonsillotomes of graded sizes, which usually meet all requirements.

A practice based upon these ideas has given the writer as much satisfaction as any operation known to other departments of laryngology. And espe-

cially so, if preceded, as it should always be, by prior eradication of the ever antedating nasopharyngeal disease, which, as indicated above, I regard as the primary cause of this form of hypertrophic disease, as it is well known to be of the other forms of hypertrophic disease of the nose and naso-pharynx.

ANTIPYRIN IN THE TREATMENT OF PULMONARY CONSUMPTION.

BY THOMAS J. MAYS, M.D.,

PROFESSOR OF DISEASES OF THE CHEST IN THE PHILADELPHIA POLYCLINIC, AND COLLEGE FOR GRADUATES IN MEDICINE.

Antipyrin is probably one of the most useful drugs in our materia medica. I do not refer so much to its antipyretic action as I do to its influence as a general tonic in the adynamic stage of pulmonary consumption. It is indeed valuable in every stage of this disease, but it seems to give better results in the final stage than in any other. Of course it must not be regarded as a panacea, but whenever its beneficial action becomes manifest it gives rise to wonderful results. My attention was first called to its usefulness in this disease by a paper from the pen of Dr. J. Holland, of St. Moritz, Switzerland, which was published in the *London Practitioner* (Vol. xxxiv, p. 321). His results were so striking that I beg to abstract one of the cases which he relates.

In July, 1884, he was consulted by a lady who was in advanced consumption, and who had that morning spat up some blood. She had a cavity in the left apex with extensive softening all around it, together with softening in the other apex. She had a troublesome cough and considerable expectoration, and her evening temperature was as high as 103° F. He advised total rest in bed and small doses of morphia and digitalis, and on the following day her temperature was 101.4° in the morning, and 103° in the evening. He now prescribed 15 grs. of sodium salicylate every three hours, and the next evening her temperature was 103.6°, and her cough was more troublesome. He administered 20 grs. of antipyrin every three hours until she had taken a drachm. She was less feverish and felt better one hour after taking the first dose. She slept well, her cough improved, she began to eat better, and altogether felt more comfortable than she had done for weeks. The next evening her temperature was 100.4°. She took the antipyrin two or three times a day, and on the sixth day her temperature was normal. In a month from the time he first saw her she had gained 3 lbs., and only coughed and expectorated in the mornings. The physical signs had improved in proportion, for the softening in the right apex had cleared up, and had conspicuously diminished around the cavity in the left side; the cavity itself showed signs of healing, and freer

breathing was heard all over the left lung. The following winter she spent at St. Moritz, gained 15 lbs., temperature nearly normal since the previous August; became able to walk ten miles with very little fatigue, her appetite and digestion remaining excellent.

In the *Medical and Surgical Reporter* for August 11, 1888, I detailed several cases which were treated with antipyrin, and in some of which I think the results were probably as striking as in Dr. Holland's case; and regarding this drug as an indispensable adjuvant in the treatment of phthisis, I have since then found abundant evidence to confirm the favorable impression which I gathered from my earlier experience with it. To demonstrate this I will abstract a few cases from my note book, which are not specially selected for this purpose. About four months ago I was called in consultation to see a young lady living some distance from the city, who was found to be suffering from the last stage of phthisis. She had a large cavity in one lung, and another one forming in the other, she had a constant cough, a copious expectoration, hæmoptysis, a high temperature, a very rapid pulse, extreme emaciation, no appetite, coated tongue, a dropsical effusion of the lower extremities, and so much exhaustion that she was scarcely able to move. We agreed to give her 7½ grs. of antipyrin every three hours and nothing else of importance. I heard nothing from the attending physician for three weeks, when he wrote that a remarkable change had come over the patient. The œdema had not improved, but she had lost her cough almost entirely, expectorated very much less, her appetite had improved, she gained in strength, and was able to walk about. The fever had also subsided, and the chief complaint she had then was a cutaneous eruption brought out by the antipyrin. While permanent results were out of the question in this case I am quite certain, from what I have seen in other instances, that the amelioration in her condition was due to the antipyrin.

Another case is that of a young man aged 24, who consulted me last April. He had been ailing for some time, coughed, expectorated, lost flesh, had hæmoptysis, and no appetite. His temperature at that time was 102° in the evening. There was found a cavity in his right lung, and crepitation in the opposite one. He was placed on antipyrin—15 grs. two or three times a day, and kept quiet for some time. After the temperature approached the normal point the drug was given in 7½ gr. doses three or four times a day, and was alternated with 4 grs. of phenacetin every four hours, every other week. He now weighs 10 lbs. heavier than he did, has a good appetite, and his cough and expectoration have almost disappeared.

The third and last case which I shall relate is that of a young man, aged 20, who was first seen about two years ago. He had lost his mother,

father and sister on account of phthisis, and he himself was suffering from the third stage of the same disease. In a short time after taking the antipyrin he began to mend in symptoms and in physical signs. The cavity in his left lung became more quiet, his cough, expectoration and appetite improved, and in the course of two months he gained 9 lbs., and continues well up to the present time.

While it is true that antipyrin is given for the purpose of subduing the fever of phthisis, we must not lose sight of the fact that it has a capital influence on this disease after the fever has subsided. Phthisis is undoubtedly a constitutional and not a local disease, depending ultimately on a depreciated nervous system,¹ and it is in virtue of its selective affinity for the nervous system, that antipyrin acts as an antipyretic and, associated with other well directed treatment, it yields the beneficial therapeutic influence in this as well as in all other nervous diseases. It should therefore be continued in smaller doses after the fever has gone. In conclusion it must be added, that if it is given for a protracted period it produces a rash of the skin, which can, however, be obviated by alternating it with phenacetin.

MEDICAL PROGRESS.

A NEW METHOD OF PERCUSSION.—Dr. KABIERSKE, of Breslau, who fully recognizes the value of mediate percussion (by means of the plessimeter), has been studying the matter of immediate percussion, because it seems to him easier and more convenient, with a view to avoiding the numerous difficulties which attend the present method (*Ther. Monatsh.—Med. Chir. Rund.*). For this purpose he has devised an instrument similar to a tuning-fork, with the handle cylindrical and covered with rubber, and the blades rounded off at the ends. The handle of the instrument is held between the forefinger and thumb, and raised and lowered by them without moving the hand. Percussion is thus rendered easier of performance, because only one hand is required; the results are said to be more accurate, since among other advantages, much smaller surfaces can be examined at a time, the thickness of the blades being but 7 mm. (about $\frac{1}{4}$ in.); thus this might almost be called punctate percussion. The author has preferred his percussor above all other means in examining the apices of the lungs, assuming (perhaps not with justice), that no investigations into the movability of this portion of the lungs have yet been made. At any rate it is worthy of notice, that Kabierske can, with this

instrument and after sufficient practice, easily detect apical dulness which would be sought for in vain with ordinary methods of percussion. A further advantage of the instrument is that it will serve as an aid to the sense of touch, especially in percussing out the heart, the area of which the author was able to outline in a way different from that previously employed. By laying the handle flat on the surface, the instrument makes a good plessimeter, especially in abdominal percussion, and has more than ordinary value in the percussion of small areas, since it covers less service than the implements heretofore in use, and the sound it gives is loud and clear. Its weight is 15 grams ($\frac{1}{2}$ ounce). Although the sound given out by this instrument when used as a plessimeter is less than that made by the ordinary plessimeter, it is still loud enough for all purposes.—*Weekly Medical Review.*

PERNICIOUS ANÆMIA IN CHILDHOOD.—A paper on pernicious anæmia in childhood, contributed by Drs. AD. D'ESPINE and C. PICOT, of Geneva, to the Section of Pædiatrics of the International Medical Congress (1890), is published in the *Revue de Médecine* for October 10. Each author contributes one case, and they give brief notes of four others, which are all they have been able to find recorded in the literature of the subject. In both the cases now published for the first time the course of the malady was very brief; in neither case did the symptoms endure more than about one month. Dr. D'Espine's patient was about 2 years, Dr. Picot's 13; both were healthy children in whom marked anæmia rapidly developed without any discoverable cause; the possibility of the presence of *bothrioccephalus latus* was not overlooked, but the exhibition of male fern was not followed by the expulsion of a worm. In the younger child there was at an early stage some gastric disturbance, and the administration of castor oil led to vomiting, but no diarrhœa; in the elder child, on the other hand, there were at an early stage attacks of colic and diarrhœa, and one or two attacks of vomiting; both suffered from loss of appetite and continual thirst; both presented purpuric patches, and the younger petechiæ also; the gums in both were healthy; epistaxis occurred in both, but was severe only in the elder and towards the termination of his illness; the blood in both was pale and did not coagulate properly. In both there was a firm œdema of the lower extremities, and in the younger an anæmic cardiac murmur, and towards the end a *bruit de galop*. Dyspnœa was present in both, and in the elder child was very severe; in fact, the most prominent symptom. In the younger child there were two slight accesses of fever ten days and a week before death, and for the last four days moderate remittent fever; in the elder there was no fever. A necropsy was

¹ "Pulmonary Consumption a Neurosis," by Thomas J. Mays, M.D., *Therapeutic Gazette*, November and December, 1888; see also *Medical News*, May 25, 1889; *Journal of Inebriety*, April, 1889; and *Medical Times and Register*, August 10, 1889.

obtained in Dr. Picot's case. The abnormalities noticed were: liver large, firm, pale yellow, and of fatty appearance, gall bladder empty; spleen nearly twice the normal size, soft and congested; the stomach was healthy, with the exception of two or three vascular points; the duodenum, jejunum, and ileum were healthy to within four or five inches of the ileo-cæcal valve; below that point the intestine was thickened, as were also the cæcum and the appendix vermiformis; there was no ulceration, and no swelling of Peyer's patches; on section the intestine had a greyish lardaceous aspect; the corresponding mesenteric glands were enlarged; the rest of the large intestine was healthy. Dr. Mayor made a microscopical examination; he found all the coats of the intestine except the serous copiously infiltrated with leucocytes; these leucocytes were not contained in the reticulum, and Dr. Mayor concludes that the lesion was not lymphadenoma. The thymus gland was persistent in this boy, large, heavy, and lobulated. In the younger child iron and arsenic was exhibited without any benefit, and quinine had little or no effect on the fever. The authors discuss the etiology of the disease, which they attribute to "an auto-intoxication of gastro-intestinal origin," but are apparently unacquainted with the more recent work (see *British Medical Journal*, July 5 and 12, 1890) of Dr. William Hunter, from whose earlier work they quote. They discuss the rarity of pernicious anæmia in childhood, and venture on a hypothesis connecting these fatal cases with other cases of severe anæmia in childhood not due to diarrhœa, or imperfect feeding, cases in which there is anæmia without wasting associated, as they believe, with abnormal fermentations in the stomach or intestines, and often primarily dependent on the dilation on the stomach produced by overfeeding. Their hypothesis is that these cases really belong to the same category as the pernicious anæmia of adults, and that the reason why the anæmia so rarely becomes truly pernicious is that the hæmatopoietic activity, of the bone marrow especially, is so much greater and more intense in infancy and early childhood than during adult age.—*Brit. Med. Journal*.

EFFECTS OF REMEDIES UPON THE SYSTEMIC AND PULMONARY CIRCULATION.—The Harveian oration of DR. JAMES ANDREWS, of St. Bartholomew, delivered at the Royal College of Physicians and Surgeons, London, Oct. 18, 1890, and reported in *The Lancet* of Oct. 25, is worthy of a critical reading. We quote from his oration that portion which treats in particular of the effects of remedies upon the two circulations.

Through the kindness of Dr. Bradford of University College Hospital, and of Dr. Bokenham, assistant to my colleague, Dr. Lauder Brunton, in the science work-room of St. Bartholomew's Hos-

pital, I am enabled to lay before you the following statements as to the comparative effect of certain substances upon the systemic and pulmonary circulations. Their researches were carried on entirely independently of each other, and yet their results are practically identical. In looking at the pressure tracings taken by them one cannot but be struck by the smallness of the variations in the pulmonary, as compared with those in the carotid artery; but it must be remembered that in consequence of the lower natural pressure in the pulmonary artery alterations in pressure in either direction produce about twice the effect upon the rapidity of the lesser circulation which corresponding changes do upon the greater.

Muscarin.—In the *British Medical Journal* for Nov. 14, 1874, Dr. Lauder Brunton gives the following account of the action of muscarin on the heart. Having thoroughly narcotised a rabbit with hydrate of chloral he commenced artificial respiration, and opened the thorax. Both sides of the heart seemed to be equally filled, the veins only moderately distended, and the lungs rosy. On injecting a little muscarin into the jugular vein everything at once changed. The lungs became blanched, the left side of the heart became small, the right side swelled up, and the vena cava became greatly distended. After a short time a little atropine was injected into the jugular vein, and everything instantly returned to its normal condition. The left side of the heart regained its former size, the right side diminished, the distension of the veins disappeared, and the blanched lungs again assumed a rosy hue. Distrusting his own personal observation Dr. Brunton got two observers who knew nothing about the experiment, and reported it before them, noting down their observations, which agreed exactly with his own. It is all but impossible, I think, either to doubt the accuracy of the record of this experiment, or to attribute the phenomena observed (especially the simultaneous distention of the pulmonary artery and the blanching of the lungs) to any other cause than the action of vaso-motor nerves. Subsequent observers seem to have failed to obtain the striking effects witnessed by Dr. Lauder Brunton, but his account is substantially confirmed by Dr. Bokenham, who tells me that muscarin in a small dose caused rapid fall in the carotid pressure, with, in most cases, a rise in the pulmonary pressure. This rise, however, is not long maintained. The pressure in the pulmonary artery sinks to normal, whilst that in the carotid more slowly rises to its original level. A large dose seems to produce paralysis of the heart and rapid fall of pressure in both circuits.

Amyl nitrite.—This given by inhalation, caused rapid fall in carotid pressure, with simultaneous marked rise in pulmonary pressure. Carotid pressure then rose, and during this rise the pulmonary pressure resumed its original level.

Nitro-glycerine.—In the cat one-fiftieth of a grain produced a temporary great fall of the carotid, with a slight rise of the pulmonary pressure. When, however, the carotid fall had reached its lowest point, the pulmonary pressure also fell. The carotid pressure then rose, but not to the normal figure. At the beginning of this rise the pulmonary pressure showed some tendency to fall, but remained nearly constant. In the dog one-fiftieth of a grain produced a primary fall in the carotid, with little or no effect in the pulmonary pressure. A subsequent gradual rise of the carotid pressure then took place, with a very slight fall of pulmonary pressure during the greater part of the rise.

Digitalis.—Digitalin caused steady rise of blood pressure both in carotid and pulmonary arteries, with great slowing of pulse. Tincture of digitalis in dogs caused slight fall in carotid pressure, following soon after injection. At this time practically no effect on pulmonary pressure. Following this a steady rise in both pulmonary and carotid blood pressure. Infusion of digitalis in cats caused primary rise in blood pressure, both in carotid and pulmonary arteries, followed by slight but more permanent rise. (The primary rise here was probably due to the fact that a large quantity of fluid had to be introduced, as the same result followed the injection of a similar quantity of water).

Tincture of strophanthus.—In cats a small dose (min. j to ij) produced a primary fall of pressure in both carotid and pulmonary arteries, and a subsequent rise in pressure almost up to normal. The heart at the same time was slow and irregular. A large dose produced first a great rise of carotid pressure, the pulmonary pressure sinking slightly at first and then rising slightly. Then great quickening of heart with steady fall of pressure in carotid, the pulmonary falling to, but not below, its original level.

Ergol produces primary rise in pulmonary, with simultaneous fall in carotid pressure. This fall, however, is of short duration; subsequently both pressures rise.

Aconite.—This produces a fall in pressure in both carotid and pulmonary arteries.

Strychnine.—This produces in both carotid and pulmonary arteries, a rise in pressure, especially marked in the pulmonary artery.

Chloroform.—Both pressures fall together.

Ether.—Both pressures rise together.

Atropine (sulphate of) produces first a steady fall in carotid pressure, the pulmonary sinking at the same time, but in much less degree. During this period the heart is slowed and the vagus nerve is excitable. Next pressure rises in both, and the pulse becomes more frequent, the inhibitory power of the vagus being gradually abolished. When the pressure reaches its highest point the heart cannot be stopped by stimulation

of the vagus, and a second dose of atropine will have no further effect.

Quebracho (tincture of) produces in the carotid artery a primary fall, in the pulmonary artery a slight rise, followed in the carotid by a steady rise to a higher point than normal, whilst in the pulmonary artery the higher level already reached is maintained. Finally, in the carotid artery the pressure becomes very great, whilst in the pulmonary it does not rise above the slightly higher level it reached at first.

In the graphic records of these experiments there are many things of great interest, but from lack of time I have confined myself to one point only—viz., the pressure relations of the two circuits to each other. And it is clear that in some cases these relations, under the influence of the the same drug, vary in a manner which could scarcely have been ascertained without the aid of direct experiment. It is difficult to arrive at any classification of them beyond this: that if the systemic pressure rises, then the pulmonary pressure also rises; if the systemic pressure falls, then the pulmonary may either rise or fall. And even this is only true of the primary effect of the drug, for among the later effects, for example, in the case of amyl nitrite, and to a less extent in that of nitro-glycerine, the pressure in the pulmonary artery may fall whilst that in the carotid is rising.

LAPAROTOMY UNDER COCAINE.—A woman, æt. 40, was admitted as an in-patient under Dr. Barnes, physician to the Cumberland Infirmary, on July 7. She had for some years suffered from a tumor in the right side of the abdomen. After consultation with Dr. Maclaren, surgeon to the hospital, she was advised to submit to an exploratory incision. While she was considering this she rather suddenly became worse. Her abdomen became distended and very tender; she vomited frequently; her loss of strength increased day by day. On October 4, her urgent state was fully explained to her, and she agreed to take such chance of relief as an exploration might afford. Her condition seemed so extreme that she might not recover from a general anæsthetic, so Dr. Maclaren proposed to try if the operation could be done with cocaine. A 20 per cent. solution was used, and of this 12 minims were injected. Two punctures were made, and the solution injected drop by drop along a line of 2 inches, just under the skin, except for the last two drops, which were injected into the deeper tissues. Five minutes were allowed to elapse, and an incision was then made two inches above and parallel to Poupart's ligament. There was no difficulty in doing the operation; the patient never moved. The peritoneum was studded with malignant nodules; a mass of malignant tissue (omentum) adhered to the abdominal wall. The bowel was not distended, and it was evident that

nothing could be done, so the wound was sewn up. The patient died four days after, the course of her illness being uninfluenced for good or evil by the operation. What the patient felt during the operation was very trifling. When questioned she said that it was nothing compared to her sufferings during the previous few days, that it was not greater than she had suffered in her confinements, which had been easy ones, and that what she felt most was the stitching. The introduction of the finger and the passage of a glass tube in various directions to allow fluid to escape were quite painless. At Dr. Maclaren's request she turned herself on her side to allow the fluid to gravitate to the opening, and afterwards said she felt it running out, and thought it was blood. She was a very thin woman, which no doubt made the use of the cocaine more efficacious and the operation easy. Post-mortem examination showed much malignant disease of the peritoneum and omentum, and a distended gall-bladder containing numerous stones, one impacted in the duct. The condition of the wound was perfect.—*British Medical Journal*.

MICROBES IN THE STOMACH.—DR. KIANOVSKI details in the last two numbers of the *Vrach* some observations he has recently made upon the bacteria contained in the stomach before and during digestion, with the object of determining the effect of the gastric juice upon them. He found that the fasting stomach of a healthy person always contains a large number of microbes, and that in the earlier part of digestion the number of these bodies is also considerable, and that it depends mainly on the number introduced by the food, saliva, etc. Notwithstanding this, the gastric juice, or rather perhaps the free hydrochloric acid in it, tends to exert a decidedly destructive influence upon the microbes. No effect appears to be produced upon the process of digestion by these bodies.—*The Lancet*.

THE CONNECTION BETWEEN DISORDERS OF THE GENITAL SYSTEM AND SKIN DISEASES.—This has been accepted in the case of acne, of acute circumscribed cutaneous œdema, and sometimes in eczema, but scarcely ever has the association been more fully worked out than in the example of chronic urticaria by DR. FRANK, of Prague. In a woman aged 28, unmarried, urticaria and disorders of the sexual system commenced simultaneously at the age of 25. The symptoms pointed to chronic oöphoritis and salpingitis, and the urticaria burst out with greatest intensity at the menstrual periods. The ovaries were completely removed, and the patient made an excellent recovery. The urticaria at once ceased and did not recur. She gained flesh, and all the local symptoms referable to the sexual apparatus vanished. Dr. Frank observes: "It is a

known fact that during female sexual life the normal genital functions, as well as the disturbances to which these are liable, exert a notable influence on the development and on the condition on the entire nervous system. As a result of long-continued chronic sexual disorders, from the persistent pain and emaciation, an altered irritability of the nerves, particularly of those distributed to the vessels, arises. Further, from the circumstance that a reciprocity between the genital system and the skin is easily observed in various physiological and pathological processes, the conclusion is established, that the cutaneous nerves are implicated in these disorders."—*Zeitschrift für Heilkunde*.

PERIODICAL HÆMOPTYSIS AFTER REMOVAL OF BOTH OVARIES.—DR. PAUL RAYMOND (*Gazette des Hôpitaux*, October 14, 1890, p. 1096), describes a case in which M. Pozzi had, in 1888, removed both ovaries from a woman, then aged 25. The patient remained three months in hospital, and no uterine "show" has ever been seen since. Every month, however, a flow of white fluid appears and lasts for two or three days. The patient suffers from headache, without lumbar or abdominal pains, and suddenly vertigo and flushing of the cheeks come on; these symptoms are followed by hæmoptysis. The spitting of blood is not preceded by any feeling of heat or weight in the chest. Nausea without hæmatemesis sometimes complicates this abnormal menstrual period. The hæmoptysis occurs four or five times daily, and lasts two or three days, sometimes waking up the patient at night. Several ounces of blood are thus lost without sensible detriment to health. The pulmonary hæmorrhage has continued monthly since January, 1889. There is evidence of incipient phthisis at the right apex. This case, says Dr. Raymond, shows that when the sanguineous "show" ceases after castration, the congestive tendency and other phenomena of menstruation may continue. Vicarious hæmorrhage may occur, and it is easy to understand how a new tuberculous deposit is liable under these circumstances to become the seat of bleeding. The author refers to a case of Graves' disease following removal of the ovaries, reported by Dr. Mathieu in the same journal (1890, p. 643). Uterine hæmorrhage was never seen after the operation, but the patient became, subject to the most distressing flushings of the face and great nervous agitation. The thyroid gland swells; in fact, the patient is in the incipient stage of Graves' disease, though the symptoms seem to have become "disciplined," so as to be marked only at the monthly period. These cases show that a patient after removal of her ovaries is in the state of a woman with amenorrhœa. True menstruation ceases, but the menstrual period may remain, reacting on the

whole organism and manifesting itself by hæmorrhagic, vasomotor, nervous, or other symptoms, which by their regular recurrence alone may entail serious consequences.—*Brit. Med. Journal*.

A REMEDY FOR PALPITATION.—DR. GINGEOT (*Rev. Gen. et Clin. et de Ther.*), recommends as a valuable remedy for palpitation—one that has proved serviceable to him—the application of cold to the precordial region. Attention must be paid to the method of applying cold. The simplest plan of all is to apply a wet sponge over the heart in the morning before dressing. At night, when in bed, the patient or an assistant may put a cold compress over the heart, well covered with dry bandages, to retain moisture and prevent any wetting of the clothing. When this compress is warm, the patient may remove it, and will probably fall asleep. There are objections to the ice-bag, one being the condensation of insensible perspiration upon the surface of the skin. The ether-spray is a simple and convenient method of refrigeration. With proper instruction as to necessary precautions in the use of ether, the patient can apply cold in this way at any hour of the day or night. Palpitation of purely nervous origin seldom fails to be greatly benefited by the application of cold; and a certain success often follows its use in cases of palpitation due to organic disease. Equalizing the heart's action will often prevent an increase in its size. It is also useful in aneurism and passive dilatation.—*Therapeutic Analyst*.

THE SURGICAL TREATMENT OF TUBERCULAR PERITONITIS.—The surprising and inexplicable success which has attended the opening of the peritoneal cavity for the treatment of tubercular peritonitis, is the subject of an editorial in the *University Medical Magazine* for November. Evidence has been accumulating till it is now convincing, that even an exploratory incision is frequently followed by permanent cure of the local tubercular processes.

KÖNIG (*Centralblatt für Chirurgie*, No. 35, 1890) has collected 131 cases of peritoneal tuberculosis treated by abdominal section, of which 23 were greatly improved; 84 were cured (65 per cent.); of these cases 30 (24 per cent.) exhibited no signs of intra-peritoneal tuberculosis for several years following abdominal section. In only 3 per cent. could death be attributed to the operation. As to the method by which these cures were obtained, examination of the cases shows that there was only one condition common to all; that is, the belly was freely opened, and a certain amount of intra-peritoneal manipulation was practiced. Even the employment of anti-bacterial agents seems to be absolutely without influence, except that apparently a greater percentage of cures followed where no disinfectants were used

A question of major importance is as to whether only certain forms of peritoneal tuberculosis can be cured by section. As is well known, the effusion may be serous, sero-fibrinous or purulent; may be circumscribed or diffuse. The tubercles may vary in size, being miliary in one case, in another as large as a hazel-nut. The peritoneum may be smooth, roughened, thickened, or covered with a pseudo-membrane. In so far as clinical studies go, it would seem that all these different forms have undergone resolution after abdominal section, and consequently that they are all curable.

Peritoneal tuberculosis is dependent upon the extension of the tubercular inflammation from adjacent organs, or upon direct infection, by means of the bacilli circulating in the blood. Phillips found the lungs involved in 92 per cent. of the cases, the pleura also in 56, and the bowel in 75. Intestinal invasion by tubercle is frequent, the serosa becoming quickly involved, but this involvement may remain strictly localized, and may undergo spontaneous resolution if the original source of infection, the intestinal lesion, cicatrizes. When, however, the peritoneal involvement comes from a large organ, and is extensive, it is as difficult to conceive the *rationale* of spontaneous resolution as it is to explain in what way operative procedure, except that of total ablation of the disease, can possibly be of the slightest avail. Yet the fact remains that a gratifying percentage of success follows simple opening and intra-abdominal manipulation in cases of tubercular peritonitis.—*Boston Med. and Surg. Journal*.

MANAGEMENT OF GONORRHOEA.—LANG (*Wiener Med. Wochenschrift*, October 2, 1890) discusses some of the causes of the prolongation and complications of gonorrhœa. One of the most important points in the treatment of gonorrhœa is, he thinks, the proper regulation of eating and drinking. In some cases attention to these is all the treatment that is necessary. The injection chiefly used by the author is a solution of sulphocarbonate of zinc of a strength of from one-fourth to one per cent. Stronger solutions may be employed if a mucilaginous menstruum is used instead of water. It is important to pay attention to the size of the syringe. Patients, if not otherwise instructed, will often use a large syringe, and by injecting too much fluid injure the urethra. Lang uses syringes of three sizes holding respectively, one and a half, two, and three drachms, and to each case orders the size which seems most suitable.—*Brit. Med. Journal, Med. News*.

THE MICROBES OF PNEUMONIA.—DR. QUEISNER has examined the lungs of a number of children and adults dying from pneumonia, his results showed that the pneumonia coccus of Frankel and Weichselbaum is the usual bacterial

cause of true croupous pneumonia. This coccus was also found in the majority of cases of broncho-pneumonia. In both children and grown up people the sputum contained the coccus at the very commencement of the lung affection, and its existence appeared to form a very good sign of the invasion of pneumonia of one kind or another. In the lungs of ten children who had died of various forms of pneumonia, primary as well as secondary to measles, diphtheria, and tuberculosis, Friedlander's pneumonia bacillus was not once found, but the coccus was found in eight cases. In several instances it was impossible to distinguish between the catarrhal and the croupous form, as even in undoubted catarrhal cases a very perceptible quantity of fibrinous exudation was found.—*Lancet*.

THE NATURE AND TREATMENT OF ECZEMA.—DR. UNNA reviews the position of this most interesting question, and, as usual, throws a new light on the subject. The standpoint which he takes up is the parasitic origin of eczema. He first contrasts the earlier opinions as to the influence of microorganisms on the skin. He shows that it is the strongest proof of the harmlessness of those which occasion the so-called vegetable parasitic diseases that they proliferate profusely. They would not be able to develop insidiously, almost imperceptibly, in the horny tissue if their excretion products exercised any very injurious or irritating effects on the living prickle-layer and cells of the cutis. Where we have to deal with organisms which are much more seriously injurious, we shall not obtain much microscopic evidence of their presence, for the more harmful their effect the fewer are necessary to bring about well-marked signs of irritation, under which the organisms will on their side suffer. In such cases only cultivations on artificial nutritive media can lead to any exact knowledge of the affections of the epidermis. In regard to eczema, the first systematic cultivation experiments have revealed an unexpectedly rich flora in the upper skin. It is scarcely conceivable, he thinks, that this enormous mass of organisms can have no connection with the etiology of eczema. However justifiable the keenest criticism may be with regard to any single parasite which is claimed to be the true and only cause of a certain affection of the epidermis, it is quite as unjustifiable to maintain a general skepticism against the parasitic nature of these affections in general. *The true and essential cause is the inoculation of the germ*, a germ for the most part, probably, of vegetable nature. Eczema, however, is only produced when the germ proliferates in the epidermis and its appendages. To effect this it is necessary, according to the parasitic theory, that this affected epidermis should be a good nutritive basis; and this condition embraces actually

everything which has been previously placed among the various predisposing and exciting causes. External warmth and moisture, simple inflammations, and stases, as well as the whole legion of external irritants, may be described as exciting causes, or better as *accidental improvements of the nutrient base*. That which is common to all the causes which have been discussed in the text books up to the present time is, *that they can render the skin, and especially the epidermis and the nutritive fluids which penetrate it, favorable to the growth of the specific germs*. Eczema is, in his opinion, a chronic parasitic catarrh of the skin, with desquamation, itching, and the disposition to respond to irritation by exudation and well-marked inflammation. The treatment of chronic eczema divides itself into two heads—(a) By the use of anti-parasitic measures the germ itself is attacked; this is the *direct treatment*. (b) On the other hand, by it, the epidermis, which is the nutrient soil, becomes less suitable for the growth of the specific germ; this is the *indirect treatment*. In the search for new specifics against the various forms of eczema, their harmlessness for the general organism must be taken into consideration; and with regard to the reducing medicinal agents in particular, it must be noted whether there is an absence of irritating properties in their oxidation products.—*British Journal of Dermatology*.

STERILIZATION OF RUBBER CATHETERS.—DR. ALAPY (*Annales des Maladies des Organes Génito-urinaires*, July, 1890) describes a new method of effecting the sterilization of these instruments, which possesses, he asserts, the merit of being very effective, easy to carry out, and harmless to the instruments. After drawing attention to the effects of various antiseptics, such as carbolic acid, sublimate, etc., and heat as ordinarily applied, he goes on to describe his own plan, which practically consists in wrapping up the instruments, not more than three or four in a packet, in ordinary blotting paper, the ends of which are just twisted up. These packets are then placed in glass tubes, the mouths of which are sealed with a plug of cotton wool. The glass tubes are exposed for half an hour to ordinary steam, that is, to a temperature of 100° C. The packets of blotting paper are then removed, and kept in a drawer or box till they are required for use. They remain sterilized for any length of time provided the paper is not opened, as is shown by the fact that they are incapable of infecting either sterilized bouillon or sterilized urine.—*British Medical Journal*.

CALCIUM SULPHIDE IN CROUP.—The *Med. Reg. (Ed.)* recommends the use of the above drug in doses of one-tenth gr. hourly for the worst cases.

SATURDAY, DECEMBER 6, 1890.

WINCKEL ON WESTERN OBSTETRICIANS.

PROFESSOR WINCKEL seems to think that the obstetricians of the West do not know very much about pelvimetry. At least, this is the construction we put upon the following sentences that may be found on page 460 of Edgar's Translation of Winckel's:¹ "When I hear statements made, such as those I often heard in America, in 1886, that narrowing of the pelvis hardly ever occurs there, I can only say that the clinical observation of normal and abnormal labor is still at a very low ebb in the whole of North America, with the exception of New York, Boston, and Philadelphia. Not alone are the majority of obstetrical wards very imperfect, but even in the larger services of this kind, for example, in the San Francisco County Hospital, they are entirely inaccessible to the student, and there is no question of the thorough working up of the material for observation there contained."

Certainly, this is a statement, *ex cathedra*. Professor Winckel's visit to the United States was of brief duration, and his reception by the profession was not remarkably cordial. In fact, until within a very recent period, he has been a comparatively unknown man in America. While in Chicago, unannounced he paid a visit to the Cook County Hospital, where he was hospitably received by one of the internes.

This recent graduate never having heard of Professor Winckel, politely conducted him

¹ Lehrbuch der Geburtshülfe. Leipzig: Verlag von Veib & Comp. 1889.

through the wards, and *en route* gave him some "pointers" on the preservation of the perineum and on the conduct of labor. The attention to these instructions was so close and so marked, that the young man, pleased with his attentive pupil, familiarly slapped Professor Winckel on the back, and cordially invited him to call again, to see some obstetrical operations!

Notwithstanding these severe and sharp animadversions, western obstetricians have given presumptive evidence of capability in their appreciation of Winckel's book. Publishers inform us that the sale of Edgar's translation is large and constantly increasing. Indeed, there are those in the trade that think this work will largely substitute American and English text-books. This fact, we regret, inasmuch as the book, taken as a whole, is inferior to at least two American treatises. The hearty welcome accorded Winckel's "Midwifery," we take it, is a typical example of the broad, liberal, American common sense, that quickly recognizes merit, totally irrespective of its source. In the light of Winckel's ungracious words, the large sale of the book is an instance of *noblesse oblige*, that the Germans would do well to imitate, seeing that, as at present informed, no similar case has been recorded in the annals of Teutonic medical literature.

Now, as to the truth or falsity of the allegation, we venture the opinion that midwifery, as an art, is carried to a much higher degree of perfection in America than on the Continent of Europe. With us, not only do women occupy a much more exalted position in the scale of human greatness, than in Germany or on the Continent generally, but also more or less highly qualified physicians replace more or less irresponsible midwives. It is then the natural and inevitable resultant of the conditions of our civilization, that our women should receive better care during confinement, than is the case on the Continent of Europe.

As to the infrequency of the contracted pelvis in the native-born American woman, that question was finally settled before the birth of Professor Winckel.

With us, the conditions of life among the working classes, both in cities and in the country, as respects abundant food, fresh air, and commodious dwellings above ground, are so favorable, that rhabdomyositis is very uncommon, and osteomalacia

almost unrecorded. With us, among primiparæ, "lightening before labor"—the engagement of the head and lower uterine segment within the pelvic cavity,—is a constant occurrence, and it affords a strong presumption that the passage is big enough for the passenger. We do not measure the pelvis, simply because experience has demonstrated that it is not, as a general rule, a necessary precaution.

While this arraignment of the obstetricians of the West, and of Canada, by Professor Winckel is in the highest degree presumptuous, unwarranted and in bad taste, it may be well for the profession to act upon the suggestion. It is right to be taught by an enemy. Unquestionably, pelvimetry is not practiced to the extent that it deserves application. As to the utilization of the material in our hospitals for the purposes of clinical observation and of instruction, that is utterly out of the question with our present Republican form of government and hospital system.

MOUNTAIN-FEVER OF COLORADO.

DR. L. HUBER has described the fever of the mountains as it occurs at an elevation of 4000 feet above sea-level, in the *Medical News*. The author resides at Rocky Ford, Colorado, at a point where a rich valley has been rapidly converted, under an irrigation-system, into a farming country. The climate is dry, almost rainless; the soil is dry and sparsely covered with vegetation prior to the introduction of irrigation for agricultural purposes; marsh lands and stagnant ponds are almost unknown; the river currents, flowing through well-defined channels, are strong and there is no stagnation whence effluvia of a malarial character would be expected to rise. The supplies of drinking water are drawn from the irrigation ditches, filtered more or less thoroughly and stored in cisterns; when carefully filtered and stored in clean reservoirs the water will remain clear, tasteless and odorless for months; it is however hard and is called "alkali water." Opposed as these conditions are, for the most part, to our preconceived notions of the habitat of malarial fever the author is clearly of the opinion that mountain fever must be grouped with the diseases owning a malarial origin. In confirmation of this opinion, he states that ague and typical remittent fever have been observed by him in persons who

have not been away from the lofty region, of which he writes, for a number of years; the cases were contracted there and the remittent type is not identical with that form of fever which is usually known as "mountain-fever." The symptomatology of the latter is sketched as follows: beginning with a premonitory chill or chilly sensations, a febrile stage is ushered in which is more or less marked and persistent. The temperature ranges from 102° to 105° at the onset, but ordinarily falls several degrees during the first week. Remissions may occur, but they are neither uniform, nor marked; intermissions will often follow the onset and continue for a week, if the case is untreated, when the fever will return and, assuming a continued type, persist for two to four weeks. There are often localized pains in the head, back and limbs, in children especially severe distress in the gastric region will be noticed; the headache is often excruciating. Shooting pains, passing up and down the spinal column are often quite marked. These symptoms may closely simulate those of spinal meningitis, and sometimes the patient may lose the power of voluntary motion. Tremor may exist. In adults the tongue is coated excepting the tip, and sometimes the edges; in children the enlarged papillæ project through the coating and the tip of the tongue becomes strawberry-like; a clean tip to the tongue is noticed in nearly all those cases that ultimately assume the typhoid type. The ratio of pulse and temperature is commonly normal, but the pulse may be slow. Nausea and vomiting are not infrequent, but they do not persist. The bowels may be either loose or confined, the latter state being more frequent among children and is difficult to regulate by medication. Liver and spleen may be enlarged. Tenderness in the right iliac region is infrequent, but tympanites may arise. Delirium is not usual, but when it does occur it is low and muttering. Bronchial irritation and cough are not infrequent. The conjunctiva is usually suffused, and may show slight signs of jaundice. In children the pupils are widely dilated. The skin is apt to continue dry while the fever lasts, sweating occurring when it abates. The disease often determines with a copious sweating and free action of the bowels and kidneys. Convalescence is slow and accompanied with a strong tendency to the development of a mild though obstinate quotidian

intermittent fever. Relapses are prone to follow at the septenary periods, unless the case is closely watched and treated; in view of which it is always well to continue the use of antiperiodics for two or three weeks after convalescence is established. The fever undoubtedly tends to a self-limitation, but it may be so thrown out of its course by perturbing treatment as to take a firmer hold upon the patient and to thus become more grave. On general principles it may be said that medication should be primarily directed to the maintenance of open emunctories and the elimination of the *materies morbi* through them. The action of quinine and its congeners cannot always be depended upon to check the fever, or it is slow in producing the desired effect; in the high altitudes where this fever is found these drugs often cause an unpleasant impression upon the nervous centres.

In conclusion, it may be said that the term "mountain-fever" is not peculiar to Colorado, although the name of that State is perhaps more frequently attached to the title of the fever than that of any other, but it is more or less known throughout the whole Rocky Mountain region, as a term for a disease which may or may not be one and the same for all those widely separated localities; there is room for a fuller and more accurate knowledge in regard to the fevers of our western ranges of mountains. Dr. Huber is of the opinion that he has met with the mountain-fever as far to the eastward as in the valley of the Arkansas river, in western Kansas, although it was not there known by that appellation. His later experience, for several years, in Colorado has convinced him of the identity of the fever in the two very dissimilar situations.

PSOROSPERMES IN RELATION TO DISEASE.

In a recent number of the *Archives de Médecine Expérimentale*, DR. MELASSEZ gives the history of his discovery of psorospermes in man, and especially in epithelioma. In 1885 DR. ALBARRAN brought an epithelial cancer, removed from the maxilla, for examination. The coccidia were found in the preparation, but as the neoplasm was ulcerated, they might have been introduced secondarily. Subsequently, in 1889, DR. DARIER gave him sections from an obscure cutaneous affection (Paget's disease), in which protoplas-

mic masses were found in the interior of the epithelial cells. These psorospermes, analogous to those found in the liver of the hare, were also found in old sections of epithelioma and of acne varioliformis. These discoveries were reported at the time, and subsequently WICKHAM found the psorospermes in a nasal epithelioma, and CORNIL, DARIER, THOMA and SJÖBRING have published observations confirming the discovery of these organisms in epithelioma from various localities.

Recently VINCENT, in a communication to the Société de Biologie, reported that in numerous examinations of sections of epithelioma from various localities, he found among the epithelial nests or in their vicinity, organisms that resembled psorospermes. These bodies, about the size of mucous corpuscles, are surrounded by a refractive membrane, sometimes thin, sometimes quite thick, according to the age of the parasite. The protoplasm is occasionally amorphous, though more often granular and sometimes pigmented. In the centre of the cell there is a nuclear mass, round, triangular, or vaguely polygonal; sometimes it is formed by a voluminous agglomeration of round granules. Usually the shape of the psorosperm is round, though this may be modified by compression. To detect them very fine sections should be rapidly passed through ammonia of 15.9 Boume, washed in water, colored for five minutes in a concentrated alcoholic solution of safranine; then partially decolorized in acetic acid, washed in water, and the decolorization completed in alcohol until the sections have a rosy tint; then immerse in oil of cloves, xylol and balsam. A double coloring may be obtained with fluoresceine or hæmatoxylin. The psorosperm, colored red, may be separated from the protoplasm of the cell in which it is included, by the retraction of its membrane from staining. It is not rare for some of the psorospermes to fail to take the staining fluid. Efforts to cultivate the psorosperm have not succeeded.

DR. L. PFEIFFER, in a recent brochure on protozoa as the cause of disease, states that where the psorosperm is included in a cell, sometimes the nucleus of the cell takes part in the hypertrophy. Sometimes it is atrophied, and the parasite, substituting itself for the cell, lives as a normal cell by borrowing the elements for its nutrition from its vicinage. Sometimes the germs

of the parasite are accumulated in the cell and a small number only are developed. In the latter case the infection is not very dangerous to the animal organism.

Organisms of this class have been found in several species of snails, in the intestine of mice (the *cimeria falciforme*), in the intestine and liver of hares, in the blood (diphtheria) and the tissues (variola) of birds. In man they seem intimately associated with the development of molluscum contagiosum, Paget's disease and epithelioma.

EDITORIAL NOTES.

WAITING FOR THE VERDICT.—By cable dispatch to the New York Associated Press, we learn that on November 22, the Emperor of Germany bestowed the Grand Cross of the Order of the Red Eagle upon Robert Koch. This is the first time that this decoration has been bestowed upon any one who did not possess the preceding classes of the order. We further learn that Prof. Koch disclaims responsibility for the statements put in his mouth in regard to his experiments. He blames the press for raising exaggerated hopes of instant benefit in every form of tuberculosis. Prof. Virchow, speaking in the *Medicinische Gesellschaft*, referred to the subsidence of the enthusiasm, but defended Prof. Koch against the charge of prematurely publishing his discovery. Prof. Koch, he said, only consented to the disclosures already made at the request of Minister von Gossler and several of his medical colleagues, Drs. Virchow, Levy, and Bergmann. Every one in Prof. Koch's confidence supports his protests against the sensational anticipations regarding the results of the remedy.

Meanwhile unreasonable complaints are coming to the surface of want of accommodations for tuberculous patients in Berlin, as well as a clamor regarding favored doctors, stinted lymph supply and unseasonable climatic conditions. Much dissatisfaction is also expressed that the seal of secrecy has not as yet been removed, so far as the modes of preparation and the essential elements of the discovery are concerned.

We deprecate the absurd rumors and immature opinions that are dispensed in the interviews of the secular press, both at home and abroad, as calculated to wreck a really great reputation. Koch has been so free from the juggleries of the

charlatan, and withal such a candid investigator that we think that any imputation of concealment an aspersion. At all events the same military government which recognized the talents of a Moltke, has still further and more nobly honored itself in the decoration of Koch, not so much for what is expected as for what has already been done. Having the rights of a benefactor, and being an honest man, he may be safely entrusted with a choice of methods. As yet, he has not had the benefit of a further and fuller statement, so that none of his critics can claim any privileges until Koch himself is ready with his case before a jury of his peers. His opinions are always entitled to respect if not to full credence. Claiming so little for himself and never with the blare of the trumpet, he unconsciously presents to the world the type of the ideal physician.

UN SOUND ATHLETICISM.—A sanitary census has recently been made in an athletic club of New York City, and it was shown thereby that it had quite a number of damaged members. Out of thirty-three all-round athletes in the club five years ago, three had died by consumption, five have to wear trusses for hernia, four or five are lop shouldered, and three or more have impaired hearing and catarrh. For robust health and longevity it is best not to look among those who go their full lengths in modern systems of athleticism.

LOSS OF LIFE ON ENGLISH RAILWAYS.—The *British Medical Journal* has pointed out the frequent occurrence of railway accidents that are directly or indirectly due to intemperance in alcoholic drink among the employés of the companies, and has recommended that the example set by a number of American companies should be followed, who have adopted special rules to secure sobriety on the part of their workmen. This has been done, according to the *Journal*, because it has proved to be the best guarantee against accident; fifty-four companies insist upon total abstinence among their men, while on duty; and twenty companies, while "on duty and off;" and one company will not engage any who are not total abstainers.

A new departure in cremation is reported. A patent has been taken out in France for an electric furnace for the rapid incineration of human remains.

TOPICS OF THE WEEK.

LEPROSY IN THE REPUBLIC OF COLUMBIA, SOUTH AMERICA.

The local authorities have drawn attention to the alarming spread of leprosy lately in this republic. It is impossible to obtain reliable figures, but putting the entire population at 6,000,000 inhabitants, the lowest estimate gives 18,000 lepers. The tuberculated, non-tuberculated, and mutilating forms are all met with, the tubercular form being the most common.

In this country, the disease occurs chiefly in places having a temperature of 73° F. to 64° F., damp and low-lying districts being especially favorable for the development of the disease; whilst places having a temperature of 80° F. and upwards seem to have some influence in mitigating the course of the disease. This is seen in the Government lazaretto at Agna-de-Dois, two and a half days' journey from here. Here the unfortunate victims undoubtedly obtain some relief from their sufferings, and in some cases improve sufficiently to be able to earn their own living, though no systematic course of treatment is adopted at that establishment. Very few cases are reported from places having a temperature of 80° F., and of those cases nearly all said to have contracted the disease in colder climates.

In favor of the contagious nature of the disease there is the strongest evidence. In districts in which the disease was formerly unknown, it has appeared and spread with great rapidity, the first cases appearing shortly after the return of former inhabitants of the district who had contracted the disease in a distant province, but contagion seems only to have occurred where the leprosy and healthy lived together on terms of great intimacy, eating and drinking out of the same vessels and using the same clothes. On the other hand, where more attention was paid to cleanliness, cases are recorded where the healthy remained unaffected.

As regards the hereditary aspect, no case is recorded of children being born leprosy, but the offspring of lepers have become lepers generally about puberty or a few years later, though some show signs as young as 6 years of age; but considering the bad hygienic conditions generally present, many of these so-called hereditary cases may really be due to contagion.

As to articles of diet, the greater number of cases occur where fish cannot be obtained; in these places, hog's flesh in various forms, impure water, the immoderate use of cayenne pepper and *chicha*, a drink made from the fermentation of maize, are considered as favorable to the development of the disease.

The race most frequently attacked are the whites, next the mixed Indians and whites, then the pure Indian, and finally the (African) negro race, which seems to be the least frequently attacked.

The principal other diseases occurring in leprosy districts are, in order of frequency, malarial fevers, various hepatic diseases, dysentery, rheumatism, and scrofula.

That localities of a certain temperature, namely, from 64° F. to 73° F., are the most infected districts there is no

doubt; and it is popularly believed that sudden changes of temperature from heat to cold are frequently the means of producing the disease.

And another factor I believe in producing the disease, speaking, of course, of Columbia, lies in the poor and insufficient food, bad ventilation, and the overcrowding, so common among the poorer classes in this country.—Dr. Edward H. Hicks, of Bogota, *Brit. Med. Jour.*

THE "MORGAGNI" AND "LISTER" BAS-RELIEFS AT ROME.

The *façade* of the Policlinico now advancing to completion at Rome will, as we have already stated, consist of two parts—one representing the medical, the other the surgical, wards of the institution. The former will have as its distinctive ornament a bas-relief in honor of John Baptist Morgagni, the Father of Medical Pathology, and five of the leading sculptors of Italy have sent in their designs for the subject prescribed by the "Commissione Giudicatrice" the well-known artists Bartolini, Basce, Pizzichelli, Zocchi, and Ximenes being the competitors. The subject is "Morgagni delivering a lecture in the Pathological Theatre." The decision of the "Commissione" will shortly be announced, and we can only say at present that Ximenes, by his own consent, has been withdrawn from the competition. The bas-relief for the surgical *façade* will represent the "Father of Antiseptic Surgery," also in a characteristic *pose*, and the competing sculptors engaged on it have to send in their designs at an early date. The names of the sculptors and the artistic effects they seek to convey we shall then be able to give.—*The Lancet.*

PHYSICAL EDUCATION.

Civilized man often tends to begin at the wrong end of things; or, at least, while striving for a desirable end, to ignore some essentials for success, simply because, viewed in the faulty perspective of civilization, they seem inconspicuous. The discussion on the claims and limits of physical education in schools, published in the *British Medical Journal* of November 1, is to be doubly welcomed; for it proves not only the existence of a hiatus in the educational system which obtains amongst us, but indicates that amongst those best qualified to recognize that lack there is now aroused an interest so deep and widespread as to afford good hope of its being made good ultimately. While many people have hitherto been content to forget that education can really be only the "bringing out" of the latent power and the proper guiding of the innate tendencies of the individual, still more have overlooked the fact that this nursing and training process is not merely applicable to, but actually necessary for, body as well as mind. Savagedom compels the one; civilization implies the other; but, as a broad rule, either tends to exclude the other in these two opposite conditions. Each chapter of the world's story is a repetition of the fact that, after a nation has emerged from barbarism, there comes a stage in its history in which the physical perfection essential to the successful savage dwindles in proportion to the attainment of more intellectual culture by the individual. In the age-long race between the nations, stamina must tell no less than

speed; and the intellectual spurt must fail if the general staying power of the race is progressively diluted by those less vigorous individuals whom a one-sided system of education unfits for protracted struggle, while the amenities of a modern civilization protect them from extinction.

The safeguard against this danger clearly lies in the systematic carrying out of the physical side of true education, begun in the earliest years of life, and applied in appropriate fashion to both sexes. It may be easier to begin at the top, and the examples set by the larger and the older schools undoubtedly influence the rest; but permanent success can only be attained by working from the foundation upwards; by making due care of the body such a habit of the child that respect for the body and a just pride in the exercise of its full powers shall be ingrained in the moral nature of every man and woman. A full realization of these facts will supply the modern *paterfamilias* with a satisfactory answer to more than one aspect of his recurrent question, "What to do with our boys"—and girls?—Editorial, *Brit. Med. Journ.*

ENCOURAGE HOME SCIENCE.

When we read of the encouragement Koch is receiving from the German government, of the clinical material, laboratory facilities, and funds placed in profusion at his disposal, we are constrained to admit that there are elements of value in the paternal style of government. Nobody grudges the little bit of taxes that goes to such a purpose. But here, where everything is left to individual exertion, too often it is seen that what is everybody's business is assumed by nobody. The importance to humanity of such investigation as Dixon's cannot be overestimated. Not all the wars, nor all the pestilences, "since first the leaky ark reposed in the mud," have destroyed a tithe of the lives that have fallen victims to the tubercle bacillus. Not a home exists but has put on mourning for some loved one dying from consumption. Yet not an effort is made to put our own countrymen on an equality with the European investigators, as regards facilities for this work.—*Times and Register.*

OLIVER WENDELL HOLMES "DE SENECTUTE."

The present age is remarkable, among other things, for the physical and intellectual vitality of its old men. It is not only that—thanks to the advance of medicine, preventive and curative—we have more old men amongst us than formerly, but that, so far from lagging superfluous on the stage of life, the veterans continue to play most of the principal parts with all the ardor, and sometimes more than the versatility, of youth. In all departments of modern life—in politics, in the Church, in the army, in science, and in literature, we see men whose years are far beyond the psalmist's limit predominant not only in influence and reputation, but in the amount and quality of their actual work. Among the octogenarians on whose mental brow time writes no wrinkles, none is more interesting to medical men than the genial "Autoerat" of so many hearts both in England and America, whom, in spite of the poet's days which he wears so gracefully, we are proud to claim as a professional brother. Oliver

Wendell Holmes, who celebrated his 81st birthday on August 29, is still one of the most vivacious of men; age cannot wither the freshness of his interest in life, nor deaden the cheerful sparkle of his style. Even of "crabbed age" and the inevitable sorrows and bereavements which it brings with it he writes with an easy wit, quite untinged with cynicism, which *circum prœcordia ludit* and brightens the dismal subject so as to make it amusing even to his fellow-sufferers. From the purely medical point of view his account of his mode of life is instructive as well as interesting. For a long time back, he says, he has taken extreme care of himself. Never robust, he was still wiry in his earlier and maturer life; but since he reached the age of 80 his hygienic vigilance is unceasing. The rooms which he daily occupies are equipped with barometers, thermometers, aërometers—with every kind of instrument, in short, to prevent his incurring the slightest risk of taking cold. As pneumonia is the deadliest foe of old age, he does his utmost to keep it at a distance. He never gets up during winter until he knows the exact temperature, or takes his bath without having the water accurately tested. He lives by rule, and the rule is inflexible. His time is scrupulously divided—so much allotted to reading, so much to writing, so much to exercise, so much to recreation. His meals are studies of prudence and digestion. He understands the specific qualities of all ordinary foods, and never departs from the severest discretion in eating. To this strict hygienic discipline Dr. Holmes attributes his good health and the retention of his mental vigor.—*Brit. Med. Journal.*

A BACTERIOLOGICAL INSTITUTE AT ST. PETERSBURG.

By the munificence of Prince Alexander Petrovitch of Oldenburg, the Russian capital will soon have a well-appointed institution for the study of bacteriology. The institution, which is to be on a magnificent scale, will comprise operating and lecture rooms, private rooms for the professors, large laboratories, fitted with every requisite for research and supplied with abundant material, special rooms for microscopic work, etc. The building will be lighted throughout by electricity. The material, as well as the intellectual, needs of the workers, are to be provided for by refreshment rooms, buffets, and even bedrooms. The total cost of the institution is estimated at 1,650,000 francs (\$330,000).

CONTAGIOUS TUBERCULOSIS.

Dr. Ollivier has recently reported a case of contagious tuberculosis. A family of seven occupied a house at Neuilly. In two years five out of the seven were attacked with tuberculosis; two are dead and three are seriously ill. The house had formerly been occupied by a family suffering from tuberculosis; in 1887 a child died in it from that disease. It is supposed that this case, which was the first, is the origin of the contamination. Dr. Ollivier concludes that it is dangerous to inhabit a house which has been previously inhabited by tuberculous patients, unless it be thoroughly disinfected. The paper should be stripped off, and the walls whitened with lime; the wainscotting and floor should be scraped and washed with a 1 in 1,000 solution of corrosive sublimate.—*Medical Record.*

PRACTICAL NOTES.

TREATMENT OF THE ALGID STAGE OF CHOLERA.

In the Fiume Hospital the method by which the algid stage of cholera was treated during the last epidemic was by giving gum ammoniac internally, together with stimulants, and injecting sulphuric ether hypodermically. According to Dr. Ritter von Giacich, the director of the hospital, this plan, which was always adopted, proved most successful, a great improvement taking place in 50 per cent. of the cases in a couple of hours' time. This made itself manifest, not only by a rise of temperature and a stronger pulse, but also by the expression of the face becoming less pinched and anxious, after which the patient made good progress towards convalescence. Warm baths were often administered with advantage. Where three hours elapsed after the treatment above mentioned without manifest improvement, the case always proved fatal.—*Lancet*.

FOR a child, 8 years old, suffering from debility after an attack of acute Bright's disease, Hollofer prescribed the following:

- R. Tr. Ferri chlor., ℥j.
Acidi acetici, ℥ij.
Strychniæ sulph., gr. ⅓.
Liq. ammon. acet., ℥iiss.
Syr. toltani, q. s. ad. ℥iij.
℞. Sig. ʒj every four hours.

CHLOROFORM IN CONVULSIONS.

Inhalations of chloroform are invaluable in arresting convulsions in children of 2 years or under. Give them a whiff of it while in the convulsion. The paroxysm having been broken, the following should be given to prevent recurrence:

- R. Sodii bromidi, ʒj.
Chloral hydrat., ʒss.
Aq. menthæ pip.,
Syr. toltani, āā ℥iv.
℞. Sig. ℥ss; one every half hour until child is quieted down.

—*Times and Register*.

SULPHONAL IN DIABETES.

Dr. Casarelli, of Pisa, mentions the favorable action of sulphonal in diabetes. This drug diminishes the quantity of sugar in the urine, also reducing the polyuria and the thirst. These results were obtained by doses of from 5 to 30 grs. per diem, but not to so marked a degree as with doses of 45 grs. continued for several days. The 30-gr. doses could be administered for some time without any ill effects; but although the 40-gr. doses at first caused no disturbance, it was found that, when they were continued for any length-

ened period, they caused giddiness and excessive sleepiness, which disappeared when the drug was discontinued. Sulphonal was used with good results in conjunction with both a mixed diet and a strictly meat diet; in the latter case a large quantity of sugar appeared in the urine as soon as the sulphonal was stopped. In the only case in which antipyrin had been previously used it was found to exert less influence than sulphonal.

IN a severe case of acne associated with rosacea Shoemaker advised and prescribed as follows: Wash the face in hot water, as hot as can be borne. Drink a cupful of hot water upon retiring and upon rising. Have the pustules punctured by a physician; the incision thus produced will not cicatrize, whereas, if they are squeezed, they heal with a scar. Take internally:

- R. Liq. potassii arsenitis,
Tr. nucis vomicæ, āā gtt. lxxij.
Aloiii, gtt. ij.
Aq. menthæ pip., q. s. ℥iij.
℞. Sig. ʒj ter in die.

Apply externally:

- R. Acidi borici, ʒj.
Lauolini, ʒij.
Ol eucalyptol, gtt. v.
Ung. zinci oxidi, ʒj.
Bismuthi subnit., ʒj.
℞. Sig. Ft. unguentum.

—*Times and Register*.

DR. HARE gives for acute stage of bronchitis in children:

- R. Tr. aconiti, gtt. xij.
Syr. ipecac. ℥ss-ʒj.
Liq. potassii citratis, q. s. ad. ℥iij.
M. and S. One teaspoonful every three hours.

For the later stages:

- R. Ammonii chloridi, ʒj.
Ext. glycyrrhizæ fl., ℥iv.
Aquæ dest., q. s. ad. ℥iij.
℞. and S. One teaspoonful three times a day.

FOR PAINFUL SKIN DISEASES.

- R—Salolis, gr. x.
Plumbi carbonat., ʒss.
Ung. mentholis, ʒss. ℞

Menthol ointment contains five to fifteen grains of menthol to the ounce.—Shoemaker, *Times and Register*.

A FORMULA FOR INSECT BITES.

One of the very best applications for the bites of mosquitoes and fleas, also for other eruptions attended with intense itchings, is: Menthol in alcohol, one part to ten. This is very cooling and immediately effectual. It is also an excellent lotion for application to the forehead and temples in headache, often at once subduing the same.

SOCIETY PROCEEDINGS.

Southern Surgical and Gynecological
Association.

Third Annual Meeting, held in Atlanta, Ga., November 11, 12 and 13, 1890.

(Concluded from page 806.)

SECOND DAY—AFTERNOON SESSION.

DR. W. O. ROBERTS, of Louisville, read a paper on

REMOVAL OF STONE FROM FEMALE BLADDER
THROUGH THE URETHRA, WITH CASES.

This paper was devoted simply to his individual experience in the extraction through the urethra of stone from the bladder of the female. The cases thus treated were six in number; the ages of the patients ranged from 15 to 56 years. Four were married, but only two had borne children. The stones were phosphatic in four cases, uric acid in one, and an incrustated fringed body in another. In one, a very hysterical patient, the stone had for its nucleus a piece of soft wood. In one the patient had a vesicovaginal fistula which had been closed by an operation some months prior to the occurrence of the symptoms of stone. In another the bladder had been opened by a surgeon in doing an ovariectomy upon the patient a year before the stone was discovered.

In four of the cases the stones were single, in one there were two, and in one nine. In this case the patient had passed at various times a number of small stones, from two to seven at a given micturition. These stones varied in size from that of a grain of wheat to a grain of coffee. In two years she had collected 184 stones, a number not representing all she had passed.

The extraction was done in every case under chloroform, the patient being profoundly anesthetized. The urethral dilatation was begun with forceps, and completed by means of the fingers. The little finger being first introduced, the ring finger next, and finally the index finger. The fingers were well oiled. In Case 1 the stone was found to be almost an inch and a half in diameter. In Case 2 the stone was found in the urethra, and proved to be a piece of soft wood heavily incrustated with urinary salts. In case 3 the stone was spherical, and had a diameter of about one-half inch. In case 4 the stone was ovoid, its long diameter being an inch, the shorter three-fourths of an inch. In Case 5 there were nine stones, the smallest measuring circumambiently two and one-fourth inches; weight eighty-four grains.

DR. WILLIAM PERRIN NICOLSON, of Atlanta, Georgia, presented a paper entitled

WET ANTISEPTIC DRESSINGS IN INJURIES OF
THE HAND.

After dwelling upon the importance of the subject, both from the standpoint of the future earning capacity of the patient, and the large amount of financial compensation demanded from corporations, he stated that for seven or eight years past he had looked after the surgery of several railroads and manufacturing establishments, and in that time had been called upon to treat more than three hundred hand injuries, representing all grades of injury from slight contusion to complete destruction of the larger part of the hand. The especial point that was urged in the paper was the doctrine formulated by Verneuil—*never to use a scalpel in a hand injury*. The old teaching, that when a finger was crushed you should go far enough behind the injury to secure a sound flap and amputate, was pernicious in the extreme, and had cost thousands of fingers that would have been restored to usefulness. Only such parts as were actually destroyed and pulped should be removed, and all the tissues to come away could be amputated with the scissors. Projecting pieces of bone could be removed with pliers until reduced to the level of the fleshy parts. In compound fractures the parts should be coaptated as well as possible, and the line of separation be determined by nature, and under strict antiseptic dressings. Such a slough was harmless. Another point to which attention was forcibly called was the utilization of blood clot in filling up ragged injuries, and by its substitution the restoration of lost parts. When a finger was crushed off, the end should be trimmed with scissors, and the clot utilized in building up a tissue over the bone. In reference to dressings, Dr. Nicolson said that he had tried almost all varieties, and had finally obtained the most satisfactory results from keeping the parts constantly bathed in a non-poisonous antiseptic solution.

In dealing with these wounds they were first cleansed as well as possible, and then bathed in sublimate solution. Over all wounds a piece of aseptic rubber tissue or oiled silk was placed, then iodoform and sublimate gauze, and finally over all a covering of rubber tissue, into which at some convenient point a small opening was made. The patient was then given a bottle of antiseptic solution, to be carried in his pocket if moving about, and instructed to pour at frequent intervals enough into this opening to saturate the dressings. He uses almost exclusively listerine, combined with a small amount of carbolic acid, in the proportion of half an ounce of the former and half a drachm of the latter, in a six ounce mixture. If there was much pain, a small amount of aqueous extract of opium was added. These dressings were not disturbed until the third day, when they were removed under antiseptic, to preserve the integrity of the blood clot.

Wet dressing was substituted at the end of about a week by the ordinary antiseptic dressings, kept moist by external covering of rubber tissue. Should sloughing occur, it is kept wet for a longer time by the antiseptic. Under this treatment pain was reduced to the minimum. Suppuration never occurred, and the separation of sloughs was facilitated by the warm moisture.

DR. T. J. WILSON, of Sherman, Tex., read a paper on

UTERINE MOLES AND THEIR TREATMENT.

In the few cases that have come under his observation, they have been more troublesome and elicited more anxiety than most writers indicate they should, and the hæmorrhage in some of the cases was alarming. Then, too, there were some points noticed in his cases which he had failed to find described in text-books.

All authorities seem agreed upon the etiological and pathological view generally taken of it, that it is a blighted or altered conception; the ovum having perished, its covering or the placenta, if formed when this change takes place, becomes attached to and continues to receive nourishment through the uterine walls, and remains or becomes an organized product until it is thrown off; and this condition is attributed by some to the vitality retained in the villi of the chorion.

He had never met with a case that was lying loose in the uterus, but all were more or less adherent to its walls, and most of them to the posterior wall. They had to be taken away piecemeal, and the surface well curetted, washed out, and carbolic acid or Churchill's iodine applied to the surface. They all require after-treatment, because all except one case of hydatiform mole had endometritis and endocervicitis, two had severe cervical lacerations and erosions. Most of them had a greater flow than usual at the subsequent menstrual periods until the inflammatory condition was relieved. In two cases the general health, while not robust, was fairly good; the others more or less delicate, none of them in perfect health. None had any history of a cancerous cachexia nor of syphilitic taint; one was tuberculous. His experience had taught him to believe that if these cases do not receive treatment at a proper time there are two great dangers to be apprehended, viz.: hæmorrhage, which, if not an immediate cause of death, is capable of leading indirectly to that end—and septic poisoning.

In the treatment, if the cervix is sufficiently dilated and hæmorrhage troublesome, the mass should be promptly removed. If this cannot be done, a hot antiseptic douche should be given, followed by a careful and efficient tampon, with the internal administration of ergot and anodynes if required, directing quiet, rest and simple diet. In from twelve to fifteen hours the tampon should be removed and the foreign body extracted as

completely as practicable; this will require a good stout pair of forceps. He had used the ordinary dressing forceps and placental forceps, for the purpose. An excellent instrument in some cases is Emmet's curette forceps. The surface should be well curetted with a wire curette, the uterus thoroughly washed out with a hot solution of bichloride of mercury, and Squibb's crude carbolic acid or Churchill's tincture of iodine well applied to the surface. If much bleeding ensues—and this is not usual—the application of persulphate or perchloride of iron gives good results. The patient is put to bed and kept there as long as the indication in each special case may require. She is put upon a tonic treatment, and hot vaginal antiseptic washes. In from three to five days the uterus may need curetting again and another intra-uterine douche; then the application of iodine about twice a week, alternated occasionally, perhaps, with carbolic acid as long as may seem necessary, and the cure, if possible, completed of any uterine disease that may exist. The patient's general health is carefully looked after and her mind tranquilized.

THIRD DAY—MORNING SESSION.

DR. G. FRANK LYDSTON, of Chicago, read a very elaborate and lengthy paper entitled

A REVIEW OF THE TREATMENT OF VARICOCELE, WITH CASES.

He said, in discussing the merits of various operative procedures, it was unnecessary to take them up in detail. The *raison d'être* of many specially devised and named operations is apparent only to the operator. For practical purposes the various methods may be divided into, 1, acupressure; 2, subcutaneous deligation; 3, open deligation; 4, deligation with resection of veins; 5, deligation with resection of scrotum; 6, resection of the scrotum.

The employment of acupressure, to Dr. Lydston's mind, was an evidence of a lack of faith in modern antiseptics. It reminded him of the Dutchman's method of cutting off his dog's tail an inch at a time so that it would not hurt him so much. Gradual obliteration of veins has all the dangers of immediate deligation in a marked degree, and had none of its advantages. The term acupressure covered practically all methods of gradual obliteration of the veins of which Davat's operation is an illustration. Subcutaneous deligation is not essentially dangerous in skilful hands. Simple as the operation appears, however, accidents have occurred. The operation is done in the dark and more tissue is included in the ligature than is necessary. Strangulation of tissue is not conducive of safety. Scrotal hæmatocele, phlebitis, septic infection, thrombosis and embolism are possible. The vas deferens has been included in the ligature. He does not

condemn the subcutaneous operation in suitable cases, and in skilful hands, but he believes there are better and safer methods on the average. There is little choice between deligation without disturbance of the veins and deligation with resection of the veins, excepting the remotely greater danger of sepsis in the latter. Gould's method of division by cautery he believes to be the most dangerous operation yet devised. The dangers of the open method are in a less degree those of the subcutaneous deligation. If open deligation be determined upon, the operation should be done as high up as possible in the straight portion of the veins, and a single ligature applied to the vein. Deligation with resection of the scrotum he considers to be the ideal operation, in the majority of cases requiring surgical interference. His plan is as follows: An incision is made parallel with the spermatic cord, just below the external ring. This incision should be about one inch in length. The cord is hooked out with an aneurism needle, the vein separated and tied, the ligature is cut through and the cord dropped. Sutures and antiseptic dressings complete the operation. The scrotum is now amputated by the improved Henry operation. Dr. Lydston uses decalcified bone drainage tube, and juniperized silk ligatures and sutures. Resection of the scrotum he considers the simplest and safest operation for varicoceles of moderate size. In the more marked forms the affection invariably recurs to a greater or less extent. He does not, therefore, consider the so-called Henry operation a radical cure in the true sense of the word. The author reported a large number of cases operated upon by various methods with results, and, as far as could be learned, the subsequent history of the patient. The author had noticed hydrocele as a result of subcutaneous deligation in two cases, one operated upon by himself, and the other by another surgeon. The doctor reported one very interesting case in which the scrotum was continually bathed in bloody perspiration, and in which the seminal ejaculations were heavily tinged with blood.

DR. WILLIS F. WESTMORELAND, of Atlanta, presented a paper on *Morbid Reflex Neuroses*.

DR. GEO. A. BAXTER, of Chattanooga, read a paper on

SILICATE OF SODA; SOME NEW METHODS OF USE
IN SURGERY,

in which he said the jacket of baked silicate of soda which he would present to the Association possessed all the qualities to be found in the plaster, firmness and support, and weighs actually one pound and six ounces. It is neater in appearance and finish, can be perforated like leather for ventilation, which plaster cannot. It is even lighter than leather without its costly process of construction, and has the same advantage over

the woven wire jacket with the additional advantage over both these latter and all others of this class, that it can be constructed by any surgeon at any time or in any place. Dr. Baxter suspends his patient and puts roughly a plaster jacket around her and cuts this as soon as it has hardened enough to retain its shape, hereby lessening materially the time of suspension, the most trying ordeal with this or the plaster, and not without its dangers when long continued,—bind the cut edges together where it has been cut down directly in front with cords, and then place a core of paper in the center. This paper core is used for two reasons: 1, to heighten the cast and take as little plaster as possible, and 2, to dry it the more readily by heating the inside. This done, the plaster is poured around the core and inside the cast, which gives him a mould of the body in extension and counter-extension, exact in every respect. Around this is made the silicate jacket after the manner of the plaster roller bandage, weaving one-half inch metal strips in the meshes of the bandage at a distance of four inches apart around the whole cast, an inside lining of a knit shirt having been first placed over the cast. The whole is then placed over a coal oil stove and allowed to dry out, which it does in from one-half to two hours less, especially if the cast has been previously dried. This process of heating not only dries the silicate, but bakes it well, and renders it impervious to the action of water or the perspiration, and gives it sufficient strength to allow of it being perforated for ventilation. It is now cut from the mould with a straight incision down the center, two pieces of leather, to which button, hooks or eyelets have been previously attached, sewed up and down the front on each side, then the whole can be laced up solid or loosened and taken off at will. The necessity of taking off a jacket or leaving it on during the whole course of treatment will, of course, depend upon the character of the disease and of the injury under treatment.

DR. EDWIN RICKETTS, of Cincinnati, Ohio, contributed a paper entitled

SURGERY OF THE GALL BLADDER,

in which he said to Langenbach was due the credit of totally extirpating the gall bladder, and to J. Marion Sims we owed a debt of gratitude for establishing the operation of cholecystotomy.

Dr. Ricketts reported seven cases of gall stones.

Case 1.—Mrs. ———, aged 38, married, consulted him in 1880, for a tumor in her right side in the region of the gall bladder. Said she had passed by the bowel, following a severe attack of hepatic colic, a number of gall stones. She was emaciated and suffered from what she claimed was neuralgia of the stomach. She was slightly jaundiced and bowels constipated. Upon examination of the abdomen the tumor was well marked

and nodulated, above which was the liver surface smooth. He made the diagnosis of gall stone, and urged an operation. The patient's physician, however, urged the expectant plan of treatment which was accepted by the patient. She then went to the country and in less than three months had an attack of hepatic colic, followed by peritonitis, dying inside of three days.

Case 3.—Ellen ———, colored, age 50, consulted him for a markedly distended gall bladder which made its appearance after a hard day's work over the washtub. She had been sick for ten days with fever, temperature reaching 103°, rapid pulse, clayish stools, with occasional attacks of hepatic colic, though not severe. He opened the gall bladder, turning out one pint of fluid which consisted of bile, mucus and pus, stitching the gall bladder up against the peritoneum. After three days catarrhal plugs were washed out of the common duct through the abdominal incision in which had been deposited a glass drainage tube. The fistulous tract is still open, discharging periodically, but with no bad results to the patient.

In *Case 4*, a diagnosis of cancer of the liver was made by the attending physician. The gall bladder was opened and the stone turned out weighed 128 grains, and the common duct was filled with catarrhal deposits.

Case 5.—After incising the gall bladder there escaped first about one drachm of pus, after which Dr. Ricketts turned out 23 stones. A diagnosis of cancer of the liver in this case was made by the attending physicians.

DR. HUNTER P. COOPER, of Atlanta, Georgia, reported a case of *Fracture of the Femur due to Fragility*.

DR. GEO. H. NOBLE, of Atlanta, followed with an illustrative paper on *Proccidentia Uteri*.

THIRD DAY—AFTERNOON SESSION.

DR. W. HAMPTON CALDWELL, of Lexington, Ky., read a paper on

RECTAL MEDICATION,

in which he said that several years ago he was convinced of the utility and safety of rectal administration of medicine, and had ever since regarded it as a most important plan of treatment. Since we accept the theory of the local origin or manifestation of the majority of diseases, this idea of rectal administration of medicines was more readily accepted as scientific in its applications than at any time heretofore. The rectal suppository consisting of cocoa butter, incorporated with the various therapeutical agents, affords the most efficient and pleasant mode of administration in our possession. Rectal suppositories satisfy all requirements as a local or constitutional remedy. They are neat, convenient, and in almost every

instance preferred by the patient to the administration of the same drug by mouth. In the administration of the anodynes it is certainly a superior method of administration of all others, as the sensitive stomach is no longer a barrier or excuse in the administration of even the most disagreeable medical agents, for we well know in many instances that this organ is either tolerant to opiates, or the patient has an invincible objection to taking them, the impossibilities of the rectal administration being thrown up is one great advantage over all other methods of administration. The effects of rectal medication embrace a wide range of actions, including anodyne, antiseptic, alterant and astringent. In severe pain they certainly afford the best and safest source by which our patient's suffering can be relieved, as the action upon the rectal surface of a diffusible anodyne is quite rapid and produces an effect about as soon as when administered by the stomach. In all inflammatory or painful affections of the abdominal or pelvic organs, this plan of administration has succeeded better than all others with the author.

DR. THAD. A. REAMY, of Cincinnati, Ohio, reported a case in which he removed a stone weighing 365 grains, by vaginal cystotomy, from the bladder of a child six years of age, with injury of the ureter. Operations done for closing the bladder were difficult, but ultimately successful. He exhibited the stone and made some comments on the case.

He felt after the stone was removed, that it would have been better to have made supra-pubic cystotomy. Had he known the size of the stone, he would have probably done that operation. But in view of the fact that it was partly encysted, that the bladder walls were much inflamed and thickened, also the fact that in the child the parietal peritoneum dips much lower down in front of the bladder than in the adult, it became a serious question whether this course would have been better than the one pursued.

It was not clear whether the ureter was damaged in the removal of the stone, or was exposed by the sloughing which occurred much later on. He was inclined to favor the former view, and that the discharge of urine into the tissues of the bladder wall, in the line of suture, was to no small degree responsible for some of the failures in closing the bladder. However, until the last operation the most critical examination failed to discover the ureter.

Though Parvin, Campbell, and others have turned an exposed ureter into the bladder the speaker was not aware that it had heretofore been done in a subject so young. The vagina being so small, rendered the manipulation difficult in the extreme.

DR. JAMES A. GOGGANS, of Alexandria City, Alabama, read a paper on

THE SURGICAL TREATMENT OF EMPYEMA.

He said during the last eighteen months he had treated six cases of empyema which developed in the wake of pneumonia, all of which have made perfect recoveries. These patients varied in age from 3 to 35 years.

Surgical treatment was the one which has been the most successfully employed. Spontaneous cures, he said, were rare—so rare that surgical interference was the rule. There were many methods of operating for the removal of pus from the pleural cavity, but they may be classified under two general headings: 1, The closed method, which consists in removing the pus by simple puncture with some kind of trocar or modern aspirator and allowing the puncture to heal at once. 2, The open method which consists in making an incision more or less free with the introduction of some kind of drainage tubes to maintain the perfect evacuation of the fluid, and admit of medicated washings, and to promote free ingress and egress of air that has been passed through an antiseptic dressing. The surgical treatment then being an absolute necessity, we cannot overestimate the importance of making the diagnosis certain by resorting to exploratory puncture with a hypodermic syringe. We can assure the patient and friends that no evil results can come from this procedure, and that the prognosis positively depends upon this means of settling the diagnosis.

OFFICERS FOR 1891:

President.—Dr. L. S. McMurtry, Louisville, Ky.

First Vice-President.—Dr. J. McF. Gaston, Atlanta, Ga.

Second Vice-President.—Dr. J. T. Wilson, Sherman, Tex.

Secretary.—Dr. W. E. B. Davis, Birmingham, Ala.

Treasurer.—Dr. Hardin P. Cochrane, Birmingham, Ala.

Place of meeting, Richmond, Virginia, second Tuesday in November, 1891.

NEW INSTRUMENTS.

VON KLEIN'S INTUBATION THIMBLE.

BY CARL H. VON KLEIN, M.D.,
OF DAYTON, O.

Among the most treacherous looking instruments in intubation of the larynx is the gag, and those who have performed the operation frequently know that there is nothing so shocking to the parent's feeling as when the gag is applied and slips, which in nine cases out of ten will produce bleeding of the gums, and when blood is seen they will beg, "Doctor, don't torture it, let

it die;" while in reality they are not hurt, but a slight bruising of the gums. However, I have had cases where the teeth broke out, and especially when the alveolar process of the maxillæ was very light the teeth turned out. I have of late

FIGURE 1.

become so disgusted with the gag, that I have intubated without, and have taken the chances of being bit. In one case I was badly bitten. I have now devised a thimble as shown in Fig. 1. Which is placed on the left index finger with which the glottis is elevated; hence, I perform with the finger two functions: the thimble on the first joint from the metacarpus as a gag, and with the two other joints to elevate the glottis as shown in Fig 2.

FIGURE 2

The thimble is made of coin silver and heavy enough to prevent bending it together with the teeth.

When the intubation is performed I pull the finger out and leave the thimble between the teeth, which the patient soon lets fall. The instrument will be known by surgical instrument dealers as "von Klein's Intubation Thimble."

BOOK REVIEWS.

ASTHMA CONSIDERED SPECIALLY IN RELATION TO NASAL DISEASES. By E. SCHMIEGELOW, M.D., of Copenhagen. London: H. K. Lewis, 1890. Pp. 90.

The author states this essay to be an attempt to show how far diseases of the nasal cavities may affect asthmatic attacks and to modify the opinion that asthma is the result of a local nasal disease, the care of which would *eo ipso* cause the disappearance of the reflex neurosis as held by Prof. Hack, of Freiberg. He takes, with Germain-Sée, the position that asthma must be considered as a bulbar neurosis consisting in an excessive reflex irritability of the respiratory centre, which may be disturbed in its action by any competent peripheral irritation, and that nasal diseases sometimes, but not necessarily, constitute such an inciting factor in the asthmatic attack. In his own material he has noted asthma associated with nasal polypæ in 22 per cent. of his cases, and with chronic rhinitis in 8 per cent. The entire subject receives painstaking and fair-minded treatment which, in the present professional attitude toward reflex neuroses, is most commendable. The Continental bibliography and the historical matters relating to asthma are interestingly set forth in the introduction. It is a comprehensive and valuable addition to the literature of the disease.

THE THROAT AND NOSE, AND THEIR DISEASES. With one hundred and twenty illustrations in color, and two hundred and thirty-five engravings. Designed and executed by the author. By LENNOX BROWNE, F.R.C.S.E., Senior Surgeon to the Central London Throat and Ear Hospital; Surgeon, and Aural Surgeon to the Royal Society of Musicians; Consulting Surgeon to the Newcastle Throat and Ear Hospital, etc. Third Edition. Revised and Enlarged. Philadelphia: Lea Brothers & Co. 1890. Chicago: A. C. McClurg & Co. Royal Octavo, pp. 716. Price \$6.50.

The early exhaustion of the second edition of this very valuable work has enabled the author not only to thoroughly revise, but to greatly enlarge the text, so that the present edition is in a very considerable measure an original work. Especially is this true of that portion which treats of intra-nasal and naso-pharyngeal diseases.

The science of laryngology and rhinology is making such unparalleled progress that only the most recent records properly represent its advancement.

The present addition is of special value, as affording the latest investigations and literature upon this important subject. The anatomy of the parts considered is fully given and admirably illustrated. The methods for the inspection of the mouth, fauces and larynx are fully described, both by text and illustration. All of the various forms of diseases of these parts are considered, with reference to their etiology, pathology, and treatment. Forty-five pages are given to a critical study of diphtheria and the directions for its treatment. Syphilitic diseases of these organs are fully considered. Tubercular affections, benign and malignant neoplasms, and neuroses, are critically described, and associate aural maladies, as well. The uses of gargles, sprays, and local appliances, and the various forms of needed apparatus for every variety of treatment are presented and copiously illustrated. The various surgical procedures necessary to the treatment of these organs are fully described, including tracheotomy, laryngotomy, intubation, etc. As a practical work on the treatment of diseases this will be found an exceedingly valuable volume. The methods are fully set forth in the text, and references are made to a very complete and valuable list of formulæ. The engravings are upon wood, and all reproductions from the author's pen-and-ink drawings, by the photo-engraving process. Fifteen colored lithographic plates containing one hundred and twenty illustrations give an added value to the volume.

While this work will be of essential service to the specialist it is one that should find a place in the library of every practicing physician. It serves admirably to illustrate the progress that is being made in medical literature, and especially in the departments which are considered.

The mechanical execution of the work is a credit to the publishers, so long and so favorably known to the profession.

MEDICAL DIAGNOSIS. With special reference to Practical Medicine. A Guide to the Knowledge and Discrimination of Diseases. By J. M. DA COSTA, M.D., LL.D., Professor of Practice of Medicine and of Clinical Medicine at the Jefferson Medical College, Philadelphia; Physician to the Pennsylvania Hospital; Consulting Physician to the Children's Hospital, etc. Illustrated with Engravings on Wood. Seventh Edition, Revised. Philadelphia: J. B. Lippincott Co. London: Henrietta St., Covent Garden. 1890. Price \$6.

A writer so long and so favorably known as is Dr. Da Costa needs no introduction to medical readers at home or abroad. Six editions of his

work upon Diagnosis have been given to the public, and a copy is found upon the shelf of every considerable medical library. The value of his writings is well appreciated in other lands. A second German edition has just appeared in Berlin, a Russian translation has been made, and one in French is forthcoming. The inquiry is no more made, "Who reads an American book?" Aside from the ability of the writer the importance of his subject must command appreciation of the work and a liberal patronage everywhere. The power to discriminate diseases lies at the very foundation of all successful medical practice. The need of such a guide is imperative and universal. The author has fully appreciated that want, and in his successive editions it has been met in an admirable manner. The present edition has undergone that thorough revision which renders it abreast of the times. The agency of microorganisms in the production of disease is well considered. With this revision it continues to be, as it has been in times past, the standard work upon medical diagnosis.

SAUNDERS' POCKET MEDICAL LEXICON.

This dainty little volume, prepared by John M. Keating, M.D., of Philadelphia, and published by W. B. Saunders, 913 Walnut St., in that city, will be found to be a very serviceable pocket companion for practitioners, and especially for students in the class-room when larger works of the same kind are not easily accessible. It seems to be remarkably accurate in terminology, accentuation and definition. A full-faced type renders the reference to words as easy as in the larger works. Students will find the little volume very serviceable. A brief list of poisons and their antidotes is found at the close of the book.

DESCRIPTION OF THE JOHNS HOPKINS HOSPITAL.

By JOHN S. BILLINGS, M.D. Baltimore: Publications of the Johns Hopkins Hospital. 4to, Illustrated. 1890.

This is a rare specimen of book-making on a rare subject and occasion. It is equally a monument to Johns Hopkins, to John S. Billings and to scientific medicine. While we believe that there are many grave errors in these plans which would not be made again, the care and attention to the facilities for teaching, marks an era in the history of American medicine. Doubtless many municipal hospitals will be modeled after this typical institution, for in buildings as in living organisms morphology determines and is determined by function.

Two sentences may be quoted from Dr. Billings' address at the opening of the hospital. If these words could be appreciated by sentimentalists it would do more for hospital management in the United States than all their political meddling:

It is well known to those familiar with the subject, that

the sick in a hospital where medical instruction is given, receive more constant, careful, and thoughtful attention than do those in a hospital where no such instruction is given. The clinical teacher must do his best; keen eyes will note every error in diagnosis, every failure in results of treatment. (p. 33.)

Let these words be emblazoned on the entrance of every hospital supported by public funds and by private charities, for the acute and chronic diseases of mind and body, and the shameful stories of cruelty, neglect and mismanagement will disappear.

RAILWAY SURGERY. FOR RAILWAY SURGEONS, etc. By C. B. STEMEN, A.M., M.D., LL.D. With numerous Illustrations. St. Louis: J. H. Chambers & Co. 1890. 8vo, pp. 315.

This book sets forth substantially the large practical experience of the author in this particular surgical field, and a *résumé* of numerous papers submitted in medical societies by surgeons on topics germane to the title and the text. Interesting and instructive suggestions and directions for the management of railway emergency situations and the transportation of the injured make up several chapters, but it cannot be said that any part of the work is novel, and much of it is not abreast of recent surgical methods and surgical literature. In many places evidence of hasty preparation is apparent. The style is often vague, the construction grammatically faulty and the proof reading defective. Reported cases are so lacking in detail that their value is frequently lost, and directions for operative procedure lack essential clearness. Injuries of the brain and spinal cord are superficially treated, and the matter of spinal concussion is left practically to quotations from Erichsen and Hammond. In his preface the author states it as his "strong belief that a treatise on this special department was greatly demanded." If such a need existed, it has not been fully met by this volume.

PRACTICAL ELECTRICITY IN MEDICINE AND SURGERY. By G. A. LIEBIG, JR., Ph.D., and GEO. H. ROHÉ, M.D. Philadelphia and London: F. A. Davis. 8vo, pp. 383. 1890.

The authors have produced an eminently useful and practical book, which can be commended to the practitioner who proposes to use electricity in the treatment of disease or for surgical work. Part I, of over 140 pages, gives a somewhat extended account of the physics of electricity which might possibly with propriety be left in large part to technical text-books. The presence of numerous algebraic formulæ gives an appearance of mathematics which to many may be more alarming than otherwise, though the subject is skilfully and plainly handled. Part II sets forth electro-physiology with many instructive and new illustrations, and electro-diagnosis is considered, somewhat briefly. The chapter on apparatus re-

calls rather prominently, by its cuts and text, the catalogues of various manufacturers. Part III takes up the applications of electricity and special electro-therapeutics in an optimistic spirit which is captivating, but may lead to some disappointment, it is feared. The list of diseases in which electricity is recommended embraces pretty much the entire nosological table of human ills. Apostoli's method is fully explained, but late experiments in regard to the germicidal quality of galvanism are not mentioned. The book is well arranged, profusely illustrated and clearly printed, with a useful appendix of tables and formulæ.

THE PHYSICIAN'S VISITING LIST. Philadelphia: Lindsay & Blakiston. 1891.

This little annual has reached its fourth year of publication. The needs and convenience of physicians have been carefully considered, and in the judgment of the publishers it most nearly meets their wants. Its tables are ample, its arrangements have given very general satisfaction. It is compact, convenient, and durable, and for these reasons it continues to be a favorite.

A TREATISE ON NEURALGIA. By E. P. HURD, M.D. The Physician's Leisure Library. Detroit: Geo. S. Davis. 12mo, pp. 153. 1890.

This little brochure gives in an interesting and practical manner a *résumé* of the most accredited views on the subject—in which the French writers, however, preponderate. In classification the author follows Vaulair and divides all neuralgias into idiopathic and symptomatic, assigning to the former group much the larger number, though intimating that advancing knowledge will curtail it. Perhaps a frank acknowledgment of inability to explain the true relations of many neuralgic pains would be more desirable than the misleading designation of "idiopathic." Treatment receives many pages and is necessarily polypharmaceutical. In an appendix of thirty-six pages all the more prominent drugs that are valued in the management of the various neuralgias are considered *seriatim*.

MISCELLANY.

HEALTH IN MICHIGAN.—For the month of October, 1890, compared with the preceding month, the reports indicate that inflammation of brain, measles, scarlet fever, membranous croup, pneumonia, typhoid fever (enteric), diphtheria and inflammation of bowels increased, and that cholera infantum, cholera morbus, dysentery and whooping cough decreased in prevalence. Compared with the preceding month the temperature was lower, the absolute humidity was less, the relative humidity was slightly more, the day ozone and the night ozone were more.

Compared with the average for the month of October in the four years 1886-1889, influenza, measles and pleuritis, were more prevalent, and whooping cough, typho-malarial fever, puerperal fever, cholera infantum, inflammation of bowels, cerebro-spinal meningitis and dysentery were less prevalent in October, 1890.

For the month of October, 1890, compared with the

average of corresponding months in the four years 1886-1889, the temperature was higher, the absolute humidity and the relative humidity were more, the day ozone and the night ozone were more.

Including reports by regular observers and others, diphtheria was reported present in Michigan, in the month of October, 1890, at 55 places, scarlet fever at 79 places, typhoid fever at 96 places, and measles at 18 places.

Reports from all sources show diphtheria reported at 2 places less, scarlet fever at 25 places more, typhoid fever at 23 places more in the month of October, 1890, than in the preceding month. Measles were reported at the same number of places as in the preceding month.

ORIGINAL ARTICLES.

A FEW MORE REMARKS ON DERMATITIS HERPETIFORMIS.

Read in the Section of Dermatology and Syphilography, at the Forty-first Annual Meeting of the American Medical Association, Nashville, Tenn., May, 1890.

BY A. RAVOGLI, M.D.,
OF CINCINNATI, O.

Since Duhring, in 1884, called the attention of dermatologists to a group of eruptions of the skin under the name of dermatitis herpetiformis, interest in these eruptions has greatly increased, because many affections of this kind could find their right nosological place in dermatology. Many of these cases were formerly confounded with erythema multiformis, others with herpes iris, others with pemphigus; impetigo herpetiformis hebræ remaining a peculiar eruption out of any definite nosological class. As the bulla was characteristic of pemphigus, so every bullous eruption was characterized as such, and on account of the pruritus, the adjective of pruriginosus was added. Duhring's work consisted in definitely establishing the general symptoms which constitute the type of these eruptions and thus refer them all to one group.

1. Polymorphism of the eruption.
2. Paresthesia.
3. Chronic course and relapse.
4. Relative general good feeling.

Certainly the disease is not a new one, for we find many descriptions of eruptive diseases of this kind scattered in the books of different authors, and called with different names. To-day these various eruptions are to be referred to this type dermatitis herpetiformis. So we find herpes phlyctænoïdes in Chansit, 1852; pemphigus circinatus in Rayer, 1828; pemphigus chronicus in Racle, jr., 1841; pemphigus compositus, herpes pemphigoides oder pemphigus herpetiformis in Devergie.

Cazenav¹ had already remarked that pemphigus sometimes is accompanied with different eruptions like herpes and prurigo, and in this case the affection is like to pompholix pruriginosus willan, where the patient is troubled with itching

and burning sensation. In these cases small vesicles are mixed with large bullæ aggregated into groups, resembling herpes phlyctenoides, while large bullæ of pemphigus are scattered on the cutaneous surface.

In Bazin, under the article "Arthritides Bullosæ," we find a description of two varieties of bullous eruptions, viz., pemphigus arthriticus and hydroa bullosa, where he includes all the symptoms of dermatitis herpetiformis.

Auspitz,² under the head of "Neuritic Dermatoses," established a group of eruptions which he named inflammatory trophoneuroses with a cyclic course. He gave to this class of eruptions the general name of erythanthema, which he divided in two families, viz., those affecting the skin superficially and those affecting the skin deeply. He divided the last family in species vesicular, pustular and bullous, including herpes circinatus, iris, annulatus, herpes phlyctænoïdes, herpes impetiginosus and pemphigoides. As herpes impetiginosus he understood the disease described by Hebra as impetigo herpetiformis.

It would be superfluous for me in the brief space allowed to go on to review or recall all the authors who before Duhring described cases of this disease under one name or another, but I must refer the reader to the beautiful and complete work of L. Brocq on "Dermatitis Herpetiformis Duhring." Brocq differs with Duhring as regards the name and prefers *dermatitis polymorpha pruriginosa chronica a poussées successives*. It is a question of nomenclature, but the form remains the same, and we must be grateful to Duhring for having traced the principal symptoms which form the characteristics of this peculiar affection. The name of "dermatitis, inflammatio cutis," inflammation of the skin, seems to be rightly applied, as vesicles and bullæ are situated in a red halo, and this redness precedes the spreading of the eruption. The adjective herpetiformis gives the idea of vesicles with a tendency to aggregation.

There is no question that one of the most remarkable characteristics of this affection is the disposition to relapse, when a spot is nearly healed up a new crop of vesicles or bullæ comes up again. The genius of relapsing is so charac-

¹ Abregié, Pratique des Maladies de la Peau, 1847.

² System der Hautkrankheiten, Wien, 1861.

teristic of this affection that, as Unna remarked,³ the cases referred to by Brocq, where no relapse had been seen, ought to be excluded from this group.

Paresthesia, perversion of the sense of touch is the dominant symptom in this disease. The patient complains of an itching and burning sensation together, which often prevents him from sleeping and obliges him to scratch his thick and infiltrated skin. This symptom is so important as to distinguish a case of dermatitis herpetiformis from a case of true pemphigus. The restlessness and the continuous scratching of the patient affected with this disease contrasts a great deal with the quietness and the dread of changing position in the patient affected with true pemphigus. According to Unna pemphigus pruriginosus is to be taken out of the group pemphigus and is to be comprehended in the group dermatitis herpetiformis. The perversion of the sense of touch revealed by the itching, shows the disorder in the sensitive nerves, which is the *causa proxima* of this disease.

Polymorphism of the exanthema forms another characteristic of the disease. Papules, vesicles, bullæ and pustules are found together in a striking way; but we can assert that the predominant feature is the vesicle and the bulla. I seldom saw a true pustule, but mostly are vesicles or bullæ filled with a turbid and purulent exudation. This remark has been already made by Brocq.

The condition of the general health maintained in this disease must be considered only as relative. The patient does not lose his appetite, but on account of the itching sensation loses a great deal of his sleep, and in some cases wastes away considerably.

To give a practical example I will take the liberty of reporting as briefly as possible a case of dermatitis herpetiformis, which I had the opportunity to study from its very beginning.

A gentleman, N. S., 53 years old, in the best of health, who never had any disease of any consequence, in very good financial condition, called in April, 1889, upon me complaining of an itching sensation all over his body, but more intense on the chest and on the arms. The skin white and smooth, was covered with an abundant panniculus adiposus and did not show anything with the exception of a few small red maculæ in the middle of the chest. A mild alcoholic solution of carbolic acid was prescribed for the purpose of diminishing the itching sensation. A few days after the patient came back complaining that the itching sensation was always more intense and at this time small papules like in *eczema papulosum* were scattered on the chest and on the shoulders. Under the impression that I had to do with an

eczema papulosum a salve consisting of oxid. zinc, subnitrate bismuth, carbolic acid and vaseline was given to be rubbed on the eruption. A few days after a papular eruption was spreading all over the body and on the limbs. The skin was red and the papules some were small, of the size of a grain of millet, and some larger and polyginal in shape, and depressed in the centre, resembling exactly the papules of lichen ruber-planus. At this time I had the idea that the case was one of lichen ruber scarlatiniformis. I prescribed then Asiatic pills from two to four a day, and bath with water where some wheat bran had been boiled, assuring the patient that in a few months everything would return in the normal condition. From this time I did not see the patient. Three months after I was called in consultation to see the same gentlemen. All his body was covered with bullæ filled up with clear serum ranging in size from that of a pea to that of a hen egg. Where the bullæ were broken, large excoriations remained. In the places where bullæ had already healed up the skin was dark brown in color, thickened, and large flattened papules were raised above the level of the skin. Bullæ were also coming on the mucous membrane of the lips, of the mouth and of the throat. These bullæ soon broke, leaving excoriations. The patient was extremely nervous and excitable, but his appetite was relatively maintained, and he could take a sufficient quantity of nourishment. The patient would get better from time to time, his excoriations would heal to a considerable extent, and we would all begin to hope for recovery, but relapse was sure to occur, and always preceded by slight elevation in temperature. At one time the whole body was one sore, bed clothing and everything stuck together. We feared reabsorption and it was deemed necessary to put the patient in a continuous bath. This, however, could only be used at intervals as the patient complained of chilliness, and it was necessary to have the water at the temperature of 98° F., which made him weak and produced congestion in the circulation of the brain. The continuous bath, in spite of all the difficulties, acted very satisfactorily. The eruption of new bullæ subsided and the extensive excoriations healed up considerably in about three weeks' time. But after three weeks we were obliged to quit the bath because this chill was so bad that the patient could not stand any more. The patient was now anointed with different salves, vaseline and salicylic acid, olive oil and carbolic acid, always in very mild proportions. New bullæ continued to appear, became rapidly purulent and the patient began to show symptoms of pyæmia. Fever ranged between 101° to 103°, pulse very weak and over 120, and his life was in great danger. Abundant doses of quinine reduced the temperature and the large discharging sores were

³ Ueber die Dühringshe Krankheit und eine neue Form derselben. Monatshefte für Pract. Derm., B. ix. No. 3.

dusted with iodoform powder, covered then with iodoform gauze. This treatment helped, the fever disappeared, the excoriations gradually healed up, so that the patient was able to get up and go out riding. When I left the patient he was almost well. No new bullæ were coming, and there remained only some itching sensation. His sleep was pretty good, appetite excellent. He wished to go to some resort and he chose Old Point Comfort.

I must remark some peculiar features of the general symptoms. The urine had been carefully examined every few days and it was found always of a normal acid reaction, never could any trace of albumen be detected, urates and phosphates were somewhat in excess. The most interesting symptoms were revealed in the nervous system. At times the gentleman was somewhat stupid, taking but little interest in surrounding things, at times he was irritable, and for some time was slightly delirious during the night.

His sleep was very agitated, he slept a few minutes at a time and no hypnotic could give him a few hours of rest. Night-sweats were very profuse, especially lately, when he was improving.

In order to give a complete account of the case it must be noted that the gentleman had another relapse at Old Point Comfort. He was not satisfied with the treatment and left for Philadelphia, where he went under the treatment of Dühring. From Philadelphia he went to New York, having another relapse, and he put himself under the treatment of Elliot and Bulkley. He came back to Cincinnati with still another relapse, and is now again under my charge.

It will be seen that the general feeling of well-being which is said to be characteristic of this disease is to be taken with a grain of salt; that, indeed, there are many interesting symptoms affecting the general health and more especially the nervous system.

In the beginning I called this case pemphigus pruriginosus, and I find that it has some likeness to the case lately published by Dr. Henry G. Piffard⁴ under this same name. However, I do not see any reason for leaving these cases separated when we can refer to one group of diseases which have the same symptoms in common and have nothing to do with real pemphigus.

I wish now to call your attention to another case of the same kind in which the eruption runs an exceedingly chronic course and has a kind of progressive way of spreading over the skin by continuity.

This is a lady, Mrs. X. Z., 57 years old, who has always enjoyed good health; she is five feet tall, 170 lbs. in weight, fleshy. Her skin is very white and delicate, panniculus adiposus abundant. She has been always in very good financial condition, belonged to the highest society. Four

years ago she lost her husband under the saddest conditions. After the death of her husband many investments were found to be valueless. The loss of her husband and the financial troubles threw her into deep grief. About three years ago there appeared on the index of the left hand an eruption in form of vesicles filled up with purulent matter. The eruption slowly spread over the back of the hand for a time then stopped, but the skin remained thick and of a brownish violet color. A few months after which an eruption of vesicles appeared on the lips, around the ears and on the temporal regions, the toes and the back of the right foot. At this time I was called in consultation by her family physician. The surface was completely covered with thick, yellow brownish crusts, having the appearance of an eczema impetiginosum. After removing the crusts with applications of olive oil, the surface was found to be covered with large spots having in the center a dark brown color, with kind of papules and pustules scattered, and in the periphery deep excoriations in semicircular disposition; itching and burning sensation accompanied the eruption. Still under the impression that I had a case of eczema to deal with I applied unguentum diachylon hebræ spread on muslin. The result of this application was not satisfactory, as it brought out many more vesicles which were easily broken and left the surface more excoriated. The disease spread upon the periphery of the plaques, in the form of vesicles upon an inflammatory halo.

Vesicles and pustules of the size of a millet seed appeared on the tongue, and on the mucous membrane of the mouth and of the nose. These soon broke, causing serous discharges from the mouth and from the nose.

At this time a mild salve of resorcin was used (half drachm in one ounce of vaseline), but the burning caused thereby was so great that it was necessary to stop its application immediately. Internally, Fowler's arsenic solution, in doses from ten to fifteen drops a day, was prescribed. New conglomerated vesicles were continually developing at the edges, and forming semicircles. The epidermis covering the vesicles was easily removed, leaving the excoriations in form of crescents, extending on the parietal region. Another spot developed in the same way on the occipital region, running downward on the back of the neck. Every active remedy had proved unsatisfactory, increasing the irritation and bringing out new crops of vesicles, so we resorted to indifferent means, so as only to cover the skin and protect it from the contact of the air. The surface discharged a great quantity of serous fluid, which stuck the hair together, took an offensive smell, irritated the healthy skin with which it came in contact, and caused an unbearable itching sensation. The surface, therefore, was washed

⁴ Journal of Cutan. and Gen.-Urin. Diseases, New York, April, 1890.

twice a day with a mild solution of carbolic acid, and after having been dried as well as possible, a salve containing subnitrate of bismuth, oxyd. zinc, in the proportion of half drachm to one ounce of vaseline, with ten drops of carbolic acid, was applied with a brush. In this way the inflammation diminished and the excoriations healed up. The surface of the skin, however, remained highly pigmented, showing a dark brownish color, and because of abundant granulations it presented flat papules similar to those seen in impetigo herpetiformis.⁶

The affection was now at a kind of standstill. The excoriations remained in great part healed up, the discharge of serum nearly stopped. Once in a while a few small vesicles would appear on the old affected spots. As it was in summer time, the patient thought that if she went to some watering-place she might derive some benefit from the change of climate. I therefore lost sight of the patient for about nine months. I must express my thanks to Dr. Jos. Ransohoff, who called me again to see the case.

The eruption at this time had affected the forehead, the eyebrows, the eyelids, the nose, both cheeks, lips and chin, extended over the whole neck, down upon the breast and backwards on the shoulders, representing exactly a lace fichu. The skin was dark brownish-red, slightly swollen, with large flat papules, lighter in color, raised above the level of the normal skin. At times crops of small, miliariform-vesicles and pustules appeared, scattered over this affected skin. The edges were raised above the level of the skin, show an uninterrupted row of vesicles, whitish, pulpous, from the size of a millet seed to that of a split pea, on a red, inflamed halo, which is extended upon the healthy skin. The whole resembles to some extent a burn produced by hot water. The slightest contact or rubbing removed the epidermis, and left an excoriation in semicircular form, neatly cut as if it had been done with a penknife. The itching sensation was unbearable, but the general health of the lady was relatively good; appetite and digestion good, and bowels regular. Sleep was disturbed by the itching sensation, but in spite of it the lady got some rest at night at intervals.

It is worthy of remark that at each new eruption the patient complained of some chilly sensation towards evening, and when the eruption was spreading so badly she had also some fever. New spots are now coming, one in the middle of the breast and one under the axilla. A small bulla of the size of a pea is the beginning, and this soon dries up, forming a slight brownish crust, then vesicles appear around the first, forming the spot, which grows and spreads regularly.

At present I am treating the patient with only

ichthyol. She takes from thirty to forty drops of ammon. sulph. icht. a day internally, and externally I paint the surface with a lotion of ichthyol, aqua rosæ and glycerine, equal parts. At first it caused some burning sensation, but soon it diminished. The itching sensation has diminished a great deal and the swelling is going down. Few new vesicles and pustules are coming and the old papules are slowly diminishing. The edges are still excoriated and discharging sero-purulent matter. The face is covered with paste zinci molliis with ichthyol, according to Unna.

Looking over the literature of this disease, I find that there is an analogy between my case and a few cases which have been reported by Brocq in his "Dermatitis Polymorpha Pruriginosa Chronica a poussées Successives," *varietas gravis*. The first, No. 29, from Dr. Saddler, the eruption, spreading slowly, covered the whole body and had a fatal end. Two other cases under the numbers 31 and 32, the first from Bazin and the second from Rayer, have a great likeness to the case under consideration.

The cause of this disease is still in darkness, but without doubt it lies in alteration of the nervous system, as is the case in herpes zoster. The disease is not contagious, the fluid of the vesicles inoculated in rabbits has never given any result. The lady patient, of a very irritable nature, suffered for years under great grief. The moral trouble may have influenced her nervous system.

Brocq would not grant so great an influence to moral impressions, but would rather attribute the cause to an arthritic diathesis. In both our patients there was no sign whatever of rheumatic diathesis, although both were used to very high living. I return to my first idea, that the cause of the disease is to be found in the nervous system, which opinion is also maintained by Bulkley, Livering, Alfred Wiltshire and Wyndham Cottle for herpes gestationis.

The first symptom of this disease consists in the perversion of the sense of touch, paræsthesia, itching sensation, which shows that the sensitive nerves of the skin are affected. The itching and burning sensation in some cases is limited to the place of the skin which is affected, in others it spread all over the body. The patient cannot stand the pruritus, and scratches his skin to get some relief from his troublesome sensation. In our first patient the itching sensation was spread all over the body, but in the lady this was limited to the affected places, and preceded the new eruptive placques. It seems that the paræsthesia is the symptom which speaks most for an alteration of the nervous system. If the itching sensation follows the eruption, then it must be believed that the infiltration and the anatomical alterations in the texture of the skin were the cause of the pruritus, but in our cases itching sensation was the first symptom, and preceded every eruption.

⁶Hence the name given by Auspitz herpes vegetans Archiv s. Dermatologie 1868

The form of the eruption differs according to the variety of dermatitis herpetiformis. In a general way we may say that it begins with erythematous plaques, which run into papules, or the epidermis is filled up with serous fluid in form of vesicles and bullæ, or with purulent exudation, vesicopustules and pustules. The texture of the skin is considerably altered, it remains infiltrated, thick, hard, highly pigmented and congested, of a brownish-violet color. In consequence of the vesicles, the bullæ and of the pustules, excoriations and crusts remain on the diseased skin. In the lady we found a considerable swelling and acute œdema of the eyelids and of the face when the eruption spread on this region.

The color of the erythematous plaques in the beginning is red purplish, and disappears somewhat under the pressure of the finger, and has nothing to do with the brownish-violet color, which we find in the infiltrated plaques where the eruption had its seat. The spreading of the eruption is different in the various cases. In our first case the bullæ appeared all over in large bunches, affecting one day the genital and the gluteal region, another day the limbs and the chest, and so on until the whole body was covered with bullæ. In the second case, however, the disease spread with the greatest regularity and the new eruption appeared on the edges, while at times relapses of pustules and vesicles occurred, scattered irregularly on the old infiltrated spots.

In a recent relapse in the first case, we can notice small reddish papules surmounted by small vesicles, of the size of a pin head, aggregated together like sudamina, spread over large regions of the body, while small pustules are scattered on the limbs. In the second case the vesicles are no larger than a millet grain to a split pea, brilliant like pearls, disposed in circles on the edge of the spot. The vesicles are easily broken, and the slightest contact removes the epidermis in form of shreds, leaving the corium uncovered. It is remarkable that any irritation, or any pressure is liable to bring out a new crop of vesicles. Vesicles come often on the occipital region which rests on the pillow. Just in the middle of the breast, where the springs of the corset rub, a new plaque is now coming. Another plaque of numerous vesicles is now formed under the armpit, where the two surfaces of the skin come in contact. Vesicobullæ are frequently developed on the tip of the fingers of the right hand from any attempt to sew or stick a pin, or button her clothes.

Comparing the two cases, we see that both are of long duration, but in the first we see a kind of tendency to acuteness, while in the second we see a tendency to chronicity. In the first, in each relapse there is a stormy appearance of vesicles and bullæ, while in the second we see the vesicles slowly formed and slowly but surely progressing.

I cannot say much about the duration of the

disease. Both our patients are improving, their general health is pretty good, appetite maintained, digestion fair, bowels moved regularly. The pulse is good, the heart in normal condition, no remarkable change in the chemical constitution of the urine. The patients did not lose much in their weight, and everything shows that the principal functions are in complete order. This removes any idea of fear for the life of the patients at present. The patients from Bazin and Bulkley were permanently cured. This encourages us, and we hope for the best.

What about treatment? While I was reporting the clinical history of the cases I told what we were administering to our patients. A great many remedies have already been tried, but all without satisfactory result. Milk diet, alkalines, purgative mineral waters, tartrate of potassium, arsenic, iodide of iron, tonics, strychnia, belladonna, atropia, cinchonidia, ergotine, tincture cantharides, iodide of potassium, etc.

Iodide of potassium has been already condemned. In some cases the arsenide of soda seems to have done good, especially Hutchinson claims great benefit from it. In both our cases we found arsenic of no account, if not pernicious. Fluid extract of ergot seems to have been of some benefit in our first case, but did not seem to have been of any benefit in our second case. I am actually trying internally ichthyol in the lady, and we can say that it has been useful, as she is somewhat better. She takes sixty drops a day in three doses.

Externally we can say that we have applied everything which can be found in the dermatological formulary. Unguent diachyl. hebræ, ungu. zinc. benzoat, unguent resorcin, aristol, oleate of bismuth, oil and carbolic acid, liniment oleo calcarium, covered with cotton, baths with amyllum, powders, etc.; but all without satisfactory result. I must remark that every time that unguent diachylon has been applied, more vesicles have come out. It seems to me that any slight irritant means applied on the skin, has increased the fury of the disease. I must state that I am treating the lady now with ichthyol. For the face, neck and shoulders I am using gelatine zinci mollis with 2 per cent. of ichthyol. This has calmed the burning sensation. The itching is not so intense. The papules are flattened, and no new vesicles or pustules are coming on the affected places. The raw edges covered with this gelatine do not cause pain, and in some places are healing up. I think that this paste has given me more satisfaction than any other remedy used. For the breast I am using now ichthyol, aq. ros. and glycerine, equal parts, does not irritate, many excoriations have healed up, and I feel encouraged to keep on in its use.

In our first patient while under the treatment of Elliot also, ichthyol has been used in association with aq. calcis and oil of sweet almonds, and the patient improved considerably.

It seems to me that ichthyol has a peculiar sedative influence upon the final nervous ramifications. In several cases of pruritus, it has stopped the itching sensation, when every other remedy had failed. In many cases of nervous eczema, especially in children, a lotion of

Ammon. sulphoichthyol, ʒij.
Aq. ros.,
Glycerine, aa ʒss.

has given very satisfactory results. In the lady patient referred to, when any indifferent application caused burning, and eruption of new vesicles, ichthyol does not produce discomfort, diminishes the itching, and the excoriations, under the dark cover of the ichthyol, seem to heal up faster.

A well regulated diet is strictly necessary in the treatment of this disease. Our patient is now on an exclusive milk diet. Coffee, tea, wines and liquors are strictly forbidden.

Anything which is capable of producing erythema or urticaria, like strawberries, clams, lobsters, etc., must be avoided. Meat alimentation must be greatly reduced. The most digestible food must be selected. The bowels must be carefully watched and regulated accordingly.

With this case we have obtained some improvement of this interesting, proteiformis disease, which I dare to call "Dermatitis Herpetiformis Progressiva."

INSTRUMENTS AND APPLIANCES FOR THE ADMINISTRATION OF OXYGEN.

Published for the Philadelphia Society Medical Society, Oct. 2, 1880.

BY JOHN AULDE, M.D.,
OF PHILADELPHIA, PA.

Having long entertained a favorable opinion of oxygen, it occurred to me some time ago that it would be of some interest to the members of this society if an opportunity were afforded for examining the various instruments and appliances for its exhibition. I have, therefore, made a collection of the different instruments which are now on the market, and shall endeavor to point out briefly the manner in which they are to be used in the treatment of disease. This agent has attracted considerable attention, more especially within the past five years, although ten years ago it would probably have been considered rank quackery to favor the use of oxygen. The large number of favorable reports which have recently appeared in medical literature furnish sufficient evidence to warrant us in making an effort to become more familiar with its advantages. My remarks this evening will be devoted exclusively to a description of the apparatus, dealing only incidentally with the therapeutical indications.

The first instrument which I show you is that manufactured by the White Dental Manufactur-

ing Company, of this city. The gas is supplied in cylinders containing 40 and 100 gallons, respectively; and attached to the cylinder we have a cloth-covered rubber bag which serves the purpose of a reservoir, so that only a small portion of the gas escapes, and thus the quantity inhaled can be measured. Attached to the inhaler, and forming a part of the apparatus, is a bottle partly filled with water, and as the patient inhales the gas, it passes through this water, and then enters the pulmonary tissues in the form of moist oxygen; it can be taken pure or mixed with atmospheric air, and unless the patient inhales the gas too rapidly no bad effects follow its administration. When properly practiced, inhalations of the gas have rather a pleasant and agreeable effect, and the only danger from rapid inhalations is that which would follow rapid breathing under any circumstances. The value of the muscular exercise in the procedure is an item which should be considered. (Fig. 1.)

The next apparatus to which I call your attention is made by the same manufacturers, and is intended for the exhibition of the gas by enemata, when for any reason its administration by inhalation cannot be practiced, or when, as in the case of typhoid fever we desire to obtain the more immediate effect of the gas upon the diseased structures. This apparatus consists essentially of two parts, connected with each other by means of rubber tubing. The one is a closed copper vessel, while the other is open, and the gas is forced into the rectum by the pressure of the water in the open vessel, the closed receptacle having first been filled with water, and connected with the cylinder until all the water had been displaced. This is a useful combination; but in the absence of the apparatus, the gas can be introduced into a bag, and pressure made upon it, when the gas will be forced into the lower bowel. In the present instance, the pressure is regulated by the height to which the open vessel containing the water is raised. (Fig. 2.)

A few years ago, I read with great interest an account of some experiments conducted by Dr. Kellogg of Battle Creek, Michigan upon guinea-pigs, by means of the rectal insufflation of oxygen gas. He found that, on opening the abdomen and isolating a loop of the mesentery, the introduction of the gas into the rectum caused the blood circulating in the veins to change to the arterial hue; on withdrawing the gas, the blood at once assumed the venous hue. These, and other experiments, go to show that the blood readily takes up oxygen and distributes it to the tissues, thus favoring combustion, but there never have been any demonstrations made to prove that the use of this gas would cause increased combustion and abnormal waste of the tissues through hyperoxygenation.

These cylinders are furnished by the manu-

facturers containing either pure oxygen gas or a mixture of oxygen in combination with nitrous oxide (nitrogen monoxide.) This gas, as you know, is used by dentists and surgeons for the production of anæsthesia, but when so used it is

directly from the cylinder, better results follow, on the supposition that the gas still retains some of its expansive force (due to compression) after reaching the lung structures, but this is doubtful. (Fig. 3.)

FIGURE 1.

administered in concentrated form ; when diluted, it acts as an exhilarant, and I presume it partakes of both these characters when combined with oxygen, and a considerable quantity slowly inhaled. It certainly has a quieting effect upon the nervous system, and often is far superior to the pure gas, or that diluted with atmospheric air.

The apparatus shown here is that manufactured by the Walton Company, of New York ; the cylinder contains one hundred gallons of compressed gas, two-thirds being pure oxygen, and one-third nitrous oxide. The inhaler is in the form of a bottle half-filled with water, and this is connected with the cylinder by a small rubber tube, which, with the glass tube in the inhaler, carries the gas to the bottom, when it makes its escape in the form of bubbles, as shown when I turn the stop-cock. In using this instrument, the patient or an attendant turns the stop-cock, allowing the gas to escape, when the patient inhales freely by deep inspiration, and the gas is immediately turned off. This operation is repeated a number of times during a *séance*, according to the directions of the physician. It is claimed that when the gas is used in this manner,

It not infrequently happens that we wish to send gas to our patient, or it may be demanded in the case of an emergency, and in such instances the gas can be drawn from the cylinder, collected in a cloth-covered rubber bag made for the purpose, and transported any reasonable distance. It is then at the command of the physician, and can be used by the nurse as required. The bag which I show you will hold ten gallons, and this usually will be quite sufficient for a day, when the container must be thoroughly washed with a solution of alcohol and water, in order to remove any impurities which may occur from the action of the gas upon the rubber lining of the bag.

The instruments which I have thus far exhibited require that the physician should purchase gas, but that which I now show you is a machine that I have had in use for several years, which enables the physician to make pure oxygen gas, which can be stored in a small office gasometer, or it can be used or distributed among patients in cloth-covered rubber bags such as I have exhibited. This is the oxygen generator introduced to the medical profession some years ago by Dr. Wallian, of New York, and is very complete,

and, withal, convenient for office use. The mixture of chlorate of potassium and binoxide of manganese is placed in the retort, and under this retort I now place a spirit-lamp constructed on the same principle as the argand burner. In a few minutes you will observe that the gas begins to form and passes through the different wash-bottles, and is finally collected in the rubber bag. The mixture from which the gas is made contains about seven parts of chlorate of potassium to one part of the binoxide of manganese, and in this proportion but little heat is required, and from ten to twenty-five gallons of pure gas can be prepared in as many minutes at a comparatively small cost.

FIGURE 2.

In order to purify it, the gas is first passed through a solution of caustic soda, two bottles, and is next carried through a weak solution of nitrate of silver, and later through pure water. Ordinarily one would suppose that the gas would then be free from all impurities, but this is not the case, as it has been found on examination that gas thus prepared contains a minute quantity of chlorate of potash, and, in order to prevent this from passing over, it is necessary to pass the gas through a moderately thick layer of absorbent cotton. The presence of crystals of this substance has been demonstrated in cotton so used, after a considerable quantity of the gas had been allowed to pass through.

This machine I have found of service in the treatment of emergency cases, where oxygen was

indicated, and although the first cost is greater than when compressed gas is used, I have no doubt but that the general practitioner could frequently use it to advantage, as it is simple in construction, and made in a substantial manner. (Fig. 4.)

FIGURE 3.

You are aware that nascent oxygen can be obtained from hydrogen dioxide, and I desire therefore to call your attention to the form of an inhaler which I began using a number of years since, before I had the advantages afforded by a generator. It is a plan which can be utilized for those living at a distance from the physician's

FIGURE 4.

office, or in the absence of the gas itself it may often be employed with much benefit. The inhaler, filled about one-third full of warm water, is placed in a quart tin cup, and a tablespoonful, more or less, of the solution of the peroxide of hydrogen placed in it, when nascent oxygen begins to be given off, and the patient inhales by using the mouthpiece.

Sometime ago, in the preparation of an article on "Creasote" (*Notes on New Remedies*, October, 1890), I took occasion to refer to a very excellent apparatus, kindly loaned to me by Lehn & Fink, of New York, and the invention of Dr. Daywalt, of San Francisco, for inhalations of that drug. It appeared so complete in detail that I could not withstand the temptation to present it for your consideration as a suitable inhaler for

fifteen-volume solution may be used in the local treatment of boils and carbuncles, or it may be used by patients suffering from uterine and vaginal affections by means of a tampon saturated with the solution and introduced into a gelatin capsule (veterinary size). A tampon prepared in this manner may be allowed to remain *in situ* over night, followed by the free use of hot water. There is no instrument which offers to us such a wide range of application for the peroxide of hydrogen as this ingeniously constructed appara-

FIGURE 5.

the peroxide of hydrogen. The bottle in which the solution is placed is exposed on a sand-bath, which is heated by an alcohol lamp. The special advantage to be gained from the use of this instrument is due to the fact that we have a constant record of the temperature, a suitable thermometer being so adjusted in the cork that it reaches the liquid at the bottom while the mercury is in full view. (Fig. 5.)

FIGURE 6.

tus placed on the market by Marchand, of New York. It is not only an atomizer, but also a vaporizer, and is so well adapted for local employment of this valuable remedy that it merits more than a passing notice. Throat, nasal, and bronchial troubles are so common that the physician will find himself behind the times who fails to take advantage of the benefits to be derived from the local employment of the peroxide by means of the atomizer and spray. Being perfectly harmless to the most delicate tissues, and wholly free from objectionable characteristics as regards

FIGURE 7.

Peroxide of hydrogen is also of service when employed as an antiseptic, and is of special value when there is a breaking down of tissue with the formation of pus. A small quantity of the usual

taste and smell, both the spray and vapor can be liberally used in the treatment of all forms of diphtheria, croup, and beginning quinsy, with the best prospects of success. (Figs. 6 to 7).

DISCUSSION.

DR. S. SOLIS-COHEN: I take exception to the remark of Dr. Aulde that ten years ago, the use of oxygen would have been looked upon as quackery. I am sorry that, in speaking of peroxide of hydrogen, Dr. Aulde did not speak of ozonic ether, which was introduced by the same man who has given nearly all that has been of service in recent years—Dr. Benjamin Ward Richardson. It is an ethereal solution of H^2O^3 , much stronger than the solution in water. I have seen good results in threatened collapse in typhoid fever and other low conditions from the hypodermic use of ozonic ether. I believe that this is not due to the ether only, but that the oxygen is of decided value.

DR. M. PRICE: I would like to ask to what the benefit from the use of nitrous oxide is attributed? Fifteen years ago we used nitrous oxide at the dispensary for the extraction of teeth. Many consumptive cases in which it was used came back in a few weeks stating that they had never been so much benefited as from inhalation of the nitrous oxide. My explanation is that the nitrous oxide, acting as an anæsthetic, lessens the pain of respiration, and the patient in his efforts to secure air expands the lungs, filling portions of them that have not been used. The action is just the same as where we break up the adhesions about an ankylosed joint under ether. I have employed the nitrous oxide in many cases of phthisis with advantage, and dentists have informed me that they have often been told by consumptive patients that they had been benefited by the inhalation of nitrous oxide.

DR. AULDE: Several years ago, I made some investigations with a view to the employment of Dr. Richardson's ozonic ether, but did not adopt it in practice for the reason that it gave off the fumes of ether, which is very objectionable to many persons; and second, because of its expense. As my remarks were not intended to deal with the therapeutic applications of oxygen, except incidentally, I cannot enter into a discussion of the physiological action of nitrous oxide, referred to by Dr. Price. In the course of my remarks I mentioned the supposed action of the nitrous oxide when given in concentrated form, as well as when diluted.

PUNCTURE AND COLLODION IN HYDROCELE.—For the treatment of hydrocele Leroy recommends that one-third or one-fourth of the fluid be withdrawn by means of an aspirator, after which the whole scrotum is painted with a thick layer of collodion, which is to be renewed every twenty-four hours. A cure results in from twelve to fifteen days. M. Broquet also has employed this treatment with success in three cases.—*Weekly Medical Review*.

THE PHONOGRAPH IN TESTING HEARING.

Read before the Chicago Medical Society.

BY GEORGE F. FISKE, M.D.,
OF CHICAGO.

It is certainly no exaggeration to say that scientific examination and treatment of the ear began with Anton von Troeltsch's method of using a perforated concave mirror reflecting daylight or artificial light into the ear. It is also probably true that since that time, 1855, more time and labor have been spent in attempts to devise satisfactory hearing tests than upon any other question of otology. Aurists have clearly recognized this lack and have known just what they wished to accomplish.

To give a definition of normal hearing power one must consider the hearing with regard to intensity of sound, ability to hear loud or soft sounds, with regard to the pitch, and the tone, quality and also the distinctness with which rapidly recurring tones or noises can be separated by the ear. It is in consequence impossible at present to establish an absolute standard of normal hearing. Practically, three means of testing are used: the watch, or similar instrument; speech, whispering or loud voice; and musical tones, tuning forks or musical instruments. Any examination of the hearing to be satisfactory must include all these tests, and we have for each test a standard as normal, which is however not arbitrary, depending, as it does, upon the degree of quiet in the room used, upon the voice of the examiner, the age of the examined, etc. To illustrate: in testing with the watch it is not infrequent to find a young person who hears the watch at the normal distance while ordinary conversation is heard at the distance of three or four feet with difficulty. If then we employ the watch alone in examining such a patient it is easy to make a serious mistake in diagnosis and prognosis. Then, again, in examining a man over fifty years of age it is the rule that the hearing distance for the watch is very greatly reduced as compared with youth. It may be that the watch is heard only upon contact with the ear, while whispering and loud voices are heard at the standard distance. Much more rarely there is a great difference between the hearing of words whispered and spoken.

I remember the case of a man forty-three years old with no history of aural or nasal disease, who asked me to test his hearing because he chanced to be present while his daughter was being treated. He heard whispering at three feet in a room where thirty feet was the normal distance, but to my astonishment on changing to spoken words he distinguished them at the normal hearing distance; in this case forty feet.

Similar variations, which can perhaps properly

be termed physiological, present themselves in examining with the tuning fork, due in some cases to education of the ear as regards the limit for high or low tones. Now the voice is by far the most important of our tests, not only because it is more necessary in daily life to hear the human voice than any other sounds, but also because it is heard with more constancy through life, with less variation on account of age. But this, our most important means of testing, is also by far the most uncertain. Not only is it extremely difficult to reproduce exactly the volume and quality of a given voice, but the voices of different examiners vary so greatly that the patient's statement that he heard two years ago Dr. So and So's voice at such and such a distance would be in very many cases of no help to the present examiner. The watch can be made an accurate test by making a standard watch of a certain loudness, which shall be adopted by all aurists. Politzer's acoumeter and new hörmesser accomplish this fairly well at a moderate cost. It is also possible to measure very accurately the hearing for musical tones by using as standard König's graduated tuning forks and steel rods. One might perhaps nevertheless claim that the voice as at present used suffices for all practical purposes, and this is true as regards testing persons of normal hearing, or testing differences of hearing before and after extracting inspissated cerumen as well as before and after treatment in acute catarrhal and purulent middle ear disease. But we have to consider also the different forms of chronic middle ear disease.

Formerly—some years ago—non-suppurative chronic deafness was regarded as incurable, perhaps made worse by treatment, and the patient was dismissed with the statement that nothing could be done for him—that he would not get worse, or, again, that as his general health improved his hearing would return. The patient was thus turned over to the mercies of the quack or of the enterprising manufacturer of patent invisible ear drums, whose advertisements still grace our periodicals.

To-day many of these chronic cases are cured entirely; many are improved; in some the progress of the disease is arrested, in others delayed, while in some cases there is certainly no help from treatment and sometimes a more rapid decrease in the hearing following it. In all these chronic cases it is important to measure the hearing for speech.

It is remarkably true that chronic catarrhal middle ear diseases are amenable to treatment in inverse ratio to their time of progress. When the aurist is consulted in the early stages of the disease it is of the utmost importance to know and to make the patient know two things, 1, exactly how much the hearing is impaired as compared with normal hearing, and 2, whether there

is improvement or loss, however slight, between two dates, separated by a certain interval. Whether no treatment is given or change of climate advised or treatment directed to nasal catarrh or locally to the ear, it is of equal importance that such tests should be conclusive to the patient. This is however often impossible, when dependent upon the aurist himself. Aside from variation due to colds, age, etc., the patient places no such confidence in the physician's voice as in the test types of the oculist, hanging at the other end of the room, with the normal visual distance clearly marked upon them. Even with confidence on the patient's side and perfect conscientiousness on the physician's, it is impossible to reproduce with absolute exactness the words whispered or spoken—say one year after the first examination, and a slight mistake here might lead to a great mistake in prognosis and in treatment. At present records are of value only to the aurist making the examinations.

To sum up briefly we need a method of testing the hearing which shall 1, make use of human speech; 2, which shall be accurate and independent of the examiner; 3, which shall make a record capable of interpretation and use by other aurists.

It is believed that in the phonograph we have the only instrument which at present fulfils these conditions.

Prof. Lucae, in Berlin, has invented the phonometer, an ingenious instrument which measures the strength of expiration in speaking certain words. This fails in that it does not measure the clearness of articulation. Since the invention of the telephone many electrical acoumeters have been invented in which the tone is given by an electrical tuning fork, and the hearing distance for certain tones accurately recorded. Such instruments have been invented by Hartmann, Jacobson, Gradenigo and others; but they do not give articulate speech, which is an absolute necessity.

The thought that the phonograph would theoretically give the desired means of testing the hearing occurred to me long ago, as it has probably occurred to many others. It is, however, only recently that I have been able to use it in my own practice. In speaking in Berlin with Prof. Trautmann upon this subject he expressed the belief that it would prove useless in testing imperfect hearing because of the necessity of using a tube in the ear to transmit the sound, and because of the slight volume of sound. My own method of using the instrument is to dispense with all connection by tube to the patient's ear, measuring the distance in metres or feet at which the patient can repeat words previously spoken into a cylinder turning at a certain speed and then reproduced by the phonograph, the patient being placed at first beyond hearing distance and

then gradually brought nearer the instrument. I then record name of patient, date, and hearing record upon this same cylinder, either giving same to the patient or keeping it carefully put away. In addition to this voice test I test through a tube one meter long the softest whisper which the patient can distinguish. My attempts to use whispering to measure the distance in the same way as with the voice have failed for the reason that the hearing distance for the normal ear is only from one to two feet. My own experience has shown that Prof. Trautmann's objection as regards volume of sound is not valid, the phonograph reproducing words with such volume that the normal ear hears and repeats them at forty feet in a quiet room, thus giving good range for testing slight and moderate loss in hearing distance.

In testing patients having partial hearing, one heard loud whispering at fifteen feet, the phonograph at twelve feet; another the loud whispering at five feet and the phonograph at two and one half feet; a third whispering at three feet, phonograph at one foot. These and similar cases show what one would expect—that the human voice is heard relatively farther, by those persons whose hearing is imperfect, than its reproduction by the phonograph. Those patients who did not hear the whispering at all, did not distinguish the words of the phonogram, yet in such cases, where the loud voice is heard at two feet, one can test with the phonograph and the hearing tube. In case of those persons who hear shouting alone, or very loud speech, any accurate measurement of the hearing distance is almost impossible, and it is certainly not possible with the phonograph at present.

Among the objections occurring most forcibly to me during my work upon this subject the first was that it is not the human voice which is used, though a wonderfully perfect reproduction by mechanical means, and that the volume and quality of the voice lose in transmission. Yet the volume of sound is sufficient to give a range of forty feet to record differences in hearing distance, or more than the length of the room usually at the aurist's disposal, and the quality still permits of the recognition of a friend's voice. A new diaphragm still thinner than the one in present use is expected within a year, and this will undoubtedly add to the accuracy of reproduction and to the volume of tone.

The second objection was that the prepared cylinder, or phonogram, must in case of consultation be carried about by the patient and if lost, the record is lost. To obviate this I have in some cases prepared two cylinders, giving one to the patient and keeping one myself. The hope presenting itself to me before experimenting was that one person should speak into a cylinder and this cylinder be indefinitely reproduced by the electrotyping process, and fac simile phonograms be

used by all aurists possessing phonographs, as all oculists use printed copies of Snellen's types. In fact this process has been carried so far that five accurate copies have been made of a given cylinder, although at a very great expense, and Mr. Edison hopes to make indefinite reproduction practicable.

Thirdly, the objection occurred as to the possibility of variation in different machines. The chief points where variation in the part of the machine would make variation in the reproduction are the glass diaphragm and the sapphire needles. The glass diaphragms are three one-thousandths of an inch in thickness and both they and the needles are made as exactly alike as is possible to skilled machinists. I have tested this question practically by taking the same cylinder and using it in the same room on three different machines taken from stock at random, having the hearing distance controlled by another examiner whose hearing is normal, and by myself, and we could detect no difference in the hearing distance for the different machines. The possibility of the sapphire points being screwed in loosely or similar mistakes cannot be obviated, which is true of any instrument of precision.

Among less important objections are the cost, sixty dollars per year. Then the wearing out of the cylinder by use, which can however be neglected, as one cylinder has repeated thirty-four hundred times before becoming indistinct, while I have myself tested the same cylinder one hundred times with no discernible difference in clearness of tone. The time which is necessary for its use is also an objection to the instrument. This holds however only for the first examination; afterward no more time is necessary than in other methods of testing.

In using the phonograph it is desirable to have a room which is quiet—indeed, this is the only way in which uniformity can be obtained, and a second examiner make a comparison with the previous phonographic record, phonogram, brought by a patient. The instrument itself is undoubtedly familiar to you all. The only points of adjustment are the speed of the cylinder and the screw which, after a cylinder is put on the phonograph, enables the reproducing needle to fit exactly in the grooves in the wax made by the recording needle. Both adjustments are very easily made. In practice I set my own instrument at one hundred and twenty revolutions per minute, which speed seems to give the best reproduction.

In concluding I can only say that my own experience has satisfied me that my phonographic tests and records are far more reliable and accurate than any I have been enabled to make by any other method. And yet it seems to me equally certain that in the future this method of testing will be rendered still more perfect.

THE CLINIC.

DIAGNOSIS OF AN ABDOMINAL TUMOR ;
BROKEN NEEDLES LEFT IN WOUNDS ;
PROSECUTIONS FOR ALLEGED
MALPRAXIS.

A Clinical Lecture delivered at the University Hospital, Philadelphia.

BY WILLIAM GOODELL, M.D.,
OF PHILADELPHIA.

The age of this woman is 43 years, she is married and has had eight children. I have not seen her before, and she has been sent to me by her physician for a diagnosis of her case. Her present ill health began after an attack of pleuropneumonia, with vesical disturbances, especially a burning and scalding upon urination. She still menstruates regularly and has no uterine trouble. But she complains that she has no appetite; that she always has a sensation of fullness over the epigastrium; that after eating she feels distressingly distended; that during the last four weeks, for no apparent reason, she has been losing flesh, and that there has developed in her abdomen "a swelling." "Swelling" is the euphemism she employs, because the word *tumor* has a hateful sound in every woman's ears.

As I look at this abdomen and gently percuss it with my finger tip, I see a wave travelling over its surface, and there is transmitted to my hand on the opposite side a very marked sense of fluctuation. Fluid being evidently present, the next question to be answered is this: Is this fluid free, or is it in a sac? If it were in a sac, it would lie in front of the intestines and I should have a dull sound on percussion, especially in the region of the navel and below it. But if the fluid were free, the intestines, as they contain wind, would float upwards on the surface of the liquid, and consequently give resonance on percussion. But on percussing now I find there is no dulness whatever, even at the most prominent portions of the abdomen. I think, therefore, that this fluid is free in the abdominal cavity. Yet in this opinion I may be mistaken; that is to say, the fluid may not have been originally free, for it may have escaped from a ruptured ovarian cyst. Yet if this condition had been caused by such a mishap, there would be the history of a sudden and serious peritonitis, or certainly of great peritoneal pain with more or less collapse; but upon inquiring I cannot elicit the history of such an occurrence, so that I still believe that this fluid in the abdominal cavity was free from the start and not from a ruptured cyst. Now this free fluid in the cavity of the abdomen comes usually from some disease of that great vital tripod—the liver, the kidneys and the heart. I shall start with the liver, as I am nearest to that organ. There is no enlargement of it, and no cirrhotic atrophy.

There is, in fact, nothing wrong with it in so far as I can make out, but not being a liver specialist, I may fail to detect some of its more recondite diseases. Nor can I find anything abnormal with the heart to explain the presence of this abdominal fluid. The urine has been carefully examined and proves that the kidneys are perfectly healthy. There is no history in this case of chronic peritonitis, so that up to this point I am at a loss to account for the dropsy.

This compels me to make an examination of the pelvic organs. The patient's nates are well drawn over the edge of the table, and her feet held by two assistants. I find here an enlarged womb, as well as a laceration of the cervix. But these lesions can have no bearing whatever upon the case in hand. The measurement of the uterus is plus three inches. I can find, then, no pelvic cause for her trouble; but she is very nervous and so incapable of thoroughly relaxing her muscles that my diagnosis is not complete. The only way to examine her satisfactorily would be to remove the fluid and then to exhibit ether, if the neurotic element were still in the way. However, before I tap this patient I shall hand her over to the Medical Department, in the hope that they may there either diagnose her case or remove this ascitic fluid without resorting to an operation. (The patient was here removed.) There is such a thing as a saddle-bag cancer straddling the spine and pressing upon the large veins which lie there. This will be readily discovered when she has been tapped. I did not say this in her presence because *cancer* is a forbidden word to a suffering woman, and I hardly knew how to explain my meaning by another euphemism.

PROLAPSUS UTERI AND METRITIS FROM CER-
VICAL LACERATION.

This woman has had three children and all of her labors were natural. She complains of having had leucorrhœa, pelvic pains and backache since the birth of her first child. Dr. Taylor tells me that she has had a bad cervical tear and also a cystocele; but upon the latter I shall not attempt to operate today, as I have not the time.

I ask the question: Why does this woman suffer so much pelvic pain? The trouble began primarily in the laceration of the cervix, which by keeping up a source of constant irritation invited an abnormally large blood supply to the part. The result of this overflux of blood is well expressed by the single word, hypernutrition. The weight of the uterus being thus increased, it became displaced and pressed abnormally upon adjacent structures, which could not bear the weight without resenting it.

She is now put in Sims' left lateral position and when the speculum is introduced the vagina is ballooned up by the air's rushing to fill up the

vacuum. I then take a stout shoemaker's thread and pass it through the cervix, in order that I may by this means draw the uterus down to within easy reach. The laceration, which is red and angry looking, presents some degree of ectropion. The sound gives a measurement of plus three inches. Taking hold of this string, I hold the organ in position while I denude the lips of the old laceration on either side, taking care to leave on each lip and opposite to each other ribbons of undenuded tissue in the middle where I wish to make my future os and cervical canal. This bad tear which those of you who are on the front benches can readily see, is what used to be called an "ulceration of the womb," and is still so called by some physicians who compose the rear-guard of our profession. I am often at my wits end to know what I should bring before you in the way of an operation. If I have one like this—which is almost concealed from view—very few of you can see what I am doing. On the other hand, if I do a laparotomy, which all of you would be able to see, the operation is one which most of you would and should never perform. Yet you must see the larger as well as the smaller operations, but I generally reserve the latter for the ward classes, which being limited in numbers, can see every step of the operation. Therefore, at our next clinic I expect to remove, in this amphitheatre, a large solid fibroid tumor of the uterus, and the week after a very large and diseased kidney. I have reserved them specially for these occasions because the operations will be visible to all.

I am not left-handed, but by resting my elbow on the table I can use my left hand pretty well in working with this long handled knife, which I prefer to scissors. Scissors do not cut so smoothly as a knife and, therefore, do not leave a wound, which can be so perfectly coaptated. The cervix was so soft, large and angry looking that I feared pregnancy, until I had made a careful examination into the case. But as a result of this condition there is an unusual loss of blood, from this operation which is generally comparatively bloodless. Having denuded all the torn surfaces, and having left a narrow undenuded ribbon in the middle of each lip, I am now ready to sew it up. The needles for this operation should always be so tempered that they will bend before breaking, otherwise they will be liable to break off in the hard cervix which is sometimes as tough as sole leather. When once they break off it may be impossible to find the fragment without an injurious dissection of the parts. Not long ago I casually heard that a skilful surgeon in a distant city was about to be sued for \$10,000 damages, because it was accidentally discovered by another physician that the former had left a piece of broken needle in a perineum which he had repaired.

I accordingly wrote to this brother in distress

that, if my evidence could help him out of his difficulty, I should be glad to furnish it. For I had more than once left at least half of a needle in the cervix and at another time fully an inch of a large needle in the perineum. These patients are perfectly well and to this day do not know that they are carrying portions of surgical instruments in their bodies. I also recalled to him the fact that many hysterical girls have with impunity converted themselves into human pin-cushions by swallowing innumerable needles, which have travelled all over the body and been extracted at places very remote from the stomach. I presume there is not a surgeon, who has not broken needles and left a fragment in his patient's body, without the slightest mischief accruing. When one can tie, as many have, the pedicle of an ovarian or uterine tumor with iron or silver wire and drop it into the abdominal cavity to remain there until doomsday; or when we get broken bones to knit by uniting them with strong iron wire; or when one can leave for weeks, as I have done in chronic peritonitis, a glass drainage tube in the highly sensitive and vulnerable abdominal cavity; surely a needle in the cervix or one in the perineum can do no more harm than an earring.

But these attempts to prosecute a physician on the slightest provocation, have made me very cautious. For instance, I never perform an oöphorectomy, without explaining in the presence of competent witnesses, why I wish to perform the operation and what will be its results. A very unfortunate English physician neglected this precaution, and as the result lost money, health and an enviable hospital appointment, although he won finally at the end of a protracted, expensive and most worrying suit at law. The husband complained that his wife was unsexed; the wife, that she was not told what the nature of the operation was to be; the narrow-minded directors of the hospital, that the surgeon had operated without calling in counsel.

Let me give you one of my experiences: Not many years ago one bitter cold day in winter a poor man came to my office from a town several miles distant in a neighboring State, begging me to come to the aid of his wife who had been long in labor and could not be delivered.

It was in the midst of my office-hours, the weather was very cold, the fee offered was not a tempting one and I requested him to go for some one else. But he begged so hard that for humanity's sake I could not refuse. When I got there I found that his wife had a shoulder presentation, and had been attended by four physicians, who each in turn had tried in vain to turn the child, and deliver her. They were all present and as the question of embryotomy had come up they had sent for me. The woman was much exhausted, and we all felt that her only chance lay in a speedy delivery. She had been kept more or less

under ether for hours, and a little more was now given her. Knowing that the womb had moulded itself to all the irregularities of the child, which moulding had prevented version I concluded to try a wrinkle of an old French accoucheur whose name I have forgotten. It was this: I caught hold of the hand of the shoulder which did not present and made traction on it. This manoeuvre turned the child over, on its long axis, and extricated its body from the uterine mould which had "set" around it like a cast of plaster. I was then able very readily to make podalic version, and to deliver the body as far as the head. But here an unexpected difficulty occurred, one which I have never met with before or since. The long irritated cervix or the lower zone of the womb closed like an iron collar around the neck of the child and imprisoned the head. While I was trying to release it, the woman suddenly and unexpectedly died. All this occurred within a very few minutes.

I shall not describe the scene that followed; it was a very painful one. My only consolation was that I had done my duty. Now, would you believe it! A few days afterwards each one of the physicians present, including myself, was notified that a suit for malpraxis had been instituted against him. I put my case in the hands of a lawyer, who gave me a letter to a leading citizen of that town, asking him to stand bail for me in case I should be arrested, as I might be at any time when called there on a professional consultation. For, of course the plaintiff would be only too glad to arrest me and try me in his own State. For months I carried this letter in my pocket, but I never had to use it, for when the matter came to the pinch we all showed such fight, that the case was abandoned. This is the second time that I have been threatened with a prosecution for alleged malpraxis; but in it I also more than met the plaintiff, and that case was also abandoned.

In this relation let me tell you what I read in the daily papers the other day, showing how careful we all should be to surround ourselves by safeguards: A physician in Belgium, in a case of necrosis of the leg of a child warmly advocated excision of the dead bone. The mother said she would give her consent as soon as the grandmother was willing; but it took the old lady exactly one year to make up her mind. Her consent being obtained, the child was etherized and the diseased bone laid bare; but it was then found that the necrosis had proceeded so far during the year that it was impossible to save the limb. Accordingly, the surgeon assumed the responsibility of amputating the leg. He was sued by the father and had to pay him 10,000 francs for damages.

In this country, surgeons of note were often prosecuted for the unavoidable shortening of fractured long bones, especially of the thighs,

during the process of repair. Indeed, if I am not in error, even the late Prof. Samuel D. Gross, with all his reputation, had to stand a suit for malpraxis. But this is becoming more and more rare, because the community is getting more and more intelligent. The practical lesson that I wish to impress upon you all, by citing these examples, is simply this: that if the public presumes to attack the professional characters of men who are your medical teachers, how careful you should be in all important cases to guard yourselves by calling in older and more experienced advice—and by getting the responsibility shared.

Again; never say there is absolutely no danger whatever in any operation or in any surgical procedure. On this point some years ago I got a bitter lesson: I was asked by a patient, upon whom I was about to operate at one sitting for a laceration of both the cervix and the perineum, whether there was any danger to be feared from the ether. I laughed her to scorn and called it the child's play of the operation. But mark the result: both operations were performed and very satisfactorily too, but as the lady emerged from ether-narcosis, incessant vomiting set in which could not be controlled by any means known to me, or to a consultant whom I called in. On the fifth day she died from heart failure, from this very etherization from which I said there was no danger. Therefore, I now never tell a patient that there is no danger whatever in any operation.

So take this lesson home with you to day: Never to promise too much to your patients; for as you are not sure what the day will bring forth, you certainly never can be sure what an operation may bring forth.

MEDICAL PROGRESS.

IMMUNITY AND INFECTION.—These conditions have recently attracted marked attention from Continental writers, especially in Italy and France. Numerous theories have been advanced, none of them can be said to have been wholly satisfactory, or to account for all the varying and apparently contradictory facts.

CHARRIN et ROGER (*Contribution à l'étude expérimentale du surmenage. Son influence, sur l'infection. Arch. de Physiol.*) have made some experiments regarding the effect of fatigue upon infection, upon lines laid down by Solowieff, who demonstrated upon horses and men that great fatigue favored the development of certain infectious disorders. In their experiments animals were employed, that had been exercised in a revolving drum. The reaction of different species to this treatment was found to vary greatly, rabbits and guinea-pigs soon presented evidences of pain,

fright and vertigo, that were soon followed by a fall of temperature and death. Dogs, cats and white rats bore this extreme exertion without special disturbance, and after running twelve hours in the drum would be in a normal condition the following day.

In the first experiment thirty-six white rats were inoculated, part with a weak culture of anthrax and part with the bacillus of "charbon symptomatique." Twenty-one of these animals were placed in the drum and allowed to run from two to eight hours, the remainder were reserved for control. The results in all the experiments were nearly equal, the animals that were fatigued died in less time than those which were allowed to remain quiet; in some instances the animals that were allowed to rest would survive the infection—the others invariably died.

THERAPEUTICS OF GASTRIC DYSPEPSIA.—M. GEORGES contributes (*Revue Médicale de l'Est*, September 1, 1890) a paper on this subject, based on a number of experiments he has made on the relative digestive powers of natural and artificial gastric juices. Cubes of hard-boiled white of egg were placed for a certain length of time in an artificial gastric juice containing HCl and pepsin in varying dilution. He finds (1) that to effect a speedy and satisfactory digestion of hard-boiled egg or of roasted and raw meat it is necessary to use a gastric juice containing a large quantity of HCl and a minimal quantity of pepsin. (2) The hydrochloric acid ought to be employed sufficiently dilute; a 0.4 per cent. dilution appears to be preferable to one either weaker or stronger, such as 0.1 per cent. to 0.2 per cent. or 1 per cent. (3) The best proportions of HCl (0.4 per cent.) and pepsin are about 5 cubic centimetres of acid to 2 centigrams of pepsin. (4) It is necessary to employ the artificial juice thus made in sufficient quantity to obtain the best result. Thus if the above proportions of acid and pepsin be taken as the unit, it may be said that the digestive power of the juice increases with the quantity employed, and that the increase is in the proportion of 12 to 8. This only applies, however, within certain limits. A combination of 40 cubic centimetres of a 0.4 per cent. solution of HCl with 8 to 10 centigrams of pepsin gives the best results of all. His observations on the digestive capabilities of natural gastric juice were made on 142 specimens taken from 69 patients. In 8 cases of "chlorotic anæmia" the contents of the stomach were found on eighteen occasions to have no digestive power at all; on two occasions they possessed a slight power; and on one occasion digestive power was normal. In each of these cases the addition of pepsin failed to modify the digestive action; in one instance, indeed, it appeared to delay it. The addition of HCl, on the contrary, had a very marked effect in 12 cases,

but was without result in 8 cases. Of all the degrees of dilution employed, 0.4 to 0.6 per cent. of HCl gave the best results. In 9 cases of gastric ulcer the digestive power of gastric juice was found to be excellent on nineteen occasions, and absent altogether on ten. In these ten instances pepsin was found to be hurtful in its action on three occasions, while HCl (0.4 per cent.) restored the digestive power on six occasions. Analogous results were obtained in 92 specimens of gastric juice obtained from 52 different cases, including such affections as tabes, catarrhal jaundice, acute and chronic gastritis. In 87 of these 142, the gastric juice was without digestive power. The addition of HCl (0.4 per cent.) proved useful in 16 cases, while pepsin entirely failed, even impeding the digestive process on twelve occasions. The result, therefore, of the observations on 142 samples of gastric juice was that 115 were found without digestive power. In all these cases pepsin had no action, appearing sometimes to be even hurtful (sixteen times). The conclusion he draws from these data seems, then, justified—namely, that pepsin is useless where the dyspepsia is due to some primary or secondary disturbance in the gastric secretion, while hydrochloric acid can be used with advantage in such cases. A further series of observations on the digestive power possessed by various medicinal preparations containing as their basis hydrochloric acid, pepsin, pancreatin, or papain, showed that they were without action in all cases; they did not facilitate digestion either in the case of artificial or of natural gastric juice.—*Brit. Med. Jour.*

THE DISORDERS OF SLEEP.—In a recent article DR. WEIR MITCHELL devotes himself to a consideration of a topic of more than ordinary interest—the disorders of sleep. Our text-books usually contain brief and unsatisfactory chapters on sleeplessness and its treatment, but further than this they seldom go; yet sleep is infested by a multitude of derangements whose uncertain pathology has hitherto rendered their classification very imperfect.

The little actually known regarding the nature of sleep, has perhaps tended to keep in abeyance speculations regarding the disorders that accompany the somnolent state; for in addition to the fact that the sleeping brain contains less blood, or that the blood within it circulates more slowly than in the brain awake, we know nothing, and can only affirm in a general way, that sleep is a condition of the nerve cells, a definition even less satisfactory than that given by Sidney Smith to the person who asked him what an Archdeacon was, when he replied that an Archdeacon was a person who performed archdeaconal functions.

The periods before and after sleep are often found to be states of unusual liability to halluci-

natory disturbances. These periods Dr. Mitchell has, for convenience, termed the prædormitium and the post-dormitium. Baillager, whose brilliant researches have covered every region of delusional manifestation, found that hallucinations in the prædormitium were exceedingly liable to be prodromes of an outbreak of insanity. In the half-conscious state the control of ideas is lost, and fantastic shapes crowd upon the mind as the outcome of external sensory impulses.

Another derangement, perhaps allied to the intellectual disturbances just mentioned, is an emotional derangement, which consists in an intensely aggravated sensation of fear. This seldom occurs in the prædormitium and generally follows a sleeping period. Faulty digestion may contribute something to this, and the painful emotion may be the subjective interpretation of visceral impulses, as the emotion appears without traceable parentage in dreams or sensory illusions. More frequent in occurrence than this, is the condition known as "the fidgets," where the patient, filled with all manner of unreasonable fears, is a prey to perpetual unrestfulness.

Another peculiar sleep disorder is sleep- numbness or nocturnal paresis or paralysis, which differs from all similar paræsthesiæ, being unlike those of neurotic, anæmic, gouty or asthenic origin. Some have deemed this paræsthesia to be connected with a subsequent attack of diabetes. First thoughts would naturally revert to excessive overwork or tobacco as responsible for this form of paralysis. Dr. Mitchell, however, appears convinced its origin is central.

Sleep-ptosis or palsied eyelids is another disorder allied in character to these just noticed. Dr. Mitchell reports two cases. The patients awake with palsied lids; when opened they close again. This is one of the night palsies of temporary duration.

Sleep-pain is a frequent hysterical symptom. Any one, however, who has suffered from the leg-ache peculiar to sleep, will realize that pain can certainly persist throughout the sleeping period.

Sleep-jerks of choreic character are among the most common phenomena when the motor area is involved. These are more frequent than tonic spasms, which are manifested but rarely.

The whole subject of sleep disorders is one of great interest, and deserves to be patiently and carefully studied.—*Physician and Surgeon.*

DIETETIC MANAGEMENT FOR DIGESTIVE DISTURBANCES IN CHILDREN.—DR. G. RHEINER, in *Wiener Klin. Woch. (Therap. Monatsh.)*, warns above all against beginning the treatment of digestive disturbances in children with drugs; the dietetic management is and will remain the most simple, as well as by far the most rational. A child that manifests moderate gastric disturbances

shortly after being weaned, should again be nourished from the breast, in order to quickly relieve it from its digestive difficulties. In cases of gastric dyspepsia occurring in bottle-fed babies, Rheiner warmly recommends washing the stomach, as introduced by Epstein, of Prag. After this procedure the digestive powers of the stomach will probably remain weak for a few hours, and for a short time it will be necessary to replace the water lost by the body by a suitable diet. As such, albumen and water (the white of an egg to a pint of water), barley water, or a very weak infusion of tea, suggest themselves. In intestinal dyspepsia we should carefully guard the stomach against disturbing influences. For this reason anti-diarrhœal mixtures should not be at once administered; we should rather order an exclusive diet of milk and barley gruel to a suitable proportion of water. Here the constipating qualities of barley gruel are valuable as compared with oatmeal gruel; the latter, used in constipated infants, will, as a rule, bring about two or three loose evacuations per day. In closing, the author emphatically remarks that in many cases we can get along altogether without drugs.—*Weekly Medical Review.*

THE FUTURE OF DERMATOLOGY.—In the Dermatological Section of the meeting of the British Medical Association of the current year the address was made by JONATHAN HUTCHINSON on the above subject.

The object of his address was mainly to point out the value of dermatology as a field for clinical observation, and as a department of general medicine.

He showed what the laws were which governed the study of dermatology, and how rich a field it formed for the student. The aim of all true-hearted specialists was to break down the walls of specialism. He referred in illustration to the instructive nature of the group of maladies known as herpes, and the peculiar influence of arsenic upon it. Despite the etymology of its name, no true herpes ever creeps or spreads in the least. What was seen in a large majority of disorders of the skin led to the belief that common inflammation, however produced, was more or less infective. His belief was that it was possible to exaggerate the importance of the doctrine of the infectiveness of common inflammation.

Treatment should rather be aimed at the repression of local inflammation, and at preventing dissemination by infection. He referred to the action of inheritance on skin diseases, and said that Kaposi's disease was one of the best examples of "family disease," which he said simply seemed to be the inheritance of a skin that would not bear exposure to sun and air. Then, again, the battle of the hypothesis of cancer would have to be fought out on the skin, and rodent ulcer

might indeed, by itself alone, form an epitome of our knowledge of the subject. In melanosis the picture was completed, and the infection of the blood was seen in its fullest energy. He next referred to the opportunities offered in connection with skin diseases for the study of therapeutics and for observations on the action of drugs. Arsenic, of course, stood foremost among those concerning which we have collected important and even astonishing facts.

There was no more wonder-producing fact in the whole range of therapeutics than the ease and rapidity with which arsenic contracts and cures common pemphigus. There may occasionally be exceptions, but, as a rule, not another bulla appears after the remedy has been commenced. We have, indeed, ceased to see any cases of "chronic pemphigus" since this fact has been made known. How the drug acts we know not, neither do we know the real nature of the malady which we cure. It does not always cure it, but it always changes it for the better. He who would unravel all the mystery of how the bullous eruption may be cured and the scaly one changed, how the skin may be made to clear up in one case and muddy and brown in another, how peripheral neuritis may be produced to end finally, unless prevented, in some severe form of paralysis and death, and how in rare instances the nutrition of the skin may be so influenced that keratosis and even cancer may be the result, will certainly find that he has his work cut out for many years.

In the study of dermatology he pointed out that we have in the first place to avoid narrowness and specialism, and in the second place to develop to the utmost our knowledge.

Only the foundation of the subject has as yet been laid.

More minute examination was needed in every direction, and the careful examination and record of clinical facts exactly alike.

All possible aids must be invoked.

The microscope, the photographic camera, the artist's pencil, but, above all, the trained eye and the pen of the skilled and patient observer, must be brought into full use. No one can make the attempt to classify skin diseases without soon perceiving that many well-recognized forms claim a place in more than one group. We are engaged in a very different task to those of the zoölogist or botanist, though, after all, the differences are only in degree, and they encountered the same difficulties, only to less extent. They, like ourselves, have to recognize connecting links, hybrids, and mongrels. In order that dermatology should prosper as a part of medicine, it is essential that we should learn to use our names lightly. Nothing has more impeded the progress of dermatology, nothing makes its study more repellant to the student, or its knowledge more difficult of attainment, than the habit of giving an

arbitrary name to every little group of phenomena, treating that name as if it represented a substantive and isolated reality, and insisting that the facts of disease should be made to group themselves in accordance with our conventional nosologies.—*The Lancet*.

PLEXIFORM NEUROMA.—E. LACROIX and P. BONNAUD (*Arch. de Méd. Experimen.*) describe the case of a lad 12 years of age that for the past six or seven years presented a slowly enlarging growth upon the left shoulder. The tumor was not painful, the skin movable, pigmented, and sensibility lessened. The tumor was readily movable upon the subjacent tissues, and presented a general appearance like that of an inflamed varicocele. The operation revealed a mass of fibres varying from a thread to a feather-rib in size, and extending between the muscular septa. Microscopic examination showed the tumor to consist of mostly hypertrophied nerve fibres, the nervous elements as well as the connective tissue participating in the hypertrophy. It was connected with nerve bundles and simply consisted of an enormous number of Remak's fibres, with here and there a fibre presenting the medullary sheath.

EARLY DIAGNOSIS OF KIDNEY TUMORS.—M. GUYON believes that surgical intervention is indicated, both for diagnosis and treatment, when characteristic hæmaturia and pain distinctly localized in one or other loin are met with, and in his opinion the time when the tumor is perceived must not be waited for. The cystoscope, though of service, is a defective means of diagnosis in his experience, and fails to declare which is the affected kidney. *Periodic* microscopic examination of the urine is needful before deciding that hæmaturia is absent.—*Annales des Maladies des Organes Génito-urinaires*.

RAPID DILATATION OF URETHRAL STRICTURES.—DR. P. SETTER reports the following modifications of Le Fort's method, as practiced in Brun's clinic. After induction of anæsthesia a filiform bougie is passed through the stricture. A well oiled catheter is then screwed to the bougie and carefully inserted, using the latter as a guide. The dilatation is kept up from five to fifteen minutes, after which the catheter is withdrawn and replaced by one of larger calibre. This is followed by a third and fourth, and if the resistance is not too great, the largest sized instrument can be introduced. This method is contra-indicated in tight strictures where too much resistance is encountered, in cases where the urethra is very sensitive, and finally in cases where rapid relief is required. Aside from these, the method is excluded in comparatively wide, or in impermeable strictures.—*Centralbl. f. d. Gesammte Therapie*.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE.,
CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the Treasurer, Richard J. Duglison, M.D., Lock Box 1274, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, DECEMBER 13, 1890.

PROFESSOR KOCH'S NEW REMEDY.

No other event produced an impression so profound in the vast assemblage of medical men at Berlin, as did the reading of a paper by DR. KOCH, in which he stated his definite conviction that not only had the bacillus of tuberculosis been identified, but that he had in hand the remedy for its control. It had been his purpose before its publication to subject it to a most thorough testing, and in every particular to perfect the details for its use. But a discovery of such untold value could hardly be held in confidence. The public press had already contained such exaggerated statements that at the urgent solicitation of his friends, rather than from his own inclination, he was induced to present to the International Congress a preliminary paper upon his treatment of tuberculosis. He then intimated that as soon as his investigations should be in some measure completed he would more fully communicate to the world the facts with reference to his discovery.

In the *Deutsche Medicinische Wochenschrift*, of November 15, his second communication is published. No one who peruses this article can fail to appreciate that if his clearly expressed convictions shall be fully realized, it will prove the most important communication ever given to the world by human hand.

We mark with utmost satisfaction the candor with which he gives expression to his belief and we by no means hold him responsible for the head-

long conclusions to which some of his followers at once attained. Since the meeting at Berlin he has summoned to his aid a number of eminent men whose names are a guarantee for the fidelity of their work, and in connection with his paper we also find the statement of the results of their individual work, all strongly confirmatory of his claim.

In reading his paper we confess to a disappointment at the outset from the fact that he still declines to divulge the nature and physical character of his new remedy. In the absence of the material facts, it is not within our province to criticise. We cannot believe that a name destined to be so illustrious, and a remedy—if such it shall prove—of such inestimable value shall be degraded to the service of mercenary ends and freighted with shekels.

The remedy is described as a brownish transparent fluid not easily decomposed, of which a cubic centimetre of a 1 per cent. solution is a dose, to be introduced by hypodermic injection preferably upon the back of the patient between the shoulder blades, in which location it produces less reaction and causes less pain. Human patients are found to be far more susceptible to its influence than are the animals generally used in making experiments. Thus it was found that while a guinea pig would readily tolerate the injection of two centimetres of this fluid, one-eighth of that amount would produce intense effects in a healthy man.

With reference to those effects he states that in persons in health or subject to other than tuberculous diseases, hardly any special result is observable, and that this fact will be of special diagnostic value. The reaction which follows the introduction of the remedy usually begins some four or five hours afterward and lasts from twelve to fifteen hours, sometimes later and with less intensity. It begins with rigors and with fever, pain in the limbs, coughing, fatigue and vomiting. The patients recover promptly from the attack and express themselves as feeling better than before. Of course the therapeutic effects are those that most concern the medical man and the welfare of mankind. One thing he says is certain, "there is no question of a destruction of the tubercle bacilli in the tissue, but only that the tissue enclosing the tubercle bacilli is affected by the remedy." Necrosis of infected

tissue results and its removal must be sought. He reaches the conclusion that patients become more and more tolerant of the effects of the remedy as they are less and less affected by tubercular disease until, in the absence of effect, we may infer that they are cured. The remaining portion of his communication deals with the application of the remedy in lupus, in tuberculosis of the bones and joints, in phthisis and to its effects on advanced cases of that disease.

A large portion of the next issue of *THE JOURNAL* will be surrendered to the presentation of the paper of Dr. Koch entire, and to the recorded observations of those associated with him in his investigations. Medical men throughout the world will wait the verifications of results, here claimed, with interest most intense, and if in any measurable degree our hopes shall be realized, this work of Dr. Koch will mark a most signal epoch in the world's history.

JUSTICE TO THE DEAD AND THE LIVING!

A considerable amount of attention has recently been directed to the possible extinction of traces of criminal destruction of life, through the methods now in vogue among funeral directors and their agents for the beautification and preservation of the corpse for burial. One of the chief objections urged against cremation has been that the evidences of willful murder might be incinerated with the body, and medico legal investigations thus be set at naught. Certainly the same wholesale obliteration of the direct instrumentation of crime must occur, when the undertaker, as soon after death as in his wisdom sees fit, injects into the vessels and into the stomach of the silent victim, a liquid mass of potent chemical ingredients, for embalming purposes, which must inevitably affect or completely change the composition of any poisonous agent that may have been introduced during life for nefarious purposes. There is a prevailing tendency, at any rate, to relinquish into the hands of these representatives of a necessary but often unwelcome fraternity, the bodies of our dear ones, too soon after death, without question as to the treatment or consideration they are likely to receive: and embalming for burial is one of the processes of personal adornment of the corpse, which tickles the fancy of the thoughtless, but frequently

makes the judicious grieve. That is a sentimental view of the question, however, which we need not pursue further.

As a matter of medico-legal interest, it is our duty as medical men to interpose some check to this fashionable folly, to say the least of it; but also, to put it more forcibly, to inhibit, by some, severe legislative restriction, a practice that will, sooner or later, in some important criminal case, interfere seriously with the detection and punishment of guilt. Toleration of such procedures is almost equivalent to direct encouragement and sanction of them.

THE QUESTION OF THE REMOVAL OF THE JOURNAL TO WASHINGTON.

While, at the meeting of the Board of Trustees which was recently convened in Washington to consider this subject, some were in favor of such change and of immediate removal; to others it seemed a matter of such moment as to require not only careful consideration and deliberation before action, but that upon a question so important the views of the entire Association should be had, and that the decision of its members, rather than a vote by the Trustees, should govern.

The proceedings of the meeting of the Board will be found in this number of *THE JOURNAL*.

The responsibility for such action will devolve upon the membership, and at its next meeting the Association will doubtless decide the question. Editorially *THE JOURNAL* will not pass upon the question nor seek to influence those whose judgment must be final.

EDITORIAL NOTES.

FAITH CURE IN A NUTSHELL.—A very pithy statement—only a little short of being an aphorism—has been contributed against the validity of the proofs that organic disease can be removed by the faith process, as follows: "Clear medical testimony would *compel belief*, but the vague statements of the cured only *confirm doubt*." This striking antithetical declaration is by the pen of a layman, in the English journal, called *Regions Beyond*, devoted largely to missions in Africa. So far as the world at large is concerned, one or two good, clear medical certificates that organic troubles have been cured, would set the question at rest forever. The difficulty is, of course, to

get them. As an example of the kind of cure the cured patients themselves are content to report, we may point to the case of a man of some prominence having organic eye disease, said by the patient to have been cured by the prayer of faith; but if a cure was effected it must have been done without a restoral of vision as a proof, for the man was never able thereafter to read a single line, any more than he could before he was "healed." He is said to be in an expectant attitude, believing that so soon as the strength of his faith is what it should be, he will be able to use his eyes for vision. And yet he continues to maintain that he has been healed. The testimony of such minds must indeed "confirm doubt" among all thinking people.

NOTES FROM A PARIS CORRESPONDENT.—Professor Koch, whose reported discovery of an effective cure for consumption has attracted so much attention, will probably ere long exchange his chair at the Berlin University for a professorship devoted entirely to the study of bacteriology. He will thus be enabled to carry out his desire to apply himself wholly to the study of zymotic and infectious diseases, including not only cholera and tuberculosis, but also typhus, anthrax, diphtheria, and similar affections.

Dr. Liebreich, an eminent Professor of Therapeutics in the University of Berlin, in opening his winter course of lectures recently, dwelt on the enormous importance of Prof. Koch's investigations. He pointed out that in all remedies for disease there are two equally important groups, viz.: those dealing with causes and those dealing with symptoms. The most interesting thing about Dr. Koch's discovery, he said, was the fact that the process of cure he proposes is founded on a knowledge of the nature of the tubercle bacillus, that is, of the cause of tuberculosis. Dr. Liebreich hopes that the further application of Dr. Koch's method will greatly facilitate the effective treatment of infectious maladies of all kinds.

Numbers of persons suffering from consumption have already applied to Dr. Koch with a view to his method of cure being tried on them, but the reply they have received is that the treatment cannot at present be carried out except at Berlin, and not in hospitals, but only privately.

The well known medical authority, Prof. Schrötter, of Vienna University, claims to have discov-

ered, quite independently of the Berlin Professor, R. Koch, a cure for tuberculosis. He has engaged to give a detailed explanation of his remedy at the meeting of the Vienna Society of Physicians. The preparations he employs in curing the disease are said to consist of compounds of prussic acid.

THE PHONOGRAPH IN PRACTICAL INSTRUCTION REGARDING PULMONARY DISEASE.—Dr. J. Mount Bleyer, of New York City, has been carrying on some experiments with the phonograph as a means of recording the various coughs and other sounds emitted by diseased throats and lungs, also the voices of singers when in abnormal conditions. As an instructive object lesson in diagnosis these recorded signs upon the phonograph may be useful as a uniform demonstration to classes of students, from year to year; uniformity being a feature of practical teaching that has never been aimed at because impracticable, if not impossible, in the days before the "sound writer" came into use. As a means of drill to those whose sense of hearing has not been quickened by previous musical tuition, the phonograph may prove very useful.

WHENCE THIS NAME?—The South Carolina "Redbones" have been thus described in an interview with Senator Hampton:

"There is a singular race of people in South Carolina called the 'Redbones.' Their origin is unknown. They resemble in appearance the gypsies, but in complexion they are red. They have accumulated considerable property and are industrious and peaceable. They live in small settlements at the foot of the mountains, and associate with none but those of their own race. They are a proud and high-spirited people. Caste is very strong among them. They enjoy life, visit the watering-places and mountain resorts, but eat by themselves and keep by themselves. When the war broke out several of them enlisted in the Hampton Legion, and when the legion reached Virginia there was a great outcry among the Virginians and the troops from other States because we had enlisted negroes. They did not resemble the African in the least, except in cases where Africans had amalgamated with Indians. This intermixture, which is common in the Carolinas, produces marvellous results. It takes the kink out of the hair of the African, straightens

his features, and improves him in every way except in temper. These Afro-Indian people are devils when aroused, and as slaves were hard to manage."

DR. GUSTAVE MONOD, some time Professor in the Faculté de Médecine, Paris, died on October 16, at the age of 86. He belonged to a highly respected family of Swiss origin, several members of which have been prominent pastors in the French Protestant Church. Dr. Monod leaves a son who is an *agrégé* of the Paris Medical Faculty and surgeon of the St. Antoine Hospital.

CHARCOT'S JOINT DISEASE IN AUSTRALIA.—At a medical meeting in Sydney, N. S. W., was brought forward the first and only case of that affection clinically examined in Australia. The patient, according to the narration in the *London Medical Recorder*, October 20, was a Frenchman by birth, aged 39 years, and was presented by Dr. Scott Irving of the University of Sydney. The affected joints were those of both hips and the left knee. The case attracted a lively interest among the medical men present, and a desire was evinced to become familiar with its salient diagnostic points. The case appears to have been a most typical example of the disease, and a history of syphilis eighteen years previously was given in connection with it.

MEDICAL MISSIONARY CONVENTION IN CHINA.—The medical missionaries residing in China had a conference or convention at Shanghai last May. It lasted three days and the meetings were full of interest. There are reported to be 101 medical practitioners at work in various parts of that country, 34 of these being women. One or more missionary hospitals are inaugurated every year.

A SANITARY SERVICE FOR THE RED SEA.—Premier Crispi, of Italy, has just caused to be distributed to the representatives of Italy in foreign countries a circular, in which he proposes the convening of an International Commission with a view to institute a sanitary service for the Red Sea. He suggests that two international sanitary offices be established, one for the medical visitation of ships which enter the Red Sea from the Indian Ocean, and the other for that of ships which pass from the Red Sea to the Mediterranean. Another proposal in his circular is to the effect that in connection with each of the two

offices should be instituted an international sanitary station, where the ships must put in for disinfection when found to have cases of infective disease, actual or suspected, on board.

JENNER AND KOCH.—It is interesting to note the increased respect now paid to the memory and struggles of Jenner by those who are led to write hopefully of the discovery of Koch. One of our daily contemporaries gives a pithy summary of the reception ordinarily accorded to our great medical benefactors, a part of which is worthy of quotation here: "Small-pox was once even more prevalent in the world than consumption is now and scarcely less deadly. It held the position that its practical eradication has given to phthisis. But a physician found a means to fight it so effective that now many doctors in twenty years of practice never see a case. It is likely to become a medical curiosity. Yet this remedy was reviled, and the man who discovered it was denounced in his day as a charlatan and an impostor. This should at least warn the revilers not to be too hasty about Koch.

"That also was the story of a microbe made nearly harmless by the discovery of how to get at him. Jenner, it is true, did not know there was a microbe. Nearly every phase of his discovery was empirical. It was the same with the great discovery that overcame the malarial fevers. The Spaniards learned from the natives of Peru that fever could be cured by drinking the water of certain ponds around which grew the cinchona trees, and it is likely that these ponds were simply solutions of quinine. It is a great part of the function of science in such cases to give us reasons for what we already know, but Koch has reached his conclusions by strictly scientific stages. Can men of science regard his discovery as less valuable on that account?

"All the great discoveries, however, have passed through the same phases. Some deep thinker labors patiently for years, consumes his days and nights in difficult and baffling experiments and at last makes his way to the light. He is at that period the one man in the world who alone possesses all attainable knowledge of the subject. His discovery is welcomed at first in that spirit of enthusiasm for great things which is the best impulse of the common mind. But soon the doubters are heard from. The smatterers—men who

give hours where he has given years of study—come to the front to belittle his labors. There is, nevertheless, a scramble to realize the advantages. *Haste, incapacity and confusion cooperate to do harm. His method is applied in erroneous ways, the promised results are not obtained, the discovery is discredited and all seems to end in a grand delusion.*

“But happily that is not the real end of the story, for the silent and honest workers continue and the good makes itself felt. It will be thus with Koch's discovery. The charlatan clamor and activity that swarm to the front when fortunes are to be made do their little harm and die away, and when these clouds pass the world *will find that it is the richer for a great and effective remedy against a terrible disease, and in this all the people have good reason to rejoice.*”

THE prize of one hundred dollars offered by the American Association for the Study and Cure of Inebriety for the best original essay on the pathological lesions of chronic alcoholism capable of microscopic demonstration, has been awarded to Dr. P. F. Spaink, Baarn, Holland.

THE Russian Government has made an appropriation of 1,500 roubles annually for the maintenance of a Pasteur Institute in Tiflis for the cure of hydrophobia.

At the Medical Congress of Cuba, Dr. Lyada read a paper on yellow fever, which disease he affirms not to have existed in Cuba before the African immigration.

THE AMERICAN DENTIST IN PARIS.—The following item in the *Illustrated London News* reflects the status of American dentistry at Paris: “Dr. T. W. Evans, the eminent dentist and proprietor of the *American Register*, has returned to Paris from a visit to Carlsbad. On Tuesday last, he invited a number of the dental and medical profession of the French capital to witness the operation, known as ‘dental grafting,’ which was performed by Dr. W. Younger, of San Francisco, who has a brilliant reputation in this department of conservative dentistry.”

THE NATIONAL PENSION FUND FOR NURSES IN ENGLAND.—This is a kind of mutual benefit combination among nurses to provide at low cost against the accidents of disablement and declining years. The Princess of Wales is its presiding

officer. About \$290,000 is the fund acquired within the very short time that has elapsed since its founding. The motto of the association is, “Thrift and Benevolence offering rest to Age,” and the seal represents two strong young damsels helping an aged woman with a crutch to ascend some door-steps.

SPECIAL MEETING OF THE BOARD OF TRUSTEES OF THE AMERICAN MEDICAL ASSOCIATION.

Held at the Riggs House at Washington, D. C., November 13, 1890.

Present:—Drs. Hooper, Hollister, Love, Nelson, Shoemaker and Hamilton.

The meeting was held in pursuance of the following call of the President:

LITTLE ROCK, ARK., Oct. 31, 1890.

Dear Doctor:—A majority of the Board of Trustees of the American Medical Association deem it essential for the best interests of the JOURNAL, that a meeting of the Board should be called to convene in Washington, D. C., and have so signified the same in writing. Therefore, in compliance with said request, I hereby appoint Thursday, November 13, 1890, at 10 o'clock A.M., at the Riggs House, Washington, as the time and place of meeting.

It is important that each member shall endeavor to make it a point to be present. Very truly yours,

(Signed) P. O. HOOPER, President.

The letter on which the foregoing call was made is as follows:

WASHINGTON, D. C., Oct. 14, 1890.

DR. HOOPER, President Board of Trustees, Little Rock, Ark.

Sir:—We, the undersigned, have the honor to request that a meeting of the Board of Trustees be called to meet in Washington, at your convenience, in November, to consider the report of the Committee on Permanent Place of Publication of THE JOURNAL; and also that of the Committee on Advertising.

(Signed) JOHN B. HAMILTON.

“ JOHN V. SHOEMAKER.

“ I. N. LOVE.

“ W. W. DAWSON.

“ D. E. NELSON.

The minutes of the previous meeting were read and as it nowhere appeared that the salary of Dr. Hollister, while acting as Supervising Editor, was fixed at \$250.00 a month, on motion, it was ordered to be incorporated in the minutes of this meeting to take effect from the last meeting. The Secretary stated that he had no record of the meeting of the Board at which the foregoing action was taken, and that it was done during his temporary absence.

The proxy of Dr. Dawson and Dr. Moore was

presented by Dr. Hooper, who was by them authorized to cast their votes.

The Chairman of the Committee on Management stated that no meeting of the Committee had been held. He presented summary statements of receipts and expenditures with a list of payments made by advertisers for the month of October. The circulation of *THE JOURNAL* since April 1, 1890, had increased about 200, notwithstanding that nearly 300 names had been dropped from the lists for non-payment of dues. The question of incorporation was discussed and on motion of Dr. Love it was ordered that application be made for a certificate of incorporation.

Referring to the book of records, the Secretary stated that his letter of resignation as editor was omitted from the book, and on motion of Dr. Hollister it was ordered to be inserted.

Then, on motion, the Board took a recess until 2:30 P.M.

AFTERNOON SESSION.

The Board met at 2:30, and the Committee on permanent place of meeting, Dr. Love, Chairman, made a report in favor of Washington, as a permanent place of publication. He spoke as an individual member of the Committee. He advocated the appointment of a business manager.

DR. NELSON thought the question should be postponed until the next meeting of the Board.

The report of the Committee was then taken up for discussion.

DR. SHOEMAKER spoke of the necessity of strengthening *THE JOURNAL*, and advocated Washington as a permanent place of publication. He felt bound to those who put him on the Board to vote for the National Capital as the permanent place of publication.

DR. HOLLISTER argued in favor of submitting the question to the Association in session.

DR. HOOPER spoke in favor of delay, as he wished the question to come before the members of the Association, but said he would vote for Washington as a permanent place of meeting if it could be shown as the best location. He wanted it inserted in *THE JOURNAL*. He wanted a committee appointed to give the arguments or the reasons why *THE JOURNAL* should go to Washington, and have it published in *THE JOURNAL*.

DR. SHOEMAKER moved that the report be received and a special committee be appointed at once to formulate a plan as soon as the com-

mittee can do so, and report on the removal at this meeting, of which committee Dr. Hooper shall be chairman.

DR. HAMILTON said that so far as expense was concerned, if it were removed to Washington there would be no additional expense over that now involved in the publication at Chicago.

The committee, Drs. Hooper, Love, Nelson and Shoemaker then retired and presented the following report, which was adopted. Dr. Hollister voted No.

Resolved: That the sense of the Committee be that the home of *THE JOURNAL* of the Association should be permanently at Washington, D. C.

Resolved: That the Trustees incorporate the foregoing resolution in their report to be presented at the next meeting of the Association.

DR. SHOEMAKER, from the Committee on Advertising, reported that as the place of meeting was to be changed, he recommended that the committee be continued, with the addition of Dr. Nelson.

On motion it was ordered that the minutes be printed in *THE JOURNAL*.

DR. SHOEMAKER offered the following, which was adopted.

Resolved: That the Trustees recommend the members of the Association, or the various State and local medical societies in affiliation with the Association, to contribute or subscribe funds for the erection of a permanent building as a place of meeting as well as a library and office for the American Medical Association.

The Trustees desire a full discussion of the foregoing resolutions, and it was moved that in order to insure uniformity in the discussion it be requested that communications for *THE JOURNAL* on this subject be limited to fifteen lines.

On motion the Board adjourned until 10 A.M., Friday.

FRIDAY, 10 A.M.

The Board met pursuant to adjournment. Present: Drs. Love, Hooper, Hollister, Nelson and Hamilton.

On motion of DR. LOVE it was ordered that Dr. Hollister be instructed to make such contracts as may be necessary for the conduct of *THE JOURNAL*, until the next meeting of the Association.

At 11:45 A.M., the Board called at the Executive Mansion and paid their respects to the President of the United States.

On motion the Board adjourned subject to the call of the President.

JOHN B. HAMILTON, Sec.

TOPICS OF THE WEEK.

CEREBRO-SPINAL FEVER.

This disease causes annually between 400 and 500 deaths in the State of New York. In 1889 there were 400 cases distributed over less than 100 localities, and including 20 out of the 30 cities of the State. It is a remarkable fact that although New York reports deaths from cerebro-spinal fever every month in the year, not one is reported from Brooklyn. In fact, since 1884, there has been but a single death reported from this cause in Brooklyn. By statistics it is shown to be a disease occurring at all times of the year, its greatest prevalence being in the spring months, and the least prevalence during the summer. The uniformity of its existence is noteworthy. No other disease is so constantly present, as shown by its mortality. Another notable fact is the steadiness with which it clings to a locality in which it has become settled. In New York, Buffalo, and Troy it is epidemic, while in other towns it has occurred in an epidemic manner. As to the causation of the disease, nothing very definite is known. A morbid principle seems to inhere in the locality affected, but what the conditions are which favor this inherence is not known. It clings to large cities, and with equal persistence to rural villages. A high level of the ground-water has been observed to exist in districts chiefly affected, and therefore it is proposed, as a remedial measure, that such places ought to be drained. The co-existent prevalence of pneumonia with cerebro spinal fever, two diseases frequently associated, could not be recorded.—*Tenth Annual Report, New York State Board of Health.*

EARLY RISING AND LONGEVITY.

Professor Humphry's recent Collective Investigation Report on Aged Persons, contains some very positive evidence on a matter which has already engaged the attention of moralists as well as physicians. "The opportunity for nutrition to do its restorative work was in nearly all provided by the faculty of 'good sleeping,' to which was commonly added its appropriate attendant, the habit of early rising." Thus there is a relation between early rising and longevity. No doubt many people will hastily seize upon the sentence just quoted, and employ it in edifying lectures or essays for the perusal of youth, or embody it in popular medical works. Important qualifications follow in Dr. Humphry's report, but they are likely to be overlooked. Doubtless the habit of early rising is, in itself, healthy; most of all, it is a good sign of health, when it evidently signifies rapid recovery from fatigue. Again, it usually denotes a strong will, the gift, as a rule, of a good physical constitution, or at least the safeguard of average bodily strength. Late risers are generally either invalids or persons of bad habits, idlers who are never free from other vices besides idleness. The nervous exhaustion which keeps a man wakeful throughout the small hours produces sleep late in the morning. This exhaustion is invariably due to one of several life-shortening influences, especially anx-

ety or indiscretion in diet or drink. Early rising is thus rather one effect of certain favorable influences, another result of which is longevity, than a cause of longevity. To turn a weakly man out of bed every morning at 7 o'clock will not prolong his life. It will be noted that by "good sleeping" Professor Humphry signifies quick sleeping, "that is, the reparative work which has to be done in sleep is done briskly and well." Here, again, we have an effect of a cause; but preventing a weakly subject from sleeping more than four or five hours nightly would not cause him to live long, but would rather tend to shorten his life. Equally important are Professor Humphry's observations which show that by "early" he does not entirely mean the time by the clock. The word "has a relative significance with reference to the time of going to bed. A person who retires to rest four hours after midnight and gets up at 10 A.M. may be strictly regarded as an 'early riser.'" Thus, early rising is synonymous in long life histories with short sleeping, which means rapid recovery from fatigue, a sign of bodily strength. These scientific facts in no wise contradict the alleged value of early rising as a practice to be cultivated by all persons in good health. It is excellent as moral discipline, and eminently healthy as a matter of fact. Most persons will eat three meals daily. When a man gets up late those meals will probably follow each other at too short intervals to be wholesome. When he is an early riser it will probably be otherwise. He can enjoy a good breakfast, and by the time for his lunch or mid-day dinner he will have an honest appetite again.—*Brit. Med. Journal.—Weekly Medical Review.*

CONCERNING POSSIBLE THERAPEUTIC USES OF HYPNOTISM.

I am not very sanguine as to the future of hypnotism as a curative agent in nervous or other diseases. According to my own researches—and those researches date back eight years or more—the method is vastly more limited than one would imagine from the exaggerated claims which have been of late advanced in its behalf by over-zealous medical men. Let me mention a few of those limitations. In the first place, only a certain (unknown) percentage of persons are amenable to the hypnotic influence; or, to express it more exactly, only a limited number of persons are hypnotizable with the present means at our command. Secondly, the effects obtainable are evanescent; for, unless we hypnotize the patient so often as to incur the risk of doing him an injury, we cannot hope to perpetuate the suggestions sufficiently to do any good.

From these considerations it follows that the permanent effects which one may hope to produce upon the material economy through this class of psychical forces must be insignificant. Functions may, it is true, be exalted or depressed for the time being, but qualitative changes in the structures themselves are impossible. The internal capsule, the thalamus, the motor convolutions, the sensory tracts in the cord once destroyed, are not to be restored by any form of interference. Moreover, a physiological substitution (in Bernheim's sense)

for these and analogous structures, seems well beyond the farthest bounds of physiological probability. Hence, as I have previously mentioned, all attempts to apply hypnotism to the treatment of organic diseases are opposed to sound thinking. Indeed, I regard such proposals as hurtful to science, and particularly medical science, inasmuch as the reputation of the profession for sound judgment is thereby greatly jeopardized. The facts which the advocates of such questionable methods have to present are still too few in number, and too meagrely substantiated, to form the basis of affirmative argument. What then is the position which hypnotism may be expected to assume in the neuro-therapy of the future? In my opinion, the rôle which it is destined to play is a subordinate one. In the light of its present and past history, I do not see how it can be otherwise. As an adjunct in the management of minor degrees of hypochondria, morbid apprehension, depression, and hysteria, it may sometimes be invoked, but then only as a collateral expedient, and largely with a view to rendering the patient more tractable and amenable to other elements in the plan of treatment. The aid afforded by an appeal to the expectancy of the sick is familiar to every physician; by invoking the aid of the hypnotic state such an appeal may be made with an energy which is not attainable while the patient remains in the ordinary mental condition. But, while the miracles recorded by enthusiastic writers make, like Munchausen's tales, entertaining reading, they are not likely to enter into the sober realities of the consulting-room.

In view of what we now know of it, hypnotism is to be dealt with by the physician; for it is evident that a competent medical man is alone in a position to judge of its real or imaginary advantages. Certainly, only such a man should be allowed by our statutes to invoke its assistance in the treatment of diseases, however insignificant.—J. Leonard Corning, *Med. Record*, November 8, 1890.

THE CLINICAL USE OF THE PHONOGRAPH

has been attempted in this country, but without very great results. Better success seems to have been obtained in London. The *British Medical Journal* says that Mr. Ernest Hart recently suggested to Colonel Gouraud that the phonograph might with great advantage be employed to record the characteristic changes in voice-sound which mark a variety of diseases, such as whooping-cough, laryngismus stridulus, and the characteristic forms of dysphonia indicative of some forms of hysteria, and partial paralysis of the vocal cords, dependent upon pressure upon the recurrent laryngeal nerve. This suggestion Colonel Gouraud readily acted upon, and Dr. Felix Semon kindly consented to select from his patients at St. Thomas's Hospital a few cases in which pathological varieties of phonation were present. This was carried out with great success, and on Tuesday night, at a social gathering at 38 Wimpole street, at which a considerable number of eminent medical men happened to be present, the phonograph reproduced the characteristic vocalization of some of these diseases with the most realistic effect. The whoop of whooping-cough,

with the intervening cries of the patient, were as vividly reproduced as if the child were in the room, and so also were the hoarse utterances of a case of stenosis of the larynx. The opinion was generally expressed that this new application of the phonograph to the purposes of diagnostic and clinical instruction constituted a solid gain for teaching, and probably for many other purposes.—*Medical Record*.

IMMIGRANT DERMATOSES.

Dr. James C. White calls attention to the fact (*Journal of the Cutaneous and Genito-Urinary Diseases*) that immigrants import skin diseases into this country. First there are those skin affections which are directly caused by life on shipboard; then there are those induced, after arrival, by influences not previously operative; and finally the direct importation of diseases more prevalent in other countries. In the last class may be included scabies, favus, lupus, leprosy, melanosis lenticularis progressiva, and prurigo. The author states that unless some more stringent laws are made to keep out of our country the pauper and dirty populations of Europe, the direct importation of the diseases we have been considering, and those which may arise as well from the filthy habits they bring with them and transmit to their children, must follow with increasing magnitude. To obviate such a condition the following measures are suggested: 1. To cleanse all immigrants of animal parasites on landing by treatment of person and clothing. 2. To retain in quarantine all immigrants with other contagious diseases, including venereal affections, a sufficient time for treatment. 2. To return to their homes all persons affected with such contagious diseases as it is impracticable to treat in such a way, as leprosy, tuberculosis, and advanced syphilis. 4. To provide for efficient medical inspection of foreign ports of emigration, with the power of arresting importation of dangerous diseases to this country.—*St. Louis Medical and Surgical Journal*.

PYOCTANINE.

The aniline colors have among them several members of the fraternity of antiseptic substances. Pyoctanine is the name of the violet and yellow members. Other aniline colors will probably assert their properties in that line within a short time. Heretofore we could often find out to what antiseptic substances a surgeon was partial by the various odors that permeated him as with a garment, but at present the hues that variegate his hands will give him away. Members of the profession that are endowed with an artistic eye will be able to dress wounds with picturesque effect. Too liberal an employment of primary colors will be described as rather harsh treatment. There will be simple, steady, reliable elderly gentlemen who will be content with a monochromatic dressing, while others, often of lesser years and more æsthetic tendencies, will stake their reputation and their patient's welfare upon an application of substances cunningly mingled, so as to resemble more in general effect the every day patchwork quilt of our aunts and the coat of Joseph.—*International Jour. of Surgery*.

PRACTICAL NOTES.

MR. HUTCHINSON'S TREATMENT OF RINGWORM.

Mr. Jonathan Hutchinson gives, in his *Archives of Surgery*, the prescription upon which he has "settled down in tolerable content" for the treatment of ringworm, after having tried a great variety of remedies without equal satisfaction. He relies chiefly on chrysophanic acid. He orders as a wash for the scalp one drachm of Wright's liquor carbonis detergens to the pint of hot water. Twice a week the scalp should be well washed with this, and all scales and crusts should be removed. The hair is cut close or shaved. The chrysophanic-acid ointment contains a drachm of chrysophanic acid, twenty grains of ammoniated mercury, a drachm of lanoline, six drachms of benzoated lard, and ten minims of liquor carbonis detergens. This ointment is to be rubbed in more or less freely, according to its effects, night and morning, or latterly every night only.—*N. Y. Med. Journal*.

PREVENTION OF THE TOXIC EFFECTS OF COCAINE.

Dr. Gluck (*Med. Rec.* June) writes on this subject. He uses a combination of cocaine and carbolic acid, dissolving two drops of the acid in one drachm of distilled water, and then adding ten grains of cocaine hydro-chlorate. Carbolic acid is itself an anæsthetic, and as it coagulates albumen and forms a superficial eschar, it prevents the rapid absorption of cocaine. He claims that the anæsthetic effects of cocaine are increased by this mixture, that its toxic effects are prevented, and that the solution is rendered aseptic.—*Review Ins. and Nerv. Disease*.

PHENACETINE.

Thompson says: In any given case of nerve pain where one might suspect a weak or fatty heart, phenacetine is to be preferred to antifebrine. It does not seem to act quite so surely as the latter, but after using three and a half ounces of it, I much prefer it to antipyrin. Such is my experience of phenacetine, after a fair trial. In seven or eight grain doses every four hours, it is a safe and effectual remedy in all neuralgias, be they in the head, back, or any other part of the body.

Rift (*Bull. de Ther.*) reports very favorable results from large doses of phenacetine in acute articular rheumatism, particularly that of gonorrhœal origin. He gives the fifteen grains every three hours the first day, increasing the dose the following day, until the pain is relieved and the joints become movable. This occurs as a rule when six or eight doses per diem are given. These large doses are continued for three days longer, then gradually reduced to three times per day fifteen grains one week longer, and then

omitted. Treatment by this plan reduced the time to twenty-one days, while that by the salicylate is thirty-five, and by antipyrin twenty-five days. In twelve cases so treated no heart symptoms were noticed. Relapses are unusual if the above plan is followed.—*Times and Register*.

IMPURITIES UNDER THE FINGER NAILS.

We are all, doubtless, familiar with the common belief of people in the poisonous properties of the finger nail. We have, indeed, ourselves seen some severe inflammations caused by the scratch of a nail. So general a belief must, according to Herbert Spencer, have something of truth, and modern bacteriology has furnished the demonstration. It is not the nail *per se*, of course, that poisons, but something that is on or under the nail. Seventy-eight examinations were recently made in Vienna (says the *British American Journal*) of the subungual spaces, and there were found: of micrococci, 36 kinds; of bacilli, 18 kinds; of sarcinæ, 3 kinds, and common mould spores were very often present.

Personal cleanliness should be insisted on in everybody, but how necessary is it for the surgeon. Antiseptics can never and will never successfully *take the place* of soap and water and the scrubbing brush, but as additions to this process they must, in the light of the demonstrations before us, be henceforth forever included in the routine practice of the conscientious surgeon. The habitually clean will, of course, have less trouble in the preparation of the hands, but the necessity for attention to details in the cleaning of the hands and nails has now been made plain by the valuable experiments of Furbringer, confirmed by many others and the practice of surgeons like Billroth, who now adopts the suggestions of these investigations in his operative work.—*New Orleans Med. and Sur. Journal*.

CREASOTE IN DIABETES.

The *Lancet* says, two cases of diabetes have been treated with excellent results by Valentini, by means of creasote administered internally. In one case, four drops per diem were given at first, this quantity being afterwards increased to ten drops. Under this treatment the sugar disappeared, and did not return when the patient began to eat starchy food. The other patient was given six drops per diem, and did equally well.

ANÆSTHESIA IN SMALL OPERATIONS.

For this purpose Dr. A. Dobisch, of Zwittau, recommends spraying the parts for one minute with the following: Chloroform, 10.00, ether, 15.00, menthol, 1.00. This produces complete anæsthesia of the skin lasting from two to six minutes.

SOCIETY PROCEEDINGS.

The Gynecological Society of Boston.

214th Regular Meeting.

THE PRESIDENT, W. SYMINGTON BROWN, M.D.,
IN THE CHAIR.

DR. JESSE F. FRISBIE read the following paper, entitled:

A PECULIAR CASE.

On the morning of March 31, 1888, I was hastily summoned to the bedside of Mrs. P., the beautiful and accomplished wife of one of the most enterprising young men of Newton. I was informed she had been suffering very severely all night with pains and cramps in the bowels. I was also informed that she was a little more than seven months pregnant. She had been married about two years and this was her first pregnancy. Her age was 23 years.

When I first saw her the pains were regular, and she appeared very weary and worn from sleeplessness and suffering. I at once diagnosed premature labor, and upon making a digital examination found the os dilated and the fœtus nearly half expelled—a footling presentation.

In the course of an hour I succeeded in removing a male fœtus and the placenta. There was hardly the slightest tinging, with blood, of the rather scanty secretions, and of "waters" there had been practically none, so slight had been the moisture at the time the membranes ruptured. The fœtus corresponded to the size of one five and a half or at most six months, shrivelled and shrunken, and in an advanced stage of disintegration, if that term can be used without indicating decided decomposition. There was but little odor of putrefaction, but I could, with my fingers, as easily pick the skin and tissues from the body as I could had it been thoroughly cooked. The placenta was rolled into a ball, hard and compressed, bloodless and friable. The appearance of fœtus and placenta presented unmistakably the condition of a fœtus that had been dead many weeks. The rolled up, compressed and bloodless placenta, and the absence of blood and amniotic waters, were caused by the gradual contraction of the uterine walls during the weeks following the death of the child. There being, during this period, no flow of blood to the placenta or child, absorption of blood and waters had gone on as uterine contractions took place.

Further investigation revealed the following history: The patient was a native of Nova Scotia. For several years before her marriage she had suffered from some uterine disease for which she had received little or no regular treatment. She had suffered at times from acute nephritis, and at this time there were ample evidences of a chronic nephritis, the effect of the acute attacks

referred to. In addition to these she had a weak, and at times a painful and irregular heart. These two last may have been inherited from her mother, as I found (upon her becoming a patient of mine), that she had suffered from the same diseases for many years. After her menses appeared, which was at the age of 13 years, she had been more or less hysterical. Notwithstanding all these complications my patient was a well developed and rather fleshy young woman.

She had suffered from the usual attendants of pregnancy, and also from a circumscribed, sensitive and sore spot to the right of the median line, below the umbilicus, apparently nearer the uterus than the right ovary. This she had been troubled with, at times, previous to conception. Some four or five weeks before I was called to attend her, she had met with an accident—a fall—striking upon the back near or below the kidneys. From the effects of this fall she had suffered, more or less, all the time till her confinement. No movement of the child had been felt after that fall, and she was not sure that motion had been felt for a little time previous. The os uteri, which was only partially dilated, presented to the finger the decided appearance of inflammation, or perhaps excoriation, and in my opinion the slight traces of blood, seen at time of confinement, were caused by the blood being forced out from the os or its neighborhood, as the parts dilated and the child was pressed down and expelled. The after-pains were quite strong, and the uterus readily contracted to the size of a small orange.

For weeks she had suffered from uterine pains almost daily, sometimes quite severe. She supposed these to be abdominal pains consequent upon her condition and to be naturally expected, and the entire night before her morning delivery she had suffered intensely with the same kind of pains, the only difference being in degree. She hardly more than had a suspicion that labor had begun. Even this suspicion was repugnant to her, as she was very anxious to bear a living child. In fact, during a thirty years' practice, I have never seen a woman who appeared to desire a child so much, and the loss of which occasioned so great disappointment and grief.

Taking into consideration the past history of this patient and the conditions existing at time of delivery, I naturally felt grave apprehensions as to the future outcome of the case. Accordingly, from the first the treatment was thoroughly antiseptic. Absolute cleanliness was insisted upon and as far as possible carried out. The vagina was douched twice a day with a solution of carbolic acid in water—1 to 40—as hot as could be borne, at the same time sponging the external parts with the same solution. The bowels were kept open with gentle aperients and enemas.

For several days everything seemed to progress satisfactorily. On the fifth day after delivery a

severe chill occurred which was immediately followed by high pulse, and temperature accompanied by a heavily furred tongue and rapid sinking of the heretofore good spirits and stamina. Apparently the cause of this sudden break down was the communication to her of the sad news that a near relative of hers, in her own home, had died after a few days' illness. Immediately thereafter the sensitive and tender spot in the right side, to which reference has been made, became exceedingly painful and continued to cause great suffering for many weeks. At the same time the right leg became tender and painful from the body to heel, and the suffering at times was almost greater than she could bear. Swelling supervened with the general appearance of phlegmasia dolens. Accompanying these, although at first with rather obscure symptoms, septicæmia developed and my poor patient seemed to have the whole decalogue of diseases. As the days passed on and she grew gradually weaker there was almost a constant pain at the heart which caused her great distress.

Fearing from the first that septicæmia might develop my whole treatment had been antiseptic and supporting. The bowels had been kept open by enemas and the little strychn. et belladonna pill. Quinine, brandy, wine, etc., were given for supporting tonics and morphine, by mouth; hypodermic and vaginal suppositories to relieve pain.

With the development of septicæmia the uterus became hot and very tender, while a profuse discharge kept the nurse busy. Every three or four hours the vagina was thoroughly doused with a hot solution of carbolic acid. But for these precautions the odor would have been unbearable, and even with them, at times the smell did not remind one of a peach orchard or breezes from Araby the Blest, Tincture of iodine and hot fomentations to which tincture of opium was added were freely applied to the abdomen. Liniments of soap, laudanum and arnica were applied to the leg. About the third week from the confinement I called Dr. H. O. Marcy in consultation. He coincided with the treatment, suggesting in addition the use of iodoform suppositories. These were freely used to decided advantage.

At the expiration of two more weeks the patient was able to sit up. A little over-exertion, with perhaps a slight cold, and a relapse followed. The pain in right side and leg returned and became very severe. The pain at the heart also gave her intense suffering. But there was no return of the uterine discharge as it had been three weeks previously. After the most careful examination, I could not discover any lesion of the heart except weakness, and sometimes a little irregularity in beat—functional rather than organic.

About this time meddlesome and over officious

friends insisted upon another consultation. The husband yielded and Dr. J. H. Chadwick was called in.

After making a careful examination and finding the uterus easily movable, at about normal temperature, and the general condition of the patient satisfactorily improving, he informed the husband and friends that they were unnecessarily scared about nothing, and recommended a practical continuance of the treatment then in force.

She continued to improve, and with the occasional use of tr. of digitalis and acetate of potash, combined with triticum repens, made a good recovery, with the exception that the circumscribed spot on the right side still remained sensitive and at times painful. Several months after, she had leucorrhœa for which was ordered a douche of hot water to which was added zinc sulph. or cupri sulph. in small quantities, once or twice daily with excellent results. Other local treatment was advised but not carried out.

A year and a half after her confinement she conceived again, and on the 29th of last November I delivered her of another 7 months' child—alive—which weighed $2\frac{3}{4}$ pounds and lived four weeks. A few hours after her pains began she had a convulsion which was followed by five others during the succeeding ten hours, and convulsive twitchings about face and neck for four or five weeks. The first two days she was unconscious and that time has ever been a blank to her. The first of these convulsions occurred on Tuesday morning and the child was born on Thursday morning.

Chloroform was at once administered and Dr. H. M. Field called in consultation. Afterwards hypodermic injections of morphia were given frequently till the convulsions ceased. For reasons which have now escaped me, we did not deem it judicious to dilate the os and deliver. If my memory serves me the os was then not dilated to the size of a ten cent piece. The bowels had been thoroughly evacuated by enemas long before the convulsions occurred. After the convulsions ceased she was fairly comfortable till her delivery. The pain in side and leg reappeared in a few days, but not to so severe an extent as at the previous confinement.

About three weeks after her confinement the tumor (?) fibroid or fibrine, which I now exhibit to you, was expelled, without any pain and without her knowledge, from the uterus. From that time she made a good recovery. To her and my gratification the circumscribed tender, and at times painful spot in the side has ceased to trouble her, from the time this tumor was thrown off. She is now in comparative health.

DR. GERRY said that he had been much interested in the paper. He thought that the patient had suffered from septicæmia and from the treatment he had noted the absence of curetting. He

believes that it has been stated that septicaemia comes on if at all about the third day and so he suspects if there is a rise of temperature then and intra-uterine treatment should be substituted.

DR. CONWAY stated that he seldom uses anti-septic treatment in midwifery; in fact he has only used it twice in treating 1500 cases and neither time was he satisfied with the results. Cleanliness, however, is all important and it is on this that he relies.

DR. ELLIOTT mentioned the case of a lady whom he had delivered the day before. She had a history of having been delivered two years previously and having a temperature at that time of 103° and 104° F. and later she had typhoid treatment in the City Hospital. For four days before this last delivery her temperature was 104° F. and her pulse was 120, but as soon as she was delivered the temperature came down to normal.

DR. STEVENS remarked that his experience had been a little different from Dr. Gerry's in that he has found that a rise of temperature on the third generally means that the flow of milk is being established, and further that when septicaemia is present it frequently comes on not till the fifth to sixth day and it may be delayed until the seventh day.

DR. KELLER asked if a microscopic examination of the specimen had been made? [answer by Dr. Gerry—No]. The Doctor then remarked that septicaemia comes on later than the third day, but yet if a chill comes with a rise of temperature on the third day, then look out.

DR. BROWN, the President, said that he had enjoyed the valuable paper very much. The question arises, was the death of the first child probably due to this tumor. This he thinks is not the case. The woman was delicate and this tumor is probably a submucous fibroid. Septicaemia generally comes from the fourth to the seventh day but there is no regularity about it. The idea now prevails that there is no such thing as milk fever as such and that the rise on the third day is due to a commencing septicaemia.

DR. FRISBIE in conclusion said that the womb contracted to about the size of a small orange within a few hours after delivery. As all of the membranes came away he had no suspicion of anything wrong and so there was no indication for the curetting, etc., that had been mentioned.

THE INTELLIGENT FOREIGNER ON BRITISH PIETY.—According to the *Zeitschrift des Oesterr. Apoth. Vereins*, a special prayer-book for medical men has just been published in England. It contains a selection of suitable prayers for delivery on the occasion of surgical and other operations. There should be a companion prayer-book for the patient.

FOREIGN CORRESPONDENCE.

LETTER FROM PARIS.

(FROM OUR REGULAR CORRESPONDENT.)

The Chirurgical Treatment of Tuberculous Peritonitis.

At a meeting of the Chirurgical Clinic at the Hôpital de la Salpêtrière, M. le docteur Terrillon took for his lecture the following interesting study, viz.: "The Chirurgical Treatment of Tuberculous Peritonitis." A report of this lecture is just published of which I here give the contents.

We are about to study to-day an affection which has for a long time almost exclusively belonged to medicine, but which falls more and more under the dominion of surgery. I wish to speak of tuberculous peritonitis, of which we have, at this moment, an interesting example in our hospital.

You have been able to see, just now, in my ward, a young girl of sixteen years, pale, meagre, who presents a particular deformation of the abdominal region. The stomach is globulous, pointing forwards, as that of a woman affected with a cyst of the ovary. To profile, especially, this analogy is striking.

When one feels the abdomen, one becomes easily enough sensible of a rounded mass, as globulous, which fills it entirely. The surface of this mass is not smooth as that of a cyst of the ovary, but granulous and irregular.

If one control by percussion these data furnished by the palpation, one is astonished to find everywhere a quantity of sounding bodies. There is only then in some sort an appearance of tumor.

If we touch afresh the abdomen, in order to examine it more carefully we shall then be able to perceive two new signs which will aid us in forming the diagnostic: There is, firstly, a sensation of snowy friction that one perceives in depressing lightly the lateral parts of the stomach; in the second place, some little grumblings of the bowels provoked by the profound pressure, one describes them under the name of "intestinal cries."

In presence of these phenomena, in order to assure to the diagnostic a greater precision, we have submitted the patient to the chloroformic anaesthesia. Once the muscular resolution obtained, we have proved that the abdominal wall relaxed itself a little. The appearance of abdominal tumor becomes less clear to the palpation, but one feels the small hard granulations, disseminated on the surface of the intestines. In the left flank, and more particularly in the right flank, one finds two or three masses of about the size of a mandarin. The peritoneal friction is found again upon nearly all the points of the stomach. We have equally practiced the rectal touch, which has not given us any important token.

Thus, in this case, we are in presence of an affection of peritoneum having provoked a secondary contracture of the muscles of the anterior abdominal wall, contracture which gives place to an appearance of tumor. This is, besides, a fact well known and that one observes in many circumstances, and I have been able to show you, some time since, several hysterical women who have been sent to me with the diagnostic of cyst of the ovary, and who had in reality, only contracture of the abdomen with tympany.

Nevertheless, between these abdominal symptoms of simulating hysteria, a tumor and the actual case, there exists a capital difference. With the nervous the appearance of tumor disappears completely under the influence of anæsthetic sleep. Here, on the contrary, the stomach, in becoming altogether more supple, presents, under the wall, some hard, resisting parts, superficial with respect to the intestine; that which indicates a lesion of the peritoneum.

Our patient is then affected with a tuberculous peritonitis. Her clinical history comes besides to the support of the physical exploration in order to confirm the diagnostic.

She has always been unhealthy and pitiful. Three years ago, she had already suffered during several months, of the stomach, at the same time she complained of vomitings and of diarrhœa. Her affection probably dates from this epoch. Afterwards, all had resumed its original order, when in the month of January last, the same troubles have reappeared, with more violence, at the moment of the appearance of the menstrual discharge. The patient has, since this period, suffered from sharp abdominal pains; some frequent and returning vomitings during several days, afterwards discontinuing, have much fatigued her. Finally, she has presented some alternatives of constipation and of diarrhœa. Since about a month, she has been ordered to keep her bed.

In presence of these functional troubles, the doubt is no more possible: we have to do with an unlooked for tuberculous peritonitis, without appreciable cause, in a young girl, and this is a fact frequent enough.

It rests with us to discuss the treatment that we ought to institute for this patient. But before doing so, I wish to describe to you, in some words, the lesions of the tuberculous peritonitis, its march and its complications.

I will not insist on the pathological anatomy of this affection, and I will only recall to you the particularities thereof which are essential to know in a surgical point of view.

You know that, when one examines at the autopsy, or at the course of a laparotomy, a tuberculous peritoneum, the lesions show themselves under two aspects very different.

In the first case, the parietal serous, as the vis-

ceral serous, is recovered with tuberculous granulations. These granulations remain often isolated as a seed bed to the surface of the peritoneum, and provoke an ascitic effusion more or less abundant. This form of tuberculosis has received the name of "ascitic form." Sometimes this ascitic tuberculous peritonitis presents some characters enough specious. At the same time as the ascites, are produced some false membranes which partition the effusion in several isolated bags. It is then than one often confounds peritoneal tuberculosis with an abdominal tumor, above all with a cyst of the ovary.

The second form is more rare; it is characterized by the absence of liquid, thus it has received the name of "membranous form." In this case, the tuberculous granulations, in irritating the peritoneum, have provoked the production of false membranes which retie the intestinal anse and the large epiploon in an irregular mass adherent to the abdominal wall. In these plastic, membranous forms, are often formed some centres of encysted suppuration, of which the volume is sometimes considerable.

The march of the malady is no more susceptible of a uniform description. In the great majority of cases, tuberculous peritonitis is a chronic affection; but it is not rare to see it commence by an acute state, as with our patient, and present successively some remissions and some outbursts. Nevertheless the ascendant chronic march accompanied with accidents of the side of the intestine, is the most common.

An important fact, upon which I desire to insist, is that habitually tuberculosis rests limited to the peritoneum, and does not invade the other organs, at least during several years.

You comprehend the great importance of this fact in a surgical point of view, for if the lungs, for example, are affected, there is then a contra-indication to all operation.

I tell you, that these unfavorable circumstances are relatively rare. Notwithstanding they are able to present themselves, and I will on this account cite to you an example which will show you the embarrassment in which the surgeon can then find himself. Three months ago, I was called in consultation concerning a young officer who presented sometime since abdominal phenomena quickly developed: ballooning of the stomach, vomitings, diarrhœa. One found by this patient the sensation of peritoneal friction of which I have spoken to you. I diagnosed a tuberculous peritonitis, but, in spite of the persistence of the patient and his surroundings, I refused all intervention, for there existed at the two summits of the lungs hollow sounds, and some humid cracking noises and, more, some profuse perspirations. My intervention would have been useless, for it concerned a tuberculosis of rapid march. The patient died, a few days after, from the progress of the

affection which was accentuated as much on the side of the lung as on the side of the abdomen.

I desire also to call to your observation that tuberculous peritonitis develops itself nearly always in young persons and even in children, principally between the age of 12 and 20 years. The patients that I have latterly attended for this disease, were 12, 17 and 18 years of age. It is well to remember, however, that, in spite of its frequency at this age, it is able to reappear later, towards 30 or 40 years. You will find, in a thesis, very well made, of Dr. Hemey (1866), some examples of tuberculous peritonitis in the adult, independent of other lesions.

Finally, what is the termination of the malady? I have not considered it necessary to tell you that its prognostic is unfortunate and that, if one does not intervene, the patients finish always by succumbing to the progress of the affection. The fatal termination can be hastened by some complication. There is thereof one which, although rare, ought to interest us particularly. These are those facts of pseudo-contraction, that one finds sometimes in the course of the peritoneal tuberculosis. I have lately observed thereof a case, which I will relate to you:

In 1887, a young girl entered into my ward at the Salpêtrière, with some phenomena of intestinal occlusion enough marked: ballooning of the stomach, fæcaloid vomitings, contracted features. According to the antecedents of the patient and the abdominal palpation, I thought it to be a tuberculous peritonitis, and as the phenomena of contraction ruled the scene, I practiced laparotomy. I found some tuberculous lesions of the peritoneum very extended, but especially important to the level of the S iliac. There were there some granulations so abundant that the visceral peritoneum had the thickness of the little finger, and flattened the intestine against the wall of the basin. I tore this neo-membranous production upon several points, not being able to displace it entirely. Besides, I practiced some punctures of the intestine, with the apparatus of Potain, in order to clear it of the gases that it contained. This intervention brought a notable relief to the patient, but she died, three months after, of generalized tuberculosis.

It only remains to us, now, to study the treatment of tuberculous peritonitis.

Formerly, one only opposed to this affection a medical treatment: vesicatories, unguent Neapolitan, revulsion. One succeeded thus in easing the patients, under all its forms, but not in curing them. Fifteen years ago, Kœnig, making an error of diagnosis, practiced a laparotomy, believing to be in presence of a cyst of the ovary, and fell upon a purulent bag of tuberculous peritonitis. He cleansed it with care, closed the abdomen, and was quite astonished to see the healing persist after this operation.

Examples of this species multiplied themselves very soon, and the interventions in some cases of unsuspected tuberculous peritonitis did not fail to be numerous. Finally, surely, it is no more hazard, but by fixed resolution that one opens the abdomen in cases where this affection has been acknowledged. There exist actually many observations of this kind. We find, in a communication made before the Italian Society of Surgery in 1889, by Cecherelli, of Parma, the summary of eighty-five published observations, which have given the following results, after surgical intervention for patients affected with tuberculous peritonitis: healings, 52; deaths, 25; ameliorations, 6.

This intervention can take place under two circumstances very different. When there is ascites or when there are some purulent encysted bags, the intervention is quite natural. Truly, it is most frequently in this case that one has practiced it, and nearly always with success.

The operation consists in opening largely the abdomen. When one has proved the presence of tuberculous lesions, the purulent or ascitic bags are emptied. It is afterwards necessary to practice a minute cleansing of the abdominal cavity with sponges soaked in an antiseptic solution, such as those of thymol and of phenic acid. I generally use a solution of phenic acid.

It was in these conditions that I have operated upon a young girl, last year, who was affected with tuberculous peritonitis of ascitic form. After having incised the abdominal wall on a length of 12 centimetres, I fell upon an ascitic effusion of 7½ litres. I raised with care the totality of this liquid, and touched all the points of the peritoneal surface with sponges imbibed with a phenic solution at 200. The abdominal wound was sutured and a large drain put in its inferior angle. I left this drain in place thirty-six hours, and during this time there flowed out at least 1½ litre of liquid. The abdominal reuniting was perfect, and the reëstablishment of the patient complete. Since, I have been informed that the healing is well maintained.

I have also had occasion to intervene, at the same epoch, for a purulent encysted tuberculous peritonitis. It concerned a young girl of 11 years, in whom one had diagnosed a pericæcal abscess. The bag, that I incised, was filled with tuberculous granulations and with yellow and thick false membranes. She was cleansed with a phenic solution at 1-20. Afterwards I made the suture and instituted the drainage. For a year the healing has been maintained.

In sum, with tuberculous ascites, be it generalized, be it encysted, surgical intervention gives place to perfect results.

Even as we have already indicated it, this form of tuberculous peritonitis is the most frequent; so it is our duty to examine if one ought to intervene in the other cases; that is to say, in those where

the peritonitis has a dry or membranous form, as that which exists in our patient. The greater part of the surgeons think that it is preferable to abstain in this case, on account of the extended adhesions uniting the intestine and the epiploon, and hindering to penetrate largely into the abdominal cavity. M. Truc, in his thesis of aggregation (1886), advances this same opinion. It is, really, difficult to understand if in simply tearing some false membranes, one is able to make an intervention useful to the patient.

I have been able, besides, to find in medical literature some observations of this kind; but I have personally observed a fact which permits me to conclude in favor of the utility of laparotomy, even in these unfavorable circumstances. This history is most interesting; so permit me to describe it with some details: It concerned a young girl of 18 years, who was sent to me, in 1886, by M. le Docteur Duffau, of Laon (Eure-et-Loire) and by M. le Professeur Lannelongue. She had a projecting stomach, voluminous, and to the palpation as well as to the percussion, one had the sensation of a solid tumor adherent to the abdominal wall. I thought it to be a sarcoma developed in this wall, and I decided to practice laparotomy. This operation was made in March, 1886, in presence of M. Lannelongue. The abdominal wall was abnormally vascularized, very bleeding. I arrived upon the peritoneum, thickened and adherent. It formed a sort of breastplate of the thickness of the hand, composed of a tissue of false membranes infiltrated with tuberculous granulations. I incised it largely. I sought afterwards to separate the false membranes which agglutinated the intestinal ansæ among them, but I was not able to arrive there. I was obliged to close the stomach, little satisfied, I confess, with my intervention.

The operative results were benign: the fifteenth day, the patient rose. At the end of twenty-two days, she departed for the country.

I thought that she had certainly soon succumbed to the progress of this affection, when I learned, a year after, from her physician, that the patient was much better. At the end of eighteen months, the patient came to see me at the Salpêtrière, and I proved, to my great surprise, that she was completely healed. The stomach was supple and appeared absolutely normal.

This fact is so surprising that one has the right to ask oneself if it be really the surgical intervention which has healed the patient, or if the affection has not made this retrocession of itself. I believe, for my part, that there is in laparotomy an empirical side that we shall ourselves explain perhaps still later, but which we are only able in effect to prove. I am, however, persuaded that the operation has had, in this case, a favorable influence.

I will cite to you, besides, some examples of

healing for analogous peritoneal productions, which I have observed several times. It is even so, in numerous cases of ancient salpingitis, having provoked some years since some outbursts of pelviperitonitis, laparotomy demonstrates that the basin is filled with false membranes uniting the intestinal ansæ among them, and that the tumor is so adherent that one is not able to displace it. The surgeon contents himself then with making movable as much as possible the intestine and the epiploon, he cleanses with care the surfaces thus torn and closes the abdomen. In these examples, I possess thereof four, well defined and quite authentic. Not only the chirurgical intervention relieves the patient, but one sees shortly after, the impotence produced by these membranous formations disappear and the intestine retake its normal functional state.

Lastly, I have made before you an operation of this kind upon an overseer of the Salpêtrière. The relief has been so considerable that the patient has been able to resume her occupation, though laborious. Nevertheless, I had not removed any of the affected organs; I had only destroyed some adhesences.

Thus, in the presence of these facts, I shall not hesitate to practice a laparotomy on our little patient. We have placed to her the diagnosis of tuberculous peritonitis; we know within a little what are the lesions that we shall find at the opening of the peritoneum, and I believe that she will benefit much by an operation. It is the right and the duty of the surgeon to practice this intervention, which is besides, for the patient, the only chance of salvation.¹

A. M. G.

LETTER FROM LONDON.

(FROM OUR OWN CORRESPONDENT.)

Prof. Koch and his reported cure for Consumption—The Tortoise Field Hospital Equipment—Medicinal Rings—Hydro-chlorate of Glutin-Peptide—Miscellaneous Gleanings.

Professor Koch's reported cure for consumption arouses intense interest and expectation in the Teutonic medical world. After long experiments Dr. Koch has so far perfected the discovery that he will give a full account of his method in a public lecture at the December meeting of the Berlin Medical Association. He does not expect to cure patients in an advanced state of the disease, because other parasites have then attacked the lungs while his remedy only kills the tuberculosis bacillus. But he is certain of success in the early stages, his process being curative, not

¹ The patient was operated on May 5, 1890, and presented to the Society of Surgery June 18 last. A large incision upon the median line gave access into the peritoneal cavity, filled with false membranes and granulations. Several intestinal ansæ were liberated. The wound was closed without drainage. The patient has given news of herself by letter October 1, 1890, and declares herself to be absolutely healed.

preventive, like vaccination, although it resembles the latter process by lymph being injected under the skin. Eight persons are now undergoing the cure at a Berlin hospital. The Government will establish a Bacteriological Institute to enable Dr. Koch to carry on researches. At present the remedy is only produced at great expense, so a private society is being formed to monopolize the manufacture under Dr. Koch's management and to furnish funds for supplying the lymph to the poor.

The arena of the Chelsea Hospital Grounds, has just been occupied by the Military Equipment, Stores and Tortoise Tent Company, the directors of which had invited a company of experts to inspect a number of ingenious appliances necessary to the active operations of an army in the field. The company is principally interested in the Tortoise Field Hospital Equipment, the invention of Captain Tomkins, which has already gained the Empress Augusta's gold medal, and first prize at Berlin in 1889, a gold medal of the Liverpool Military Exhibition and many others. The principal aim of the inventor is to produce a ready means for the shelter and treatment of the sick and wounded as near to the field of battle as possible, which while containing nearly all that may be required for a field hospital will at the same time have the greatest mobility as a field flying hospital. The Tortoise hospital is contained in four wagons, and is capable of being removed from the wagons and carried on pack animals. In a mountainous country it may be carried by the Bearer Company or fatigue men on the stretchers, which form bedsteads in hospital. The whole hospital consists of 54 or if necessary, 60 beds carried in three wagons, each wagon being in itself complete with 18 or if necessary 20 beds, as a third of the hospital. For the medical staff and attendants a smaller four wheeled wagon contains tent accommodation with beds for two surgeons, two superintendents, six nurses and one cook, together with all the requisite appliances. The weight of the three wagons when packed is 4,800 pounds including packs and panniers, requiring on military roads four horses at the rate of 11 cwt. per horse. The apparatus has already been used with considerable success in British Volunteer Camps, and a committee of the French war department is considering the question of adopting it throughout the army of the Republic.

There has recently been published for private circulation, a little work descriptive of magical rings which were at one time very seriously believed in. Physicians were wont to wear rings in which stones were set, and these stones were credited with the possession of many virtues. Sometimes it appears the patient was simply touched with the ring; sometimes he put his finger in it for awhile. Many a patient has worn

such a ring to stop hæmorrhage. If the result followed, the ring was unreservedly regarded as the healing agent; if the cure did not follow, nothing is told about it. Also in the middle ages magic rings were worn bearing the names of three wise men who presented gifts at the birth of Christ. They were Melchior, King of Nubia, who gave gold, Balthazar, King of Chaldea, who offered incense, and Jasper, King of Tarshish, who brought myrrh. These rings were considered specially efficacious in warding off various forms of disease, more particularly cramps. A remnant of this superstition still remains in some country places where certain affections of the eyes are treated by rubbing the part seven times with a wedding ring.

Of recent years many preparations of mercury have been devised, intended for hypodermic injection, but so far all have exhibited undesirable features. It is now believed that a substance has been discovered which is, in the first place, effective while having as slight toxic properties as possible; and, in the second place, it is unirritating and causes very little pain when injected. The new salt is described as a hydrochlorate of gluten-peptone in combination with corrosive sublimate. By treatment of gelatine with dilute hydrochloric acid, a hydrochlorate of gluten-peptone is obtained, containing 12 per cent. of hydrochloric acid. This is entirely soluble in any proportion in both water and alcohol, and to it is added mercuric chloride. When trying the medicinal effect, a salt containing 25 per cent. mercuric chloride was used. Physically this occurs in white, glassy lamellæ, forming a hygroscopic powder. The aqueous solution is stated not to be precipitated by caustic alkalis, by the alkaline carbonates by the blood nor by albumen. Both the solid substance and the solution may be kept in well stoppered bottles without decomposition for twelve months if the light be not excluded. Owing to its combination with peptone, the corrosive properties of the chloride are obviated to some extent, and the entire absence of sodium chloride is thought to be an advantage. The employment of the drug has now extended over a period of nine months, during which time sixty patients have been treated, 170 injections being given altogether. The dose is of a gr., equivalent to of a gr. of mercuric chloride. The investigations have shown the new remedy to have numerous advantages, which may be briefly stated: 1. It is certain and quick in action. 2. The injection is accompanied by very little pain. 3. As there is little irritation of the skin, a rash is not produced when the salt is used.

The National Health Society has organized a course of six lectures on home nursing. The lectures will be accompanied by demonstrations, and will be given at the new offices of the Society. The Society will also give a course of lectures on

cooking, especially making a feature of invalids' dishes.

The St. John Ambulance Association has recently been doing good work among the employes of the Great Eastern Railway Company. At a recent distribution of certificates, a demonstration was given by the members of the Railway Ambulance Corps, wounded men being taken from the compartments and from beneath a railway carriage and conveyed away on a stretcher. The work was most effectually done, and was highly commended by the officials of the St. John Ambulance Association who were present.

At the present time many medical students in London find considerable difficulty in obtaining the necessary facilities at their own schools for going through a course of operative surgery on the dead body. In view of this, the Royal College of Physicians and Surgeons and the Apothecaries' Society have decided to accept the certificates of operative surgery of the private School of Anatomy and Physiology, directed by Mr. T. Cook. The school has already been recognized for this purpose by the University of London and by the War Office for several years.

A new monthly journal devoted to hypnotism and kindred subjects has recently begun to appear in Italy.

The powerful representations made with regard to the rank and status of medical officers in the British Army have been considered at a conference held at the War Office, and the question of rank and title for medical officers is now receiving the personal attention of Mr. Stanhope. It is thought that the Medical Staff Corps will be created a Royal Corps, and that in official lists the names of medical officers will appear according to seniority, and not at the bottom as at present.

G. O. M.

DOMESTIC CORRESPONDENCE.

A Correction.

To the Editor:—Mr. J. Greig Smith has called my attention to my unintentional misstatement of his views on page 643 of THE JOURNAL, for November 1, 1890. I hasten to say, therefore, that a reference to his "Abdominal Surgery" shows that he has clearly stated that floating kidney is always congenital, but movable kidney as a rule is acquired. Very truly yours,

W. W. KEEN.

1729 Chestnut St., Philadelphia, Dec. 1, 1890.

NECROLOGY.

SURGEON-GENERAL JEDEDIAH HYDE BAXTER, of English descent, was born in Stafford, Orange Co., Vt., May 11, 1837. He was educated in his

native State, receiving his medical degree in 1860. He then went to Washington, but in 1861 relinquished private practice and entered the United States service as Surgeon to the Twelfth Massachusetts Regiment, Col. Fletcher Webster. He was promoted to be Surgeon of the United States Volunteers in 1862, and was brevetted Colonel in 1865. In 1867, July 20, he was appointed assistant medical purveyor, and in 1874 was made chief medical purveyor, which office was created expressly for him.

He was a member of the Public Health Association, and American Medical Association, a corresponding member of the Boston Gynæcological Society and of the Philadelphia Academy of Natural Sciences. He was a contributor to scientific periodicals and the author of "Medical Statistics of the Provost Marshal General's Bureau." In 1876 he married Florence Tryon, daughter of the late William Tryon, of Washington.

On August 16, last, he was appointed Surgeon-General in the place of Surgeon-General Moore, retired. His friends had frequently urged his appointment to the office whenever a vacancy occurred, and when Surgeon-General Barnes died in 1881 he was promised the post, but lost it through the assassination of President Garfield.

His death occurred from paralysis with which he was stricken on December 1, on the third day, at two o'clock in the morning. He was buried in Arlington Cemetery, five foot battalions, a platoon of light artillery and two troops of cavalry acting as escort. The War Department closed its doors on the day of the funeral.

DR. PROCTOR THAYER, formerly professor of surgery at the Cleveland Medical College, died October 1, in the sixty-seventh year of his age. He was a native of Williamstown, Mass. For about 50 years, with exception of a part of two years during the late war, he was connected with the Western Reserve College, or one of its departments, as student or as teacher. About a year ago ill health impelled him to withdraw from his duties in the surgical professorship.

DR. ALBERT VOGEL, the eminent specialist in diseases of children, died at Munich, on the 9th inst. His well known text-book in pædiatrics was passing into its eleventh German edition at the time of final sickness, and had been honored with repeated translations in foreign lands. His professional reputation had been made at the University of Dorpat, whence he was retired with many distinctions, by the Emperor of Russia, at the end of his twenty years' professorate. This occurred in 1886, when Vogel made haste to return to his native city, Munich, where the welcome given him by the authorities and the medical profession was as warm as his de-

parture from the home of his life-work had been honorable and full of appreciation on the part of his former associates. He was at Munich the centre of many circles of influence, hospitable and social as well as professional, and was much sought after by medical visitors at that University town, and most cordial and generous were the attentions that he was pleased to dispense. He had only a little passed beyond his three-score waymark, when his final sickness occurred.

DR. CHARLES T. BEAN, died at his home, Chelsea, Mass., November 24, æt. 67 years. He was a native of Maine, a graduate of the Medical School, Bowdoin College in 1860, and was the original Lieut.-Colonel of the 24th Maine, a nine months' militia regiment in the early part of the late war. An exchange quotes his weight as being 460 pounds at his death.

DR. RICHARD J. LEVIS, who retired from practice in 1887, died at Kennett, Pa., November 12, of pneumonia, at his home, "Cedarcroft," for years the home of Bayard Taylor. He was born in Philadelphia in 1827, and was the son of Dr. M. M. Levis. He studied medicine at Jefferson College, Philadelphia, and was graduated in 1848. At various periods during his active professional life Dr. Levis was surgeon to the Wills Eye Hospital, the Philadelphia Hospital, the Pennsylvania Hospital, the Jefferson Hospital, and the Philadelphia Polyclinic and College for Graduates. From 1877 to 1887, he occupied the place of president of the board of trustees of Jefferson College. He also served as president of the Medical Society of the State of Pennsylvania in 1885, and as president of the Philadelphia County Medical Society during 1885-1886.

MISCELLANY.

HEALTH IN MICHIGAN.—For the month of November, 1890, compared with the preceding month, the reports indicate that cerebro-spinal meningitis, puerperal fever and inflammation of kidney increased, and that cholera infantum, dysentery, inflammation of brain, diarrhoea, cholera morbus, typhoid fever, pleuritis, measles and whooping-cough decreased in prevalence.

Compared with the preceding month the temperature was much lower, the absolute humidity and the relative humidity were less, the day ozone and the night ozone were considerably less.

Compared with the average for the month of November in the four years 1886-1889, cholera morbus, influenza, inflammation of kidney and scarlet fever were more prevalent, and typho-malarial fever, whooping cough, dysentery, measles, inflammation of brain, inflammation of bowels, cholera infantum and puerperal fever were less prevalent in November, 1890.

For the month of November, 1890, compared with the average of corresponding months in the four years 1886-1889, the temperature was higher, the absolute humidity and the relative humidity were about the same, the day ozone and the night ozone were less.

Including reports by regular observers and others, diphtheria was reported present in Michigan, in the month of November, 1890, at 65 places, scarlet fever at 68 places, typhoid fever at 50 places, and measles at 23 places.

Reports from all sources show diphtheria reported at 10 places more, scarlet fever at 11 places less, typhoid fever at 46 places less, and measles at 5 places more in the month of November, 1890, than in the preceding month.

FURTHER COMMUNICATION ON A CURE
FOR TUBERCULOSIS.

BY PROFESSOR R. KOCH.
OF BERLIN.

[Translated for THE JOURNAL.]

A few months ago in an address before the International Medical Congress, I described a remedy that would render animals refractory to the tubercle bacillus, and would stop the tubercular process in those already affected. Since that time observations have been made upon human beings, which are described in the following pages.

It was originally my intention to complete these observations, and to gain extensive experience with the use of the remedy, and also its preparation upon a large scale before publishing anything. But, in spite of all precautions, so much has reached the public, and such false and exaggerated ideas have been formed, that it now seems necessary to avoid further error by giving an account of the present state of the inquiry. Naturally this report can be but brief and many important questions must remain open.

The investigations have been carried on under my direction by Dr. A. Libbertz and Stabsarzt Dr. E. Pfuhl, some of which are finished and others still in progress. The necessary patients have been furnished by Prof. Brieger from his policlinic, Dr. Levy from his private surgical clinic, Geheimrath Fräntzel and Oberstabsarzt R. Köhler in the Charité Hospital, and Geheimrath von Bergmann in the University Surgical Clinic. To all of these gentlemen as well as their assistants who have helped in the observations, I wish to express my deep obligations, and to thank them for their lively interest. Without this extensive assistance it would have been impossible to have advanced the subject so far in a few months.

Regarding the origin and preparation of the remedy, I cannot now make any statement, as my work is not yet completed, and it is reserved for a further communication.¹

The remedy consists of a clean brownish liquid, that does not require any special care in keeping. In use it must be more or less diluted with distilled water and is then liable to undergo decomposition, from bacterial vegetation; it then becomes cloudy and is no longer fit for use. To prevent this the solution must be heated and preserved under cotton plugs, or what is more convenient, a one-half per cent. solution of phenol may be employed. By frequent heating and also when mixed with phenol it seems to lose some of its strength, especially in very dilute solutions; for this reason I have generally employed a freshly diluted specimen.

In the stomach the remedy has no effect; to obtain its action it must be injected beneath the skin. In our experiments we have employed exclusively a small syringe suggested by myself for bacteriological work; it is furnished with a small rubber ball and has no piston. Such a syringe is easily kept aseptic by washing with absolute alcohol, and to this we attribute our absolute freedom from abscess in more than 1000 injections.

After several trials we would fix the point of election, for the injections, at either between the shoulder blades or in the lumbar region. In these places the injection causes little, and usually no local reaction, and is always painless.

As regards the effect of the remedy upon man, it was apparent from the outset that he reacted very differently from the guinea pig, the animal usually employed in these experiments. A further proof of the rule that experiments upon animals are not sufficient to confirm like relations upon the human being.

Man was found to be extraordinarily more sensitive to the action of the remedy than guinea pigs. One can inject 2 ccm. of the fluid into a healthy guinea pig without causing special inconvenience. In an adult healthy man one-fourth of a ccm. will cause an intense reaction—in relation to the body weight, one fifteen hundredth of the quantity readily borne by the guinea pig.

The symptoms produced by an injection of 0.25 ccm. I have experienced myself; they were in short, as follows: Three to four hours after the injection pain in the limbs, weakness, inclination

¹Physicians wishing to use the remedy can obtain a supply from Dr. A. Libbertz, (Berlin, N. W., Lüneburgerstrasse 28, II.) who has undertaken the preparation of the remedy, with the coopera-

tion of r. Pfuhl and myself. I wish, however, to remark that the obtainable at present is somewhat small, and larger supplies only be had after some weeks.

to cough, difficult respiration which rapidly increased; in the fifth hour a chill came on that lasted one hour; at the same time nausea, vomiting, and an elevation of temperature reaching 39.6° ; after twelve hours some heaviness remained, the temperature sunk, reaching the normal on the following day. Heaviness of the limbs, fatigue persisted for some days, as did a little pain and redness at the site of the injection.

The smallest dose producing a reaction is about 0.01 ccm. (equal to a cubic centimeter diluted one hundred times) as determined by numerous observations. Most men react to this dose, with slight pain in the limbs and fatigue lasting but a short time. In a few, a slight rise in temperature was noted, reaching 38° , or a little above.

While such an extraordinary difference in the dose is noted between experimental animals and man, in other respects there is a great similarity.

The most important of these is the action of the remedy upon the tubercular process, of whatever kind.

I will make no further reference to its effect upon animals, as that would carry me too far, but will at once turn to the extraordinary effects produced upon tubercular human beings.

The healthy man reacts, as we have stated, to 0.01 ccm. slightly or not at all. Sick people who are not tubercular react in much the same way, as we have shown by abundant observations. In the tubercular, however, the relation is very different; when the same dose (0.01) is injected² a strong, general as well as local reaction is noted.

The general reaction consists of fever, which is usually ushered in by a chill, the body temperature reaches 39° , sometimes 40° , and occasionally 41° . This is accompanied by pain in the limbs, coughing, great fatigue and often nausea and vomiting. In a few cases slight yellowing of the skin, and in some others a measles like eruption on the breast and throat. The attack as a rule begins from four to five hours after the injection and lasts for from twelve to fifteen hours. Exceptionally it may appear later and run with less intensity. The patients are but little affected by the attacks, and as soon as it is over feel reasonably well, commonly better than before.

The local reaction can be better observed upon those whose tubercular process can be seen,—for example, lupus. In these, changes appear that show the specific anti-tubercular action of the remedy to a surprising degree. Some hours after an injection into the back, far removed from the diseased point, the lupus patches begin to swell and redden, commonly before the beginning of the chill. During the febrile stage the swelling and redness increase, and may reach a high

grade, so that the lupus tissue appears brownish-red and necrotic. The swollen and reddened lupus mass is often surrounded by a sharp white ring, about one centimeter broad, which in its turn is surrounded by a broad red ring. When the fever subsides the swollen lupus tissue begins to go down, and in two or three days it may disappear. The lupus masses are covered with a soft exudate that rapidly dries in the air, forming a crust, which falls off, in some cases after a single injection, leaving a smooth red cicatrix. Usually several injections are required to remove the lupus tissue,—but of this later. It is important in this connection to note that the process limits itself strictly to the affected portions of the skin; the smallest and most obscure masses are brought into view, while the cicatricial tissue in which the lupoid process has ceased are not affected.

The observation upon lupus is so instructive and convincing as to the specific action of the remedy, that every one who wishes to employ it, ought to begin his observations upon a case of lupus.

Not so apparent, but still objective in character is its action, in tuberculosis of the joints, lymphatic glands and bones; in which increase of pain, swelling and reddening of the superficial parts can be seen.

The reaction in the internal organs, the lungs for example, is not so apparent unless we assume that the increased cough and expectoration are evidence of such local action. In these cases it is the general reaction that is dominant. We may, however, assume that here changes are produced like those directly observed in lupus.

The reaction above described invariably takes place after a dose of 0.01 ccm. if a tubercular process is present any where in the body. I do not think I go too far if I assume that we have in this remedy a most important aid to diagnosis. One will be in a position to diagnose doubtful cases of phthisis, before bacilli or elastic fibres present themselves in the sputum and before the process reveals itself by physical signs. Glandular affections, latent bone tuberculosis, doubtful skin tuberculosis and the like, will be by this means easily recognized. In apparently cured cases it will be possible for us to definitely determine if the diseased process has ended its course, or if some diseased spot remains from which, like a spark under the ashes, the diseased process may be again lighted up.

Its power to cure is, however, of greater importance than its diagnostic relations.

In describing the changes produced in the skin affected with lupus by a subcutaneous injection of the remedy, I said that after the subsidence of the swelling and redness the parts did not return to their former condition, but that they were more or less changed. In some cases after a sufficient injection the mass dies and is later cast off. In

²To children from three to five years of age we have given one-tenth of this dose *i. e.*, 0.001, to very weak children only 0.0005 ccm., with this last vigorous but not dangerous reaction has been obtained.

other cases there seems to be a melting down of the tissue; in these cases repeated injections are needed to complete the process. In what way this action is brought about is not yet certain, as the necessary histological observations have not yet been made. One thing, however, is certain, that the tubercle bacillus is not killed, but the tissue surrounding the bacilli is alone affected. Beyond this, as is shown by the redness and swelling, we have deep seated changes in the nutrition of the tissues, which according to the use of the remedy destroys them quickly and deeply.

To recapitulate, the remedy does not destroy the bacillus tuberculosis, but the tuberculous tissue, and this clearly defines the limits that bound the action of the substance. It only has the power to affect living tuberculous tissue; dead tissue like caseous masses, and necrotic bone are not affected; in the same way it has no effect upon dead tissue destroyed by itself. Such dead masses may contain living tubercle bacilli, which may be cast out in the necrotic tissue, or under special conditions may again infect neighboring healthy tissue.

This peculiar action of the remedy is most important in order that its therapeutic power may be made as useful as possible. For this purpose the living tuberculous tissue must first be destroyed, and then everything possible should be done, for example by surgical means, to remove the infected tissue; where this is not possible, and the organism must itself eliminate the destroyed tissue, the remedy should be repeatedly employed to protect and prevent the reinfection of healthy tissue.

While the remedy destroys tuberculous tissue, and only operates upon living tissue, it has another and very peculiar property, namely, it may be given in rapidly increasing doses. This may be referred to simple toleration, but when one thinks that the initial dose may be increased 500 times in three weeks one can hardly refer it to tolerance, as no similar remedy of equal potency acts in this way.

The phenomena must rather be explained by the fact that at first considerable living tuberculous tissue is present, but after each injection it becomes less and less, so that there is a rapid decrease in the reaction even with increasing doses. As soon as the patient reacts in the same way as one free from tuberculosis then we may assume that all infected tissue has been destroyed. The treatment should then be continued in increasing doses, with interruptions to prevent reinfection, as long as tubercle bacilli are present in the body.

If this conception and the inference that follows it is correct the future alone will show. They are conclusive so far as I am concerned, in determining the method of treatment, which in our experiments was as follows:

To begin with the simplest case, namely, lupus,

we have always injected a full dose 0.01 ccm. and allowed the reaction to follow; after one or two weeks another injection of 0.01 ccm. and so on until the reaction became weaker and finally stopped. In two of these cases, with facial lupus, a smooth scar was obtained in one case after three injections and in the other four. The remaining cases, still under treatment, are greatly improved. All of these patients had had the disease for many years and been treated in various ways, but without result.

In a like manner the glandular bone and joint tuberculosis were treated, receiving large doses at comparatively wide intervals. The results were the same as in lupus, rapid healing in the recent and mild cases, and slow progressive bettering in the severe forms.

The relational conditions are very different in the phthisical, that constituted the bulk of our patients. Patients with tuberculosis of the lungs are much more sensitive to the action of the remedy than those affected with surgical tuberculosis. The early dose of 0.01 ccm. was soon reduced for the phthisical to 0.002 or even 0.001 ccm., and to this they strongly reacted; from this small beginning dose, it may be rapidly increased to a quantity that is well borne by other patients. We recommend that the phthisical be given 0.001 ccm.; when this is followed by an increase in temperature, the same dose should be given daily until no further reaction is produced; then the dose should be increased to 0.002 until this no longer produces a reaction, and so on, increasing the dose 0.001 or at most 0.002 until 0.01 or higher is reached. This mild course is imperative in feeble patients. When this method is employed the patient may be brought to rapidly tolerate large doses, without special rise of temperature. Some strong phthisical patients were treated with large doses to begin with, which were rapidly increased; in these cases a favorable result was more quickly obtained. The action of the remedy in phthisis generally expresses itself by an increase in the cough and expectoration; later these lessen and in the favorable cases ultimately disappear, the expectoration losing its pus and becoming mucus. The number of bacilli (and only those patients who presented bacilli in the sputum were selected) decreased only when the expectoration became mucus in character. Then they occasionally disappeared, to be found again from time to time, until they were no longer present. At the same time night sweats ceased, the general appearance of the patients was improved and they increased in weight. Those cases in the early stage were freed from all symptoms in from four to six weeks, so that they can be regarded as cured. Also patients with not too large cavities were nearly healed. Only in those cases where there were large cavities, no objective betterment could be seen, but in these there was a lessening of expect-

toration, and an improvement in the subjective conditions. From these observations I must affirm that *this remedy will cure phthisis with certainty in the early stage.*³ Perhaps it may also be successful in the cases not too far advanced.

Phthisical with large cavities, or those with complications: for example, those whose cavities are infected with the micro organisms of suppuration or who present incurable changes in other organs, will only exceptionally obtain benefit from the use of the remedy. For a time even these cases may be benefited. One must however think that in these cases the original process is affected in the same way, but the power to throw off the dead mass by a secondary suppurative process is lost.

Involuntarily the thought is awakened as to whether the new method cannot be used in connection with surgical measures (*i.e.*, operation for empyema) or other curative means, in the relief of these severe cases. I most strongly advise against the routine use of the remedy in all tubercular processes, without discrimination. The simplest will be the treatment of beginning phthisis and surgical affections, but in all other forms one should employ every resource of medical art; the treatment should be individualized, and all other methods should be employed to aid the action of the remedy. In many cases I have received the decided impression that careful nursing of the patient exercised a most important effect upon the curative result, and for that reason I would recommend the employment of the remedy in special institutions, where the patients can be carefully observed and well cared for. How far the present methods of cure, mountain climate, open air treatment, etc., may be usefully combined with the new measure is not yet determined; but, I believe that these curative factors may be usefully employed in many cases, especially in neglected and severe forms as well as in the convalescent stage.⁴

The important point in the new cure is its earliest possible application. The object should be to employ the treatment in the beginning stage of phthisis when it may completely eradicate the disease. Therefore it cannot be too strongly stated that the early diagnosis of phthisis is now of greater necessity than ever before. Until now the presence of the tubercle bacillus in the sputum, has been regarded more as an interesting side issue, that confirmed the diagnosis, but was of no further importance to the patient, and for that

reason it is often neglected, as I have recently determined in several phthisical patients, who have been under the care of several physicians without having their sputum examined. In the future this must be different. A physician who neglects any diagnostic means and especially if he fails to examine the sputum that an early diagnosis may be made, fails in his duty to the patient, as upon this depends the early application of the specific treatment, and perhaps the life of the patient. In doubtful cases an injection for diagnostic purposes should be made.

Then only will the new curative agency become a blessing to suffering humanity, when all cases are treated in their incipiency, and we shall no longer see those severe and neglected cases, that now form such fruitful sources of infection.

In closing, let me remark that I have purposely omitted statistical tables and descriptions of special cases in this article, as the physicians who have furnished patients will themselves undertake the publication of results, therefore I wish to make this communication as objective as possible that I may not anticipate their communications.

CASES TREATED BY KOCH'S METHOD.¹

PROFESSOR VON BERGMANN'S CASES.

Dr. v. Bergmann's anxiously expected address and exhibition of cases treated by Professor Koch's method took place on Sunday evening, November 16, before a numerous and select audience of invited guests. The Minister of Public Instruction, Herr von Gossler, and amongst other celebrities Professors Virchow, Gerhardt, Liebreich, Waldeyer, and Olshausen were present. In beginning his address Professor v. Bergmann referred in stirring words to the intense emotion which, since Koch's publication, had seized not only suffering but also healing humanity. He then discussed the cases that had come under his own observation, which were cases of 1, lupus, 2, glandular tubercnolosis, 3, tuberculosis of the joints and bones, and 4, tuberculosis of the larynx. Five lupus patients were exhibited, to whom a subcutaneous injection of one centigram had been applied the same morning between 8:30 and 9:30 A.M.; all these five cases showed the general and local symptoms spoken of by Koch—namely, fever and inflammation. The lecturer remarked that the unerring certainty with which an attack of fever, accompanied by rigors, followed the application of the remedy, was of the highest interest from a medical point of view. This general reaction was invariably accompanied by a marked action on all tuberculous parts of the body—visible in cases of lupus. Of the patients exhibited, some showed tempera-

³This statement requires modification in so far, that up to the present no conclusive experience can be adduced to show that the cure is lasting. It is apparent that relapses are not excluded. But we may assume that they may be overcome as rapidly and easily as the first attack.

⁴On the other hand it may be possible that cured patients may have acquired an immunity similar to that found in analogous infectious conditions. But, for the present this must remain an open question.

⁵As regards brain, laryngeal and miliary tuberculosis, the material at our command has been too small to furnish proper experience.

¹British Medical Journal.

tures of 41.0° C., and even higher. The lupus spots were enormously swollen and very red, this reaction being the more marked in proportion as the case was a more recent one. One of the patients had suffered from the disease for twenty years and one for twenty-nine years. On Sunday morning, before the subcutaneous injection was made, Professor Gerhardt had designated the first of these cases as a slight and superficial one; nevertheless, an enormous reaction followed the injection, tending to prove that there was more lupus than had yet been found, and that Koch's remedy finds out the most secret places and nests of tubercle bacilli.

The next five patients exhibited were treated in presence of the assembly by Stabsarzt Dr. Pfuhl, subcutaneous injections in varying doses being applied to the back. One of the patients was a sickly looking lad of 17, who had been under Professor v. Bergmann's and the late Professor Volkmann's treatment for the last fourteen years. "Now the poor fellow will have relief at last," said Professor v. Bergmann, smiling.

The next set of three patients exhibited had been under treatment for some time, and had gone through a course of subcutaneous injections, the reactions becoming weaker after each injection. Here partial cure was already visible; but the application will be continued until no reaction at all can be observed.

Professor v. Bergmann resumed his address by remarking that the value of the remedy was enhanced by the control experiments that could be made in the case of healthy subjects, or those affected by other diseases, which were all-important for diagnosis. He illustrated this by exhibiting a patient suffering from an affection of the cheek, which might have been considered tuberculous. The experimental subcutaneous injection produced no feverish reaction. Probably this case was syphilitic.

The second group exhibited contained two cases of glandular tubercle, in the person of two little girls of scrofulous appearance. Here the reaction was marked.

The third group comprised sixteen cases of tubercle of the joints and bones, with suppuration, fistulæ, and similar phenomena. Some of these, to whom a first injection had been applied, showed the usual symptoms: the joints were much swollen and highly colored, and movement was scarcely possible. Others had been treated by repeated injections. One of these, who suffered from consumption and tuberculous inflammation of the knee-joint, was so severely affected by the injections (intermittent pulse, faintness, etc.), that there seemed cause for anxiety. He had, however, recovered, and was progressing favorably.

The last patients exhibited excited special interest, as they were cases of tubercle of the

larynx. Professors Gerhardt and von Ziemssen had in both cases found serious lesions of the larynx. And here the remedy showed its diagnostic value as a means of distinguishing cancer from tuberculosis.

In summing up the cases exhibited, Professor v. Bergmann said that from the local and general phenomena which had already shown themselves the prognosis was decidedly favorable. Nevertheless, in many cases surgical operations would still be unavoidable, as abscesses and dislocations could only be cured by mechanical means. In these cases it would be of the highest importance to guard against relapse by the repetition of Koch's treatment, and thus both methods united gave the brightest prospect of success.

DR. W. LEVY'S CASES.

The *Therapeutische Monatshefte* publishes an extra supplement containing an account of cases treated by Koch's new method in Dr. Levy's clinic. The report, written by Dr. H. Feilchenfeld, Levy's assistant, is here summarized: The treatment was begun on September 22, that is, not quite two months ago. This comparatively short time has sufficed to show in what cases complete recovery may be hoped for, and where only amelioration of symptoms can be expected. No definite opinion could be formed as to the length of time necessary for perfect recovery. Feilchenfeld cites three cases of lupus, one of which is a sort of test case, and has already become celebrated in the history of the investigation. In this case the phenomena of reaction all took place in the typical form, with which Koch's paper has made the world familiar. A complete cure seemed to have been effected—it was as though the diseased tissue had been cut away with a chisel. Further subcutaneous injections, however, proved that the end of the trouble had not been reached, and that in spite of superficial cicatrization there was plenty of tuberculous tissue below awaiting destruction. Even now the patient cannot be considered cured. In a second case of lupus the general condition of the patient became much worse after each subcutaneous injection, and severe pains persisted, especially in the bones of the affected arm.

A third case of lupus is interesting, because of all cases treated in Levy's clinic it is the one furthest advanced towards recovery. In this case the subcutaneous injections no longer produce a reaction. Here too, however, Dr. Feilchenfeld speaks of "provisional cure" only, as no final verdict can be given after two months in a disease which runs its course so slowly as tuberculosis does.

In cases of tuberculosis of the bones and joints, cures were effected, that is, no reaction followed even large doses of the subcutaneous injection. The same result was obtained in cases of glandu-

lar tuberculosis. Turning to his cases of consumption, Dr. Feilchenfeld states that three patients in the first stage of phthisis were dismissed as cured, their sputum having been found free from bacilli, and the auscultatory signs having considerably decreased. Dr. Feilchenfeld, however, does not consider these two facts a complete proof of definitive cure. Bacilli may disappear from the sputum to reappear after a time.

As regards the more advanced forms of phthisis, where cavities have already formed, Dr. Feilchenfeld remarks that no complete recovery has been observed. But the general symptoms of the disease—night sweats, etc.—disappeared promptly. Even in the worst cases there was a diminution of expectoration. There was no increase of weight, even where the general condition was much improved. On the other hand, no loss of weight was observed, even in the most advanced and desperate cases.

PROFESSOR FRAENTZEL'S CASES.

At Monday's meeting of the Verein für innere Medicin, Professor Fraentzel gave an account of the cases treated in his clinic by Koch's method. He divided them into two classes: 1, those in the first stage of phthisis; 2, those in advanced stages of the disease (disintegration of tissue, cavities, etc.). In the latter group no change of condition could be observed. Two patients died during treatment; their cases were desperate from the beginning. The post-mortem examination showed no indication of the commencement of recovery. Fraentzel utters a word of warning against using large doses at the beginning of treatment in advanced cases, and cited one case in which death ensued after twenty-four hours. As regards the first group of patients—early stages of consumption—Professor Fraentzel was able to record decided improvement. Expectoration was easier and more abundant after the injection, while the cough decreased. The general condition visibly improved; the appetite became keener, the weight increased, and the night sweats disappeared. The microscopic examination of the sputum demonstrated first a decrease, and secondly, a change of the bacilli. They seemed stunted; nevertheless, their vitality was not destroyed. Fraentzel is of opinion that the treatment, even in the most successful cases, must be continued for a considerable time to guard against relapse.

PROFESSOR GERHARDT'S CASES.

In a clinical lecture given in the presence of many distinguished physicians on Tuesday, November 18, Professor Gerhardt gave an account of his experiences with Koch's remedy. He exhibited three cases specially fitted to illustrate the progress made in the diagnosis and treatment of tuberculosis. The first case was one of tuber-

culosis of the throat, in which various methods had been tried without effect. On Sunday, 2 milligrams of Koch's fluid were injected, and a decided reaction was observed on Monday. Considering the success which has attended a similar case in v. Bergmann's clinic, Professor Gerhardt thinks recovery very possible. The second case was in the initial stage of consumption, whilst the third patient showed an affection of the apex of the lung which aroused suspicions of tuberculosis. Tubercle bacilli had not been found, but this is no absolute proof of the non-existence of tuberculosis. Koch's fluid was injected on Sunday; no reaction ensued, which is a conclusive proof that the affection is not tuberculous. Professor Gerhardt, in conclusion, spoke some serious words of warning. He said it was absurd to imagine that Koch's treatment was of so simple a character that by subcutaneous injection consumption could be simply driven out of the body; on the contrary, in order to apply it successfully, the physician would have to use the most careful discrimination.

THE FIRST ENGLISH CASE OF LUPUS TREATED BY KOCH'S METHOD.

The following information, dated Tuesday, November 18, is forwarded to us from Berlin, by Mr. Malcolm Morris and Dr. Pringle: The patient, who is in a private room at the Royal Clinic, under the care of Professor v. Bergmann, is a man aged nearly 22, who has been under Mr. Morris's care since the beginning of 1885, when lupus of the face first developed. Previous to this he had suffered from various strumous manifestations. Since the lupus first showed itself on the nose it had appeared on the gums and palate, and had been several times operated upon with benefit. Caseous glands have also been removed on five occasions. The patient, who appeared to be in perfect general health, was first inoculated on Sunday morning, November 16, at 8:45 A.M., Professor Koch himself being present. His temperature, taken 15 minutes after inoculation, was 36° C., in eight hours it had attained its maximum of 40.15° C. At this time the patient was suffering from extreme *malaise*, headache, dyspnoea, nausea, and thirst. The changes in the parts affected by lupus were very remarkable, the local manifestation exactly corresponding to those descriptions already published. Gradual fall of temperature ensued till it reached 37.6° C., at 3 A.M., on November 17, attended by abatement of all the constitutional symptoms. The temperature again rose to 38.6° at 3 P.M., and had since gradually declined to normal. The local alterations, which demand more minute descriptions, will be communicated with the history, temperature chart, and other details regarding the case as soon as the treatment is completed.

SURGICAL RELIEF FOR BILIARY OBSTRUCTION.

Read in the Section of Surgery and Anatomy, at the Forty-first Annual Meeting of the American Medical Association, at Nashville, Tenn., May, 1890.

BY HENRY O. MARCY, A.M., M.D., LL.D.,
OF BOSTON.

The surgery of the gall-bladder opens another and an extremely important field for operative interference. Biliary obstruction has been, from the earliest times, recognized as a cause of most severe suffering attended with the gravest dangers.

With very few exceptions, operations for its relief have been considered beyond the *pale* of surgical domain, until within a few years, and even now, although abdominal surgery is almost universally accepted as justifiable, in a multitude of varying conditions, only a very few surgeons have attempted operation upon the gall-bladder.

My own experience is limited to the following cases which, inasmuch as they illustrate a variety of conditions, are of sufficient importance to put upon record.

Case 1.—Dr. W—, aged 72, a physician of exceptional intelligence, had clearly diagnosticated repeated attacks of suffering, extending over a number of years, as due to biliary obstruction, a gall-stone. Although somewhat jaundiced, the more prominent and dangerous symptoms were caused by the continuous vomiting. The attack preceding the operation, which was performed July, 1887, was more severe than any previous one, causing imminent danger to life. Pulse rapid, temperature slightly above the normal, no food retained upon the stomach, rectal alimentation maintained for several days, emaciation pronounced. There was pain and tenderness just to the right of the median line, and upon pressure an ill-defined enlargement was felt.

Upon section, the base of the liver was easily found, and a rather small, undistended gall-bladder, intimately bound to the transverse colon by old and firm adhesions. The finger, carried in the direction of the common duct, easily detected a gall-stone of considerable size, which was dislodged and retracted into the lower portion of the gall-bladder. A prolonged attempt at separation of the adhesions was made, with considerable loss of blood from the divided tissues, which were exceptionally vascular. After consultation with Dr. Worcester, who ably assisted me in the operation, it was reluctantly determined unwise to proceed farther, and the wound was closed. Marked relief followed for a few days; the exploratory wound healed by first intention. The old symptoms, however, soon supervened, followed by death. A careful autopsy was made by Prof. Frost, of Hanover, who reported that a calculus, about the size of a walnut, was in the greatly dilated common duct, producing complete occlusion. Although the hepatic structure was not

materially changed, yet the old adhesions, binding the gall-bladder to the transverse colon, were so extensive, that the post-mortem dissection was made with difficulty and, on this account, further operative measures would have been, in his judgment, unjustifiable.

Case 2.—Mrs. R—, in middle life, extremely fleshy, a patient of Dr. Cunningham of Cambridge. When seen by me in consultation, persistent vomiting had continued for several days, ushered in by extreme pain in the right hypogastrium. She was slightly jaundiced, pulse small and rapid, condition considered one of extreme danger; referable to biliary obstruction. She had had several previous attacks less severe. On section, extensive adhesions were found, binding a moderately distended gall bladder to the surrounding parts completely overlaid, as in the previous case, by the transverse colon. With some difficulty I dislodged and retracted a biliary calculus from the common duct, but deemed it unwise to attempt its removal, because of the impossibility of freeing the gall-bladder and bringing it within the lips of the wound. Rapid recovery followed with primary union, a free flow of bile into the intestine ensued, and the patient now, at the expiration of about two years, continues well.

Case 3.—Mr. J—, formerly a sailor, aged about 45, had been under my care for some months, suffering from supposed cancer of the pylorus. He developed rather rapidly a fluctuating tumor in the region of the gall-bladder, of fist-size. Was considerably emaciated and markedly ænemic. This condition made the former diagnosis doubtful, and operative measures were advised and gladly accepted. Entered hospital October, 1887, and assisted by Drs. Holt and Nelson I made an exploratory incision. Immediately upon opening the abdomen, the cystic tumor pressed into the lips of the wound. The tumor was carefully attached to the peritoneum by a double row of continuous tendon sutures and then opened. About six ounces of a whitish, mucopurulent fluid escaped, without a seeming trace of bile. Exploration detected no trace of biliary calculi; the finger carried deeply was brought in apposition to a thickened mass in the region of the outlet of the stomach. A large double drainage-tube was inserted, about which the lips of the wound were closed. It was washed out for some days with a weak solution of sublimate; the secretion amounted to several ounces daily. Contraction slowly followed, leaving a sinus which closed only after several weeks. Marked improvement followed for a time, but death occurred some months later, and the autopsy revealed primary cancer of the stomach, with a secondary deposit studding the liver.

The cystic duct had been closed from the secondary changes which had ensued; the interesting specimen is here shown.

Case 4.—Mr. M—, aged 45, of regular habits, a healthy, hard-working man until eighteen months previous to operation, April 29, 1889. Had developed rather rapidly a well marked jaundice, with frequently returning intermittent attacks of excruciating pain followed by vomiting. Had been supposed by his physicians dying of cancer of the liver. Skin dark copper tint, emaciation not extreme. Stools light gray, urine dark brady color. Diagnosis, occlusion of the common duct, possibly gall-stone. I was assisted in the operation by Drs. Didama and Jacobson of Syracuse, N. Y., and Dr. Nelson of Boston. Present Drs. Warner, Cunningham, and others. Liver was enlarged and very darkly colored. Gall-bladder distended, extensive adhesions to the surrounding parts. United it to the lips of the wound as in previous case and incised. Careful probing detected no evidence of stone, and it was determined that the cystic duct was occluded from an inflammatory process. Put in drainage-tube and closed the wound about it without much expectation of benefit. A free discharge followed with continued and rapid improvement. Jaundice lessened and when seen in September had entirely disappeared. The wound closed, appetite good, strength, in large measure, returned and he does light work. He continued to gain strength until March of the present year when jaundice returned with a repetition, in a minor degree, of former sufferings.

Case 5.—Mrs. P—, aged 40, has had several attacks of biliary colic of a serious character, accompanied with jaundice. The last attack preceding the operation occurred in August, 1889. Life at that time thought to have been imperilled, she has not been quite well since. Entered my private hospital. Has severe local pains, some vomiting, markedly jaundiced; dark urine; clay-colored stools. Thick abdominal wall, beneath which a considerable sized fluctuating tumor is well defined, the base of which is quite on the line with the umbilicus. Operation October 26, 1889, assisted by Drs. Clark and Nelson.

Immediately upon dividing the peritoneum, the cystic growth distended the lips of the wound. It was attached to the peritoneum by a double row of tendon sutures and incised. Ten ounces of thin, light colored bile escaped, floating out with it a gall-stone, the size of a large almond. Careful probing revealed the presence of another calculus in the common duct. All effort at dislodgment failed, and as much force as was deemed justifiable was used in the attempt to crush it, but without avail. The bladder was washed out with a sublimate solution, the stitches cut away, the wound packed with a sponge after having somewhat forcibly drawn the gall-bladder through it. Even this procedure did not enable us to seize and remove the calculus. I then divided the walls of the duct with scissors, and everted

its edges from over the roughened calculus which was even then removed with difficulty. The thickened mucous membrane of the duct and bladder was joined by a fine continuous tendon suture, and in like manner the peritoneal edges were carefully coapted, while over all a third layer of suturing with tendon, a continuous sero-serous stitch intrafolded the edges of the entire wound of the viscus measuring about four inches. The abdominal wound was closed by buried animal sutures, in the usual manner, and sealed with iodoform collodion. Free vomiting of a large amount of bile followed the recovery from ether. Rapid convalescence ensued without incident, and the patient remains vigorous and active. This rough mulberry-looking calculus, grape-size, was the offending member, weighing when dried fifty-nine grains.

A brief review of the history of the surgical measures devised for the relief of biliary obstruction is of great interest and value. Thudicum reports that Johannes Fabricius removed gall-stones from the bladder of a living subject in 1618.

Monsieur Petit of Paris first published his admirable memoir, on the diseases of the gall-bladder in 1743. I review, at considerable length, his article, found in the *Memoires of the Royal Academy of Surgery*,¹ since nothing more valuable, even to the present, has been published upon this interesting subject. In the first part of his contribution, he analyzes with remarkable clearness the differentiation of the varying conditions of the obstructive diseases of the biliary passages. He cites a long series of interesting cases occurring under his own observation, supplemented by a report of autopsies. He clearly defines clinical distinctions between abscess of the liver and the distention of the gall-bladder as follows. "Fluctuation in consequence of retained bile appears suddenly, in an abscess it is some length of time before it is apparent; in the one *it is suspected before it is recognized*; in the other recognized before suspected. In the one there may be doubt as to the point of fluctuation, while in the other it is known at once by the touch." He points out very clearly the dangers from operative measures which he thinks would be necessarily fatal if the contents of the gall-bladder should escape into the peritoneum, and as a consequence restricts all operative measures to the class of cases where inflammatory changes have caused adhesion of the cyst to the peritoneum.

He analyzes these changes with the closest scrutiny in order to make definite, as far as possible, such conditions before operation and then states, "What I have observed should moderate the ardor of young men who desire always to cut, but should therefore an unwise timidity cause them to let pass the occasion of operation in cases

¹ Tom Premier, 1781, Page 265, 56, etc.

where they are persuaded the tumor is caused by dilation of the gall-bladder, occasioned by retention of the bile? If the observations on the first two cases show that a few of these tumors cannot be opened except at the risk of the life of the patient, those on the third case show that there are those cases which may be opened without danger." . . . "If convinced that the tumor is adherent, that the life of the patient is in peril, we should not hesitate to open the bladder, for we should not wait for nature to perform miracles. It is true she does commence, since she causes the adhesion, and opening the gall-bladder without adhesion is always fatal, but it is the duty of the skilful surgeon to observe nature and to profit thereby, to seize upon the favorable moment to act himself, when he sees that nature needs his aid, and that she cannot complete what she has commenced without it. If we can be assured of the adhesion, then we may open without danger the tumors which are found in these parts, and then shall we add two new operations to surgery, one, in cases where the retention of the bile is extensive and danger to life imminent, the other, lithotomy, or extraction of stones from the gall-bladder. The existence of the stone and adhesion being assured, the operation is without danger. It is in just these cases that the skillful surgeon can show his genius. We can pass the sound into the urinary bladder for determining stones in it, why not pass the sound into the gall-bladder for the same purpose, and if stones are found, why not extract them as from the urinary bladder? If we can without rashness open the gall-bladder when it is adherent, we can pass the sound without rashness, and if stones are found there, what reproach should be to him who does not dare to extract them, and what praise should be given to the surgeon who would remove them?"

Petit then gives a series of interesting illustrative cases in detail, one of which is that of a woman, 37 years old, previously vigorous, where a tumor of the gall-bladder supervened after an attack of biliary colic. This increased in size, until it extended even to the crest of the ileum, suppuration and discharge followed, with the escape of seven or eight gall-stones. Six months after, the patient came under Monsieur de la Pegroneé. At this time the discharge was abundant, of purulent character, mingled with bile. After careful probing of the fistula, he made an incision about three inches in length, extending to the middle of the right rectus muscle, which was followed by the escape of a considerable quantity of pure bile. Without difficulty a sound was carried into the gall-bladder to the depth of about four inches which he believed entered the common duct, in which location he thought a small stone was lodged and displaced. He reports the case two years later, the fistulous tract

remaining through which is a free escape of healthy bile, and the patient appears to have entirely recovered her former health.

Case 11.—Observed by Monsieur Sarran. A woman, aged 64, had colic, followed by complete jaundice. A tumor appeared in the right hypochondrium which finally opened spontaneously, leaving a fistula, which, from time to time, discharged. At the time of operation the fistulous opening was at the side and a little below the umbilicus. The sound entered the fistula to some distance, beneath the muscles of the abdomen, where was felt a hard foreign body.

An incision was made upon it, and a biliary calculus four inches long by three in circumference was withdrawn. Upon the opposite side, at the left of the linea alba, was felt another mass at the depth of an inch and a half, from which was extracted a second stone by the prolongation of the first incision. Complete cure followed in about two months.

Case 12.—Reported by Monsieur Habert, Docteur de Sarbonne. A woman, having been jaundiced for a long time, with a very considerable tumor in the right hypochondrium, after a severe attack of colic accompanied with convulsions, passed by the bowel a gall-stone, weighing three and a half drachms, two inches and a half in length, one and a half in diameter, three and a half in circumference, polished at its ends in facets. The tumor diminished in size, and health was slowly reëstablished.

Petit's work was discussed by some of the leading surgeons of his time, with little resulting profit to sufferers, and in large measure was forgotten, even Richter, who published a half a century later, making no reference to it, in his monograph upon the subject. The latter made original studies upon jaundice and the causal conditions. He determined that the general pigmentation of the tissues might occur without obstruction to the free flow of bile from the gall-bladder, and also that the outflow might be entirely prevented and the jaundice-state not supervene. The more common cause, he believed, lay in a perverted action of the liver, dependent upon a derangement of the hepatic circulation. He gives, however, in symptomatic detail a case of obstruction in the common duct from a calculus which went on under his care to death, and figures the specimen, without the hint of a possible relief from surgery. As an interesting illustrative case I quote the report of the autopsy.²

"Mr. S., gouty diathesis, age 40. Troubled with jaundice four years. In hospital two weeks. The gall-bladder was five inches long and two broad, quite full of dark bile and contained thirty gall-stones. The ductus choledochus and the

² Aug. Gottlieb Richter, M.D., Prof. Med. University, Goettingen, 1793.

parts about were preternaturally distended. On cutting into the substance of the liver a very great quantity of dark brown bile issued as from a sponge, of the same nature with that which was found in the gall-bladder. There was a stone in the ductus choledochus which, on account of its uncommon size, I have caused to be engraved on the annexed plate. It weighed three ounces and five drachms. All around the stone there was fluid bile, so that this fluid had evidently passed by the stone into the duodenum. It fell into three pieces on being taken out. The external surface resembled a very firm extract of liquorice. On some places there are evident marks of smaller stones adhering to it. The thick end of the stone was in the duodenum, the most pointed was turned towards the neck of the gall-bladder." He gives another case of interest as follows: "A woman died in the hospital in the highest degree of jaundice. On inspecting her body, no gall-bladder was found, but in its place only a skinny substance of a very small size, in which no cavity could be discovered. The whole liver was full of white concretions, apparently of the nature of calcareous earth, of different sizes, from that of a cherry to that of a pea, which floated on water. . . . Most of the concretions lay under the external membrane, some few in the substance of the liver. These probably contained the irritating matter which occasioned the jaundice."

He concludes by stating, "that real obstructions are very seldom the cause of jaundice; where they do occur, they occasion an incurable disease, for this cause neither can be discovered, or removed." . . . "If stones are sometimes the cause of the jaundice, they act probably by occasioning irritation and spasm, which stops the biliary ducts, or deranges the course of the fluids in the hepatic system, and in such cases no other medicines but sedatives are of any use."

In 1798, Richter devised a litho-triptor for crushing gall-stones, and explained how the fragments could be removed by washing. In certain cases he also advocated operative measures, by first bringing about adhesive inflammation of the gall-bladder to the abdominal wall, and making an incision, as a second operation, after sufficient time had elapsed for securing a firm union.

Morgagni³ mentions a case where the common duct was as large as the stomach and contained calculi of different sizes.

Dufresne, in 1847, recommended the use of caustic over the dilated gall-bladder in order to cause adhesive inflammation before opening. About that date, Recamier advised the use of the trocar. Thudicum, in 1859, reviewed the entire subject carefully. He recommended abdominal section over the cyst, and the suturing of the unopened gall-bladder to the peritoneum, and after

sufficient time had elapsed for a firm union, completion of the section.

Trousseau furnishes an interesting chapter upon the subject, with the report of cases, advising surgical procedure after the manner of Petit, but he emphasizes the observations of Boyer who declared that there was but two signs which indicated the adhesion of the cyst, immobility of the tumor and puffiness of the integuments. In order to insure adhesion, Trousseau advised the insertion of thirty to forty steel needles with large heads which were allowed to remain three or four days. This process is repeated three times before peritoneal adhesion is supposed to be firm. He states that internal biliary fistulæ are quite beyond our means of treatment. He dismisses the subject with the acknowledgement that little good is to be expected from treatment except opiates and sedatives.

Frerichs, in his classical treatise upon diseases of the liver, offers little of value as to treatment of biliary obstruction and states, "We must never think of evacuating the contents of the gall-bladder by means of puncture, except when the rapid increase of the tumor endangers rupture, or where symptoms of hectic consumption supervene." When there are adhesions, the operation may be had recourse to without hesitation; but when there are no adhesions, or their existence is doubtful, he precautions to secure first adhesive inflammation, as advised by Bégin and Recamier. This consisted in dividing the peritoneum and dressing the wound with charpié, in order to produce firm adhesions.

It would appear that the first case of cholecystotomy, successfully performed in modern times, was by Dr. J. S. Bobbs,⁴ of Indianapolis, reported under the title, "A Case of Lithotomy of the Gall-Bladder." A woman, aged 30, tumor just inside of iliac bone, tender to pressure, diagnosis doubtful, probably ovarian. Operation June 16, 1867. Incision made between the umbilicus and pubis, omentum adherent, incision enlarged to an inch above the umbilicus on the right side, tumor five inches in length, two in diameter. Incision through the lower margin caused several small bodies, size of rifle bullets, to escape. Closed the incision of the sac by single stitch and cut the ends of the suture closely. Closed the wounds with suture and adhesive plaster. Examination of the calculi left no doubt as to their character; were of light specific gravity, and numbered between forty and fifty. The fluid was perfectly free from coloring matter. Recovery very satisfactory with no return of local trouble at the time of report, ten months after operation.

Dr. J. Marion Sims operated in Paris, April 18, 1878.⁵ Patient under observation by her phy-

³Morgagni—Letter 37.

⁴Transactions of Indiana State Medical Society, 1868, p. 68.
⁵British Medical Journal, 1878, Vol. 1, page 811.

sician since previous January. Aspirated what was supposed to be a cyst of the liver, thirty-two ounces of dark-colored fluid. She continued deeply jaundiced, clay-colored stools, scanty high-colored urine. Under antiseptic precautions, an incision was made three inches in length, upon the right side, parallel to the linea alba. Cyst wall exposed, aspirated by trocar twenty-four ounces of dark fluid. Withdrew the emptied gall-bladder quite external to wound. Enlarged the incision and removed sixty gall-stones varying in size. Stitched gall-bladder to lips of wound. Operation tedious and difficult, lasting one hour and sixteen minutes. Death occurred eight days after, and at autopsy sixteen more calculi were found remaining in the duct. Dr. Sims' report of the case is in careful detail, and to the operation he gave the name since adopted, cholecystotomy ($\chi\omicron\lambda\zeta$ —bile, $\kappa\upsilon\omicron\tau\iota\varsigma$ —bladder, $\tau\omicron\mu\zeta$ —incision).

To Mr. Lawson Tait, of Birmingham, however, is justly accorded the high honor of having established, upon a sure basis, operative interference upon the gall bladder. Up to date, Feb. 18, 1888,⁶ he reports forty-one cases of cholecystotomy, with only two deaths, these occurring on account of malignant disease. Mr. Tait follows closely the principles first laid down by Dr. Sims. He says, "The conclusions drawn from the surgical experience of these cases, is that the entire possibilities of the treatment of gall-stone and distended gall-bladder are exhausted in Dr. Sims' original paper, and that no further extension of it seems possible."

Recently Dr. Senger reported in the *Berliner Klinischer Wochenschrift* what he calls a new operation. The gall bladder is drawn as far as possible up from the wound, and sutured to its margin. After a day or two, adhesions will have formed and it is then opened and emptied, but immediately closed. When the wound in the bladder shall have healed, the surrounding adhesions are divided and the organ returned within the abdominal cavity. The object of these measures is of course to restore their parts to their previous normal condition, deemed by him unsafe to attempt at a single operation. Langenbeck criticises the operation as untrustworthy by reason of adhesions being too recent and offering little advantage over that of biliary fistula which can usually be readily closed if it seems desirable.

Every physician of experience has met with cases of biliary obstruction from varying causes with fatal results. These conditions are much more common than might at first appear. Many interesting clinical histories are reported in the journals, too frequently followed with verification of diagnosis by post-mortem examination. In all the pathological collections, more or less interesting specimens are found in considerable

number. In Dr. Jackson's catalogue of the Warren Anatomical Museum, in Boston, published in 1870, no less than sixty specimens, from as many different patients, are preserved, showing diseases of the gall bladder and ducts; the larger number, of biliary calculi.

It was earlier believed that simple extravasation of bile into the peritoneum was fatal. Our present knowledge would teach that the bile *per se* may be absorbed by the peritoneum without causing much trouble, although wounds of the gall bladder are generally fatal because of attendant septic infection.

The most important question that arises in the discussion of the subject is, If cholecystotomy is a justifiable operation, when should it be performed?

Injuries.—Without doubt, in every case of wound or perforation of the gall-bladder, operative measures should be instituted without delay, since without surgical interference, there is little prospect of recovery.

Empyema.—Where empyema of the gall-bladder exists, there can be no doubt but that recourse should be had to operation, as early as the condition of the patient may seem to warrant. The temptation to aspirate should be resisted, since it is in itself dangerous and cannot afford permanent relief.

Cystic Dilatation.—When the gall-bladder has become cystic, in all cases, surgical interference is indicated. Aspiration may aid in diagnosis as to the character of the fluid, and possibly the detection of the calculus, but at the most, it is only palliative.

Biliary Obstruction.—Although patients do live an indefinite number of years with gall-stones, frequently dying of other diseases, the recurrent attacks of colic are exhaustive and often fatal in their complications; jaundice induces dangerous cholemia; suppuration may be incident upon the changes which supervene from the presence of foreign bodies in the gall-bladder. Long continued obstructive jaundice and the changes which have occurred in the tissues, is doubtless an unfavorable complication, since thereby the patient's vital power is greatly depreciated. In complete obstruction of the common duct, cholecystotomy may prevent death from cholemia by permitting the escape of the biliary fluids externally. It is clearly established that the nutrition of the tissues may be maintained without the mingling of the biliary secretion with the contents of the intestinal canal.

A very considerable class of cases where obstruction exists in the common duct, merit our serious consideration, as to the means to be established for its relief. The earlier measures which we have reviewed, where only a fistulous tract was sought to be formed externally, fail in many cases of the desired result. The theoretic

⁶ British Medical Journal, Feb. 18, 1888.

perfection of the operation consists in the restoration of the parts, as far as possible, to their former normal conditions. For every reason a permanent fistula has very serious objections.

When the cystic duct alone is obstructed, and no bile enters the gall-bladder, an abundant quantity of clear albuminous fluid is secreted from the mucous surface more or less changed, and this is illustrated in my case number three, where the organ contained no foreign body. If the hepatic and common ducts are unobstructed, there will remain a free flow of bile into the intestine without jaundice and the consequent changes which ensue from the liver. Where these conditions exist, with considerable cystic dilatation, there remains to the surgeon a choice of operative measures, either of opening the bladder with drainage, or of removing it altogether—cholecystectomy, as recommended and performed by Langenbeck. Dr. Smith⁷ reports nine published cases of cholecystectomy where "one death only can be attributed to the operation."

Only recently Dr. Meredith⁸ states that "this operation has lately been performed with success in several instances, notably by Mr. Thornton, with excellent results. After thoroughly cleansing the interior of the injured gall-bladder, the peritoneum covering its neck is cleanly incised, and the cystic duct is then freed from its connections sufficiently to allow of its being ligatured and divided. Any bleeding vessels are then tied, and the edges of the divided peritoneum are accurately united by suture over the ligatured duct, a glass drainage tube being finally inserted before closing the abdomen."

Cholecystectomy can be favorably considered only in a very limited number of cases, where the gall-bladder has undergone marked pathological changes and its duct is so altered that the functions of this viscus are not likely to be restored. When these conditions pertain, there can be little doubt but that it better be removed, in the same manner as a cystic growth in any other part of the abdomen, yet in many cases the ease of operation and resultant safety will cause suturing to the abdominal wall, with drainage, to be preferred. When excised, the entire secreting membrane of the cyst should be carefully removed from the base, and the divided edges inverted by a continuous sero serous suture. The operation is completed by closure of the abdominal wound, usually better without drainage.

Obstruction of the Common Duct.—In a great majority of operative cases there is obstruction of the common duct, and when this occurs from a biliary calculus, methods of procedure, to be effective, must be such as to clear the passage, in order to allow a free escape of the biliary secretion into the intestinal canal.

A calculus in the gall-bladder alone rarely causes obstruction in the common duct. On this account the surgeon should not content himself in a completion of the operation without ascertaining, as far as possible, the patency of the canal into the intestine. This cannot always be easily determined. When a calculus is found in the common duct, it may often be dislodged by gentle manipulation and removed from the gall-bladder.

When it is impossible to do this, the efforts of the surgeon should be directed towards the possibility of safely crushing it *in situ* with well padded forceps after the method of Richter, revived by Mr. Tait. It must remain a matter of individual judgment, as to how much force may be applied safely in the crushing, as well as to its method of application. If it shall prove impossible to remove the fragments by irrigation, they should be made sufficiently fine to allow their easy escape through the undilated portion of the duct into the intestinal canal. If, on account of the hardness of the calculus, or the condition of the surrounding parts, it shall be deemed unwise to attempt crushing, the further division of the duct, in order to obtain access to the stone, is advised, as illustrated in Case 5 in my series above reported.

Mr. Meredith⁹ recommends the following: "In dealing, however, with a small and friable sac which has been unavoidably much injured during the extraction of the calculi, the above procedure may prove exceedingly difficult, if not impossible. Under such circumstances, one of two courses may be followed, provided always the patency of the duct has been ensured. The first of these alternative measures consists in carefully suturing the opening in the gall bladder and returning it into the abdominal cavity. This plan was first carried out, I believe, by myself in 1883, but my patient unfortunately died. The procedure has latterly, however, been successfully effected by other operators, and its adoption, in suitable instances, is fully justified, provided that means for drainage of the peritoneal cavity in the immediate neighborhood of the sutured gall-bladder be taken."

When this has been accomplished, we are enabled to assure ourselves of the remaining portion of the duct. Other calculi may be present, or inflammatory changes may have supervened which render it still impermeable. When we have ascertained that no further obstruction remains, we are then under the necessity of making at least a partial closure of the canal, since it is impossible to attach the widely divided lips of the duct and bladder to the abdominal wall. In this instance, we may close the wound in part and use drainage, as is more commonly recommended, or complete the operation as I did in Case 5. This latter method of complete closure of the

⁷ Greig Smith, "Abdominal Surgery," p. 552.

⁸ Lancet, April 19, 1890, "Present Position of Abdominal Surgery."

⁹ Lancet, April 19, 1890.

gall-bladder was first suggested by Sir Spencer Wells, and so far as I have ascertained it has been attempted in only three instances, one of which, as reported by Mr. Tait, was followed by a fatal result, because of escape of bile into the peritoneum.

To close so long a wound effectively would seem improbable by any method of interrupted suturing. The use of silk, as the material for suturing, no matter how prepared, would be likely to result disastrously, since it produces much irritation in the wound, which would be especially true if applied in repeated layers. The coaptation of the parts, as effected in Case 5, is simple, rapid, and makes a wound at once fluid proof; a method which I have adopted for years, in all cases of intestinal suturing. When the edges of the duct and gall-bladder have been thus coapted, the operation is finished by closure of the abdominal wound *without drainage*.

So far as I have been able to ascertain, however, the attempt at incision of the duct to remove a calculus has not been made, except in Case 5, of my series. Dr. Meredith suggests excision in his recent paper.¹⁰ "Failing of success by any of these methods, (of removing a calculus within the duct) its removal by excision, followed by careful and accurate suture of the duct might possibly be performed with success."

One of the serious, and I am constrained to believe not seldom, dangers, resulting from biliary calculi, while yet retained in the gall-bladder, results from reflexive irritation as evinced by nausea and vomiting. It is now some years since the first case of this type came under my observation, the sufferer being a physician of exceptional wisdom. His diagnosis was perfectly correct, which he desired me to ascertain in the event of his death. The calculus which I here present was free in the gall-bladder, without obstruction of the biliary, or common duct. The immediate cause of death was from hæmorrhage into the stomach, produced by continuous retching.

Some years later, a similar case came under my observation, where the diagnosis was equally clearly determined, and demonstrated by an autopsy, and where operative measures were not favorably considered by the patient and family, as well as by the consulting physician.

In cases where the common duct is permanently occluded from inflammatory or other changes, the cystic duct remaining open and the gall bladder not especially disorganized or adherent, it remains for consideration, if a permanent fistulous opening may not be effected between it and the duodenum. In a considerable number of cases on record nature has pointed out the possibility of this method by allowing to escape, through such a fistulous tract, calculi from the gall-bladder into the intestine. In a most interesting case un-

der my observation a few years since, I urged the opening of a distended gall-bladder, since the patient was dying of extreme cholemia. The post-mortem examination showed a non-malignant, inflammatory, complete closure of the common duct.

Winiwater successfully established a communication between the gall-bladder and the transverse colon. However, in this situation, the physiological effects of the biliary secretion are lost. Dr. Gaston,¹¹ of Atlanta, Ga., reports a series of experiments upon dogs where he established a permanent communication between the duodenum and the gall bladder. Winiwater advocates a modification of his operation, by selecting some portion of the small intestine which can be brought most conveniently into apposition with the gall-bladder, since the duodenum is not sufficiently movable to be adjusted.

These are sutured by the peritoneal surfaces only, and after five or six days adhesions should have been formed sufficiently strong to admit of a permanent opening being made. Although such an operation, as far as I know, has not been attempted upon the human subject, conditions may arise in which it should be taken into serious consideration.

The technique of the operation in cholecystotomy is comparatively simple. Incision may be in varying direction. Mr. Tait advocates the division parallel to the median line, just external to the rectus muscle. In my own cases, the parietal incision has been made parallel to the ribs. After having opened the abdominal cavity, the gall-bladder is examined by the finger. If the tumor is very large, its contents may at once be evacuated with an ordinary trocar. Oftentimes the walls of the greatly distended gall bladder are very thin. In such instances it may be wise to make use of a small aspirating needle, instead of the trocar. The puncture should be made in the most dependant portion of the tumor. The abdominal cavity must be carefully protected by aseptic sponges to prevent the escape of any of the fluid into it. It may be a wise precaution, which I adopted in Cases 3 and 5, to unite the edges of the peritoneum to the gall-bladder carefully, by a running suture, prior to opening it. If the tumor is not very large, and the emptying of its contents with drainage is all that is required, suturing in this manner before opening is to be generally advised. It is easier effected with the gall-bladder tense, and gives more accurate coaptation than can be secured by uniting the gall-bladder when flaccid and empty.

The incision is now made into the gall-bladder sufficiently large to admit the finger and an examination of the contents is carefully made. Calculi may be removed by forceps, or scoop, care being exercised not to injure the delicate struc-

¹⁰ Lancet, April 19, 1890.

¹¹ Atlanta Med. and Surg. Journal, September and October, 1882.

tures. If a stone is impacted in the neck of the gall-bladder, or the cystic duct, its removal will be attended with exceptional difficulty. The right fore-finger within the abdominal cavity may aid in its dislodgment, assisted by gentle procedure of operative measures, from within the duct. This failing, crushing by forceps carefully padded, or protected by rubber may be attempted. After crushing, the fragments should be removed through the wound if possible. If crushing proves impracticable, division of the parts, until the stone is reached, should be made, followed by closure, as already described.

If, as may be found expedient in a great majority of cases, a fistulous opening is determined upon, a soft rubber drainage-tube should be inserted, and the wound dressed with absorbent material. I have used with advantage a soft-rubber double drainage-tube, inserted into a diaphragm about the size of a half dollar. These have been especially made for me in one piece.

If the common duct is patent, the fistula will voluntarily close in a few weeks. It has been used, as an argument in favor of suturing and drainage, that adhesions are formed which would render easy the division, in the line of the old cicatrix, in case of subsequent obstruction, a contingency worthy of consideration.

Cholecystotomy may be accepted as an operation already established, worthy of adoption by the surgical profession. Present experience abundantly warrants this conclusion. More brilliant triumphs await its future development, when operative interference will be advised much earlier than at present. The more serious complications which render the operation especially difficult arise from previous inflammatory attacks with their resultant pathological changes.

In the *American Journal of the Medical Sciences*, for October, 1884, Drs. Musser and Keen tabulate all the hitherto recorded cases of cholecystotomy. They number thirty-five, by sixteen different operators, with ten deaths. Three fatal cases from hæmorrhage, one from peritonitis, the remaining cases death probably due to the previous condition of the patient. Since 1884, the histories of about one hundred cases of cholecystotomy, have been published by more than one-third as many different operators. It is safe to predict that the future history of operative measures, for the relief of biliary obstruction, will furnish one of the most brilliant chapters in surgery.

One of the most serious of all the abdominal diseases, as evinced by acute pain, prolonged suffering, and great mortality, confessedly without remedy from medicine, cholecystotomy offers help to the hopeless with an attendant danger in the hands of the experienced surgeon, of as small a percentage as in ovariectomy. By present demonstration, the closure of intestinal wounds by suture, or even resection, is to be preferred

over an artificial anus. If operations upon the gall-bladder are undertaken, at a time when the organ itself is not materially changed, remaining free from adhesions to the surrounding parts, it would seem a safe conclusion that an opening, made into this viscus, should be closed with as great safety and as good reason as in that of the intestinal canal. If attempted, it should be completed with as much care and exactitude as in the latter instance.

It has been clearly shown that an *aseptic animal suture* is not only far safer when properly applied than silk, but that it also possesses the great advantage of causing an abundant proliferation of connective tissue along the tract of the buried suture. It may also be safely applied in repeated layers in order to coapt broad surfaces, in a manner unsafe to attempt with silk. After a considerable period it disappears to be replaced by vitalized tissue. Such a suture, itself *aseptic*, *aseptically* applied, in an *aseptic wound*, furnishes an important aid in dealing safely with wounds of the gall-bladder. There can be no doubt but that its proper use adds another factor of the highest importance in aseptic surgery, adding much to the safety and subsequent resulting good.

We cannot but believe that the animal suture, especially that from the tendon, properly preserved and prepared, furnishes the surgeon with an aid of the highest importance. By means of its use, the tissues in nearly all the varieties of operative wounds, can at once be coapted and retained in position without further disturbance.

COMPARATIVE VALUE OF MERCURY AND THE IODIDES IN TREAT- MENT OF SYPHILIS.

Read in the Section of Dermatology and Syphilology, at the Forty-first Annual Meeting of the American Medical Association, at Nashville, Tenn., May, 1890.

BY JAMES T. JELKS, M.D.,
OF HOT SPRINGS, ARK.

MEMBER OF HOT SPRINGS MEDICAL SOCIETY, STATE MEDICAL SOCIETY OF ARKANSAS, CHICAGO MEDICAL SOCIETY, AMERICAN MEDICAL ASSOCIATION, AND PROFESSOR OF SURGICAL DISEASES OF THE GENITO URINARY ORGANS AND VENEREAL DISEASES COLLEGE OF PHYSICIANS AND SURGEONS OF CHICAGO.

"However long mercury has been employed as an antisymphilitic, general assent has not yet been gained by any doctrine concerning the utility of its administration, the results which it may produce in syphilitic patients, the period at which its administration should be begun and how long it is to be continued." So wrote Zeissl.

Burenspring says that mercury exercises a curative action on all syphilitic lesions and that it rapidly causes disappearance of the symptoms. He also says the further development of the process is not prevented by mercury: that the disease

is simply protracted, and that by reason of this, tertiary forms develop and the disease becomes incurable. He also says: "Tertiary syphilis is not mercurialism, it is always syphilis, but modified; syphilis in a system changed by mercury." He says further, that "whatever treatment is adopted, syphilis is a disease which impairs profoundly the entire organism. Cases of rapid recovery are rare. Gradual extinction of the disease is the rule, and may happen after mercurial as well as non-mercurial treatment. The advantage of mercurial treatment is that it rapidly ameliorates the symptoms of the disease and effects their recovery, but this is more than counterbalanced by a double disadvantage. Inasmuch as it impairs the entire constitution, it favors the development of destructive local forms; making the disease latent, often for months and years, and delays definite recovery. Non-mercurial treatment is often unable to prevent the severe and extensive appearance of the symptoms, particularly at the beginning of the disease, but it offers the great advantage that it never conceals the disease when it is not cured, and accelerates its definitive recovery."

Diday says, "From 1838 to 1860 I systematically dispensed with the use of mercury during the existence of the primary lesion and the first appearance of the secondary symptoms. I used mercury only in exceptional cases, when the nature of the symptoms imperatively demanded it." Finally, since 1860 he has used what is really a mixed treatment. He gives mercury occasionally—where it is needed, and says mercury is unable to destroy the virus of syphilis; and divides his treatment into "opportunistic method" and "regular method." By the former he means an effort to assist nature in her constant fight against the intruder. In experimenting on patients afflicted with syphilis he found that those to whom he gave mercury in the primary stage had the secondary manifestations of the disease in forty-three days, the period of secondary incubation was that long; while those who did not use mercury during this period had the secondary manifestations in forty-nine days. And he says that both classes of patients suffered from relapses in exactly the same manner and the same proportion.

H. Zeissl, believing that mercury did not cure syphilis, divided his hospital patients into three classes—those to whom he gave mercury on the first appearance of the secondary eruptions, those to whom iodine was given and those to whom *nothing* was given. He noted that those patients to whom he gave inunctions of mercury frequently were relieved of the manifestations of the disease in ten to fourteen days. Again, those to whom he gave iodine were relieved in from fourteen days to four to eight weeks; and, lastly, that those patients to whom he gave *nothing* had the

eruptions disappear completely in four weeks in some cases, while in others they lasted several months.

Here we have the natural history of syphilis before us. Indeed, we might have expected as much from the fact that syphilis has been treated successfully by almost all the remedies of the pharmacopœa, and from time to time advocates of sarsaparilla, stillinger, burdock, poke roots, berberis aquafolium, cundurango, manaco, hunger cures, purging cures, water cures, etc., have brought them prominently before the profession. Each would have its day; recently the majority of the profession have about discarded all of them and confined themselves to the two "old reliables," mercury and iodine.

H. Zeissl claimed "that the severe gummy syphilides appeared much earlier after the mercurial treatment than after either the iodine or expectant plan, and that relapses are much more frequent and obstinate after the mercurial treatment than after the expectant plan."

He also says that those patients may be counted as cured who, after the disappearance of the earlier eruptions without treatment, have no relapse within one year; that one year's freedom from syphilitic eruptions after the disappearance of the first secondary manifestations, said disappearance being brought about by the expectant plan of treatment—that those patients have been cured. He further says that it is only when the iodine and expectant methods have failed that mercury should be used. He also says the expectant plan takes longer to cure the symptoms, but that the relapses are less frequent than after the mercurial treatment. That treatment with the iodides is next in efficiency *after* the expectant plan, and that when the symptoms do not yield to either the expectant plan or the iodide treatment, then a small quantity of mercury causes them to rapidly disappear.

Sigmund holds almost the same views, though he has been a most pronounced advocate of mercurial treatment. He says that "science and experience positively favor the view that the proper time for general antisyphilitic treatment is in the second stage of the syphilitic development, and that at this period it should be begun *only* if important organs and systems are involved, or if the nutrition and vigor of the organism suffer seriously. In affections of mild grade and in certain organs, suitable local treatment will suffice even during the second period of the disease." He regards iodine of great value even in the second manifestations of the disease.

E. Finger, of Vienna, agrees with H. Zeissl, and gives iodine in preference to mercury in the condylo-matous stage.

Kaposi says: "The more vigorous and persistent the treatment during the first acute stage, the more certainly relapses and a protracted

course of the disease are prevented." He believes in the vigorous use of inunctions of mercurial ointment.

Fournier advocates the vigorous mercurial course of treatment continuing over a period of one to three years, mercury for a few weeks or months followed by a period of rest on the "expectant plan."

M. Neisser follows Fournier's plan of treatment and says "the treatment should be chronic." He gives one "main cure," as he calls it, by inunctions, and follows it by internal administration of some of the milder forms of mercury. His "main cure" is repeated once a year for three years, but he also "attributes unusually severe symptoms to an excessive use of mercury."

Caspary says "the use of mercury is not a matter of indifference;" advises its use during the stage of eruption, but does not advocate its administration during the period of quiescence. He also says, "Vigorous treatment after the manner of Fournier, in the early stages of the disease, delays relapses—but that the relapses are very apt to be severe."

Unna is opposed to the protracted use of mercury in syphilis, and lays all the late manifestations of the disease to unoxidized mercury in the tissues. He also says that some cases of cerebral syphilis in which the patients have difficulty in walking, seem to get worse under administrations of mercury.

Rumpt says, "There are isolated cases of cerebral syphilis in which mercury seems to exert an injurious influence. In a few cases of cerebral syphilis with mild delirium, use of mercury was followed by coma which yielded to the use of iodides" This I can corroborate from personal experience this last year. A medical man consulted me for what was evidently cerebral syphilis. Under mercurial inunctions his cerebral symptoms got worse, and improved when the mercury was stopped and iodine given.

A gentleman from Texas also came to me with cerebral syphilis. Had had an attack of cerebral apoplexy due to syphilitic disease of the arteries. Under use of mercury he got worse, and I was compelled to stop its use and place him on the iodides alone.

M. Zeissl reports several cases in which he had used vigorous mercurial inunctions, and in which severe relapses of syphilis follow; so that now he does not give mercury until he has failed after a ten weeks' trial with iodine, commencing the administration of the iodides only after the secondary eruptions have existed for six to eight weeks. Then, if the iodides fail him, he resorts to mercury, agreeing with the opinion of H. Zeissl, "that it is not the mercury that hurts the patient, but mercury given at improper times." He says that now he continues the iodine course for six months, or at most a year, after the syphilis

has disappeared. If relapses occur he again resorts to the iodides—and if the symptoms disappear very slowly, or not at all, then he uses mercury.

In contrast with this opinion of M. Zeissl and others, Otis advises the commencement of mercury as soon as the chancre indurates, and urges its protracted and vigorous use. He reports some cases in which the use of the drug was not pushed as vigorously or as early as he thought it ought to have been, where grave tertiary lesions resulted.

Van Buren and Keyes advise the use of mercurial treatment as soon as the diagnosis is made, and urge this as the safest plan for the patient, increasing the mercurial up to point of tolerance then dividing the dose in half, and continuing the smaller dose for a period of one year or more.

My own plan has been to give mercury when the secondary manifestations of the disease appear, and to continue it after the eruption has disappeared for a period of six months, then the so-called mixed treatment for six months, and follow this by a six or twelve months' course of iodides alone. But the longer I live and the more I see of syphilis, the more I am inclined to give iodides, giving mercury when the iodides fail to relieve the case. In all the later manifestations of the disease I use only the iodides.

So we have here syphilographers divided into two groups: one favoring and urging the administration of mercury as soon as a diagnosis is made, and continuing the use of that remedy for long periods of time; the other giving it only when the manifestations of the disease do not yield to the iodides—and then giving it only until the disappearance of the eruptions. The one group laying many of the grave lesions of the later period of syphilis to the fact that mercury was improperly given, both as to time and quantity—the other claiming that these appearances of the disease were due to the fact that not enough mercury was given, or that it was not given in sufficient quantity or not protracted over a sufficiently long period of time.

My own opinion is that they are supplementary one to the other. As I have said before, some of the graver lesions of syphilis seem to get worse under the administration of mercury, and yield rapidly to the iodides. Of course, all of us have seen patients who could not bear the mercurial treatment. Again, there are others in whom the mildest iodine course is followed by very grave symptoms.

In using mercury for syphilis I prefer the ung. hyd. I have found in a very large experience that it produces its effects very promptly, and that it is less liable to disagree with the digestive apparatus than any of the salts of mercury administered internally. In ordering the mercurial I use 1 drachm of the 50 per cent. hyd. ung. rubbed into the skin every night, of course carefully

watching its effects, for on the slightest evidence of salivation it must be lowered in quantity or discontinued altogether; occasionally I find a patient who is very greatly depressed by this quantity. In that case I lessen the dose by half and continue it until the manifestations of the disease have disappeared. Of course this is an inconvenient mode of administration of the remedy, in persons whose occupations take them from home a great deal of the time, and who have not the facilities for warm baths. For this class of patients I order the protoiodide of mercury in $\frac{1}{4}$ gr. doses, and prefer the gelatine coated pills to those which are sugar coated. In giving the iodides for syphilis one thing is important to bear in mind, and that is, that the dose of 3 to 10 grs. is all a mistake. I commence its administration with 15 grs. and increase it 1 gr. a day until the manifestation which called for it has disappeared, and occasionally I have carried the dose up to 1,000 grs. a day.

Practically speaking, the point I wish to impress upon this body is, that there is no limit to the dose of the iodide save that which is indicated by its effects.

One of the most convenient modes of administering it is in the form of saturated solution: here 1 minim represents 1 gr. of the salt. Of course this should be largely diluted with water before it is given. For the grave forms of nervous syphilis I never give the smaller dose, but at once commence its administration in 50 gr. doses, and have had no reason to regret such a course. The same plan is pursued when a gummy deposit exists in the pharynx and nasal or post-nasal cavity. In both these classes of cases we desire to produce a rapid absorption of the gummy deposit, and so prevent its breaking down, thus protecting the patient from the horrors of such softening.

MEDICAL PROGRESS.

GENERAL SHRINKING OF THE AORTA A CAUSE OF HEART DISEASE.—Under the above title DR. A. SCHABERT (*St. Petersburg Med. Wochenschr.*) describes a case and gives an extensive *résumé* of the literature of the subject. He refers to the old case reported by Joh. Fr. Meckel in 1750. The patient, a girl 18 years of age, had complained from early life of palpitation, with anxiety and severe pain—like angina pectoris. *Sectio cadaveris* showed an enormously enlarged heart that nearly filled the left half of the thorax, a

very small aorta with a diameter less than one-half that of the pulmonary artery. This interesting specimen is still to be seen in the museum in Halle. In 1765 Morgagni described several similar cases, also Andral (1836), Bouilland (1837), and King (1840).

Insufficiency of the aorta generally presents the clinical picture of dilatation of the heart, that cannot be referred to other causes; it affects young persons and causes death with symptoms of asphyxia. A later condition is that of hypertrophy, and when this has reached a degree that will overcome the increased resistance presented by the aorta, then the patient may be comfortable for a time. A third group of these cases belong to those in which the mitral valve is involved as a secondary condition. From a diagnostic point of view the case of Riegel is exceedingly interesting. The patient, a man 29 years of age, complained for years of palpitation, which later ceased. He was always employed at severe manual labor, had never had rheumatism. Later dyspnoea increased and dropsy presented itself. Presented on examination the following conditions: Medium sized man, well-nourished, with marked dyspnoea (36 to 40 per minute). Dilatation of the heart, to the left of the nipple, and to the right past the sternal border. Dulness in the second intercostal space, in which a systolic murmur could be heard, that is loudest just over the pulmonary valves, and is conducted along the vertebræ. Small and hard pulse, the right constantly smaller than the left. Liver enlarged. Œdema of the lower extremities. Urine high-colored, but free from albumen. Left recurrent laryngeal nerve paralyzed, left vocal cord in "cadaver position." Lung infarct.

The dulness, and systolic murmur in the second intercostal space, enlargement of the heart, recurrent paralysis, and difference in the radial pulse, led to the diagnosis of aneurism of the aorta. The post-mortem examination revealed a very different condition. The aorta was found to be greatly contracted, and the physical signs were due to the following conditions: The dulness was not caused by the aorta, but by dilatation of the right auricle. The systolic murmur was caused by pressure of the pulmonary artery upon the aorta. Recurrent paralysis was caused by pressure of the enlarged pulmonary artery upon the nerve. Unevenness of the pulse was simply an accidental condition.

The author's patient presented nearly similar symptoms. Six days before coming to the hospital complained of severe pain in the left breast, anxiety, hurried breathing, increased area of heart dulness that extended as high as the second intercostal space to the right border of the sternum. A few days' residence in the hospital improved the patient so much that he insisted upon returning to his home. About three months later he

presented himself with an increased area of heart dulness, and an apex systolic murmur. The liver was enlarged, extending two and one-half finger widths below the umbilicus, the pulse became irregular, and after about one month the patient died and was sent to the autopsy room with a diagnosis of pericarditis and mitral insufficiency. Post-mortem examination revealed an enlarged heart and a very small aorta, the latter presenting just above the valves a circumference of only 4.3 cm. Considerable serum was found in the pleural, peritoneal and pericardial sacs. "Nutmeg" liver and congested spleen.

The writer attributes the fatal issue in this case to the advent of the pericarditis, that seriously impaired the nutrition of the heart muscle.

DIAGNOSIS OF ABSCESS OF THE LIVER.—PROF. P. K. PEL, of Amsterdam (*Berlin. Klin. Wochenschr.*) closes a brief article on the above subject with the following sentences: The objective symptoms of this condition are chronic hectic fever; enlargement of the affected organ is a constant sign, which is generally characteristic in that the right lobe enlarges upward. The line of liver dulness is dislocated upward, and instead of being horizontal is curved, with the convexity upward. The line of dulness does not change, as in normal conditions, by deep inspiration, or by lying upon the left side.

Subjective symptoms are pain in the hepatic region, which radiates backward, psychical depression, anorexia and sleeplessness.

Etiological considerations have an important bearing upon diagnosis, such as, tropical dysentery, residence in the tropics, gall-stones, inflammations in the territory of the portal veins, abdominal typhus, echinococcus, trauma, etc. It is, however, to be remembered that in many extra-tropical cases the etiology is very obscure.

The author closes with the statement that there are abscesses of small size centrally located, that do not present a distinct clinical picture, and in which an absolute diagnosis is impossible.

TREATMENT OF FACIAL ERYSIPELAS.—By DR. LEHNRECHER (*Munch. Med. Wochenschrift*, September 16, 1890).—Our ideas about erysipelas have been altered by recent bacteriological study and the discovery of the streptococcus erysipelatis. Formerly surgical erysipelas was separated from the spontaneous exanthematous erysipelas. In 1889 Trousseau definitely stated that both forms had a local starting-point; and previously, in 1849, Zuccarini showed, as Gerhardt had pointed out, that in fatal cases of typhoid, complicated by exanthematous erysipelas, purulent collections and degradation products were present in the cavities about the face, and that the so-called exanthematous erysipelas was due to decomposition products resulting from suppuration

and ulcers being taken up into the tissues and lymph vessels.

Out of eighty cases occurring in three years, seventy-four had facial erysipelas and forty-seven of these had some chronic inflammation about the nasal mucous membranes, or cracks, crusts, and ulcers there. Zulzer, in a recent monograph, in which treatment is exhaustively stated, does not lay any special stress on the treatment of the nose.

It is well known how numerous are the local remedies which are supposed to limit the disease, yet it is admitted that none of them attain their object. Neumann and Gerber paid more attention to the starting point of erysipelas, and Kaposi most of all. He says the nasal cavities must be inspected, pustules opened, and crusts removed, by tampons of oil.

It appears to the author of every importance that in cases of erysipelas starting from the nose gentle irrigation should be used with a 3 per cent. solution of boracic acid. It is astonishing what masses, etc., may be removed in this way. Collection of pus, etc., in the nose are easily explained, when one remembers the large space there is, filled with crevices, and also the cavities which communicate with the nose. These are often affected with catarrh extending over long periods. The air drawn into them dries the secretion and sets up decomposition in virtue of the microbes with which it is laden.

When the nasal cavities have been cleaned by the irrigation, tampons of boracic ointment made up with vaseline may be applied. With the removal of the exciting cause, the local treatment of erysipelas may be limited to the covering up of the inflamed surface with wool or oil compresses.

TROPIC DISTURBANCES.—M. MORVAN always contested the view that the malady which bears his name was identical with syringomyelia, but abundant clinical observations have demonstrated that the two conditions are closely allied. He based the distinction upon a study of the sensibility; in the *maladie de morvan*, tactile sensibility is affected at the same time as that of pain and temperature. The authors who admit with Roth the identity of Morvan's disease and syringomyelia, maintain that in the former sensory troubles are usually not marked or absent, while in syringomyelia they are never absent. Thus far the clinical observations nor the post-mortem examination of Gombault and Reboul have not settled the question of the medullary changes in these diseases, therefore the following observation of Joffroy and Achard (*Arch. de Med. Exper. Annales de Der. et de Syphil.*) fill an important lacuna in the pathology of these affections.

A woman seventy-five years of age, had before the age of thirty an affection of all the fingers with the exception of the right thumb and the

little finger of the left hand, that persisted for two months, but disappeared after the elimination of some osseous fragments, leaving the characteristic deformity. The integument was not thickened. Tactile and temperature sense diminished on both palmar and dorsal surfaces, as well as on the lower two-thirds of the forearm. Muscular atrophy pronounced, but no signs of kyphosis or scoliosis. Autopsy revealed the spinal cord greatly diminished in volume, with irregular cavities, distributed through the cervical region, especially affecting the anterior and posterior grey cornua. Sclerosis of the posterior columns reaching the medulla. In the dorsal region round nodular masses of neuroglia centrally situated, displacing the central canal. Diffuse sclerosis in the white substance. Some changes were noted in the peripheral nerves of the upper extremities, and at some points atrophy of the fibres with Wallerian degeneration.

In the above case we find associated the peculiar symptom complex of Morvan with the anatomical changes peculiar to syringomyelia. It is, however, to be remembered that the symptoms of central nerve lesions are determined more by their location than by the peculiar pathological changes in the tissues.

THIOL IN SKIN DISEASES.—In April of the current year PROF. SCHWIMMER (*Therap. Mon. Hefte*) published his results in treating skin affections with the patented thiol. The drug was used in watery solution, one part to three, or in the form of salve, one part to ten. The writer especially recommended the drug in dermatitis herpetiformis, less warmly in acne vulgaris and acne rosacea, as well as eczema. Thiol in general has a similar action to that of ichthyol, and its therapeutic indications are much the same. It presents some advantage over the former in that the skin and linen are not stained so freely.

Schwimmer, in a recent number of the *Wien. Med. Wochenschr.*, affirms his earlier experience with the drug, and claims that it is especially indicated in those cases where a drying and astringent effect is desired.

TREATMENT OF DIABETES.—At the Congress of Berlin DR. DUJARDIN-BEAUMETZ read a paper on the treatment of diabetes which presents some points not altogether new, but which are apt to escape notice unless recalled to our attention: Prognosis in the disease can only be founded, he considers, on the results of rigid dieting; that is, it is not the relative weight of the sugar excreted in twenty-four hours which makes a case the graver or the more hopeful, but the less or greater diminution which the prescribed regimen can effect. As for the question of its curability, that can only be answered with the utmost reserve. There are cases wherein the sugar has absolutely

disappeared under its total exclusion from the food of the patient, but in which the tendency to excrete it is as great as ever.

It is interesting to see what enormous quantities of sugar can be given to healthy people without a trace appearing in the urine; and, on the other hand, to know that we cannot increase the amount excreted by a diabetic beyond the point naturally reached under an unrestricted diet. The exclusion of sugar and saccharogens from the food, all the world knows, is the main point in treatment, but the difficulty is to do it and yet not render existence too intolerable to the patient; and bread seems to be, in an inverted sense, *la pièce de résistance*, the *crux* in diabetic bromatologia. There are various more or less unsatisfactory substitutes, gluten bread and gluten bread, some with so much starch in it that the gluten is a vanishing point. There are almond-meal cakes, proposed by Seegen (or Pavy?) and sorgum bread, but the former is so nice that one soon gets tired of it, and the latter is so disagreeable that few care to commence with it. Then, there is *fromentina* and *legumina*, made from the embryos of wheat and beans—they say—there is little starch, much albumen therein.

But all have the same defect; like bran itself, which is sometimes used, they are but chaff and draff, at a monstrous price and the minimum of satisfaction if really what they profess to be, and just as starchy as bread itself, we may be quite sure, if diabetics like them. Dr. Dujardin-Beaumont was the first to suggest, "then give starch, but as little as possible." Let the daily allowance be a single potato weighing about a quarter of a pound, well boiled, and eaten with plenty of butter. Else order the crust of bread: there is somewhat more starch in it than in an equal weight of the crust, but then, one cannot eat so much of it, and the bad and tender teeth of diabetics make even that little go a very long way.

Again, they must not be allowed to eat any fruit; its glucose is the very form of sugar we wish to avoid. Then their beverages: for they are necessarily thirsty souls. Unless there be coexistent albuminuria—when we must choose the least of two evils—give no milk, it always augments the sugar. Of alcohol they can take extraordinary quantities without getting tipsy, because so much of it is at once swept out by the kidneys, but not without damage to those important organs. Therefore, proscribe spirits, liqueurs and strong wines altogether, and only permit weak wine-and-water. Light beer may be given, no stout nor porter, and extract of malt is, of course, forbidden.

Tea, coffee, cocoa, maté and kola are not only valuable as affording unobjectionable beverages, but they give the nerve stimulus diabetics so often need; and since the discovery of saccharine they can be made safely palatable, also, without

the use of glycerine, which often did harm by irritating the bowels. Another point is gymnastics. When the disease was looked upon as an exaggeration of the functions of organic life, complete repose seemed called for; but this is surely a mistake, and, short of fatigue, the patient should have abundant exercise. Nor should hydropathy be neglected; it is often of the greatest value, and holds a place between dieting and medication. As for the action of alkaline mineral waters, it is probably not so much upon the liver as in the general nutrition of the body that they are beneficially exhibited; and when combined with arsenic, as Martineau suggested, and with the addition of lithia, we have probably the best treatment yet known to us. Direct the patient to take before each meal—

Carbonate of lithia, 5 grs.

Fowler's solution, 2 drops.

in a glass of effervescing alkaline water.

But pharmacy has recently done more than this for us: the discovery of bodies which act electively upon the axis of the spinal cord, as quinine and bromide of potassium do, are of great value in diabetes, but above all antipyrin, which affects the thermogenic centres. The author has shown that this latter remedy diminishes both the polyuria and the percentage of sugar. In *diabetes insipidus* it acts extremely well, only one must take care not to confound the excessive passage of watery urine, due to renal insufficiency, with this disease. And in interstitial nephritis antipyrin only does harm. In suitable cases the dose is $\frac{1}{2}$ to 1 drachm a day. And we must not keep up the rigor of the treatment too long; human nature is weak, and monotony itself weakens the constitution; after a time give a larger potato, a slice of bread, a lump of sugar as a relaxation.—*Provincial Med. Journal*.

STARVATION AND LIABILITY TO INFECTIOUS DISEASE.—CANALIS and MORPURGO (*Oesterr-ungar, Centralbl. f. d. Med. Wissenschaften*, No. 27, October, 1890) have recently made observations on this subject. Their experiments were made with the anthrax bacillus, the animals chosen being those most resistant to this disease, namely, pigeons, hens, and rats. Most observers have regarded pigeons as very sensitive to the anthrax poison. Canalis and Morpurgo find, on the contrary, that they show great resistance, for, out of 12 pigeons inoculated with anthrax only 2 died, one on the fourth and the other on the seventh day after inoculation. They sum up their results as follows: 1. Animals previously immune can be rendered sensitive to infectious disease by withholding food for a period. 2. In the case of pigeons, immunity against anthrax is completely lost if from the time of inoculation all food is withheld. 3. On the other hand, pigeons starved for six days before inoculation can be rendered

immune against anthrax if again fed subsequent to inoculation. 4. This is not the case if subsequent to inoculation they are starved for a further period of two days before they are again fed. The disease in this case, however, runs a longer course. 5. Well-nourished pigeons inoculated with anthrax virus take the disease, if even eight days later food is entirely withheld. 6. This would seem to indicate that the anthrax bacillus is capable of maintaining its vitality for at least several days after subcutaneous injection, and then producing this disease. 7. This increased sensitiveness towards anthrax, as the result of starvation, cannot be ascribed to the fall in the temperature which ensues, since a similar fall of temperature artificially produced in well-nourished pigeons does not deprive them of the immunity they previously possessed. 8. Hens also can, to a certain extent, be rendered sensitive to anthrax by starvation. 9. The great majority of them succumb to the disease if previously to inoculation they have been starved from three to seven days. 10. Rats—at least, the white variety used by Canalis and Morpurgo—retained their immunity against the disease, even if starved for a long period.—*Brit. Med. Journal*.

CAMPHORATED SALOL IN MIDDLE EAR SUPPURATION.—Numerous non irritating antiseptics have been lauded of late in the treatment of middle ear suppurations. Peroxide of hydrogen and boric acid have stood at the head. CUVILLIER (*Revue de Laryngologie*) has taken advantage of the power which camphor possesses of forming a liquid when brought in contact with certain substances belonging to the phenol group, to give us a new antiseptic, which he says is unirritating—certainly a *sine qua non* in the treatment of middle ear disease. He uses the following method: The meatus is carefully cleansed with a 5 per cent. solution of boric acid, and a small wool tampon saturated with camphorated salol is carried into the canal and an external antiseptic dressing applied. This should not be allowed to remain more than twenty-four hours.

NUMBER OF NERVE FIBRES IN THE OCULOMOTOR NERVE OF THE NEWBORN AND ADULT.—SCHILLER (*Comp. Rend. d. Sci. Medical*) has recently made some observations upon the number of nerve fibres found in a cross section of the oculo-motor nerve in a newborn cat and those of an adult. The research was undertaken with a view of ascertaining if an increase took place in the number of cellular elements as age and growth advanced. The results showed that the number of fibres remained about the same, the apparent increase in the size of the nerve trunk being due to an hypertrophy of the individual elements. In adults the nerve fibre is from three to six times the size which it has in the newborn.

MARRIAGE AS A REMEDY.

An old man, who had been an eminent physician and teacher, remarked that no act of his life gave him more regret, than his counsel to a wealthy, dissolute inebriate to marry. The result of that marriage was nine children. One was an epileptic, one was insane, two more feeble minded, hysterical, and very irregular persons. Two drank to excess, one of whom was a petty criminal. Three other children of this family died in infancy. Of the three grandchildren not one seemed to have average vigor or mental capacity. He remarked that the misery and suffering which came from this error of counsel, would at last end in the final extinction of the family.

In another instance an equally able physician, after years of unsuccessful treatment of a feeble minded, unstable, hysterical young woman, advised marriage. Insanity, inebriety and epilepsy were pronounced family diseases in her ancestors. Her marriage with a neurotic man resulted in six children, two of them dying in infancy, one is in the reform school, a thief and alcoholic; the fourth was married to a low Italian at fifteen, and is an impulsive strange woman; the fifth became insane at fifteen and suicidal; the last and youngest, has fits or periods of unconsciousness from any strain or excitement. These are not phenomenal cases, and are not uncommon in every community. They are presented to bring out the fact, of the exceeding danger of thoughtless counsel to marry, to neurotics and persons who are markedly degenerate, and have strong hereditary taints.

In a recent lecture by DR. STRAHAN, before the Medico psychological Association of England, "On the Propagation of Insanity and Allied Neuroses," he urges that one of the most prominent causes of the increase of insanity and nervous diseases comes from marriage. He mentions the great difficulty in ascertaining the facts, because of the tendency to conceal family history in all cases; yet notwithstanding all the falsehoods of relatives the English Lunacy Commissioners were able to trace 25 per cent. of all the insane to this cause. From 25 to 90 per cent. of all insane are said to come from heredity. These are the two extreme figures, of eminent authorities who have examined this subject. Beyond all questions of possible dispute, numerous and well sustained facts, show the hereditary transmission of disease and diseased tendencies, and the degeneration which comes from marriage of defective ancestors. Nothing can be more serious and reprehensible, than medical advice to marry, or consent to the union of defectives, the results of which there can be no question. The unstable neurotic man or woman, the inebriate, the eccentric, the evident weak and degenerate, rarely ever in any possible way become stronger by marriage. The danger of propagation of all their defects and diseases is so pronounced, and certain, that the experiment is hazardous in the extreme.

Our present knowledge of the causes of nervous disease, sustain this statement fully. There is no restriction of marriage to-day except in the pronounced idiotic and raving maniac. No one is so diseased or deformed, or crippled, or defective in mind or morals, but may marry and become a parent of degenerate, helpless children, as far as the law is concerned. While this is a sad reflection on the intelligence and civilization of to-day, it reveals a field of reform which medical men of all others should occupy at once. All medical writers are unanimous in condemning marriages between defective and disordered persons, and yet public sentiment would not sustain to-day any special laws of restriction. Obviously this is one of the great fields of prevention of disease, that both medical men and legislators will occupy in the near future.

To day all advance in this direction comes from those who breed animals for various purposes. Here a knowledge and application of a vast range of facts produce certain anticipated results, which

could be obtained with the human family with equal certainty. The duty of medical men, irrespective of all public opinion is to teach the doctrine of heredity, not of any special form of disease, but the transmission of defects, and of lowered vitality, and particular tendencies or taints, that cripple and disable the coming generation. To teach the laws of propagation, and thus prevent disease at the beginning, and cut short the terrible process of nature that hurries the victim down the road of misery and sorrow, to final extinction.

Never counsel marriage as a remedy or means of relief for neurotics or persons of defective heredity. Elevate and dignify marriage as a means to raise the race in every way from its childhood age. Although *Utopia* is far away, there are evident signs of progress towards it, and when marriage becomes a subject of strict legislation, a long stride forward will be taken.

MAKE HASTE SLOWLY.

It is not singular that when a remedy for tuberculosis is announced, the medical profession of the entire world should endeavor at once to verify its claim and pass judgment upon its merit. As soon as it was known that there was a possibility of demonstrating the truth or falsity of DR. KOCH's claim thousands of men, representing almost every prominent medical centre upon the two continents, have gone with utmost haste to Berlin, with the two-fold purpose of securing the newly discovered remedy, and of gaining the necessary instruction as to the method of its administration.

Not only so, but the victims of consumption are thronging the streets of that city by thousands, and the faith of the laity was hardly ever so committed to any medical discovery as they are to this. In the onset of this intense excitement it is needful that our medical men shall pursue a conservative course. It is not needful that they shall be skeptical, nor that they shall prejudge the facts. Nay, it is the glory of conservatism that it holds its way in its progressive course fully abreast all well attested facts, but it is also to its credit that it goes no farther. If a remedy for this dreaded scourge of the human race shall have been found, we cannot possibly be too prompt in the use of all legitimate methods for

its application. But it were a cruelty beyond expression to raise the expectation of mankind to such a pitch as this announcement has done, and then to doom it to disappointment. The character and standing, at home and abroad, of the men who have this remedy in hand, forbid for a moment the thought that they would practice upon the credulity of men for mercenary ends. They are surely honest in their convictions. But is it not possible that the untold value of such a discovery may have led to the indulgence of over-sanguine expectations and to an over-statement of practical results. The danger is that the ardent desire to give to mankind such a priceless boon, will lead to expressions more radical than can be realized. Time must be an element in the decision of this question. It is surely the part of wisdom that evidence shall precede judgment, and it is due to our suffering patients, the victims of consumption, that our promises of cure shall be only such as they may surely realize.

KOCH AND HIS CRITICS.

In general the attitude of the medical press has been fair and judicial, with a full disposition to accord to DR. KOCH, his own time and pleasure as to the manner he shall make his discoveries known. We notice now and then a spirit of carping criticism in these particulars and a disposition to belabor the eminent investigator for not immediately unbosoming himself. It would seem that any one who had devoted eight years to the solution of a problem of the utmost importance to science and humanity ought, at least, to be accorded the meagre privilege of dictating the manner of its publication. Dr. Koch has shown no disposition to profit directly by his discoveries, and it would seem that if he withholds it for a time it is probably for a good reason, and with his simple statement the profession ought for the present to be satisfied.

It is apparent on a careful reading of his original paper, that it is not a remedy that can be used indiscriminately in every case of tuberculosis. For he distinctly delimits its curative effect to the earliest stages of phthisis and to certain local affections, warning the profession that all medical and surgical means are to be used in combatting the disease. The tone of his paper is eminently fair and free from special

pleading. It is to be regretted that the great bacteriologist could not quietly pursue his investigations, and place them completed and symmetrical before the profession.

Another class, followers of the new school in pathology, who refer many diseased processes to parasitic germs; it is amusing to see how gingerly they have approached the new light and how carefully they have refrained from committing themselves. Stoutly affirming, as they have for years, that each germ and ptomaine must have its living or chemical antidote, when the demonstration was offered they drew back. When the great high priest of the microorganisms brought forth the glad tidings, they stood like doubting Thomas, afraid to believe.

THE NATURE OF KOCH'S "REMEDY."

While it is perhaps idle, we cannot refrain from speculating a little as to the nature of the substance used by Koch. When his paper was read before the Congress it was supposed that it was in the nature of a minimized virus, a kind of inoculation like that of PASTEUR. This idea came from confounding the researches of GOUCHER and MARTIN who published their papers shortly after his. A careful reading of KOCH'S communication would at once dispel this, as he speaks of it as a remedy or substance, in much the same terms as one would speak of a drug. Since the second paper, some salt of gold has been thought to be the curative agent. We doubt, however, if it belongs to any of these classes, as no known chemical substance or drug will produce the stormy febrile movement, with the exception of those that are formed as a result of bacterial growth. It will be remembered that we referred editorially, some weeks ago, to a substance obtained from beer yeast that produced a quick, sharp, febrile movement, (the malaise, pains, etc., caused by Koch's injections are but post-febrile phenomena). Another substance termed "tox albumen" has been obtained by the cultivation of the Klebs-Löffler bacillus. Not only are these products raised by the nature of the bacillus but also by the soil in which they grow and other conditions. We venture the prediction that the "remedy" belongs to those substances produced by the action of bacterial growth.

EDITORIAL NOTES.

A VEGETARIAN'S RECONTANTION.—The *Medical Record* has a note concerning a certain Dr. Alanus, formerly a leader among the vegetarians of Germany, who has felt constrained to return to a meat-diet. The occasion of this change of mind was in the fact that he found his arteries were becoming atheromatous while he was yet under 40 years of age. At first he knew not how to account for this premature degeneration, since he had at no time been a drinking man, but having one day taken up one of Ernest Monin's semiological essays showing that an abstinence from meat-diet tended to produce atheromatous changes in the blood-vessels, his eyes were opened. He therefore abandoned an exclusively vegetable dietary, at the same time lamenting that a single brutal fact could so completely upset a vast and beautiful theoretical structure.

PAINLESS GOUT.—Mr. Jonathan Hutchinson has published in a late number of his *Archives of Surgery* some of his interesting experiences in rheumatism and gout. Pain is a symptom that is not essential to gouty inflammation. When gout affects the cutaneous and cellular tissues chiefly, it may very well happen that there is little or no pain. In many cases of even acute gouty inflammation, redness and swelling may be present while pain is almost wholly wanting. In such cases the diagnosis of erysipelas might very likely be made; for as Mr. Hutchinson says he has seen, in some instances, the œdema spread up the limb, and this suggestion as to diagnosis would appear to obtain an item of important corroboration.

THE INSULAR TREATMENT OF DIPSOMANIA.—Dr. Karl Kahlbaum presented before the Berlin Medical Congress considerations to show that this question has become a subject of international importance. He spoke of the painful position of the psychiatrist who is asked to advise in cases of chronic alcoholism. In his view, many of these patients were diseased before they became inebriates, or they presently became diseased in consequence of the drink. In either case the misery resulting is the same, an overmastering desire for alcohol which cannot be subdued or avoided. The chain of symptoms of alcoholism, such as tremor, paralysis, epilepsy, partial or general mental derangement, is well enough

known, but it is not always considered sufficiently important for a lodgment of the inebriate in some medical institution, which is in reality the only fit place for him. As soon as these morbid phenomena lighten up and disappear the patient is allowed to be discharged as cured, but the strong presumption is that no sooner will he have regained his liberty than he repeats his error. If he were retained longer in hospital there might be more hope of a genuine cure, but most institutions are glad to be rid of him and the patient himself is endowed with little patience with his detention, and his own desire is to leave without much reference to the state of his cure. It is also true that the institutions for inebriates are too limited and at the same time exposed to danger. The plan which seems to offer the most hopeful results would be a general consensus to have an island set apart for these subjects of intemperance. Nothing short of a combination of medical men, with the assistance of some wealthy layman, will overcome the difficult problem where inebriate retreats must be established; this company should undertake the management of the island, under a State authority to prohibit the importation or production of every kind of alcoholic drink. An even wider scheme of organization might follow later under which the inebriate might have his family transported to the island along with him, and in this case it would become necessary to provide the means of employment and livelihood for these people, and agriculture in some of its forms would probably be the least objectionable pursuit at the outset of the undertaking. Such an organized insular colony might also be useful for some cases of morphine addiction, tabagism and other forms of irrational indulgence. Dr. Kahlbaum supports this insular *modus medendi* by the following considerations bearing upon the mechanism of the extravagant thirst for alcohol present in these cases: The presumption of those who look for a physical basis for this desire is founded on the theory that a molecular change takes place in the nervous system which disturbs the equilibrium when the alcoholic derivative is withdrawn after a long continuance of its use. When the unsteady molecular stage has been reached the alcoholic longing is intense and nothing short of total abstinence will conquer it. If the organic impressions have not been too deep or too wide, this molec-

ular condition may soon be restored to its former equipoise by the withdrawal of its cause, but where organic changes have taken place, a much longer time will be necessary for a restitution of tone. Absolute denial of alcohol is the rational mode of treatment for alcoholic habituation, but this must be continued long enough to remove the morbid changes and their consequences.

THE BACTERIAL WORLD.—This is the title of a monthly illustrated magazine for the study of microorganisms and diseases of bacterial and parasitic origin, the first number of which will appear January 1, 1891, under the editorial supervision of Paul Paquin, M.D., Director of the Bacteriological Laboratory, State University, Columbia, Mo.

One of its distinguishing features will be a series of studies in bacteriology which will enable the physician in his home to keep himself abreast of the best methods of investigation, and the successive articles upon hygienic medical and surgical bacteriology will meet an essential want of which every physician is conscious, and which he is anxious to satisfy. Each number will contain from thirty to forty pages, well illustrated, at a cost of \$3 per year. We bespeak for this new journal a liberal patronage.

THE UNIVERSITY MEDICAL MAGAZINE.—This valuable monthly medical journal proposes to add to its already well-filled columns a new and, as we anticipate, an exceedingly valuable department, devoted to Medical Progress. The Sections will be under very able supervision, as follows: That of Medicine will be conducted by Drs. William Pepper and James Tyson; Surgery will be represented by Drs. D. Hayes Agnew and J. William White; Therapeutics will be supervised by Dr. Horatio C. Wood; Gynecology will have the special services of Dr. William Goodell; and Obstetrics that of Dr. Barton Cook Hirst. The policy of the magazine will be to limit itself strictly to the publication of original matter. The editorial supervision, at present so able, and the added labor of those whose names we have enumerated, are an ample guarantee for the production of a journal of a very high order of merit, which shall more and more redound to the credit of American medical literature.

Weiss, of Vienna, says that an early symptom of locomotor ataxia, is inability of the patient to walk backwards, while in other ways the patient may walk with rapidity and certainty.

TOPICS OF THE WEEK.

PROTECTION FROM DIPHTHERIA AND TETANUS BY INOCULATION.

By the courtesy of the *Deutsche Medicinische Wochenschrift* your correspondent has received advanced proofs of an article on the prevention of diphtheria and tetanus in animals, based upon experiments in the Hygienic Institute at Berlin, made by Dr. Bebring, assistant in the institute, and Dr. Katasato, of Tokio. After long experimentation these observers claim to have cured animals suffering from either of these diseases—diphtheria and tetanus—by the inoculation of the serum from the blood of animals already infected. It is claimed by a large number of experimenters, first, that the blood of rabbits protected from tetanus possesses the property of destroying the tetanus poison. Second, that this property is possessed by the non-cellular serum obtained from the blood. Third, that this property is of so constant a nature that it also remains active in the organism of other animals, so that notable therapeutic effects are produced by the transfusion of blood or serum. Fourth, the property of destroying the tetanus virus is absent in the blood of those animals which are not protected against tetanus, and if the tetanus virus is injected into non-protected animals, it can be so demonstrated, even after the death of the animals, in the blood and other fluids of the body.

In the test of the degree of immunity a rabbit previously protected received 10 cc. of a germ containing virulent tetanus bacilli culture, of which five-tenths cc. sufficed to make a normal rabbit yield inevitably to tetanus. The protected rabbit remained entirely healthy. He had not alone secured immunity against infection with living tetanus bacilli, but also against the tetanus virus, as he tolerated twenty times the amount of a poison which suffices to kill, without exception, normal rabbits.

Blood was taken from the carotid artery of this rabbit. From this fluid blood (before coagulation) two-tenths cc. were injected in the abdominal cavity of one mouse; five-tenths in that of another mouse. At the end of twenty-four hours both animals, together with two mice, were injected with virulent tetanus bacilli, and to such an extent that they were attacked by tetanus twenty hours afterward, and died in thirty-six hours. On the other hand, both previously treated mice remained perfectly healthy. The larger amount of blood was allowed to stand until serum had formed abundantly, and of this serum six mice received each an injection of two-tenths cc. into the abdominal cavity. After the infection, which occurred twenty-four hours later, all six animals remained healthy, while the unprotected mice died of tetanus in less than forty-eight hours. Therapeutic results may also be secured by the serum in the following manner: The animals are first infected by inoculation, and then the serum is injected into the abdominal cavity. Experiments with the serum were also made tending to show its great virus-destroying property. Of a ten days' tetanus culture, which had been made free of

germs by filtration, .0005 cc. sufficed to kill a mouse at the end of four to six days, and .0001 cc. to kill in less than two days.

Now, we mixed .0001 cc. of this culture and allowed the serum to act twenty-four hours upon the tetanus virus contained in the culture. Of this mixture, four mice received each 2. cc. up to .033 cc., or more than three hundred times the dose otherwise fatal to mice. Four mice remained permanently healthy, while the unprotected mice died at the end of thirty-six hours from .0001 cc. of the culture. The mice, in all the hitherto-mentioned series of experiments, both those into whose abdominal cavity serum was injected, and those who were injected with a mixture of tetanus virus and serum, have remained permanently protected. They resisted subsequently repeated inoculations with virulent tetanus bacilli. This fact is especially noteworthy because in the innumerable individual experiments no mouse, no rabbit, in fact, no animal hitherto tested, had been found protected, and because the very long continued attempts in the Hygienic Institute to make animals safe against tetanus by the hitherto known methods, have been entirely unsuccessful. The authors claim that they are justified in drawing the conclusion that the above expressed interpretation of the occurrence of immunity which at once, and without any difficulty shows a positively effective, and for the animals, entirely innocuous method of producing immunity, also satisfied the need of preventing its causation. As a matter of course, experiments were also made with the blood and serum of non-immune rabbits. This blood and serum proved therapeutically, as well as prophylactically, to have no influence upon the tetanus virus. This was also true of cow, calf, horse, and sheep serum, as was shown by special experiments. The blood within the vessels of living non-protected animals also possesses no tetanus destroying properties, as appeared from the following experiment, which was repeatedly made:

Animals who received a subcutaneous injection of .5 cc. of a virulent tetanus culture, free from germs, died after five to six days with typical symptoms of tetanus. At the autopsy, in almost every case, a serious transudation is found in the pleural cavity. Of this transudation .3 cc. on the average, suffices to produce tetanus in a mouse, and to kill the animal, and in the same dose the blood of a tetanus-poisoned animal again produces tetanus in mice. In conclusion, the authors express a hope that the principles demonstrated in these experiments may in time be applied to the treatment of diphtheria and tetanus in man.—Berlin Correspondent, *Medical Record*.

THE INFLUENCE OF ELECTRICITY UPON THE LOWER FORMS OF LIFE.

Slight electric shocks from a coil (induced current), increase the rapidity of the protoplasmic movements; stronger ones cause tetanic contraction, and numerous and powerful ones produce coagulation. "A constant current causes contraction and imperfect tetanus; and if powerful and long kept up, the positive pole produces in the *Amœbæ* near it the same changes as dilute hydrochloric

acid, and the negative pole the same changes as are produced by an alkali such as potash." Upon Infusoria, weak electric currents first quicken the ciliary motion and cause movement of rotation, then swelling of the protoplasm, slower movements and finally apparent solution of the protoplasm. Moderate currents produce a tetanic contraction of the protoplasm and of the cilia, while the contractile vesicle is unaffected. Strong currents cause liquefaction of the protoplasm.—Geo. E. Fell, M.D., *The Microscope*.

THE COAGULATION OF THE BLOOD.

M.M. Arthus and Pagès (Brown-Séguard's *Arch. de Phys.*, October,) have propounded a new theory of the coagulation of the blood. Starting with the idea that the curdling of milk presents analogies with blood coagulation, these authors, after applying the same methods of investigation to the two processes, have arrived at the following conclusions: 1. Oxalates, fluorides, and alkaline soaps render blood non-spontaneously coagulable, even when added in very minute proportions. 2. It is upon fibrin formation, and not ferment production, that the action of these bodies is exerted. 3. These bodies produce this effect by removing soluble calcium salts from the blood. The addition of a trace of a soluble calcium salt renders blood once more coagulable after it has been rendered non-coagulable by the addition of soluble fluorides, oxalates or soaps. The rôle of calcium can be played by strontium, but not barium or magnesium. 4. The ash of the most carefully washed fibrin contains calcium salts, and the amount of clot obtained is proportional to the amount of calcium when a minute amount only is present; hence the molecule of fibrin contains calcium. This may be replaced by strontium. 5. The ferment is unable to act upon fibrinogen, except in the presence of a soluble calcium salt. 6. The rival theories of Al. Schmidt and Hammarsten are reconciled by adopting the view that fibrinogen undergoes in the presence of the ferment and of soluble calcium salts a transformation into an insoluble calcium compound—fibrin. Schmidt's fibrinogen contained no calcium, while his fibrinoplastin did; Hammarsten had no need of fibrinoplastin, for his fibrinogen contained the necessary lime. 7. The curdling of milk is due to a transformation of casein under the influence of a ferment, giving rise to the formation of an insoluble calcium compound. The clotting of blood is an analogous process. Green, of Cambridge, showed a few years ago that the presence of a minute quantity of calcium was essential for the production of a clot, but M.M. Arthus and Pagès have much extended his observations.—*Brit. Med. Journal*.

CHOLERA THREATENED.

According to the secular exchanges, the Eastern countries have become the subject of cholera ravages. Abyssinia has suffered a loss of more than 10,000, Spain is infected, and India has been reached. More than 80,000 have perished in Japan, Korea and the contiguous Asiatic provinces of Russia. All this loss within a few months.

"The danger of the present epidemic," says one account, "is greatly increased by the yearly pilgrimage of

Moslems to Mecca. The great body of these ignorant Mussulmans who congregate in Mecca are filthy in their habits, and by consequence readily contract the disease, and thus spread the infection in Syria, Turkey, South-eastern Austria and the provinces of Northern Africa. The present plague exists to some degree in most of these countries, but it will soon be augmented by these Mecca pestilence breeders."

The course of the plague is like to that followed in the past, namely: the route from Bekor to Alexandria and through the Levant. We are nevertheless consoled by the assurance that quarantine enactments are more comprehensive, prophylaxis more complete, and therapeutic measures are to be perhaps more trustworthy. At all events, a very encouraging feature is that there seems to be less alarm on the part of the public than ever was known before. The popular idea is that the predicted spring visitation is a mere probability, likely to be behind time.

AN ANECDOTE OF SIR ASTLEY COOPER.

Before Astley Cooper was 40, he had a practice in value rising \$75,000 a year; indeed, his books show one year's fees collected, \$105,000. In 1820, at the height of his success, he was called in to remove a steatomatous tumor from George IV's scalp. On the day appointed, he waited upon his Majesty. Lord Liverpool and other cabinet officers occupied a room adjoining that in which the King was. In preparing for the operation, Cooper was observed to be pale and nervous, when Lord Liverpool, taking hold of his hand, said: "You ought to recollect that this operation either makes or ruins you. Courage, Cooper." This timely rebuke so impressed him that every trace of anxiety vanished, and he performed the operation with his wonted dexterity. This won his baronetcy with remainder to his nephew, who succeeded to the title.

NO MAN LIVETH TO HIMSELF

Among the animals to which man gives his involuntary assistance, we may mention first, four different Cestodea, or tape worms, which live in the intestines; three or four Distomes, which lodge in the liver, the intestines or the blood; nine or ten Nematodes, which inhabit the digestive passage or the flesh. There are also some young Cestodes, named *Cysticerci*, *Echinococci*, *Hydatids*, or *Acephalocysts*, which find in him a *crèche* to shelter them during their life. These always choose enclosed organs, like the eye-ball, the lobes of the brain, the heart or the connective tissue. We also provide a living for three or four kinds of lice, for a bug, for a flea, and two ascarides, without mentioning certain inferior organisms which lurk in the tartar of the teeth, or in the secretions of the mucous membranes.—(*Van Beneden*.)

And after these come *the microbes!*

A LEGAL DEFINITION OF TOTAL HELPLESSNESS.

A bill has been introduced into the United States Senate defining "total helplessness" as applying to all persons who lost a leg or an arm at or so near the joint that an artificial limb cannot be used, and granting all such persons a pension of \$72 per month.

PRACTICAL NOTES.

TURPENTINE IN TYPHOID FEVER.

Dr. H. C. Wood advises a return of the turpentine treatment of typhoid fever as practiced by Dr. G. B. Wood. He begins its use about the twelfth or fifteenth day, thinks it lessens the tendency to hæmorrhage, and ameliorates other symptoms due to the local lesions.

His formula is :

- R. Oil of cloves, gtt. vj.
 Oil of turpentine, f ʒ jss.
 Glycerine.
 Mucil. of acacia, āā f ʒ ss.
 Syrup.
 Water, āā q. s. ad f ʒ iij. ℞.

Sig. Dessertspoonful every three hours during the day.—*Medical News*.

FOR ACUTE ECZEMA AND IRRITABLE CONDITIONS OF THE SKIN.

- R. Cocainæ hydrochlorat., gr. iij.
 Atropinæ sulphat., gr. j.
 Morphinæ sulphat., gr. ij.
 Ung. acidi carbolici, ʒj. ℞.
 —Shoemaker, *Times and Register*.

IRRITABLE BLADDER.

Dr. E. L. Tunstall recommends the following mixture in cases of irritable bladder :

- R. Potassium citrate, 4 drachms.
 Fluid ext. triticum repens } of each 1 oz.
 Tincture of hyoscyamus }
 Fluid ext. of buchu, ½ ounce.
 Water sufficient to make 3 ounces.

One teaspoonful in a wineglassful of water three or four times daily.—*Medical Summary*.

CHLOROFORM LINIMENT.

- R. Chloroform, 4 ounces.
 Camphor, 1 ounce.
 Fluid vaseline, sufficient to make 8 ounces.

Dissolve the camphor in the chloroform and then add the fluid vaseline. Of course, the amount of vaseline may be varied according to the strength of the liniment desired. It is said that this makes a much more useful application than chloroform liniment made with olive oil.—*Medical News*.

SALOL IN MALARIAL DIARRHŒA.

Dr. Moncorvo, of Rio Janeiro, strongly recommends salol in the treatment of diarrhœa, complicating malaria, in childhood. His paper, which is published in the *Revue Mensuelle des Maladies de l'Enfance* for October, contains a series of cases of various ages. He states that the diarrhœa rapidly decreases, and soon ceases altogether, and the stools are no longer offensive; flatulence and colic, due to abnormal intestinal fermentation, cease to be troublesome. His gen-

eral conclusion is that salol is a valuable agent for producing "intestinal antiseptis in children with enteritis or entero-colitis of malarial origin." He administered the remedy suspended in mucilage, and found it well taken, even by very young children. No poisonous symptoms were ever observed to follow its use. The dose given to an infant in the first few months of life was 15 to 20 centigrams (about 2 to 3 grains); for a child under 2 years, 25 to 50 centigrams (about 4 to 7½ grains); above 2 years, from 1 to 2 grams (15 to 30 grains).—*British Medical Journal*.

TINCTURE OF SUNFLOWER IN MALARIAL FEVERS.

Zubovitch has described in *Vratch* his use of sunflower in a variety of malarial affections. He has used the drug in the form of a tincture of either the fresh bark of young stems or of the fresh flowers. Of this he would give to an adult a wineglassful three times a day, the administration to be continued for two or three days after the paroxysms have been broken up. His experience leads him to state that, 1, the sunflower treatment is competent to the permanent and complete cure of malarial fever in from three to ten days; 2, it has overcome cases that have not yielded to quinine; 3, its range of application is limited to no type of malarial poisoning, all the various types in which he has tried it being alike equally amenable to it; 4, no unpleasant symptoms have been manifested as due to the drug except an occasional profuse night-sweat; and 5, the tincture of the flowers seems to act more rapidly than that of the bark.

THE RAW THROAT OF DYSPEPSIA.

Cases of symptomatic cough without physical signs present themselves to every chest clinic. The patient generally reports, also, some pain in the sternal region and under the left scapula; constipation frequently a concomitant. Such cases are dyspeptic in origin, and the cough is popularly known as "stomach-cough;" pyrosis may be present with or without regurgitation and a bitter taste in the mouth, and other signs associated with dyspepsia. If the throat is very raw or sore and the soft palate relaxed the following gargle may be ordered :

- Sulphate of zinc,
 Carbolic acid, of each, 4 grains.
 Glycerine, 4 drachms.
 Water, 3½ ounces. ℞.

Use as gargle three or four times daily. This is a favorite at the University of Maryland clinic, and is known as "McSherry's gargle" from its originator, Dr. H. Clinton McSherry, of Baltimore. Internal treatment by means of tonic or antacid remedies will also be required in many cases.

SOCIETY PROCEEDINGS.

Medical and Chirurgical State Faculty of Maryland.

Semi-annual Meeting held at Cambridge, Md., November 11th and 12th, 1890.

THE PRESIDENT, DR. T. A. ASHBY, IN THE CHAIR.

DR. A. H. BAYLEY, of Cambridge delivered the *address of welcome*.

DR. T. A. ASHBY delivered

THE PRESIDENT'S ADDRESS.

After hastily reviewing the early history of the Faculty, its power, its control of the medical profession in this State and its high authority, he spoke of the causes which led to shrinkage of its membership and its loss of authority over the profession. The meetings had always been held in Baltimore. This made it a local society. These semi-annual meetings were started to interest the county members, the fees were reduced and a large accession of members was the result. The Medical Practice Act was vetoed by the Governor, who was influenced by unprincipled politicians. This was a direct insult to the respectable members of the medical profession of Maryland. Physicians have no lien on an estate, no preference in court.

The profession of this State should organize in order to achieve success. This can only be done by this Faculty. To this end local societies should be encouraged in all the counties of the State. Since last year over one hundred members have been added to the society and the prospects were most encouraging.

Dr. R. Winslow then read a paper entitled

SIMULTANEOUS DISTAL LIGATION OF THE RIGHT COMMON CAROTID AND RIGHT SUBCLAVIAN ARTERY FOR SUPPOSED INNOMINATE ANEURISM. RECOVERY FROM THE OPERATION.

A dissipated woman had five miscarriages. There was pulsation at the root of the right side of the neck at the sterno-clavicular articulation. She was put on low diet and given iodide of potash, ten grains. Effect not being good, an operation was performed and the subclavian and innominate arteries were ligated at their distal ends. She was kept quiet for some time and now seems to be well. In such cases if the aneurism shows no tendency to break or cause great inconvenience, try postural treatment and the iodides and postpone operation. He then gave some statistics of similar operations, and the number of aneurisms in age and sex. His operation is not dangerous when done antiseptically and with an absorbable ligature.

DR. R. W. JOINSON thought in 1871 very few antiseptic operations were performed, and even now surgeons do not always operate antiseptically. It is not a point of election whether you do a distal or a proximal ligation. The strong pulsations of the heart are apt to break through the weakened arterial walls. He also thought that the absorbable ligature was by far the best.

DR. WINSLOW said that most men mentioned were those who operated since antiseptics were introduced, and it was fair to presume that they used it.

DR. S. T. EARLE then read a paper on the
USE OF ELECTROLYSIS IN STRICTURE OF THE RECTUM.

The definition of electrolysis should be exact. A good battery and a reliable milliamperemeter are both indispensable. A Leclanché battery of 30 to 50 cells is sufficient. A salt solution on the skin increases the electrolytic action. He related several cases in which he used electrodes gradually increasing in size, and in suspicion of syphilis giving the iodide of potash.

DR. WINSLOW asked if these cases had been under observation long. The cure can not be maintained too soon after the operation.

DR. W. S. GARDNER referred to one case noted in which an electrode no larger than a match could be introduced, while after a short time Dr. Earle claims to introduce an electrode one inch in diameter. Was this electrolytic action or simply dilatation?

DR. EARLE said that one case operated on two years ago was practically well now. As for the electrode, he said that often an electrode could not be introduced at first, and after the current was turned on it went in easily.

DR. W. P. CHUNN referred to one of the cases mentioned in which Dr. Earle said there was a neoplasm in Douglas' cul-de-sac. This disappeared after treatment. Did he think it was a growth removed by the electricity.

DR. PRESTON said he had not used electricity in this connection, but only in facial blemishes, etc. He thought the idea was only to decompose the tissue by a weak current, and not to cauterize it by a strong current, as Dr. Earle seemed to do. Some currents are too high.

DR. EARLE said in reply to Dr. Chunn that it was not a myoma, but simply an infiltration of tissue around the rectal walls. In reply to Dr. Preston he said his experience with both weak and strong currents in these cases was that the strong current was decidedly better. These currents do not produce cauterization.

DR. S. K. MERRICK then read a paper on
SOME OBSERVATIONS ON FIBROMA OF THE NOSE AND NASO-PHARYNX WITH A REPORT OF THREE CASES.

After defining fibroma and observing that the

cause was not evident in that the negro who was subject to uterine fibroids never had nasal fibroma, he drew up a general sketch of the diagnosis and treatment and then related at length these three cases.

DR. JOHN N. MACKENZIE then read a paper entitled

POST-NASAL OBSTRUCTION IN CHILDREN.

This is a subject of the utmost importance. It is wonderful that only in the past fifteen years it has been studied. Meyer, of Copenhagen, was the first to introduce it in 1875. He called it adenoid growth of the naso-pharynx. The adenoma of the vault of the pharynx is the most common cause. It is generally post-nasal. Obstruction of the nares is incompatible with viability of the fœtus. It is most common in children from the fourth to fifth month. Pliny spoke of it. It grows from the vault of the pharynx as a mass of adenoid tissue, called by the Germans the tissue of Luschka, although discovered by Schneider. It begins by a proliferation, then small tumors appear which may hang down in the pharynx like stalactites or bunches of grapes. The papillomatous form of pharyngeal growth is more frequently met with in this part of the country, while patients from the West and Lake regions present the greatest varieties of growth. In Boston the stalactite variety preponderates. In England he found this very common. The diagnosis is sufficiently easy. It may be confused with a fibroma of the vault of the pharynx, but the treatment is the same. Those who do not make the diagnosis with the rhinoscopic mirror may use the finger. It is like touching an earthworm, and if blood is on the finger when withdrawn, these two facts will confirm the diagnosis. He uses the forceps which bear his name. When a child is brought to him with nasal obstruction or with symptoms of non-suppurative otitis media, he introduces those forceps without making a diagnosis, and rarely fails to bring away the growth. These growths have a great effect on the child, who breathes through his nose; his nose becomes flattened and he has a frog face. This facial expression is characteristic. Meyer, of Copenhagen, uses a "ringmesser" or guillotine knife introduced through the nose. The best methods seem to be the forceps. As a rule, he does not use anæsthetics. Occasionally the hæmorrhage is very severe.

DR. B. W. GOLDSBOROUGH, in referring to Dr. Merrick's paper, said he had seen one of the patients and he was entirely well.

DR. WILMER BRINTON asked what was the smallest child operated on by Dr. Mackenzie?

DR. MACKENZIE said he did it to those in arms, three or four months. In referring to Dr. Merrick's paper he said the instrument was apt to break, as it had done once in his case. He said

he did the operation every day, and at the Johns Hopkins Hospital in one month he did it 170 times.

DR. S. K. MERRICK said he used Mackenzie's forceps. In the cases where he could not reach with the forceps he used his finger with success.

DR. WILMER BRINTON read a paper on

PROLAPSE OF THE FUNIS,

in which he related four cases which occurred in a thousand of his.

DR. W. P. CHUNN asked what the hæmorrhage was from in Dr. Brinton's cases.

DR. B. W. GOLDSBOROUGH said he had a case of this kind. He tried to stop the hæmorrhage in vain. Everything failed until he applied turpentine to the fundus of the uterus and all bleeding stopped.

DR. BRINTON said many people had never seen a case like the one he related. He had seen four, and in one he applied the forceps and the hæmorrhage came from the cervix. He kept tampons in for several hours, and gave ergot. He feels sure that the blood did not come from the interior of the uterus. It should be decided what course shall be followed the very minute the funis presents.

DR. W. S. GARDNER said such cases were very difficult to treat, and needed prompt attention.

DR. J. C. CLARK, of Federalsburgh, presented a case of

PROFOUND ANÆMIA.

He brought the case for diagnosis. The patient had been an invalid for eight years and had been under his treatment for the past year without much sign of improvement. The history is very imperfect. His countenance is poor, sight very bad, he complains of muscular weakness and sick stomach, nausea, and occasional vomiting; has a poor appetite, and feels languid. There has been no improvement for eight years—no better, no worse. He is pale. The urine contained no albumen.

DR. WM. OSLER examined this case, and suggested that it was profound anæmia due to trouble in the large intestine. Such cases often have these retinal changes noted in this case, with gastro-intestinal changes. The patient was not much emaciated. In these cases iron is not good, but some form of arsenic is better. Cases of pernicious anæmia often fail to improve under iron and recover under full doses of arsenic.

DR. W. S. GARDNER then read a paper on

THE RELATION OF ALBUMINURIA TO PUERPERAL ECLAMPSIA,

in which he gave the results of a large number of cases at the Maryland Maternité. Heat and nitric acid were used. His conclusions were:

1. The presence of albumen in the urine of a pregnant woman is not sufficient cause upon

which to base a prognosis of probable eclampsia.

2. The failure to find albumen in the urine of a pregnant woman is no evidence of the absence, or at least of the continuance of the absence of the condition that gives rise to puerperal convulsions.

3. Albumen is so frequently found in considerable quantity in the urine of patients, immediately after the appearance of puerperal convulsions, that we are justified in making the statement, that the convulsions are the probable cause of the albuminuria.

DR. BRINTON was much pleased with this paper. He thought if we could collect a large number of cases, much more than presented in this paper, we should be warranted in drawing conclusions as he has done. We cannot always look to the kidney lesion as the cause of death.

DR. G. J. PRESTON thought that some conditions of the central nervous system might cause the trouble.

DR. OSLER said, that in Montreal he had made the autopsies for ten years, and that in not a single instance were the kidneys in such cases found normal, except in one case, which showed an immense cranial hæmorrhage—the clot extending from the third to the fourth ventricle of the brain.

DR. GARDNER thought this experience rather exceptional.

DR. PRESTON asked if the woman was systematically examined in each instance?

DR. GARDNER said that the urine was examined, in a routine manner, in each case, and was done with average care. The object of these urinary examinations was to see if this prognosis of eclampsia could be made before pregnancy.

DR. R. W. JOHNSON then read a paper entitled, *The Surgical Treatment of Non-pyæmic Abscess of the Liver, with Report of a Case*, in which he principally advocated aspiration, even in the smallest abscesses, as opposed to incision. The aspirator should be used in diagnosis.

DR. R. WINSLOW said that such cases were not so infrequent in this climate as many supposed. All cases he had seen were Germans. He does not agree with Dr. Johnson in the treatment with the aspirator. Small abscesses may be cured by the aspirator. An abscess of the liver should never be allowed to break. It may break inward, and cause death.

DR. WM. OSLER said he had seen more abscesses of the liver in the sixteen months that he had been in Baltimore, than in five years in Philadelphia. Some abscesses will not get well by aspiration; often they are so low down in the liver that they cannot be found except by laparotomy. Very often there is also a multiple pyelo nephritis. He related a case in which the diagnosis was only made by incision.

DR. PRESTON also related a case of hepatic abscess occurring in his practice.

DR. JOHNSON closed the discussion.

DR. GEO. J. PRESTON read a paper on the DIFFERENTIAL DIAGNOSIS AND TREATMENT OF PERIPHERAL NEURITIS.

He gave the pathology of the disease, its manner of invasion, the symptoms, and said it was often confounded with polyo-myelitis in the adult. He related a number of cases occurring in his practice. He thought that it was of more common occurrence than was usually supposed.

DR. WM. OSLER agreed with Dr. Preston in saying that peripheral neuritis was more common than usually supposed. There are often mistakes in the diagnosis, unfortunately. The gait is very characteristic. It is the "steppage" of the French, in which the foot is lifted high, to get the toes raised off the ground. This is so characteristic, that the diagnosis can be made from it alone. He had seen it after alcoholism, arsenical poisoning, and typhoid fever. It is so much like locomotor ataxia, that an unfavorable prognosis is apt to be made. He referred to a case in his own practice in which neuritis was mistaken for ataxia.

DR. H. HARLAN then read a paper entitled *Pyoktanin in Eye Diseases*. He was led to use pyoktanin from its unusual claims, as given in *Merck's Bulletin*. He thought it impossible for it to do so much. He had given it a very thorough trial, and was more than pleased with it. In some cases nitrate of silver was better.

DR. H. WOODS then read a paper on the *Injurious Use of Remedies in Eye and Ear Diseases*, in which he discussed the use of wrong remedies or strong remedies producing harm. Much of this was done by the general practitioner, who did not want to pass a case over to a specialist.

DR. HARLAN said he had seen such cases as related by Dr. Woods.

DR. WM. P. CHUNN read a paper entitled *Remarks on Vaginal Examinations*, and gave some very useful hints, and was well received by the Society.

DR. CHAS. P. NOBLE, of Philadelphia, thought the touch was often better than the speculum, except in cases of deep-seated tumors of the uterus, etc. He spoke of the methods of examination at the patient's house, etc.

DR. WM. B. CANFIELD read a paper entitled *Immunity and Protection from Disease*, in which he reviewed the latest theories on this subject.

After the election of new members, and routine business, the Society adjourned.

SUNBURN ON THE ALPS.—This is the subject of a paper in the *Alpine Journal*, by Dr. R. R. Bowles, Kolkstone, England, whose contention is that sunburn is caused by the violet or ultra rays of light reflected from the snow, which reflected light is not, of necessity, the same in quality as that which is incident.

New York Academy of Medicine.

SECTION ON ORTHOPÆDIC SURGERY.

Stated Meeting, October 17, 1890.

V. P. GIBNEY, M.D., CHAIRMAN.

NON-UNION OF FRACTURED RADIUS.

DR. C. A. POWERS exhibited a patient in whom this condition had existed for many years, and also showed an extension apparatus which had given relief. The first fracture occurred twenty-nine years ago at the junction of the middle and lower thirds. A re-fracture took place eighteen years later, and united with deformity and disability. The radial nerve had become involved in the callus, and this gave rise to such intense pain that she underwent an operation for its relief, five years later, in which the bone was again fractured. All attempts to cause this fracture to unite failed. When she came under the care of the speaker in May of the present year, it was found that the carpus had slipped upwards with the lower fragment of the radius, and had caused the ulna to project very forcibly against the soft parts, giving rise to much pain in the region supplied by the ulner nerve. As further operative measures were not deemed advisable, a simple extension apparatus was applied, and had answered admirably.

DR. A. M. PHELPS said that he thought it had been wisely decided not to subject the patient to further operation, as fractures of the radius and of the lower third of the tibia were peculiarly prone to non-union. Out of about three hundred osteotomies he had had only one case of non-union, and that was after an operation for the correction of an anterior tibial curve. Operations by himself and others had failed to bring about union. Thomas, of Liverpool, claimed that such fractures could be made to unite by pounding the parts with a mallet; but in his experience, this method had not proved successful, and he thought that where there was muscle between the ends of the bone, and the peculiar ivory-like condition of the ends of the bone, which was not uncommonly present, none of the methods heretofore proposed were likely to prove successful. He had very recently proposed and performed an operation which he thought might prove successful. It consisted in cutting down upon the ununited fracture, freshening the ends of the bone, and grafting in between them a part of the forearm of a dog, both patient and dog being secured in plaster of Paris. When the graft had united firmly, the dog's leg would be amputated, and the skin flaps of the dog united to those of the patient.

HIP-JOINT DISEASE AFTER TYPHOID FEVER.

DR. J. MC. G. WOODBURY presented a girl of 11 years, who six months after a severe attack of typhoid fever was found to have some limitation

of motion and pain at the right hip, with distension of the capsule. Flexion caused lordosis, and some pain. She was treated by counter-irritation over the joint, and a plaster of Paris spica bandage, and was allowed to walk around upon a high patten, with crutches. Now, after a period of eight months, there was no pain.

A CASE OF OSTEO-MALACIA.

DR. WOODBURY also presented a case of this nature. The patient had lived in Switzerland until 20 years of age, and had suffered considerably from exposure during the late war. On October 26, 1886, when 43 years of age, he sustained a fracture of the surgical neck of the left humerus, and between that date and May 26, 1890, he received five other fractures, viz., two of the left humerus, two of the right humerus, and one of the left clavicle. Most of these fractures were caused by very slight falls. During the last three months, but more particularly since the first of last August, a tumor has been rapidly growing between the sites of the two fractures of the shaft of the right humerus. Two small tumors may be observed upon the clavicle—one at the point of the fracture, and the other, to the inside of it. A specimen removed from the large tumor with a harpoon was sent to Dr. J. S. Ely for microscopical examination, and he reported that it contained "polyhedral cells, and occasional large spindle and giant cells." He adds, that this "speaks very strongly for sarcoma." A loud murmur, similar to that heard in aortic aneurism, is audible over the large tumor. Dr. Woodbury said that as in cases of tumor of the middle of the spinal cord, osteo-malacia due to trophic disturbances is one of the early symptoms, concurrent with disturbances of sensation, he had referred the case to Dr. M. A. Starr with the hope of learning more about the etiology of this interesting condition. Dr. Starr examined the patient on two or three occasions—the last time, only a few days ago—and had reported that there was no central lesion of the cord. The patient had had no pain with the fractures, or upon re-setting these bones, and this, together with the fact that there had been no fractures of the lower extremity, seemed to favor the view that the condition was due to a syringo-myelia, or tumors of the cord.

DR. POWERS said that Dr. Woodbury's case of multiple fracture with tumors was very similar to a case of multiple sarcomata which he had recently presented to the Surgical Section.

DR. V. P. GIBNEY thought that the pulsation in the tumor might be due to the condition of the tumor itself—in other words, it might be a pulsating sarcoma.

ANKLE-JOINT DISEASE.

DR. A. B. JUDSON presented a case of this disease which he said was interesting because the

child had suffered from this condition almost all her life. The disease began at the age of 1 year and she is now about 7 years old. Notwithstanding that she had been under mechanical treatment only two years, she had recovered with but little disability and deformity. There was considerable lateral motion at the ankle-joint; extension was almost normal; flexion was arrested at about ninety degrees. Scars on both sides of the ankle showed where abscesses had opened spontaneously. There was a difference of one inch between the two calves, and the shortening amounted to only a small fraction of an inch. This result had been obtained by the aid of the simple brace, and without resorting to operation.

DR. JOHN RIDLON presented an astragalus which had been removed by Dr. B. Farquhar Curtis from a child, which had been brought to the speaker when only six weeks old. He had faithfully tried stretching, and the various retentive appliances during a period of one and one-half years. Dr. G. S. Huntington had then operated by Dr. A. M. Phelps' open method, but without improving the condition. The specimen which he presented was interesting on account of two bony prominences which it showed, and which apparently had been the obstacle to flexion of the foot.

THE TREATMENT OF ANKLE JOINT AND TARSAI DISEASE.

The paper of the evening, with the above title, was read by Dr. T. Halsted Myers, who also presented a patient illustrative of this subject.

DR. MYERS said that tubercular inflammation might attack, first, the synovial membrane, later, the cartilage, and lastly, the bone; or the primary local focus might be in the bone. While it was still confined to the synovial membrane, a number of surgeons recommended erosion. If it had attacked the bone, many more urged operative methods, irrespective of the general health of the patient. The author considered only the latter condition.

Simple incision was of no advantage, for we had no element of tension, as in acute processes, and we only opened new channels of infection, leaving the original disease unchanged. The usual method of treatment, curretting the abscess walls, and the sinuses, could not be expected to remove all disease, and would greatly increase the risk of absorption. The success which had been secured in some of these cases seemed to be due to the power of the antiseptic agent to render inert the bacilli which remained. The rational method was to remove all the disease at once; but apparently healthy bones contained tuberculous foci, and hence, it was a most difficult problem to know when to stop, and in fact, this could not be determined at the time of operation. If all the disease were successfully removed, the

duration of treatment was less than under conservative methods. The ultimate results were, however, less satisfactory. He had seen a considerable number of misshapen and atrophied feet after operative treatment, which were weak and painful, and required support to render them able to bear the weight of the body. He had not observed such results from conservative treatment. It was confessedly difficult to ascertain the ultimate results; and although Dr. Schaffer had kindly placed the records of the New York Orthopædic Dispensary at his service, he had not been able in the short time at his disposal to do more in most of the cases than quote the histories.

The number of cases treated before July, 1888, was fifty-five, and of these, he knew personally that at least twenty-one were cured. Five were cases of synovitis, and sixteen of osteitis. The average duration of treatment in the latter was twenty-one and one-half months, the longest case being under treatment fifty-five months. The results in all were extremely good; yet under careful private treatment, still better results should be expected.

From our knowledge of the various ways in which the bacilli of tuberculosis may be spread in the body, it would seem that a primary tubercular process in a joint must be extremely rare. Drs. Prudden, Northrup, Biggs, and Thacher, to whom he had written for information on this subject, all considered that these affections were generally secondary, but agreed that primary joint lesions did occur. The practical importance of this was that the danger of general infection from a joint lesion which was not interfered with surgically was an entirely unknown, and probably extremely small, quantity.

Of the whole number treated (fifty-five), but three had died—one of diphtheria, one while tarsal disease was active, and the other, six months after a note of "nearly cured" had been recorded. In neither of the latter was the cause of death stated. However, in Dr. Scudder's report of eighteen cases of excision, six deaths occurred; three were due to the operation, or its direct effects; another might have been; and the other two were from tuberculosis, but occurred one and two years after the operations.

The treatment of synovitis consisted in absolute protection of the joint from traumatism. In children, he considered a perineal crutch absolutely necessary while walking. Ordinary crutches were invariably laid aside at times, and the joint left unprotected. In addition to this crutch, the foot should be protected by a splint to avoid local injuries, and to maintain a good position. There being no involuntary muscular spasm, while the disease was confined to the synovial membrane, traction was not necessary.

In cases of osteitis, the same protection of the joint was imperative, and if there were pain and

spasm, indicating the necessity for traction, this could be applied at the ankle, by means of a Dow's brace, or the apparatus of Dr. Sayre, or Dr. Foster.

The application of adhesive plaster to a painful ankle required more care than a dispensary case was willing to give, especially when abscess was present. For this reason, he had found it most serviceable to employ a leg brace, or plaster splint, worn constantly, and a perineal crutch for walking, which could be laid aside at night; or the Dow's brace as modified by Dr. Shaffer might be used.

Abscesses should be left entirely alone, and the sinuses simply kept aseptic. After the joint was considered cured, it was well to wear an ankle brace for some months to prevent twists. The malpositions found in the acute stages, were almost entirely due to muscular spasm, and did not require tenotomy, or other operative treatment.

In the later stages, there might be bony changes, and these, if not painful or progressive, did not require treatment. However, if these conditions did exist, and yet there was no evidence of active disease, an attempt should be made to restore and preserve the normal relations of the parts.

The value of hygienic surroundings during the treatment of these cases, could not be over-estimated. His observations had been made on children only, and for contrast, an extended series of cases in the adult would be very valuable. Without exception, every one of his cases of ankle-joint or tarsal osteitis in children had done well under conservative treatment, and he had yet to see the case which he would condemn to erosion or excision.

DR. N. M. SHAFFER said that his own experience led him to think that one point in Dr. Myers' paper should be particularly emphasized, *i.e.*, the necessity of absolute protection of the articulation. He had accomplished this in practice, whenever possible, by the use of a modification of Dow's brace, and had found that adhesive plaster was rarely required, as a well fitting shoe made efficient counter traction. He thought that the further removed the tuberculous joint was from the centre of the body, the more benign was the disease, and the less the danger of general infection; and he was inclined to speak more strongly of the conservative treatment of ankle-joint disease, than of any other articulation in the body.

DR. RIDLON thought these cases did well with the Dow's instrument; but with this as with some others, we could not secure immobilization, but only protect the joint from the jar of walking. He had seen such excellent results in cases of suppurative ankle-joint disease without any treatment whatever, that he often doubted how

much of a good result could be attributed to the treatment received.

DR. H. W. BERG said that he had had such good results in the treatment of phthisis by the administration of the bichloride of mercury in doses of one-twenty-fourth of a grain, three times a day, that he was inclined to believe the old theory that tuberculosis was really a change in the syphilitic virus due to passing through several generations. He considered that splints like Dr. Judson's were imperfect, for, by taking their bearing from the outside of the foot, intra-articular pressure was increased. To diminish this pressure, the foot must be adducted and rotated inwards.

DR. PHELPS was of the opinion that the vast majority of these cases were cured by immobilization and relief of intra-articular pressure, but in suppurative cases, he believed that the soundest and most scientific surgery demanded operative measures. If we could protect the hip-joint as well as the ankle-joint, we ought to get equally good results in hip-disease. He believed that these cases were inoculations of pathogenic germs on a diseased surface, and that they were purely local.

DR. R. H. SAYRE exhibited a splint which his father had devised for an adult with ankle-joint disease. He agreed with Dr. Ridlon, that it was difficult to apply traction at this joint, but he thought this splint solved the problem. His views regarding the prognosis and treatment of this disease, were in accordance with those just expressed by Dr. Phelps.

DR. SAMUEL LLOYD said that fifteen cases of adult ankle-joint disease had been treated in the New York Post-Graduate School by the so-called conservative method, but the relapses had been very frequent, and he thought this method was less likely to yield good results in adults than in children. In answer to questions from the Chairman, he said that several of the cases were due to injury, and a number of them were suppurative, while four were recorded as synovitis. Two of the cases had been discharged as cured before 1883, and were known to be well in 1889.

DR. JUDSON protested against the statement that cases of disease in the ankle would do equally well without treatment, although neglected cases of ankle-joint disease would have nothing like so bad a deformity as those at the hip.

DR. H. L. TAYLOR also spoke about the different mechanical conditions present at the various joints. The weight of the limb exerted great leverage upon the joint, especially in a spasmodic condition of the muscles. It is more marked at the hip than at the knee, and very much more noticeable than at the ankle. He referred to a case of ankle-joint disease occurring in a distinctly phthisical subject, where the sinuses were treated

by injections of a saturated solution of iodoform in ether. The beneficial effect upon the healing process was almost magical.

DR. GIBNEY said that about ten years ago, the Surgical Section of the Therapeutic Society of New York, spent about two years collecting data relative to the comparative results obtained by the operative and non-operative treatment of this condition; and the conclusion was, that the conservative method yielded the greatest number of useful ankles, even in cases where the foot was seamed with cicatrices. There were two or three operative cases having a high degree of equinus, and a stiffened and shortened joint, and one or two flail joints were also shown. In his experience, cases of adult ankle-joint disease relapsed again and again on the slightest provocation; later on, abscesses would appear; still later, pulmonary signs would develop, and then amputation would follow. As regards the mercurial treatment of tuberculous disease of the joint he need only call attention to the fact that many years ago the routine treatment for these cases at the Hospital for Ruptured and Crippled was one twenty-fourth of a grain of the bichloride of mercury in the tincture of bark, three times a day; and the results attained by this treatment were certainly far from striking.

DOMESTIC CORRESPONDENCE.

Shall The Journal be Removed to Washington?

To the Editor:—The short editorial in THE JOURNAL of December 13, touching the question of its removal, is to the point. The responsibility of such a change should be with the members of the Association. The objection to leaving the decision of the matter to the next meeting is, that it will be composed largely of members from one section of the country, and those not in attendance, but equally interested, will be deprived of a voice in the matter. The question is too important to be settled by a partial vote. But how is it to be determined whether the Association is for or against its removal?

Let the question be submitted to the whole Association. For this purpose prepare blanks for votes. These can be sent with THE JOURNAL. When filled by those entitled to vote, send direct to the Secretary of the Association.

In this way, it appears to me the sense of the members may be obtained with but little trouble, and a possibly vexatious question satisfactorily adjusted.

MADISON REECE, M.D.

Abingdon, Ill., December 12, 1890.

To the Editor:—In compliance with the invitation of the Trustees to discuss the resolutions re-

ferring to the removal of THE JOURNAL from Chicago to Washington, I beg leave to inquire what reasons the Committee have for making this change? This is a question which has agitated the American Medical Association more or less for years, and at one time assumed a sectional aspect, of the East vs. the West. The former seemed to hold to the idea that all the brilliant minds of our profession resided in the East, and for this reason the home of THE JOURNAL should be nearer the Orient.

Whilst I have no reflection to cast on the brilliancy of the medical profession in the East, yet I am of the opinion that that argument will no longer hold good.

It does seem to me that there are quite a number of good and sufficient reasons for keeping THE JOURNAL at the old homestead, where it was born, spent its childhood days, grew into manhood, and has matured into a good, healthy, robust adult, able and willing to take care of itself. Chicago is not only a great city but a great medical centre, and well worthy to be the home of our National Journal. It is not only more central, but a much greater railroad centre than Washington, its great trunk lines extending in all directions across the continent, from north to south and east to west, on which the fastest trains fly to and fro like the weaver's shuttle every hour, thus facilitating the rapid collection of material for THE JOURNAL, as well as the speedy distribution of THE JOURNAL to all parts of the world.

In conclusion: until there is a preponderance of evidence showing the unquestioned necessity for such a change, I stand as I did before, in favor of THE JOURNAL staying where it is.

R. HARVEY REED, M.D.

Mansfield, O., December 13, 1890.

Ether and Chloroform in Convulsions.

To the Editor:—On page 835 of THE JOURNAL for December 6, chloroform is suggested for convulsions in children, without any word of caution. I have used both chloroform and ether in convulsions of children, and, while I am not sure of any dangerous result from the anæsthetic *per se*, yet I never give it without extreme caution.

The following case is the first of the kind in my practice, and I have not related the case to any one so far who has had a similar experience—therefore I suppose it must be unusual. July the 25th last I was hurriedly called to see a little boy aged 4 years, who had been under treatment for fever and vomiting during the day. I found him in a convulsion which had lasted about four minutes. I noticed nothing unusual about the case, more than we usually see in a child with a convulsion, and supposed it was caused by excessive vomiting and fever.

I gave him a few minims of ether by inhala-

tion, which checked the spasm about the third inhalation. As I had my finger on the pulse all the while, I noticed that it disappeared with the spasm. I at once applied my ear to the chest and noticed that the heart was beating at about the rate of 250 per minute. This rate lasted perhaps twenty seconds, then dropped to the rate of about twenty-five beats to the minute. This pulse-rate continued about ten seconds, when the heart stopped. Respiration was not perceptible after the spasm left.

I learned from the attending physician a history of malaria. Patient had been treated with domestic remedies for "dumb chill" for two weeks previous to the attack, the last chill leaving patient with vomiting and fever, for which the physician was called in about four hours previous to the convulsion. He did not consider patient seriously sick, and was shocked to learn of the sudden termination of the case.

W. F. ROCHELLE, M.D.

Jackson, Tenn., December 8, 1890.

Seventh International Congress of Hygiene and Demography.

To the Editor:—I am requested by the Honorary Secretaries of the Committee of Organization of the Seventh International Congress of Hygiene and Demography, to call attention to the fact that this Congress will be held in London during the week beginning August 10, 1891.

The Governments of all countries, and municipalities, and all public health authorities, universities, colleges and societies occupied in the study of the sciences more or less immediately connected with hygiene, are invited to coöperate and appoint delegates to represent them at the Congress. The Prince of Wales will preside.

A Committee of Organization has been formed of which Sir Douglas Galton is Chairman, and Prof. W. H. Corfield and Mr. Shirley F. Murphy are Honorary Secretaries. An exhibition of articles of hygienic interest will be held in connection with the Congress. The last of these Congresses was held in Vienna in 1887, and was attended by over 2,000 persons, and it is expected that the London meeting will be one of great magnitude and importance. Very respectfully,

JOHN S. BILLINGS, M.D.,

Member of the International Permanent Committee.

Washington, D. C., October 27, 1890.

DR. SAMUEL BOURNE SWETT, the Boston Surgeon, died December 6. He was probably the last survivor of that colony of young physicians in Paris of whom Holmes has lately written in the *Atlantic Monthly*. He graduated from the Jefferson Medical College in 1834.

NEW INSTRUMENTS.

KOCH'S HYPODERMIC SYRINGE.

A very important result of bacteriological study is seen in the introduction of instruments that can be readily and thoroughly sterilized. To

this end surgical instruments are now made as simple as possible and with the fewest number of crevices for the accumulation of dirt. An instrument, to be acceptable at this day, must possess not only simplicity of form but must also contain no materials that prevent it from being subjected to the most approved methods of sterilization.

In order to secure the advantages of an entirely aseptic instrument for the injection of his inoculation lymph, Prof. Koch has invented a new syringe to take the place of the old Pravaz pattern. Owing to the universality of the interest taken in Koch's new method of treating tuberculosis, this instrument will doubtless come rapidly into vogue throughout the world.

Through the courtesy of Messrs. Chas. Truax & Co., of Chicago, we are enabled to present a cut of one of the first of these instruments to be imported into this country. It is a very simple matter to sterilize this syringe each time after use. To accomplish this purpose a rubber bulb has been substituted for the piston of the older instruments. The cylinder is provided with a centimetre scale etched upon the glass, each division of the scale representing one-tenth cm. The metal work of the syringe is particularly well fitted to the cylinder in an air-tight manner. So that the instrument can easily be taken apart and cleansed, which is best accomplished by means of absolute alcohol.

NECROLOGY.

DR. JAMES I. STEWART, died December 6, at his home in Erie, Pa., aged 66 years. He graduated from the Medical Department University of Pennsylvania in 1848, and entered the U. S. service as surgeon of the 3rd Pennsylvania Cavalry in July or August, 1861, but resigned March 11, 1862, after a hospital experience in Washington, D. C. He became President of the Penn-

sylvania State Medical Society in 1879 and was member of the Medical Congresses of 1876 and 1887. He also was a delegate to the Tenth International Medical Congress at Berlin, and had just returned. The sorrow of his life was the murder by the Apaches of his only son Lieut. Reid Stewart some eighteen years ago.

DR. E. HUGGINS BISHOP, one of the oldest residents of New Haven, Conn., died at his home on October 2. He was born in New Haven on February 11, 1807, and was therefore in his eighty-fifth year at the time of his death. He was a graduate of Yale, class of 1826, and of the medical department of the college in 1829. Most of his life was spent in the practice of medicine in his native city, and was for several years president of the New Haven Hospital Society. He retired from active practice about ten years ago.

MISCELLANY.

IN MEMORY OF RICHARD J. LEVIS.—At a meeting of the Faculty of the Philadelphia Polyclinic and College for Graduates in Medicine, the following preamble and resolutions were unanimously adopted:

WHEREAS the Divine Ruler of the Universe has seen fit to remove from among us Dr. Richard J. Levis, our friend and our colleague, therefore be it *Resolved*, that not only in the Emeritus Professor of Surgery of the Philadelphia Polyclinic but the whole medical profession have lost an honored and faithful co-laborer, and the community have cause to mourn a skilful and learned physician and honest and sympathizing friend.

Resolved, That by his kindness of manner, by the thoughtful interest which he always manifested in the younger members of the profession, by his encouragement, his earnestness, and his example, he had endeared himself to all, and that if we fitly honor and cherish his memory we must emulate his zeal, and vie with each other in carrying forward the great work in which he was so ardently engaged.

Resolved, That we tender to his family in this sad hour of affliction, our heartfelt sympathy.

Resolved, That these resolutions be handed to the family of our beloved friend, and to the medical journals.

THOS. J. MAYS, President.
S. SOLIS-COHEN, Secretary.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from December 6, 1890, to December 12, 1890.

Capt. Charles M. Gandy, Asst. Surgeon, now on leave of absence, will report in person, without delay, to Col. Eugene A. Carr, Sixth Cavalry, at Rapid City, S. Dak., for duty with troops in the field, reporting also, by letter, to the commanding General, Dept. of Dakota. By direction of the Secretary of War. Par. 14, S. O. 287, A. G. O., Washington, December 9, 1890.

Capt. Marcus E. Taylor, Asst. Surgeon, is relieved from further duty at Boise Bks., Idaho, and will proceed, at the expiration of his present sick leave of absence, to Vancouver Bks., Wash., and report in person to the commanding officer of that post for duty, reporting also, by letter, to the commanding General, Dept. of the Columbia. By direction of the Secretary of War. Par. 17, S. O. 287, A. G. O., Washington, December 9, 1890.

Official List of Changes in the Medical Corps of the U. S. Navy for the Week Ending December 13, 1890.

Medical Director Delevan Bloodgood, ordered to Charleston, S. C., to represent the Medical Corps U. S. N. at meeting of American Public Health Association.

P. A. Surgeon H. E. Ames, ordered as delegate to Charleston, S. C.

Surgeon D. N. Bertolette, detached from Naval Hospital, Philadelphia, and ordered to special duty in connection with World's Columbian Exposition.

P. A. Surgeon S. H. Dickson, from the "Atlanta," and granted two months' leave of absence.

P. A. Surgeon A. R. Wentworth, to the "Atlanta."

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine-Hospital Service, for the Two Weeks Ending December 6, 1890.

Surgeon C. S. D. Fessenden, leave of absence extended seven days. December 4, 1890.

Surgeon P. H. Bailhache, granted leave of absence for twenty days. November 28, 1890.

Surgeon W. H. H. Hutton, to proceed to Solomon's Island, Md., on special duty. November 29, 1890.

Surgeon H. W. Sawtelle, granted leave of absence for ten days. December 2, 1890.

P. A. Surgeon C. T. Peckham, granted leave of absence for ten days. December 1, 1890.

Asst. Surgeon S. H. Hussey, when relieved, to proceed to New Orleans for duty. November 24, 1890.

Asst. Surgeon J. F. Groenevelt, when relieved, to rejoin station. November 24, 1890.

Asst. Surgeon L. E. Cofer, ordered to temporary duty at Boston, Mass. Nov. 24, 1890.

ORIGINAL ARTICLES.

EMPHYEMA AND PULMONARY ABSCESS.

BY P. C. REMONDINO, M.D.,
OF SAN DIEGO, CAL.

Your interesting editorial on the necessity of a careful diagnosis in these affections, so as not to overlook the possibility of an empyema, are to the point. Too many patients are sent to sanitoriums with an hepatized lung requiring *absolute rest* even to the point of strapping the chest at times, and are simply told that they will not require any medical advice, but on their arrival they are simply to take all exercise possible—advice that they not only take but are sure to overdo—a weakened heart and an impervious lung, with its tissues on the balance as to whether they shall go towards health by proper resolution or go into softening and decay, very soon render a simple case of the most common results of pneumonia that would otherwise recover, into one simulating a case of advanced phthisis, and with the same disastrous results. Eighteen years of practice among a class of pulmonary invalids, with some scores of post-mortems that in many cases developed the fact that quite a large percentage of pulmonary fatal cases were not of tubercular phthisis, or even of simple, chronic consumption, but cases originating in an acute sthenic pneumonia or pleurisy, ending by improper and careless advice about “roughing it” into an inevitable break down of the lung and the patient.

Not alone is the poor patient allowed to die and be buried after an easily avoidable death, but his progeny must go through life feeling that “tubercular phthisis” is in them and of them, to dissuade them from this or that vocation, interfere in prospective marriage ties, and make many reluctant to launch offspring, with such a taint, into the world. Then, again, the life insurance examiner stumbles against the phthisical death of father, brother or uncle, to make him hesitate as to the advisability of taking the risk. The effect of a mistaken diagnosis in such cases is far-reaching—even in years after the poor patient has been resolved into the elements, arising

now and then to harass his progeny and to cloud his life with dark forebodings.

During eighteen years I have in my own practice run on to six such cases. One very interesting case being that of a Russian physician who became an inmate of the San Diego County Hospital, as a consumptive. On admission he asked me as a favor to allow him to treat himself as he knew what was best for him, even declining a physical examination which I proposed making. He had been in Chicago hospitals, and also in those of San Francisco before coming here. One Sunday morning on my hospital rounds I entered his room, as he was in the act of drawing off his under-shirt, his back was towards me and the opening door caused a coughing spell, when I at once caught sight of the bulging intercostal spaces on inspiration and the greater extent of the right chest when compared to the left. The aspirator withdrew *seventy-four ounces* of pus. The patient made a tolerable fair recovery (having been ill two years), and was able to resume the practice of his profession, dying some two years afterwards from exposure during a cold winter in the mountains while in the arduous work of his profession. Now, here was an intelligent physician, well skilled in diagnosis, well read, and with great clinical and hospital experience in the hospitals of St. Petersburg and of Moscow—with seventy-four ounces of pus filling his right pleural cavity and he perfectly oblivious of the fact.

Another case had carried seventy-eight ounces of pus in the left pleural cavity for over a year, coming from the malarious plains of Italy in the meanwhile. The attack originating in a pleuropneumonia consequent on convalescence from a protracted attack of malarial fever. This patient was laboring under blood poisoning at the time of operation, and died about six weeks afterwards from that cause.

One case, also of great interest, a gentleman from Spokane Falls, Washington, had an attack of pleuro-pneumonia in December, 1889, which nearly took his life. From this he escaped with an hepatization of the lower lobe of the right lung, and extensive adhesions of the pleura to the side and back of the same side. His physicians, Drs. Essig and Manley, then advised a

change of climate, directing Southern California as the proper locality. The patient came here, and on the advice of one of the local physicians he departed for the mountains, to an altitude of some 3,000 feet. He then fell in the care of another physician. While in the mountains he failed very rapidly, and on the advice of his brother, from Spokane Falls, he finally decided to return to San Diego for other advice. On his arrival here his wife called upon me, and asked me as a favor, that if I found her husband past all help to tell her privately, and to advise a removal back to Washington, where he might die among his friends and relatives. On my examination I found a large framed man who had always been well up to the time of his present illness, had weighed 207 pounds, but was now emaciated and broken down; feet and legs œdematous, face puffy, hands also œdematous, very short breath and a constant cough. The left lung exhibited all signs of perfect physiological health, as well as the right, excepting a circumscribed spot of dulness about the size of a dessert plate in the rear and lower portion of right chest. The lower edge of the lung along the side seemed healthy and perfect, along the side and above that the same flat dulness was perceptible; the front was chequered with spots of dulness and resonance. I diagnosed the case as one of pulmonary abscess and decided on an operation, in which I was assisted by Drs. McKay, Davis and Magee, of this city. On our consultation it was hard to demonstrate the presence of pus by any of the usual symptoms or signs, as the pus was enclosed in a close and tight sac, which gave neither metallic tinkling, wave motion, bulging or any other sign. The first aspiration withdrew forty ounces of sweet pus, and a subsequent tapping with a large canula and trocar brought twenty-five ounces more. The cavity was then well irrigated with a solution of salt and water until the water was returned clear. The tube through the canula was then allowed to remain for eight days, the last five of which showed only a little discharge of pinkish fluid; canula, tube and all were removed and the puncture allowed to close. Two hours after the operation the patient was in the greatest comfort. The œdema of the face began to subside and the yellow tinge of the skin had disappeared. The pain in the knees and elbows with which he had been racked night and day, and the distressing cough all left him as if by magic, he rapidly picked up in strength and his temperature, which before the operation never was less than $101\frac{1}{2}^{\circ}$, fell to 98° in the course of two hours, and never again rose to 99° during the first eighteen days, after which he was allowed to leave his bed.

I am satisfied that the abscess was in its formative stage on his arrival in Southern Cali-

fornia, and that the mountain exercise and the practice of chest pounding to which his physician subjected him in pursuance of his form of practice (natural healing) hastened the formation of pus. The case was one of great interest, especially so from the obscurity with which the reading a diagnosis was beset, and the rapid recovery, to say nothing of the almost instant relief that followed the operation.

I agree with you in your remarks on plentomy. I have operated by the Peyrot method, but have every reason to prefer the aspiration even if persisted in after the method of Bulau. As to irrigation, I would not advise carbolic acid or the iodine washings; after either I have always noticed a tendency to temperature elevation, especially after carbolized water (very weak even, with the acid first well rubbed with glycerine, has never been satisfactory to me). I prefer common salt, an ounce to the quart or even much stronger is well tolerated.

Physicians do wrong to their patients in not advising them to call on a physician arriving at a health resort. The frequency of the occurrence of cases like the above would indicate the need of an occasional physical exploration, which in many cases would undoubtedly save many from an untimely grave.

CLINICAL OBSERVATIONS ON THE INGESTION OF BORACIC ACID AND ITS EFFECT ON THE SKIN, THE BORACIC ACID ERUPTION SO-CALLED.

Read in the Section of Dermatology and Syphilography, at the Forty-first Annual Meeting of the American Medical Association, held in Nashville, Tenn., May, 1890.

BY WM. T. CORLETT, M.D., L.R.C.P., LOND.,
PROFESSOR OF DERMATOLOGY IN WESTERN RESERVE UNIVERSITY,
CONSULTING PHYSICIAN FOR DISEASES OF THE SKIN TO
CHARITY AND ST. ALEXIS HOSPITALS, ETC.,
CLEVELAND, O.

In November, 1889, my attention was called to a rash occurring in diphtheritic patients treated with large doses of boracic acid. Dr. Sihler, in whose practice the cases occurred, informed me that it appeared after adopting the boracic acid treatment; he had never before seen the rash in diphtheria.

During the months of December, January and February following, I had the opportunity to follow five cases in the practice of the same physician. The onset, course and other clinical features of the rash appeared with marked uniformity. It made its appearance on the seventh or eighth day after the commencement of boracic acid. First on the forehead, neck and cheeks almost simultaneously; then it invaded the trunk and extremities in as many successive days. In its course it bore a close resemblance to rubeola.

Nor was its course the only resemblance it bore to this disease; the rash itself in color, form and distribution, presented a striking similitude to a mild case of measles. On the contrary, the rash was not elevated above the surrounding skin, and it was more itchy than rubeola usually is. It subsided gradually in the course of from three to five days.

That the rash might be due to the diphtheritic poison had occurred to me; to eliminate this, as well as to further test the effect of the drug on the skin, December 2, 1889, sixteen subjects were given the same quantity per diem (5j) as given by Dr. Sihler in the treatment of diphtheria. These subjects were selected from the different departments of the Polyclinic, and were seen from time to time by myself and colleagues. With two exceptions—*sycosis non-parasitica* and *psoriasis*—they were free from any eruption on the skin, and most of them were in a fair state of health.

At the end of a week three escaped from further observation; in four gastric disturbances—nausea, loss of appetite, etc.—were so marked that the drug was discontinued after a few days use. No effect was noticeable in the skin. A fortnight passed, one or two more dropped out, no rash.

Of the eight that continued a month, one presented a few itchy tubercles on the forehead. These tubercles involved the sebaceous glands, they were surrounded with a bright red areola, they remained stationary for a month, at which time the drug was discontinued. Of the sixteen, six continued the drug three months, and one seventeen weeks. This latter thought the treatment benefited some visual disorder, and continued with a tenacity worthy more brilliant results. In this case there appeared at the end of four months half a dozen itchy tubercles with a reddish areola, similar to those in the preceding. They were situated on the forehead, scalp and chest.

Boracic acid eruptions, or more properly, eruptions following the use of the drug, have been reported from time to time. These eruptions have differed widely in clinical appearance as well as in other characteristics.

Stillé says a pustular eruption sometimes follows the long continued use of boracic acid. Gower reports in *The Lancet* of September 24, 1881, two cases that developed a typical psoriatic eruption from its use, covering a period of one or two years. In these cases it was found that by adding a few drops of Fowler's solution the eruption disappeared. Morrow, in his admirable monograph on drug eruptions, cites in addition to the above, an instance in which a 4 per cent. solution used as an injection for several days was followed by an erythematous rash over the whole body. Two other instances are cited by the

same author of an erythematous rash over the face, trunk and extremities, after washing out the pleural cavity with a 5 per cent. solution.

Few drugs, if any, have the power of causing the wide range of eruptions herein cited as supposed to be due to boracic acid. Neither does there seem to be any uniformity as to time, or clinical features, in the cases reported. Gowers added arsenic to the boracic acid and the eruption left, which, as we know, might follow any scaly eruption from whatsoever cause.

Of the sixteen subjected to an experimental use of the drug, only two showed signs of a cutaneous disturbance; this is strange when we consider that in all there was marked disturbance of the gastro-intestinal tract, which of itself is capable of producing cutaneous lesions.

The eruptions in these two cases were similar; at the same time they were such as one frequently sees in the subjects of acne when suffering from gastric derangement.

So far then, as these observations go, they teach that if there be an eruption due to the ingestion of boracic acid, its presence is so inconstant; its clinical features are so ill-defined, as to leave grave doubts as to its entity.

THE METRIC SYSTEM AND THE SEVENTH DECENNIAL REVISION OF THE U. S. P.

Read before the Missouri State Pharmaceutical Association 1890.

BY H. M. WHELPLEY, M.D., PH.G.

It is probable that in less than two years the seventh decennial revision of the Pharmacopœia of the United States of America will be in the market and ready for the pharmaceutical and medical professions. The progressive druggists of the country will adopt it their law and guide in the manufacture of pharmaceutical preparations and the identification of all official substances. The doctors who are alive to the interests of the times will look to the pharmacopœia for all information that it contains for physicians.

Among the new features of the revised work will be the adoption of the metric system of weights and measures in the manufacture of preparations. The system of "parts" in the previous revision was more conveniently handled by the metric system than any other, but the new work will have the decimal system itself prescribed.

There seems to be some misunderstanding among the pharmacists of the country as to just what it means to thus adopt the metric system. Some have formed the idea that the doctors will then be obliged to write prescriptions in that system, and I have even talked with those who had conceived the idea that patients must give up the

old-fashioned drops, teaspoonsful, etc., for cubic centimeters. Let such persons learn, once for all, that the pharmacopœia is not a guide in prescription writing or dosing. The adoption of the metric system signifies that druggists are to use it in manufacturing the official preparations made in the drug store. They can buy them, sell them, dispense them, and dose them out in any manner they see fit, for it in no way affects the manufacture. The convention at Washington recognized the system as being the most convenient for druggists to use in this manner, and perhaps it will be many a day before the medical profession becomes sufficiently advanced to adopt it in prescription writing.

Still less excusable is the complaint that some druggists have made when they objected to the new system, as it would cause them to throw away their old scales and balances and buy new ones. Only those ignorant of the first principle of weights and measures could stumble into such a shallow complaint. As far as the weighing goes only the new set of weights must be added. I do not think that any scales or balances are sufficiently stubborn in their innate nature to refuse to respond to metric weights.

Again some one has objected to the metric system and refused to learn a new language for the sake of it. I think they must have studied "French in Twenty Lessons" or "German in Two Weeks" and become scared at the mere mention of a foreign word. It is, indeed, strange that it is necessary to answer such an objection as this, for the terms in the metric system are from the Latin and the Greek. These two languages go far towards making up all words we learn in pharmacy and medicine. Then, when we come to realize that the words "milligram," "gram," "cubic centimeters," "kilo" and "liter" are all that a druggist or doctor need learn, it is strange that any one should for a moment object to the system on the score of the language. In this connection I must quote from a committee of the American Association for the Advancement of Sciences, where it says: "For the use of these professions (medicine and pharmacy) six lines contains all that is necessary," as follows:

- 1,000 milligrams make 1 gram.
- 1,000 grams or cubic centimeters make 1 kilo or liter.
- 1,000 kilos make 1 ton.
- 65 milligrams make one grain.
- 15½ grains make 1 gram.
- 31 grains make 1 ounce troy.

I advise those who object to the metric system to devote a few minutes to its study before they continue to condemn it.

In becoming familiar with the metric system, first study the principle of the system and then learn its relation to other systems.

As nearly all of the text and reference books in pharmacy devote more or less space to the con-

sideration of the metric system, there is no excuse for a druggist saying he cannot find an explanation of the system. May the time soon come when they will all be familiar with it.

MEDICAL PROGRESS.

TREATMENT OF BLEPHAROSPASM.—This annoying and at times intractable affection is treated by Giraud (*Thèse de Paris*) by forcible dilatation. Under cocaine anæsthesia the lids are widely separated, by a pair of retractors, or a spring speculum. The separation of the lids is carried to the degree of exposing the conjunctival cul de sac, and it is maintained for three or four minutes. Only in rare cases must this procedure be repeated more than three or four times.

PHOTOPHOBIA CURED BY ANÆSTHESIA OF THE GASSERIAN GANGLION.—GUTTIÉREZ-PONCE, in the *Recueil d' Ophthal.*, relates the circumstances attending this somewhat novel procedure. The patient, a boy, aged 13, suffering from acute diffuse keratitis, was attacked with violent sneezing as soon as the lids were opened and light fell upon the cornea. This the writer attributed to direct irritation of the branches of the ophthalmic division of the fifth pair of nerves supplying the cornea. To overcome this condition a few drops of chloroform was instilled into the right external auditory meatus, and after a few minutes the eye could be opened and thoroughly examined without exciting sneezing.

POISONING BY FILICIS MARIS.—Up to the present three cases of poisoning by this drug have been reported; two of them proving fatal. A recent case reported by HOFMAN (*Wien. Klin. Wochenschr.*) is that of a little girl 5½ years of age, who was given 7.5 grams of the ethereal extract of filicis maris, for the removal of a tapeworm. At the end of one and one-half hour deep sleep ensued, which was followed at the end of three hours by convulsions and death. The post-mortem examination was negative; it simply showing a preëxisting miliary tuberculosis of the lungs and abdominal organs.

ANOSMIA.—DR. ZWAARDEMAKER, of Utrecht (*Schmidt's Jahrbucher*), presents a clinical analysis of the somewhat rare and by no means important disorders of olfaction. He divides the affection into four general groups: a. respiratoria, a. gustatoria, a. essentialis and a. intra-crania. Under essential anosmia he classes those from acute catarrhal inflammations of the nasal mucosa, toxic forms from poisonous gases or fluids, or those caused by absence of the peculiar pigment found in the region of the olfactory.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE.,
CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the Treasurer, Richard J. Dunglison, M.D., Lock Box 1274, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, DECEMBER 27, 1890.

CONCLUSION OF VOLUME XV.

With this number THE JOURNAL reaches the conclusion of its fifteenth volume. Seven and a half years have elapsed since the Association assumed the responsibility of publishing its Transactions in the present form. So far as we know, not a single member of the Association now dissents from the method then adopted.

Each year has witnessed a growth of confidence in the enterprise, until its permanency is reasonably assured. We come to the close of the present volume with a constantly enlarging list of contributors, with an increasing membership, and with an advertising patronage never so liberal as at this date. The members of the Association will be gratified to know that not only is THE JOURNAL free from debt, but that it has, of funds, enough in sight to enable it to close the financial year with a satisfactory balance in its treasury. The confidence of a generous advertising public is best indicated by constancy of its patronage.

It will be the aim of the Trustees, to whose supervision it is confided, to make THE JOURNAL more and more fully representative of every medical interest. It welcomes to its columns the proceedings of all medical societies in affiliation with the Association. It is in hearty sympathy with every effort for the advancement of medical education. It seeks the welfare of all legitimate practitioners, and welcomes to its files all medical journals which have at heart the upbuilding of the profession and the welfare of the people.

It seeks from the membership a generous support, and an earnest effort to increase its circulation and to enhance its usefulness.

THE MEDICINE OF THE FUTURE.

Attempts to forecast the future are notoriously involved in much difficulty and uncertainty. The advice of HOSEA BIGLOW: "Don't never prophesy unless you know," will always have more or less pertinency. Nevertheless, so long as curiosity continues to be as potent a motive as at present, the effort will probably continue to be made. He would have been a bold man who should have ventured to predict, fifty years ago, the progress that has been made in medical science and art, and it would certainly be unsafe to attempt to say what will not be accomplished in the next fifty or hundred years; but there are certain tendencies, at the present time, which may, perhaps, throw some light on the probable future course of events. If we compare the best specimens of the medical profession of to-day with their predecessors of a century ago, it may enable us to imagine, to some extent, in what way our successors of a century hence will differ from us.

Of course, the well educated physician of to-day knows a multitude of facts, of importance to him in his practice, of which the greatest men of the past had no conception. This, however, is not, to our mind, the most striking difference between the physicians of the present and of former days. A more important contrast may be found in the relative emphasis laid on the cure and the prevention of disease. Of course there are many survivals of a type characteristic of a bygone age, and it is not unlikely that skepticism in regard to therapeutics may have often been carried too far. Still, it may safely be said that there are very few intelligent physicians of the present day who feel anything like the confidence in their greatly increased resources for combating disease that was felt by the great body of the profession in the bleeding, blistering, purging and puking which made up the great part of the routine of medical practice within the memory of some now living, and, although the progress made in the treatment of disease is by no means to be despised, it can scarcely be questioned that it has consisted almost as much in abstaining

from mischief as in doing good. The records of the Massachusetts General Hospital seem to show that, allowing for differences in the class of patients treated, the death-rate from pneumonia in that institution has not varied very materially since it was opened. Cholera, yellow fever, scarlatina and typhoid fever, do not present any such lowering in the death-rate of those attacked as to be a matter for very much congratulation, and the multitude of remedies recommended for pulmonary consumption shows how unsatisfactory its treatment is. On the other hand, the mortality from cholera, yellow fever and typhoid fever, taking them as examples of diseases in which, until comparatively recent times, there was nothing that could be called an efficient prophylaxis, has been so reduced wherever proper sanitary measures have been carried out as to make it reasonably certain that nothing but the universal enforcement of such measures is needed for their complete extermination.

At first sight, surgery, in its various branches, may seem to be an exception to this rule, but the exception will be found to be more apparent than real. The advances in methods of diagnosis and in operative technique have been, in some departments, very great, but by far the most important difference between the surgery of to-day and that of a comparatively recent period consists in the intelligent application of means to prevent those diseases which formerly so often frustrated the best work of the surgeon. The therapeutics of pyæmia and septicæmia, when the source of infection is not accessible, cannot be said to have made any great advance; it is to the precautions against their occurrence that the greatly diminished mortality from surgical operations is mainly due.

Considered from this point of view, the comparison that is sometimes made between the advancement of surgery and medicine is not so much to the disadvantage of the latter as might, at first, appear. The surgeon, as such, only benefits those who come under his treatment; the sanitarian, even without official authority, may be able to preserve the health of numbers who, but for him, might have sickened and died.

During the last decade the death-rate in England and Wales averaged 1,144 per million less than during the ten years preceding—equivalent to a saving of about 30,000 lives per annum.

This is by no means the whole of the saving; a high death-rate implies a large amount of sickness among the survivors, with loss, not only of the time and earnings of the sick, but of those who are occupied in caring for them. There can be no reasonable doubt that the greater part of this immense saving is to be credited to the efforts of the medical profession directed to the improvement of sanitary conditions.

The superiority, even in the present state of our knowledge, of prevention to cure of disease comes out conspicuously in a comparison of the death-rates of Birmingham and Manchester. Both are manufacturing cities, of not far from equal population, and it is not to be supposed that there is any very material difference in the skill of the physicians of the two towns, taken collectively. Birmingham is widely known to be a remarkably well-governed city, in the thoroughness and efficiency of its sanitary administration as well as in most other respects, while Manchester bears a very different reputation. The death-rate of Birmingham is eighteen, and that of Manchester twenty-nine per thousand inhabitants—a difference of nearly 40 per cent.

Sanitary science is yet in its infancy, and the little knowledge we have has been applied, thus far, on a very limited scale. Whatever advance may be made in therapeutics, it seems safe to predict that the relative importance of preventive medicine will continue to increase for a long time to come, and that the physician of the future will be, to a far greater extent than at present, the adviser of his clients, rather than a tinker, called in to repair damages.

The applications of medical science to some of the most important and difficult social problems are just beginning to be dimly perceived. Although the practicability of a physical diagnosis of crime may, perhaps, be thought to be the dream of enthusiasts, it is becoming clear that the majority of habitual criminals and prostitutes consists of persons whose organization was originally defective, and who are only to a limited extent amenable to the motives that govern the conduct of persons of thoroughly sound mind. A recognition of this fact must, in time, work a great change in criminal jurisprudence. Here, again, it will, in time, be recognized that prevention is better than cure, and that cure is to be effected, if at all, not by penalties arbitrarily inflicted in

a spirit of revenge, but by a course of training scientifically adapted to substituting habits of order and industry for the lawless impulses of a defective character.

Inebriety, again, is coming to be recognized as not merely a vice, but at least equally a disease. The man who has saturated his body with alcohol for a series of years has not merely contracted an injurious habit; he has poisoned his nervous system until it is no longer equal to the effort of self-control that might reasonably be demanded of a healthy man.

These examples are enough to show that, in the not distant future, we may expect that the medical profession will afford a field for statesmanship of the highest order. It is not to be expected that the prejudices of ages will pass away at once, but truth will prevail in the end, and sooner or later it will be understood that the man who teaches his fellows how to preserve their own lives is at least as honorable as he who enables them to destroy the lives of others, or to gain possession of their property without compensation

EDITORIAL NOTES.

BLINDNESS IN RUSSIA.—There are said to be no fewer than 189,872 blind persons in European Russia, Poland, and the Caucasus. In Russia the proportion of blind per 10,000 inhabitants is 21; in the Caucasus it is 15 for men and 14 for women; while in Poland it is only 7. There are three regions in Russia where blindness is particularly prevalent—in the extreme north-west to the west of the White Sea, in the east near the Asian frontier, and in the west near the Polish frontier. The condition is said to be on the increase, chiefly owing, it is supposed, to the spread of purulent ophthalmia neonatorum.

THE FIRST INSANE ASYLUM IN CHINA.—A committee has been formed in Canton, under the chairmanship of Dr. J. G. Kerr, to obtain funds for founding an insane asylum for Chinese. At the present time there is no such institution in the whole of China, and at the missionary hospitals considerable embarrassment has from time to time been caused by the application of lunatics for treatment. In many instances these unfortunate persons have been left on the hands of the physicians, who have no suitable accommodation for such cases. Messrs. Deacon and Co.,

of Canton, will receive subscriptions, and the scheme is strongly advocated by Professor E. P. Thwing, of Brooklyn, New York.

AN ENLIGHTENED DONOR.—M. Alfred Nobel, who is described by the *St. Petersburg Medicinische Wochenschrift* as "the well-known Russian petroleum prince," has given a sum of 50,000 crowns to the Carolina Institute of Stockholm to be applied for the furtherance of experimental research in the sphere of medicine. A committee of Stockholm professors has decided that four-fifths of the interest shall be used every year in aid of scientific investigations on subjects connected with the healing art, the remaining fifth being allowed to accumulate to form a reserve fund.

A NOTE OF WARNING.—From the *British Medical Journal* we quote the following: At the first meeting, for the present session, of the Royal Physical Society of Edinburgh, the opening address was given by Dr. Sims Woodhead, retiring Vice-President. The subject was bacteriological science, and he uttered a word of warning in regard to the too hasty conclusions that were being rushed at in regard to the curability of tuberculosis pulmonum by the new method of Koch. He urged that while Koch himself had been able to support almost every thesis he had hitherto proposed, it was meanwhile necessary to wait till evidence had accumulated sufficiently to afford proof.

Observations on the pulse have shown that after injection the pulse is quickened, at the same time becoming soft, dicrotic and irregular. So compressible is it in some cases, that collapse can only be averted by the free exhibition of stimulants.

Some of von Bergmann's cases are said to have already relapsed. It is also stated that in a case of lupus under the care of Dr. Levy, which was shown as an example of complete cure, the disease recurred with great intensity a fortnight after the discontinuance of the injections.

At a meeting of the Berlin Society of Public Hygiene on November 24, Dr. Köhler summed up as to the discovery by saying that the remedy is unquestionably of considerable importance as an aid to diagnosis, but that, as regards its curative efficacy, the medical profession must suspend its judgment till more definite information, both as to the details of the treatment and its results, is forthcoming.

TOPICS OF THE WEEK.

MICRO-ORGANISMS IN GREAT CITIES.

Professor Tarnier, in his course of lectures on obstetrics, in 1890, referred to M. Miquel's researches on the relative abundance of microorganisms in different places. One to the cubic metre of air is the proportion at the top of a high mountain. In the Parc de Montsouris, in the south of Paris, M. Miquel found 480 microorganisms to the cubic metre of air, whilst in the Rue de Rivoli the proportion was 3,480. In a new room in the Rue Censier he found 4,500 to the cubic metre; more, that is to say, than in the centre of Paris in the open air. In a room in the Rue Monge, he counted 36,000, in the Hôtel Dieu 40,000, and in the Pitié, an older hospital, 319,000 microorganisms to the cubic metre. At the Observatory, Montsouris, 650,000 microbes were found in a gram (15 grs.) of dust; in the room in the Rue Monge the amount was 2,100,000. In the hospitals the proportion was so high that counting the number of microbes in a whole gram of dust was found to be impossible. The dust is the great conveyor of microorganisms. At 2 A.M., when a city is most quiet, the fewest germs are to be found in the air, at 8 A.M. the industry of domestic servants and dustmen has already made the air teem with germs. At 2 P.M. the proportion has again greatly fallen; at 7 P.M. it is once more high, for many houses are being "tidied up;" besides, sundry kitchen operations are unhygienic. Thus the "small hours," unfavorable in many respects to patients hovering between life and death, are the least septic of the twenty-four. The day proportions indicate that household duties cause more septic diffusion than is excited by traffic and industry.—*Brit. Med. Jour.*

THE NEW THEORY OF HEREDITY.

Scientific circles throughout the world have been somewhat agitated of late, by a new theory of heredity broached by the celebrated German biologist, Professor Weismann, of Freiburg. This theory is so subversive of current opinion on matters with which it deals, and assails so many beliefs that were previously deemed impregnable, that a brief review of the leading indications of the theory may not be inopportune.

Professor Weismann's theory seeks to explain what no doctrine of heredity has hitherto adequately accounted for—how a single microscopic cell, imbedded in the ovum of the mother, can reproduce parental characteristics even to minute details and frequently characteristics of grandparents or more remote ancestors. Darwin's doctrine of pangenesis attempted a solution of this problem by assuming that the cells of the body threw off gemmules which were ultimately concentrated in the reproductive cells, the germ cells thus becoming essentially co-substantial with the other cellular elements of the body. The doctrine of pangenesis never, however, held a very sure footing, and its overthrow only seemed to be awaiting the birth of the next biological theorizer.

Two leading principles underlie the basis of Weis-

mann's theory, both of which will strike some as being more in the nature of assumptions than as well-ascertained data for a far-reaching biological induction. The first of these is, that death is not a primary attribute of living matter, and the second is, that characters *acquired* by the parent are not transmitted to the offspring.

The protozoa, the unicellular organisms are, however, alone endowed with this immortality. Composed of undifferentiated protoplasm, apparently structureless, and with no unlikeness in parts save for the nucleus, these organisms yet essentially perform all organic functions. They may be dried up by frost or drought, but under appropriate conditions they resume their active life. The protozoon may of course be destroyed by fire or accidental agencies, or it may be eaten. It enjoys a potential, although of course not an absolute immortality; under the normal conditions of its environment death does not overtake it. Unfortunately, for the higher inferences the theory would otherwise encourage, the endowment of immortality does not pertain to the metazoa, the many-celled organisms; for, as soon as an organism is sufficiently ambitious to become many-celled it has practically sealed its fate, it has "put on mortality," a conclusion which will doubtless be exceedingly gratifying to the metaphysical pessimists. The metazoa arise from the protozoa by "unequal fission," through the failure of certain unicellular organisms to "divide completely." "The first multicellular organism," says the Professor, "was probably a cluster of similar cells, but these units soon lost their original homogeneity. As the result of mere relative position there arose division of labor, some of the cells were especially fitted to provide for the nutrition of the colony, while others undertook the work of reproduction." The outer cells of the cluster in constant contact with the nutritive medium would be differentiated for nutrition, while the inner cells would undertake the work of reproduction. In these latter cells the reproductive function would be so specialized that they would become the germ-cells, in the nucleus of which resides the germ-plasm. The possession of this would constitute these cells the immortal part of the metazoa. Thus the fundamental key to an interpretation of the facts of heredity lies, according to Weismann, in the "continuity of the germ-plasm." This germ-plasm is so stable that "it absorbs nourishment and grows enormously without the least change in its complex molecular structure," and heredity is secured by the transference from one generation to another of this exceedingly stable substance with a definite molecular and chemical constitution.

All this being so, acquired variations have no direct reaction on the unalterable germ-plasm, and are, therefore, not transmitted. The organism that has acquired one eyedness, or one leggedness, or circumcisedness does not transmit these characteristics, because both parent minus the parents' individually acquired characteristics, and offspring arise out of the same substance, and the offspring must of necessity resemble the parents,

But it will be asked how then do variations in organisms occur? Solely through natural selection, for each new organism combines the hereditary tendencies de-

rived from the male and female germ-plasms. This results in individual differences, which multiply in geometrical ratio, so that "in the tenth generation a single germ contains one thousand and twenty-four different germ-plasms with their inherent hereditary tendencies, and as continued sexual reproduction can never lead to the reappearance of exactly the same combinations, new ones must always arise."

Professor Weismann does not entirely deny the influence of external forces upon the germ-cells. In his essay on "The Continuity of the Germ-Plasm," we read: "I am compelled to admit that organisms may exert a modifying influence on their germ-cells." What he does deny is, that functionally-acquired variations or "soma-togenic" variations are not transmissible, only the "blastogenic" variations—the variations occurring in the germ-cells. In this way we understand why club-foot is hereditary, while one-eyedness is not.

Possibly the weakness of Weismann's theory lies in the unsatisfactory way in which it accounts for psychical evolution. How serious are the issues involved in the new theory is exemplified in the following quotation from Herbert Spencer's "Factors of Organic Evolution," which fairly represents the hitherto accepted theory of psychical evolution.

"If functionally-produced modifications are inheritable, then the mental associations habitually produced in individuals by experiences of the relations between actions and consequences, pleasureable or painful, may in the successions of individuals generate innate tendencies to like or dislike such actions. But if not, the genesis of such tendencies is, as we shall see, not satisfactorily explicable."

We refrain from indicating the interesting relations that could be established between this theory and the problem of disease-transmission, or from showing how syphilis and hare-lip originate in "blastogenic" modifications. We also refrain from indicating the exceptions that might be taken to Weismann's argument all along the line, or the objections that could be urged to almost every proposition. We are content if we have shown the great value Professor Weismann's views have been, in stimulating inquiry regarding the soundness of the foundations of any and all theories of heredity.—Editorial, *Physician and Surgeon*.

THE DEADLY CIGARETTE.

Death from cigarette smoking appears to be not uncommon amongst boys in America, according to the *Medical Record* of New York. It appears that two cases occurred during the last week in October; a boy aged 14 died, it was reported, of heart disease "superinduced (*sic*) by excessive use of cigarettes." A boy aged 16 hanged himself because his father refused to give him money to buy more tobacco. A year ago Dr. Broomhead reported a case where a boy aged 13 died presumably from the effects of cigarette smoking. Valvular disease of the heart was discovered after death. Our contemporary wisely adds that since it is not admitted that tobacco can cause organic heart disease, it must be inferred that cigarette smoking is fatal in boys who have cardiac or other dis-

ease already. Kjelberg has described a nicotine psychosis, in which depression and suicidal tendencies are often observed. It is more frequent in snuff-takers and tobacco-chewers than in smokers. We must not overlook the fact that many of the young gentlemen who smoke in America have other unhealthy habits, and their mode of living is often demoralizing. The same applies to many British boy smokers. Well-trained lads suffer less, and being well-trained are prevented from smoking to excess, if at all.—*Brit. Med. Journal*.

THE REDUCTION OF THE GENERAL DEATH-RATE.

There is a belief that the death-rate is reduced by modern civilization. It is interesting to be able to secure positive observations supporting this belief. It is well known that in England and Wales such observations have been made extending over a term of years. Earr's first life tables were based upon the mortality in 1838 to 1854 in England and Wales. Comparing this with the last life table, and we find that by the old table the mean life-time of males was thirty-nine and ninety-one one-hundredths years, while by the new table it is forty-one and thirty-five one-hundredths years, a gain of about a year and a half upon the length of life of each male. Hence a million males would live one million four hundred and thirty-nine thousand, *plus*, more years than during the period of the old table. The expectation of life at birth of females has been augmented by two and seventy-seven one-hundredths years. Two millions of population will thus live more than four millions more years than they would during the period covered by the old table; or sixty millions of people would live one hundred and twenty millions more years than they would have done at the beginning of the present century. Further, the gain in these lives is mainly between the ages of 25 and 65, the most valuable portion of life. According to Earr, the minimum value of each life is about eight hundred dollars. It is easy to see that the momentary gain from this reduction of death-rate has been enormous.—*American Lancet*.

CABLEGRAM RECEIVED DECEMBER 15, 1890.

A long cablegram received from Dr. Guiteras may be summarized as follows:

"A greater degree of caution is being observed, especially as to the selection of cases of pulmonary phthisis subjected to the lymph treatment. The results in this disease at least, are as yet inconclusive. Many cases are not decidedly improved. There is some risk of complication. Both pneumonia and meningitis have been observed. The general situation may be summed up by stating that a spirit of caution prevails in Berlin to-day."

DOMESTIC CORRESPONDENCE.

Hypnotism.

To the Editor:—I think you have done the profession a good service in bringing before it the excellent paper by Dr. Lackersteen on "Hypnotism," with the comments upon it by the able gentlemen who spoke at its conclusion. I regard as in the right line the suggestion of Dr. Lackersteen that a judicious committee be created to examine into the uses of the hypnotic state, together with its abuses also, and give public, authoritative protests against popular exhibitions of it by wandering mountebanks. As a popular affair the whole thing, in my judgment, should be stamped out as dangerous and destructive.

I had occasion, some years ago, to attend some of the exhibitions given by Carpenter in Tremont Temple. He had found in his travels several facile subjects, which he took from place to place, and with whom he did his most marvelous feats. His chief dupe was a tall, sandy-complexioned man, who was arranged to take his seat in the back part of the audience, and on a look from Carpenter would instantly lose self-control, and go over the backs of the seats before him and clamber upon the platform. Of course this made a sensation to start with.

Now it happened that this man was married, and his wife gave birth to a pair of twins in my presence as consulting physician. She, like him, was very nervous, and though there was nothing unusual in the confinement, had to crown all by a subsequent eclampsia, which was relieved by a little chloral and chloroform. One of the children, the smaller, appeared fairly well, while the other was fretful and cried most of the time, and died after a few weeks. When the wife was being confined the husband acted like a crazy man. He came into the room, but soon left and went down stairs, where I found him lying on his back on the lounge, writhing, kicking and pulling his hair, and moaning at a great rate. His face was red and his eyes suffused with tears. Now all this was without reason, unless we assume that the sight of his laboring wife hypnotized him into labor himself. Surely, in this case, the mountain labored without the appearance of a mouse even. I assured him that his wife was all right and he the father of a pair of boys, and got him out of his "symptoms." After this I had quite a long talk with him, only to be impressed with the sad destruction of mind which the habit of hypnotism is capable of producing, assuming that this man had any mind to start with. Frequently do visions of this almost demented creature rise to my mind, impressing me more and more with the delusions and damage of the dangerous habit, for either it reduces wise men to fools or makes fools the puppets for the sport of the more intelligent. In

either case, due professional dignity should frown on public exhibitions of strong wills making sport over human weakness. Respectfully,

E. CHENERY, M.D.

Boston, November 24, 1890.

Dr. Josephus Craft, of Cleveland, O., Claims to have Discovered the Identical Lymph of Dr. Koch.

To the Editor:—Through some experimental research that I was led to make about two years ago, in reference to a bacillicide, certain peculiar results were attained which surprised me.

Not being a man of wealth or leisure, nor having a Government appropriation to keep the wolf from the door, I was obliged to drop it for the time—thinking that perhaps I might take it up some time in the future and push it to a satisfactory completion if possible, with my limited means for doing such work.

Hearing of Dr. Koch's announcement of the discovery of a substance that would cure consumption, lupus, and other allied maladies, I beheld me that perhaps it would be well to follow up the experiments already begun.

When I read of the effects of his discovery, it impressed me forcibly that it was in the same field in which I had been looking. I thought that perhaps I might discover what would produce the same happy result. I immediately began on the same base I had left, "cutting and trying," all the time working with the same preconceived objective point in view. I have reached that point. Those results I have succeeded in establishing. Now I am not unmindful of the gravity of the astounding announcement I am about to make, especially if it be not true, when I say that I have discovered the identical lymph of Dr. Koch.

I have put the lymph to the crucial test upon rabbits and guinea pigs, and finally upon myself, with effects identical with those described by Dr. Koch. I find it to be a tremendously potent agent; so that .01 of a cubic centimetre, or even less, of what I denominate a 2 per cent. dilution, produces its characteristic effect.

I shall have to rely upon what I have gotten in a physiological state as yet, for I have not applied it to consumption, etc. Dr. Koch, in describing the effects of his lymph upon himself, says:

I injected .025 of a cubic centimetre in the upper arm. Three or four hours after the injection had been made, there was experienced a contraction of the limb, and at the same time there was a desire to cough, with dyspnoea. These symptoms increased rapidly, and four or five hours thereafter I experienced an unusually violent rigor, the shivering lasting nearly an hour, and was accompanied by nausea and vomiting. Temperature rose to 105.2°. After twelve hours the symptoms began to abate, and the temperature fell, and the following day became normal.

The heaviness of the limb and the lassitude continued for some days, during which time the arm into which the injection had been made continued painful and red.

The following is the effect of my lymph upon myself. I injected .50 of a cubic centimetre in the outside of my thigh at 9:45 P.M., retiring immediately. At 2 A.M. I woke with considerable dyspnoea and a desire to cough frequently. Took my temperature and found it 97°, pulse 84. I again retired, but could not sleep from nervous excitement, perhaps partly due to finding the effect of Dr. Koch's remedy "on time" in my own case. (Some of Dr. Koch's cases which have been treated since he was, experience a lowering of temperature below normal the first few hours.) After rising in the morning I found my temperature normal, pulse 86, dyspnoea and cough still remaining. At 9 A.M. I felt well enough to start out and see my patients.

Soon after starting I began feeling rigors with considerable general malaise. I continued my work until 1:30 P.M., when I was having decided chills, temperature 105.5°, pulse 104, some dyspnoea still remaining, with twinges of wandering pains, and waves of nausea coming and going, but no vomiting. At 5 P.M. temperature 102°, pulse 104, dyspnoea not all gone, occasional nausea, slight wandering pains throughout the body, point of injection getting red and somewhat painful. Retired early but felt nervous, with general weakness. Next morning no nausea, fair appetite, dyspnoea gone.

I am a healthy man, but have had in one of my nostrils for years a small epithelial sore, crusting over and exfoliating in a few days, to repeat the crust and again come off. This little sore became inflamed and tender, but has now dried up and no crust reforming. Now, this is my case from the effects of my lymph. The foregoing was Dr. Koch's case from the effect of his lymph.

My lymph is of a syrupy consistence, and in its more concentrated form slightly brownish in color, but in the diluted form for use is slightly smoky-looking, but transparent. Dr. Koch is using a much stronger solution than I, for he used only .025 of a cubic centimetre, while my largest injection was .50 of a cubic centimetre; the effects upon each of us, as can readily be seen, were very analogous.

In order to have the verdict of the medical fraternity upon this lymph, which I am sure is Dr. Koch's, I will immediately send samples for testing to prominent physicians in New York, Philadelphia, Cincinnati, Chicago, St. Louis and St. Paul.

By following Koch's directions, with the dosage of my lymph, you will realize just what you would with his lymph in his dosage.

Work will immediately be commenced here in the different hospitals, in conjunction with the physicians of this city. As soon as possible arrangements will be made for treating the sick generally. Respectfully,

JOSEPHUS CRAFT, M.D.

64 Streator Ave., Cleveland, O.

BOOK REVIEWS.

AMERICAN BULLETIN VISITING LIST.—This little volume is in some respects quite original, and we invite inspection, believing that many physicians will incline to the use of a book thus arranged. Its tables are ample and the new remedies are fully represented. F. A. Davis & Co., Publishers. 1231 Filbert Street, Philadelphia.

THE PHYSICIAN'S ALL REQUISITE TIME AND LABOR-SAVING ACCOUNT BOOK.—F. A. Davis & Co., Philadelphia. This is a combination of an account book and ledger—is at once condensed in arrangement and simple in its method of presenting the items of each and every account at a single glance. We commend the work in every thing except its name.

MISCELLANY.

SCIENTIFIC STUDY OF INEBRIETY.—The American Association for the Study and Cure of Inebriety will hold a series of monthly meetings, in the hall of the New York Academy of Medicine, for the medical study of Alcohol and Opium Inebriety. Special phases of this subject will be discussed each evening in papers by leading authorities, followed by remarks and reports. The first meeting was held on December 10, "The Relation of Life Insurance to Alcohol and Opium Inebriety," was presented. January 7, 1891, "Alcohol: its Physiological and Pathological Action, and its Use and Abuse in Medicine," will be discussed. "Inebriety, its Etiology and History," will be the topic for February 18. "The Curability of Inebriety, its Treatment and Relation to other Diseases," will be the subject for March 18. In April, "The Medico-legal Relations of Inebriety," will be studied. It is the purpose of this Association to confine these discussions entirely to the medical and scientific side, with the view of reaching some general conclusions from which more accurate researches can be made.

A cordial invitation is extended to all medical and scientific students to be present and join in this special study of the "Drink Disease and its Problems." Dr. T. D. Crothers, of Hartford, Conn., is the Secretary.

PROF. NICHOLAS SENN has resigned the professorship of surgery and surgical pathology of Rush Medical College, Chicago. The resignation was accepted at a meeting of the faculty previous to the college memorial exercises at Central Music Hall.
