ENUMERATIO

SPECIERUM VARIETATUMQUE GENERIS DIANTHUS:

CUM DIAGNOSIBUS FORMARUM MINUS COGNITARUM.

TRIBUS SILENEÆ.

Subtribus DIANTHEÆ.—Semina peltata, hilo faciali. Embryo rectus. Styli 2, a basi distincti.

1. VELEZIA.—Calyx anguste tubulosus, acute 5-dentatus, 5 vel 15-costatus. Stamina 5. Torus haud elongatus. Herbæ annuæ.

2. DIANTHUS. — Calyx multistriatus, 5-dentatus, bracteatus. Stamina 10. Torus saepius in gynophorum plus minus elongatus. Herbæ saepius perennes, rarius suffruticosæ.

3. TUNICA. — Calyx turbinatus vel elongato-tubulosus, obtuse 5-dentatus, 5 vel 15-costatus. Stamina 10. Torus parvus. Herbæ.

Genus DIANTHUS. — Calyx tubulosus, 5-dentatus, tenuiter et æqualiter multistriatus, nervis parallelis ad quodque sepalum 7, 9, vel 11 (3 in *Proliferastro*) parte membranacea inter 5 nervorum fasciculos; bracteis (*i. e.*, squamis calycinis) per paria calycem involucrum cingentibus, paribus inæqualibus. Petala 5; lamina abrupte attenuata saepius in unguem elongatum, integra multidentata vel fimbriata, rarissime retusa, elegantia saepe maculata. Stamina 10. Torus saepius in gynophorum stipitiforme plus minus elongatus. Ovarium uniloculare; styli 2, a basi distincti. Capsula cylindrica oblonga vel rarius ovoidea apice dentibus valvisve quatuor dehiscens. Semina orbiculata vel discoidea, supra convexa, compressa, concavave parum infra, ad medium faciei interioris planæ vel concavæ umbilicata. Embryo rectus, in albumine saepius excentricus. Herbæ perennes nonnunquam annuæ, rarius suffruticosæ, ramis articulatis, teretibus vel tetragonis, ad nodos tumescientibus. Folia exstipulata, angusta graminea, supremis subulatis, saepè glauca; marginibus scabris. Inflorescentia terminalis; flores solitarii cymoso paniculati fasciculati vel capitati, vulgo rosei pureive, nunc rubri, rare albi, nunquam lutei.

This genus is sufficiently marked off from *Velezia*, and is more nearly allied to *Tunica*. The generic description as given in the 'Genera Plantarum' is slightly modified to include Kunth's section *Kohlrauschia*, which has usually been included in *Tunica*: but, in the form and structure of the capsule and seeds, and the habit of the species, is nearer the type of *Dianthus*.

The genus is distributed through Europe, Temperate Asia, and N. and S. Africa.

Most of the forms are perennial; a few are annual or even biennial. The cæspitose habit of many of the perennial forms is due to the development of dense and leafy barren shoots, in which the internodes are almost suppressed. The rootstock produces barren shoots, and ascending flowering stems; the former, when not in the form of a rosette of leaves, are more or less decumbent from the crown, and curved away from the latter, so that the lower part of the stem is protected from fracture by the wind. The stems are either terete or angular, i. e., they may assume a cylindrical or prismatic form; in the latter case the number of the angles bears a definite relation to the phyllotaxis. As the leaves are opposite and decussate, stems that are not cylindrical have four angles. Angular stems are more frequently than not glabrous. In a few species the surface of the stem is viscid, but this viscosity is not confined to a glabrous surface. The barren shoots are more leafy than the ascending flowering stems, but they never become soboles or stolons. Throughout the genus the nodes are well-developed, and such as to give the stem a jointed appearance; and this is the more marked from the fact that the lamina springs direct from the stem without any intervening petiole. The internodes, which are almost suppressed in the barren shoots, in the flowering stems appear to bear some sort of relation to the leaves borne upon them, being sometimes equal in length to the leaves, sometimes double the length, and the ratio seems to obtain to the apex of the stem, where both internodes and leaves become shorter. Examples of shortened internodes are seen in the rosette of leaves at the base of the stem of *D. Caryophyllus*, in the fascicled leaves of the barren shoots of *D. plurarius*, and generically in the squamiform leaves beneath the floral organs. In the flowering stems of *D. longicaulis* the nodes are very distant. Since the intercalary growth is at its maximum, and persists longest at the base of each, in *Dianthus* similarly as it does in Grasses, it is at this point in the vicinity of the lower node of each internode, that is found localised heliotropic flexion. But certainly positive heliotropism is very feebly expressed in the genus. It is rarely that the stems spring as absolutely simple from the crown of the rootstock. They may affect a simplicity by a bifurcation deep in the cæspitose shoots at their origin, or by producing two divergent flowers at their termination. It may be difficult to determine to what extent their divergence from the rootstock is distinct, and how far the terminal capitulum may be reduced to a few flowers on a stem; perhaps a more trustworthy minor character is the acuteness of the angle of divergence near the base or apex. The characteristic mode of branching is cymose, frequently in dichotomies. It often happens in the upper part of the stem that the multiparous cyme, in impoverishing itself, continues as a biparous cyme, and that a biparous cyme degenerates in its turn to a uniparous cyme, developing only therefore one of its branches. Thus we see in some forms a biparous cyme terminating in helicoid or scorpioid uniparous cymes. The significance

of the tumid nodes will be appreciated when their internal structure as distinct from that of the internodes is elsewhere discussed.

*Leaves*.—The two leaves of each whorl are opposite. The successive whorls of two leaves alternate so as to produce the decussate phyllotaxis. In *Syringa* and *Sambucus* the leaves are similarly arranged. It is the most frequent of alternate whorls of two leaves, but in *Rhamnus catharticus* the two leaves of each whorl are usually at a slightly different level. The mature leaf is symmetrical, though in the aciculate leaves of a few species, such as *D. pinifolius*, this is not always patent: it is sometimes contorted at the base. Of the three parts of the typical leaf the petiole is absent; the absence of this is compensated for by the length of the sheath and the strength of the node. The midrib is usually strong, and determines, by its position in the mesophyll and its relative size to that of the leaf, the character of the laminar surface, whether plane, carinate, or canaliculate. If it is placed nearer the inferior surface of the lamina, the leaf may be both carinate and canaliculate, or it may be carinate and plane, according to the thickness; but a leaf that is canaliculate on the superior surface is never plane on the inferior. The leaves are connate at the base, and frequently contracted at that point, resembling in this respect those of *Lonicera*, but never approach the perfoliate modification. The form of the mature leaf is linear and grass-like; those of the barren shoots are generally longer and broader than those of the flowering stems. The latter are more or less elongate-linear, while the former approximate the lanceolate-linear form; apices more or less acute, often very acuminate. The glaucescence characteristic of so many species temporarily disappears on pressure of the leaf between the moist fingers. The margin is entire, but is not sharp, as in that of the leaf of grasses, and is often ciliolate. The leaves of some species are of firmer texture than others, occasionally almost crassulaceous. They are firm and rigid, and conduplicate in vernalation, and often remain triquetrous in aestivation, which is, however, more apparent than real, in consequence of the well-marked carination or prominent midrib. The cataphyllary leaf is represented in the well-marked leaf-sheath. This last partakes of the triplasic character of stipule, petiole, and scale. The uppermost leaves, distinct from the calyx, by some authors called bracts, are but squamiform modifications of the true foliage leaves. The true hypsophyllary leaves occur immediately beneath the floral organs, where they form an epicalyx of bracteiform scales, generally in two pairs.

*Bracts*.—These organs, above referred to, are very variable in form, texture, colour, and number. The number is not always constant in the same species, and where there are three pairs, the inferior pair are always longer and narrower than the other two pairs, thus approximating in form the uppermost leaves. The bracteiform appearance of the uppermost leaves, the variable form of the bracts themselves, the transformation of floral organs under cultivation, the gradual differentiation of the appendages of the caulomes, their character as accessories both of the nutritive and reproductive organs, demonstrate the truth of Goethe's law respecting

the metamorphosis of similar organs of plants. The study of the bracts themselves as a link in the continuity of the nutritive and reproductive organs exhibits remarkable relations. Growing close under the perianth, they form part of the flower: they resemble the leaves in their decussate arrangement, and the petals in their general contour. In their colour they exhibit also transitional characters; sometimes herbaceous, like the foliage leaves, sometimes stramineous or coriaceous, sometimes tinted purple or red, like the petals and calyx-teeth. They are generally four in number to each flower, but vary from two to sixteen. When there is but a single pair, they rather approximate in form the foliage leaves. It also appears that one of their functions in many species is to protect the delicate tissue of the calyx from perforation by insects attempting to reach the nectar from below, instead of approaching from above the flower, and by this means brushing the anthers and fertilizing the ovary. Bracts with mucronate points are generally closely applied to the tube of the calyx, whilst those forms with acuminate points are patent. Groups of allied species may be thus distinguished. The length of the bract is determined rather from its aristate prolongation than from the length of the lamina. How closely the differentiation of the appendages of the essential reproductive organs is related to the form and variation of the nutritive organs is seen in those cases where groups of organs or of their appendages are transformed into those of next higher or lower type under changed conditions of environment. From an organogenetic point of view Willkomm seems inclined to regard them as an artificial rather than a natural factor in classification. It is true that in the atypical subgenera the uppermost leaves partake often of a bracteiform nature, instead of remaining herbaceous up to the floral heads, e.g., in *D. prolifer* the floral head is surrounded with an involucre of submembranous bracts, whilst each flower, except the central, is rolled up in coriaceous scales of a similar kind.

*The Flower.*—The morphology of the entire plant, and particularly of the flower, is that most favourable to entomophilous cross-fertilization. For in typical forms the barren shoots springing from the crown of the rootstock are short and decumbent, and thus expose the ascending and conspicuous flowering stems. And these are simple and paucifloral, or slightly branched, thus distributing the inflorescence over a proportionally wider area. The inflorescence is always terminal, and consequently not concealed by the dense barren shoots. The flowers are for the most part specious; when solitary, they are large and conspicuous; when small, they are collected into dense fascicles. The general coloration of the flower, and the frequent variegation of the lamina of the petal, is an inducement to the most fastidious of hymenopterous passers-by, associated as it often is with the most fragrant perfume, and easy accessibility. In the solitary or geminal flowers of *Caryophyllastrum* the petals are repand, large and specious, slightly excavated, and well supported on the cup of the strongly-ribbed calyx; in the fasciculate inflorescence of *Carthusianastrum* and the capitular inflorescence of *Prôliferastrum* their close

apposition gives mutual support, and a large variegated area. The stamens and petals spring from an annular ridge of the torus encircling the gynophore, which latter is in the form of a prolonged axis between the calyx and the corolla. This ridge bears on its inner border a yellow, fleshy cushion, which is the nectary, and in its glands there is secreted the honey which attracts the fertilizing insects.

*Perianth.*—This consists of three parts—(1) the imbricated bracts; (2) the gamosepalous calyx; (3) the corolla of five distinct petals. The metamorphosis of the floral organs is well shown in the production of double flowers by cultivation. These double flowers in the carnations and pinks are produced by the assumption of a petaloid appearance by other organs. Not always, however, are the supernumerary petals either reverted stamens, or carpels, or petaloid sepals, but are instances of abnormal pleiotaxy, without reversion of essential organs to flower-leaves. The teratological tendency of the specific forms is towards petalody. The prolongation of the torus into a stipitiform gynophore seems to be analogous to the internode between the two successive whorls of foliage-leaves, and in this case separates the whorl of the calycine from the whorl of the corollary leaves.

*Calyx.*—Cylindrical, sometimes contracted above, occasionally as much as to become turbinate in form. It is multistriate, and the nerves are well-marked and parallel. The fasciculus of nerves to each lobe is bounded by a membranous part marking the division into sepals.

*Petals.*—Each of the two parts of the petal is quite distinct. The unguis is very pale; the lamina is bright-coloured, but frequently paler on the under surface. Chorisis in the petals is reduced to its simplest form, *viz.*, a capillary outgrowth at the junction of the lamina with the unguis, and is the homologue of the corona in *Silene* and the ligula in *Lychnis*. The segmentation of the lamina to such an extent as is seen in the fimbriate species is very unusual in flowers; and the retuse lamina of *D. glumaceus* is the least specialized modification of the laminar margin. In the same species petals may be entire and dentate, but they are never found in the same entire and fimbriate, or dentate and fimbriate.

*Stamens.*—The dichogamous development of the essential organs is usual throughout the genus, and thus functionally approaches the diclinous condition. In the individual flowers of the same plant the reproductive organs are almost invariably proterandrous, but this proterandry takes place at different times in the different flowers of the same plant; this is well seen in *D. deltoides*. This dichogamous mode of development undergoes a certain modification, to serve similar purposes in *D. Armeria* and other species. Though proterandrous functional activity is the form of dichogamy which generally obtains, it is not so well marked in this plant; consequently that modification obtains which is adapted in other cases to intercrossing among hermaphrodite flowers in which synthesis is the rule, *i. e.*, where the maturation of the stigma is synchronous with that of the anthers. The petals are grooved by the respective filaments of the five outer stamens. The colour of the anthers is as variable as

that of the laminæ of the petals; when the latter are dark, the anthers are often deep purple.

*Ovary.*—This organ is unilocular, with remains of apparent dissepiments. The styles are white and slender, and free at the base. The dehiscence of the capsule bears a more definite relation to the number of the styles and the phyllotaxis than to the other reproductive whorls.

Subgenus I. *CARTHUSIANASTRUM*.—Caudex annus v. perennis; perennibus turiones decumbentes steriles emittens atque multos caules adscendentibus floriferis. Folia bracteiformia (suprema) sub floribus laxa. Inflorescentia cymoso-paniculata, v. fasciculis dichotomis v. capitulis aggregatis. Calyx subcylindricus. Petala semper dentata. Torus parum elongatus.

Sectio I. *ARMERIUM*.—Herbæ annuæ. Caulesteretes. Bractæ 2. Calyx dentibus 9–11 nerviis. Petala barbulata.

1. D. *Armeria L.* Nym. Consp.  
var. *subhirsutus Schur.*—Plus minus hirsutus. Flores mayores.  
var. *armeriastrum Wolfn.*  
var. *pseudarmeria Wierzb.*  
var. *subacaulis Schur.*—Caules puberuli; flores atropurpurei;  
forma humilis.
2. D. *pseudarmeria M. B.* Nym. Consp.
3. D. *corymbosus Sib.* Nym. Consp.  
var. *Poiretianus Ser.*
4. D. *tenuiflorus Griseb.* Nym. Consp.
5. D. *glutinosus B. et Hld.* Nym. Consp.

Sectio II. *SUFFRUTICOSI*.—Perennes suffruticosi. Inflorescentia non densa; cymis paniculatis v. fasciculis dichotomis.

Subsect. 1. *TUBULOSI*.—Calyce apice non attenuato.

6. D. *arboreus L.* Nym. Consp.
7. D. *fruticosus L.* Nym. Consp.
8. D. *pendulus B. et Bl.* Boiss. Fl. Or.
9. D. *actinopetalus Fzl.* Nym. Consp.
10. D. *elegans d'Urv.* Nym. Consp.
11. D. *Bisignani Ten.* Nym. Consp.
12. D. *virgatus Pasq.* Nym. Consp.—Caules 60 centim., ramosi.  
Folia elongato-linearia, acuminata. Inflorescentia dichotome paniculata, rosea. Bractæ 12, ovatæ, acutæ, adpressæ.
13. D. *Bertolonii Woods.* Nym. Consp.—Caules 60 centim., ramosi.  
Folia linearia, acuta, carnosa, carinata. Flores fastigiati.  
Bractæ 8, lanceolatæ, acuminatæ ad  $\frac{1}{4}$  calycis longitudinem.
14. D. *juniperinus Sm.* Nym. Consp.
15. D. *aciphyllus Sieb.* Nym. Consp.
16. D. *rigidus M. B.* Nym. Consp.

Subsect. 2. CONTRACTI.—Calyce apice attenuato.

17. D. Friwaldskyanus *Boiss.* Nym. Consp.
18. D. gracilis *S. et S.* Nym. Consp.

var. *ponticus Wahl.*

Subsect. 2. CARTHUSIANOIDES. — Folia stricta. Bracteæ siccæ.  
Calyx dentibus lanceolatis. Petala obovato-cuneata, barbulata.

36. D. carthusianorum *L.* Nym. Consp.  
var. prox. 'eu-carthusianorum.'  
a. *eu-carthusianorum L.*

- b. nanus *Swt.* — Caules pauci 7 centim. Bracteæ flavæ, nunc brunneæ. Lamina =  $\frac{1}{2}$  unguis, purpurea.
- c. humilis *Brügg.* — 10 centim. Folia elongato-linearia, 10 mm. Lamina alba =  $\frac{1}{2}$  unguis.
- d. vaginatus *Vill.*
- varr. prox. ‘atrorubens All.’
- e. carmelitarum *Reut.*
- f. anisopodus *Ser. mss.*
- g. Pontederæ *Kern.* — Folia radicalia linearia, caulinia elongato-linearia, vaginæ longitudine 4-plo longiore latitudine. Inflorescentia fasciculis 6–12 florum. Calyx dentibus triangularibus. Lamina =  $\frac{1}{2}$  unguis, supra rubello-purpurea infrà rosea.
- h. sanguineus *Vis.*
- i. atrorubens *All.* — Folia elongato-linearia, vaginis purpureis caulis diam. duplo longioribus. Inflorescentia densa. Lamina =  $\frac{1}{2}$  unguis, atrorubens.
- j. pauciflorus *Briigg.* — 38 centim. Fasciculis 2–6 florum. Lamina =  $\frac{1}{2}$  unguis, atrorubens.
- k. chloæphyllus *Schur.* — Glaucus 13 centim. Folia elongato-linearia; vaginâ caulis diam. 3-plo longiore. Lamina rubra.
- l. congestus *G. et G.*
- m. roridus *Schur.* — Folia elongato-linearia. Inflorescentia capitulis 6–8 florum purpureorum. Lamina =  $\frac{1}{2}$  unguis.
- n. saxigenus *Schur.* — Caules 38 centim., numerosi, scabri. Folia elongato-linearia. Inflorescentia capitulis 2–6 florum purpureorum.
- o. australis *Panc.* — Caules puberuli. Folia radicalia elongato-linearia, caulinia linearia. Inflorescentia fasciculis 6–12 florum purpureorum.
- p. minor *Schur.* — 19 centim. Bracteæ flavæ scariosæ. Lamina purpurea.
- q. pratensis *Ptck.* — 30 centim. Folia linearia. Bracteæ flavæ. Lamina purpurea.
- varr. prox. ‘consanguineus’ (bracteis oblongo-ovatis).
- r. consanguineus *Schur.*
- s. subfastigiatus *Schur.* — Caules 36 centim., suprà teretes. Folii vagina caulis diam. 4-plo longiore. Inflorescentia fastigiatocapitata. Bracteæ flavæ.
- t. rupicolus *Schur.*
- u. lancifolius *Schloss. et Vukot.*
- varr. prox. ‘pumilus’
- v. sabuletorum *Heuff.*
- x. pumilus *Schur.*
- varr. prox. ‘ferrugineus.’ — Bracteis diam. trans. æqualis apice basique, lateraliter per marginem, paralleli-planis.
- y. gramineus *Schur.*
- z. ferrugineus *L.*

- a<sup>2</sup>.* *tenuifolius Schur.* — Caules tenues. Folia linearia. Inflorescentia capitulis 2–6 florum rubrorum.  
 varr. prox. ‘ atrorubens Jacq.’
- b<sup>2</sup>.* *ternatus Schur.* — Caules 64 centim. Inflorescentia fasciculis ternatis. Bracteæ rubræ. Lamina =  $\frac{1}{2}$  unguis.
- c<sup>2</sup>.* *surulis mihi.* — Folia acicularia; vagina rubra, caulis diam. 4-plo longiore. Flores utroque capitulo 4–6. Lamina purpurea.—Transsylvania austr. Herb. Kew.
- d<sup>2</sup>.* *vaginatus Ch.w.* cf. *d.*
- e<sup>2</sup>.* *giganteiformis Borb.*
- f<sup>2</sup>.* *atrorubens Jacq.* — Caules 30 centim. Folia linearia; vagina caulis diam. triplo longiore. Inflorescentia capitulis 3–6 florum atrorubentium.
- varr. prox. ‘ vulturius.’
- g<sup>2</sup>.* *alpestris Balb.* — Inflorescentia capitulis 4–6 florum atrorubentium.
- h<sup>2</sup>.* *glaucocephalus Wierzb.*
- i<sup>2</sup>.* *subalpestris Schleich exs.* — Inflorescentia capitata. Bracteæ flavæ. Lamina suprà purpurea, infrà flava.
- j<sup>2</sup>.* *parviflorus Schur.*
- k<sup>2</sup>.* *vulturius G. et T.*

37. D. *Knappii A. et K.* Nym. Consp.  
 var. *rosulatus Borb.* — Folii vagina atque calyx purpurei.
38. D. *ambiguus Panc.* — Glaber. Caules simplices 4-angulares. Folia elongato-linearia, acuminata, plana 3-nervia, vagina caulis diam. 4-plo longiore, patentia. Inflorescentia capitulis densis 22–28 florum. Bracteæ 4 ad calycis apices mucronatæ, patentia. Calyx purpureus, dentibus acuminatis 9-nervis.—Serbia.
39. D. *Schlosseri mihi.* Hb. Mus. Brit. coll. Schlosser apud Janobor in Croatia.—Glaber. Caules 45 centim., teretes, simplices. Folia elongato-linearia, acuminata 3-nervia, adpressa; vagina caulis diam. duplo longiore; radicalia 100 mm., caulinia 70 mm. Flores capitati. Bracteæ 6, obovatae ad  $\frac{1}{3}$  calycis partem mucronatæ adpressæ. Calyx purpureus apice attenuato.

var. humilis *Nym.*

var. alpinus *W. et L.*

var. nivalis *W. et L.*

213. D. Langeanus *Willk.* Willk. et Lange, Prod. Fl. Hisp. iii.

Subsect. 4. PUNGENTES.—Caules simplices. Bracteæ acuminatæ.

214. D. graniticus *Jord.* Nym. Consp.

215. D. leptoloma *Steud.* Steud. in Pl. Schimp. Abyssin. iii. (1761).

216. D. pungens *G. et G.* Flore Française (*non* Linn. Sp. Plant.).

217. D. serratus *Lapeyr.* Abr. Pyren. 241.—Caules 4-angulares.

Folia acuminata, elongato-linearia, 3-nervia, stricta, radicalia 24 mm., caulinia 30 mm. Flores geminati, rosei. Bracteæ lanceolatæ ad dimidium calycem patentes. Calyx rubellus. Petala non contigua, lamina dentata.

218. D. acuminatus *mihi* (*nomen vetus revictum*). Syria.—Cæspitosus, glaber. Caules teretes. Folia elongato-linearia acuminata patentia 5-nervia, inferiora recurva, superiora incurva; vaginæ folii diam. æquante. Bracteæ lanceolatæ ad dimidium calycem. Calyx dentibus lanceolatis.—Hb. Mus. Brit., Aucher-Eloy, no. 526.

219. D. sphacioticus *B. et Hld.* Nym. Consp.

220. D. lactiflorus *Fzl.* Boiss. Fl. Or.

221. D. judaicus *Boiss.* Boiss. Fl. Or.

222. D. benearnensis *Loret.* Nym. Consp.

223. D. liboschitzianus *Ser.* Boiss. Fl. Or.

var. integrerrimus *Bge.*—Folia latiora. Bracteæ in aristam longiorem calycem subæquantem. Lamina obovato-cuneata, integrerrima.

var. multicaulis *B. et Hldr.*

Subsect. 5. GYMNOCALYX.—Caules ramosi. Bracteæ minutæ scariosæ, adpressæ, arista incurrente  $\frac{1}{3}$  calycis.

224. D. cinnamomeus *S. et S.* Nym. Consp.

var. pallens *S. et S.*

225. D. leptopetalus *W.* Nym. Consp.

226. D. subacaulis *Vill.* Nym. Consp.—Cæspitosus, glaber. Caules 8 centim., furcati, 4-angulares. Folia 22–24 mm. patentia canaliculata; vagina caulis diam. æquante. Calyx purpureus apice attenuato dentibus lanceolatis mucronatis. Petala purpurea contigua, lamina integra obovato-cuneata, = unguis.

Subgenus III. PROLIFERASTRUM.—Herbæ annuæ. Folia bracteiformia (suprema) sub floribus densa. Flores capitati. Bractæ 2. Calyx 15-costatus, apice pentagono attenuato. Petala retusa. Torus parvus. Capsula oblonga.

- 227. D. Cyri *F. et M.* Ind. iv. Hort. Petrop. p. 34.
- 228. D. glumaceus *B. et C.* Boiss. Fl. Or.
- 229. D. obcordatus *R. et M.* Boiss. Fl. Or.
- 230. D. prolifer *L.* Nym. Consp.
  - var. scabrifolius *Clav.*
  - var. laevis *Clav.*
- 231. D. velutinus *Gus.* Nym. Consp.
  - var. Sartorii *Frhl.* Ellwang, Sartori 240.

The investigation of a natural genus and of the specific forms which it includes, and the close study of the special morphology of such a genus, often throw a light on the physiological significance of a much larger section than that which comprises the forms under observation. It is for this reason, therefore, that it is interesting to note the various forms, referable to a natural genus, existing under various conditions of climate and locality, and subjected to the diverse circumstances of their environment. As soon as we begin to group morphological facts into general propositions, we cannot fail to recognise *a posteriori* what was to be expected *a priori*, the indefiniteness of distinction. And though the general phases of organisation in allied species may appear to mark off one from another, it is impossible to separate absolutely groups of characters which structural affinity links. It is by these means that we are enabled to see the gradual differentiation of allied forms from a few or one primary form after a succession of generations under favourable conditions or otherwise for the modifications of certain organs: for Evolution, whether referable to the vegetal, animal, or social organism, implies insensible modifications and gradual transitions.

*Dianthus* is a genus in which very many species can most readily be crossed, and which lend themselves easily to variation and hybridity; though the correspondence between systematic affinity and the facility of crossing in other genera is by no means strict: for in the allied genus *Silene*, which contains a much larger number of species, and in which the systematic affinity is as well developed, the most persevering efforts have failed to produce between extremely close species a single hybrid. DeCandolle considered plants of the same species (1) to have in common numerous and important characters, which are permanent during several generations, under the influence of varied environments; (2) to have flowers easily fertilising among themselves, and producing seeds most usually fertile; (3) to be affected by temperature and other external agents in a similar or nearly similar manner; (4) in short, as plants of similar structure, known certainly to have descended from a common stock for many generations. These data lead up to Darwin's conclusion that botanical species are only a higher and more permanent class of varieties. The gradation of varieties by art, with consequent

deterioration of organs essential to the natural maintenance of the species, seems to be done with equal efficacy, though more slowly, by nature, without such deterioration of vital parts, and adapted for the balance of their internal relationships with those of the environment; and resulting in the formation of varieties, which, fertilizing among themselves, and remaining permanent through successive generations, ultimately attain to specific rank.

In this genus the less constant characters, and for this purpose more valuable for the better diagnosis and distinguishing marks of the species are—the number and form of the bracts forming the epicalyx, the form of the lamina of the petals and their apposition, the character of the calyx-teeth, the form and structure of the capsule, the form and structure of the seeds, and the disposition of the fascicles of veins in the leaves of the barren shoots and flowering stems. Characters more constant are—the form of the calyx, the nature of the margin of the lamina of the petals, presence or absence of a beard at the junction of the lamina with the unguis, the relative lengths of the petals, filaments, and styles of the flower, the breadth of the vagina of the leaf, and the disposition of the flowers.

From the materials accumulated for a monograph on the genus I have made this abstract in advance, and hope to work out its completion shortly. Great difficulty has been experienced in determining a *via media* in the matter of species; in avoiding the tendency to species-splitting to which the systematist is liable, as well as the habit of lumping allied forms more congenial to the synthetical botanist. The wholesale exclusion of synonyms far exceeding the number of specific forms has itself entailed much research. For the purposes of its study I have made use of all the available material in the Herbarium of the Museum of Natural History at South Kensington, in the Kew collections, in the National Herbarium at the Jardin de Plantes in Paris, and in the Botanic Garden of Brussels; as well as from many recent specimens kindly sent by botanists. I have especially to thank the late Prof. Josef Pancic, of Belgrade, for a valuable collection of specimens from Servia, Bulgaria, and Roumania.

And here I am led to believe, as many others have found, that the deeper one pursues researches into any single small group of animals or plants, the more one is impressed with the consistent phenomena of variation, even when carried into the minor details of natural processes. As Herbert Spencer says, these phenomena are unobtrusive while the fairly-uniform conditions of a species maintain fair uniformity among the physiological units of its members; but they become obtrusive when differences of conditions, entailing considerable functional differences, have entailed decided differences among these units; and when the different physiological units, differently mingled in every individual, come to be variously segregated and variously combined.
