University of Maryland

University of Maryland Theses

Early Doctor of Medicine and Doctor of Physic Dissertations with  
Corrected Tables of Contents

These manuscripts described as either an Inaugural Dissertation or an Inaugural Essay were submitted to the University of Maryland for the Degree of Doctor of Medicine and/or Doctor of Physic during the years 1813-1887. The individual dissertations were bound together during the 1940's. The original tables of contents for the bound volumes contained multiple errors in authors' names, titles, and/or years. To address these errors, an additional "Corrected Table of Contents" has been inserted at the beginning of each volume.

The project team who investigated and corrected the tables of contents were: Richard J. Helle, Historical Librarian/Preservation Officer; Maria Milagro Pagan, Metadata Management Librarian; Angela Cochran and Carol Hurling-Henry, Preservation Division; Sarah Rowley, Asset Review and Megan Wolff, Services Division.

These dissertations were digitized in 2011-2012 and are available at the UM Digital Archive ([www.library.umd.edu](http://www.library.umd.edu)) and the Internet Archive ([www.archive.org](http://www.archive.org)).

University of Maryland Theses

Early Doctor of Medicine and Doctor of Physic Dissertations with  
Corrected Tables of Contents

These manuscripts described as either an Inaugural Dissertation or an Inaugural Essay were presented to the University of Maryland for the Degree of Doctor of Medicine and/or Doctor of Physic during the years 1813-1887. The individual dissertations were bound together during the 1940's. The original tables of contents for the bound volumes contained multiple errors in authors' names, titles, and/or years. To address these errors, an additional "Corrected Table of Contents" has been inserted at the beginning of each volume.

The project team who investigated and corrected the tables of contents were Richard J. Behles, Historical Librarian/Preservation Officer; María Milagros Pinkas, Metadata Management Librarian; Angela Cochrane and Carol Harling-Henry, Resources Division; Sarah Hovde, Abra Schnur and Megan Wolff, Services Division.

These dissertations were digitized in 2011-2012 and are available at the UM Digital Archive ([archive.hshsl.umaryland.edu](http://archive.hshsl.umaryland.edu)) and the Internet Archive ([www.archive.org](http://www.archive.org)).

Berry, John	Hydrocele of the Tunica Vaginalis Testis
Stuart, Joseph N.	Tetanus
McCeney, Edward	Icterus
Wilson, Paca	Causes of Sudden Death and the Means of Preventing It

---

<sup>1</sup> Additional notes on the subject of this thesis are found written in pencil, upside down, and in reverse order on the verso of the last four leaves of the thesis. It is not clear if these notes were meant to be a draft, or if they were written as an afterthought on the subject by the author or another person on a posterior date.

In speaking of Apoplexy, the disease of which am about to treat, I shall not pretend to claim originality. The disease has been called by several different names, or more properly, several diseases have been confounded with Apoplexy viz. Lethargus, Catalepticus, Carus, and Coma, these are supposed to be the same disease, differing in degree only; but of these it is not my intention to speak, therefore I shall confine myself strictly to Apoplexy. The term Apoplexy has been given the disease from the suddenness of its attack, it is derived from the Greek words  $\alpha\pi\omicron\lambda\epsilon\chi\eta$  which signifies upon an  $\alpha\pi\omicron\lambda\epsilon\chi\eta$  to strike suddenly. In this disease the whole of the external and internal <sup>senses</sup> ~~senses~~ and the whole of voluntary motion, are in a great degree abolished, while respiration and

<sup>4</sup>  
the action of the heart continues to be performed  
it has also been called by the Latins Morbus Attenu-  
tus they have also called it Liceratio from a belief  
that it was produced by planetary influence

D. Buller has placed this genus of disease in  
the class Neuroses and the order Comata he has also  
taken notice of nine Genera of this disease beside those  
which are symptomatic. First. Apoplexia Sanguinea  
and this he defines to be universal Plethora with a  
determination of blood to the head Second. Apop-  
lexia Serosa which generally happens in old  
and Leucophlegmatic persons. Third. Apoplexia  
Hydrocephalica in this genus the disease is produced  
by the pressure of water upon the brain Fourth

5  
Apoplexia Atrialiaris observed in Atrialiaris  
or melancholic temperaments Fifth Apoplexia  
Traumatica when the head is injured by violent  
external force Sixth Apoplexia Venenata from poison  
ous matters whether taken internally or applied  
externally Seventh Apoplexia Mentalis from passion  
of the mind Eighth Apoplexia Cataleptica in  
which respiration is not stertorous and though  
the limbs maintain any occasional position  
give way to force applied to them Ninth Apoplexia  
Suffocata as happens from hanging or drowning.  
The division of the disease into so many genera  
tends more to confuse than to instruct the young  
practitioner. Apoplexy most frequently attacks persons  
at an advanced age and Dr. Cullen says especially

<sup>6</sup>  
those above sixty years of age but a great majority of  
the cases which I have seen have occurred in persons  
under fifty and in those of short necks and flatthoracic  
habits and who have passed a sedentary life and used  
a full diet. Those who have been intemperate both in  
~~eat~~<sup>diet</sup> and drink or those who have indulged in one  
and not in the other have been attacked by the  
disease. The sudden suppression of an accustomed haemorrhage  
monstrous. The most frequent precursory symptoms  
are fits of giddiness, head ache haemorrhage from the  
nose some transitory interruption of vision and  
hearing and these two senses are also false in some  
cases a fluttering of the tongue frequent drowsi-  
ness and repeated attacks of incubus but these  
precursory symptoms are by no means uniform for the

for the disease in some cases suddenly attacks the patient without those symptoms having appeared but when these symptoms do occur they enable us to foresee the impending danger and to avert its fury by a proper attention to the present state of the patient's system and by a due regard to regimen we may enable one if not entirely to escape this too fatal disease at least to evade its attack longer than he otherwise would have done. When the disease has come on suddenly it has <sup>been</sup> frequently observed to have been induced by violent exercise. this remark I have seen verified in the case of a Farmer who though for some time previous to ~~the~~ <sup>his</sup> attack had led a very active life: had in the earlier part of his life been quite sedentary in consequence of his avocations at that time and had in the whole

of his life been a very free liver and by these two latter causes had acquired a predisposition to the disease he was of a plethoric habit answering very well the description already given of those most liable to the disease This gentleman after a severe exercise of almost a whole day was suddenly attacked in the absence of any premonitory symptoms of the approach of this malady. Although says Dr. Cullen the whole of the body is affected with the loss of sense and motion it sometimes takes place more upon one side than on the other and in this case the side least affected is frequently convulsed. Stertorous breathing is often present and has been supposed to indicate the violence of the disease but this is denied as it has not at all been present in a complete and most violent

state of the disease. After having thus enumerated most of the principle symptoms of the disease we will now advert to the causes and first to the proximate cause which has been defined to be whatever interrupts the motion of the nervous power of the brain to the muscles thereby destroying voluntary motion or so far as sense is affected whatever interrupts the ~~sentient~~ ~~communication~~ the motion of the nervous power from the sentient extremities of the nerves to the brain. Such interruptions are said to be produced by some compression of the origin of the nerves or by something destroying the mobility of the nervous power the loss of sense and motion in particular parts of the body may be occasioned by a compression

of the origin of the nerves going to that part or by  
 compression of the same nerves at a point inter-  
 mediate between their origin and the part diseased  
 by such compression. Compression of the origin of the  
 nerves may be produced in different ways viz:

by a depression of a part of the Calvaria. A congestion  
 of the vessels of the brain has also been said to ~~have~~  
 produced it but on this subject there is a contrary  
 of opinion. It is Dr. Nathaniel Putter's opinion that  
 this is a frequent cause of the disease. It has on the  
 contrary been maintained by Dr. Davidge as well  
 as other distinguished Physiologists that a congest-  
 ion of the vessels of the brain never does take place.  
 It may be produced by tumours either of the bone  
 or soft kind

If compression of the origin of the nerves be from a depressed portion of the brain case it is to be removed but this operation more properly appertains to surgery

The consideration of bony tumours and also of fleshy tumours may be omitted as in most instances they are neither to be discerned nor cured by any means. The effused fluids are of two kinds they may be either a portion of the common mass of the blood poured out by vessels carrying red blood or it may be serum or a fluid resembling serum which is poured out by the exhalants. This fluid alludes to resembling serum has been supposed not to be serum but to be a fluid changed by the action of the small vessels from which it escapes however be it serum or a changed fluid it makes no change of treatment in the disease these effusions have been said to be pro-

12  
duced by whatever ~~can~~ increases the impetus  
of the flow of blood in the arteries of the head the  
same cause has been ascribed to the congestion of the  
blood vessels of the brain this is a probable cause if  
congestion of these does ever take place but as there  
is a difference of opinion on this subject among  
the most enlightened Physiologists it therefore cannot  
be expected that one of my inexperience would  
presume to hazard an opinion in opposition to  
either of the parties who thus dissent. An impediment  
in the free return of blood from the vessels  
of the brain has also been enumerated among  
the causes of effusion of serum. There are two  
other causes of this serous effusion. The one is  
a relaxation of the exhalants. The second is an  
over proportion of watery parts in the blood.

which is therefore ready to mind of by the exhal-  
 ants - but whether corporeal be produced  
 by a serous or a sanguine effusion the indicati-  
 on of cure are the same or nearly so so besides  
 these, other causes are taken notice of by authors  
 as the Mephitical arising from fermenting  
 liquors the fumes which arise from Mercury  
 lead and other metallic substances have  
 produced it. The means of prevention of those  
 noxious poisons is I think very correctly given  
 in the 115<sup>th</sup> Sec: of the 1<sup>st</sup> lines of the practice by  
 Dr. Cullen and I think it need not be surpris-  
 ing here to transcribe it I believe says the D.<sup>n</sup> their  
 immediate and direct action to be on the nervous  
 power destroying its mobility because the same  
 poisons show their power in destroying the

irritability of the muscles and of the nerves con-  
 sists <sup>with</sup> them when both of these are entirely separate  
 from the rest of the body. Having thus taken notice  
 of the chief causes of Apoplexy and of its symptoms  
 I shall now proceed to give the treatment when there  
 is evidently a predisposition to the disease all  
 exciting causes ought carefully to be avoided the  
 most common causes of the disease have been ~~also~~  
 already stated the immoderate use of spirituous  
 liquors ought also to be carefully avoided an indulg-  
 ence of the appetite in high seasoned dishes must  
 be restricted in short all the causes calculated  
 to induce Plethora should be avoided but when  
 this Plethora or in other words this predisposition  
 to Apoplexy is either hereditary or is acquired by  
 intemperance in eating or drinking remedies

should be employed for its cure if it be produced by  
 intemperance the cause should be removed and  
 bloodletting and abstinence from animal food  
 should be enforced. The mode of bloodletting has  
 been considered of importance some have recom-  
 mended it to be taken from the Jugular vein from  
 the temporal artery &c. the operation <sup>of</sup> Venæ Section  
 has also been thought more effectual when per-  
 formed in the side opposite to that most affected  
 but I think for the sake of dispatch the arm most  
 convenient to the Physician should be bleed  
 from. Purging is also a very important remedy  
 this should be attempted by stimulating inject-  
 ions and if the power of deglutition remain  
 active Cathartics should be administered Emetics  
 have been recommended but these have been

objected to on the presumption that it would  
 impel the blood to the brain with so much vio-  
 lence as to rupture the vessels or if they are already  
 ruptured to cause a more copious effusion where  
 the stomach contains a hearty meal it will  
 generally be ejected from the stomach. if a  
 considerable quantity of blood be drawn from the  
 arm or jugular vein or from any convenient  
 and safe vessel and in this case very beneficial  
 effects have resulted. blistering has been recom-  
 mended but I think an <sup>very</sup> ~~very~~ important remedy  
 in the early stage of the disease Stimulants  
 have been almost universally employed but I  
 think these might be employed advantageously

in cases of suspended animations but do not  
think them useful or their employment warrant-  
able in Apoplexy as the violent efforts in vom-  
iting will as before stated impel the blood  
to the brain with so much violence as to incre-  
ase the effusion or rupture the vessels which are  
not yet ruptured. If a poison introduced into  
the stomach produces Apoplexy and if a sponta-  
neous vomiting occurs it should be encouraged  
by draughts of tepid water and by the remedies  
usually recommended in cases of poison. If  
stimulents in the later periods of the disease  
become necessary they are to be employed  
and the most proper will naturally be

resorted to by the skillfull and judicious practitioner. The affusion of cold water has been the  
ught to be of much value ~~from~~ <sup>in</sup> rousing a person  
from the insensible state. When there is a  
full habit or a plethora existing the specifick  
applied to the back of the neck has been useful  
in overcoming this predisposition so also is a  
ster introduced into the back of the neck these  
are merely used for the prevention of Apoplexy  
but when Apoplexy seriously threatens there is  
nothing which can be substituted for copious  
Vena section. If Apoplexy actually does occur  
bleeding is immediately to be employed and

if as above stated the power of deglutition remain  
 to the patient cathartics should be administered  
 and their operation promoted by injections.  
 cupping the temples also leeching may be emp  
 loya with good effect. rest should be strenuously  
 enforced the head being considerably raised by  
 pillows above the level of the body and if the  
 patient recovers a total avoidance of the pre  
 disponent causes <sup>likewise</sup> and of plethora should be  
 strictly adhered to by the patient. A paroxysm  
 of deep intoxication has been confounded with  
 Apoplexy but may be distinguished by the ~~process~~  
 generally by the history of the case and by the  
 smell of liquor being perceptible in the

breath deep sleep resembles it in some degree  
 but is readily distinguished by the patient being  
 aroused by the application of volatiles applied  
 to the nose by pinching or by calling him  
 in a loud tone of voice it is also confound  
 with Palsy and Syncope but is distinguished  
 from the former by its being an affection of  
 the whole of the powers of sense and voluntary  
 motions and from Syncope by its being attended with  
 the continuance of respiration and the action  
 of the heart,

An Inaugural Dissertation  
Submitted to the examination  
of the Provost and medical  
Professors of the University of  
Maryland,

by their friend

Alfred Rudnall

of Northumberland County V.R.G. 1828  
in the year of our Lord A.D. 1828. A.D. 1828.

The first part of the  
 manuscript is a list of  
 names of the members of  
 the committee. The names  
 are written in a cursive  
 hand and are arranged in  
 a list. The names are  
 as follows:

The following lines are respectfully  
 dedicated to the Medical Professors in  
 the University of Maryland - as a  
 small tribute of regard and esteem  
 entertained for them, both as private  
 individuals and public Teachers  
 by their friend -

Alfred W. D. M. H. C.

Remarks on Tetanus.

The disease which I am about to give a description of, is one which has in former times excited terror in every medical Practitioner, who had the misfortune to witness a case of it.—

I mean Tetanus— A genus of disease, in the class Neuroses, and order Spasmi, of Cullen, characterised by a spasmodic rigidity of almost the whole body.— The varieties of this Disease which are described by Dr Cullen are, First, Opiethotonos when the body is violently drawn backwards, by the contraction of the Dorsal muscles— Secondly, Emproethotonos, when the body is bent forwards— Thirdly, Picuroethotonos, when the body is drawn to either side and Fourthly, Tismus, or locked jaw.— Though I consider them one, and the same disease and these distinctions of course unnecessary.

Causes.

Tetanic complaints may arise from many and various causes such as, punctures, lacerations, amputations and fractures of the limbs— Gunshot wounds, wounds in the palms of the hands and soles of the feet, by means of nails, or splinters of wood, — the Injury done to the feet by Frost, cutting the umbilical cord in new born Infants, and the sudden application of cold to the body after it has been exposed to extreme heat— It has also been sometimes induced by certain

Journal of the

The first part of the journal is a general account of the weather and the state of the country. It is written in a simple and plain style, and contains many interesting particulars. The second part is a description of the different parts of the country, and is written in a more elegant and polished style. The third part is a collection of letters and papers, which are written in a variety of hands, and contain many valuable observations and accounts.

Index

This index contains a list of the names of the different parts of the country, and of the different persons mentioned in the journal. It is written in a simple and plain style, and contains many interesting particulars. The first part is a list of the names of the different parts of the country, and the second part is a list of the names of the different persons mentioned in the journal.

poisonous vegetables received into the stomach— as  
Hemlock— Stramonium &c. — This Disease is  
said to occur most frequently in warm climates,  
and in the warmest weather of those climates,  
but this is by no means a general rule, for we  
sometimes have it in our winters.

This Disease affects all ages, sexes, Temperaments  
and Complexions— but the nervous and irritable  
are most subject to it. — Some have said  
that negroes are more predisposed to attacks of it,  
than white people they are more frequently  
affected with it but this, probably arises from  
their being more exposed to injuries than the whites,  
and not from predisposition, they are more liable to  
tetanus, because they are more subject to injuries as  
they generally go barefooted and from that  
circumstance are very often wounded about the feet  
with nails, splinters of wood, broken glass &c. &c. —

Symptoms.—

This Disease sometimes comes on suddenly to a  
very violent degree but more generally it approaches  
by slow degrees to its violent stage.

It commences with a sense of stiffness in the back  
part of the neck which, goes on increasing until  
it renders the motion of the head difficult and  
painful— After the rigidity of the neck has come  
on there is commonly at the same time a sense of

uneasiness felt about the root of the tongue - which, by degrees generally becomes a difficulty of swallowing and if, the disease is not combated properly at length an entire interruption of it.

While the rigidity of the neck goes on increasing there arises a pain often very violent at the scrobiculus Cordis, and shooting from thence into the back. — When this pain arises all the muscles of the neck and particularly those of the back part of it are affected with spasm pulling the head strongly backwards. At the same time the masticating muscles are affected and the jaws are violently clenched, so that it is sometimes necessary to extract a tooth to introduce any thing into the stomach. — This is what writers have named Locked jaw and is very troublesome; the tongue is sometimes very much injured by the teeth in consequence of its being thrust out of the mouth during the interval of spasm and it is in that way that it is so often injured. — When the disease has advanced thus far the pain at the bottom of the sternum returns very frequently — and with it the spasm of the back part of the neck. As the disease thus proceeds a greater number of muscles come to be affected

with spasm. — In succession to those of the neck, and jaws, those of the back bending the whole body strongly backwards and this is what has been called Opisthotonos. —

The muscles of the superior extremities are not, the only muscles affected, for both the flexor and extensor muscles of the legs are very rigid, and the limbs are very stiff. —

During the whole of the disease the abdominal muscles are violently affected with spasm, so that the abdomen is strongly retracted and feels very hard.

At the height of the disease every organ of voluntary motion seems to be affected; and among the rest the muscles of the face: The forehead is drawn up in frowns, the eyes are sometimes distorted, are commonly rigid and immovable in their sockets; The cheeks are drawn backwards towards the ears so that the whole countenance expresses the most violent grining, under these universal spasms a violent convulsion commonly comes on and puts an end to life.

The attacks of this Disease are seldom attended with high fever although there may be occasionally some: — And it is said, by some that at the commencement of this Disease the pulse is

often full and frequent, tense and strong.—  
But I believe in the majority of cases,  
there is no fever of consequence; and most  
commonly the pulse is weak and quick.  
In this disease the head is seldom affected  
with delirium, or confusion of thought till the  
last stage of it.

In this disease I believe the natural functions  
are not either immediately, or considerably  
affected, however occasionally there is vomiting  
in the early part of the disease but, this  
generally continues a very short time;  
And it is quite usual for the appetite  
of hunger to remain through the whole course  
of the disease, and the food that is taken,  
seems to be regularly digested, however this  
is in very small quantity.

The excretions are sometimes affected but not  
always—The urine is sometimes suppressed, or is  
voided with difficulty.

The belly is sometimes costive this I think  
originates from opiates, for we have no accounts  
of it unless opiates were used.

This disease until very lately generally proved  
fatal, this was owing very much to the manner  
in which patients were treated by the older  
practitioners; For we know that until very lately

Physicians were not acquainted with a method of cure and that, since a more proper method has been known and carried into effect, many have recovered:— It may be concluded that the fatal tendency of it is not so unavoidable as has been supposed.—

In judging of the disease in particular cases, we may observe, that, if it comes on very rapid it is more severe than when it comes on more slowly.— (The first case of Tetanus, which I saw terminated fatally on the fourth Day.)

This disease if not properly treated, often proves fatal before the fifth, or sixth, Day, and when a patient has passed this period he may be said to be in greater safety, and in general the disease is the safer, the longer it has continued.

It is to be observed however that the disease is dangerous for many days after the sixth.

Treatment.

I come now to speak of the treatment which should be carried into effect with perseverance, and experience has taught us that Opium, and Mercury, has often proved an effectual remedy, but to render them so they must be given in large quantities so that we may have their full effects.

I am fully persuaded that opium is very seldom given in sufficient doses.

The practice has been, to give it either in a liquid, or solid form, not in very large doses at a time, but in moderate doses every one, two, or three hours; this practice will do if its effects are not suffered to go off, however it does not seem to operate in this Disease, as it does in others; For although it procures some remission of the spasm, and pain, it hardly ever induces any sleep, or occasions that stupor, or delirium which it often does in other circumstances, when much smaller quantities have been given.

It is therefore observed that in this affection there should be no retailing, that it should be given by wholesale and it should be given as largely, and as frequently, as the symptoms of the Disease may seem to demand. It must however be observed that though the first exhibition of the opium may have produced some remission of the symptoms yet, the effects of it do not long continue in the system and this disease being very ready to return, it is very necessary by the time that the effects of the opium given, are going off and especially upon the

least appearance of the return of the spasms, to repeat the dose in the same quantities as before.— This practice should be very strictly pursued as long as ever the disease showed any disposition to return: And it is not until after the Disease has already subsisted for some time and when considerable and long continued remissions have taken place, that the doses of the Opium may be diminished and the intervals of exhibiting them, be more considerable.

Opium administered in this way, has in many cases been successful, and probably would have been so in many others if, it had not been too sparingly used, either from timidity of Practitioners or from its exhibition being prevented by that interruption of deglutition which so often attends this disease. Which latter circumstance requires that, the medicine should be immediately and largely employed upon the very first approach of the disease, before the deglutition becomes difficult or if this opportunity be lost the medicine in sufficient quantity and with due frequency should be thrown into the rectum by glisters.

It has been recommended to employ opium with

some of the antispasmodics, such as musk, and camphor, this I think is a very weak practice and would answer a very little better purpose than opium alone, in one case I see opium and musk combined but it terminated fatally. Blisters to the neck were also used.— What would be the effect of Emetics in this disease— We know, that they produce powerful effects sometimes in relaxing the muscles in spasmodic and convulsive Disorders.

The warm bath has also been spoken of as a remedy. Purgatives has been very highly recommended by some of the Continental Practitioners.

I do not know how they would answer as I have never seen them used.

Bloodletting should not be used except in plethoric subjects.

Blistering was at one time very much used, it is asserted by some Practitioners that it is always hurtful.

Moxa has been used with decided advantage in late years, it should be applied all down the spine, and the eschars dressed with mercurial ointment— so as to keep up a discharge for sometime Cold bathing has also been recommended by the Continental Practitioners.

I am induced to believe that not one half

of the remedies recommended are of any service. I think that wine, Opium, Moxa, and Mercury are the principal remedies to be relied on in this disease. — Of these remedies, the Wine, Opium, and Moxa, retard the progress of the disease. — Preventing death from exhaustion until the Mercury shall have time to eradicate it, by converting the Tetanic affection into a mercurial action. — However I should strongly recommend Opium and Wine, for without their aid the Mercury would not have time to act, although they are insufficient of themselves without mercury. The Mercury should always have its full effects, and this effect, should be kept up for some time, for if it is not the Tetanic affection will certainly return.

The Mercury should be used very extensively, applying it in large quantities in the form of Mercurial Ointment.

Tobacco has also been found useful and spoken very highly of, by Dr Jackson of Northumberland in Pennsylvania — in a case which occurred in his Practice — produced by an injury received on the back of the hand by a splinter of bone, the part had healed, and he made an incision into it, and applied a poultice over it, made of a strong decoction of Tobacco and linseed meal. —

He applied it from the hand to the shoulder, and changed it every six hours: A similar application was made to the scrobiculus Cordis—in order, to operate on the whole system.

In six hours, the symptoms had ameliorated, and the same means were continued with the addition of Castor oil to open the bowels—Thirty six hours from the first application, the Tobacco produced some nausea, and so much vomiting on the third day, that the whole complaint appeared to be subdued, his stomach was now restored by cordial nourishment—Drink. ℞. Huxhams Tinct—About the same time Erysipelas of the arm came on, succeeded by Mania a Potu which rendered the use of opium, Camphor, &c. necessary.—vid. Med. Rec. Oct 1824 page 315

### Prophylactics.

The best preventives of Tetanus consist in the conversion of punctured into incised wounds by means of a scalpel, or some such instrument, and the exciting of suppuration in wounds that, are lacerated.

These precautions should be used immediately after the injury is received, and before the Tetanic symptoms shall have made their appearance if circumstances exist to prevent the dilatation of punctured

wounds the application of some escharotic should be used such as ley, Corrosive Sublimate, Spirits of Turpentine, Tincture of Cantharides, and Nitrate of Silver.

These should be followed by poultices so as to bring on suppuration.

If the patient cannot swallow, food should be thrown into his stomach by means of a gumelastic tube.

This may be done by removing a tooth or two.

Essay on Cantharides

Cantharides when applied to any part of the surface of the body produce inflammation of the skin, and in a few hours there is a preternatural discharge from the capillaries. This discharge being accumulated between the cuticle and cutis vera, is called blister. A similar evacuation of fluid may be produced by other acrid substances such as sinapisms, and many others. But no experiments hitherto made have been attended with such success, as to entitle them (sinapis) to such general use as the cantharides: and they are seldom had recourse to, except when the flies cannot be obtained or where in consequence of the extreme torpor of the system they have been found ineffectual.

The ancients were not entirely ignorant of the powerful effects of blisters although their application was confined to very few diseases. It is said that the Arabians were the first to use them with a view to rouse their patients from a lethargic state. The physicians that succeeded them for sometime used them indiscriminately in every state of morbid action in the system. From an ignorance of the <sup>proper</sup> period in which they were indicated (as it may be supposed they did great injury by too early an application of them. our knowledge of the efficacy of blisters may be attributed to a dispute which took place between some Italian physicians relative

The account was not entirely correct  
of the financial affairs of the  
although their application was confined  
to very few details. It is said that  
the Secretary was the first to see this  
and a view to show their financial  
a letter was sent to the Secretary  
that the matter was important and  
then immediately on my return  
would return in the afternoon of  
an examination of the papers in order  
they were introduced as they were  
that all these things were being  
of the nature of their own knowledge  
of the affairs of the State and

59

to their use in a plague which prevailed in the sixteenth century. Their application cannot be considered as yet regulated in all cases they are even now often prematurely applied and seldom without manifest injury to the patient. In the application of blisters we have a very convincing illustration of the necessity of attending to the state of the system before we prescribe a remedy. This principle is inculcated with much ardour by a learned and ingenious Professor of the University of Maryland — upon this principle is founded the art of alleviating and curing diseases and as such should never be forgotten by a practitioner of medicine — Much has been said about

Faint, illegible handwriting, likely bleed-through from the reverse side of the page. The text is mirrored and difficult to decipher.

the manner in which blisters<sup>61</sup> operate  
one party maintaining that an absorption  
of the cantharides takes place, and that  
all their good effects are derived in this  
way - Another that they act by revulsion  
only. It appears that the former party were  
led to their opinion by observing that  
strangury is produced by the absorption  
of the acid particles of the cantharides,  
This fact they conceived to be sufficient

That some part of the cantharides is  
sometimes taken up into the system by  
means of the absorbents is very cert-  
-ainly proved by the phenomenon of  
strangury - The absorbed part appears  
to be particularly determined to the urinary  
organs sometimes producing by its irritating  
action inflammation on the neck of the

63

bladder and consequently pains, dysuria  
Blisters are powerfully stimulant. we  
may infer this from the increased force  
and frequency of the pulse which is prod-  
uced by them. and from the great deter-  
-mination of blood to the part which is  
in contact with the flies, occasioning infl-  
-ammation and effusion. When blisters are  
applied to the extremities they give a centrip-  
-ugal determination to the disease, thereby  
saving parts essential to life as in yellow  
fever &c. The operation of blisters is both  
stimulant and sedative. They answer the  
purpose of metastasis better than any  
other medicine in use. Dr. Rush tells  
us " that it is from ignorance or inatt-  
-ention to the proper period or stage of  
fevers in which blisters have been applied

Handwritten text, likely bleed-through from the reverse side of the page. The text is extremely faint and illegible due to the age and orientation of the document. It appears to be a continuous paragraph of text.

that there have been so many disputes among physicians respecting their efficacy when applied in a state of great arterial action they do harm: when applied after that action has nearly ceased they do little or no good. The period in which blisters are useful is called by him the blistering point. Blisters are applicable in local and general diseases. We must keep in view the principle which I have before said is so strongly inculcated by a learned Professor

In the malignant state of fever which appears in the plague yellow fever &c blisters may be applied to the extremities. after the morbid action has been in some measure

that this has been the case  
among physicians respecting this  
value of the in a variety of cases  
actions they do know when

but to the  
action had

reduced by plentiful evacuations. <sup>67</sup>

The determination which they produce to the surface often presents congestion and inflammation in parts essential to life. They have been used in the plague with great advantage, as the irritation which they occasioned invited the disease to parts not absolutely necessary to the vital functions, and thereby prevented the too often fatal consequences of congestion in the viscera. Dr. Rush in his treatise on yellow fever says that blisters when applied in the proper period of this disease (yellow fever), did great service. This time was, when the fever was so much weakened by evacuations, that the

artificial pain which is produced by the stimulus of the blisters destroyed, and like a conductor conveyed off, the natural pain of the body?

In typhus or the low state of fever, blisters may be applied as stimulants with considerable advantage. ~~and~~ To obtain this to the greatest extent, they must be small and repeated, and never suffered to discharge long: as the evacuation would counteract the purpose for which they are intended. In the typhoid or slow nervous ~~state~~ fever Dr. Huxham used them (blisters) with advantage, and from their operation in other states of fever, we can entertain no doubt of their application being attended

with efficacy in this,

71

The intermittent fever is sometimes so obstinate, in consequence of marsh miasmata producing so great a degree of action in the system, that the bark has been found inefficacious, and in many cases extremely injurious. When such cases occur, the patient's pulse is found to be moderately tense. By premising blood letting, or the abstraction of the excitement from the blood, & repels to the surface, by blisters to the wrists, the bark will always be found effectual.

Blisters are very important remedies in the treatment of the

of the law of the land.

73

different varieties of phlegmasical  
diseases.

In acute pulmonary affections  
especially blisters are recommended  
physicians disagree as to the proper  
time for employing them in pneumonia.

That blisters may be employed early  
in this disease is proved. Without  
doubt however they will be more  
beneficial after the reduction of the  
vehement arterial excitement,

In relation to this point Dr. <sup>m</sup>Boström  
makes the following remarks:

It has  
sometimes ~~occurred~~ struck me very  
forcibly; says he; That the pre-  
cipitate application of blisters to the

Chest. before general or local blood  
~~letting~~ letting, is a prejudicial pr-  
 -actise: at least I have seen hy-  
 -drothorax rapidly follow it, from  
 the increase of the general and top-  
 -ical excitement which blisters thus  
 applied had apparently produced.

This point is therefore worthy of  
 further investigation in the acute  
 pulmonary inflammation<sup>3</sup>  
 +

In the treatment  
 of hepatitis blisters are very useful;  
 and in inflammation of the bowels<sup>3</sup>  
 and peritoneum they are indispensable

In all these affections the blisters should

be large and applied immediately  
over the parts affected.

In all those  
affections of the throat known by  
the names of cynanche tonsillariz,  
parotidea, maligna, and tracheitis.  
blisters are very useful applied  
in the proper time.

In rheumatism  
I believe every practitioner can  
testify to the efficacy of blisters,  
Their good effects must be ascri-  
-bed to their producing a new  
action on the skin which is more  
violent than the inflammation  
seated within, and probably the

79

evacuation which they occasion  
contributes in some measure to  
relieve the inflammation of the  
ligaments. by lessening the quantity  
of the determined fluids to the  
part—

In gout by determining  
the inflammation to external parts  
blisters often prevent morbid  
congestion from taking place  
in the viscera—

In the maniacal  
state of fever. as in all other states  
of morbid actions we must be  
directed by the action of the

blood repels as to the proper time  
 for using them. for the application  
 of them when the system is highly  
 excited, or too enfeebled, would  
 not be attended with advantage  
 but on the contrary with very  
 great injury.

In the apoplectic, phre-  
 -nitic and lethargic states of fever  
 blisters may be applied to the  
 head or neck with advantage  
 we must consult the state of  
 the system and bring it to  
 the point proper for their app-  
 lication, by evacuation

as to require blood letting and  
blistering to a considerable extent

To obviate or remove the inflamm-  
-atory determination to the lungs  
blisters should be applied to the  
thorax as being more efficacious  
than when applied to distant parts.

This disease often continues a  
long time after the contagion  
has ceased to act. and that from  
~~habit~~ the power of habit alone.

In this case they have a powerful  
influence in destroying the force of  
habit. by the new disease which

they produce. Strangury produced  
by blistering has been attended with  
an immediate removal of cough  
in this disease.

In colera infantum  
blisters applied over the stomach,  
are very effectual in removing  
the sickness at the stomach and  
suppressing the diarrhoea. Their  
efficacy is more certain combined  
with the pure <sup>air</sup> of the country.

The fever which is sometimes produced  
by the irritation of the gums in  
dentition. is often cured by a blister

to the back of the neck, or one behind each ear, after evacuations have been made. The difficulty of getting blood from children and of exhibiting sufficient doses of medicines renders epispastics, not unfrequently the only remedy to be depended on. Blisters are sometimes very efficacious when applied locally. The application of a blister to the tract of an inflamed vein is a practice of much value. This treatment was first used introduced by Dr. Physick, a small plaister of simple cerate spread on linen, is to be applied to the orifice, and over this a blister large enough to cover the whole inflamed part

extending three or four inches from the orifice in every direction 35

In concluding this essay permit me gentlemen, to acknowledge the sentiments of gratitude I feel for the civil and polite attentions received from you individually, and the information derived from you collectively as Professors of this institution. I fondly anticipate the day when this University will hold a rank distinguished in the records of medical history, where the true principles and practice of the different departments of the science of physic are ably taught and the dogmas of ignorance and prejudice consigned to oblivion

To Mr Reynolds, M.D.

Sir.

Under your direction I received the first rudiments of medicine, & to you I dedicate <sup>my</sup> ~~the~~ first effort in the science.

I am induced to do this by two considerations - first, because it is the only way I have at present of acknowledging the many obligations I am under to you: second, because I believe, that you will view favourably any imperfections the attempt may labour under.

I remain

Sir

yours very much

obliged

To Mr. J. J. [unclear]

Dear Sir

I have the honor to receive the first installment of your  
order of 2500 shares of the first effort of the  
company.

I am indebted to you for the 2500 shares  
and first installment of the same which have  
been received by the company and which you  
will find in your account. I believe that you  
will be pleased to find your contribution to the  
cause of education.

I remain

Dear Sir

Yours very much

respected

An Inquiry &c.

In selecting mania as the subject of an inaugural thesis, my object was, not so much to advance a new doctrine, as to establish an old one.

It is not without a considerable degree of "fear & trembling," that I enter upon so difficult & so abstruse a subject; but as my object is truth, I shall persevere it, at least, with firmness, if not correctness.

I define mania to be a disease of part, or of all the faculties, of the mind. But, before entering upon the inquiry, it may, perhaps, be proper to state what those faculties are; not that I intend to be so presumptuous as to attempt to say what is the nature of the mind, but that I may endeavour to ascertain the seat of some of its diseases.

The faculties of the mind, according to some writers, are "understanding, memory, imagination, passions, principle of faith, will, the moral faculty, conscience, & sense of the Deity." Its operations sensation, perception, judgement, volition &c.

The mind is put into operation, by impressions made upon it, thro' the medium of the external senses, as the different colors make impressions on the organs of vision, odours on the organs of smell, different surfaces on the sense of feeling, sounds on the auditory nerve, sweets & acids on

the organs of taste; thus a communication is preserved between man & the material world. When any of these organs are diseased, false impressions are conveyed to the mind - the mind directs the will improperly, & we have incoherent actions: thus, a man imagines he sees a spectre, & he flies to avoid it. A disease in any of the faculties is the first step to madness.

In conducting our inquiry we should be led, as well in this as every other disease, first, to ascertain, if possible, the seat of the disease, second, its pathology, <sup>third</sup> its causes, & fourth its removal or palliation.

Concerning the seat or proximate cause of mental derangement, there have existed a variety of opinions. The ancients supposed that madness was derived from morbid functions of the liver; & as this viscus is very liable to disease, the opinion received considerable countenance from its being very often found in a morbid condition, on dissection after death. Subsequent writers refer it to the spleen; while more modern ones contend that it cannot be referred to either the one or the other, & that it has its seat in the blood vessels of the brain, or in excessive arterial action, produced from the same causes, which produce fever.

Without stopping to inquire into these different opinions, to ascertain their connectness, or to enter into any metaphysical speculations concerning them; I will merely remark, that, if the disease could, with propriety, be referred either to the liver, or spleen, or blood vessels of the head, we might be led, to expect, from the remedies successfully used in these diseases, more fre-

want cures of madness, than we are in the habit of wit-  
reping.

In rejecting all the theories which have been advanced  
on this subject, we should only be actuated by the hope of  
producing something which approximates nearer to the  
truth; whether we shall succeed or not, rests with future  
investigators to determine - We shall at least make  
- step towards it, if we fail in our attempt, we may  
perhaps, kindle a spark, by which some more success-  
ful genius may fire his torch, & thus penetrate the gloom  
which envelopes this intricate subject.

We conceive madness to be entirely, a nervous  
disease.

To illustrate this position, we shall form  
the nervous system into three divisions: viz: -  
Those of sensation, in which we believe the disease  
to be exclusively situated, when these nerves are in  
a state of disease, & we can easily imagin an hun-  
dred causes, which may produce a derangement in  
their functions; those of motion, & those of sympathy.

That the disease is thus situated, we infer  
I. From a total absence of some of the senses, & a per-  
version of the rest in every madman: Thus, one  
will tear his blanket & roll it up, then cry most  
hideously until the "Sea Serpent" is removed from  
his cell - Here is evidently a diseased nerve, trans-  
mitting false impressions to the brain. Another  
is insensible to taste & smell, & will swallow any-  
thing presented, even of the most disgusting char-

ter, without the least nausea being produced. A  
turd is insensible to the temperatures of heat & cold  
in so remarkable a degree, that he will burn his legs  
to blisters, without evincing the least concern at it;  
Dr. Rush relates the case of a man in the Pennsylvania  
Hospital, who would stand in one position, in the cold,  
until mortification was produced, without manifest-  
ing the least pain, or disposition to move.

II. From sudden impressions made upon the nerves,  
frequently removing the disease; such as fear, terror  
&c. For examples of this nature, consult Rush on the  
mind, Eschschon on mental derangement, and every  
other writer, who wrote on the subject.

III. From the disease disappearing on the accession of <sup>(another</sup>  
which had a tendency to abstract morbid irritability  
from the diseased nerves: thus, the patient, who perceived  
the sea serpent in his blanket, took the confluent  
small pox in the Maryland hospital, & died; but pre-  
vious to his death he became perfectly sensible, &  
spoke as rational as any one.

And VI. From its seldom appearing in persons, who have  
not attained the years of maturity. The manner of account-  
ing for this, is, first external objects do not pro-  
duce the same impressions in youth, that they do in  
adult age; 2<sup>d</sup> impressions made in youth are of a  
transient nature, & soon forgotten, whereas in adult age,  
the impression, ~~the~~ of a beautiful object is continued un-  
till the nerve, on which it is made, becomes diseased, from

For another the least possible delay in the

long action: just as the continued impressions from odours, on the olfactories, produce hysteria & other diseases bordering on madness; or just as the whole system becomes debilitated from long continued exertion, & then inducing disease by keeping up the exertion.

Causes,

We come now to consider the most frequent causes of mental derangement. These are, hereditary predisposition; - this disposition exists in a latent state, & is transmitted from the parent in the same manner that gout is; but whether transmitted by bloodvessels, nerves, bones, or muscles, "is a mystery locked up in the strong box of nature;" but that the disease is inherited by the offspring from the parents, is a fact, which, I believe, is not at all questioned now. Injuries of the head, so as to make pressure on the nerves of sensation, a constant habit of intoxication, onanism, extreme absence from coition, superstitious dread, religious fanaticism, all the passions, as. Excessive grief or disappointed love, A peculiarity in the formation of the cranium. out of all the maniacal patients now confined in the Maryland Hospital, more than two thirds of them have some peculiar formation of the skull. Some have remarkably small round heads, while others have long narrow heads; others again have their skulls narrow & small at the base and wide at the top, not unlike the heads of hydrocephalic children. Excessive use of Mercury, inordinate gratification of the venereal appetite, the sudden repulsion of

Faint, illegible handwriting at the top of the page, possibly a title or header.

utaneous eruptions, violent arterial action, such as is found in puerperal convulsions, & in fevers which attack gross & plethoric habits, insolation, worms in the alimentary canal, continued attention to any one subject, the excessive use of narcotic medicines— Many more might be enumerated, but these are sufficient to show the variety of causes, which produce mental derangement, in some one of its forms.

Madness may be divided into three forms, viz: Furious Madness, Melancholy, ~~or~~ which is considered hypochondriasis; & madness from an imbecility of intellect, each of which will require a separate consideration in this paper. In this, however we shall not attempt those delicate distinctions which mark the boundaries between eccentricity of character, & actual madness; but consider certain deviations from propriety, as another degree of the same disease.

Symptoms.

Furious madness makes its approach by some peculiar symptoms; such as restlessness & watchfulness, anxiety about imaginary things, incoherent expressions & eccentricity of conversation & conduct, considerable irritability of temper, hostility to friends & relatives, sadness & languor. The skin is pale & cool, sometimes the face is flushed, a singularly wild & vacant stare is visible on the countenance; there is either a total want of appetite, or there exists a morbidly increased one, the bowels are obstinately costive, a considerable degree of headache is frequently present. When nearly the whole of these symptoms are present, we may form a tol-

Faint, illegible handwriting at the top of the page, possibly a header or introductory text.

Second section of faint, illegible handwriting, appearing as a distinct paragraph.

Third section of faint, illegible handwriting, occupying the bottom half of the page.

terable correct prognosis of the character of the approaching disease. When these symptoms are completely formed, we have a wild, ferocious expression of the countenance, an appearance of fulness in the ~~throat~~ face, with red eyes & flushed cheeks, the patient becomes very boisterous & clamorous - he whistles or sings incoherently, makes long & ridiculous speeches, uses very obscene language, curses & swears most honorably, loses all sense of shame & delicacy, rends his cloaths, stalks about in a complete state of nudity; and, finally, to finish the melancholly picture, the patient degrades himself beneath the brute creation, by acting the most disgusting scenes imaginable.

In this stage of the disease, the skin is cool, & not the least moisture can be discovered on it; and, what is very remarkable, there is no secretion from the mucous membrane of the ~~nose~~ nose. It is mentioned by Dr. Rush, & to satisfy myself of the correctness of the observation, I made an examination of all the patients who were deranged in the Maryland Hospital, & found it to be the case in every one, with one exception - The pulse is sometimes hastened a little, but it is more frequently natural - The frequency of the pulse just alluded to, may be referred to nervous irritation. In this state of madness, one or more of the nerves of sensation are destroyed, and the others become very acute; just what occurs, when a man loses his sight, the sensation of feeling becomes very acute; hence, maniacs hear very acutely

Although they taste nothing, and smell nothing.

Different causes, however, produce different symptoms— thus the Sarcens, a poor, destitute, & naked horde of beings, unskilled in the use of arms, or the art of war, had their imaginations inflamed with a new doctrine, & became partially <sup>deranged;</sup> & thus fearlessly attacked fortified towns & citadels; nor did they raise the siege until the place capitulated. Here the continued idea, of beautiful virgins & plenty of wine, by long action on the nerves of sensation, brought on a disease of the mind, which caused them to devastate the most beautiful, & fertile countries of Asia, Europe, & Africa. The same causes produced the same effect in the wild ~~and~~ visionary ~~Crusaders,~~ when they marched to the holy land. The remedies to be used in this disease, depend upon ~~upon~~ the cause that produced it; I shall, therefore, say nothing of the treatment until we shall have described the different forms of disease.

The next form of mania is melancholly, or as some authors call it Hypochondriasis.

The elder physicians were often very unhappy in their use of terms in medicine. Of this we have sufficient proof, if we but open their nosological books. Technical words ~~swarm~~ <sup>swarm</sup> our eyes in every direction, and if they do not confound us, at least puzzle our wits, in ascertaining their precise meaning, and original application.

Hypochondriasis is that term which was employed by the ancient prosologists, to denote an erroneous state of mind, produced, as they conceived

by a derangement in the functions of the liver, or some other viscus of the hypochondriac region, but, it is, however, abundantly proven, that the disease is not derived from a diseased liver, or any other of the viscera:— The term is therefore incorrect, and not applied with strict propriety.

As this form of mental derangement appears most evident in an erroneous perception and judgment of things relating to the person & circumstances of the patient, Dr. Rush proposes to call it *Tristamania*

Various epithets are applied to this disease in common conversation, the hyppos, spleen, vapours, low-spirits, &c are all synonymous with hypochondriasis in it various grades. As the author of this essay has been more in the habit of turning his attention to the phenomena of diseases than their characteristic distinction, it will be sufficient to observe that Dr. Cullen has given the following character of it, "dyspepsia, languor, want of energy, sadness, & fear from uncertain causes; with a melancholic temperament."

Persons of nervous & hepatic predispositions are most subject to melancholly.

Hysteria some times resembles melancholly, but there are certain prominent features, by which they may be distinguished from each other. The blood vessels are more affected in hysteria than in melancholly, the nervous system in the latter is always in a state of torpor, in the former great mobility prevails, hysteria ap

*[The page contains several paragraphs of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper.]*

hears in paroxysms attended with occasional delirium, it is not so with the other - hysteria is alleviated by cold, melancholly by warmth.

That it combines with hysteria is proven by many facts. Some melancholic patients are dull & sad at the same moment, at another, they are gay & vivacious to an extreme. They are among the most boisterous laughers, & are addicted to great merriment & mischief. These are convulsive effects, and can only be explained on the supposition that they are borrowed from hysteria.

Persons advanced in life are more subject to the disease than the young.

Causes

The remote causes operate, first on the body, second on the body through the medium of the mind, & third on both at the same time.

Among the first, are all debilitating occupations of a sedentary kind, fatigue, irregular diet, hunger, watchings, unwholesome food, chronic fevers &c.

The second variety comprehends all the excesses of the passions & emotions, joy, grief, anger, shame, disappointment, vexation, religious distress, intense study &c.

The third kind, or those which operate on the mind and body at the same time, are all perplexing employments, where the mind is hurried, & the body fatigued, as professional practice, teaching school &c. the various forms of the venereal disease, by inducing debility, & at the same

Faint, illegible handwriting at the top of the page, possibly a header or introductory text.

Bottom section of the page containing faint, illegible handwriting, possibly a signature or concluding text.

time exciting emotions of shame and sorrow in the mind, have made many a melancholly patient.

Symptoms.

These are very various. Indigestion, flatulency, costiveness of the most obstinate kind, which requires the most powerful incitements to move the bowels; diarrhea, an excessive secretion of bile, dry skin; & an increased flow of urine, slimy stools; deficiency of appetite; preternatural appetite, cholic, tumed abdomen, tinnitus aurium, throbbings of the temples, indistinct vision, palpitations of the heart, burning of the hands & feet &c.

The mind is as variously effected as the body. It is languid, & inactive, and can seldom be employed in thinking on any subject, but that of personal distress. The imagination is in search of doleful images "with a wing that never tires." A thousand fancies are continually excited in the brain; almost every disease lends a share in forming these symptoms of this.

As consumption is the most frequent & fatal disease, it is not to be wondered that it should stand foremost among the chimeras of the patient's brain. If a cough happens to trouble him, he has an abscess in his lungs without doubt; his fears immediately create an hectic fever; should his hands & feet feel a little warmer than usual, it is a certain indication in his mind, that the ravages of this direful malady are commencing.

*[The page contains several paragraphs of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is too light to transcribe accurately.]*

Should the unfortunate patient have been lured by a stream  
 at, & attacked by the venereal: notwithstanding the poison  
 has been completely eradicated from his system; he is  
 constant fear of having his palate, or the inside of his  
 nose destroyed, by the inroads of the resuscitated distemper.  
 His imagination conjures up to his view the loss of repu-  
 tation & of friends; & predicts ruin & misery through  
 the remaining part of his life:— Again, he believes  
 his heart is dilated into an aneurism, or has concre-  
 ted a polypus, if peradventure through shame debility  
 it palpitates or beats with a little irregularity.

Thus in turns he has a stone in his bladder; an  
 abscess in his liver; and a tapeworm in his belly.

His mind is effected by certain extraordinary  
 fancies. He is firmly convinced at one crisis  
 that his body is transformed into a plant & needs the  
 wholesome showers of heaven to make him grow; or,  
 perhaps, he may imagine himself a teapot, under  
 this belief, he is in an awful situation if he be  
 too roughly handled; and he shivers at the ideas of  
 being broken to peices. Probably he has conversed  
 himself with child; or to sum up the conclu-  
 sions of his fancies, he persuades himself that he is  
 expiring, & with no more ado he suffers the pangs of  
 dissolution & lies a lifeless corpse. Nothing, under  
 these circumstances will quicken him into life,  
 but some applicatio— like the actual cantery—

This powerful stimulant cannot fail to in-  
 flame his feelings to the most sensible belief  
 that he has yet to die.

 detailed study of the subject. It is shown that  
 the theory of the subject is not yet fully developed  
 and that there is a need for further research.

These are not the worst of the patients mental sufferings.

He is sometimes in despair, here we irresistably exclaim "alas poor gonick!" This state of his mind is induced by a full persuasion that he cannot be saved in another world, and that eternal misery is to be his fate hereafter.

This spiritual distress of the patient, is produced by wrong views of the character of the Deity, & of his own sins. Every little neglect in his religious exercises in former life, recoils upon his mind, with apprehensions that they were the most fatal remissions of duty, & he looks forward with all the horror imaginable, to the time when he will <sup>be</sup> cast into endless torment.

But it were an endless task to rehearse the almost innumerable symptoms attending this malady. Believing that enough has been given to enable the discerning to form a correct prognosis, we shall now proceed to the consideration of the last form of mania-

### Imbecility of Intellect.

This is either congenital or adventitious - The first is the effect of some pre-disposition inherited from the parents; or some mal-conformation of the brain - The second arises from a long continued disease in the system; from sudden impressions made upon the mind, from grief, & joy, & several other causes, which it is unnecessary to mention -

### Symptoms.

These are generally known, as there is scarcely a town that has not one or two in it - They are said to be "foolish;" that they are "cracked"

that they are "hair brained" &c. The patient has an unmeaning countenance; he laughs at every thing & continually; he makes use of trifling expressions, & is fond of the society of children, he is irritable in his disposition, careless about his dress, or extremely neat. patients with this form of madness, are remarkable for their loquacity, they generally talk when in company, & always mutter when alone; they are amused with trifles, especially fond of sweetmeats &c. hence old people are so fond of their grand children, that they <sup>frequently</sup> spend all their time with them.

These symptoms are sufficient to enable us to form a prognosis of the nature of the disease, as it is by no means a difficult one to ascertain.

Treatment.

We shall hasten on to consider the remedies which are necessary in each form of the disease— These are "moral & Medical."

When mania is the consequence of hereditary predisposition, medicines are seldom if ever of use:— Our treatment must consist in rendering the situation of the unfortunate patient as comfortable as possible— This may be done in a variety of ways; by kind & gentle treatment from the attendants:— no excuse can be received in pollution of an offence committed against one of those miserable beings— by keeping the apartments, in which they are confined, well cleansed & ventilated, by using Dr. Rush's tranquiliser; thus preventing the patient from rending his cloaths, & injuring himself— in short, to treat them just as we would wish ourselves to be treated, if we were in the same melancholly situation.

107

When it is produced by any other cause, such as injuries of the head; here the patient comes under the cognizance of surgery & may be relieved by an operation—when from intoxication, we must abstract the stimulus slowly & administer emetics & cathartics, anodynes of some narcotic, opium, perhaps is the best; from insolation, the antiphlogistic treatment must be resorted to, cold applications to the head; the strictest regard must be had to his diet, he should be kept in a room where he would not be exposed to too much light; his bowels should be kept soluble, with neutral salts &c.

When from *omania* the patient must be confined in such a manner, as will prevent his continuing so shameful a practice, when from excessive venery, he must, in the same manner be prevented from indulging his sensual appetite—The man of feeling, may, thus very frequently alleviate the symptoms if he can not remove them. Labour has been recommended by some writers; but in that form of mania, to which the above treatment is applicable, it can seldom be resorted to, as the patient is in such a state, that he cannot be managed when at liberty.

The above treatment is applicable in that form of the disease, which has been called furious madness.

We shall now go on to consider the treatment in the second form of the disease, or that which we have called melancholly.

The remedies for this, form themselves into two kinds: viz. those that act through the medium of the alimentary canal, & those that produce

their peculiar effects on the organs of sensation —

When the disease is attended with symptoms of indigestion, costiveness, flatulency, diarrhea &c. as al ready enumerated, medicines which relieve those symptoms must be given — Indigestion must be obviated by a strict attention to diet; costiveness must be prevented by laxative medicines, & diarrhea by correcting the morbid secretions of the intestines. An excessive secretion of bile should be prevented by alterative medicines, such, as small doses of calomel, the blue pill, or the nitro-muriatic bath, exercise of various kinds may be resorted to, such as riding on horse back, or in a carriage, swinging & sailing; moderate exercise on foot has been recommended. Thus, the judicious practitioner, by a proper regard to symptoms, will generally insure success.

With respect to the remedies which act on the organs of sensation; there are such as may occur to the practitioner at the time. The disease occurs, as has already been stated under a variety of forms, & our treatment must be regulated accordingly: — Thus, if the patient imagin himself some great man, we must favour the belief, & treat him, with all the care & attention, as if his disease was a real one; & observe all the respect, in his presence, which such characters are in the habit of receiving, until an opportunity may present itself to dispell his visionary greatness. If he imagin himself transformed into an animal, as is very frequently the case; such as a dog or a cat, or even a hog, he may have his food thrown to him in the same manner that we would feed those animals; ~~we may~~ by this cre-

# A Dissertation &c

From the prevalence of this disease in the United States, & from the mortality which has attended its appearance on our sea port towns, the attention of Medical men was generally attracted. The most distinguished of the age, in the profession of medicine made every exertion to discover the cause, the seat, & the best plan of treatment.

Great credit is due to professor Rush, for the first correct theory of the Yellow fever. Its pathology was soon determined from Post mortem examination, accurate observation, & experience. No disease perhaps has had more talent engaged in its examination than the present one; & none perhaps has caused so much litigation; and still one or two points are sub judice. I refer particularly to the doctrine of contagion. The physicians of the North, firmly believe it to be contagious; & some deny that it ever originated in this country, but that it is always imported;

In writing an inaugural dissertation on this subject, I am fully aware of the ability, with which it has already been handled, by men, who will be a lasting honor to the profession, & whose usefulness will not cease with their existence. This renders me more diffident in writing on this subject, however, having seen the disease in a climate that is not generally known & whose diseases have not been described. I thought perhaps that some remarks might be made, which, would throw some light on this important & very interesting subject. If this feeble attempt should be useful in any way to the science of medicine, my exertions will be amply rewarded

in the year 1777  
by  
John Jay  
of the City of New York

Authors in describing this disease have given it various names. The yellow fever of the West Indies is the most common for this disease, but as yellowness is one of its symptoms & which can generally be prevented by proper treatment, it certainly cannot be properly used. Dr Rush calls it the Bilious remitting Yellow fever, which, is certainly a more appropriate name, & more expressive in some measure of the nature of the disease. It has also been called the plague, however I have adopted the common term.

We have says professor Rush, this fever, like the steady blowing of the equinoctial gales, we have it again assuming a milder remittent type, sometimes imitating the character of common intermittent fever, but rapidly paving its insidious way to the destruction of the patient. From its ever varying type, for says Professor Potter, we find no two epidemics requiring the same treatment, & wearing the same livery. It will be admitted that the disease as called by Dr Rush is the most appropriate it has yet received. If another should be given, any word that would define accurately the appearance & expression of the eye, would be the most appropriate. Language however it will be found inadequate to describe it; yet once seen, it will never be forgotten.

Causes.

This is another point which is not settled. many Physicians of the present believe the disease is always imported, & hence the strictness observed, in some of our sea ports as regards the Quarantine Law, which are a disgrace to all concerned in their enactment, for they carry on their very face, the strongest marks, of folly & ignorance. There are so many facts, that prove beyond controversy, that the disease

Centered heading or section marker, possibly a name or title, written in a larger, bolder hand than the surrounding text.

Second block of faint, illegible handwriting, continuing the mirrored text from the reverse side of the page.

has originated in places that have had no connection with foreign, or vessels from places where the disease prevailed. Marsh Effluvia is generally admitted, among those, who have seen the disease frequently, to be the cause, not only of the Yellow fever but also of the common bilious & intermitting fevers of our country; as a necessary consequence they would be deemed by those who believe it is a foreign disease. Let us examine into the facts which present themselves, to those who reside in that part of the country where these fevers are prevalent. On the Eastern Shore of Maryland, where the bilious and intermittent fevers are common every year. Foreigners who visit these countries, during the summer & early in the fall are seized with the bilious & yellow fever, & die with the black vomit, which those who are opposed to this doctrine consider as placing the character of the disease beyond doubt, whilst those who have been raised & continue to reside there, will enjoy good health, or have the ague & fever, which they do not regard. Here the same cause is acting on both at the same time, & producing diseases, of the same kind only more violent in degree. Stronger evidence could not be asked, than the diseases of the American Colony of blacks at Cape Mesurado on the coast of Africa. These people when they first settled on that coast, died in great numbers with the Yellow fever, so great was the mortality, that it was thought it would be necessary to abandon the settlement, they have however become acclimated, & now enjoy good health & what are the diseases to which they are now most subject? Common, mild intermitting; when this fever is prevalent, what do we find among foreigners, who visit that place? a violent & fatal fever, which destroys them in two or three days, with the black vomit the last struggle comes on, & death soon closes the scene. Let one of these blacks return to the United States for a winter

The manuscript is written in a cursive hand, and the text is extremely faint and illegible. The page contains approximately 25 lines of text, which appear to be a continuous paragraph. The ink is very light, and the paper shows signs of age and wear, including some staining and discoloration. The overall appearance is that of an old, well-used document.

and then return again to Africa & he will have the Yellow fever. This has been repeatedly observed in the inhabitants of the West Indies, for, if after residing immediately on the shore, or in the large towns, they go into the interior of the island, and remain for some time, upon coming down on the coast, they will be seized with <sup>the</sup> Yellow fever.

This is proof sufficient to convince the unprejudiced mind, that the Yellow fever & Bilious fever have a common cause & that they differ only in degree. To account for this difference certainly cannot be difficult. The habitual Laudanum taker will, with impunity receive at one draught, a dose sufficient to destroy two persons who are unaccustomed to its use, without any inconvenience to himself; in the same way, the Constitution becomes accustomed to the action of this poison, so much so, that it may not produce any disease, but the atmosphere that one man breathes with impunity, who has been habituated to it, will, soon produce violent disease & death in him who has never been accustomed to its action.

The Yellow fever as described by Professors Rush & Potter, as it occurred in the United States, at or soon after they wrote, bore the same general character as that I was witness to, in the West Indies & required the same active treatment. I had an opportunity of feeling that state of the skin, which is produced by Mercury & which Dr Good calls a "diapnoe", This was the first evidence I had of the Mercury affecting the system. From Dr Good's accurate description of this state of the skin, I remarked as soon as I felt the patient that the Mercury had had the desired effect, which was manifested in a few hours from the patient's complaining of his mouth. It is not requisite that I should describe the Yellow fever of this country which has been so ably done, by men whose celebrity will be the proud incentive to seek

*[The page contains approximately 25 lines of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is too light to transcribe accurately.]*

141 5

tion in the youthful candidate, for Medical distinction, these remarks, I thought necessary to make before attempting to describe the disease, as it occurred on board the United States Schooner Shark during a cruise of six weeks on the coast of Africa. The Shark sailed from the U. S. in November & arrived at the American Colony at Cape Mesurado in February. some few of the colonists were labouring under chills & fever, generally they were healthy, our crew was remarkably so, when we arrived & continued so for some time, as we generally were at sea every day or two & the men were <sup>not</sup> much exposed. Before describing this disease, as it occurred on board the Shark, I think it necessary, in order to elucidate the subject as much as possible, to make a few remarks on the country & climate, these cannot be as accurate as I could wish, but shall be as perfect as my limited observations extended. The country is thickly covered with low wood, and large timber. The soil is very rich, more perhaps more so, none, where vegetation is more rapid, & luxuriant. The seasons are divided into wet & dry. During the wet season, the rain falls in torrents, & almost deluges the face of the country after a heavy shower the air is close, & together with the perpendicular rays of the sun renders it, almost insupportable. When the dry season comes, on vegetation thrives, astonishingly, it soon grows rank, falls, & putrefaction takes place; large collections of stagnant-water filled with vegetable matter in a state of putrefaction, are to be found along the banks of the river. We have the diseases arising from Marsh Effluvia prevailing during the year as putrefaction is continually going on. Yet they are more violent at one time of <sup>the</sup> year than at another. Our stay was during the dry season. In the morning until the sea

Faint, illegible handwriting on a lined page, possibly bleed-through from the reverse side. The text is mirrored across the lines and is mostly illegible due to fading and bleed-through.

Breeze sets in the air is warm & oppressive; about 9 o'clock we have the sea breeze which is refreshing & invigorating. In the afternoon we have the land breeze which produces a change in the temperature of the air, that is truly surprising. It becomes cold, chilly, & damp, & warm clothing is necessary. Many degrees difference will be found in the Thermometer during the twenty four hours. In the afternoon the mist is always so great that the sun becomes obscured about 4 o'clock.

It may easily be conceived that the air coming over such a country, would be loaded with moisture & the poisonous effluvia which is continually evolved from these wide extended marshes.

What Constitution <sup>could</sup> stand with these changes occurring every day. Cold, the great enemy of our race, here acts with certainty, predisposing the body to receive the disease, the cause of which disease is continually acting & surrounding him. his anxiety & dread which a knowledge of the unhealthiness of the climate increases, also renders him a more easy & certain victim to his insidious foe.

All those who were taken with this fever complained of violent pain in the head & back, great uneasiness in the Epigastric region, & more or less irritability of the Stomach. all had the red, muddy & glassy eye. From the want of the written account of the most <sup>reflects</sup> case that occurred, I am unable to be as accurate as I could wish.

The patient was a stout man & of good constitution, he was seized with a violent chill, soon after rising in the morning succeeded by a high fever, pain in the head and back great irritability of the Stomach & great uneasiness at the epigastric region

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

The state of the pulse, I do not correctly remember, but to the best of my recollection, it was depressed. he was bled freely that night & took Calomel during the day, no evacuation from the bowels took place, & an injection was administered. the next day the patient was able to walk <sup>on</sup> the deck, & complained but little, every thing looked favourable, except the eye which still continued to have the same unnatural appearance as at first. On the third day in the morning, he was again seized with a chill, followed by fever, in the afternoon he had another chill. On every other day he was better, the patient not appearing to be much debilitated for the first 2 or 3 days. the active treatment was continued, as the evacuations shewed that the liver was deeply involved; for notwithstanding the continual vomiting no bile was thrown up from the stomach. On the fifth day the debility became very apparent & his countenance indicated much distress. it was now found necessary to change the treatment. Tonics & Stimulants were ordered. On the morning of the sixth he was evidently sinking, about 4 in the afternoon he was seized with convulsions, followed by the black vomit & delirium. the patient on being asked how he felt answered, 'horribly!' at 8 he was again seized with convulsions & expired with the black vomit running out of his mouth. Yellowness here did not take place to any degree until after death, when the whole surface became yellow. this was the first case that occurred & the only one that terminated fatally. To another who was seized with same symptoms, a large dose of Calomel was administered, & the patient was sponged

with vinegar and water, during the continuance of the fever to great advantage. Tonics were given as soon as possible & the patient soon convalesced.

The sponging has been much recommended, & it certainly has been found highly useful. It is hazardous, in fact impossible to pursue the same active treatment, as in the disease of this country & the West Indies, as experience warrants me in asserting. On our passage to the United States, from Havana, several of our men were seized with the yellow fever, the symptoms were not so strongly characteristic of yellow fever, as those on the coast of Africa. but yet required several bleedings & active cathartics, & the fever was not removed, until some mercurial impression had been made on the system. This fact shows the difference between the disease of the two countries. One of the Colonists, who has paid attention to the disease, after considerable observation, remarked, that he found, that foreigners would not bear an active treatment more than a day or two & then required to be supported. The most successful treatment of the disease was, to use strong Mercurial cathartics in the first instance, venesection being cautiously used, together with sponging & diaphoretics. They have an article indigenous to the country which is found to be highly useful, as a diaphoretic & also a decoction of the leaves of the orange & lime trees is also useful.

The early use of tonics is absolutely necessary, as they otherwise soon sink. Under this plan of treatment the disease is found manageable and a voyage to sea soon restores your patient.

The first part of the book is devoted to a general history of the world, from the beginning of time to the present day. The author discusses the various ages of the world, and the different nations and empires that have arisen and fallen. He also touches upon the progress of science and the arts, and the state of the human mind in different ages.

The second part of the book is a more particular history of the British nation, from the first settlement in the island to the present time. The author describes the various reigns of the British monarchs, and the different states of the nation under each of them. He also mentions the various wars and revolutions that have happened in the island, and the progress of the British empire to the present time.

The third part of the book is a history of the British colonies, from the first settlement in America to the present time. The author describes the various colonies that have been planted in America, and the progress of each of them. He also mentions the different wars and revolutions that have happened in the colonies, and the state of the colonies to the present time.

The fourth part of the book is a history of the British empire, from the first settlement in the island to the present time. The author describes the various parts of the empire, and the progress of each of them. He also mentions the different wars and revolutions that have happened in the empire, and the state of the empire to the present time.

Connected with this subject, there are two circumstances of some importance, the one is that remaining on shore all night is almost always attended with sickness. Out of 4 who remained on shore all night, 3 were sick and one died.

A physician who resided there for some time, informed me, that after he got well enough to go on board ship, to sleep if he left the shore before sun set, he escaped his chill, but he invariably had it if he remained for any time, after that period. Johnson on the diseases of tropical climates has also mentioned a fact of this kind. The other is, that constipation for two or three days is followed by high fever & is often fatal to the foreigner, whereas those, who reside there feel no inconvenience whatever, this, say some, is easily explained, the liver is in a state of congestion & the intestines have not those accustomed stimulants, from there being no bile secreted. If this be the cause, ought a cathartic, which only evacuates the contents of the alimentary canal relieve the liver and restore the secretion. I am of opinion that <sup>it may be</sup> a congestion might be produced in the liver, which has already been debilitated by the action of heat & consequently and consequently more sensible to the effects of Marsh Effluvia, by the operation of an active cathartic. What is the effect of a warm climate on this viscus? it stimulates the organ to action & we find the quantity of bile increased; the long continued application of stimulants to <sup>any</sup> organ will debilitate it, heat as the writer on warm climates, <sup>proves</sup> has a stimulant effect upon the liver. It consequently produces debility, of the organ, & it becomes more liable to disease, Marsh Miasma acts on it with power & the result is disease. The faeculent contents of the alimentary

I have here and if there were other things to show that  
the Empire of Britain were as so, the same as that the  
Protestants were the enemy only a saint in Green-hall

Canal, I should suppose must have some effects on the fevers of this kind. The Physicians of <sup>the</sup> West Indies endeavor to restore the secretion of the liver by the use of Calomel in large doses, but they also pay great attention to the removal of the faeces, & keep the bowels soluble. My attention was called to this subject, from a case of Typhus fever, under the care of Professor Rush & mentioned <sup>by</sup> Professor Potter in his lectures. This patient had been stimulated for some time, Dr Rush raised him to a certain degree by tonics &c, but he became stationary, notwithstanding the most powerful tonics were used, a diarrhoea seized him & his convalescence was rapid & the use of tonics was no longer necessary, after having heard of this case. I saw a patient who had a low muttering delirium, stupor & difficult to be roused & scarcely answering the questions that were put to him.

Yet all these symptoms were removed by the free action of a cathartic, which had been given whilst the patient was labouring under these symptoms and the pulse which was before weak & small became fuller & softer & the patient fell tranquilly to sleep.

I think if more attention were paid to the bowels in these fevers, our attention would be rewarded by the speedier convalescence of our patients. Yet it not be understood, that I approve of purging in all stages of fever. If I did patients in certain stages of fever, would soon be hurled into eternity. From the sympathy that is observed to exist, between the bowels & various other organs in different diseases, I am induced to believe, that a soluble state of the bowels would be more advantageous than is generally supposed, & that we are too often deterred from this practice.

There is no doubt, however, that a fact that  
really true when the cause given, that also  
may be seen the effect - and the operation of it  
known that the disease was imported into the colonies in  
one of his allegators from Palestine in 1721  
in all a force, we say that in those words we found  
all the medicines accounts to the formation of this disease  
that the the thermometer says there  
also could be seen summer & tropical weather  
with the important proportion of men here - then to  
men are reported case of men and to other medicines  
our eyes for the cause in the Report, the account  
given by nature of the day and the account says that from the  
the words of the allegator I have seen who the having no  
fair of the disease and nothing to guide them but the  
words and words made up of the Hebrew and  
words said of these great accounts to be really possible  
that seem to be made on to the system from above  
to nearly say the system for in the disease is not by  
infection and the word Palestine - Also naturally the

the mind and the physical climate of Europe, and the  
in the mind & present course of Europe they have 10  
No. Palestine according to the very great form - Palestine

from our too great fear of debility. The prophylaxis is the same on the coast of Africa, as advised by Dr Potter & others as regards the disease in the United States. The bowels to be kept soluble, diet moderate, abstaining from ardent spirits, unless accustomed to their use, carefully guarding against exposure in the sun, & to the night-air; keeping the feet & body dry, never remaining on shore after sunset, & by no means all night, a careful attention to these directions, will prevent the disease or render it light. As to the question of its contagious character I am decidedly an ante contagionist. Were this disease contagious, we should have had none left to tell the dismal story of our miserable end, as ten persons in one case slept in one apartment, with a man who died of the disease, & the marine guard <sup>who</sup> were the only sufferers in the West Indies, from being exposed at night, on post, were confined during the whole of their sickness, on the same small deck where 20 or 30 sailors slept, every night, & they slept almost in contact with each other, & yet not one had the disease, for my own part I visited these men frequently, & never had the least fear on account of its being contagious.

These remarks have been made with diffidence, to be an author so young, was far from my wish. Yet necessity hath compelled me to the task. The inaccuracies of youth must be looked over, when improvement may be expected from the stimulus to exertion that is given to the youthful enquiring mind, from reading the writings of a Rush & many others, who have done honor to their age, & country, & last, though not the

to Manchester, and hence to Manchester  
about the year 1721 or 2 - Mr. Deane  
tells us that the first and second  
of 1691 that a law passed in Boston  
to have the plates which were made  
to have the plates which were made  
that made the appearance of words to be  
preferable to the way when the plates  
made the appearance, we find from account of my  
very minute from Europe and amongst the  
of the country from printed at various  
in whose continuance we have seen the  
ways of the plates making any new  
sent respect to it, however, but though we have not  
had sufficient document from the date and  
age of antiquity to say positively that it was the  
disease which destroyed the inhabitants of the west  
as others in 1729 # 90 and in many other places  
yet it is possible when we see the accounts  
in what we might find been for  
ought we can say knowing all the materials  
we write for the choice formation of the disease  
like present in the islands and many other places

# Dissertation upon Phthisis Pulmonalis.

Study well the clime?  
Should to its manners our congenial frames,  
And mitigate those ills, we cannot shun.

The disease upon which it becomes us to treat has been emphatically as well as justly ranked among the "ap-  
probia medicorum"; and as an incontrovertable evidence  
of this fact our bills of mortality are a lamentable tes-  
timony: to use the words of an immortal sage whose time  
and talent were studiously, zealously, and indefatiga-  
bly directed to the advancement of his profession  
in a degree almost bordering upon enthusiasm - "Phthi-  
sis Pulmonalis as it is justly denominated is of all  
diseases one of the most fatal." When we take a cir-  
cum-spective view over the extended field of nature  
and as idle spectators animadvert upon our insigni-  
ficance and imbecility; what description of

1840

Faint, illegible handwriting covering the majority of the page, likely bleed-through from the reverse side.

subjects do we find fall victims to its deadly influence?  
 Alas all! but amongst them stand conspicuous those who  
 have arrived at the most engaging period of life and  
 those perhaps the fairest of our race. Must talent  
 then be spent in vain? Must researches then be  
 spent in vain? That same enterprise which snatched  
 lightning from the clouds. That same philosophy,  
 and erudition, which has thus high elevated a sci-  
 entific profession; it yet remains for to discover a  
 specific for what we conceive to be the great-  
 est enemy to the human race.

Phthisis Pulmonalis is understood to be that affec-  
 tion in which a general wasting or consumption  
 of the body arises from a disease of the lungs.  
 Notwithstanding the want of Information upon  
 this disease, which has been manifested by some  
 of the most enlightened of the Profession much

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

diversity of opinion as regards its Pathology has been advanced. Whilst by some it has been doubted whether the disease strictly speaking can be considered Idiopathic. By others it is considered to be invariably symptomatic of other diseases. Pneumonia - Catarrh - Scrophula - Haemoptesis - and several other genera have been mentioned as being the exciting causes of Phthisis; but this with the rest of the Pathology must yet remain a desideratum. The theory however of the disease being one "sui generis" appears in itself reasonable and we find it substantiated from the circumstance of the disease making its appearance and approaches in such an insidious and formidable manner as frequently to be beyond the reach of human skill before its deadly effects shall have been promulgated.

It has been remarked that a peculiar description of subjects are more susceptible

I have the honor to acknowledge the receipt of your letter of the 10th inst. in relation to the  
 matter of the application for a license to sell and dispense with the  
 sale of spirituous liquors in the town of ... I have conferred with the  
 selectmen and they are of the opinion that it is not expedient to grant  
 such a license at this time. I am, however, of the opinion that it would be  
 better to grant a license for a limited period of time, say for one year,  
 and then to reconsider the matter at that time. I have no objection to  
 your making such a license as you may see fit. I am, Sir, very  
 respectfully,  
 Yours,  
 ...

of this disease than others and these have been described as being of a sepsifolous diathesis. Whether any real advantage is to be derived from this kind of distinction or not it yet remains to be discovered.

*Pneumonia Pulmonalis* has as an attendant in every instance that modification of fever termed " hectic " this great and prominent characteristic has been described as making its appearance sometime before a fatal termination takes place - much controversy of opinion has been entertained as regards this of all most distressing symptoms it therefore becomes us to remain silent until further and more satisfactory investigation be reported.

Writers when describing disease have thought proper to adopt by way of perspicuity certain classifications, and in order that our present object may be facilitated we for similar causes will adopt a plan approved; although disapproved

of by some upon whom the meed of praise has not been lavished undeservedly. The causes and symptoms of Phthisis have been modified and magnified to so great an extent by nearly every one who has attempted the subject; that it is less a source of astonishment than of mortified feeling, why so much yet remains undiscovered. We will now proceed to a description by observing an arrangement which to us appears plausible as well systematic.

Those species have been denominated the Catarrhal, the Apostematous, and the Tuberculous, In every modification of Phthisis, the symptoms have been referred to three heads — the Pneumonic or Pulmonary symptoms the symptoms of Hectic Fever & the supervening or what has been termed consequent symptoms. We will briefly commence by describing the Pneumonic symptoms as occurring Catarrhal Phthisis

*[Faint, illegible handwriting throughout the page, possibly bleed-through from the reverse side.]*

Cold is looked upon as being the great fountain and throne of all Catarrhal diseases; this modification of Phthisis makes its approach with that same undeviating train of symptoms which characterize this class of disease. After the more violent Pneumonic symptoms shall have subsided, others of a more distressing character are said to develop themselves, and first "Tussis" which may be described as being one of the most prominent features of incipient Phthisis this peculiar disagreeable and troublesome cough we find much aggravated when in the recumbent posture, at the same time we do not find it wanting for disagreeable sensation while in any other position. After this the chief part of the organ shall have proceeded with an almost irreparable devastation, others, of an equally alarming character follow up the afflicting scene. Dyspnoea - sense of soreness in the Thoracic region -

Gold is found in many parts of the world  
and is one of the most valuable metals  
known. It is used for many purposes  
and is also a store of wealth. The  
amount of gold in the world is  
estimated to be about 100,000 tons.  
It is found in veins and lodes  
in the earth. The most important  
sources of gold are the United States,  
Australia, and South Africa. The  
United States has the largest amount  
of gold in the world. It is also  
one of the most important metals  
in the world. It is used for many  
purposes and is also a store of  
wealth. The amount of gold in the  
world is estimated to be about  
100,000 tons. It is found in veins  
and lodes in the earth. The most  
important sources of gold are the  
United States, Australia, and South  
Africa. The United States has the  
largest amount of gold in the world.

and with these attend an expectoration which by this time assumes a yellow aspect, disagreeable both in taste, and smell: occasionally instances we find mingled with the matter expectorated streaks of blood said by discerning men to be an indication of a scrofulous diathesis. Upon this latter clause it remains not for the inexperienced to animadvert, suffice it to say, that the medical opinions of medical men should always be open to impartial investigation as well as rigid scrutiny and if erroneous or inconsistent with Medical Philosophy, talent, and experience, and aspiring ambition, it becomes to controvert. We regret that it is not in our power to dwell more extensively upon this as we conceive to be important points; the confined limits of an Inaugural Dissertation, together with the reflection, of its perchance peculiar uninteresting to the gentleman into whose hands these sheets are considerations abundantly obvious

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

to justify us in abandoning our contemplated arrangement.

Another variety has been described as being the Pneumonic Symptoms occurring in Apostematous Phthisis.

This variety has been described also as being much less frequent than former, its symptoms more prominently characterized and its result a more fruitful source of lamentable contemplation.

Apostematous Phthisis is a consequence upon a large abscess formed within the cavity of the Thorax; the former has been described as being ushered in with cough, and other catarrhal symptoms and as being a consequence upon atmospheric vicissitudes: whilst the Apostematous or the stage we are about to describe would be by those who advocate the theory of the disease being a con-

sequence upon certain other diseases and by those who mingle causes with effects attributed in all probability to an Pneumonia, to an Haemoptesis, or to some other Inflammatory Thoracic disease; we do not conceive that any important advantage can result from this kind of distinction, but we do conceive it to be of vital importance to know whether certain diseases as they are described to be are exciting causes of Phthisis Pulmonalis or what plausibility would make them appear to be merely precursory symptoms. Upon this point much of a speculating nature has been invested in, which has not only had a tendency to render intricate what might otherwise have been considered simple but to render still more complicated a complicated subject.

Authors accounting for abscess forming in the chest af-

Faint, illegible handwriting, likely bleed-through from the reverse side of the page. The text is mirrored and difficult to decipher.

sign as its most frequent cause an hæmorrhage taking place from the lungs. Dr. Cullen has dwelt upon this subject with so much pertinacity, that he has ventured to rank it under the genus of *Hæmoptisis*, and as is generally presumed erroneously viewed it a sequelæ of that affection. that this variety of *Phthisis Pulmonalis* does often commence with a spitting of blood no one pretends to deny; but it would be equally artificial and equally justifiable to place *Intermittent* under the genus *Cholera*, because it has as a frequent precursory symptom *Nausea* and *Vomiting*. *Vomica* may then be considered as a consequence of *Hæmoptesis* or spitting of blood from *Pulmonary Predisposition*. Blood though emanating from the lungs is not to be considered as the only source

The first part of the paper is devoted to a general  
 consideration of the subject, and to a statement of the  
 objects which it has in view. It is then divided into  
 three parts, the first of which is devoted to a  
 description of the nature and extent of the  
 disease, and to a statement of the symptoms  
 which it produces. The second part is devoted to  
 a description of the nature and extent of the  
 disease, and to a statement of the symptoms  
 which it produces. The third part is devoted to  
 a description of the nature and extent of the  
 disease, and to a statement of the symptoms  
 which it produces.

of this variety of disease, Inflammation of the Lungs as well as external thoracic injuries deserve a conspicuous part in this of all most afflicting tragedies. Pain, Dyspnoea, and other Phthisical symptoms attendant upon the incipient stage of Aposstema are said to be comparatively speaking inconsiderable, in this state of things severe fits of coughing will frequently supervene attended with but little expectoration; and in this point consists the great diagnosis between catarrhal and apostematous Phthisis. We had intended dwelling more at length upon this variety of the disease, but when we find Philosophical sages here drop their pen, surely it must be an indication of their having reached a "Ne plus ultra" point.

a point not to be transcended by the inexperienced  
however enthusiastic. We come now to a descrip-  
tion of the most frequent as well as most  
dangerous of all the species of Phthisis.

The Pneumonic symptoms attendant upon the Tu-  
berculous Phthisis approach in many respects

the variety last described it would there-  
fore be superfluous to recapitulate what  
has already been said. Tuberculous Phthisis

in consequence of its arising from the greatest  
variety of exciting causes, is of course of most  
frequent occurrence. But however numerous  
and varied those exciting may be all of them  
operate as giving rise to this variety or mod-  
ification of Phthisis, on one general principal,

17.  
a great deal to be done in the way of  
improving the education of the people.  
One of the most important of these is  
the improvement of the quality of  
the instruction given in the schools.  
The present system of education is  
in many respects defective and  
the necessity of reform is evident to  
all who have given thought to the  
subject. It is already too late to  
reform the existing system, but  
in consequence of its being far the  
most defective of any system of  
education in existence. But however  
this may be, we can do all that  
is possible to improve the present  
state of things, and to lay the  
foundation of a better system for  
the future.

viz. as inducing those peculiar tumours termed tubercles  
 which have been found in the lungs of patients  
 who have died in this stages of Phthisis: the symp-  
 toms attendant upon this variety of the disease are  
 comparatively speaking inconsiderable, in the in-  
 cipient stage cough and other Pneumonic symp-  
 toms are by no means urgent, and in most ca-  
 ses no remarkable pain of breast attends, and  
 when it does it is neither fixed or constant;  
 and contrary to what happens in Apostematous  
 Phthisis the patient can lie with equal fa-  
 cility on either side. Most frequently the mat-  
 ter expectorated in this stage of the disease  
 is a thin watery fluid slightly tinged with

191 14.

blood, it has been described as having very much that appearance of sanies which is often discharged from scrofulous sores. When this state of expectoration takes place "Hectic fever" is seldom wanting to a considerable degree.

Much contrivety of opinion as regards the pathology of "Hectic" has been entertained by some of the most enlightened of the profession. After viewing strictly the different theories advanced upon this subject we are inclined to consider that which arises from a certain irritable state of the system induced by an absorption of pus to be the most probable as well as plausible conjecture.

blood, it has been described as having  
that appearance of virus which is often  
charged from infectious virus. The  
of epithelium takes place. The  
delium wanting to a certain extent.  
absent outbreak of disease in  
pathology of the virus has been  
some of the most important of the  
year. After nursing directly the  
the virus administered upon the subject  
required to consider that which  
a certain extent state of the  
the end of an outbreak of virus to be  
probably will be as follows.

"The Hectic Fever" is very generally not of the continued form - but consisting of remissions and exacerbations; and from this circumstance it has been justly described as being a variety of Intermittent. All that is necessary to mention in this state of things is the description of Pulse attendant upon hectic fever, which in most instances is seldom observed to be under 100 and frequently above 120 strokes in the minute. In some instances of Hectic the pulse is full and hard; but more frequently small and hard during the paroxysm as well as intermission. After this distressing symptom shall have been observed for some time; others

of an equally alarming character make their appearance, those have been termed the supervening and then again they have been considered as sequelae of "Hectic." It is doubtful in our minds whether they can be considered strictly speaking either; they may be perhaps like hectic symptomatic of the progress of the disease from an absorption of ill-conditioned matter from the Lungs, the probability is though that if not induced they are at least much aggravated by the hectic fever.

A picture in itself deplorable 'Tis now we approach with a feeling no less painful than a consciousness of our inadequacy to depict.

of an equally charming character, and  
perhaps, has been found in no other  
and then again they have been considered  
specimens of the best. It is thought  
whether they can be considered as  
any better than many of the others in the  
symptoms of the disease of the  
from an exhibition of the same  
from the large, the color of the  
if not entirely the same at least  
produced by the same cause.  
A better method of the disease  
good with a few others of the same  
and a number of our specimens of the

Human Misery is in no instance more strikingly exemplified than in the one which now presents itself to our consideration, and the one which now it is our province to describe. After all the foregoing distressing symptoms shall have made their appearance upon the stage of humanity, characters equally conspicuous terminate the tragical scene.

Emaciation or wasting, has been justly numbered amongst the prominent Pathognomies, of confirmed Phthisis Pulmonalis, and in no part of the system is this symptom more obvious than in the face, here, it has been termed the "Facies Hippocrates" in short the whole system becomes so completely reduced that it has been represented

to be as it were a living skeleton. With emaciation attends aphthous spots both upon the tongue and mouth, which in the end not unfrequently degenerate into ill conditioned ulcers. These aphthae & consequent ulcerations are particularly observed in the apostematous phthisis, when the expectoration of purulent is considerable, and when, in place of the appearance of mild pus, the discharge has degenerated into an Ichorous state. This affection of the mouth has by some been ascribed, and probably not without reason, to the action of the expectorated on the mouth. To the same cause, acting upon other parts of the alimentary canal, especially,

on the Intestines, has been ascribed another symptom,  
 very common and very distressing, the colligative diarr-  
 hoea, as well as colligative diarrhoea colligative  
 sweats, With these as they are called supervening symp-  
 toms, and the continuance of Heetic it is by no means  
 surprising, that the disease after arising at this  
 state should in almost every case have a fatal  
 termination. Having thus superficially mentioned  
 the causes, and symptoms of Phthisis we will  
 now proceed to a part of our subject, which  
 we promise shall neither be tedious or lengthy

Much has been said about the treatment  
 of this disease, and as in every other disease  
 it is our province to remove as far as is practi-

The first part of the paper is devoted to a description of the  
 various forms of the disease, and the manner in which they  
 are communicated. It is shown that the disease is not  
 contagious, but that it is spread by the agency of  
 insects, and that the most common mode of its  
 transmission is by the bite of a mosquito. The  
 symptoms of the disease are described, and it is  
 shown that they are very similar to those of  
 malaria. The course of the disease is also  
 described, and it is shown that it is usually  
 fatal. The paper concludes with a description of  
 the various remedies which have been proposed  
 for the treatment of the disease, and a  
 summary of the results of the experiments which  
 have been conducted in regard to its  
 transmission.

able and as soon as is practicable, all exciting causes; and thus it must be an object with the practitioner, to counteract, as far as is practicable the ill-consequences of purulent absorption. The means of affecting this removal must, in the different species, be accommodated, to the nature of that particular source from whence the purulence is furnished.

In the Catarrhal Phthisis the source of that purulent matter which produces the symptoms is a mere inflamed surface; hence, our first indication of cure is to diminish that impetu. with which the blood passes through the systemic but more particularly

could not be done as a practical matter, all the  
 country; and that it would be an object worth  
 the best of the country to counteract, as far as  
 possible, the disadvantages of the present  
 law. The means of affecting this  
 result, in the different cases, is  
 stated, to the nature of the business  
 from which the proceeds are  
On the Contract of the  
 present matter which produces the  
 kind of a more important business  
 our first intention of ever to  
 that matter with which the  
 in through the system but

The pulmonary circulation, a diminution of this  
 impetus may be obtained in different ways. The  
 second indication requiring to be fulfilled in  
 the cure of this variety of the disease, is the res-  
 toration of a natural condition to the vessels  
 of the lungs, and with a view of fulfilling  
 this indication, much more is to be derived  
 from regimen than from medicines, and par-  
 ticularly from gentle exercise, pure air, and  
 a mild nutritious diet. In the treatment  
 of Apostematous Phthisis much cannot be  
 said, and we regret much that the same words  
 are applicable, to the third and last or that  
 stage termed Tuberculous Phthisis. Near-

by all of the most eminent writers, have introduced articles in the treatment of Phthisis Pulmonalis described by them as specifics in the disease, we must content ourselves by briefly mentioning those which have mostly excited the attention of the medical world.

We had occasion before to remark that different means had been employed for the purpose of lessening the force of the heart and arteries, and for this purpose the Digitalis of Dr. Beddoes has not held an obscure rank, but to speak in the words of an illustrious Potter like its author has sunk perhaps to rise no more, this remedy we conceive to be not

of the nature of the matter  
 which has been mentioned in the  
 text of the paper is that  
 the author has not been able to  
 find any other instances of  
 the same kind.

The fact however appears to be that  
 different means have been employed for the  
 purpose of determining the form of the  
 particles and for this purpose the  
 of Dr. Beck has not been so  
 but it is clear in the case of an  
 other that the author has not been able to  
 find any other instances of the same kind.

only dangerous in its effects, but inefficient in its consequences, it should therefore deservedly be abandoned from the catalogue of medicines employed in the treatment of Phthisis Pulmonalis. Another article the deleterious effects of which upon the animal economy stands unrivalled within the covers of Materia Medica, has excited attention in no small degree from the votaries of the healing art; and notwithstanding the train of pernicious symptoms, necessarily consequent upon its administration, sages worn out in the shafts of professional prosecution, sages whose eminence

and whose immortality, has strengthened with  
their strength, and grown with their growth, has  
placed it as a curative in a superlative degree.

M. Guy Lussac says he has constantly  
found that the Hydrocyanic-acid adminis-  
tered to the unhappy consumptive, not only  
appeased pain, but diminished frequency of  
cough, moderated and rendered more easy  
expectoration, and lastly procured the patient  
sleep at night, without any colliquative sweats;  
he goes on still further to state, that those  
who are accustomed to follow the march  
progress of Phthisis and witness the sufferings  
without number of those individuals attacked

was under consideration - the  
the strength, and power of the  
placed it a committee in a separate  
Mr. Bayliss says he has  
found that the

appeared then, but  
group, manifested  
experiment, and  
they at night without  
regard to this matter to  
who are referred to  
group of  
which

by this terrible malady and by which they are overpowered, will easily appreciate the benefit of this practice. Encomiums equally extravagant have been lavished upon the article, by men equally eminent, and perhaps equally aspiring. With regard to the employment of Emetics in this disease: they have been mentioned as being in all probability servisable, when not given in large or frequent repeated doses, of this class of medicines Tart: Ant: has been selected as being most servisable. All the class of Stimulents have been employed and as palliatives are considered to be very appropriate remedies. Another important remedy yet remains to be

by this terrible calamity and of which the  
 are everywhere with every reference to the  
 lot of the people. The calamity is  
 has been caused upon the whole of mankind  
 of moment and perhaps equally as distressing  
 regard to the employment of the people in this  
 manner: they have been prevented as being in all  
 probability numbers who are not given a large  
 a frequent repeated loss of the staff of  
 made since that date: but our resources are  
 very much diminished. All the staff of the  
 only have the employment of the people in  
 are not reduced to the very smallest number  
 this. Another important remedy of the same is in

treated of; the administration of Calomel, particularly in the inflammatory form of the disease, which we view as being the only form that can be cured, has acquired celebrity in a degree of no small consideration. Bloodletting in conjunction with the last mentioned remedy appears to be means placed in our hands by which we are to grasp from inevitable destruction myriads of the human family.

With those crude and undigested remarks we close, soliciting from the generous reader a liberal perusal of the same, and reminding him that upon our part it has been a matter of compulsion and not of choice.

This is a disease apparently of  
 Modern origin. I say apparently be-  
 cause altho it may have existed  
 yet it has not been described by any  
 of the Ancients with even a tolerable  
 degree of accuracy. To Dr Home of  
 Edinburgh is justly due the credit  
 of having first called the atten-  
 tion of the Profession to this in-  
 teresting subject. Dr Cheyne has given  
 in the fullest and best account of  
 this disease. Since "the enquiry of  
 Dr Home into the Cramp" it has been  
 noticed by many authors, most of  
 whom have atleast given a differ-  
 ent appellation to the disease, if

they have advanced nothing new

The Croup mostly attacks children  
 between the second and seventh years  
 of their age: a complete immunity  
 from the disease is however enjoy-  
 ed by no age. Adults are much less  
 liable to attacks of this formidable  
 malady than infants. This seems to  
 be owing says Dr Gregory "to some  
 alteration which the mucous Mem-  
 brane of the Trachea undergoes  
 about the age of Puberty. Altho  
 the disease generally appears in a  
 sporadic form, yet it sometimes

prevails as an epidemic, as was  
lamentably case in Virginia in the  
year 1789, when the Father of our  
Country fell a victim to it.

It is not my intention in this essay  
to enquire concerning the great diver-  
sity of opinion which exists among  
Medical men, with regard to the  
Pathology of the Disease. Tracheitis  
or Croup is an inflammation of the  
Mucous Membrane lining the Tra-  
chea, from which it is often exten-  
ded to the muscles surrounding the  
Larynx; the case has also sometimes  
occurred, the disease commencing in  
the muscles, and travelling downwards.

In the latter instance it must be  
confessed that some degree of spas-  
modic contraction of the muscles  
will occur; such however is the  
situation and office of these mus-  
cles that a complete closure of  
the Larynx cannot be effected.

This disease generally arises from  
improper exposure to Cold or damp  
Atmosphere. Those persons who are  
exposed to great vicissitudes of the

Faint, illegible handwriting on aged paper, likely bleed-through from the reverse side of the page.

27

weather are much more liable to the disease, than they who reside in Countries uniformly Cold. and it is on this account that Cases of Tracheitis are most generally met with in the United States during the winter & Spring. The slightest causes will produce this disease in those Children who have once had an attack of it. in such constitutions a common Catarrh will almost invariably be followed by the Croup. It is however a fortunate circumstance that second attacks of the disease are seldom so violent as the first; they nevertheless require the utmost caution on the part of the Physician.

Tracheitis has been thought by some very eminent Practitioners to be a contagious disease even the acute Dr Gregory seems inclined to adopt this opinion. There are however so far as I have been able to learn no evidences of the fact. there is on the contrary every reason to believe that the disease is not contagious. The same cause which produced it in one child of a family may give rise

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

to it, in another; and if we admit <sup>229</sup>  
the contagious character of Trachetis  
we must extend the doctrine so as  
to include all those diseases con-  
sequent upon the application  
of cold to the Body. - But where can  
that individual be found who will  
assert that Catarrhs Pneumonia or  
Rheumatism are contagious diseases?  
The same cause evidently producing  
all these diseases, and no reason can  
be assigned why any one of them  
is contagious, and the others not.  
But whilst I deny the contagious  
character of this disease, I am  
willing to admit, that it may  
be founded on Hereditary Pre-  
disposition. Dr Patter asserts that  
it is as certainly an Hereditary dis-  
ease, as Gout or Phtisis. I shall  
not attempt to discuss this question  
as it is one which can only be  
decided by experience, but shall  
proceed to enumerate some of  
the most common symptoms of  
the disease. - Some days previous to  
to an attack of the disease the child

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

231

appear inactive and fretful, the eyes are dull and heavy - symptoms of Catarrh succeed, a hoarseness attended with a peculiar shrill and ringing sound in speaking and coughing, which has been happily compared to the barking of a small dog or Foxit has also been supposed to resemble the noise from a Brazen Tube. Chilliness sometimes attends the first stage of the disease, a pain is felt about the Larynx, great difficulty of breathing, accompanied with a whizzing sound in inspiration, the cough is generally dry but if anything is spit up it is generally a purulent matter; sometimes however films are discharged resembling portions of a membrane. Together with these symptoms the pulse is hard and frequent the patient is restless and complains of an extremely uneasy sense of heat. The External Fauces on examination sometimes exhibit no appearance of Inflammation

233

most frequently, however a redness  
and even swelling is observable. It  
is remarkable that the natural func-  
tions as well as those of the Brain  
are seldom much disturbed. Chil-  
dren are often seen running about  
taking their food, indulging in  
the amusements peculiar to their  
age, apparently in good health  
whilst in reality the disease is  
rapidly advancing. if its progress  
be not promptly checked all the  
symptoms soon become much ag-  
gravated. The respiration is ex-  
tremely laborious, the cough dif-  
~~ficult and~~ troublesome and  
expectoration more difficult  
and in a few hours suffocation closes  
the scene.

The duration of the disease  
depends generally upon its violence  
and the means which have been em-  
ployed for its cure; when no medi-  
cal treatment has been resorted  
to, it, almost frequently, terminates  
fatally in about 24 or 36 hours.

Faint, illegible handwriting on aged paper, possibly bleed-through from the reverse side. The text is mirrored and difficult to decipher.

235

It is all important, that the alarming symptoms should be moderated during the first twelve hours of the disease; unless this can be effected the patient generally dies soon after. If however by the efforts of nature or by the assistance of art the child recovers from what has been called the second stage of the disease, the convalescence is always tedious, and attended with expectoration of portions of membrane. In milder cases when the breathing is less difficult in the commencement, about the second day the skin becomes moist, the fever abates, the cough is less troublesome, and the voice gradually recovers its natural tone.

A peculiar morbid appearance is observable in the examinations of those who have died of this disease. a membrane or tube of coagulable lymph, is found lining the whole extent of the Trachea descending even to the bifurcation of the Bronchia. Dr Potter says this body is found not only throughout the Bronchial bifurcations

tent throughout many of their extreme  
 ramifications into the smallest vessels,  
 as was beautifully illustrated in a sub-  
 ject prepared by the Dr for the demon-  
 stration of the late Professor Wistar of  
 Philadelphia. This contains the Dr  
 is a secretion from the inflamed ves-  
 sels of the part, and is of all consisten-  
 cies from the smallest change from  
 health to the secretory process perfect-  
 ly formed in inflammations. The  
 secretion of the more compact form  
 to which the appellation of membrane  
 has been given, seems to be the fibrine  
 of the Blood semi-organized. At  
 The this membrane is generally found  
 in the Trachea of those who have  
 died of Croup, still it is not to be  
 considered either as a constant or  
 necessary part of the disease. Dr  
 Gregory has observed that its for-  
 mation is always indicated by the  
 manner in which the child breathes  
 viz. throwing the head back so  
 as to put the Trachea on the stretch

With regard to the treatment of this  
 disease there seems to be some <sup>alteration</sup> diversity

of opinion among Medical men. A  
 Pathological distinction has been made by  
 some, which is of no practical impor-  
 tance. If there be such a thing at all  
 as a primary Spasmodic Croup, it must  
 invariably depend upon an Inflamma-  
 tion of the muscles of the Glottis, and  
 therefore the same remedies are to  
 be employed in the first stage of  
 the disease, whether it be an inflam-  
 matory or Spasmodic affection.

The Croup has been divided  
 into two stages; the first being that  
 of high inflammatory action. The  
 second is distinguished by the forma-  
 tion of that prternatural mem-  
 brane already spoken of. In the  
 first stage, it should be our ob-  
 ject to subdue Inflammation  
 by all the means in our power and  
 thereby prevent the formation of that  
 membrane which blocks up the pas-  
 sage of air into the Lungs, inducing  
 suffocation and consequently death.  
 To accomplish this first indication  
 the most powerful antiphlogistic  
 remedies should be promptly em-

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

employed. our chief reliance is to be placed in general and Local Bleeding emetics, the warm bath, and purgatives. If however we do not succeed in relieving the first stage of the disease, it then becomes our duty to endeavor to promote expectoration, and to support the strength of the system, which is generally much weakened by the previous depletory measures. For the purpose of answering these indications, recourse may be had to squills, Camphor opium, and other Loric medicines an occasional emetic may also be exhibited, and as a last resort

Tracheotomy - has been recommended

I shall now say a word or two with regard to the particular remedies which have been recommended for the cure of this disease, and first of Bloodletting. This in my humble opinion is our Sheet Anchor. It is never injurious. it may however sometimes be unnecessary. In the milder forms of the disease where there is not much inflam-

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

natory action, an Emetic will often supersede the necessity for the employment of any other remedy. One bleeding in the first stage of the disease is of more importance than half a dozen afterwards.

Emetics are always necessary and should never be omitted for this purpose. The Tartar Emetic or Spueacuantra may be employed. If however after being given in very large doses they fail to produce the desired effect, the Corrosive Sublimate may be resorted to with the greatest advantage. Small doses repeated from the commencement of the disease, has been strongly recommended. "This practice says one in whose skill and experience I have an almost unlimited confidence" is rather calculated to injure the reputation of the medicine, than to cure the patient. It should be given in doses so large as to shock most of the

timid Practitioners of the present <sup>day</sup>  
who are deterred from employing this  
valuable remedy to any useful extent  
by the fear of salivating their Patients  
Dr. Pater says there is but little danger  
of producing a severe Thyralism by  
Calomel in this disease. he has seen  
but one case out of several hundred  
No one of these remedies should  
be relied on in violent cases to the  
exclusion of the others. Bloodletting  
being premised a judicious com-  
bination of Calomel & Tartar Emlic  
will generally cure the Patient -  
nor should the assistance of the  
warm bath be despised. The app-  
lication of Blisters to the Throat has  
been recommended - its propriety is  
to me ~~not~~ very questionable. It seems  
Blisters, may sometimes extend to  
the inflamed membrane, and  
consequently aggravate the dis-  
ease. The decoction of Polygala  
Seneca has been lately introduced  
into the practice as a remedy for  
this disease by Dr. Archer of Mary-  
land. It is my opinion too stimu-  
lating to be of any advantage in

the first stage of the disease. when how-  
 ever the inflammatory symptoms have  
 subsided in a great degree ~~subside~~ - ~~its~~ em-  
 ployment will <sup>generally</sup> ~~in many~~ <sup>be attended</sup>  
 with the most beneficial results. It  
 is unnecessary for me to say any thing with  
 regard to the other medicines which  
 have been recommended in this disease. At  
 the first stage they ~~may be beneficial~~  
 must be injurious, in the last they  
 may be useful. Bronchotomy is al-  
 together inadmissible in Croup for this  
 simple reason, that we are unable there-  
 by to remove the membrane which is  
 the cause of the obstruction - and besides  
 it prevents us from employing other rem-  
 edies -

Pulmonary Consumption is a disease, concerning which a variety of opinions have been given, and even at the present day Physicians widely differ with regard to its Pathology; Some contend that the disease never appears without the presence of tubercles in the lungs, while others say that Pulmonary Consumption can exist independent of a scrophulous pre-disposition.

As it would be not only tedious, but also useless, to attempt an elaborate discussion of a subject, which probably may never be decided, I will merely submit my opinions with regard to the real nature of the disease, innumerate the principal symptoms and mention those remedies which appear to be most useful;

By the term Pulmonary Consumption, I would imply that disease, which is the consequence of Tubercles seated in the cellular connecting membrane of the lungs; Whether or not this term could be properly applied to other diseases of the lungs it is not for me to decide, but merely for the sake of precision, I am disposed to think, that the peculiar wasting of the body and of the lungs caused by the inflammation and suppuration of tubercles seated in the lungs, alone deserves the name of Pulmonary Consumption;

Those who have tubercles in the lungs, are evidently of the strumous Temperament, and it still remains to be proved

whether or not tubercles be ever formed in the lungs without an hereditary predisposition to them.

The Strumous Temperament appears under two modifications, the one is found in those who have, naturally, pale skins, loose flabby fibres and a sluggish pulse; The other in those who have ruddy complexions, firmer fibres, and a brisk circulation. And in both modifications there is an unusual irritability of the capillary arteries;

In children we can generally determine whether or not they are predisposed to Phthisis, by the smooth and rosy appearance of their cheeks, their fair hair and delicate blue eyes: The forehead is generally prominent, and it is remarked that the lips of scrophulous children are tumid;

As the child advances in years we perceive the maturing of different glands of the body, which as the patient grows riper in age, progress in growth: and I am disposed to think that almost all of those diseases, which we hear spoken of as affecting different joints, are no more, nor less than the effects of Scrophula;

As the general characters of Scrophula are so well known I will not longer dwell upon them, but proceed to describe its appearance in the form of Pulmonary Consumption

255

This disease seldom appears before the age of puberty, It is usually excited by causes which produce Inflammation, The patient complains of a weight or uneasiness in the chest, this sensation is attended by a cough which is generally dry, short and tickling, then appears to be considerable exertion, and the face is usually flushed, the pulse is frequent and sometimes tense,

As the disease progresses, the pain in the chest becomes more acute and often extends to one shoulder.

The cough becomes more troublesome, and at length expectoration comes on: The Lips of the patient are generally, preternaturally florid,

At this stage of the disease hectic symptoms are more apparent, the patient is harassed with evening fever and night sweats. These symptoms continue till the pus formed by the suppuration of the tubercles in the lungs has been expectorated, which in the early part of life will be accomplished in a short time,

The patient is then considerably relieved for that period and has few unpleasant or alarming symptoms until the same process of Inflammation and suppuration comes on: The patient, however is not entirely relieved from hectic symptoms; some cough and fever still remain—

As the patient still advances in life, the general health becomes more impaired, from the repeated struggles which he has survived, and his whole system becomes reduced & grows long continued hectic fever; nights are spent without repose, and each returning day presenting the same or a more condition of his system, renders life almost a burden;

In the forming stage of Pulmonary Consumption, we have many remedies which exert a very beneficial influence, in warding off the disease, but when Pththisis becomes confirmed very little can be accomplished by the Physician. In the forming stage, or before inflammation of the tubercles has progressed in any considerable degree, Bloodletting is a remedy of inestimable value, Digitalis has been used with the same view but it has been observed "That the injurious effects of Digitalis often precede its good effects;" and I would suppose that in every case of Consumption the lancet will accomplish every object which could be expected from Digitalis; Blood should be drawn in small quantities, and the operation should be frequently repeated. Thus are many cases of Pththisis in which Mercury given with precaution, exerts the most salutary effects; Cases in the forming stages, which are not attended with considerable action, have often been prevented from terminating in suppuration, by using

*[The text on this page is extremely faint and illegible, appearing as ghostly impressions of handwriting.]*

the Blue pill so as slightly to effect the gums.

Those who are predisposed to Pulmonary Consumption, should be very cautious in their dress. Flannel should be worn next the skin in winter by all, and in summer also, by the more delicate. It preserves the equilibrium of temperature, and prevents the system from being injured by every change of weather, and as our climate is so very precarious, it is my opinion, that this prescription should by no means be neglected.

Another important prescription, is Exercise; The Consumptive patient, in clear weather, should take exercise freely, particularly in the mornings, it gives tone to the digestive organs, and invigorates the whole system.

Attention should be paid to regimen and diet. The patient should take animal food in moderation, and it should be the principal article of food. All irritating and indigestible articles should be avoided.

Blisters or setons are almost indispensable in the prevention of this disease. A discharge from the surface should constantly be promoted by either a blister or a seton.

The cold Bath has also been highly recommended by some Physicians - and: But the most effectual means for preventing this disease is a Removal to a warm climate, and to a climate which is free

from many vicissitudes of weather,

These are the principal means which are used for the prevention of this disease. When Consumption becomes confirmed, as I before observed, very little can be done by the Physician

however we have some medicines which afford some relief. Opium is generally freely used in the latter stages of Consumption. When the patient passes nights without sleep, has great irritability, and is harassed by a continual cough, I am of opinion that Morpheus might be given with great advantage as it possesses all the sedative but none of the stimulative qualities of Opium. This also will answer every purpose for which Prussic acid has been given.

When the colligative sweats are copious, the Balsom Copaiba given as a Diuretic generally lessens the sweat.

As I intended merely to make some general remarks on this disease, I will end, after mentioning some diseases which may be mistaken for Pulmonary Consumption, and mentioning some differences which distinguish them, from True Phtisis.

Ulcerations in the Trachea has often been mistaken for Pulmonary Consumption, this often arises from an insidious inflammation. It is attended with a tickling cough, the voice is slightly

Faint, illegible handwriting, likely bleed-through from the reverse side of the page. The text is mirrored and difficult to decipher.

changed, and uneasiness is experienced in some part of the Trachea. The breathing is sometimes oppressive, and there is generally slow increasing fever. Inflammation of the adjacent parts also very often exists at the same time; In the first stage of this affection Mucus and Lymph are expectorated, but as soon as ulceration takes place the sputa are mixed with pus; After this disease may have continued for some length of time fever is manifested, but it is not attended with the copious night sweats which characterize the True Plectic. When inflammation of the Trachea becomes chronic, soreness is felt by pressing on the Trachea, which sensation is not experienced in Pulmonary Consumption.

Chronic Inflammation of the Bronchiae is another disease which may be mistaken for Consumption. It at first resembles a common Catarrh, but by the increasing fever, and duration of the disease we are made sensible of its nature. When it has progressed so far as to make an abscess in the lungs themselves it is very difficult to distinguish it from Tubercular Consumption. In the first stage it may be distinguished by the wheezing and Catarrhal character of the disease and by the patient not wasting flesh and strength as always happens in Tubercular Consumption; The face

Faint, illegible handwriting, likely bleed-through from the reverse side of the page. The text is mirrored and difficult to decipher.

265

from the onset assumes a sickly palidity, and the lips are of a leaden hue, whereas in Tubercular Consumption the face is alternately pale and flushed and the lips are beautifully tinged with a bright red.

When the more acute forms of Pleurisy have been subdued an obscure kind of increased action is often left which <sup>sometimes</sup> ~~it~~ becomes chronic, this however may arise without being preceded by acute Inflammation, The patient has slow fever at night and has oppression in the chest: There is occasional cough, which is most troublesome in the morning. Goreness will be felt in the integuments of the side affected, particularly if pressure be made, The disease progresses until dyspnea and emaciation are the two principal symptoms. In this stage it can be distinguished from Pthisis by the colour of the patients skin, and the difficulty of breathing which is increased by using the least exercise.

Chronic Inflammation of the lungs themselves has very often been mistaken for Tubercular Consumption, This disease in its progress bears a strong resemblance to Tubercular Consumption but a history of the patients life preceding the attack, and by procuring a knowledge of the health of the patients predecessors, we can generally ascertain whether or not the latter disease exists,

*[The text on this page is extremely faint and illegible, appearing as ghostly impressions of handwriting.]*

An  
Inaugural Dissertation

To the Honorable Secretary of the Treasury

The following is a list of the names of the persons who have been appointed to the office of Assistant Secretary of the Treasury, and who have taken the oath of office and qualification, and are now acting as such.

John C. Thompson

March 14, 1845

Introduction

The many difficulties which present themselves to the mind of the writer, in selecting the subject of his inaugural Essay, influence in a great degree his choice. It cannot however be expected that one who has neither age nor experience to support him, can produce anything new in relation to disease. — I shall therefore content myself by giving as far as my limited abilities and time will enable me, a history of the causes, symptoms and treatment of the disease under consideration, known by the term Hydrocephalus Internus. Having chosen this subject for the following pages, it is my intention "safely to tread the beaten track;" and with this view shall quote the opinions advanced by Whist, Quin, Rush & others.

Introduction

The many difficulties which attend the study of the  
science of the mind, in relation to the subject of  
the soul, have, of late years, attracted the attention  
of many of our countrymen, and it is not  
surprising that they should have done so, inasmuch  
as the subject has been treated in a manner  
which is highly interesting and instructive.  
The object of this work is to present a  
clear and concise view of the principles  
of the mind, and to show the connection  
between the mind and the body, and  
the influence of the mind on the body.  
It is intended for the use of students  
of the law, and of those who are  
interested in the study of the mind.  
The author has endeavored to present  
the subject in a manner which is  
both clear and concise, and which  
will be found to be highly interesting  
and instructive.

# Hydrocephalus Internus.

The earliest correct description of this very interesting and too frequently fatal disease was, as well as I am informed given to the world by Whytt, whose observations on it, were not published until the year 1768. This valuable author describes with great accuracy the cause and advancement of the disease.

Cullen in the edition of his nosology, published in 1785 recognizes this disease under the term *Apoplexia Hydrocephalica*.

Quin of Dublin, in his Inaugural dissertation published at Edinburgh in 1779, and a subsequent Essay in 1790 describes *Apoplexia Hydrocephalica* with much more accuracy and propriety, ideas altogether new as to its theory.

Rush, our celebrated countryman not long afterwards adopted a similar theory of the disease to that of Quin, & in his works, has given us a paper in which he mentions the inflammatory nature of *Hydrocephalus Internus*.

Whytt in speaking of its proximate cause, seems to make it depend upon a loss of balance between exhalation and absorption; and indeed this was the opinion of the

ancient as well as the modern writers, concerning Dropsies in  
other parts of the body.

Quin suggested the inflammatory nature of this disease in  
his Inaugural Essay, written in 1779, and in a treatise, subse-  
quently, confirms this view of the disease, by additional observations  
and numerous cases of dissection.

The same opinion was adopted by Rush, (med. Inq. vol. 2  
page 143) about the same time, to which increasing weight is given  
by discoveries on dissection, shewing the fatal issue of many the  
cases treated by anti-phlogistic remedies.

The writer would venture to defend the opinions of the two  
last named authors; and for this purpose he conceives it will  
necessary attentively to consider the causes of this disease, the  
symptoms and the mode of practice, which has been found  
most successful in treating it.

Hydrocephalus Internus, may probably be divided into  
primary and secondary.

Rush enumerates the following causes "falls or bruises upon  
the head, certain positions of the body and childish plays,  
which tend to increase congestion, inflammation and subsequent-  
ly an effusion of water in the brain." — Now we have every  
reason to conclude from these very valuable remarks, that  
falls, bruises or blows on the head, do produce inflammation

*[The page contains several paragraphs of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and difficult to decipher.]*

5

not only of the external integument, but also the lining membrane  
of the cranium; which too frequently terminate in suppuration  
and gangrene. The other direct causes mentioned by Rush  
to which more might be added, especially the influence of the  
Sun or a reduced temperature, can scarcely be supposed  
to act in any other way than by increasing the quantity of  
blood in the vessels of the brain, and resulting in an inflam-  
matory action in them. — The causes enumerated by Rush  
as acting indirectly in producing the disease under consid-  
eration, are surely fitted to produce an inflammatory ~~action~~  
disease; These are states, either of inflammation or irritation  
in other parts of the system; and when the disease is thus  
produced, there is a mere translation of it, and not a  
change of morbid action; Surely, the membranes and the  
structure of the brain are different from that of other parts  
of the system, but then, they have not the power of producing  
an action in the vessels, sui generis. The effect of their  
operation, therefore upon the brain must be an excitement of  
irritation or inflammation. These causes are, 1<sup>st</sup> Intermitt-  
ents Remittent and continued fevers, 2<sup>nd</sup> Rheumatism, 3<sup>rd</sup>  
Influenza Pulmonalis, 4<sup>th</sup> Eruptive fevers & Worms. —

Having briefly noticed the causes of this disease, I propose  
next to take notice of the symptoms which attend it, and  
also of the appearances upon dissection after death, being further

*[The page contains several lines of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and difficult to decipher.]*

proofs of its inflammatory nature.

214  
The symptoms of *Hydrocephalus Internus* as related by Whist appear to me to be as minute, at least, and as correct as those detailed by those who wrote subsequent to him, however, as the work of Quin is more modern and sufficiently correct, I will insert his description of the symptoms.

In general the patient is at first languid and inactive often drowsy and feverish, but at intervals, cheerful and apparently lively and free from any complaint. The appetite is bad, often nausea and vomiting occur through the day, the skin hot and dry towards evening. Soon after these symptoms appear, the patient is attacked with sharp headache, chiefly in the forehead, and if not there, in the crown of the head, it is sometimes however confined to the side or sides of the head, and in that case, when the posture of the body is erect, the head often inclines to one side, particularly that side affected. This headache is also frequently accompanied with an affection of the stomach, the vomiting being more troublesome when the pain is less violent and vice versa.

"The light is disagreeable to the patient at this period. cries much, sleeps but little, and when he does sleep, grinds his teeth, picks his nose, appears to be uneasy, often screaming as if greatly terrified. The bowels in a majority of cases

*[The page contains several paragraphs of handwritten text in cursive script, which is extremely faint and largely illegible due to fading and bleed-through from the reverse side. The text appears to be a letter or a formal document.]*

are much confined, though it sometimes happens, that they are in an opposite state. The pulse in this early stage does not indicate any material derangement.

When the symptoms above mentioned, have continued for a few days, subject as they always are in this disease to great fluctuation; the axis of one eye is generally found turned inward, to the nose, and the pupil upon that side rather more dilated than the other. And when both eyes have their axes turned inward, which sometimes happens, both pupils are observed to be larger than in health. The vomiting becomes more constant, and the headache more excruciating; at this period every symptom of fever makes its appearance; the pulse is frequent, the breathing very quick and exacerbations of fever take place towards evening, the face occasionally flushed, usually one cheek more than the other, temporary perspiration breaks out, but does not alleviate the condition of the patient. Epistaxis takes place about this period; also delirium and that of the most violent kind, particularly if the patient has arrived at the age of puberty, which together with all the preceding symptoms of fever, continues for a while to increase, until about the fourteenth day, often a much shorter space of time shall have elapsed since the appearance of the symptoms which were first mentioned in the above detail.

8

The disease undergoes that change which, suddenly, points out the commencement of what has been termed the second stage. The pulse becomes slow, but unequal, both as to its strength and the interval between the pulsations. The pain of the head or whatever part of the body had previously been affected, seems to abate, or at least the patient is less sensible to it, the interrupted slumbers or perpetual restlessness which prevailed during the earlier period of the disease are succeeded by an almost lethargic torpor, the strabismus and dilatation of the pupil increases, the patient lies with one or both eyes half closed, which, when minutely examined will be found almost completely insensible to light, the vomiting ceases, and whatever food or medicine is offered, is usually swallowed with apparent voracity, the bowels at this period generally remain obstinately costive.

"If every effort made by art fail to raise the sinking powers of life, the symptoms of what has been called the 2<sup>d</sup> stage are soon succeeded by others which more certainly announce the approach of death. The pulse again becomes equal, but so weak and so quick, that it is almost impossible to enumerate it. A difficulty of breathing nearly resembling stertor apoplecticus is often observed, sometimes the eyes are suffused with blood, the flushing of the face is more frequent than before, but of shorter duration, and followed

by a deadly jaundice; red blotches sometimes appear <sup>289</sup> on the body  
or limbs, deglutition becomes difficult and convulsions general-  
-ly close the scene.

The symptoms not less than the causes of  
Hydrocephalus Internus, demonstrate its inflammatory nature.  
The intolerance of light, the morbid sensibility of the auditory  
-ary nerve, the delirium and flushings of the face can be explain-  
-ed upon no other principle.

One or two more points shall be noticed under this head the  
in favour of the inflammatory nature of this disease; one  
first of the discoveries after dissection. - In relating to  
the evidences of morbid action, shewn by human dissection,  
especially when connected with a knowledge of the progress  
of the symptoms during the continuance of the disease, we may  
be considered as appealing to the highest source of information,  
with regards to the phenomena of diseases. Three particulars  
are to be noticed in attending to the appearances after  
death. - 1<sup>st</sup>. The thickening of the membranes of the brain  
the existence of inflammatory crusts, and the engorged &  
distended state of the blood vessels. The frequent occurrence  
of these things as consequences of inflammatory diseases of the  
Thorax and Abdomen, cannot or ought not to lead the  
least shadow of doubt with a candid and intelligent  
mind, that the same appearances of these kinds of

*[The page contains approximately 25 lines of extremely faint, illegible handwriting in cursive script. The text is mirrored across the page, suggesting bleed-through from the reverse side. No legible words or phrases can be discerned.]*

10  
29

*Hydrocephalus* arise from the same cause.

In speaking of the appearances on dissection of those who die of *Phrenitis*, a highly respectable author says "there is often a quantity of water effused into the ventricles." When we compare these appearances with those who have died of *Hydrocephalus*, we cannot help, I think, regarding this disease as a species of *Phrenitis*," (Wilson on febrile diseases, vol 2, page 96). The effusion into the joints which follows acute Rheumatism, & that which succeeds to inflammation of the Pleura, Peritonaeum and other inflamed internal surfaces, would seem at least to give countenance to the supposition that the fluid in *Hydrocephalus* is produced by the same cause.

I admit that the analogy here presented does not unambiguously prove this to be the case, for by assuming this position, we must deny that Dropsical affections ever do arise from any other cause than inflammation, which I am not prepared to do.

The thought just hinted at leads to the consideration of the last particular, in relation to the appearances upon dissection; (194) which is the peculiar property of the fluid, viz its refusal to coagulate by heat; and this property distinguishes it from ordinary Serum, and thus proves it to be a fluid thrown off from the circulating blood either by secretion, or some equivalent process. Quain Professor of the Theory and Practice has taught us that incoagulability is a property belonging to Dropsical effusions

1790

The following is a list of the names of the persons who have been admitted to the office of Justice of the Peace for the County of Middlesex, in the year 1790. The names are arranged in alphabetical order, and are taken from the original list, which is deposited in the office of the Clerk of the Peace for the County of Middlesex.

20 41

into every cavity, and therefore infer that Dropsy, in whatever part of the body, it may occur, is an inflammatory disease.

In Quin's treatise (appendix, case 12) there is an instance of fluid formed in the Brain being coagulated by heat; With the exception of this single case, I neither know nor even recollect of any circumstance to oppose the general doctrine.

This property of incoagulability, as before mentioned distinguishes it very pointedly from serum. It is a charged fluid, and from the symptoms of the disease of which it is an immediate consequence, we have sufficient reason to believe that it is the result of inflammatory action. This theory of the inflammatory nature of the disease under consideration, receives additional confirmation from the condition and temperament, of the subject whom it most frequently attacks. It is, says Fothergill vol 1 page 71, a disease that happens, so far as I have had an opportunity of observing, more commonly to lively, healthy active children in whom of course acute diseases rather than of a low active, or activity, may be supposed to prevail. The next point to be noticed according to the arrangement of this treatise, will be the means of cure, which have been found most effectual in the treatment of Hydrocephalus Internus. However, before entering upon this part of my subject, I will say a few words relative to a prevention of this fatal disease.

Faint, illegible handwriting at the top of the page, possibly a header or introductory text.

Main body of faint, illegible handwriting, consisting of several lines of text.

295 12

The means of prevention may be classed under two general heads, each embracing many particulars, too numerous to be related here. The first general means of prevention is, avoiding all the direct causes which tend to excite the disease. Second, by endeavouring to remove as speedily and effectually as possible, all those diseases which act as indirect causes, in producing it. — The first head of precautions may be addressed to the nurse, or the patient, for this disease is not confined to children alone; and the second, more properly is addressed to the Physician.

Having premised these reflections on the preventive method, I will now return to the consideration of the remedies which have been found most useful.

The first means to be noticed is bloodletting; and this exhibits another most decisive proof of the correctness of the theory adopted in this treatise. Venesection, though recognized by Quin in his list of remedies, was unfortunately but seldom resorted to by him, if we may be permitted to draw any conclusion from the cases, reported to have been treated by him. In seven cases, successfully treated by our celebrated Quin, venesection was practised more or less in every case. This course should be adopted in the early part of the disease, and should be frequently repeated, always taking care to contact the pulse. Bloodletting from the

*[The page contains several lines of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and difficult to decipher.]*

Irregular pain has been recommended by some, this however has its disadvantages. Blood drawn from the arm, in a proper manner, will reduce the general excitement as effectually and equally as quick as if taken away from any other part.

Local bloodletting, I conceive to be of great advantage. The great importance of this will be very evident, for while general bloodletting only reduces the force of the circulation, local bloodletting tends to relieve the distended and engorged state of the vessels of the part affected; which state is not only the cause of the effusion so much to be dreaded, but also acts as the cause of excitement of the general system. The second remedy is blisters. There has been and still is much diversity of opinion relative to the modus Operandi of blisters among Medical writers and practitioners.

That they act as a stimulus to the part applied as well as generally, cannot be denied; A secondary, tho' not less important, is the abstraction of a portion of the more fluid part of the blood. Rush says they are proper in every stage of Hydropcephalus Internus. In the early part of this disease this application should be preceded by general bleeding; and it is proper to keep up the discharge from the blistered surface for a short time, the better to secure your aim; and for this purpose the Ungt. Epispast. may be used to great advantage. Letons and Issues have been recommended by some, but in my

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and difficult to decipher.]*

249 14

quinn they are too slow in their operation for a disease of this nature.

Cathartics, are the third class of remedies to be noticed. They should be assiduously employed from the commencement. And the best agents for this purpose are, probably the cooling Salts. They are more speedy in their operation and seek to occasion large watery discharges. A combination of sulphat Potasse cum sulpho: Salapæ or Salapina, nitrate of Potash will be found very useful. Calomel is more readily recommended by all writers. When used to procure a purgative effect, it should be combined with one or more of the above named remedies. In an advanced stage of the disease, Mercurial friction may be resorted to, but should not be depended upon alone. As the bowels are disposed to be torpid in this disease, much larger doses will be requisite, than under ordinary circumstances. Cold applications eminent to be considered. - Cold water, vinegar and water, or pounded Ice put into a bladder, have all been found of much service in abstracting heat from the head. The application of Ether or other vapourizable fluids, by their sudden absorption of a large portion of caloric, are unambiguously calculated to produce a good effect. The position of the patient is by no means an unimportant

*[The page contains approximately 25 lines of extremely faint, illegible handwriting in cursive script. The text is mirrored across the page, suggesting bleed-through from the reverse side. No specific words or phrases are discernible.]*

14

consideration. The head should be as much elevated as  
convenient; the room kept perfectly dark and very cool.  
much light being very injurious. All noise should be  
avoided in cases of morbid sensibility of hearing.

As premised in the introduction nothing original is  
pretences on my part. — In my humble opinion, however,  
the credit of first showing this to be an inflammatory disease  
belongs to Quin. His theory, plausible and defensive  
as it really is, would indeed merit but little estimation  
were it not that it leads to a system of practice, which  
experience has proved to be far more successful than  
any other which has been recommended. It is this con-  
sistency between the theory and the results of practice  
which gives to the former their only value.

By a course of strict investigation and close observation,  
Quin and Pouch, have exhibited the true nature of the  
disease which has been the subject of this Essay; and  
they have instituted and recommended a course of practice  
which if attentively pursued, promises more than any  
other, to restrain the ravages of <sup>the</sup> Pyæcephala, Internus.

An  
Inaugural Dissertation  
On  
Hydrocephalus Internus  
By  
Edward H. Louder

For  
The Degree  
Of Doctor of Medicine

Maryland. March 15<sup>th</sup> 1828

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

Perhaps there is no disease in Nosology which is described, by such a variety, of names, as the one which I have selected as the subject of my Inaugural Dissertation.

Although we call Hydrocephalus a disease, it is more, from the tyranny of custom than strict pathological accuracy; as the derivation of the term implies, it is a collection of a watery fluid ~~secreted~~ in some part of the brain, and is the effect of a slow chronic inflammation of that organ. it is described by Doctor Cullen under the title of serous apoplexy; but the fluid which is found in the brain of those who have died of this affection does not resemble serum, except in appearance as it will not coagulate, by heat or any chemical agent; therefore we cannot

Faint, illegible handwriting, likely bleed-through from the reverse side of the page. The text is mirrored and difficult to decipher.

with strict propriety subscribe the ~~with~~  
 Serous apoplexy; others again describe the  
 disease, as a chronic inflammation of the  
 brain, *Phrenitis chronica vel subacuta*, this  
 appellation is more suitable than any other  
 to the condition, in which the vessels are  
 in, at the time, the fluid is deposited  
 and is therefore, a more appropriate term  
 I think than any which has, as yet been  
 applied; Doctor Good in his excellent work  
 on the study of medicine, calls it *Cephalitis*  
*profunda*, what his object could have been  
 for adding *profunda*, I cannot conceive  
 otherwise than he intended that the water  
 secretion always commenced in the  
 ventricles, which are situated in the interior  
 of the Brain; if that was the Doctor's object  
 he is certainly correct, as that is the usual  
 situation of the incipient secretion,

Faint, illegible handwriting on aged paper, possibly bleed-through from the reverse side. The text is mostly illegible due to fading and the age of the document.

311  
although he may be correct, as far as respects  
the seat of the disease; I cannot subscribe  
to his opinion, concerning the proximate  
the Doctor thinks, debility to be, the proximate  
cause of this, as of all other forms of dropsy,  
by debility. I understand a relaxation of the  
exhalents, and consequently an infiltration  
of the serous or ~~thin~~ parts of the blood  
through the ~~secret~~ mouths of the exhalents  
in this respect he does not differ from  
Doctor Cullen, except in the name of  
the affection, as both perfectly, as to the  
nature of the fluid agree; there are some  
who suppose the proximate cause of all  
dropsies to be a debility of the absorbents  
and among the advocates of this theory  
Doctor Darwin was the most prominent  
who is deservedly more celebrated for his  
poetical, than medical productions

313

It was at one <sup>time</sup> a popular opinion, but which is, too often, but another name for popular error. That this affection, was generally intimately associated with a scrophulous diathesis of the general system; there are instances of congenital Hydrocephalus, when a separation of the cranial bones, has taken place to an almost incredible distance, and children under such circumstances, have lived in apparent ease and comfort for several years.

Such occurrences as these are sometimes supposed to depend upon, an hereditary scrophulous taint but it is a subject as yet sub judice, and would afford abundant materials, for the theoretic speculations of those, whose genius may unravel the mysterious and almost inscrutable intricacies of its cause, such instances are comparatively rare, and generally

come under the cognisance of the <sup>705</sup> <sup>Tradition</sup> obstetrical  
the few remaining advocates of the impu-  
delics of the gastric pathology, think Hydro-  
cephalus to be frequently connected with a  
disordered state of the chilo-poietic viscera  
when this is the case, the Brain I imagine  
is predisposed, and the congestion of the diseas-  
ed viscera, excites the action of the heart, and  
~~the~~ Brain being the weakest part, it conse-  
quently must be the first to suffer, and when it  
does, the vessels take on a secretory action, and  
deposit the fluid in the ventricles. The presence  
of worms in the intestinal canal, occasion-  
ally give rise to symptoms of Hydrocephalus  
but such symptoms are speedily removed, by  
the exhibition of proper Anthelmintic  
medicines. our illustrious countryman Doctor  
Rush who is deservedly acknowledged, to have

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

317

written one of the best chapters, in his enquiring  
on Hydrocephalus, that has ever been presented  
to the medical world; he thinks, that in the  
very highly acute form of Pnenitis, the inflam<sup>mation</sup>  
ion is so great, as to transcend the grade  
of secretion, as is frequently the case in cynanche  
trachealis, and hence the term cynanche sicca.  
The Doctor thinks that the vessels of the Brain  
are in a condition, intermediate between that  
of <sup>serous</sup> apoplexy, and the high inflam<sup>mation</sup> stage  
of Pnenitis, consequently they are labouring under  
chronic inflam<sup>mation</sup>, a condition which is  
certainly the most favourable for that secre<sup>tory</sup>  
process which takes place, at the time the  
fluid is deposited; now if we impartially take  
into consideration the causes which operate  
on the <sup>brain</sup> in producing this disease, and the  
nature of the fluid, which is deposited

Faint, illegible handwriting on aged paper, possibly bleed-through from the reverse side. A small red mark is visible near the center.

we must certainly view Hydrocephalus to be the effect of a chronic inflammation, wherein the vessels assume the function, of secreting vessels as they frequently do in chronic rheumatism producing permanent lameness; the greatest source of error in the treatment of this disease with many Practitioners was in considering it a disease of debility; but the great apparent languor and debility, which attends those labouring under it, is always partially removed by bloodletting; equally as much blood can be frequently abstracted in such cases as in gastritis where the pulse is not the surest and most infallible criterion before bloodletting, we cannot for a moment suppose that it is debility, which induces the patient to complain in a low muttering<sup>tone</sup> of his head, debility would not in the first instance

1

Faint, illegible text, possibly bleed-through from the reverse side of the page.

cause the pupil to contract, and the <sup>321</sup>retina<sub>+</sub> <sup>to be</sup> morbidly sensible to light; as the disease advances, and the pressure on the Brain increases, the origin of the nerves must be equally affected, and deprived of their usual energy and power, the pupil then dilates, and the retina is capable of bearing a stronger light. From the records of medicine, and personal observation, it would appear, that this disease was in some families constitutional; the vessels of the Brain in those persons so affected, I imagine are in a very excitable state, and the first ~~exciting~~ <sup>exciting</sup> cause, which is applied induces them to take on a secreting action as this disease is always in my opinion produced by the usual causes of inflammation<sub>+</sub>, and most frequently succeeds

*[Faint, illegible handwriting throughout the page]*

u +

+

those inflam<sup>m</sup>atory fevers, which have not<sup>3</sup> been  
properly treated by bloodletting, and other  
antiphlogistic remedies; where there is a great  
determination to the head, I am confident  
I do not stand alone, in considering  
chronic inflam<sup>m</sup>ation as exclusively its  
proximate cause, and in considering  
the disease as the effects of inflam<sup>m</sup>ation  
I shall adopt a course of treatment  
strictly antiphlogistic, as the conclusion  
of my thesis; which I think is applicable to  
it, according to the views I have taken, and the  
theory I have adopted of its cause.

Although the absorbents are never primarily  
affected, in the incipient stages of dropsy  
they are concerned in its cure and that  
actively, from the circumstance of <sup>their</sup> taking  
up the fluid which is deposited, and

and removing it from the system by the <sup>325</sup> different excretories; and from the circumstance of the doubt, which has, for a long time agitated the votaries of medical science, as to the presence of absorbents in the Brain, this formidable <sup>an</sup> affection has been looked upon as an incurable disease, although, the diligent and persevering Anatomist has failed to prove the existence of lymphatics in the Brain by ocular demonstration; nevertheless can we for a moment doubt their existence we certainly admit the Brain, the supposed seat of all our intellectual operations, to be <sup>an</sup> organized body, and as such it must be endowed with lymphatics.

But we have a stronger proof than this in favour of our position; have we not both read and heard of large portions of Bra

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

being removed, and what other outlet  
 could there have been, except it was  
 through the medium of the Lymphatic  
 system; then if large portions of disor-  
 ganized Brain could, <sup>be</sup> removed, and  
 without the least detriment to the  
 Patient, surely, the watery secretion can  
 be, which <sup>very</sup> much disturbs the general  
 health; our object, should then be in the  
 first place, to lessen the action of the heart  
 and thereby, put a check to this secretory  
 action which is going on in the vessels  
 of the Brain, which is most promptly  
 and effectually done by the lancet, we should  
 not be intimidated, ~~at~~ on seeing the depression  
 which the patient, is apparently almost  
 overcome to with, such symptoms usually attend  
 compression of the Brain from other causes

Faint, illegible handwriting, possibly bleed-through from the reverse side of the page. The text is too light to transcribe accurately.

such as extravasated blood, and collections of matter within the encephalon; because we cannot draw ten or twelve ounces of blood from a child labouring under this disease, we should not, on that account refuse to draw any; how many valuable lives have been rescued from the confines of the grave, by the abstraction of four or five ounces of blood, by a judicious practitioner.

If we turn our attention to the state of the circulation, we will generally find it to be in that condition, which imperiously demands the use of the lancet; we should not be deterred, in small pulses provided they be hard and tense, from drawing blood particularly in cephalic affections, as they almost invariably improve, after the operation has been performed; after bloodletting

Faint, illegible handwriting on aged paper, possibly bleed-through from the reverse side. The text is mostly obscured by the paper's texture and color.

has been carried to its proper extent, a ques-  
tion naturally arises, have we no auxiliaries  
to it, I would answer in the affirmative  
calomel from its well known power of  
promoting <sup>absorption</sup>, would be an excellent adju-  
vant in the treatment of this formid-  
ble affection, especially when it is carried  
to that extent as to affect the salivary  
glands; more have recovered from this disease  
under a salivation, premised by proper evac-  
uations by the lancet; than under any  
other mode treatment; if vesicatory, I imagine  
we might also assist in the cure of this  
disease, but too much reliance, should not  
be placed on them in such a formidable  
affection

A Dissertation on  
Pneumonia

Submitted to the

Professors and Trustees of the  
University of Maryland

For the degree of Doctor of Physic

By Leander W Goldsborough

Of Frederick City Md.

March 15<sup>th</sup> 1828

A. S. Johnston  
Chancellor  
of the Court  
for the County of  
New York  
at New York City  
March 15th 1822

To Dr Charles H Goldborough

This essay is affectionately inscribed  
as a testimonial of gratitude for  
his care and attention whilst super-  
intending the authors advancement  
to professional life.

To the Honorable the President

of the United States

Washington

Dear Sir

I have the honor to acknowledge

the receipt of your letter of the 10th

Introduction. The difficulty of writing without experience and the hazard of attempting subjects about which there exists great diversity of opinion is sufficient to make every one cautious in selecting the subject of his inaugural thesis. Influenced by these considerations we have fixed upon a disease which although pretty well understood is still possessed of sufficient interest to require the attention of physicians. As to originality we claim none, none can be expected, all we wish to do and all we shall attempt is to treat the disease as it has been treated and to point out what we shall presume to consider as errors too generally received.

# Pneumonia.

341

Pneumonia derived from *pneumon* a lung is a genus of disease in the class *pyrexia* and order *plegmasia* of Dr Cullen. Under this title he comprehends "the whole of the inflammations affecting either the viscera of the thorax or the membrane lining the interior surface of that cavity." This is certainly the most judicious plan of treating the matter, for had he attempted to distinguish between the varieties of different authors he must have failed, but if he had succeeded, what advantages would have resulted from it? In a practical point of view none. The rapidity with which inflammation of the serous membranes spread is itself sufficient to upset the

notion of giving names in this disease derived from the part supposed to be affected. As to the term Peripneumony although some may doubt the existance of such a case, it is more than probable that it frequently occurs, and is always characterized by greater violence than the inflammation of the pleura. But as we cannot always distinguish the one from the other and as perhaps in neither case is the inflammation exclusively confined to either the substance of the lungs or their investing membrane the word might be abolished; or if retained, retained only to express a more violent pneumonia.

*Symptoms.* This disease comes on with occasional chills and flushes of heat, accompa-  
nied

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

345

with the usual disagreeable sensations ushering  
in all febrile affections. The patient becomes  
restless, the pulse quick and the skin preter-  
naturally warm. He begins to cough and  
complains of pain in some part of the thorax.

These symptoms continue to increase the  
skin becomes hot, the pulse quick strong  
hard and full. The cough which at first  
was moist is now dry and excessively painful.

The breathing is difficult and irregular  
in consequence of the pain being increased  
by a full inspiration. Which (the pain) is  
now completely developed. It is not always  
fixed, sometimes it is felt in one part of the  
thorax and sometimes in another. It is generally  
more severe on one side, frequently the right

Faint, illegible handwriting, likely bleed-through from the reverse side of the page. The text is mirrored and difficult to decipher.

but as often on the left, in either case the patient cannot lie well on the side affected.

As in all violent inflammations the secretions are ~~are~~ checked, the tongue is furred and the urine high-coloured. Having detailed the symptoms as well as I could we shall proceed to say a few words about the

Causes. This disease most frequently happens to persons of vigorous constitutions, and those who are much exposed to the vicissitudes of weather. It most frequently happens in the spring though it may occur at any season of the year and to all ages sexes and conditions. Cold applied to the body in some form or other is universally admitted as the most frequent remote cause, though it may arise from others as excep

exertion of the lungs, drinking cold water when warm and perspiring is mentioned in Johnson's journal as having caused the disease.

**Terminations.** The most frequent termination of pneumonia is by resolution this may be known by the gradual manner in which the pulse is restored to its natural standard at the same time that the cough pain and difficulty of breathing subside with the return of the different secretions. Suppuration is another termination of this disease; the tendency to which may be ascertained by the pulse becoming softer and more frequent by the patient being affected with slight chilly sensations with a pale and anxious countenance. The pain is less acute and

351

when together with these symptoms or rather as they advance, the difficulty of breathing continues the pain subsides or is remarkably dull and obscure with a weighty sensation in the side we may generally infer the existence of matter. Other terminations of pneumonia are spoken of as gangrene which is very rare.

A much more frequent when it ends fatally is effusion of blood and serum into the bronchia and cellular texture of the lungs producing suffocation.

**Treatment.** The first step in the treatment consists in copious bloodletting. This is the most powerful means we have of reducing the excitement equalising the circulation and preparing the system for other remedies.

By drawing of a sufficiency of the circulating fluid we prevent many ill consequences ~~too~~ too

353  
frequently the result of a protracted pneumonia.

Besides all these advantages it relieves immediately the violent pain which the patient suffers, relaxes the surface of the body, promotes expectoration and the operation of sweating medicines, the advantages of which you cannot always profit by unless preceded by bleeding. Some writers talk much about the cautious use of the lancet in this disease, they tell us that we should be governed by the age constitution and condition of the patient, that the quantity necessary to be taken from one man would sink another &c. Now the fact of the business is that although we admit in part the correctness of this reasoning we say that as a general rule the pulse is the only criterion by which we are to be governed; every body knows that an old man will not bear the loss of as much blood as a young

one, neither is as much required for the very reason that he does not so rapidly redeem it. So long as the pulse is hard and the pain and difficulty of breathing continues we must bleed.

The blood should be drawn from a large orifice in order that a decided impression be made at once. The physician should keep his fingers upon the pulse and not be satisfied until it is reduced below the natural standard. If it be the first or second bleeding and the pulse very high and bounding he should carry it to the extent of inducing sickness or fainting, for in this disease as in all inflammatory cases the pulse will rise and become more irresistible unless you at once adopt decisive measures. Generally two such attacks with the lancet will be sufficient to bring the

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

case under the controul of milder measures and as pneumonia is sometimes cured by expectorants and diaphoretics we shall proceed to some remarks about them - And first of - Digitalis. This article has been employed by Dr Barton and others with a view to its expectorant and sedative effects. We should certainly not expect much advantage from it as an expectorant it has not we believe answered the purpose of physicians generally, besides the theory of its operation is perhaps more obscure than that of any other article of the class.

As to its power of controuling the action of the arterial system I we know nothing, never having it used the difficulty however of regulating the dose and the admitted superiority of other means are sufficient reasons for abandoning its use. The best expectorant undoubtedly is antimony. This may be given

in combination with Nitre in the dose of a <sup>379</sup>  
quarter of a grain of the former with eight or  
ten of the latter every two hours or so. Antimony  
is said by some to be beneficial by its sedatives  
qualities independant of its nauseating effects.

That this artical acts directly as a sedative  
is a new idea, it may be correct, though  
we believe we have seen it injurious in  
high inflammatory fevers where its appli-  
cation had not been premised by bleeding.

If in the advanced stage of the disease  
there is still pain with a difficulty of ~~breath~~  
~~restoration~~ and a weak pulse, one or two grains of  
Camphor added to each of the above powders  
will be of great service, especially if aided  
by the action of a blister. After sufficiently  
reducing vascular action some gentlemen are  
in the habit of giving antimony alone in tepid  
water so as to produce copious diaphoresis

this disease. They are in a few cases unnecessary though much oftener indispensable, particularly where the patient is much weakened by morbid action before the physician sees him, in which case it is not always possible to draw a sufficiency of blood to supersede their use. They should never be applied when there is much action, but after two or three bleedings they answer every indication. A fine large one should be applied immediately over the seat of the pain and suffered to remain on twelve hours. By the proper use of blisters we frequently prevent chronic coughs and other dangerous affections of the thoracic viscera. We shall now conclude with a few remarks on the use of Cathartics.

Almost all writers agree that medicines of this description will not answer in thoracic affections. The utility of keeping the bowels regularly open with cooling laxatives is agreed upon by all. Perhaps they might be carried to a greater extent. We think we have seen purging hotly induced in the first stage of the disease

with manifest advantage, the expectoration was very little if any diminished. But the truth is, in this stage of the disease the expectoration is always ~~is always~~ sparing whether you use purgatives or not. As we know of nothing to which we can refer this circumstance, unless it be excess of action, why not use this most powerful auxiliary to bloodletting until we have sufficiently lowered the tone of the pulse to trust the cure to other means? However we are not very tenacious upon the subject, we merely propose the question, with a hope that we shall some day or other be better able to judge after a more extensive examination of that best of all books Experience.

A  
Dissertation  
on the  
Atmosphere

Since the days of the alchemists it is well known that the science of Chemistry has been considered in a new light, and as subservient to very valuable and usefull purposes to mankind in general. The minds of the learned and scientific struck with the beauty and importance of its resources entered into the field of research with unmitigated ardour; and the present improved state of the science tell us what they realized.

In the period between the years 1749. 1787 a new mine of experimental research which promises the most curious and interesting results had been opened out first by the genius of D<sup>r</sup>. Black and already pursued with much sagacity and industry by D<sup>r</sup>. Priestly. But it was Lavoisier of France one of the most celebrated chemical philosophers of his time; a man whose views were far above any pecuniary consideration, who succeeded the former gentlemen in their particular views, and who devoted the last days of his life in experimental research that held the most importance on that branch of Chemistry; of which we are about

of  
the

---

The first part of the report is a general  
statement of the situation of the  
country at the beginning of the year.  
It then proceeds to a detailed  
account of the various branches  
of the public service, and  
concludes with a summary of the  
results of the year's operations.  
The report is divided into  
several chapters, each of which  
deals with a different aspect  
of the public administration.  
The first chapter is devoted  
to a description of the  
general state of the country,  
and the second to a  
detailed account of the  
various branches of the  
public service. The third  
chapter is a summary of the  
results of the year's  
operations, and the fourth  
chapter is a general  
statement of the situation  
of the country at the  
beginning of the year.

to make some brief remarks. We allude now to the discovery of the properties of certain airiform substances, gases, or (as they have been called) factitious airs. They are bodies which Chemists have called elementary or bodies which are not, in the present state of Chemical science considered as compound. They are bodies which have never been insulated they have been found only in combination with other bodies; and which had hitherto escaped the attention of Chemical inquirers.

After having said thus much as a desultory introduction to the after part of our dissertation; we will remark that it is our purpose to make some general observations on the Atmosphere or the common air which surrounds our globe. As it would be very proper we think and for the better understanding of the subject we shall proceed analytically; and first with,

## Oxygen.

This elementary body forty or fifty years ago was unknown to the scientific world; it fortunately happened however to Dr. Priestley in the year 1774, when going through the experiment of heating the red powder which was called the precipitate per se, (but now more properly called by the name of the red oxide of mercury) in a glass vessel; a quantity of air was driven off from the powder while the mer-

Chapter

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

-cury resumed its metallic form, he collected this air in a convenient vessel and examined it; he found it possessed of certain properties different from the atmosphere and in one respect he said it was much purer than the common air; he called it from the theory of the time *dephlogisticated Air*.

Scheele a Swedish Chemist shortly afterwards discovered this same gas without any previous knowledge of Priestly's discovery; he called it *Empyreal Air*; it was also called *Vital Air* by some.

Soon after this Dr. Priestly communicated his experiment to Mr. Lavoisier who with great ardour investigated the truth of Priestly's experiments; and from his investigations and observations are we indebted for the explanation of various phenomena: Lavoisier showed that the mercurial precipitate per se, by being heated in a retort, and the retort being adapted to the pneumatic trough the beak of which terminated under a gas bottle filled with water; that an air passed over from the retort into the gas bottle, which was rendered evident by the displacement of the water in the vessel; and also a very important change had been effected in the red powder, (which had previously been noticed by Priestly) which was that it had resumed its metallic lustre and brilliancy and consequently was no longer a red powder but in fact running mercury. But the non-

*[The text on this page is extremely faint and illegible, appearing as a series of light-colored lines and shapes against the aged paper background.]*

-der ~~did~~ not end here; the ingenuity and curiosity of the able Chemist led him to examine the air which he had collected; he did so, and found that it was an air highly respirable and supporting combustion in an eminent degree; for on putting a lighted candle or any other burning body in a jar of the air it burnt with increased brilliancy and force. He called it Oxygen gas: Oxygen in combination with the matter of heat or Caloric, for we do not speak of the gas in the abstract but in combination with a principle for which it has a great tendency to combine and to pass into a gaseous state.

This gas can be procured in a variety of different ways and from a variety of substances.

1. From the black oxide of manganese heated to ignition in an iron retort; or by mixing the same powder with twice its weight of Sulphuric acid in a glass retort and applying the heat of a lamp; very pure Oxygen Gas can be procured in this manner.

2. It can be obtained from Salt-petre; by putting a quantity of this salt in a coated glass retort and applying a red heat Oxygen gas is formed. But there are two objections to this mode of preparation: for first the substance which remains in the retort can never without a great deal of trouble be got out,

The first part of the book is devoted to a general  
description of the country and its inhabitants.  
The author then proceeds to a detailed account  
of the various tribes and their customs.  
He also describes the different kinds of  
agriculture and the various occupations  
of the people. The book is written in a  
clear and concise style, and is well  
illustrated with numerous engravings.  
It is a valuable work for those who  
are interested in the history and  
geography of the country.

The second part of the book is devoted to a  
description of the various tribes and their  
customs. The author describes the different  
kinds of agriculture and the various  
occupations of the people. He also  
describes the different kinds of  
agriculture and the various occupations  
of the people. The book is written in a  
clear and concise style, and is well  
illustrated with numerous engravings.  
It is a valuable work for those who  
are interested in the history and  
geography of the country.

and another circumstance is if you are not very carefull in pushing the operation at the end to obtain the greatest portion of gas, another substance will come over so as to render the gas so produced very impure. A great quantity of the gas is generated in this way for it is said one ounce of salt yields 1200 cubic inches of gas.

3. It may also be procured from the Oxymuriatic of Potash a salt that yields it in great abundance; by heating it in a small glass vessel over an Argand's lamp. The gas obtained in this manner is much purer than that produced by any other process. These are the principle substances from which Oxygen gas is obtained: but it can be obtained in a variety of other ways which it is not necessary to mention at this time. It should be observed that very oxygen gas is generated by immersing some green Vegetables (such as the leaves of mint) in a vessel of water covered and exposed to the rays of the sun; in a short time small bubbles will have collected over the surfaces of the leaves and subsequently rise through the water to the surface.

The gas when produced by any of the above processes is inodorous, colourless and therefore transparent like the atmosphere; it is heavier than the atmosphere according to Sir H. Davy 100 cubic inches at 60° Fahrenheit weigh 34 grs. All combustibles burn in oxygen gas with greatly

*[The text on this page is extremely faint and illegible due to fading and bleed-through from the reverse side. It appears to be a continuous block of handwritten text.]*

increas'd splendor or in other words it is eminently a supporter of Combustion.

It was once supposed that Oxygen gas alone was necessary to combustion; but it has since been found out that other bodies beside Oxygen gas have an equal right to be considered as supporters of Combustion.

Oxygen gas is very necessary for the support of animal life; without the use of this gas every breathing creature would cease to exist.

This gas when respired produces all the effects of a powerfull stimulant; it at first increases the strength and vigour of the body producing a degree of burning heat in the Lungs; after continuing to respire it for a long time the stimulus of the gas is more than the animal body can bear; Vertigo, Coma, Convulsions and death eventually would be the consequence no doubt from the long continued respiration of this gas; yet it is a fact well known that a mouse, bird, or other small animal will live four or five times longer in a vessel of Oxygen gas than in one filled with atmospheric air of the same dimension.

But a circumstance of great moment and one of the highest importances to us, is the relation which this gas bears to the function of respiration; for the perfect performance of which it seems necessary that Oxygen gas should be inhaled into the lungs there to effect

*[The text on this page is extremely faint and illegible due to fading and bleed-through from the reverse side. It appears to be a continuous block of text, possibly a letter or a journal entry.]*

a very important Change in the dark coloured venous blood so as to render it fit for the usefulness of the animal economy.

It appears that Dr Priestly was the first of the modern Chemists who turned his attention to respiration and he concluded from his experiments that the blood as it passed through the lungs gave out phlogiston to the air which was expired loaded with that substance (and of consequence that the purpose of respiration was to free the blood of phlogiston.

According to Lavoisier the blood absorbs no air in the lungs but it gives out hydrogen and carbon which combining with the oxygen of the air inspired form water and carbonic acid. Now there has been an objection to this hypothesis of Lavoisier in as much as the quantity of Carbonic Acid formed is exactly equal to the bulk of the oxygen which disappears; therefore this oxygen must be changed into carbonic acid in the lungs for it is known that oxygen when changed into carbonic acid does not sensibly alter its bulk. From this it has been concluded by Dr Thompson that the blood must emit Carbon and that to an extent of about 3/4ths of a pound in a day: this he considers is all that happens in the lungs; the watery vapour he allows is secreted from the blood to mix with the air expired;

*[The text on this page is extremely faint and illegible due to fading and bleed-through from the reverse side. It appears to be a dense paragraph of handwritten text.]*

385

but probably the secretion takes place in appropriate organs. Then by the loss of Carbon Venous is changed into arterial blood.

Our distinguished professor of Chemistry Dr. De Butts, with his usual ingenuity accounts for the phenomena in a different way.

From the Doctor's view of the function of digestion &c; he concludes that the colour of venous blood is owing to a portion of the Carburet of iron and as it has been proved that the colour of arterial blood is dependent on a portion of the phosphate of iron it is reasonable to suppose that the object of respiration is to change Venous into arterial blood for that purpose is the blood carried to the lungs from the right side of the heart loaded with Carburet of iron and also having in connection with it a quantity of free phosphoric acid; when this blood then arrives in the lungs it is exposed to the contact and action of atmospheric oxygen the moment the oxygen comes in contact with the venous blood it combines with the carbon which is expired in the state of Carbonic acid; the liberated air then finding free phosphoric acid (which is always found in Venous blood) combines with it and in that state passes with the other ingredients constituting arterial blood into the left side of the heart.

Oxygen in combination with the metals form a class of substances called Oxides. Carbon, Sulphur, Phosphorus &c combine with Ox-

- Oxygen is as to form a very interesting class of substances called acids; some of the metals are capable of combining with a very great proportion of Oxygen and thus forming not only oxides but acids.

From these circumstances the French Chemists considered Oxygen as the only acidifying principle this is not the fact for in the progress of the science it has been found that there are other principles that are the cause of acidity in some cases without the interference of Oxygen at all.

Oxygen is an essential constituent of atmospheric air, of water, of saline and earthy bodies; it is also a principle of animal and Vegetable matter. From all this it would appear that the relations of this principle are more numerous than any other body known.

### Nitrogen.

This gas had ~~been~~ been considered as an elementary gaseous body until the time of Berzelius who with many experiments and theoretical reasonings endeavoured to prove that it was a compound body composed of Oxygen and an unknown base for which he proposed the name of Nitricum. This base however is considered by some and perhaps with great propriety as purely hypothetical and as it never

381

has been produced in an insulated state Chemists cannot at present know any thing of its properties. A series of experiments to prove that nitrogen was a compound body have been got up by Mr. Stiers of London who precisely agrees with Berzelius in his views of the subject. Sir H. Davy's attention was next directed to the subject on the presumption that nitrogen was an oxide; which however was not attended with any better success than those of the former gentlemen. The general statement of the inquirers therefore have been found to lend no strength to the supposition that nitrogen like oxygen is any more than a simple elementary body according to the present state of chemical knowledge.

Nitrogen is said to have been discovered by Dr. Rutherford in the year 1772. It was found that after separating all the oxygen of any quantity of the atmosphere that there remained a gas which possessed peculiar properties and differed from oxygen gas or any other kind of gas which had hitherto been discovered. It was discovered that when a small animal was inclosed in a glass vessel containing common atmospheric-air and the vessel being stopp'd tight; that after a certain period the animal would die, and inverting the mouth of the vessel into water and then taking out the stopper; that the water would rise and occupy a certain portion of the vessel: the air that remained was examined; and, it was found to be a gas

unfit for respiration or combustion; it was also found that fixed air was formed in this case. Now it is not to be supposed that all the air which was left was fixed air on the contrary there was comparatively but a very small quantity; for on separating the whole of the fixed air by lime-water it was found that just  $\frac{1}{5}$  th. of the certain portion of air had disappeared and that the remainder  $\frac{4}{5}$  ths. was that air which we have just mentioned as unfit for respiration or combustion: it was called azotic gas, azote; a name given it by Lavoisier from the circumstance of its not supporting animal life.

Now it is well known that there are various gases which are unfit for the support of animal life beside this one; for this reason the name Azote was dropped and the term Nitrogen has been substituted from the circumstance of its having been found to exist in a number of nitrous preparations.

Nitrogen gas may be procured though not absolutely pure yet sufficiently so for the purpose of exhibiting its general properties in either of the following manners.

1. Mix equal weights of iron filings and sulphur into a paste with water and place the mixture in proper vessel over water supported on a stand; then invert over it a jar full of common air and allow this to stand exposed to the mixture for a

day or two. The air contained in the jar will gradually diminish as will appear from the ascent of the water within the jar till at last only about  $\frac{4}{5}$ ths. of its original bulk will remain. The vessel containing the iron and sulphur must next be removed by withdrawing it through the water, and the remaining air may be made the subject of experiment.

2. By burning phosphorus in a glass jar containing common air the phosphorus will combine with the oxygen and form phosphoric acid which will fill the jar with dense white fumes, after a short time these fumes will be condensed and the remaining air will be tolerably pure Nitrogen gas.

3. Nitrogen gas can also be procured from the lean part of flesh meat; put into a glass retort the lean of beef cut into small pieces and pour on it very dilute nitric acid then connect the retort with the pneumatic tub and apply a heat of  $100^{\circ}$  gas will be disengaged and is collected in the gas bottle.

This gas as well as Oxygen is not absorbed or not in any very appreciable quantity by water. It is lighter than the atmosphere 100 cubic inches according to Sir H. Davy at  $60^{\circ}$  Fahrenheit weigh 29.37 grains, consequently it is also lighter than Oxygen gas. It is not a supporter of animal life; for, it immediately proves fatal to animals that are confined in it. It is also a non-supporter of combustion for it immediately extinguishes all burning bodies when they are

The first part of the paper is devoted to a general  
 consideration of the subject, and to a statement of the  
 objects to be attained. It is then divided into three  
 parts, the first of which is devoted to a description of  
 the nature and extent of the disease, and to a statement  
 of the symptoms which attend it. The second part is  
 devoted to a description of the various methods which  
 have been employed for its cure, and to a statement of  
 the success which has attended them. The third part  
 is devoted to a description of the various methods which  
 have been employed for its prevention, and to a  
 statement of the success which has attended them.

295  
immersed in a jar containing it.

Nitrogen is susceptible of combination with various bodies and the compounds possess in many instances remarkable properties.

In the proportions of four parts of nitrogen with one of oxygen it composed a mixture resembling the atmosphere in all its properties: for it can be respired with safety for any length of time by an animal and burning bodies burn in it as in the atmosphere.

In combination with different proportions of oxygen it forms nitrous and nitric acids. It is also essential to animal matter; from the putrefactive decomposition of animal matters, nitrogen and another elementary principle hydrogen are evolved; they combine and form the Volatile Alkali or Ammoniac. Nitrogen in combination with Carbon forms a carburet of nitrogen or Cyanogen which compound is the base of the Hydro Cyanic acid (Cyanogen in combination with hydrogen) or prussic acid as it is still called which is well known as one of the most virulent of the vegetable poisons. Although nitrogen is a necessary constituent of animal matter yet it appears to form a very small ingredient indeed as an ultimate principle of vegetable matter. From this it appears that nitrogen bears great relations to other.

297

bodies and is little inferior to oxygen in point of importance in the great theatre of scientific pursuit.

## The Atmosphere.

It appears then from the facts stated in the preceding pages that the atmosphere is a compound or mixture of two different gases.

It is to Dr Scheele that we are indebted for the fact that the atmosphere is a compound: for it is well known that to his time it was considered as an elementary body: Fire, air, earth and water being considered as four elements. Yet it has come to pass even before the present day that those bodies that ~~then~~ were once considered as elementary have been ranked as compound bodies and on the contrary those that were once considered as compound bodies are now placed among the simple elementary bodies.

This celebrated and illustrious Chemist Dr Scheele in the course of some experiments after he had found out oxygen gas had reason to infer that the atmosphere was not a simple body. He took a glass bottle of which the bottom from it and he placed it on the shelf of the pneumatic tub and in this glass vessel he placed a small quantity

399

of the substance called Sulphuret of potash; it was supported on a stand above the surface of the water of the trough in the Vessel. After letting it remain in this situation for a time he found that a portion of the air in the vessel was taken away; for the water in the pneumatic tube had raised to a certain height in the Vessel. He after this took out the Sulphuret of potash and examined it he found that it was no longer a Sulphuret of potash but a Sulphate of potash: potash containing Sulphuric acid. Dr. Scheele found in this experiment that just  $\frac{1}{5}$ th. of the air which was originally contained in the Vessel had disappeared and the remainder was no longer fit for respiration or Combustion.

The analysis of the atmosphere was most satisfactorily demonstrated by Lavoisier by the following experiment as explained in his Elements of Chemistry more enlarged. He took a glass vessel shaped like a matrass placed in it a small quantity of quicksilver and connected the superior part of the vessel with a right angular tube the one end of which being connected with the matrass and the other end with a gas bottle which was placed on the shelf of the pneumatic tub

The following letter is a copy of  
a letter from the Secretary of the  
Board of Education to the  
Commissioner of the State  
Department of Education  
dated at Albany, N. Y. the  
10th day of June 1882.  
The letter is in the  
following tenor:  
SIR: I have the honor to  
acknowledge the receipt of  
your letter of the 6th inst.  
in relation to the  
proposed changes in the  
curriculum of the  
Common School Course  
in this State. I have  
the honor to inform you  
that the Board of  
Education has considered  
the same and has  
approved the same  
with the following  
exceptions: That the  
course of study in  
the Common Schools  
shall be such as to  
prepare the pupils  
for the study of  
the English Language  
and the Elements of  
Arithmetic, and such  
other studies as may  
be deemed proper by  
the Board of Education.  
Very respectfully,  
J. B. H. [Signature]

The enclosed is a copy of the  
report of the Board of  
Education for the year  
1881-82. It contains  
a full and complete  
statement of the  
work of the Board  
during the year, and  
of the progress of  
the Common School  
System in this State.  
I have the honor to  
inform you that the  
Board of Education  
has approved the  
same, and has  
ordered a copy of  
the same to be  
sent to the  
Commissioner of the  
State Department of  
Education.  
Very respectfully,  
J. B. H. [Signature]

He took care that the whole apparatus should be air tight and well adjusted in its place.

He then had a portion of mercury in the matras and all the parts ~~occupied~~ of the apparatus except that occupied by the small portion of mercury was necessarily filled with the atmosphere; an argand lamp was placed under the vessel containing the mercury and after keeping up a gentle heat for about 12 days he found that the mercury had suffered a considerable change, a part of it was no longer a shining fluid metal but was changed into a red powder; and also the water of the pneumatic tub had rose in the gas bottle and occupied a certain height in it. Lavoisier then examined the air which remained in the apparatus after the experiment and found that it was unfit for respiration or combustion. He next collected the red powder which was in the matras and distilled it in a retort by which operation the mercury was regenerated it appeared in fact in its original metallic state and an air was given out which being collected in a gas bottle and examined he found that it indicated the usual phenomena of supporting combustion respiration, &c; and that it was the same gas which Dr Priestly had discovered, viz; oxygen gas.

These results then afford the

403

most satisfactory evidence that the atmosphere is composed of two distinct fluids. The one is capable of giving its base to mercury, and when separated is eminently adapted to the support of animal life and combustion; the other has no affinity for mercury and does not possess the other important qualities.

The object then of Lavoisier was to calculate the proportions which these two gases bore to each other; it was very easy to measure them and accordingly he did so. His report was that the atmosphere was composed of  $\frac{1}{5}$ th. oxygen gas and the other  $\frac{4}{5}$ th. of mephitic air. — But it appears that Lavoisier was not altogether correct in his calculations for according to the experiments of the best Chemists the atmosphere is now found to be composed of  $\frac{1}{5}$ th. of oxygen gas or 21 parts in the hundred and the remainder  $\frac{4}{5}$ th. or 79 parts in the hundred is azote or nitrogen gas as it is more properly called.

It would seem then that oxygen gas is the only ingredient on which the chemical effects of the atmosphere depend. Hence combustible bodies burn in the atmosphere only in consequence of the oxygen it contains and it is only a quantity to support animal life from the same circumstance.

But as it has been before observed oxygen gas is not <sup>fit</sup> of itself for respira-

405

-tion and for this purpose is the negative principle nitrogen gas added to weaken the powerful effects of the oxygen gas or to dilute it as it were. -

The atmosphere (from *aer*, air and *sphaera* a globe) or the Common air as it is emphatically called is well known to be that diaphanous incandescent fluid which surrounds our globe. It is inferred to extend to the distance of 40 or 45 miles in height at the level of the ocean it is capable to sustain a column of water 35 feet high or one of mercury of the height of 30 inches and it presses with the weight of about 15 ~~inches~~ pounds on every square inch of surface. As we ascend the atmosphere decreases in density in geometrical proportion to equal ascents.

The weight of the atmosphere was ascertained with great care by Mr. Brande from a number of experiments at the Royal Institution he found that 100 cubic inches of air at a mean temperature and pressure of the thermometer and barometer to weigh only 30.199 grs. The atmosphere acts a very important part in equalizing temperatures; the great body of air is always in constant motion; over the torrid zones it is expanded by the concentrated rays of the sun; it being expanded its specific gravity would be lessened and consequently it would rise to the superior regions and flow over towards the poles; while the air from the temperate and frigid zones would press forward to fill up

the vacuum. This process still going on and the heatell portions coming in contact with colder portions and with various parts of the earths surface which may be hotter or colder is supposed to occasion the various currents of air which we meet with on the earths surface. In this manner also are the different currents at the surface and at various depths of the ocean accounted for; the water of the other parts of the globe mixing with the tropical waters. Thus we find a beautiful provision of nature for supporting a uniform temperature. The atmosphere then possesses all those properties which are eminently suited for the comfort and convenience of creation; a deprivation of this fluid would annihilate all nature; all the vegetable and animal creation would cease to exist; the sun would cease to send her cheerful and invigorating rays on earth, the moon would be blotted from the sight; all nature would pass into darkness and chaos would regain its pristine domain.

The air is accused as the cause of numerous diseases; and it really is so. Sudden cold checking the perspiration will apparently produce almost every form of pyrexia. Partial cold will produce Rheumatism, Pneumoniae; Damp air, Catarrhs. The continued heat of summer occasion bilious Disorders and

409  
the cold of winter a return of more active inflammation.

The pure air we breathe is often charged with bodies foreign to our comfort and health. We allude to the infinite variety of adventitious bodies which are found floating or mixed as it were with the atmosphere. Every reading man knows whether high or low wet or dry the atmosphere is always in connection with various substances the principles of which are these and they are the only ones that we shall notice in this place.

1. Carbonic Acid.
2. Watery Vapour.
3. Principle of Infection; which last has occupied the attention of men for a long time and we shall endeavour to give it some share of our attention.

Carbonic Acid, is at all times present in the atmosphere and is estimated by Mr. Dalton not to exceed one thousandth of its bulk. By Van Helmont it was called, *gas sylvestre* from being produced in vast quantities from burning Charcoal; from its apparent acid properties, *aerial acid*; and *Carbonic acid*; and *fixed air* as readily losing its elasticity and fixing itself in many bodies. It is an invisible and permanently elastic fluid; superior in gravity to the common air and most other aerial fluids. It consists of twenty eight parts of

... the ...

411

Carbon and seventy-two of Oxygen and undoubted with some Caloric. It is unfit for respiration; easily absorbed by water exceedingly destructive to animal life and produced in great quantities naturally from combustible bodies and many Chemical processes. It is found at the bottom of pits and caverns; near Naples there exists the famous Grotto del Cani which is constantly filled with it; it arises from fermenting liquors. It is heavier than the atmosphere 100 cubic inches according to Sir H. Davy at 60° Fahrenheit weigh 47.11 grains. This gas is powerfully antiseptic destroying the putrefactive decomposition. When introduced into the stomach it is agreeable and grateful and is administered with advantage in some disorders: but though it may be introduced into the stomach and intestines with good effect if breathed into the lungs it is mortal. By the respirations of animals comparatively a large quantity of Carbonic acid is formed; this results from the union of the Oxygen of the atmosphere with the carbon of the venous blood.

Plants absorb carbonic acid gas and restore in their turn pure Oxygen which combining with azote may imperceptibly to our senses renovate the atmosphere. Thus nature very completely restores the various changes in the con-

-stitution of our atmosphere which the dif-  
-ferent processes constantly going on may  
in her regular course have occasioned.

- Watery Vapour. That watery vapour exists  
in the atmosphere sometimes requires not the  
mind of a philosopher to prove. Every  
man of reason know very well that the  
atmosphere very often contains water in  
a state of vapour - Now it has been found  
that the atmosphere contains Watery Va-  
-pour at all times, at all seasons even in  
the coldest weather. It is well known that  
beside water; Camphor, Volatile Salt &c if  
placed exposed to the air will evaporate; &  
even if we view ice exposed to the air still  
a portion of it is lost by evaporation and  
we are told that the vapour produced in  
this way is different from that produced  
by boiling namely that it is not so elas-  
-tic. This sort of evaporation is called spon-  
-taneous in order to distinguish it from that  
produced by more obvious sources of heat.

It is the opinion of M<sup>r</sup>. Dalton that ma-  
-ter existing in the atmosphere constitutes a  
distinct and independent atmosphere of its-  
-elf; this opinion of Dalton's has been em-  
-ended by many and perhaps with truth  
as very erroneous; for as D<sup>r</sup>. Henry says it  
is certainly more reasonable to suppose that  
water whenever it exists as an elastic fluid  
either distinct from or mixed with others, is

415

Maintained as such by one and the same cause  
viz. the Caloric which enters into it; and not by  
Chemical solution in any gas or mixture  
of gases. It is stated that the reason Vapour  
is raised is that its specific gravity is less than  
that of water. The explanation which is  
now generally received is that of D<sup>r</sup> Hally's.

He compared the case to a solution of Salt  
in water considering the air as the water and  
the vapour as the Salt he still farther states  
in corroborations of his hypothesis that the  
collateral circumstances which favour so-  
-lution are favourable to spontaneous evap-  
-oration; such as an increase of temperature,  
extent of surface, agitation, &c. After the  
philosophic world had received this explan-  
-ation of D<sup>r</sup> Hally's a circumstance was  
remarked which threw over the whole. It was  
found by putting a cup of water on the plate  
of an air pump and exhausting all the air  
from the bell that evaporation would go on and  
to an extent greater in a given time than when  
placed in the open atmosphere the evaporation  
went on under the bell of the air pump un-  
-till it was filled with Vapour which put a stop  
to the farther evaporation of the fluid. This  
simple experiment then proves the inconsistency  
of D<sup>r</sup> Hally's supposition for in this case the  
collateral causes which he alludes to as assist-  
-ing the evaporation in the open atmosphere  
could not have operated here and another thing

917  
to be attended to was that in the experiment with  
the air pump the pressure of the atmosphere  
was taken off the surface of the water.

It is stated that vapour itself exists in the  
atmosphere in the form of small particles  
which are vesicular or little hollow globes.

Different portions of vapour are found  
at different altitudes and in different lat-  
itudes of the earth; in the torrid zones it is  
most abundant; in the temperate less and  
in the frigid zones still less vapour is found  
in the atmosphere; the quantity is however  
governed very much by the seasons of the year.

In the torrid zones very little rain falls  
Vegetation is supplied by the profuse dew which  
is formed in the night after the sun passes  
the horizon of these regions the same quantity  
of vapour is no longer kept suspended in at-  
-mosphere it consequently falls unobserved  
through the atmosphere to the ground in  
the form of dew and supplies the place of  
profuse rains which fall only in the tem-  
-perate zones. In the northern part of the  
temperate and in the frigid zones the power  
of the sun not being strong enough to re-  
-pave the water in the form of vapour  
condenses it which descends to the sur-  
-face of the earth through the atmosphere  
in the form of hail, frost, snow &c these  
are the products of varying nature pro-  
-duced by climate and change of season.

419

Principle of Infection. It was an object of great interest among the medical world in those days when the constitution of the atmosphere was first discovered to suppose that the cause of some peculiar diseases was owing to a too less quantity of oxygen in certain portions of the atmosphere; it was supposed that in high situations there was more oxygen than in low situations and especially in low marshy places there was a considerable less quantity of it. Now it was very natural for men to draw this inference yet like the fate of all hypotheses it has to fall when opposed by facts. The Chemists turned their attention to this point and to prove whether the atmosphere suffers any deterioration in this respect they collected the air of marshy places; they took it from jails, from prison ships; and from every infectious place and examined it and yet they found the very same principles in the very same quantity always they could detect no loss of either the one or the other of the principles composing the atmosphere. A very celebrated Chemical philosopher Gay Lussac ascended to a very great height in a balloon and he took with him a glass jar filled with water; when he had arrived at a very great distance from the earth's surface he emptied it and immediately corked

42

it tight; he brought it down with him to his labor-  
-atory; he first examined the air of his labor-  
-atory that there might be no mistake and  
found that it contained the usual propor-  
-tions of the two ingredients, (viz; Oxygen  
and Nitrogen gases.) He then examined  
the air which was contained in the glass  
jar and he found it to contain the usu-  
-al quantities to a fraction of a the gases  
which was in the air of his laboratory.

This then was proof enough to any  
honest minded man that the cause of  
an infectious disease was not to be attrib-  
-uted to a too great quantity of oxygen  
in the atmosphere in any given place.

But when this hypothetical notion  
had been put down by Chemical inves-  
-tigation's some who wished to explain  
the subject in a new way gave vent to their  
imagination in bringing forth the ideal  
agency of the existence of Inflammable-  
-air, Hydrogen, in the atmosphere as the  
cause of the pestilential disease Yellow  
fever we not find stop to refute this Opin-  
-ion for it has been shown by Davy that  
hydrogen cannot exist alone for any length  
of time in the atmosphere without combining  
with it; and if this be the case and in all  
probability it is the case; it would soon be  
diffused equally throughout the whole at-  
-mosphere and thereby so diluted as to be

altogether innocuous.

423  
It was the opinion of some that the existence of the nitrous acid vapour in the atmosphere was all the cause of the fatal and pestilential disease yellow fever and it was furthermore supposed that the exhilarating gas of Davy had some connection as the cause of a pestilential disease; yet from the experiments of Beddoes and Davy it cannot be supposed to exert any deleterious influences; on the contrary it has the effect of a cordial or invigorating remedy much less a deepening or debilitating effect.

A very ingenious physician of the South Dr. Shecut advances the doctrine that the infectious disease yellow fever is dependent on the existence of an aerial fluid in the atmosphere in consequence of a derangement of the Electrical Equilibrium in the air. That when by the concussion of lightning the Electrical Equilibrium is restored it is impossible for the gaseous poison or yellow fever infection to exist in such a degree as to produce the epidemic yellow fever. In support of his doctrine the author adduces a number of facts as derived from the medical history and annual meteorological observations for South Carolina. Like many

425

Other disputed points in medical sciences  
authors for the most part speak doubtfully  
as to the precise nature of the infection  
which produces fevers of various degrees of  
malignancy; we allude now principally  
to that fever which has received the name  
of yellow fever. - It is now settled by  
the majority of the learned of the medical  
world that the greatest quantity of this  
peculiar principle which has been de-  
-terminated Marsh miasma; arises from  
marshy grounds more or less impreg-  
-nated with putrid exhalations from the  
decomposition of vegetable substances.

Its activity in producing fevers is  
promoted by all those circumstances as  
increase the putrefactive decomposition  
and promote the exhalation of it; such  
as heat and moisture. When marshy  
grounds are at particular seasons of the  
year covered with water this prevents the  
miasma from rising in any consider-  
-able quantity and of consequence the dis-  
-eases are fewer and less violent. But  
when from the great evaporation occa-  
-sioned by a hot and dry summer; the  
ground is uncovered leaving it in a  
swampy state then aquatic plants, trees, &c;  
undergoing the vegetable decomposition,  
produce an exhalation which is highly

acutiores.

427

Although authors appear to agree that marsh miasma is the most general cause of the epidemic yellow fever and give the most undeniable proofs of its effects; yet we are not to conclude marshes to be the only source of this miasma. For every place where there is vegetable matter combined with moisture and a heat decomposition of the vegetable matter will necessarily take place and give rise to miasma which may be as prolific in producing its peculiar disease as that arising from a marsh.

From the preceding short view of the nature and origin of miasma it will appear that with the concurrence or absence of particular circumstances tending to increase or diminish its noxious power it must in different times and places exhibit with various degrees of strength.

Sometimes it is scarcely capable without the conjunction of other causes of producing fever; whilst at other times it may be of so noxious a nature as to affect the most robust in a short time after it has been received; and we can frequently observe intermediate degrees of its malignancy both with regard to the power of the noxious effluvia and also to the force

of the system, from habit, to resist their effects. 429

The manner in which miasma affects our system so as to prove the cause of disease is not clearly ascertained although physicians of the present day believe that it is taken in by the saliva swallowed and then taken into the stomach or either by Respiration. Some are inclined to one opinion and some to the other. The first opinion that the infectious effluvia mixes with the saliva and afterwards gets into the stomach has been embraced by several physicians of great character and learning; and as a proof of this opinion they find by not swallowing their spittle when attending the diseased they are exempt from the disease;

This appears very plausible; but we never could in our mind be led to suppose that the first impression of the cause operated in this way; for in the very few instances that might be all'd to in proof of this hypothesis it may be referred to peculiarity of constitution &c and not to that of the miasma mixing with the saliva and afterwards getting into the stomach and there fermenting with the contents of the prima via and so causing an increased secretion of bile &c!

That of respiration is more plausible the miasma is taken into the lungs during the act of inspiration it is consequently

431

brought into contact with the sentient extremi-  
-ties of the nerves and there primarily  
produce its peculiar impression as a cause  
producing the disease. By this view of the  
subject we think the phenomena of the dis-  
-ease can be more rationally accounted for.

It would require volumes to  
illustrate and examine the various points  
in dispute among medical men relative  
to this peculiar principle of infection  
as the cause of Yellow Fever we have said  
thus much on this part of the subject the  
rest we leave to those who have more time  
knowledge and experience;

Nale.

439

The term Hydrocele applies to any watery tumour, but the subject of this essay is confined to that disease which is denominated the Hydrocele of the Tunica vaginalis Testis.

This is a disease from which no period of life is exempt. Not only adults but young children are frequently affected with it, and infants are sometimes born with a congenital Hydrocele. The earliest account of this species of Hydrocele was drawn up by M<sup>r</sup> Viquerie a surgeon at Toulouse and communicated to the Academy of Surgeons at Paris. From numerous observations it is said to be much more frequent in Germany than in England. It is likewise remarked that this species of Hydrocele, is frequent and of long continuance in Jewish children.

The parts concerned in the Hydrocele of the vaginal tunic, are the following. The common bag in which both the testis are enclosed, called the scrotum, which consists of epidermis, skin, and that loose cellular membrane called the dartos, to which may be added the expanded fibres of the cremaster muscle.

The proper coats of the testicle are the tunica

441<sup>3</sup>

- albuginea, and tunica vaginalis. The former of these immediately invests the vascular portion of the testis, and is that coat which covers them while within the cavity of the ~~scrotum~~ abdomen, before they descend into the scrotum.

The latter is spread ~~over the opposite side of~~ <sup>on</sup> the said cavity and is a process of the peritoneum, placed ready for the reception of <sup>the</sup> testicle, when it shall have passed down to its destined situation.

Between the vascular structure of the testicle and the tunica albuginea there is no vacuity, but the external surface of the gland is in every part adherent to, and connected ~~with~~ with, the internal one of the investing coat. The tunica vaginalis forms a hollow cavity or bag which is unconnected at the superior anterior and lateral parts of the testicle, being at the same time firmly united to it posteriorly ~~part~~, in such a manner, that if the cavity of the tunica vaginalis was to be distended with air, such air would occupy or fill the loose and unconnected part, and produce a tumefaction not unlike hydrocele, while the testis would be found firmly attached to the hinder part of the distended cavity.

Mr Pott supposed that whatever tends to increase the secretion of fluid into the cavity of that membrane beyond the due and necessary quantity, or to prevent its being taken up and carried off by the absorbent vessels, contributes to the production of this disease. Puysh entertained the opinion that hydrocele might arise from a varicose, ~~state~~ state of the spermatic veins. Mr Ramsden conjectured, that it arose sometimes from an irritated state of the urethra.

This disease has been known to originate during an attack of rheumatism, Exposure to cold and the pressure of ill constructed trusses on the spermatic cord, have sometimes been alleged as the cause of this disease. It is also said to be of more frequent occurrence among old men and persons who ride much on horse back.

Dropsy in general and this disease often arises from an increased secretion of the arteries, or a diminished action of the absorbents; but dropsical swellings are

The first of all supports that nature has is the  
 position of parts in the body of that animal  
 and the way that nature has chosen to support  
 them up and carry off of the weight of the  
 to the production of this motion. It is  
 opinion that nature might have done  
 state of the animals. The manner in which  
 these motions from an insensible state of the  
 the mind has been known to exist during  
 of animals, I observe to be the same  
 the insensible state in the animals  
 time has elapsed as the case of the  
 also to be of one frequent occurrence  
 and persons who have been in

Dignity in nature and the mind often  
 from insensible motion of the mind, or a  
 state of the insensible but depends

generally the result of an increased secretion from the arteries. The proofs are found in the increased vascularity of the membranous surface from which this secretion is poured out, as is seen upon injection of the parts post-mortum, and also in the change which is found to be produced in membranes of similar structure after long continued dropsies; and in <sup>the</sup> gutta serena with which Hydrocele succeeds inflammation of the testis and tunica vaginalis, Hydrocele is most commonly the result of a relaxation of the arteries from whose patulous mouths an inordinate effusion of fluid takes place. It more frequently arises from this cause than from inflammation. In Hydrocele the absorbent vessels of the spermatic cord, on the diseased side, are said to be very much larger than on the opposite and healthy side. It is sometimes though rarely consequent upon inflammation of the testicle, which subsiding leaves the tunica vaginalis filled with water. It is generally a local disease but is sometimes connected with an universal hydropic diathesis

Symptoms and progress.

In general on its first appearance, the tumour is rather round, but as it increases it frequently assumes a pyriform figure, with its largest extremity downwards; sometimes it is hard, and almost incompressible, so much so, that in some few instances, it has been mistaken for an induration of the testicle; at other times it is soft and lax, so that both the testicle and fluid surrounding it are easily discoverable, It is perfectly indolent in it-self, though its weight sometimes produces a small degree of uneasiness in the loak.

Mr Pott states the transparency of the tumour to be the most uncertain sign belonging to it; he says it is a circumstance which does not depend on the quantity colour or consistence of the fluid constituting the disease, somewhat as on the uncertain thickness of the containing bag, and the concave membrane of the scrotum.

According to Sir A Cooper, upon accurate examination of the swelling, it is found to be transparent. He directs us to examine the tumour in the following way. The room is first to be darkened, the patient must then hold a candle burning brightly close to the side of the scrotum; the surgeon must grasp the posterior part of the swelling so as to render its fore part as tense as possible and shake at the swelling from the side opposite to the candle; placing his feet

The present in the first appearance, the disease is rather  
 common, but as it becomes it frequently assumes a peculiar form  
 with its largest intensity, sometimes continuing it to last, and  
 about which I have written, amount to that it is a very serious  
 it has been considered for a considerable time, and it is  
 it is left out, as that will be the result and this is  
 it is a very serious disease. It is a peculiar infection, and it  
 it might sometimes produce a small degree of infection is  
 the book.

The first case the disappearance of the disease is seen  
 must necessarily be a thing to it, as it is a disease  
 which does not depend on the great life cycle, and it is  
 the first possibility, the disease, and it is a very serious  
 of the existing case, and the disease, and it is a very serious  
 according to this report, after several examinations  
 the result, it is found to be a disease, the disease is a  
 the disease in the following way. The case is first to be  
 the patient must then hold a small amount of the disease  
 side of the disease, the disease must pass the patient  
 nothing as it is not to be found in any other part of the  
 as the result from the case appears to be a very serious

449

hand on the fore part of the scrotum he will immediately discover the transparency. The strong light of the sun falling on the part answers equally well in showing its transparency.

The quality and consistence of the contained fluid is various it is thick, aqueous,ropy, viscid, limpid, yellow, greenish, brown, bloody, clear, or turbid. It has a distinct fluctuation which may be observed by placing the hand upon one side of the tumour and gently striking it upon the opposit side. When excessively distended it feels hard. The quantity of fluid varies in different cases; a hydrocele of ordinary size contains about eight or ten ounces, but instances are on record in which four and even six pints of water have been drawn off.

The progress of the disease is generally so slow that six or seven months often elapse before the tumour approaches the abdominal-ring. This disease is more inconvenient on account of its size and weight, than painful or dangerous. When large and not supported in a bag trap it drags the spermatic cord and creates pain in the loins. It also interferes with every kind of labour in which the lower extremities are concerned, and prevents the individual from riding on horse-back. Among other characters of this case the corrugation of the scrotum disappears by the distention of the parts, and the manner in which the swelling draws the integuments from the penis prevents the full erection of that organ; a circumstance which

is frequently a source of great anxiety to the patient, who is apt to suppose his virility irrecoverably impaired. When the swelling is very large, the penis is completely retracted, and the urine dribbling over the front of the scrotum, is liable to bring on a good deal of inflammation and troublesome ulceration of the parts.

In the Hydrocele of children the testis occupies a lower situation than the same organ in the hydrocele of adult persons, and the swelling appears farther up towards the abdominal-ring; however the testis is generally placed two thirds of the swelling downwards, and at the posterior part of the scrotum.

Pressure at that part gives the sensation of squeezing the testis, It is a very moveable swelling and does not distend the part much in the course of the spermatic cord; it bends easily upon the abdomen and moves readily in all directions.

Diagnosis.

Hydrocele may be distinguished from Hernia by the occasional return of the hernial swelling into the abdomen, by the dilatation of the hernia in coughing, and by hernia disengaging from the abdomen. In sarcocele in which the testis is itself diseased, the tumour is more heavy and flatter on the side than hydrocele, and more solid, much pain is also produced by

swelling the testis, epid<sup>is</sup>ymis is often capable of being felt as a distinct  
tumour; the cord may be traced with facility. There is also great  
vascularity of <sup>the</sup> scrotum, and the general health is often impaired.

From Hematocele we may distinguish it by the greater <sup>weight</sup> of the former  
by the want of transparency by its obscure fluctuation, and  
particularly by its being usually the result of a blow upon the  
part.

From Cirsocoele it may be distinguished by placing the  
patient in the recumbent posture in which situation by pres-  
-sure on the distended veins the tumour may be made to disap-  
-pear. From Hydrocele of the cord by the latter disease extending  
some times above the ring; it is also globular when grasped and  
raised; it appears of a light blue colour is very transparent and  
extremely firm to the feel unattended with pain; it <sup>is</sup> merely  
an inconvenience to the patient from the impression it produces  
on his mind. Hydrocele may distinguished from Hernia Primitiva  
-nalis by the Hernia involving the whole scrotum, by its being attended  
with much inflammation and generally resulting from gonorrhoea.

### General Treatment.

In general when a hydrocele is left <sup>to</sup> itself in an adult  
subject, no cure can be effected by nature alone. In young-

=persons the cure is more easy, in children under six years of age  
 nature without any assistance sometimes disperses the complaint.  
 Sometimes the tumour bursts or is ruptured by external  
 violence, or from an accidental effort of the patient, Accidents  
 of this kind sometimes terminate in a radical cure.

Internal remedies have no effect in this disease  
 unless employed in a very early stage, in cases of young  
 children cold affusions of water have been found useful,  
 When this remedy is used it is recommended to be poured  
 on the part out of a tea-pot four or five times a day.  
 Active purging has in some instances effected a speedy  
 cure of this disease however it is rarely found to be  
 -useful.

*Palliative Treatment.*

Hydrocele is not a painful disease. In many cases, the  
 -patient generally prefers submitting to the inconvenience  
 it occasions for some time, rather than have recourse to any  
 surgical operation. However its weight and size finally  
 become so disagreeable that he is obliged to wear a bag-  
 -truss, a painful extension of the spermatic-cord takes place-

and the patient is very much annoyed by a troublesome excoriation caused by the friction of the tumour against the sides of the thighs. Hence the greater number of patients are very anxious for relief.

All the anterior superior and lateral parts of the vaginal coat are loose and detached from the albuginea, but on its posterior part those two tunics make one, and consequently the testicle is as it were affixed to the posterior part of the cavity of the sack in hydrocele. This being the state of the parts the operation ought always to be performed in that part of the tumour where the two coats are at the greatest distance from each other and where the fluid must be accumulated in the largest quantity.

The two instruments used for this operation are the common lancet and the trocar. For the purpose of discharging the fluid, the latter instrument is generally preferred, as the conula facilitates the escape of the water and prevents its diffusing itself in the cellular texture of the serotum, when the hydrocele is small or the

Tetanus as defined by all authors is a contraction of several of the muscles of greater or less violence and extent with tension and rigidity of the parts affected. Tetanus may be divided according to its severity into acute and chronic. The first is very dangerous, and generally mortal. Chronic tetanus is less dangerous and by reason of its more gradual progress and affords time for the employment of more numerous remedies.

Tetanus may from certain causes occur in every climate, with which we are acquainted but it occurs most frequently in the warmest climates and generally in the warmest seasons of those climates. It affects all ages and complexions. The causes from whence it commonly proceeds are cold and moisture applied to the body while it is very warm, and especially the sudden vicissitudes of heat and cold, or by punctures, lacerations, or other <sup>lesions</sup> ~~lacerations~~ of nerves in any part of the body. Possibly there are many other causes of this dreadful disease; but they are neither distinctly known, nor accurately ascertained.

If the disease proceed from cold it most frequently comes on in a few days after its application, but if it arise from a puncture of a nerve the disease does not commonly come on for many days after the injury has happened, very often when there is neither pain or uneasiness in the part, and frequently when the wound has cicatrized. Sometimes this disease comes on suddenly to a very violent degree, but it approaches more generally very gradually to its most violent state. In this case it comes on with a sense of stiffness in the back part of the neck, which gradually increa

ing renders the motion of the head difficult and extremely painful. As the rigidity of the neck comes on and increases there is commonly at the same time a sense of uneasiness felt about the root of the tongue, which by degrees becomes a difficulty of swallowing, and at length an entire interruption of it; when this pain arises all the muscles of the neck and particularly those on the back part of it are immediately affected with spasm, pulling the head very strongly backwards. At the same time the temporal and masseter muscles which upon the first approach of the disease were affected with some rigidity are now affected with violent spasm, and set the teeth so closely together that they admit not of the smallest opening. This is what commonly has been called Locked-jaw, and often is the principal part of the disease.

When the disease has advanced thus far a pain at the bottom of the sternum returns, and leaves the patient very frequently, and with it the spasms of the muscles of the back part of the neck and lower jaw are renewed with great violence, and severe pain. As the disease proceeds a greater number of muscles become affected with spasm. After those of the neck, those along the whole spinal column are affected, bending the trunk of the body backwards; and this constitutes what has been called opisthotonos. Both the extensor and flexor muscles of the inferior extremities are commonly at the

*[The text on this page is extremely faint and illegible due to fading or bleed-through from the reverse side. It appears to be a continuous block of handwritten text.]*

same time affected, and keep the limbs rigidly extended; though the extensors of the head and neck are usually more strongly affected, yet the flexors & those muscles that pull down the lower jaw are often strongly affected with spasm at the same time. During the whole of this disease the abdominal muscles are violently affected with spasm, so that the belly is much retracted and feels very hard. When the disease has made some progress the flexors of the head and trunk are equally affected with the extensors, so as to keep the head and trunk straight and strongly extended, incapable of being moved in any way, to this state the term tetanus has been strictly applied. At this time the arms which were little affected before become rigidly extended; and the whole of the muscles belonging to them being affected with spasm, except those that move the fingers which often in the most violent stage of the disease retain some mobility. The tongue also retains its mobility for a long time; but at length it also becomes affected with spasms which attacking only some of its muscles, forces it sometimes between the teeth, by which it is much injured. At the height of the disease every organ of voluntary motion seems to be affected and among the rest the muscles of the face.

The forehead is wrinkled, the eyes are sometimes

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

distorted and immovable in their sockets; the cheeks  
 are drawn towards the ears, & the countenance is expres-  
 -sive of most violent agony. Under these universal  
 spasms the patient does not long remain, for a con-  
 -vulsion soon terminates his existence. In this disease  
 the spasms are every where attended with great pain.  
 The utmost violence of spasm is however not  
 constant; but after subsisting for a short time,  
 the muscles admit of some relaxation, although  
 not so much as can allow the action of their an-  
 -tagonists. This remission of contraction gives  
 a short remission of pain, but neither is of long  
 duration. These violent contractions & pains  
 are removed from time to time, & often times  
 without any evident exciting cause. Every attempt  
 to speak, to move or to swallow, gives occasion  
 to the renewal of the spasms over the whole  
 body. The attacks of the disease are not always  
 but generally attended with febrile action, at  
 the commencement of the disease, the pulse is  
 full & frequent, tense & strong. When the spasms are  
 general and violent, the pulse is contracted, hurried and

469  
irregular; and the respiration is affected in a like manner  
but during the remission both the pulse and respiration  
usually return to their natural standard.

Frequently the face is pale, with a cold sweat upon  
it, and very often the extremities are cold, with a cold sweat  
over the whole body. In this disease the head is  
seldom affected with delirium, or even confusion of  
thought, till the last stage. so that the patient is  
sensible of all the changes of this distressing disease,  
his pain is unsupportable, he sees the desponding coun-  
tenances of his attendants and feels as if his departure  
could not be arrested. In this disease the natural  
functions are not immediately affected. Vomiting  
sometimes appears early but it is not continued,  
the appetite commonly remains good nearly through the  
whole course of the disease, & the food taken seems  
to be well digested. The excretions are generally  
deranged. It is not certain whether costiveness is  
the effect of the disease or of the opium which  
is administered, probably the latter as it is used in  
large quantities. The urine is sometimes suppressed,  
or it is voided with difficulty and pain. This disease  
has commonly proved fatal as we are told by Dr Cullen

Faint, illegible handwriting, possibly bleed-through from the reverse side of the page. The text is mirrored and difficult to decipher.

and fatality might might be considered as a <sup>47</sup> natural  
consequence as long as the disease was badly treated  
but since a more proper method has been known  
and practised, the disease has not struck the patient  
or the physician with such terror as formerly, and  
many now are cured. Judging of the tendency of the  
disease in particular cases, we may remark, that  
when it arises from a laceration of the nerves it is  
commonly more violent, than when it is the effect  
of cold; that the disease which comes on suddenly  
and advances quickly to a violent degree is always  
more dangerous, than that which is slower in its  
progress. This disease often proves fatal before the fifth  
day, and if the patient has passed this period, he may  
be supposed to be in greater safety, and generally the  
longer it continues, the safer the disease and consequently  
the less do we fear the result. However it is to be re-  
marked that many days after the fifth the disease  
continues to be dangerous; and when it is considerably  
abated, it is ready to recur again with its former  
danger. No evacuation or eruption has been known  
suddenly to check its career, and when it terminates fa-  
vourably it always recedes gradually, and often a long  
time elapses before all its symptoms disappear entirely.  
When the disease is known to arise from the laceration

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

of a nerve in any part of the body, the first and most important step to be taken towards the cure, is by every means in our power to cut off that part from all communication with the sensorium either by cutting through the nerves in their course, or by destroying the affected parts to some distance. We have several instances of great benefit from early amputation of a wounded extremity when tetanic symptoms first appear. This however should not be done unless the injury from which the disease results be inflicted on some of the smaller members such as the fingers or toes; to amputate the thigh would be putting the patient to useless torture.

Opium as taught by experience has often ~~proved~~ proved a very effectual remedy when we attempt to cure the disease by medicine. The remedies have been divided into external and internal, when the disease arises from the injury of a nerve it will be necessary to cut down and divide it, or to apply stimulating remedies or warm emollient poultices, & at the same time to give Laudanum, under this treatment the disease will be frequently removed. Both the warm & cold bath have been strongly advocated, but they cannot be relied on alone. Caustic has been often used successfully in traumatic tetanus. Of the internal remedies opium is the best & should

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

never be forgotten in the treatment of tetanus and cannot be limited, it should be given as soon as you suspect that the disease is approaching, wine or brandy may be give in very large quantities, in this disease it is almost impossible to produce intoxication; The whole class of antispasmodics, have we used the oil of Amber is among the best, & if used in larger quantity would more often prove successful it should be given in the dose of half a dram. When opium is administered it should be given in small & frequently repeated doses, at the intervals of 2 or 3 hours as the violence of the symptoms may require, it seldom induces ~~torpor~~ ~~or~~ ~~sleep~~ stupor or sleep which it does so often does under other circumstances when much smaller doses have been taken, therefore we should not be sparing in its use.

Purgatives have been administered & recommended by very respectable authority in this case - Dr Hamilton of Edinburg represents them as entitled to our confidence. But if they be useful it must be in cases of tetanus resulting from internal irritation, where the disease originates in the alimentary canal. In such cases probably emetics combined with purgatives might be useful, for besides assisting in the removal of irritation they would contribute by their nauseating quality to the relaxation of spasm. Blood-letting has been practised with advantage in this disease in plethoric subjects, regard must be paid to the state of the system in this as in all other complaints. Blisters were formerly in this disease, but it is asserted that they were

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

47

constantly hurtful & are now never employed.

Mercury in its turn was tried, & report says with success; & is now one of the principal remedies in use. This, with Opium & wine, appear to be the only remedies, upon which we can confidently rely, in the treatment of tetanus. Of these, the two latter retard the progress of the disease, preventing exhaustion, & death, from violence of the spasm, untill the former has had time to eradicate it entirely, by converting the tetanic into the mercurial action. Opium & wine being palliative rather than curative remedies are not sufficient of themselves without mercury while without their aid mercury is too slow in its operation to arrest the rapid march of the disease. The usual & best preventatives of tetanus from external injuries consist in the conversion of punctured into incised wounds by means of the scalpel & the excitement of suppuration in lacerated wounds.

These things if done immediately after the injuries have been received & before the occurrence of tetanic symptoms are of great importance but they are worse than trifling if delayed untill the disease shall have made its appearance. When the tetanic deathness is fairly formed all local applications to the injured part are unavailing even the amputation of a limb has been found insufficient to arrest its progress. Should circumstances exist to prevent the dilation of a punctured wound, the application of caustic alkali & sinapisms to the part are the best substitutes. Whatever is calculated to excite common inflammation is useful at this time. For the production of suppurative action in lacerated wounds spirits of turpentine, or a solution of the muriate of mercury followed by poultices frequently repeated are the best applications. When from a neglect of preventative remedies, or in despite of their use tetanus has made its appearance, a different course of practice must be commenced and pursued diligently. To the state of the

*[The text on this page is extremely faint and illegible due to fading and bleed-through from the reverse side. It appears to be a dense block of handwritten text, possibly a letter or a journal entry.]*

system a strict and steady attention must be paid. If the patient be plethoric and the excitement run high, or if the latter, without the former blood must be drawn and the operation repeated as often as circumstances may require; if costiveness prevail & any irritation be suspected in the bowels purgatives are to be administered as in other diseases; but as has been mentioned above as soon as the condition of the system will admit them, wine, opium, & mercury are to be given according to their effects on the system without regard to quantity. They should be given until the system has forcibly felt their action or they will be unavailing. Opium should be administered in injection in doses of from five to ten grains & repeated at short intervals until the spasms are overcome and some soporific effect produced; applying in the meantime to various parts of the body quantities of mercurial ointment, when the power of swallowing has for a long time ceased, nutritive clysters should be substituted. After surgical operations, as a prophylactic salivation, & the use of the tincture of opium mixed with the dressings has been employed to prevent symptomatic tetanus with success.

*[The text on this page is extremely faint and illegible due to fading and bleed-through from the reverse side. It appears to be a continuous paragraph of handwritten text.]*

The first part of the paper  
 is devoted to a general  
 description of the  
 country and the  
 climate of the  
 region. The author  
 then proceeds to  
 describe the  
 various tribes  
 and their  
 customs. The  
 paper concludes  
 with a list of  
 the principal  
 places visited.

# Essay on Pteris

484

Before entering upon the subject of Pteris I propose to make a few physiological remarks on the liver considering the size of this organ in all animals that possess it and how generally it is possessed being common to all red blooded animals there can be no doubt that it is of great importance in the animal economy. Whether it serves to separate any excrementitious material from the blood or produce any other effect upon it has not yet been decided. Certainly its most obvious office is the secretion of the bile which in most animals in its passage from the liver to its place of destination the duodenum communicates by means of a duct <sup>with</sup> a pear shaped reservoir denominated the vesicula fellea or gall bladder in which it is supposed to accumulate. And as ~~the~~ it ~~is~~ is generally believed that the symptoms of jaundice depend upon an obstruction to the free egress of the bile from the excretory ducts of the liver into the aboive canal and its return into the circulation. Although such is the case in general yet there have been instances in which there were a copious absorption and

Essay on Belles

When nature gives the soul of man a power  
to make a vast number of words in the  
the use of the mind in all words that  
the words of a person are not to be  
words that are in use that is of great  
value in the mind of man. The words  
of a person are not to be used for the  
purpose of making a noise or of being  
understood by the people of the world  
but of being understood by the people  
of the world. The words of a person  
are not to be used for the purpose of  
making a noise or of being understood  
by the people of the world but of being  
understood by the people of the world.

491

return of bile into the blood and at the same time  
a redundant flow of it into the alimentary canal How-  
ever the most general causes of Icterus may be referred  
to mechanical obstructions to the biliary ducts Many  
disputes have arisen concerning the manner in which the  
bile is resolved into the system but it is now general-  
ly believed that it is taken up by the absorbents of  
the gall bladder and ducts Hence it is that jaundice  
may be produced by any thing obstructing the passage  
of the bile into the duodenum Biliary concretions  
appear to be the most frequent cause of this disease  
With respect to their formation we are yet unacquainted  
The liver appears in many instances to be sound but  
in other cases it is undoubtedly diseased and from the  
morbid secretion it may become more disposed to crys-  
tallize From the analysis of biliary concretions they ap-  
pear to contain <sup>most</sup> of the ingredients of the bile From  
their peculiar crystallized structure we are led to be-  
lieve that something more is necessary to their forma-  
tion than the mere inspissation of the bile but what  
that consists in physiologists have not yet been able  
to detect Indolence of body & anxiety of mind appear

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

493

particularly to predispose to their formation therefore they are much more frequently found in women in the upper walks of life and men much addicted to sedentary occupations especially after the more active period of life Haller noticed the frequent occurrence of biliary concretions among criminals whose deaths had been preceded by long confinement but the anxiety of mind also might contribute to their formation as long as biliary concretions remain undisturbed in the gall bladder for they are generally formed there they appear to produce little or no inconvenience but from violent compression or from irritation the gall bladder and ducts contract and thus the offending substance will gradually be moved in the direction where least resistance is offered this will of course be toward the mouth of the duct not solely because the duct gradually enlarges but because there is constantly an impulse given from the accumulated secretion from behind. When biliary concretions of large size are thus thrust into the ducts they produce the most excruciating pain to which the human fabric is liable and it is generally referred to the pit of the stomach

corresponding to the opening of the duct into the duodenum  
 and shooting from thence towards the spine accompanied  
 at intervals with rigors and nausea (During the paroxysm  
 the respiration is hurried with great anxiety restlessness and  
 occasionally with delirium followed by extreme languor and  
 faintness with vomiting & occasionally with spasmodic  
 twitchings in different parts of the body Profuse sweats  
 often break out apparently from the severity of the pain  
 In the intervals of the paroxysms there is generally a  
 fullness and soreness in the epigastric and right hypo-  
 chondriac regions The patient generally experiences  
 most relief when his body is bent forward The par-  
 oxysm will continue to recur at intervals until the con-  
 cretion makes its escape into the alvine canal which  
 it will do in some instances within a few minutes in  
 others it will be for weeks in passing along the duct  
 thus obstructing the passage and producing the disease  
 which in some instances will continue for a considerable  
 time after the cause has ceased to act Biliary con-  
 cretions of such large size have sometimes passed  
 as to make physicians doubt whether they did not  
 make their way by ulceration into some part of the

Faint, illegible handwriting, likely bleed-through from the reverse side of the page. The text is mirrored and difficult to decipher.

497

intestinal canal which is highly probable as there  
are cases where they have been known to make their  
way through the walls of the abdomen

Protrunatural viscosity of the bile has often been adduced as  
a frequent cause of jaundice. It appears that this state  
of the bile may take place from a variety of causes.  
From the removal of the bile in the gall bladder and  
ducts produced by particular positions of the body  
from pregnancy and from vascular turgescence of the  
liver itself and at the same time the absorbents of  
the gall bladder and ducts still continuing to act  
if not increased in action will take up the more  
attenuate particles of the bile and thus render it  
viscid. Augmented secretion from the gall bladder  
and ducts has also been assigned as a frequent  
cause and also a too viscid consistence of the bile  
in its secretion in the liver. This species of jaun-  
dice is most frequently met with in autumn  
and it generally commences very insidiously. There  
is in this variety a diminution of appetite restles-  
ness disturbed sleep and a disinclination to exertion  
of any kind together with the general symptoms of Icterus.

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

499

Inflammation appears to be a very frequent cause of jaundice by preventing the free discharge of the bile probably by a thickening of the parietes of the ducts thus lessening their caliber. It may take place from a variety of causes it may either extend from the intestines or from the liver itself from cold and especially from taking very large quantities of cold water when the body is much heated. The symptoms attending this species of obstruction are those attending general inflammation tenderness of the epigastrium and generally commences with a chill. It has been questioned by some whether jaundice is ever produced by mere spasm of the ducts themselves. The arguments in favour of this opinion are that it has been a frequent attendant on Hysteria and other spasmodic diseases and that the attack is sometimes very transitory and from dissections there has been discovered no mechanical obstructions whatsoever in the ducts and also without any appearance of biliary concretions in the feces. It occurs more frequently in persons of very irritable habits from sudden emotions of the mind. The papiers have a remarkable effect on the secre-

Faint, illegible handwriting on aged paper, possibly bleed-through from the reverse side. The text is mirrored and difficult to decipher.

501

-tion of the bile and they may also cause a spasm  
of the ducts themselves. The symptoms attending spas-  
modic constrictions of the ducts are sometimes as  
violent as when biliary concretions are impacted  
in the ducts. The spasm indeed appears to be the  
cause of the pain in both cases. Enlargements of  
the neighbouring organs is not an unfrequent cause  
of this disease such as schirrus of the pancreas  
scrophulous glands tuberculi of the liver may ob-  
scure the parietes of the ducts as to prevent the dis-  
charge of the bile and thus produce the disease. In this  
variety the pain is not so acute and does not come  
on suddenly general emaciation attended with sore-  
ness and hardness in the epigastric region jaundice  
is also described to have been produced by mechan-  
ical distention of the duodenum by closing the valve  
of the duct. Jaundice arising from this cause  
appears to be peculiar to infants and is very easy  
of removal. It only requires the exhibition of some  
mild aperient medicine to clear the bowels  
of the impacted viscid meconium.

Having spoken of the principal causes which

Faint, illegible handwriting, likely bleed-through from the reverse side of the page. The text is mirrored and difficult to decipher.

97

give rise to the disease I shall now enumerate  
some of the most characteristic symptoms Jaundice  
generally commences with a want of appetite a  
sense of lassitude and languor depression of  
spirits disinclination to exertion of any kind  
Indigestion and general emaciation In some cases  
there is a great propensity to sleep in others wa-  
ntfulness The dejections are pale or clay colour-  
ed with the absence of the feculent smell As  
the disease increases the yellow colour makes  
its appearance showing itself first in the tunica al-  
buginea The urine becomes high coloured with a  
yellowish sediment so as to be capable of imparting  
the same colour to linen The yellow colour appears  
not to be confined to the skin alone but is diffused  
over the whole body so that the bones have been  
found tinged yellow for a very long time after the dis-  
appearance of the disease There is generally great  
itching over the whole body The bile appears to  
be diffused in the whole mass of fluids so that the  
secretions are affected even the blood itself is  
said to possess a yellow colour.

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

505

As jaundice may arise from so many different causes, some of which it is impossible to discover during the patients life and some which may be considered incurable we ought therefore to ascertain if possible the real nature of the cause which has given rise to the disease which can in general be done by attending to the various circumstances which present themselves for certainly such a discrimination must be of the greatest importance when it is considered that the mode of treatment must be varied according to the nature of the cause by which the disease is produced whether the passage of the bile be obstructed by biliary concretions or spasmodic constrictions the plan of treatment to be adopted must be nearly the same In the passage of biliary concretions of very large size through the common duct they very frequently produce from their great distention not only very acute pain but also when long continued a considerable degree of inflammation to guard against which it will often be necessary in full plethoric habits to take away blood proportionable to the

The following is a list of the names of the persons who have been admitted to the office of the Secretary of the Board of Education since the first of January, 1870. The names are given in alphabetical order, and the date of admission is given in parentheses. The names are given in full, and the date of admission is given in full. The names are given in full, and the date of admission is given in full.

501

state of the pulse and severity of the pain this should be succeeded by the use of the warm bath warm fomentations together with opiates the opiate should be given in the solid form for the stomach will often be so irritable as to reject liquids of every kind two or three grains of opium should be given at first and if relief is not obtained in half an hour the same quantity should be repeated with the intention of facilitating the passage of biliary concretions or viscid bile emetics have been used with great advantage During the act of vomiting the diaphragm and abdominal muscles concurrently contract and the whole of the abdominal viscera are thus forcibly pressed upon which must necessarily cause the gall bladder and ducts to pour out their contents freely For this purpose the antimonial emetics are preferable because they are less apt to be rejected and also excite a much stronger stimulus After the operation of emetics the bowels should be freely opened by some purgative medicine Exercise has also been useful particularly

*[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]*

504

- by that of riding on horse back by the concussion which it gives to the liver frictions and the like have been used with the same view Purgatives have been found very useful in some cases of jaundice especially in those cases where the disease arises from a too viscid state of the bile in consequence of a torpid condition of the liver In this case mercury must be used to change the condition of the liver In cases of infants where the passage is obstructed by viscid meconium purgative medicines must be principally relied upon the Nitro-muriatic acid bath hath been much recommended in cases of Stenosis It should consist of three ounces of diluted aqua regia to every gallon of water the strength of the bath should never be greater at any time for otherwise it may produce a very troublesome rash and give a yellow hue to whatever part is exposed to its action Dr Scott used it with decided advantage in almost all cases dependant on a morbid secretion of bile There has been a great variety of other remedies recommended in Stenosis such as the alkalis electricity the seed of the common hemp &c but none of them much used at the present time

On, the,  
Causes of Sudden death,  
And the,

Means of preventing it,

Death is the inevitable lot of all, Mankind; but there are few persons, whose business, or whose conduct in life, do not render it a greater, evil to themselves and their families when it takes place suddenly than when it occurs after a previous indisposition. To point out the principal causes of the sudden and unsuspected extinction of life, and the means of preventing it, shall be the Subjects of the following dissertation. It will, be necessary that I promise to adopt the opinion of the professor of the Institutis that life consists in such a peculiar organization of matter, as to be capable of producing by certain impressions, those motions and sensations which have been hypothetically ascribed, by some, writers to the mind and by others to an independent vital principle. Death of course consists in the destruction of that peculiar organization of matter, or an incapacity

Dr. The

Means of preventing it

And the

Means of preventing it

Death is the inevitable lot of all mortals and  
the one true purpose of life is to spend it  
in the most profitable manner, and to terminate it  
in the most peaceful manner. The first step  
towards this is to secure a firm foundation  
of health, and to maintain it by a regular  
course of exercise and a temperate diet.  
The second step is to cultivate the mind  
and to acquire a liberal education. The third  
step is to engage in some useful profession  
and to acquire a competence. The fourth  
step is to marry a virtuous and sensible  
woman, and to bring up a family of  
children in the most judicious manner.  
The fifth step is to live in a temperate  
and cheerful manner, and to avoid all  
excesses and dissipation. The sixth  
step is to be prepared for death, and to  
die with a calm and cheerful spirit.

519 2,

with those impressions, which produce the motions and sensations of life, the causes which produce this incapacity in the matter of the human body, and thereby induce sudden death, act more or less certainly according as they are more or less combined, according to the nature of the parts of the body on which they act according as the system is in a state of healthy excitement, or more or less predisposed to death, by previous debility, or by a previous disease. They appear to induce death by a sudden destruction of the excitement of the system, from the excessive force of impression or the sudden abstraction of them, whereby the system is rendered incapable of performing its natural office.

I shall briefly enumerate the causes, which, by inducing the above changes in the system, bring on sudden death. Extreme heat and extreme cold. Both these act with most certainty upon old and sickly people. Dr. Housham remarks, that old people are often found dead in their beds, after an extreme cold or warm night; and there are few physicians who have not had patients suddenly and unexpectedly snatched out of their hands by the extremes of heat and cold. Fatal effects have likewise followed or rather been observed when heat and cold in their extremes, have followed each other

521 3  
in a rapid succession. The rays of the sun acting upon the  
head have often produced death, by means of what is called  
by the french *coup de soleil*; and cold, combined with moisture,  
has so often produced it in the form of Apoplexy, as in  
some instances to create a belief that disease had assumed  
the character of an epidemic. Sudden changes in the weight  
of the atmosphere, some cases of kind are mentioned by  
writers. Certain matters contained in the air, these are  
several of the gases, particularly azote or according to modern  
nomenclature nitrogen gas, the carbonic Acid, and inflammable  
Air. The black at Calcutta will be a lasting monument  
of the deadly effects of azote or respired Air. Many people  
perish from sleeping in unventilated cabins and rooms, in  
consequence of Carbonic Acid eliminated from burning  
coals, and it is well known that miners are often des-  
troyed by breathing the inflammable Air which is discharged  
from subterraneous caverns. To the noxious airs some have  
added certain vegetable poisons which are said to float  
in the atmosphere; but since the rejection of the fable  
of the East India upas tree, sudden death from this cause  
has been discarded from medicine. The Air in the vicin-  
ity of the *Rhus Radicans* has been known to induce  
vex, and to inflame the skin, but I believe in no instance

*[The page contains a dense, mirrored bleed-through of text from the reverse side of the paper. The text is written in a cursive script and is completely illegible due to the mirroring effect.]*

534  
hus it suddenly extinguished the vital. To this head belongs the  
~~vital~~ Miasmas which exist in the atmosphere from the putre-  
-faction of Animal and vegetable substances. The history of  
the plague in the Old world, and of the yellow fever, in the un-  
-ited States, furnish many proofs of sudden death from this  
cause. This is not the place to inquire whether those diseases  
or death can be induced by a matter secreted in a morbid  
body, and conveyed into a healthy one; sudden death has  
sometimes been brought on by entering a small and petty  
room, crowded with persons ill with the plague! But  
the matter which induces it is not secreted. It is like the  
original Miasms, the offspring of putrefaction, and in these  
cases, derived from stagnated excretions from the bodies of  
sick people. As I am only relating facts at present,  
I hope I shall be excused from deciding on the long  
agitated question of the part of the body, on which  
the Airs and Miasms, that have been mentioned, prima-  
rily and chiefly acts, in producing their deadly effects.  
Some of them certainly act upon the body, through the  
medium of the lungs; some of them upon the whole nervo-  
ous system through the medium of the brain; And some  
of them upon the sanguiferous system through the med-  
ium of the stomachs. It is possible, Miasms may convey death  
to the body through the avenues of all the parts that have

been mentioned. I have said nothing of sudden death from  
 contagions. They are extremely limited in their number, and  
 seldom so powerful, in their first impressions as to exting-  
 -uish life. Cases of sudden death from the small pox,  
 measles and the hooping cough, and I believe rarely  
 to be met with in the records of medicine. Lightning  
 is often a cause of sudden death. It seems to act prim-  
 -arily upon the nervous system, but the blood and all the  
 muscles of the body appear to partake of its forcible  
 impression. Hence the quick putrefaction of the  
 body after death from this cause. Sudden and viol-  
 -ent emotions of the mind. Anger has in instances  
 produced death terror has often produced it. Sol-  
 -diers has often been found among the slain in ba-  
 -ttle whose bodies have been found free from wounds.  
 Their deaths have been ascribed to the wind of cannon  
 balls, Is it not probable they were occasioned by the  
 violent impression of terror upon their systems: Strip-  
 -plings wounded, it is well known, have now and then  
 produced death, from being combined with a sud-  
 -den paroxysm of fear. The passions of fear and grief  
 have occasionally induced sudden death, but it is more  
 common for them to produce it by a previous chronic  
 disease. Under this head we may bring in as a cause of

Sudden death, a sudden sense of guilt and shame. Of this there are several instances to be met with in practical authors. Great bodily exertion in labours, lifting weights and in marching, have sometimes suddenly destroyed life. Fatigue or the reduction of excitement of the system in marching more certainly induces sudden death, if it be combined with excessive heat. The histories of the late French and English campaigns in Egypt furnish a number of instances of soldiers expiring on the public roads, from the combined effects of the rays of the sun, and great fatigue acting upon their bodies. Great bodily pain has sometimes induced sudden death. The cold is often killed by excessive pain. Mr. Hunter relates an instance of the pain occasioned by the extirpation of a diseased testicle producing death. In fevers sudden death is sometimes brought on by the inability of the blood vessels to react in the chilly fit; by convulsions; and by the extreme debility which follows. The termination of a paroxysm of fever, affections of the head, from gout, and the frequent causes of sudden death. The most common of these are profuse of water or blood upon the brain inducing apoplexy. Death is sometimes the effect of a sudden effusion of blood or water in the lungs, constituting what has been called by Dr. Keck in his lectures the apoplexy of the lungs. A Spasm of the heart, produced by the gout, has in several instances, induced the sudden extinction of life. Certain poisons and many substances of an indigestible nature, also cold liquors, when the body is habitually heated, received into the stomach by their sympathy with the head, heart, or blood vessels, induced sudden death. It has sometimes followed a Spasm in the stomach from gout, also a rupture of that important viscus. The discharge of pus from the liver into the thorax, and into the abdomen, has often hurried persons

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and difficult to decipher.]*

7  
suddenly. out of life. Worms. in the alimentary canal  
have now and then suddenly. produced death, especially  
in the children, by exciting Apoplexy or general convulsions.  
The sudden rupture of an Aneurism, in the large blood  
vessels near the heart, has often become an instantaneous  
outlet of human life. It has passed away with nearly  
equal rapidity from a rupture of the bladder and  
the uterus. It has been induced by syncope, from partial  
and general causes. The sudden reduction of the ex-  
citement of the system, by Hemorrhage, by parturition by a large  
stool, by a copious discharge of matter, from an abscess  
and perhaps, by the cessation of pain, has, in sundry instances,  
brought on sudden death. Derangement producing  
suicide. I have ascribed this cause of sudden death to a  
disorder, for such is it contrary to the natural princi-  
ples of action in man, that I believe it rarely takes  
place in the perfect exercise of his reason. I shall  
say nothing of the causes, of sudden death from drow-  
ning or external causes wounds, and accidents, as being for-  
evident. I shall confine my self only to such cases,  
as are within the power of medicine.

Part. 3<sup>d</sup>. To prevent death from the extremes of heat, cool  
drinks and situations should be advised. As it  
frequently occurs in the night, and during sleep, in  
cold weather, by recommending to old and weakly people  
to lie constantly on a mattress, to prevent it from cold;  
and but light bed cloths, should be prescribed; and as death  
takes its first ~~effect~~ <sup>approach</sup> through the feet, great pains  
should be taken to keep them warm, by means of warm  
socks, wrapped in warm flannels, or Stone Socks, filled with  
warm water. The fatal effects of the stroke of the sun  
is to be prevented, by constant and gentle exercise, when  
persons, are exposed to its rays, and by protecting the head by

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and difficult to decipher.]*

an umbrella, or a cap crowned hat, covered with white  
 linnen or paper. The egyptians, says Mr. Quarr, use a turban  
 for this purpose, It is true it accumulates the heat of the head,  
 but this heat, he remarks, is less, and far more tolerable, than  
 the heat of the sun, which in the climate of egypt, is  
 often between 120° and 130° degrees. Within these degrees of heat  
 says (Dr. Russ) I have seen the natives of Bengal rowing  
 their boats, on the river Hoogly, exposed to a meridian sun,  
 and bear headed, without experiencing any ill effects.  
 The only precaution they used, was to keep their heads const-  
 antly wet by pouring over them large gourd of water.  
 By this means the neck, shoulders, and chest which  
 like the head were exposed to the sun, were kept cool from the  
 evaporation of the water. During the prevalence of the winds,  
 and that kind of weather which disposed to sudden  
 death from apoplexy great care should be taken to lessen  
 the predisposition to it, by temperate diet, and gently opening  
 physic. To prevent the fatal effects of the Gases, that have  
 been mentioned, places which are supposed to contain them should  
 not be entered, until they have been examined by a lighted  
 candle. The extinction of its light, is a sign of its containing  
 a phosphate or carbonic gas. A flame or explosion excited by the  
 blaze of the candle, indicates the presence of inflammable  
 air. The deadly effects of the Miasms from putrefied vegetable  
 and animal substances, are to be prevented by avoiding the  
 places which generate them, by lessening the predisposition  
 to be affected by them, by means of abstinence gently open-  
 ing physic, and a temporary issue, excited by a blister  
 on one of the legs, or limbs. Of the efficacy of these preven-  
 tions there are many proofs in the history of pestilential fun-  
 diseases. The means of preventing or avoiding sudden  
 death from lightning, belong to naturalists not to medical  
 philosophers. The preventives of death from violent emotions

of the mind, should be sought for in those books, which in-  
culcate the subjection of all its faculties, and operations to the  
dictates of reason, and religion. Labour and exertion dispr-  
oportional to the strength of the body, should be carefully  
avoided by all who wish to avoid or escape a sudden  
passage out of the world. The combined influence  
of heat and fatigue upon life from labour and ma-  
rching may be obviated by counter Stimuli. Ardent spirits  
have generally been resorted to for this purpose, but a garlic  
or raw Onions are to be preferred to them. By the constant  
use of these cordial vegetables, the hebrew nation was enabled  
to sustain the labour of making bricks, in the open Air  
exposed to the intense heat of the climate of egypt.  
The deadly effects of heat and fatigue were prevented  
by a part of the british army in the same country,  
during the late war, by allowing the soldiers, but a small  
quantity of water, Similar advantages are derived from  
abstaining from water altogether, by the Indians of north  
America, during the day, in their long and fatiguing  
marches, in hot weather. Death from extreme pain may  
be prevented by bleeding, Opium, hunger, and giving vent to  
its sensations by cries and groans. Of the efficacy of  
hunger in easing pain, Dr Priestley relates the following: In  
travelling through germany, he passed through a village, where a  
criminal was exposed to torture once a week, in order to extor-  
t from him a confession, of his accomplices in his crimes, three days  
before he suffered he avoided tasting any food. The sensation  
of hunger thus induced was so painful, and at the same time  
harmless in its effects upon life, as to be over balanced  
by pain and danger of the tortures inflicted upon him. Unex-  
pected death in the chilly fit of a fever, should be avoided  
by warm drinks; from excessive force of reaction in the blood

*[The page contains several lines of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is too light to transcribe accurately.]*

10  
by bleedings from convulsions, by remedies suited to the stage  
of the disease in which they occur, and from the debility which  
follows a paroxysm of fever by cordial Medicines, drinks and  
aliments. Sudden death in persons pre-disposed to it from apoplexy  
should be obviated by temperance moderate exercise,  
open bowels; not suppressing usual evacuations, nor changing usual  
habits; by occasional bleedings when the premonitory signs of  
apoplexy, and head ach take place; by avoiding tight ligatures  
around the neck, by sleeping with the head a little elevated  
and upon a mattress instead of a feather bed  
and by never sleeping upon the back, but alternately  
upon each side Dr Rush mentions several cases of palsy  
he does Dr Potter in his lectures, a disease produced by a  
more feeble operation of the cause which produces Apoplexy  
Dr Rush mentions that patients sleep upon their left side.  
Sudden extinction of life by the Apoplexy of the lungs  
Dr Rush would call it and considers appropriate and  
genuine, by Dr Potter in his lectures, by poisonous and  
indigestible matters received into the stomach, by worms  
in the alimentary canal; and by Spasm of the heart,  
could be prevented by the usual remedies for that purpose,  
mentioned in the books of medicine.  
Sudden death from cold liquor, taken into the stomach when the  
body is preternaturally heated, has been often prevented  
by plunging or rather conducting off the heat of the body  
by plunging the hands and feet into cold water, or by washing  
the mouth with it, or by grasping the vessel containing  
the liquor, provided it be made of a metal or  
any kind of earth. 12<sup>th</sup> Persons pre-disposed to  
spasms in the stomach or heart, should  
avoid the remote or exciting cause of gout; but  
when attacked by it, should flee to Laudanum, until  
the advice of a physician can be obtained.

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

When danger is apprehended of the Sudden discharge of  
pus from the liver into the thorax or abdomen, it should  
if possible, be diverted externally, by means of a caustic  
Purges which emulge the bile from the liver into the  
Stomach and bowels, would perhaps have the same effect,  
upon its purulous contents, the ducts which lead to the  
duodenum, would <sup>probably</sup> yield to the agitation excited  
by a vomit, sooner than any other part of the  
liver. 14<sup>th</sup> Sudden death from aneurisms has often been  
prevented by a temperate diet, tranquility of body  
and mind, and by small and frequent bleed-  
ings. When Sudden death is apprehended from  
Syncope, great pains should be taken to avoid  
its remote and exciting cause, and to strengthen  
the system by tonic remedies. The sudden extinction  
of life from sudden depletion, or the sudden  
collapse from distention, or cessation of pain,  
should be obviated by vicarious stimuli of other  
kinds: when they cannot be prevented by other  
means. 16<sup>th</sup> When there is reason to apprehend  
a sudden death from suicide, persons suspected of  
it, should be narrowly watched, and all the  
means of death should be removed from their  
lotitude should be prevented, and a cheerful society or  
a cheerful glass, should be advised. The excitement of  
a strong emotion of terror and pity has prevented it,  
in numerous instances. 17<sup>th</sup> In cases of Sudden death from  
many of the causes which have been mentioned, it is  
probable that resuscitation might be effected by the usual  
means, when judiciously applied, In the use of them

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

I shall only deliver the following directions: 1.<sup>st</sup> Begin with such as are of a gentle nature, and gradually resort to such as are more powerful, in all cases where the cessation of the functions of life has been induced by causes which leave the excitability of the system in an accumulated state. 2.<sup>nd</sup> In cases when by great exertions to preserve life, the excitability of the system has been expended, let no stimulus be applied for some time after the cessation of apparent life. By observing this delay, time will be given for the accumulation of some of the fluids remains of excitability in the system. 3.<sup>rd</sup> In addition to the common remedies employed to affect resuscitation, full or loud sounds applied to the ear, are calculated to produce the most salutary effects. Life often lingers longest on the ears, so says Dr. Rush in his lectures on apoplexy. This has been proved by the shrieks of distressed persons sometimes calling their apparently dead friends to life. By availing our selves of this fact, a new and powerful remedy, may be added to those which are now in common use for promoting resuscitation. That the motions of life are destroyed last in the brain (and of course in the vicinity of the ears), I think highly probably from the placid or gloomy countenance which succeeds death. They are probably the effects of the pleasant or painful operations of the mind, which survive the extinction of life in other parts of the body.

In the prosecution of our medical studies, there is no subject which presents itself to our view more interesting, than inflammation, or one for which we as surgeons are more frequently called to treat, therefore a perfect acquaintance becomes necessary.

Inflammation has been divided by surgeons into acute and chronic, simple, or complicated with disease, acute or healthy inflammation has been often termed phlegmon, and is of one kind only - Whilst morbid inflammation is subdivided into many kinds as erysipetatus, scrophulous, venereal &c. &c.

Phlegmon, or healthy inflammation is that which has for its object the restoration of diseased parts - Morbid inflammation is that which has some morbid action added to that of a healthy, such as in Carburcleg &c.

The general characteristics of phlegmonous inflammation are an increased sensibility of the part, pain, preternatural redness, accompanied with tumefaction, and throbbing. The increased redness is supposed to arise from an increased flow of blood through the small arteries of the part, sometimes it may be dependant upon a generation of new vessels, Samuell Cooper says that the swelling is dependant upon a dilatation of the vessels, to a plethoric state of the arterial system & veing to the exclusion of coagulation of lymph into the

The first part of the paper is devoted to a  
discussion of the general principles of  
the theory of the subject. It is shown  
that the theory is based on the  
assumption that the system is in  
equilibrium. The second part of the  
paper is devoted to a discussion of  
the theory of the subject. It is shown  
that the theory is based on the  
assumption that the system is in  
equilibrium. The third part of the  
paper is devoted to a discussion of  
the theory of the subject. It is shown  
that the theory is based on the  
assumption that the system is in  
equilibrium. The fourth part of the  
paper is devoted to a discussion of  
the theory of the subject. It is shown  
that the theory is based on the  
assumption that the system is in  
equilibrium. The fifth part of the  
paper is devoted to a discussion of  
the theory of the subject. It is shown  
that the theory is based on the  
assumption that the system is in  
equilibrium. The sixth part of the  
paper is devoted to a discussion of  
the theory of the subject. It is shown  
that the theory is based on the  
assumption that the system is in  
equilibrium. The seventh part of the  
paper is devoted to a discussion of  
the theory of the subject. It is shown  
that the theory is based on the  
assumption that the system is in  
equilibrium. The eighth part of the  
paper is devoted to a discussion of  
the theory of the subject. It is shown  
that the theory is based on the  
assumption that the system is in  
equilibrium. The ninth part of the  
paper is devoted to a discussion of  
the theory of the subject. It is shown  
that the theory is based on the  
assumption that the system is in  
equilibrium. The tenth part of the  
paper is devoted to a discussion of  
the theory of the subject. It is shown  
that the theory is based on the  
assumption that the system is in  
equilibrium.

interstices of the cellular substance and also to an interruption of the absorption.

With regard to the increased heat this seems to be unimaginable, as the degree of heat scarcely ever surpasses the natural temperature of the body, but we may readily account for this when we remember the extreme sensibility of the nervous system, by which they convey false impressions.

The remote causes of inflammation are numerous consisting in those of a mechanical or chemical nature such as lures, wounds, splinters, acrid substances &c. Inflammation sometime arises as consequent on some febrile disease acting upon the system and when this is the case is called symptomatic. Sometimes it seems to arise without any obvious cause & then it is commonly called spontaneous but improperly, as there can be no effect produced without there be a cause to produce that effect.

The proximate cause of inflammation has been a source of much theoretical speculation, it was supposed by the ancients that it was dependant on some morbid condition of the fluids, whilst the moderns as Cullen and others, that it is dependant on a change of the vessels & not a disease of the fluids, The absurdity of the antients may be clearly seen from a local inflammation, for were it dependant upon a disease of the fluids, we could have no inflammation

tion however slight - without bringing the whole system into a state of disease. It seems more probable to depend upon a disease of the vessels, from the fact that new vessels are sometimes formed, this may be proved by tumours, which may be extirpated without occasioning much hemorrhage, when at the same time were we to cut into the tumour, the hemorrhage would be great. It seems to me that all inflammation must be dependant upon an increased action of the vessels in the part affected, for it cannot be doubted that there is more blood sent to the part when inflamed than when in a state of health, this seems clear from the circumstance, that if we cut into an inflamed part it will bleed much more freely, than when in a natural state, neither can this be done by any increased action of the heart, for the heart sends its blood equally to the whole system, but from this circumstance it will seem, that besides the elasticity peculiar to the arteries, themselves they have also a power of dilating and contracting of themselves, we can scarcely explain on any other principle, the increased flow of blood through the inflamed part.

It has been thought by some that it is dependant upon a spasm of the extreme vessels of the part, but I think that an effusion of lymph besides the increased size of the vessels would be sufficient to overturn an such an idea as this.

The first of these is the fact that the  
 state of affairs is not what it  
 seems to be. The second is the fact  
 that the state of affairs is not what  
 it seems to be. The third is the fact  
 that the state of affairs is not what  
 it seems to be. The fourth is the fact  
 that the state of affairs is not what  
 it seems to be. The fifth is the fact  
 that the state of affairs is not what  
 it seems to be. The sixth is the fact  
 that the state of affairs is not what  
 it seems to be. The seventh is the fact  
 that the state of affairs is not what  
 it seems to be. The eighth is the fact  
 that the state of affairs is not what  
 it seems to be. The ninth is the fact  
 that the state of affairs is not what  
 it seems to be. The tenth is the fact  
 that the state of affairs is not what  
 it seems to be.

A very peculiar circumstance attending phlegmonous inflammation, is that let it be situated, where it may be in what part covered it will always point externally. If inflammation invades the socket of the tooth the abscess will point externally, immediately in the vicinity of the Cheek, than on the inner side of the alveolar process.

Inflammation differs in these varieties, in their progress and their termination, as they differ in their location, position, structure, and functions affected. Parts through which the blood circulates freely can undergo inflammation much better than one situated in a solid condition, except where the part is essential to life, and then though the part may be provided with a great deal of vascularity still it is owing to the uniformity which is required for the support of health dependent upon a sound condition. Having now given the symptoms and causes, or what we think the most reasonable, from some consideration and considerable study, we will next endeavour to give the treatment as recommended by the best modern Surgeons. In the treatment of inflammation the first to be considered is the removal of the remote cause, for if there be a splinter or any foreign substance lodged in the flesh we should first extract that, and then we should have an eye to the proximate cause, it will seem at once from what has been said that

*[The page contains several lines of extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and difficult to decipher.]*

our principal motive must be to remove that cause  
this is to be effected by those remedies which is necessary  
to subdue the increased action of the enlarged  
vessels.

Bleeding

As we have advanced the idea that inflammation  
is dependant upon an increased action of the blood  
vessels in the part affected; it will not be doubted that  
blood letting forms one of the most prominent agents  
in the reduction of this action, this should be  
done either by topical or general bleeding. Topical  
bleeding seems in many cases to be more essenti-  
al than general, when the part affected is local and  
does not bring the system into concern, topical blee-  
ding is more beneficial than general, but when any  
part is affected which is essential to life then we  
should use general and topical both, thus where the  
brain is affected if the inflammation is not speedily sub-  
dued death will be the inevitable consequence, we should  
use general blood letting when the part is not possessed  
with that power of restoration, which is peculiar to the  
muscles, as in tending about the joints, also when sup-  
puration would be the result and that perhaps to the  
destruction of the patient. Ophthalmia is a case of this  
kind although it would not destroy the patients life  
since the organ itself would be destroyed, General blood  
letting should not admitted when the inflammation

*[The page contains extremely faint, illegible handwriting, likely bleed-through from the reverse side of the paper. The text is mirrored and cannot be transcribed.]*

our principal motive must be to remove that cause  
this is to be effected by those remedies which is necessary  
say to subdue the increased action of the enlarged  
vessels.

Bleeding

As we have advanced the idea that inflammation  
is dependant upon an increased action of the blood  
vessels in the part affected; it will not be doubted that  
blood letting forms one of the most prominent agents  
in the reduction of this action, this should be  
done either by topical or general bleeding. Topical  
bleeding seems in many cases to be more essenti-  
al than general, when the part affected is local and  
does not bring the system into concern, topical blee-  
ding is more beneficial than general, but when any  
part is affected which is essential to life then we  
should use general and topical both, thus where the  
brain is affected if the inflammation is not speedily sub-  
dued death will be the inevitable consequence, we should  
use general blood letting when the part is not possessed  
with that power of restoration, which is peculiar to the  
muscles, as in tending about the joints, also when sup-  
puration would be the result and that perhaps to the  
destruction of the patient. Ophthalmia is a case of this  
kind although it would not destroy the patients life  
till the organ it self would be destroyed, General blood  
letting should not admitted when the inflammation

is trivial and excited in an old debilitated Subject  
 When it takes place in a young and plethorick we  
 should use the remedies as early in the disease as  
 possible, when the action runs very high we should  
 always use general bleeding first, to make our  
 topical remedies act the more effectual, we should  
 draw the blood from a large surface, as to the quan-  
 tity of blood to be taken we should be governed  
 entirely by circumstances, the time of the disease  
 when taken and the general excitement in the  
 system, which may always be told by the strength  
 and fulness of the pulse.

### Purging

These form the next grand feature in the catalogue  
 of our remedies for the cure of inflammation, they  
 should be of the saline kind, they not only assist  
 blood letting in diminishing the circulation, but they  
 act by producing a secretion they may be used  
 even when blood letting cannot be admitted, those  
 most commonly used is the Sul<sup>n</sup> of Soda, Sul<sup>n</sup> of  
 magnesia, and the nitrate of potash.

### Antimonialz.

Nauseating doses of antimonialz purgatives are some-  
 times very beneficial they act by removing the oppres-  
 sive dryness of the skin, and from the sympathy which  
 exist through the nervous system diminishes  
 the action of the enflamed vessels, this is accomplished

555

by the norria which is produced occasioning a tempo-  
rary debility and through these the progress of the in-  
flammation is subdued —

### Opium

When there is great-constitutional irritation together  
with great pain opium may be employed, although  
in the most-cases of inflammation opium cannot  
be administered in account of its stimulating &c  
etc.

### Diet

This in the cure of inflammation is very essential. The  
patients should be kept- from all animal food, from  
Fermented & Spiritous liquors, a neglect on the part  
of the Surgeon, to enforce, and the patient- to adhere  
to a strict antiphlogistic regimen, often is the cause  
of the inflammation terminating in that-way which  
brings reproach upon our science and in some  
cases to the destruction of our patients.

### Cold applications

- This remedy has been recommended from the know-  
ledge that heat- or rather apparent heat- has always  
been the concomitants of inflammation, and by  
the abstraction of that-heat- the part affected will be  
restored, this is done by keeping up a constant eva-  
poration on the surface. The remedies which are  
generally employed by Surgeons are of an escharotic  
or searive a nature, such as the acetate of Lead aceto-

set in water. Mr. Cooper recommends the following  
 formula acetate of lead ℥ss vinegar ℥iv distilled water  
 ℔ii, but I am inclined to think that the water & vinegar  
 contain all the virtues, because I cannot perceive what  
 the virtues of the lead can consist - as it cannot have  
 any specific action on the part, but the whole be-  
 nefit must be owing to the evaporation which takes  
 place, as the modus operandi of the lead has not  
 as yet been explained. Doctor Smith, the professor  
 of surgery in this institution has recommended an  
 evaporating ~~water~~ lotion composed of spirit and  
 water both equal parts, which has much the ad-  
 vantage of the lead & water in subduing the inflam-  
 mation, as I have had the opportunity of seeing the  
 wonderful effects during the last winter in a case  
 in our Infirmary of a man who had punctured  
 his foot with a nail, when he was brought into the  
 Infirmary, there was a violent inflammation taken  
 place and in the course of forty eight hours, all the  
 symptoms were almost subdued. Again I have seen  
 the formula which Cooper recommends fail entirely.

Warm application

This has been also recommended but it seems strange  
 that any two remedies so very opposit to each other  
 should be employed in the same case with advantage  
 but as it is experience has shown that it is so, and it  
 is thought by some surgeons that it is dependant

in some peculiar idiosyncrasy of the patients constitution, or some difference in the construction in the part affected, Of the warm application emollient pottices, have been the most frequently employed & the best is that made of Linseed meal and warm water this is made by putting the meal into the water untill they are of a proper consistence to form a pottice and then add a little oil to prevent the pottice from becoming hard

Termination of Inflammation

Inflammation after continuing for sometime, disappears without any apparent cause, or exhibits a disposition to form pus, or runs on to such a high state of inflammation as to terminate at last in the entire death of the part. The first is called resolution, the second is called suppurating, & the third and last is called mortification.

First or Resolution

The most fortunate way in which inflammation terminates is resolution this consists in a spontaneous cessation of all the symptoms, a subsiding of the redness pain Swelling, throbbing & heat of the part

Second or Suppuration

Suppuration is the next most frequent termination of inflammation, this consists in the formation of pus which modifies the symptoms rather than an entire cessation of them

Mortification

561

The worst manner in which inflammation can terminate is in mortification but luckily it is the most rare; this consists in the entire death of the part. I shall conclude with the subject here leaving a particular description of those three varieties alone leaving that they be lay more strictly to Symptomatic fever than to this place.

A Dissertation on Necrosis.

56<sup>5</sup>

The strict interpretation of this term is the death of some portion of the bony structure, but is applied by Surgeons to a disease characterized by peculiar symptoms, a frequent termination of which is the death or exfoliation of a portion of bone.

This disease commences with an acute inflammation of the bone itself or of its periosteum, accompanied with violent pain which is not at first referred to the immediate seat of the attack but to the nearest joint, it however locates itself finally on the part inflamed; The symptomatic fever which generally occurs at the same time with the pain, is of a highly inflammatory character. The termination of the local affection, is most frequently in suppura-

1. The first part of the paper is devoted to a general consideration of the subject.

The first part of the paper is devoted to a general consideration of the subject. It is a paper of a general nature, and is intended to give a general idea of the subject. The paper is divided into two parts. The first part is devoted to a general consideration of the subject, and the second part is devoted to a more detailed consideration of the subject. The paper is written in a clear and concise style, and is intended to be read by a general audience. The paper is a valuable contribution to the literature on the subject, and is well worth a read.

tion, the matter is deposited between the external periosteum and the bone, If the disease be located in the shafts of the long bones, at the same time, that the matter forms beneath the external periosteum, there is a corresponding collection between the internal lining and the bone, This circumstance has been repeatedly ascertained by the use of the trophine.

Shortly after the attack the Limb becomes swollen which is uniform until the matter escapes from beneath the periosteum, when the swelling is now circumscribed and confined to the immediate seat of inflammation. At this period there is a subsidence of the sword pain & fever in some degree, but they do not leave the patient entirely, The death of the bone in this disease

is not attributable to any peculiar <sup>3</sup>pecu-  
liarity of the inflammation, but to the ves-  
sels which give nourishment to it, being  
destroyed by the intervention of matter be-  
tween it & its periosteum.

When the matter contained beneath the pe-  
riosteum, has made its way to the surface  
and that within the cavity of the bone, has  
escaped through fissures in the same, re-  
lieving the parts from irritation and pres-  
sure the symptomatic fever in a great de-  
gree subsides, if however the collection be  
considerable and the destruction of bone  
extensive, hectic fever supervenes, show-  
ing a continuation of irritation tho' chan-  
ged, as to its character.

The process instituted for the purpose of re-  
moving the dead bone, depends upon the

571<sup>4</sup>

extent of injury, for instance if merely a small portion, situated on the shaft of a long bone be necrosed, granulations will shoot from the sound and living bone, and as occurs in the mortification of the soft parts separate the dead from the living portion, and finally urge it through the opening previously formed, and disengage it from the body, this is more likely to happen when the soft parts have been fully divided at the beginning of the disease.

When the whole circumference is destroyed it is covered by an osseous structure which envelops the sequestrum and is attached to the sound & living portions not however embracing it closely, and thus giving the limb an enlarged appearance,

5

Necrosis is almost exclusively confined <sup>573</sup> to  
to young persons seldom or never occurring  
under five or over twenty two.

No bone in the human system is exempt  
from this disease, long bones however are  
more liable, to its attacks, and of these the  
Femur most particularly, the articulations  
are never assailed by this kind of inflamma-  
tion in the first instance, sometimes however  
the joints are secondarily affected from  
the disease being communicated to them  
along the shaft of the long bone, where  
it first existed.

The line of separation is after a accuracy  
defined by the junction of the shaft &  
epiphysis of the bone, the articular portion  
remaining uninjured, it sometimes hap-  
pens however that the disease reaches the  
joint and matter is formed when it  
becomes necessary to amputate the limb to

575  
saw the lips of the patient,  
Necrosis is not always confined to one  
bone, it may occur simultaneously in re-  
-mote parts or successively which is now com-  
-mon, In regard to general prognosis a  
very great majority of patients survive the  
attack after long confinement and pro-  
-tracted suffering, it sometimes proved  
fatal but generally early in the attack  
from the high degree of symptomatic fe-  
-ver and constitutional irritation.

Diagnostic Symptoms according to Dr Smith.  
"The pain" As the disease says this gentleman is  
an acute inflammation characterized by the  
peculiar vital properties of the parts affected  
many of the symptoms must be analogous to  
those of other inflammatory affections, he has  
often known it to be mistaken and for a con-  
-siderable time treated <sup>for</sup> acute Rheumatism, even

alths: suppuration may have been observed, 51  
It frequently happens that when the disease fix-  
es on one of the long bones and near its ex-  
-tremity the pain is complained of in the ad-  
-jacent joint, it is not long however ere joined  
to the joint, but fixes itself in the inflamed  
part, This circumstance of pain referred  
to the joint has often caused ~~the~~ disease  
to be denominated Rheumatism,

The pain experienced in Necrosis is extrem-  
-ly acute, unremitting, and not much in-  
-fluenced by the motions nor position of the  
limb, The pain is often antecedent to the  
swelling, and when the latter first occurs  
it is generally diffused over a considerable  
part of the limb, especially below the part  
affected, The surface is rather firm to the  
touch but the skin is not discoloured till  
after matter is formed and advanced tow-

across the surface,

57a

The symptomatic fever is cerebral with the pain both usually occurring on the same day, the pulse both frequent and quick the stroke sudden and artery small and hard to the touch, At first the patient has occasional chills but when he complains of a sensation of cold the skin to another person feels hot. The pain is so violent that he gets little or no sleep, during the night he is often delirious, The tongue is furrowed with a soft white coat, the face is not flushed but rather pale with the exception of occasional red spots on the cheeks, The appetite for food is lost the throat considerable the stomach and bowels are not so much affected as in other febrile diseases.

It has been before observed that the appearance of the pain in the early stage of the disease.

Faint, illegible handwriting, possibly bleed-through from the reverse side of the page. The text is mirrored and difficult to decipher due to fading and staining.

Has caused necrosis to be sometimes confound-  
-ed with Rheumatism, Most, even of its early  
symptoms however are very different from those  
of that disease, the symptomatic fever and  
constitutional irritation come on sooner after  
the local attack and are much more re-  
-solved, the pulse smaller, harder, and much  
more easily compressed, and finally sup-  
-puration occurring removes all ambiguity,  
Necrosis moreover usually attacks, at that  
period of life, when rheumatism is not li-  
-able to occur, It is distinguishable from  
Typhus by the local affection, by the pulse  
which is harder and less easily compressed  
and by its not being attended with so  
much stupor.

Causes. The inflammation which produces  
necrosis is often excited by blows and injuries  
inflicted upon the limbs, sudden suppression of

*[Faint, illegible handwriting throughout the page, likely bleed-through from the reverse side.]*

perspiration, and emission in cool water <sup>53</sup> when  
the body is warm, it however often attacks with-  
out any obvious exciting cause, by which the  
diathesis is developed or concentrated upon  
a particular part.

Treatment. In the treatment of this disease  
the first step, as in all other inflammatory  
diseases should be to effect a resolution,  
The remedies however, which are most gene-  
rally employed as Venesection, cathartics  
emetics blisters, evaporating lotions, cataplas-  
ms, &c, have rarely succeeded in preven-  
ting suppuration. The most efficient reme-  
dies as directed and practiced by  
Professor Smith, of N. Haven is a free in-  
cision of the soft <sup>parts</sup> and periosteum down  
to the bone through the whole extent of the  
inflammation, thus reducing the disease  
to a simple incised wound, which is the

Faint, illegible handwriting on aged, stained paper. The text is mirrored across the page, suggesting bleed-through from the reverse side. The paper shows significant water damage and discoloration.

to be treated accordingly.

In the second stage of the disease when matter has formed beneath the periosteum the cure may still be effected without the loss of bone. In this stage of the disease an incision should be made thro' the soft parts as before directed and the periosteum divided as far as its separation from the bone, and a portion of the bone be cut out or perforated in the denuded part down to the medullary substance, that the matter collected between that substance and the bone, may escape and thus the death of the bone prevented. The best instrument for perforating the bone is a small trephine. In the third stage when the matter has made its escape through the periosteum and obtained a lodgment in the soft parts, the treatment is precisely the same

The text on this page is extremely faint and illegible due to significant water damage and fading. The visible fragments of text appear to be bleed-through from the reverse side of the page, but no specific words or phrases can be accurately transcribed.

as in the second stage, but the favourable <sup>58</sup> result is by no means so certain, as the circulation in it, (may have been too long destroyed, or the separation of the dead and living bone commenced). Nevertheless however as in the former case the incision in the soft parts should be made, taking care, to avoid important parts, such as tendons, nerves, and bloodvessels, this will not only give passage to the matter contained within, but facilitate the expulsion of the bone, if its destruction should have been extensive.

The general treatment consists in cooling purgatives & nauseating doses of Antimony & opium sufficient to allay irritation and procure rest.
