The fresh urine of bonnet monkeys successfully inoculated with human typhus blood contained, we found, during the period of fever, great numbers of the small and large cocco-bacillary forms, and the filtrate of this urine, when fresh, also contained the smaller forms alone. If, however, incubation were allowed for a few hours, they could no longer be found, their place being again taken by the large non-pathogenic forms.

By inoculation of human blood-agar with the fresh filtrate of fresh human typhus urine we have been able to obtain cultures of the small cocco-bacillus in which the small size is retained. On subculture, however, it tends to become mixed with larger forms. Injections of the first culture on human blood-agar into two bonnet monkeys gave rise to a high continued fever after the lapse of a definite incubation period of a few days.

We then turned once more to examination of the fresh blood of typhus patients, and found that after dissolving the centrifuged red cells in bacterium-free distilled water we could sometimes demonstrate the small cocco-bacillus. And, as in the case of the urine, it rapidly disappeared when the citrated blood was incubated, or when artificial media were inoculated with it, its place being taken by the larger cocco-bacillary forms. In cerebro-spinal fluid, as in urine and blood, it soon disappeared after incubation, and in its place were seen great numbers of the large forms, which also proved on injection into bonnet monkeys to be inert.

From fresh human typhus blood, and from fresh cerebro-spinal fluid, we have been able to cultivate the small cocco-bacillus on human blood agar, as in the case of fresh urine. On injection of the blood and cerebro-spinal cultures on blood-agar the procedure has in bonnet monkeys been followed by high fever after a well-marked latent period.

We are fully aware that the pleomorphism of the filter-passing infective cocco-bacillus, as well as its apparent mutation into large cocco-bacillary forms which are non-infective, is not an easy matter to prove.

The object of this communication, however, is not to lay claim to the discovery of the causal organism of typhus fever, but to show that for both diagnosis and treatment haemic infections of the urine are well worth study in every case in which continued fever occurs.

ANEURYSM OF THE AORTA DUE TO BACTERIAL INFECTION.

By J. M. Morgan and John H. Teacher.

(*Abridged.*)

The authors gave a demonstration of specimens, with brief clinical and pathological notes, from the Glasgow Royal Infirmary. The cases were of interest from their bearing on the causation and mode of origin of aneurysm of the first part of the aorta. In all there was an acute ulcerative endocarditis, which produced infection of the aorta followed by rupture (which in one case caused sudden death by bleeding into the pericardial sac), and in all there was evidence of endocarditis prior to the attack, which proved fatal. Two of the subjects were under 20 years of age.

It was assumed that the disease was of bacterial origin, the cases being characteristic ulcerative endocarditis, although this was determined by bacteriological examination only in one of them. Syphilis appeared to be excluded in all cases. Appearances indicative of repair of the ruptured aorta were present in two cases, and in one of these the aneurysm was old, the lips of the orifice being rounded and the sac thin-walled and smooth, so that it presented the usual characteristics of an aneurysm at the root of the aorta.

Cases.

Case I.—*Ulcerative Endocarditis of the Aortic Valve, Old and Recent: Old Aneurysm of the First Part of the Aorta* (Path. Reports, 5780, Dr. J. M. Cowan, 1911).

J. B., message boy, aged 14, ulcerative endocarditis, lasting twelve weeks. Four days before death right-sided hemiplegia developed and embolism in the spleen and left femoral artery.

The endocarditis affected the aortic and mitral valves. The aortic cusps were thickened and deformed by old endocarditis, and were also the seat of recent ulcerative endocarditis with large vegetations. Above the anterior cusp there was the orifice of an aneurysm about half an inch wide, square in shape, with a laceration at each of the upper corners, and smooth rounded lips. Its lower border was close to the orifice of the right coronary artery. Externally it appeared as a smooth rounded sac lying between the tip of the right auricular appendix and the pulmonary artery. Its lining membrane was smooth like the internal surface of the aorta, and it was clearly an old condition due to an earlier attack of endocarditis. The thoracic aorta was otherwise healthy.

The left common iliac artery was dilated into a fusiform swelling about the size of a plum, containing pus and a large infected embolus.

Case II.—*Ulcerative Endocarditis with Aneurysms of the Aorta which had apparently originated by Rupture of Infected Aortic Wall* (Path. Reports, 6878, Professor Hunter, 1911).

G. C., moulder, age 24. History of cardiac disease two years, and subacute nephritis about one year, previously. In the fatal illness, which lasted two months, the symptoms were those of mitral and aortic valvular disease, nephritis, and anaemia.

The heart was found firmly contracted. The left ventricle was greatly hypertrophied and showed some patchy fibrosis. The finger could not be passed into the aortic orifice, which was therefore carefully dissected open. It was almost completely blocked by a mass of vegetations, which seemed to be principally old, being calcified. The cusps were extremely deformed and adherent to one another. About a quarter of an inch beyond the valves there were two little deep pockets—small aneurysms of the aorta—with squarely cut mouths the edges of which were smooth and rounded. They probably represented old ruptures of the internal and middle coats. About one inch above the valve there was an aneurysm the size of a walnut filled with massive vegetations. To the right of the aneurysm there was a recent rupture of the internal and middle coats of the aorta with clean-cut edges, and, between them, a triangular area with soft yielding floor composed of the external coat and fibrous adhesions. The aneurysm lay in the upper part of the pericardial sac between the aorta and the right auricle. There was also a small aneurysm rising by a narrow slit-like orifice between the left carotid and subclavian arteries. There was nothing of special interest in the other organs.

Sections of the margin of the aneurysm showed a ragged edge indicative of rupture, and, at one point, an acute suppurative focus. In the vegetations near this there were numbers of beaded bacilli, mostly in colonies. They resembled the *Bacillus diphtheriae*, but lost Gram's stain somewhat readily. No cultures.

Case III.—*Ulcerative Endocarditis: Rupture of Aortic Cusps: Aneurysm of Sinus of Valsalva burrowing into Wall of Left Ventricle* (Path. Reports, 7217, Professor Hunter, 1912).

Mrs. L., aged 36. The principal features of the illness, which lasted only five weeks, were irregular fever (Widal's reaction and blood cultures negative) and symptoms of cardiac valvular disease.

The heart was slightly above the normal size. The aortic valve was incompetent, and there was fatty mottling of the inner layers of the myocardium. Vegetations covered the adjacent parts of the anterior and left posterior cusps of the aortic valve, which were both perforated, the floor of the left posterior sinus of Valsalva, and an area of ventricular wall below it. A mass like an aneurysm could be felt burrowing forwards between the pulmonary artery and the right auricular appendage.

After hardening, incisions were made in the longitudinal axis of the heart. These showed a small aneurysm burrowing into the upper part of the interventricular septum and anterior wall of the left ventricle, and a large mass of red and white thrombus extending into the adipose tissue above the right ventricle. These appeared to interfere with the left coronary artery, but not with the auriculo-ventricular bundle.

Case IV.—*Ulcerative Endocarditis of the Aortic Valve extending to the Aorta: Rupture of the Aorta and Formation of a Small Aneurysm at the Insertion of the Aortic Valves* (Path. Reports, 7368, Dr. Cowan, 1913).

C. T., a man aged 36. The illness lasted twenty-three days. It commenced as pneumonia and developed into aortic valvular disease, pericarditis, and, finally, meningitis.

Post mortem, the right lung showed pneumonia in different stages in the upper and lower lobes, abscesses in the upper part of the latter and a collection of pus containing pneumococci on the front of the pericardium and pericarditis. There was ulcerative endocarditis of the aortic valve limited to the adjacent portions of the anterior and left posterior cusps. The insertion of these and a portion of the inner and middle coats of the aorta above it had been torn out leaving a gap about ½ in. in length by ¼ in. in width which led into a small aneurysm lying between the aorta and the pulmonary artery.

Case V.—*Ulcerative Endocarditis of the Aortic Valve extending to the Aorta: Rupture of the Aorta into the Pericardium* (Path. Reports, 7491, Professor Hunter, 1913).

N. McI., a girl of 17 years, had been seriously ill from cardiac valvular disease for about four months and died suddenly.

The pericardial sac contained 5 or 6 oz. of recent blood clot, and there was pericarditis several days old. The aortic orifice was obstructed by soft vegetations with a firmer basis about the cusps, which were greatly deformed and thickened from old endocarditis. The anterior wall of the aorta for some distance above the remains of the valve was covered with vegetations and a perforation into the pericardial sac had taken place among them.

According to Osler (Clifford Allbutt's *System of Medicine*, vol. vi, p. 642), aneurysm of a sinus of Valsalva or the immediate neighbourhood in the aorta is most frequently met with in acute syphilitic aortitis. For statistical purposes the cases of aortic aneurysm and syphilis of the aorta recorded in one thousand successive *post-mortem* examinations at the Glasgow Royal Infirmary including the present series were counted, with the following result:

Aortic syphilis without aneurysm ...	37	cases.
Aneurysms due to syphilis	21	,,
Infective aneurysms	5	,,
Dissecting aneurysms	2	,,

Three out of the 21 aneurysms due to syphilis were aneurysms of a sinus of Valsalva.

In conclusion, the 5 cases which we have shown may represent a run of comparative rarities; but they demonstrate the fact that aneurysm in the region of the sinuses of Valsalva may be infective and non-syphilitic in origin, a point which might be of considerable medico-legal importance.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

ANAESTHETICS IN EYE-WORK.

IN the JOURNAL of September 12th Mr. Whiting criticizes the view that chloroform should be banished from eye-work, and that ether should be the chosen anaesthetic. He states that the Moorfields figures show that chloroform may be administered *with a reasonable degree of safety*. Is the patient to be satisfied with a reasonable degree of safety when under ether he can have practically absolute freedom from danger? For a period of more than twenty years ether has been the usual anaesthetic at the British Ophthalmic Hospital in Jerusalem, and it has been administered without a single death. Personally, I gave it there over a thousand times without ever experiencing a moment's anxiety for my patient. During the past eight years I have under ether done every variety of eye operation, including extraction of cataract, at the Birmingham Eye Hospital, the Coventry General Hospital, and the Leamington General Hospital. I have never been in any degree incommoded by the anaesthetic machinery, nor have I experienced any anxiety for the safety of my patient. During this time there have been deaths from chloroform in these hospitals. An old man died under this anaesthetic, which was given him for the enucleation of his eye. Chloroform was administered to a healthy young girl for teeth extraction. She died suddenly during the period of induction. We have had other cases. Levy[1] notes that every three days two harmless and probably useful citizens die from chloroform in England and Wales alone, and he indicates the cause of death—ventricular fibrillation.

Mr. Whiting states that three conditions which are essential in eye surgery are not satisfied by ether anaesthesia. Firstly, he says, "anaesthesia must be deeper than in most general operations, because the corneal reflex must be abolished." I entirely disagree with him. If a little cocaine be instilled, very light anaesthesia is often sufficient. For a glaucoma iridectomy, for example, the operation can be completed under gas and ether given in a Clover's inhaler almost before the effect of the gas has passed off. An excision of the eye necessitates very superficial anaesthesia if cocaine be employed as well. Enucleation is a ghastly operation to perform under local anaesthesia, even if it can be done with the minimum of pain. I have upon one occasion extracted a cataract under ether. The patient had no self-control, and a general anaesthesia was essential. Here deep anaesthesia is necessary, and a good anaesthetist should be employed. I had no difficulties from either the anaesthetic or the apparatus.

Mr. Whiting goes on to say, "the surgeon must have as much as possible of the patient's face clear of the anaesthetist's hands and apparatus."

I disagree with the expression "must." A good operator and a good anaesthetist can tacitly accommodate each other in this respect. An eye operation is often a matter of seconds; the anaesthetist withdraws his apparatus while it is performed. A squint operation can easily be done in the presence of a Clover's inhaler, and in a lid operation the apparatus is not noticed by an experienced surgeon.

Finally, Mr. Whiting states that "coughing, vomiting, or straining of any kind must not occur." My experience is that these undesirable events are quite infrequent with good gas and ether anaesthesia; chloroform has no advantage here. I find that I have generally finished an operation long before a patient could be anaesthetized with chloroform; gas and ether is far quicker.

I fully agree with all your correspondents that the "corneal reflex test" should never be used. It is the hall-mark of an incompetent anaesthetist.

Birmingham. T. HARRISON BUTLER.

[1] BRITISH MEDICAL JOURNAL, September 19th, 1914.

THE TREATMENT OF ACUTE GONORRHOEA.

THE treatment recommended in the BRITISH MEDICAL JOURNAL of September 26th demands some criticism. It may be the best in the hands of the expert who advises it, but is scarcely the one to be recommended to the practitioner. To quickly "balloon" out an acutely inflamed urethra by a hydrostatic pressure of 6 feet, through a bore of 8 or 9 mm., so that the fluid "spurts out with great force," requires more consideration than the article gives us. How can a quick filling and emptying of the urethra facilitate more than a graduated and sustained means the entry of fluid into ducts and lacunae? Or on what principles is a single bore nozzle superior to a double in ensuring the circulation of fluid in the urethral bulb?

I used the hydrostatic plan for very many years, but gave it up, as experience taught me that gentleness should be the first law in urethral surgery. I now use with greater benefit a means by which I can measure the pressure used,[1] or an ordinary Higginson's syringe. Full distension of the urethra is required, but it should, I think, be gradual and sustained, so that the fluid has a chance of being forced into the tissues, and herein lies the chief secret of the so-called "irrigation" treatment. This irrigation can act with vigour *a fronte*, but can the *vis a tergo* (if we may so speak) of the anterior urethra be anything save negligible? Can it even equal the urine stream? Of course not.

Whoever will use in lieu of the irrigation apparatus an ordinary Higginson's syringe will not regret it. With it any force, from the mildest to the greatest, any rapidity of current from the slowest to the quickest, can be used. His hand, grasping the rubber bulb, will intelligently measure the urethral resistance; it will often feel this resistance expressed in the clonic contraction of the urethral muscles. And such a means is simple and always at readiness.

I have lately adapted Messrs. Ingram and Son's "bonda" Higginson's syringe (illustrated in the *Medical Annual, 1894*) for urethral use. By it suction as well as flushing can be carried out. It affords, I think, the ideal means of treating acute urethritis.

London, N.W. JAMES MACMUNN.

Reports of Societies.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

AT the opening meeting of the Society of Tropical Medicine and Hygiene for the new session—1914 to 1915—which took place on October 16th, an important paper was read by Sir DAVID BRUCE, C.B., F.R.S., upon *Classification of the African trypanosomes pathogenic to man and domestic animals*. Dr. F. M. SANDWITH, Vice-President, took the chair, in place of the President, Sir R. Havelock

Charles. There was a good attendance of Fellows, and a lively discussion took place, indicating a considerable amount of difference of opinion as to the method of classification and nomenclature of African trypanosomes. The following took part in the discussion: Professor J. W. W. Stephens, Dr. H. B. Fantham, Miss Muriel Robertson, Dr. Warrington Yorke, Dr. C. M. Wenyon, Dr. Andrew Balfour, Dr. G. C. Low, and Sir Ronald Ross, Sir David Bruce replying. Reference was made to the loss the society had sustained by the death of Captain Henry Sherwood Ranken from the effects of wounds received when attending the wounded in France. A vote of appreciation was passed not only of the valuable work which he had done in connexion with sleeping sickness but also of the gallantry he had shown in the discharge of his duties in the firing line. At the council meeting of the society, which took place previous to the ordinary meeting, it was unanimously agreed to continue the meetings of the society as usual, but to give special attention to practical questions which might have a bearing upon prevention and treatment of diseases which might develop in connexion with the war. Sir William Osler has kindly consented to open a discussion upon "Enteric in war, with means of its prevention" on November 20th, at 8.30 p.m. Visitors will be heartily welcome at this meeting.

Reviews.

SURGERY OF THE VASCULAR SYSTEM.

To those who are interested in blood-vessel surgery, whether operating surgeons or practitioners desirous of keeping their minds alive to surgical progress and achievements, we most heartily commend Dr. Bernheim's monograph on the *Surgery of the Vascular System*.[1] It is a short but complete and eminently readable statement of the present position of this branch of surgery, and its value is greatly increased by the most beautiful illustrations it is possible to produce.

We have in former issues indicated the main features of the subject in considering the work of Carrel, Guthrie, and Jeger. The technique of blood-vessel work is now practically standardized, but there are some points emphasized by Dr. Bernheim which seem to make for greater efficiency. He firmly discountenances the undertaking of blood-vessel surgery by those who have had no opportunity of laboratory training, and believes that many failures have resulted through disregard of this injunction, as well as from indiscreet choice of cases. It can hardly be otherwise when one considers that the suturing needle is 1 in. long and extremely delicate, while the silk thread may not be thicker than a human hair.

The author points out that of the three coats of a blood vessel the adventitia is the most important to the surgeon doing vascular work; its mobility or flaccidity tends to formation of clot by slipping into the needle hole, and by acting as a fringe over the opening of the vessel. When a vessel is about to be sutured, all blood is washed away with saline solution and the whole of the parts bathed with liquid vaseline, "a neutral lubricant that keeps the tissues soft and pliable, and is tolerated by the tissues in almost any quantity." The most delicate handling with small ball-pointed instruments is essential for success.

In the chapter on direct blood transfusion the various apparatus, including the author's recently invented, are figured, and the operation is described in detail. There seems still to be a difficulty in estimating the amount of blood which has gone or is going over, the only means available being so far clinical observations on both donor and recipient. Dr. Bernheim holds that "the danger of haemolysis following transfusion has always been vastly overrated and unwarrantably feared," though on theoretical grounds he believes it proper to have haemolytic tests made if the patient's condition permits it.

End-to-end suture of blood vessels is the most difficult of all the operations, and the author has many hints to offer for its successful accomplishment. Lateral anastomosis is easier and there are many occasions for its employment. For instance, the operation of reversal of the circulation of a limb is better done by lateral anastomosis between vein and artery and proximal ligation of the vein than by the end-to-end method. A wonderful success in a severe case of Raynaud's disease affecting all four limbs with actual and threatened gangrene and excruciating pain is recorded by reversal of circulation in each limb. The full details given assists the reader's belief—the author's is well-established—in the great future opening up for vascular surgery.

The chapters on the treatment of aneurysm will well repay study. The author is not bound to any one method, and his statement on this important branch of practical surgery is characterized by perfect open-mindedness. There seems to be only one regrettable omission, and that is any reference to Colt's wire-cartridge method found successful in this country in several instances.

[1] *Surgery of the Vascular System.* By B. M. Bernheim, A.B., M.D. Philadelphia and London: J. B. Lippincott Co. 1913. (Med. 8vo, pp. 116; 53 figures. 12s. 6d. net.)

FLIES AND DISEASE.

(*Non-bloodsucking Flies.*)

Last February we spoke highly of *Flies in Relation to Disease* (*Non-bloodsucking Flies*)[2] on its first appearance, but we are not quite sure how far the syndics of the Pitt Press are justified in describing the new issue of Dr. Graham-Smith's admirable work as a "second edition." It is in truth a reprint of the first edition, with an extensive appendix of nearly 90 pages. The new matter is arranged in the same sequence as the old and careful back references are given, but, at the same time, this method of publishing a "second edition" leads, as the Scotsman said when devouring a sheep's head, "to very confused feeding."

The appendix contains some very interesting remarks on the varying sizes of flies, which differ quite as much amongst each other as do the members of the human race. The size of the adult is, of course, a factor of larval growth, as neither the pupa nor the imago ever increase in magnitude and it apparently depends on the quality and the quantity of the food, though temperature probably plays some part.

A brief reference is also made in the appendix to the house-fly's preference for certain colours. Fé has recorded that they dislike rooms lined with blue, but Dr. Graham-Smith doubts this. The reviewer has often heard it said that flies are very rare in rooms which have green walls. The whole matter requires further investigation. Mosquitos undoubtedly show a good deal of colour preference; as Professor Nuttall and Dr. Shipley's experiments showed, the favourite colour of *Anopheles* is navy blue, and the one which attracts the genus least is khaki colour—a fact which is corroborated by the well-known immunity of the "yellow dog" from gnat bites and the trouble which these insects inflict on the Newfoundland dog.

It is satisfactory to find that after the most careful investigations Dr. Graham-Smith "now puts forward with some hesitation the suggestion that the annual diarrhœa epidemic in large cities is correlated in its time incidence, dimensions, and severity with the weather conditions which influence the emergence, activities, and numbers of flies." This, of course, is no new view, but it is satisfactory to have it confirmed by so accurate and careful an observer as Dr. Graham-Smith.

RACE REGENERATION.

Towards the elucidation of the problem of race regeneration, which so urgently presses for solution at the present day, Messrs. Cassell and Co. have contributed a series of Race and Sex Booklets,[3] in which questions related to the

[3] Race and Sex Booklets. London: Cassell and Co. (6d. each net.) *Education and Race Regeneration*, by the Right Hon. Sir John Eldon Gorst; *Religion and Race Regeneration*, by the Rev. F. B. Meyer, B.A.; *National Ideals and Race Regeneration*, by the Rev. R. F. Horton, M.A., D.D.; *The Methods of Race Regeneration*, by C. W. Saleeby, M.D., F.R.S.Edin.; *Womanhood and Race Regeneration*, by Mary Scharlieb, M.D., M.S.; *Problems of Sex*, by Professor J. A. Thomson and Professor Patrick Geddes; *Morals and Brain*, by Sir Thomas Clouston, M.D., LL.D.; *Literature—the Word of Life or of Death*, by Canon Barry, D.D.

subject are dealt with by various writers. In the general introduction, Mr. James Marchant says the booklets might be called New Tracts for New Times, "since they interpret the signs and prophecies of a new world in the making, demanding the application of loftier ideals, more widely embracing principles and surer methods of advance than have hitherto prevailed." Sir John Gorst discusses in a broad and sympathetic spirit the bringing up of children for parenthood. He pleads strongly for general education as a necessary factor in the regeneration of the race, but he urges that the Home Office, the Local Government Board, and the Board of Education themselves stand in need of education. This means the education of the permanent officials, the Minister being in general little more than a figurehead. It is suggested that these officials being mostly men of university training know little except artificially of the needs and aspirations of the poor, and therefore afford only a barren soil for the growth of novel schemes. Sir John Gorst holds that the Board of Education in particular suffers from the want of the co-operation of women. The apathy of education authorities in rural districts and small towns, and the way in which they subordinate everything to keeping down the rates, is severely criticized. He despairs of making the powers of local authorities compulsory, and concludes that there is "no hope for the reformer of national education except to await the slow rising of the light of truth, which will at last illuminate even provincial minds."

The gist of the Rev. F. B. Meyer's booklet is contained in the sentence: "Social reformers may deal with method, science may discuss the laws of blending and growth, educationists may train the young, and moralists urge our nature to self-discipline and self-control, but only religion can comprehend them all, co-ordinate them with each other and supply the breath of life." With a loftier conception of wedlock he looks forward to the coming back of a statelier Eden to man.

The Rev. Dr. Horton's national ideal is "an educated community—not a herd of clerks in black coats, of professional men treading each other down in their effort to grasp the spoils of their particular careers, of a *jeunesse dorée* trained to enjoy itself and to claim by right all the fields of human delight; but—a varied population in which each one is developed and trained to the utmost for the task assigned by faculty or opportunity, task of the hand, of the brain, or of the spirit." The educational ideal should include both moral and spiritual culture.

Dr. Saleeby regards "what may be called Education for Parenthood as the principal positive method of race regeneration." This must be carefully adapted to the special conditions and circumstances of boys and girls respectively and reinforced at every point by the religious sanction. The fundamental problems of eugenics are briefly but sufficiently discussed.

Mrs. Scharlieb is eminently sensible in what she says about the training of women, woman's influence on the race and women as citizens. She deplores the fact that a wave of irreligion has passed over the land and concludes with the following warning: "The regeneration of the race will never be accomplished until the women of the country, themselves deeply convinced of the importance of right belief and right practice, devote themselves to teaching their faith to their children, and to requiring it in a practical form from the members of their household." We commend Mrs. Scharlieb's booklet, which is charmingly written, to the attention of all women and all fathers of families.

Professors J. Arthur Thomson, of Aberdeen, and Patrick Geddes, of St. Andrews, in their little book deal with the problems of sex in a manner at once scientific and suitable for the education of the people. There is no trace of the apparent relish for the stirring up of foul waters in which Zola confessed that he found such pleasure—that feeling called by theologians *morosa delectatio*—which makes many so-called "scientific" treatises on these subjects disgusting even to the average sensual man.

Sir Thomas Clouston gives an interesting account of the development of sex, brain and morals, and discusses the means of bringing about "a clean, sweet and safe society." Speaking of social reform, he expresses the optimistic opinion that nearly all legislation directed to that end has been followed by good results to society and humanity.

Canon Barry's tract is a fulmination against indecency in literature. He is particularly severe on "women who write, prompted by anarchist impulses, against the divine order of things, against law, against the virtues, on which home is built up," and whose style knows neither modesty nor reticence any more than if they had been taught the language of Messalina! To medical readers the Canon's homily would be more impressive if he did not appear to rank the late Dr. Forbes Winslow with Johnson and Coleridge.

NOTES ON BOOKS.

THE Encyclopaedia Britannica Company is, with the permission of the Cambridge University Press, reprinting in five volumes the historical articles published in the eleventh edition of the *Encyclopaedia Britannica* on France, Germany, Austria-Hungary and Poland, Russia and the Balkan States, and Belgium, Italy and Switzerland. Three volumes have already been published: that on France by M. Paul Wiriath, Director of the École Supérieure, Paris, and Mr. J. E. C. Bodley; that on Germany by Professor W. A. Phillips of Dublin, Mr. J. W. Headlam and Mr. A. W. Holland; and that on Belgium, Italy, and Switzerland by the Rev. G. Edmundson, Mr. H. Wickham Steed, formerly correspondent of the *Times* in Rome, and the Rev. W. A. B. Coolidge. As the publishers observe, the true significance of the present war cannot be grasped, nor can any wise settlement for the future be formulated, without a knowledge of those past events and conditions of which the war is an outcome. The volumes already published will, we believe, have a ready welcome from readers in this country, and their price puts them within the reach of all.[1] The volumes contain a few illustrations, chiefly portraits of persons celebrated in the history of the several countries. A sixth volume will deal with the wars of the nineteenth century from the French Revolution to the Balkan war.

MEDICAL AND SURGICAL APPLIANCES.

A Modified Tonsillectome.

MR. K. G. HEARNE, M.B. (late House-Surgeon, Salisbury Infirmary), writes: The accompanying illustration shows a modified tonsillectome designed for the enucleation of tonsils by Sluder's method. The principle involved is that of the blunt dissection of the tonsil from its bed by a movable blade, which is about one-sixteenth of an inch thick at its tonsillar end, but ground off so as to form one of two scissors blades. At the stage where the blade is driven almost completely home, and the tonsil is bulging on the far side of the ring, the final division of the mucous membrane and strands of fibrous tissue that bind the deep surface of the tonsil to its bed is completed by the meeting of the scissors edge of the movable blade with that of a fixed blade contained in the ring of the instrument, through which the tonsil has been squeezed. By this means the advantages of blunt dissection are preserved, yet cutting blades are provided at the moment they are required, and the tonsil comes away at once in the instrument without any twisting and pulling. The haemorrhage is only slight; this is probably explained by the fact that as the vessels are first stretched, and then cut across by scissors blades, their lumens occluded much in the same way that the bore of a rubber drainage tube is closed by cutting it with a pair of scissors. The blade portion comes apart readily into three pieces—the blade itself, the bed in which it travels, and the spring which controls the blade, holds the tonsil after removal, and locks the parts together. It is thus easily cleaned and sterilized. This instrument, which I have used in a large number of cases with perfectly satisfactory results, can be fitted with a handle giving either the Heath or the Mackenzie position. It has been made for me by Messrs. Mayer and Meltzer.

THE BRITISH PHARMACOPOEIA, 1914.

(Continued from page 673.)

Alterations in Composition and Strength.

The number of drugs and preparations the composition or strength of which has been changed in the new *Pharmacopoeia* is much more considerable than the number of additions. Neglecting for the present minor alterations, changes in composition have been made in fifty cases, and in strength in forty-one. In addition, the names of about forty have been altered to a greater or less extent; these three groups overlap somewhat, several preparations being altered in more than one respect. Naturally, not all the alterations are of equal importance, but a good many of them call for mention in detail. In the following notes the more important changes are dealt with first, and the order is therefore only partly alphabetical.

Belladonnae Folia.—The official drug is now the dried leaves, instead of the fresh leaves and branches. An assay process is ordered, and the leaves are required to contain not less than 0.30 per cent. of alkaloids. This is a reasonable lower limit, but as no upper limit is fixed, and the leaves sometimes contain considerably more than this, a good deal of variation in strength is still possible. Several of the preparations of the drug are also altered, namely:

Extractum Belladonnae.—The green extract, made from the fresh leaves and young branches, and the alcoholic extract, made from the root, are both dropped. The new preparation is called "extractum belladonnae siccum," but the names "extractum belladonnae" and "extractum belladonnae alcoholicum" are given as synonyms; it is an extract made from the leaves, standardized to contain 1 per cent. of alkaloids, and an addition of powdered leaf is made and the whole dried and powdered.

Tinctura Belladonnae.—This is now made from the leaves, instead of by diluting the liquid extract made from the root. It is standardized to contain 0.35 per cent. of alkaloids, instead of 0.5—that is, its strength is reduced by 30 per cent.

Emplastrum Belladonnae.—This is reduced in strength by one-half; it is required to contain 0.25 per cent. of alkaloids instead of 0.5 per cent.

Hyoscyami Folia.—The official drug now consists only of the dried leaves; formerly the fresh leaves, flowers, and branches were included under the same name. The juice of the fresh drug is dropped and the other preparations altered—namely,

Extractum Hyoscyami.—The green extract is dropped, and the name "extractum hyoscyami" now stands for an alcoholic extract of the dried leaves, standardized to contain 0.3 per cent. of alkaloids and evaporated down with an addition of powdered leaf to make a dry extract in powder, similar to the dry extract of belladonna.

There is a curious irregularity in the nomenclature of the extracts. The soft extracts of belladonna, hyoscyamus, nux vomica, and opium are replaced by dry preparations, but the name "extractum hyoscyami" remains unchanged, while the word "siccum" is added to the name of each of the other three. Extract of cascara sagrada is at present a dry extract, and its preparation is unchanged, but its name is altered to "extractum cascarae sagradae siccum." Extract of euonymus is also at present a dry extract, and its preparation is unchanged, but its name is altered from "extractum euonymi siccum" to "extractum euonymi." It is not easy to conjecture what may be the reason for such arbitrary treatment of names.

Tinctura Hyoscyami.—This is now made from the leaves only, instead of the leaves and flowering tops, and with 70 per cent. alcohol instead of 45 per cent. The proportion of drug is not altered and the tincture is not standardized.

Belladonna and henbane are the only two crude drugs which are altered; the other changes are in preparations.

Acetum Scillae; Acetum Urgineae.—Vinegar of squill is made approximately double its previous strength, and its Indian representative, vinegar of urginea, is similarly altered. The respective oxymels are now made from the vinegars, but their strength as compared with the present preparations is only slightly increased.

Injectio Cocainae Hypodermica. — Reduced to half strength; now contains 5 per cent. of the hydrochloride instead of 10.

Injectio Morphinae Hypodermica.—Reduced to half strength; now contains 2½ per cent. of the tartrate instead of 5.

A note in the text draws attention to the reduction in strength of the morphine injection, but no similar note is given on the cocaine injection.

Pilula Phosphori.—Reduced to half strength; now contains 1 per cent. of phosphorus instead of 2. The excipient is altered, oil of theobroma, lanolin, and dried sodium sulphate taking the place of wax and lard.

Tinctura Aconiti. — The strength is approximately doubled, being now about the same as in the 1885 *Pharmacopoeia*. The tincture is assayed, and required to contain 0.04 per cent. of ether-soluble alkaloid, and is thus in accordance with the international agreement.

Tinctura Colchici.—Reduced to half strength; now made with 70 per cent. alcohol instead of 45 per cent. The word "seminum" is omitted from the name. The strength is now approximately in accordance with the international agreement.

Tinctura Digitalis.—Reduced in strength by about one-fifth; now made with 70 per cent. alcohol instead of 60 per cent. The strength is now approximately in accordance with the international agreement.

Tinctura Nucis Vomicae.—Reduced to half strength, being now the same as in the *Pharmacopoeia* of 1885, and approximately in accordance with the international agreement.

Tinctura Opii.—Increased in strength by one-third; now contains 1 per cent. of morphine instead of 0.75 per cent. The strength is now approximately in accordance with the international agreement.

Tinctura Opii Ammoniata.—Reduced in strength by about one-ninth.

Tinctura Strophanthi.—Increased in strength to four times that of the *Pharmacopoeia* of 1898, or double that of 1885. The oil of the seeds is removed by a preliminary treatment with ether. The strength is now approximately that of the international agreement.

It is important that the great increase in strength of this potent medicine should be borne in mind, as all prescriptions written on or after January 1st, 1915, must be dispensed with the new tincture.

Unguentum Hydrargyri.—Reduced in strength to about three-fifths of that at present official; made with benzoated instead of prepared lard. The strength is now in accordance with the international agreement.

Unguentum Hydrargyri Compositum.—This contains the same proportion of mercury ointment as before, and is therefore reduced in strength, as regards mercury, to about three-fifths.

Unguentum Hydrargyri Ammoniati. — Reduced in strength to one-half, and made with benzoated lard instead of paraffin ointment.

Unguentum Hydrargyri Subchloridi.—The proportion of calomel is increased to double.

Acidum Nitricum Dilutum.—Reduced in strength to about three-fifths; now contains 10 per cent. of real nitric acid instead of 17.44 per cent.

Acidum Phosphoricum Dilutum.—Reduced in strength to about five-sevenths; now contains 10 per cent. of real phosphoric acid instead of 13.8 per cent.

Acidum Sulphuricum Dilutum.—Reduced in strength to about five-sevenths; now contains 10 per cent. of real sulphuric acid instead of 13.65 per cent.

In consequence of these changes all the official dilute acids, except hydrocyanic and nitro-hydrochloric, now contain ten per cent. of the respective real acids.

Confectio Sulphuris.—Made with precipitated sulphur instead of sublimed.

Decoctum Aloes Compositum.—The saffron is omitted.

Emplastrum Calefaciens.—As already noted, this is made with cantharidin instead of cantharides.

Extractum Ergotae.—This is now an aqueous extract, from which gummy and other matters are removed by precipitation with alcohol, instead of an alcoholic extract from which resinous matters are removed by precipitation with water and acid. The synonym "ergotin" is omitted.

Injectio Ergotae Hypodermica.—Since the new extract is used in making the hypodermic injection of ergotin,

the latter is altered in composition in a corresponding manner.

Extractum Ipecacuanhae Liquidum.—No lime is now used in the extraction. The alkaloidal strength is fixed at 2 per cent., instead of 2 to 2¼.

Extractum Nucis Vomicae Siccum. — A powdered extract replaces the soft extract at present official, calcium phosphate being used as a diluent instead of milk sugar. The strength remains the same.

Extractum Opii Siccum.—A powdered extract replaces the soft extract at present official, calcium phosphate being used as a diluent. The strength remains the same.

Ferri Carbonas Saccharatus. — Made with glucose instead of cane-sugar, and required to contain 50 per cent. of ferrous salts, calculated as carbonate, instead of about one-third.

Hydrargyri Oleatum (at present called hydrargyri oleas).—Made from mercuric oxide, oleic acid, and liquid paraffin, instead of by precipitation of mercuric chloride with soap; contains 20 per cent. of mercuric oxide instead of about 24.

Linimentum Hydrargyri.—This is reduced in strength to about three-fifths, in consequence of the change of strength in mercury ointment. It is now made with dilute ammonia instead of strong, and less camphor liniment.

Liquor Atropinae Sulphatis. — The salicylic acid is omitted.

Liquor Epispasticus.—Now an acetone solution of cantharidin, castor oil, and resin, instead of an acetic ether extract of cantharides; the strength is approximately the same.

Collodium Vesicans.—Since this is made with liquor epispasticus, its composition is correspondingly changed; it is also made slightly stronger, and coloured with cochineal.

Liquor Ferri Perchloridi Fortis.—The iron content is reduced from 22.5 to 20 per cent. (weight in volume); the specific gravity is increased from 1.42 to 1.49, the figure at present given being erroneous.

Liquor Hydrargyri Perchloridi.—Reduced in strength to 1 in 1,000 instead of 1 in 876; it now contains $\frac{1}{10}$ gr. in 110 minims, instead of $\frac{1}{16}$ gr. in 1 fluid drachm.

Liquor Potassae.—Reduced in strength from 6.2 per cent. of potassium hydroxide to 5 per cent. (weight in volume).

Lotio Hydrargyri Nigra.—The tragacanth mucilage is omitted.

Mistura Ferri Composita.—Glucose is used in place of cane-sugar, acacia gum is added, and the strength is slightly increased.

Olcum Phosphoratum.—One per cent. of oil of lemon is added.

Pilula Ferri.—The quantities of acacia and tragacanth are reduced, glucose is used instead of syrup and glycerin, and the proportion of ferrous carbonate is increased by about one-tenth.

Pilula Hydrargyri Subchloridi Composita.—Now made up with gum and syrup of glucose instead of castor oil.

Potassa Caustica.—Required to contain 85 per cent. of potassium hydroxide instead of 90.

Spiritus Aetheris Nitrosi.—The minimum content of ethyl nitrite is slightly reduced.

Spiritus Juniperi.—Strength increased to double; now contains 10 per cent. of oil of juniper instead of 5.

Syrupus Chloral.—Strength slightly increased; now contains 10.9 grains of chloral hydrate in 1 fluid drachm instead of 10, and is thus 20 per cent. (weight in volume).

Syrupus Codeinae Phosphatis.—Strength slightly increased; now 0.5 per cent. (weight in volume) or 0.27 grain in 1 fluid drachm instead of 0.25. The word "phosphatis" is added to the name, but the phosphate has always been the salt used.

Syrupus Ferri Iodidi.—Reduced in strength to about two-thirds, and is now in accordance with the international agreement. Part of the cane-sugar is replaced by glucose.

Syrupus Rhei.—Slightly increased in strength and made with oil of coriander instead of the fruit.

Tabellae Trinitrini.—Reduced in strength by about one-third, each tablet now containing about $\frac{1}{150}$ grain (0.5 mg.) of trinitroglycerin instead of $\frac{1}{100}$ grain.

Tinctura Camphorae Composita.—Strength of opium increased by about one-tenth.

Tinctura Cardamomi Composita.—Raisins are omitted and glycerin introduced; made with 45 per cent. alcohol instead of 60 per cent. The proportions of all the drugs are increased by about one-tenth.

Tinctura Cinchonae Composita.—Saffron is omitted.

Tinctura Picrorhizae.—Now made twice the strength of the tincture of the Indian and Colonial Addendum.

Tinctura Pruni Virginianae.—Part of the alcohol is replaced by glycerin.

Tinctura Rhei Composita.—Made with 45 per cent. alcohol instead of 60 per cent.

Tinctura Sennae Composita.—Raisins are omitted and glycerin introduced.

Trochiscus Acidi Carbolici.—Strength reduced to half, one lozenge now containing ½ grain of phenol instead of 1 grain; flavoured with lemon juice instead of tolu.

Trochiscus Acidi Tannici.—Made with tolu base instead of fruit base.

Trochiscus Catechu.—Made with fruit base instead of simple base.

Trochiscus Ipecacuanhae. — Made with simple base instead of fruit base.

Unguentum Acidi Carbolici.—Now made to contain 3 per cent. of phenol instead of 4, and glycerin omitted.

Unguentum Aquae Rosae.—Spermaceti is omitted and borax introduced. The proportion of rose water is reduced to 20 per cent. from about 37.

Unguentum Belladonnae.—Made with a mixture of lanolin and benzoated lard instead of the latter only.

Unguentum Capsici.—Made with hard and soft paraffin and lard instead of spermaceti and olive oil; strength slightly increased.

Unguentum Cetacei.—Made with liquid paraffin instead of benzoinated almond oil.

Unguentum Chrysarobini.—Made with soft paraffin instead of benzoated lard.

Unguentum Hamamelidis.—Part of the lanolin is replaced by soft paraffin.

Unguentum Iodoformi.—Made with prepared lard instead of paraffin ointment.

Unguentum Paraffini.—A little white beeswax is added.

Unguentum Plumbi Iodidi.—Made with benzoated lard instead of paraffin ointment.

Vinum Antimoniale.—Reduced in strength by one-seventh.

Vinum Aurantii.—The alcoholic strength is now given as 15 to 17 per cent. by volume instead of 10 to 12.

It will be seen that some of the alterations here noted refer to only minor points, but it is not easy to draw a line between those which are of some therapeutical importance and those which are purely pharmaceutical. Many small changes are made in other substances and some of these may be referred to in the sequel.

Changes of Name.

Most of the more important changes of name have been mentioned in the above; a few others may be noted:

Aloe.—Barbados and Socotrine aloes are not now treated as separate drugs, but are placed together under aloes. The names of the extract and pills are modified correspondingly.

Senna. — Alexandrian and Indian senna are similarly included under the one name "senna."

Alum and *Borax.*—The word "purified" is added to the names. This is probably to prevent the *Pharmacopoeia* being cited as a standard of purity when commercial alum or borax is sold for non-medicinal uses.

Red Gum.—The name "kino eucalypti" is adopted in place of "eucalypti gummi."

Strong Tincture of Iodine.—The name "tinctura iodi fortis" is adopted in place of "liquor iodi fortis"; this preparation was called linimentum iodi in 1885. The ordinary tincture now becomes "weak tincture of iodine," "tinctura iodi mitis"; no doubt it will continue to be dispensed when tincture, without an adjective, is ordered.

Chaulmoogra Oil and Ointment.—The names "oleum chaulmoograe" and "unguentum chaulmoograe" are adopted in place of "oleum gynocardiae" and "unguentum gynocardiae." The source is now correctly given as *Taraktogenos Kurzii* instead of *Gynocardia odorata.*

Pine Oil.—This is now derived from *Abies sibirica* instead of *Pinus pumilio*, and is called oleum abietis instead of oleum pini.

Turpentine.—Now called oleum terebinthinae rectifi-

catum, the last word being presumably added for the reason mentioned above under "alum."

We shall next discuss in a general way the alterations in standards for drugs and chemicals.

(To be continued.)

THE ORIGIN AND DEVELOPMENT OF THE RED CROSS.

(Continued from page 675.)

The British Red Cross Society.

The Geneva Convention, as has been seen, was recognized by eighteen Powers within a year or two of the time the Conference was held. In 1867, on the occasion of the Paris Exhibition, international conferences of the societies for aid to wounded soldiers in time of war were held from August 26th to 31st. The general committee in Paris invited the national committees of different countries to send representatives, and also asked the Governments of the leading Powers of Europe to send delegates. Accordingly delegates were sent either by the Ministers for War, or the Governments of Austria, Baden, Bavaria, Great Britain, Holland, Prussia, Russia, Sweden, and Switzerland. Some of these official delegates in a few cases represented also national committees as well as their respective Governments. All the other delegates, with the exception of two sent by the Orders of St. John of Jerusalem in Prussia, and of St. John in Spain, and one sent by the Imperial Ottoman Commission for the Exhibition at Paris, were representatives of the Sociétés de Secours aux Militaires Blessés of different countries. The countries from which delegates were sent by societies for aid to the wounded in time of war were the following: Austria, Baden, Bavaria, Belgium, Spain, United States, France, Italy, Holland, Portugal, Prussia, Sweden, Norway, Switzerland, and Würtemberg. In all there were 56 delegates. Longmore in his report on the proceedings at the International Conference adds:[1]

> No society corresponding with the national societies for aid to wounded in time of war which have been established on the Continent has been organized in England. On the Continent these societies are said to have proved themselves valuable aids to their respective Government during recent campaigns. . . . Indeed, in not only all parts of the Continent are central national societies for aid to wounded soldiers in time of war now established on a firm basis with fixed rules and under the highest support, but they appear to have taken a deep root and to be throwing out extensive ramifications in their respective countries.

A year later Henry Brackenbury,[2] after giving an account of what had been done on the Continent, and insisting on the necessity of preparation and organization, asked:

> What is England doing? We have our Nightingale fund for training nurses, our patriotic fund for relief of Crimean sufferers. Where is our branch of the International Society for the Relief of the Sick and Wounded, and what work is it doing? Where is its shipload of comforts to follow the Abyssinian expedition? There lies before us the catalogue of that most interesting exhibition of objects for relief of sick and wounded soldiers held in connexion with the International Society at Paris, near the chief entrance; and in the midst of the thousands of objects exhibited, England sends two books, and one of those is called *America and its Army*. Surely this is a slur on our national humanity, a blot on our fair escutcheon. In Heaven's name let us be up and doing. We have signed the Convention of Geneva. We are bound in honour to be working in time of peace not for ourselves alone, but for all the other nations, whose wounded may, by even the remotest possibility, ever fall into our hands. We invite discussion and action on a subject affecting both our soldiers' lives and our national honour.

With our characteristic happy-go-lucky way of dealing with all things relating to preparation for war, notwithstanding the awful experience we had had in the Crimea, we did nothing to carry the lesson implied in the Geneva Convention into effect for some years after its signature.

Another congress on aid to the sick and wounded in war was held at Berlin in 1869, at which Longmore again represented Great Britain. About 1870 he trained the first bearer company ever known in England, and he was a pioneer in the initiation of the movement in this country which after many years resulted in the formation of the British Red Cross Society. The movement ran along several separate but converging lines, chief among them being the British National Society for Aid for the Sick and Wounded in War, and the St. John Ambulance.

[1] *Help for Sick and Wounded.* London, 1870, p. 401.
[2] Articles reprinted from the *Standard* of January 7th and 27th, 1868; *Help for Sick and Wounded*, p. 449.

National Society for Aid to the Sick and Wounded in War.

The National Society was the first Red Cross Association established in England. At a meeting held at Buckingham Palace on July 17th, 1905, under the presidency of Her Majesty the Queen, Lord Rothschild, the Chairman, gave an account of its foundation. He said:

> When the Franco-German war broke out in 1870, that gallant soldier the late Lord Wantage, who had planted the colours of his regiment on the heights of the Alma, for which he received the Victoria Cross, and who had served with distinction all through the campaign in the Crimea—Lord Wantage, who knew from experience the misery and sufferings of wounded and sick soldiers in a campaign, who was aware of how little was done in those days to alleviate men fighting for the honour and glory of the sovereign of their country, took advantage of the rules of the new Geneva Convention to start a society over which he long presided—namely, the National Society for Aid to the Sick and Wounded in War. His Majesty the King was the patron of that society, and his Royal Highness the Duke of Connaught was one of the trustees. Speaking of the work of the society, Lord Rothschild went on to say that from the time of its foundation in 1870 to 1905 it expended nearly £500,000 in assisting the sick and wounded in war. In the Franco-German war it provided £223,717 in supplying food, transport, clothing, medical stores, and grants in aid of local funds. It employed in that campaign nearly 200 agents, surgeons, nurses, and others, and established more than a dozen central dépôts in France and Germany for the distribution of stores. It rendered similar good service in the Turco-Servian and Russo-Turkish wars as well as in other European campaigns. It furnished aid in the Zulu campaign of 1879, and in the Boer war of 1881. In the Egyptian campaign of 1884–5 the society expended £33,922 in the employment of surgeons and nurses, in the provision of steamers, launches, and dahabeahs, and in the forwarding of medical and surgical supplies to the front. The amount expended by the society in the South African war 1899–1902 was £162,296. Twenty-one commissioners and agents were employed, grants in aid were given, clothing and medical and other stores were provided, the hospital ship *Princess of Wales* was chartered, and the hospital train Princess Christian purchased. The work in this war was carried out in connexion with, and under the direction of, the Central British Red Cross Committee.

St. John Ambulance.

The Order of St. John of Jerusalem, of which the St. John Ambulance is a department, though sometimes represented as a survival, is strictly a revival in a different form of the ancient Order of the Knights of St. John of Jerusalem or Hospitallers. Although it is a digression from the main subject, a short sketch history of this famous Order may not, therefore, be out of place here.

In the eleventh century some merchants of Amalfi founded at Jerusalem a convent, church, and hospital for the benefit of poor pilgrims visiting the Holy Places. It must be remembered that the word *hospitium* then meant not only a hospital in our modern sense, but a house of shelter for needy wanderers. At the siege of Jerusalem by the Crusaders in 1099 Gerard, a Provençal, then head of the hospital, displayed such devotion in ministering to sufferers without distinction of creed or class that Godfrey de Bouillon, when he was chosen King of Jerusalem, authorized the separation of the hospital from the convent and endowed it with one of his manors. Many of the patients, on their recovery, gave themselves in turn to the care of the sick and wounded, and Gerard formed them into a brotherhood with a distinctive garb. Their original patron was St. John the Cypriote, Patriarch of Alexandria, who, after the first capture of Jerusalem by the Saracens in the seventh century, sent money and food to the distressed Christians of Syria. In a few years the liberality of princely patrons among the Christians made the brethren of St. John of Jerusalem a wealthy order with a number of dependent hospitals in various places. As they grew in importance they renounced the patronage of the Cypriote and placed themselves under that of St. John the Baptist. Under the second Master, Raymond de Puy, the Hospitallers became a fighting as well as a nursing order. They were divided into three classes: Knights who were all nobles (it was necessary that each parent must have sixteen quarterings, so that a *mésalliance* of a great-great-grand-aunt was a bar to admission); chaplains who were priests; and brother servants who were not noble. By degrees the military character of the Hospitallers overshadowed their original mission as an order of charity,

and they became, with the Templars, one of the chief bulwarks of the Christian Power in the East. When Acre, called after them St. Jean d'Acre, the last stronghold of the Christians, fell before the attack of the Mussulmans in 1291, the Hospitallers withdrew to Cyprus, whence for some years they waged war by sea against the Saracenic nations of the Levant. When the Templars were suppressed in 1310 their lands were made over to the Hospitallers, who, however, "had to purchase the surrender from the King and other Princes at such vast cost of money raised at such exorbitant interest that the Order of St. John was poorer rather than richer from what seemed so splendid a grant."[8]

At the height of its prosperity the Order consisted of representatives of eight different nations or *langues*, among which the English were the sixth in order. The *langues* were those of Provence, Auvergne, France, Italy, Arragon, England, and Germany. Afterwards Castile was added to the number. Each language was divided into grand priories and bailiwicks, which again were subdivided into commanderies. The ordinary knights, *Chevalliers de Justice*, were required to prove noble birth, but a certain number of Knights by favour, *Chevalliers de Grâce*, were also admitted, though not noble, in consideration of distinguished valour or other merit. They were independent of all authority save that of the Pope, and that of their own Grand Master and the Chapter of the Order. About 1240 they held in Christendom nineteen thousand lordships and manors. At first their rule was very strict, and it is interesting to note that they held bodily cleanliness as well as moral purity of great importance. But as they grew in power and in wealth they became more lax in the observance of their rule. Moral corruption, which began during their stay in Cyprus, went on increasing. Almost to the last, however, they were first class fighting men. In 1310 they seized the Island of Rhodes where they maintained themselves for more than two centuries till in 1522 Solyman the Magnificent sent an immense fleet and army against them and they were compelled to surrender. In 1530 Charles V granted the dispossessed Order the Island of Malta. There, with the exception of one attack by the Turks in 1565, they remained undisturbed till, in 1792, on the breaking of the storm of the French Revolution, the abolition of the Order in France and the forfeiture of its possessions was decreed by the Directory. In 1798, owing to the weakness of the Grand Master, a German named Hompesch, and the treachery of some of the Knights, the island was surrendered to Napoleon, then on his way to Egypt. Soon afterwards it was blockaded by an English fleet, and the garrison was compelled by hunger to capitulate in 1800. Since then Malta has been held by England.

The Knights of St. John in England.

The Knights of St. John came into England in the reign of Henry I, and their first house and hospital were founded at Clerkenwell by Lord Jordan Briset about 1110. In 1185 the church was consecrated by Heraclius, Patriarch of Jerusalem. The buildings went on growing in extent and beauty till Wat Tyler's rising in 1381, when the priory was burnt and the Grand Prior, Sir Robert Hales, was beheaded by the mob. "They went streight to the goodly hospital of Rhodes called St. John's, beyond Smithfield," says Grafton in his *Chronicle*, "and spoyled that and then consumed it with fyre causing the same to burne for the space of seven days after." At this time "the building in its widely varied decorations, both internally and externally, is said to have contained specimens of the arts both of Europe and Asia, together with a collection of books and rarities, the loss of which in a less turbulent world would have been a theme for national lamentation." It was not till 1504 that the hospital was fully restored and the South Gate—all that is left of the original buildings—was erected by the last Prior, Sir Thomas Docwra. The Prior of St. John of Jerusalem ranked as the first Baron of England. John Selden says he was "a kind of otter, a knight half spiritual half temporal." In 1540 the English Order was dissolved by Act of Parliament and its property confiscated (32 Henry VIII, cap. 24) because it "maliciously and traitorously upheld the Bishop of Rome to be the supreme head of Christ's Church," intending thereby to subvert "the good and godly laws and statutes of this realm." Some of the Knights retired to Malta; of three who remained, two were beheaded as traitors and the other hanged and quartered. In 1557, under Queen Mary, the Knights were again incorporated by Royal Charter, and some of the former possessions of the Order were restored. Queen Elizabeth, however, annexed to the Crown all the property of the Knights in England (1 Elizabeth, cap. 24).

There was also a priory in Ireland.

The Knights of St. John in Scotland.

An offshoot of the English *langue* established a Priory in Scotland, at Torphichen in Linlithgowshire, in 1124. In 1153 King David confirmed its foundation and its possessions and privileges by charter. Donations were freely bestowed upon it by several of the Scottish kings. The head of the Priory was styled Preceptor, and several of the preceptors played an important part in the councils of the kingdom. They were raised by James IV to the dignity of Lords of Parliament, and were designated by the title of "Lord St. John" or "Lord St. John of Torphichen." Sir George Beatson, in his *Knights Hospitallers in Scotland* (Glasgow, 1903), says:

> Of the actual work done in Scotland by the Torphichen Priory there are no authentic records, but we may, I think, safely surmise that it was on the lines of the more enlightened monastic views that were coming into vogue in the twelfth century. These recognized that God was to be served *in* the world and not by fleeing from it, and that the duty of the monks consisted not so much in retirement into solitude to save their own souls, as in labouring to save those of others. In short, that their lives were to be shaped, as has been said, more after the character of the parish priest, being not neglectful of the worldly and intellectual interests of their people, while developing in them a deeper humanity and a more fervent Christian zeal. Hence we find that not only religion but education, the encouragement of agriculture, trade, and manufactures, manual labour of every kind, the cultivation of learning, and the chronicling of events engaged their attention, and we may regard the monks of the abbeys and monasteries in the Middle Ages as the clergymen, the farmers, the gardeners, the builders, the schoolmasters, and the historians of Scotland in those bygone days. In all these directions we may be sure the Torphichen Priory did good work, its Knights being at the same time ever mindful of the charitable origin of their Order, and I have no doubt that at the Preceptory Gate many were fed who would otherwise have starved, and that not only were the sick admitted to be nursed and restored to health, but, in times of war, the wounded also; and it is on record that Edward I., who was injured by a kick from his horse on the night before the Battle of Falkirk, was subsequently carefully tended in Torphichen Priory. The existence both in Linlithgow and in Glasgow of houses belonging to the Knights Hospitallers raises the question as to what uses they were put to and for what object they were established. Upon this point no exact information is forthcoming. They may have served as almshouses or leper hospitals, or they may have been Friaries for the residence of Serving Brothers working amongst the city poor, just like the University settlements of the present day.

For four hundred years the Hospitallers worked in Scotland till the Reformation brought about the dissolution of the Order. Their last Preceptor, Sir James Sandilands, threw in his lot with John Knox. The Priory possessions were made into a temporal barony carrying with it the title of Lord of Torphichen. The ruins of the priory still exist, and Sir George Beatson says:

> It has been suggested that by a revival of the latter in the shape of reappointing its Prior and Subprior, the Priory might serve as a bond of union between the Order of St. John of Jerusalem and the St. Andrew's Ambulance Association, the latter agreeing to do for the Priory the ambulance work of the Order in Scotland in the same way that the St. John Ambulance Association does it in England and elsewhere. No more appropriate symbol to work under could be chosen.

Last Days in Malta.

It is difficult to discover whether the English *langue* was ever formally dissolved; probably it gradually ceased to exist as the English Knights died out. It may be inferred that this was the case, as it is recorded that in 1775 Emmanuel de Rohan, then Grand Master, erected an Anglo-Bavarian *langue*. That the Order had not forgotten its original mission of mercy is shown by the fact that in that year its galleys were sent to relieve the sufferers from the great earthquake in Sicily.

(To be continued.)

British Medical Journal.

SATURDAY, OCTOBER 24TH, 1914.

MILITARY SANITATION AT HOME.

The steps taken recently by the War Office, acting in conjunction with the Local Government Board, and after consultation with the Society of Medical Officers of Health, will, if followed by immediate and sustained action, go a long way towards reassuring the public mind and stilling the apprehensions of the medical profession with regard to the health of the Territorial Forces and the new recruits.

The letter of the Army Council to General Officers Commanding-in-Chief of Commands (page 730) conveys very definite instructions with regard to the reliance that should be placed upon the knowledge and local experience of members of the civilian public health service. Its terms show the need for the representations made in these columns during the last seven or eight weeks, and indicate the nature and causes of some of the unsatisfactory conditions which have prevailed. It will be seen that the Army Council directs the general officer to communicate with the medical officer of health of the district in which troops are to be quartered before they are marched in, with a view to obtaining his expert advice and co-operation in billeting troops under the best sanitary conditions available. Further, the medical officer of health is to be consulted when camps are formed and maintained, and his visits are to be encouraged, and it is intimated that urgent sanitary work in connexion with the removal of excreta, etc., can in many cases most expeditiously be performed by making use of the local sanitary officials, who, as is well known, are very willing to serve. It is recognized that this will raise financial questions as between the War Office and the local authorities, but it is stated that the matter is under consideration.

Mr. Herbert Lewis, Parliamentary Secretary to the Local Government Board, in a speech delivered last Monday, said that the Board had lent the whole-time services of twelve of its medical inspectors for co-ordinating the work of local sanitary authorities, and the Army Council's letter states that these inspectors will continue to visit billeting areas and camps. Mr. Lewis said also that, through the assistance of the medical officers of health and sanitary inspectors throughout the country, a system of inspection of all camps and other military premises had been arranged, and that in this way it was hoped to ensure that the defects already disclosed would rapidly disappear. He recognized that there were dangers to guard against in the future arising out of the continued occupation of camps, but he was able to say that out of some 600,000 men mobilized or recruited only 5 cases of typhoid fever had been notified in the week ending September 26th, 12 in the following week, and 10 in the week ending October 10th. Every one will agree that this reflects the highest credit upon the Army Medical Services, but the fact that even so small a number of cases should have occurred at so early a date shows the need for the measures now taken and for the systematic application, so long as the war continues, of every precaution which military or civil medical experience suggests.

We have steadily maintained that as the conditions now existing in this country are wholly unprecedented, special administrative machinery is needed to cope with them, and we are glad to find that this is now being realized by the central authorities. The responsibility for the health of the recruits lies primarily with the military authorities, not only with the medical officers, but with every officer of every rank in every unit, and not, as the Parliamentary Secretary of the Local Government Board would seem to have implied, with the Army Medical Department only. The Royal Army Medical Corps is recruited to a strength designed to give efficient medical and sanitary service to the regular army. It is doing this work splendidly, but it has its hands very full with the Expeditionary Force, and has to fill the vacant places due to the many casualties the Corps has suffered in the field. The Director-General, Sir Arthur Sloggett, is going to France to take charge of the work there, and to co-ordinate with the Army Medical Service the voluntary aid given by the British Red Cross and the St. John Ambulance Association; to facilitate this task he has been appointed Chief Commissioner in France by both these organizations. The Territorial Force has its own medical officers, civilian practitioners who patriotically gave their services to the country in time of peace. They have now to carry out onerous duties under conditions differing in many respects from the summer camps of exercise. In sanitary administration they need not only the sympathy and support of commanding officers but all the assistance that the civilian public health service is so competent to give, and which the Army Council now instructs general officers commanding to obtain. There remains the great multitude of recruits for the new armies; they as yet possess no medical service of their own, and in the meanwhile stand in need of the assistance of the civilian public health service even more urgently than the Territorials. The circular of the Army Council and the statements of Mr. Herbert Lewis refer equally to them. During Sir Arthur Sloggett's tour of duty at the front, Sir Alfred Keogh, as was stated last week, has returned to the War Office to act as Director-General of Army Medical Services at home. He has a gigantic task, but he is a man of large experience and tried administrative ability. He may feel confident that the public health service and the medical profession generally will second his efforts to the utmost limits of their powers.

ENFORCED DOGMATISM IN MEDICINE.

Sir Frederick Treves, in the brilliant presidential address he prepared for the Birmingham and Midland Institute, which is published at p. 697, dwells on the daring amount of pure fiction with which the progress of medicine is associated. His contention is that this was imposed on the profession to satisfy the demands of the people. In the early days of the human race disease was believed to be produced by evil spirits which took up their abode within the human body and caused discomfort, suffering, and death. The obvious remedy was to expel them. Hence the aid of the priest, who was credited with the ability to control the powers of darkness, was invoked. If his spiritual rites and incantations failed, recourse was had to the medicine man, who doubled that character with the part of priest, as Maître Jacques served Harpagon

as cook as well as coachman when the occasion demanded such a variation of function. The medicine man, in his own way, did all in his power to make the tenement of clay in which the evil spirit had taken up his dwelling uninhabitable; he served him with writs of ejectment in the form of foul-smelling fumigations, horrible-tasting concoctions given him to swallow, blows and other modes of violent assault. If the particular part tenanted by the spirit was the head, a hole was made in the skull to allow him to escape. These fundamental principles of the primitive art of healing continued, though varied in form, well into modern times. In Pliny's *Historia Naturalis* there is an amazing collection of remedies which were in common use for centuries before his day; they continued to be employed for centuries afterwards. In many of these can be discerned, as it were, the faint dawn of some of the most advanced methods of the present day.

In time the place of evil spirits as causes of disease was taken by disordered humours. The humoral theory of pathology dominated medicine for two thousand years, and reached the height of its power over the human mind in the seventeenth century, when it is seen in its highest expression in the doctors of Molière. Even the ridicule of that master of satire, who may well be called the *malleus medicorum*, did not kill it, as Cervantes "smiled Spain's chivalry away"; indeed, it is not by any means wholly extinct among the people even at the present day. Sir Frederick Treves finds the origin of this remarkable product of the human fancy in the dogmatism imposed by lay folk on the physician as on the priest. The law is allowed to be doubtful, and the lawyer may therefore give an uncertain opinion. But there must be no hesitation on the part of the doctor. Hence the man of art had to invent theories, and even diseases, for each of which he must have an appropriate remedy. He had in all cases, according to the teaching of a well-known surgeon who only within the past few years was gathered to his fathers, to "do something." Though the educated public has lost faith in drugging, less enlightened patients consider themselves defrauded if they are put off with advice, and seek counsel of another oracle who does not disdain to seal up the "genius" of healing in a bottle. And the colour of the fluid contained in the bottle has a real influence. Sir Frederick seems to us to overlook the effect of the imagination, which in some varieties of disease, at any rate, has more potency than all the drugs in the *Pharmacopœia*. Is not the faith of the average hospital patient in the efficacy of the medicine dispensed to him in proportion to the nastiness of its taste? This is a survival of the old doctrine that the evil spirit was to be evicted by making his abode unpleasant. It may be admitted, too, that the treatment of disease by wholesale drugging—a system analogous to the infantry fire of the Germans, who seem to pour in showers of lead on the enemy on the chance that some of it will reach the mark—was too profitable to the apothecary not to foster a belief in the power of medicines. Homœopathy did a service to medical science, though unwittingly, by insistently reminding the profession that many sick people tend naturally to recovery without drugs.

While we agree with Sir Frederick Treves that dogmatism has been the greatest hindrance to the advance of medicine, we think that for this the doctors themselves are largely responsible. The worship of authority which so long held the human mind in shackles to the ancients was by no means confined to medicine; it dominated human thought in every sphere. So strong was this influence that, just as in the Middle Ages originality in theological speculation was apt to lead to the stake, in Egypt, if an illness proved fatal the doctor was liable to a heavy penalty, even to death, unless he could show that in his treatment he had followed the orthodox lines laid down in the books and consecrated by long usage. It might therefore be truer to say that dogmatism was enforced on the profession by its leaders and accepted by the people. Popular medicine at any given time may broadly be said to represent the medical knowledge of a century earlier. But often a belief in a theory such as the evil effects of the "suppression" of a rash or in some "cooling" or "soothing" medicine survives much longer, and we think Sir Frederick Treves goes too far when he says that the whole of the spurious science in which our forefathers placed their faith has been swept away. But we may congratulate ourselves with him that, while the landmarks of the older medicine have been moved to an extent that could not have been foreseen even a generation ago, the principles on which the healing art rests have been consolidated and reduced to a few fundamental propositions. Even greater satisfaction, we think, is to be found in the fact that people are now learning to take an intelligent interest in rational medicine. The more widely a knowledge of natural processes, and of the extent to which these can be controlled by the application of scientific methods is diffused, the more surely will be brought about the complete extinction of quackery—that most noxious form of trading on human weakness.

THE DEATH OF NELSON.

TRAFALGAR DAY (October 21st) inevitably aroused special interest this year. A pathetic feature among the usual memorials around the base of the Nelson Column was the number of mourning cards and wreaths commemorating the officers and men of the Royal Navy who have so far died in maintaining that sea power which even in these early days has had so marked an influence in the present war. The time, therefore, seems opportune for recalling the circumstances of our great naval hero's death. According to the official report of Dr. William Beatty, surgeon of H.M.S. *Victory* at Trafalgar,[1] Nelson was mortally wounded in the left breast about the middle of the action by a musket ball, supposed to be fired from the mizzen top of *La Redoutable*. The Admiral was in the act of turning on the quarterdeck with his face towards the enemy when he was wounded; he was at once taken to the cockpit where he lived about two hours. "On being brought below, he complained of acute pain about the sixth or seventh dorsal vertebra, and of privation of sense and motion of the body and inferior extremities. His respiration was short and difficult; pulse weak, small, and irregular. He frequently declared his back was shot through, that he felt every instant a gush of blood within his breast, and that he had sensations which indicated to him the approach of death. In the course of an hour his pulse became indistinct, and was gradually lost in the arm. His extremities and forehead became soon afterwards cold. He retained his wonted energy of mind, and exercise of his faculties, till the last moment of his existence; and when the victory as signal as decisive was announced to him, he expressed his pious acknowledgements, and heartfelt satisfaction at the glorious event, in the most emphatic language. He then delivered his last Orders with his usual precision, and in a few minutes afterwards expired without a struggle." The following is an account of the *post-mortem* examination: "The ball struck

[1] Reprinted in Beatty's *Death of Nelson*. Archibald Constable and Co. 1905.

the fore part of his Lordship's epaulette, and entered the left shoulder immediately before the processus acromion scapulae, which it slightly fractured. It then descended obliquely into the thorax, fracturing the second and third ribs; and after penetrating the left lobe of the lungs, and dividing in its passage a large branch of the pulmonary artery, it entered the left side of the spine between the sixth and seventh dorsal vertebrae, wounded the medulla spinalis, and fracturing the right transverse process of the seventh vertebra, made its way from the right side of the spine, directing its course through the muscles of the back, and lodged therein, about 2 in. below the inferior angle of the right scapula. On removing the ball, a portion of the gold lace and pad of the epaulette, together with a small piece of his Lordship's coat, was found firmly attached to it." The bullet which killed Nelson was given by Dr. Beatty to King William IV, who placed it in the Royal collection at Buckingham Palace. It is suspended in a case of plate glass $\frac{3}{4}$ in. thick. This glass casket is lowered into the interior of a solid pedestal, which is lined with the finest steel.

THE ACCURACY OF THE "MEDICAL REGISTER."

In another column will be found a letter from the Acting Registrar of the General Medical Council calling attention to the need of the co-operation of all medical practitioners in making the *Medical Register* accurate and complete. We are assured that the Registrar's office takes great pains to avoid the inconvenience which may be caused to practitioners by the removal of their names from the *Register* under Section XIV. The duty laid upon the Council by the Medical Acts is clear, but, quite apart from this, it is obvious that it is to the interest of the profession that the *Medical Register* should be absolutely accurate.

THE TUBERCULOSIS OFFICER AND HIS WORK.

The first annual report of the tuberculosis officer for the city of York, Dr. J. Bell Ferguson, giving an account of his preliminary work in starting a comprehensive scheme, presents many points of interest to others engaged in similar efforts. In common with all who have to do with the control of pulmonary tuberculosis, he laments the utterly insufficient means for dealing with acute and advanced cases. The time, labour, and money expended on the treatment of the incipient case is usually thrown away on the return of the patient to the infected home or the society of a consumptive relative. The increasing vigilance of inspectors, set going by the revelations of the dispensary, can do something to mitigate the evil, but it can never be stopped until the advanced case is placed under legislative control. The York Dispensary is worked with a small professional staff, but enlists the services of visitors for outside cases. A dental surgeon, a secretary, and a nurse, together with the tuberculosis officer, undertake the medical and clerical work, and a municipal committee constitutes the controlling element. With the limited amount of accommodation a good deal has been done in a twelvemonth. Perhaps the most important service has been rendered in the homes of the patients by the lady visitors. The spread of knowledge in hygienic matters is always slow, but it is an essential to success in establishing a tuberculosis dispensary. The fact that the institution can already be described as popular speaks well for the tact and persuasiveness of the lady visitors and the secretary. As regards general results, it is too soon to draw conclusions, but a high percentage of improvement is recorded. Very few cases, however, were found to have lost bacilli from the sputum. A special committee, representative of all classes, is charged with the after-care of dispensary patients, and would appear to be armed with power to collect money for the purpose by means of a two day "flower crusade" in every year. Beds in open-air wards attached to an isolation hospital are available, as also in the County Hospital. Insured as well as uninsured cases are catered for, the cost of the former being partly provided by the Insurance Committee. The charge in the open-air wards is assessed at 25s. a week, and cases of surgical tuberculosis dealt with in the County Hospital are taken at 33s. The municipality undertakes the treatment of patients' dependants; whether insured or not. An open-air school is provided for children. The work would appear to have been vigorously started, and will doubtless be pushed forward as means become available. Careful and concise records, fully indexed, should prove of great value as time goes on.

MEDICAL WOMEN IN INDIA.

A lady holding the degrees of M.D., B.S.Lond., writes to us that although it is often said at home that "India is crying out" for well-qualified women doctors, this is not true in the sense that at the present moment there is work waiting for women doctors in India. There are, she says, in India some thirty or forty posts (charge of a hospital) which a well-qualified European woman may hold; a fair salary is given, quarters are provided, and private practice is allowed. At present these are all filled. With regard to junior posts in which a young medical woman might, while gaining professional experience, learn something of the languages, customs, and prejudices of the natives, and of the administration of an Indian hospital, there are few or none. These junior posts are intended for and filled by natives and Eurasians. The salaries offered, quarters provided, and the status of the post are not adequate to the needs of European women. The remedy for this state of things, according to our correspondent, lies in the formation of a Government Indian Medical Service for Women, and in the building and equipping of hospitals and placing them in charge of well-qualified and experienced women doctors. The salaries attached to the subordinate posts should be increased and the quarters assigned should be improved so that newly qualified European women should be willing to hold them for two or more years until they were sufficiently experienced to take charge of a hospital. Our correspondent goes on to say that a few months ago she answered an advertisement for the post of assistant to the obstetric surgeon at King George's Medical College, Lucknow. On asking for particulars about the work she was told she would be expected to instruct male native students in gynaecology and midwifery, both theoretically and practically. She declined the post, and we think she was fully justified in so doing. Assuming that the facts are as stated, we cannot help feeling that such a proposal made to a white woman was improper.

ANOTHER VACCINATION ORDER.

Still another amending order is now added to the list of changes in the Vaccination Acts. An "order" issued in 1910 provided what is known as Form Q, which was a notice to parents or other persons having custody of a child; it was issued by vaccination officers, and had regard to the transmission of the certificate of successful vaccination, statutory declaration, or medical certificate postponing the vaccination if the child was unfit. It has been found in some cases that this form has been read as implying that a "statutory declaration" is valid if made within seven days after the child is 4 months old. This is not the case. The Act requires that the declaration shall be made within four months from the birth of the child, and that it shall be delivered or sent by post to the vaccination officer of the district within seven days thereafter. The Order of 1910 is now rescinded, and a new Form Q is substituted for the form prescribed in that Order. There can now be no legal quibble as to the

meaning of this form in regard to the point already mentioned. Any person reading the new form should now know precisely what is required of him in the limits of the time stated. The new Order contains this additional paragraph addressed to the parent or custodian of the child: "If you propose to have the child vaccinated by some doctor other than the public vaccinator, I" (the vaccination officer) "shall be glad to be informed to that effect." The purpose of this is explained in a circular issued along with the new Order to boards of guardians which states that if the request mentioned in the paragraph above is complied with, "the vaccination officer should add a footnote to Form H" (that is, the form which contains the list furnished to public vaccinators of the names of children who have attained the age of 4 months and 7 days concerning whom none of the requirements have been made) "informing the public vaccinator of the fact, so that the public vaccinator, in arranging his visits, may be aware of the expressed intention of the parent, and may be able to defer his visit to those parents if for the convenience of his practice he should so desire." Unnecessary visits may by this means be spared. The experience of many public vaccinators is that the statement of parents who say they will employ their own doctor is often a mere excuse for deferring the vaccination or altogether evading it, and this especially in districts where the Vaccination Act is indifferently administered. There are indications that the authorities are beginning to be anxious about the possibility of an outbreak of small-pox, and it may be that in issuing this order of 1914 the Government is hoping to bring the subject of vaccination prominently forward and to stimulate vaccination officers in the discharge of their duties, as well as to clear up any misconception regarding the order of 1910.

THE GERMAN MEDICAL PROFESSION IN WAR TIME.

GERMANY is suffering from a severe dearth of medical men, many thousands of whom have joined the colours. According to *Aerztliche Mitteilungen* (No. 32) twenty-two out of twenty-six doctors in the neighbourhood of Wiesbaden have been called on for service. It has naturally been impossible for the remaining four doctors to cope with the work thrown on their shoulders, and the *Leipziger Verband* has applied to the Government for temporary relaxation of the usual qualifications required of practitioners. Permission has accordingly been granted for senior medical students, who have worked in the hospitals for two terms, to act as assistants in the treatment of club patients. Doctors who are not called to join the colours are urged by the *Leipziger Verband* to attend free of charge the club patients of their absent colleagues. The doctors remaining in Wiesbaden have undertaken to attend the private patients of their absent colleagues, and not even to receive gifts in kind for such services. Even during this crisis the Association of German Doctors has maintained its conflict with offending clubs, and as late as September 4th warning notices were published cautioning prospective applicants against more than 100 appointments, many of which were offered by large clubs. During August seven German military doctors were included in the casualties, four of whom died. One doctor is stated to have lost his life owing to "*einem tückischen Ueberfall Belgischer Einwohner.*"

ANTITETANIC SERUM.

As was mentioned last week, the Academy of Medicine held its opening meeting for the session in Paris on October 6th, but it may be interesting to add that it met weekly in private session from August 11th onwards. On that date it adopted a resolution congratulating the Royal Academy of Medicine in Brussels on the heroism displayed by the Belgian nation and army in the defence of the two countries, Belgium and France. On August 25th it took measures to encourage revaccination against small-pox, and on September 29th, after hearing a paper by M. C. Walther on the etiology and prophylaxis of tetanus, it adopted a resolution to the effect that, in view of the fact that it was important that in the case of all wounds, and especially those soiled by earth and clothing, the patient should receive prophylactic injections of antitetanic serum as early as possible, it called upon the Government to take special steps to ensure the supply of antitetanic serum to the ambulances. The Minister of War has replied that the course desired is being followed as far as circumstances permit.

THE LIMIT OF ADVERTISEMENT.

THE surviving friends of the late Sir William Smart who happened last Tuesday to look at a London daily paper from which better things might have been expected, must have seen with astonishment, not unmixed with indignation, his name and portrait figuring in an advertisement of a proprietary remedy for rheumatism. Sir William Smart, after a distinguished career in the Medical Department of the Royal Navy, during which he served in the Crimea and in China, received towards the end of his career the honour of K.C.B. and was appointed one of the Naval Honorary Physicians to the Queen. The advertisement was headed "A Great Victory," and spoke of a Royal formula placed at the disposal of the public; it asserted that Sir William Smart exerted "his great intellect towards checking, subduing, and curing the rheumatical and kindred allied complaints to which a late great Crowned Head was subject." Sir William Smart died in 1887, and now we find that Sir William Smart and Co. will supply a free treatise explaining "how Sir William Smart's treatment so surely cured." "While one may hesitate," the advertisement says, "as to the acceptance and appliance of an ordinary treatment, there can be no doubt as to the soundness, safeness, and certainty of a Royal formula." We do not know what steps the relatives of Sir William Smart may be disposed to take, but we have no doubt that they will have the sympathy and support not only of the medical profession, but of all right thinking persons.

ON Friday next, October 30th, Professor J. C. Bose, D.Sc., C.S.I., C.I.E., of Calcutta, will give a lecture at 5 p.m., before the Royal Society of Medicine, 1, Wimpole Street, W., on the modification of response in plants under the action of drugs. The lecture will be illustrated by experiments.

THE Harveian Oration, delivered before the Royal College of Physicians of London on October 19th by Sir R. Douglas Powell, dealt with advances in knowledge regarding the circulation and attributes of the blood since Harvey's time. Afterwards the Bisset Hawkins memorial medal, awarded triennially in recognition of work in advancing sanitary science or promoting public health during the preceding ten years, was presented to Sir Ronald Ross, K.C.B., in recognition of his researches on malaria.

THE presidential address to the Hunterian Society, which will be delivered by Dr. Thomas Glover Lyon, at the Barbers' Hall, Monkwell Street, E.C., on Wednesday next, at 4.30 p.m., will be on "The barber-surgeons and the medical profession." It will be illustrated by many objects of interest belonging to the company, including the famous painting by Holbein of the granting of a charter to the company, the cup presented by Henry VIII, and another cup presented by Charles II. Sir Thomas Crosby hopes to speak on the relation of the Barbers' Company to the corporate life of the City of London. Tea will be served at 4 p.m. All members of the medical profession are cordially invited.

THE WAR.

MEDICAL MATTERS IN FRANCE.

(From a Special Correspondent in Paris.)

RED CROSS WORK IN PARIS.

Floating Ambulances.

From time to time a good many wounded and sick have been moved to a distance from the front by means of barges, and this means of distributing cases seems likely to become quite common. At any rate, an association calling itself the Society of Floating Hospitals has been formed, and proposes to furnish quite a fleet of self-propelled river craft, covered in and equipped in much the same fashion as a well-appointed ambulance train. One that is already prepared for service has recently been open to inspection in the Seine, near the Grenelle bridge. It is about 120 ft. long and, though capable of carrying fifty wounded and their stretchers and attendants, is sufficiently narrow to traverse freely any of the very numerous waterways of France. The advantages of this method of dealing with wounded and sick soldiers become fully obvious only when it is borne in mind that the French system of dealing with soldiers sent down from the front is territorial in its character. Whenever possible, men requiring treatment and capable of being moved to any distance whatever are sent to the areas to which their regiments belong; consequently the distances they have to travel are sometimes very great, and the journeys, if performed entirely by train, would be trying even to a sound man. So far the practice has been to bring down the wounded from the front to a station near Paris, where all trains stop and where all the occupants of the berths are inspected. At this station there is established an ambulance whose officers decide what cases can be allowed to continue their journeys forthwith without material disadvantage, which of them should be detained for a few hours, at any rate, for the purpose of having their wounds redressed, and which cases should be removed from the train permanently and taken to a fully equipped hospital at once for immediate operative or other treatment.

Some Typical Wounds.

I am able to furnish this week, for reproduction in black and white, some sketches of typical wounds drawn from life by a senior medical student possessed of distinct talent as a draughtsman. This is Mr. D. C. Norris, of the London Hospital Medical School, who at the time he made these sketches was acting house-surgeon at Hôpital Auxiliaire No. 160 of the French Red Cross Society, and is now its senior dresser. Four of the pictures relate to cases of shell wound, and the fifth to a case in which the wound, despite its septicity and appearance, was certainly caused by a bullet from a rifle fired by a man only a few yards distant.

Case I.

The patient in this case (Fig. 1), a man aged 37, belonging to the 32rd French Territorial Regiment, was struck on the side of the chest by a fragment of shell on the afternoon of October 3rd. He was at the moment within the German lines, and for some hours lay unattended where he had fallen. Under cover of night he then found his way back to the French lines, his wound being dressed by a French army surgeon some eight hours after its infliction. Next day he was sent south in an ambulance train, and arrived at the hospital on October 6th.

He was then found to have a wound caused by a projectile which, entering in the left hypochondriac region, had passed upwards and backwards and emerged through a hole 3 in. wide close to the left scapula. The intervening track was sloughy and the surrounding superficial and other tissues in the same condition, with much ecchymosis further afield. Under a general anaesthetic a lumbar injection of 20 c.cm. antitetanic serum was first given and the track then opened up. It was found that there were comminuted fractures of the seventh and eighth ribs in the mid-axillary line and that some pieces of leather and clothing were embedded. These having been removed and the sloughing surfaces scraped away the wound was irrigated and packed with gauze.

On the following days the dressings were removed, the wound being syringed with hydrogen peroxide solution, and by October 12th the patient was doing well, the wound being clean and his temperature normal.

Fig. 1.—Shrapnel wound of side of chest, with fracture of seventh and eighth ribs.

Case II.

The patient in this case died on the fifth day after he was wounded, and the picture (Fig. 2) shows only one of his many lesions. All were due to the impact of shrapnel bullets or shrapnel shell casing, but he was so ill when he reached hospital on October 6th that nothing could be ascertained as to the circumstances except the fact that he had been wounded on October 3rd. On the right side there was a compound fracture of both leg bones, severe excoriation of the skin over the thigh, two flesh wounds over the shoulder, and a compound fracture of the lower third of the radius. On the left side there was a compound fracture just above the ankle, a compound fracture of two metacarpal bones, a lesion which resembled a large burn on the back of the hand, and a lacerated flesh wound on the outer side of the upper arm. All the lesions were markedly septic. The right leg was the seat of moist gangrene, extending to within 2 in. of the knee; the right hand was in the same state, and there was a crackling sensation on palpation of the outer side of the left foot.

The right leg and the right arm were amputated forthwith, the former above the knee and the latter below the

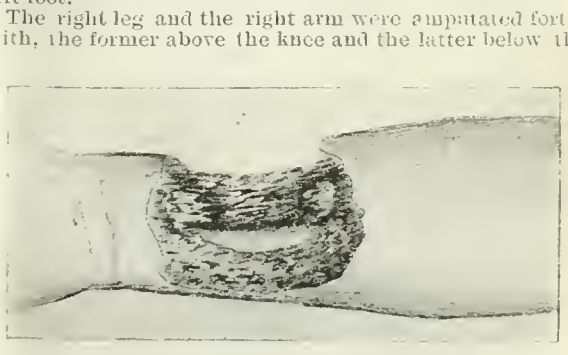

Fig. 2.—Shrapnel wound of forearm: compound comminuted fracture of right radius. Amputated 3 in. below elbow-joint for gangrene.

elbow. The other wounds were cleaned up, those communicating with fractures being opened and irrigated with hydrogen peroxide and mercury biniodide $\frac{1}{1000}$. The following morning the left leg was found to be definitely gangrenous, so this too was removed, saline transfusion being performed during the course of the operation. Death occurred the following morning, the temperature running up meanwhile to 107° F.

CASE III

In this case (Fig. 3) the patient was an officer in a French infantry regiment, wounded by a shell on September 15th. He received treatment at the field ambulance, passed the

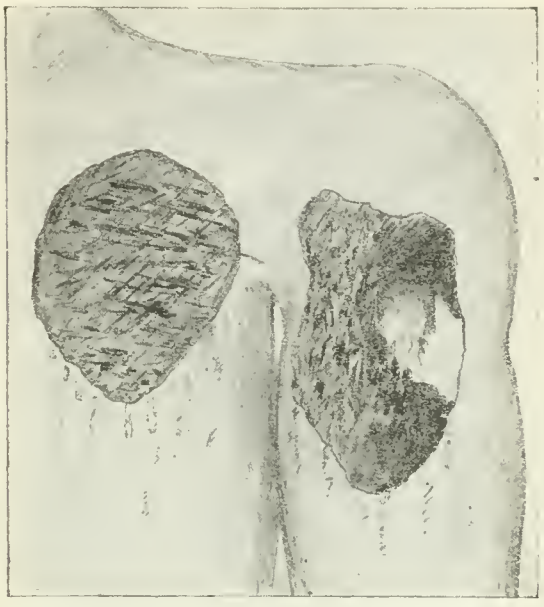

Fig. 3.—Compound comminuted fracture of humerus, with chest wound; result of shrapnel wound. Conservative treatment for eighteen days, then amputation at shoulder for secondary haemorrhage

night in a hospital a few miles distant, and next morning was put into a hospital train with the idea of his being taken to his own territorial area. On the way, however, it was thought wiser to remove him from the train and send him into Paris by a motor ambulance. On his admission to hospital on the second day (September 17th) after the injury it was found that the projectile had entered 2 in. below the point of the left shoulder and passed out on the inner side of the arm. The entrance wound was 3 in. wide, and the exit wound was of about the same size; in addition the projectile had comminuted the upper third of the humerus and just missed the brachial vessels which were exposed at the bottom of the exit wound. On emergence from the arm the missile had caused a flesh wound in the pectoral region measuring about 5 in. by 4 in. The lesions were all markedly septic, despite the early treatment secured.

The wounds were thoroughly cleaned up, and for seventeen days, during which the wounds were washed twice a day with H_2O_2, the progress of the case was favourable. On October 4th, however, severe haemorrhage from the arm started, and as it proved impossible to locate its precise origin, the arm was removed by disarticulation at the shoulder. After this the progress of the case again became favourable, the wound being almost clean by October 11th.

CASE IV.

An artilleryman, aged 19, received a shell wound of the

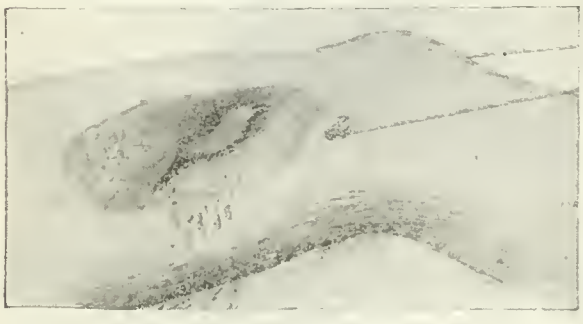

Fig. 4.—Compound comminuted fracture of femur, resulting from a shrapnel wound. Upper fragment of femur presenting in wound; lower fragment maintained in position by weight extension (5 kilograms). Sinus extends 4 in. upwards and backwards from wound.

thigh (Fig. 4) on September 15th, and had a first-aid dressing applied shortly afterwards by an orderly of the R.A.M.C. He was then carried out of the firing line to a barn, where he was laid on a bed of straw; there he remained till, on the second day after he had been wounded, he was taken down to Paris in an ambulance train. On his admission, on the third day after the date of his injury, some 3 in. of the lower third of the right femur was found to be broken into fragments, and the wound communicating with them smelt very badly.

Under anaesthesia the wound was opened up and thoroughly cleansed and fragments removed and a splint applied. The progress of the case not being satisfactory, the splint was removed three days later, hot fomentations applied to the leg, and the wound irrigated with hot lysol solution. The general state of the patient and the condition of the wound improved very much under this treatment, which was continued for several days. It was then found necessary to remove two large sequestra, one measuring 3 in. long by 1 in. thick. As there was great shortening of the limb, extension was applied. This was secured by driving in a 4-in. French nail horizontally into the inner and outer condyles and attaching thereto a weight of approximately 10 lb., the thigh and leg being raised from the bed by pillows.

After this progress was satisfactory. On October 12th there was still a freely discharging sinus, but the position of the broken ends was good, and the total shortening reduced to about an inch. When the fomentations were first applied there was considerable fever, but in a few days this subsided.

CASE V.

The chief injury in this case was a bullet wound of the knee-joint (Fig. 5), accidentally caused. The patient, a private in a British infantry regiment, was engaged in digging a trench when a comrade a few yards off accidentally discharged his rifle. First aid dressings were applied forthwith, and the patient passed the night in a field ambulance; then he was taken in a horsed ambulance to a railhead hospital, where the knee wound was redressed, and he remained two days. After this he was sent down to Paris by an ambulance train.

On his arrival, on the sixth morning after his injury, it was found that the bullet had passed through the inner

Fig. 5—Gunshot wound of right knee: compound comminuted fracture of internal condyle of femur and of internal tuberosity of tibia, with involvement of joint.

side of the right knee, exposing the joint and blowing away part of the inner condyle of the femur and the inner tuberosity of the tibia. It had then passed through the ulnar side of the arm and out at the back of the wrist, apparently without fracturing bone. The knee wound, which was lacerated and septic, was cleaned up and drained by a counter opening, the lateral patella ligament sutured with catgut, and the leg put on a back splint. For the first six days after admission the patient's condition was not satisfactory, the knee wound being painful, the patient sleepless, and the temperature rising to nearly 103° F. By the fourteenth day, however, from the date of the injury the temperature had dropped to 100° F., but the knee wound was still discharging very freely.

This last case seems to illustrate the explosive effect that a rifle bullet may sometimes have if it strikes a bone when travelling at its initial speed, and shows that septicity may occur even when skilled attention is given quite early. This point, however, was perhaps better brought out by a wound of the hand that I saw elsewhere. In this case the patient was quite positive that the distance from which he had been shot was not more than 300 yards. The missile had passed through the last four metacarpo-phalangeal joints, comminuting each of them,

and made its exit through the ulnar side of the metacarpal bone of the little finger. By means of the screen a tiny fragment of the bullet could be seen between the index and second metacarpals, and a larger fragment close to the exit wound. The latter was removed and seemed to me to be indubitably the upper sixth of the casing of a German rifle bullet. This wound, too, was very septic.

Bullet Wounds of the Chest.

I forgot to mention last week that by the courtesy of Medical Inspector Dr. Capitan I had had an opportunity of examining some of the patients whose cases formed the basis of the address delivered by him before the Academy of Medicine on October 6th. They were four in number, the other six cases having been discharged on the morning of the day that I paid my visit. Though these were the worst of the ten cases, and much less than a month had elapsed since they were wounded, only one of them was in bed; this patient was doing well, but had some fever, and it seemed to me possible that the missile by which he had been struck, and which was still lodged in the apex of the lung, was a small fragment of shell and not a bullet. The other three patients looked well, and I was rather struck by the excellent tone of their muscles, despite the unpleasant experiences of the past few weeks. In two of them the bullets seemed to have entered through the front of the chest, passing out much lower down at the back. The apparent track of the bullet in one of these cases suggested that the upper part of the back of the liver must have been at least grooved, but the clinical history of the case did not seem to confirm this supposition. In the third case the entrance wound was high in the back and that of the exit lower down in front. In this case the bullet was still lodged between the ribs when the patient was admitted; nevertheless, the amount of suppuration was very small.

All three cases showed considerable dullness on percussion on the injured side and the breath sounds were somewhat obscure. Dr. Capitan stated that these features were common to all the convalescent cases, and for this reason he considered that after their discharge they should be carefully watched for some time. Much the same view was taken by M. Reynier, of the Hôpital Lariboisière, in his discussion of M. Capitan's paper on the day that it was read. He held that no patient who had received a penetrating wound of the chest should be sent to the front again for at least three months, however well he might appear, and that meantime it was well to exhibit quinine. He added that it was his practice to envelop the chest of all patients wounded in the thorax in thick layers of cotton-wool as soon as they reached hospital, and thought that corresponding steps should be taken, if possible, directly the men came under treatment at the front.

Some Belgian Experiences.

I have had an opportunity of hearing the experiences of two English ladies, both fully trained and highly experienced nurses, who had been working for six weeks in a Belgian Red Cross hospital at Antwerp. They left the town on foot during the night that the military evacuation began. They had been told to leave five days previously, but did not feel disposed to do so as they still had a large number of patients on their hands. Finally those who could walk left of their own accord, and the helpless cases were removed by the military authorities on the night of the evacuation. The Germans having destroyed the reservoir, the only water available during the last eleven days of their stay was drawn from the Scheldt. It was so foul that its taste was perceptible even when made into coffee. This being the case a considerable amount of water-borne disease amongst the Belgian refugees would not be surprising. The experience of these ladies confirmed what I mentioned last week as to Dr. Capitan's views regarding the comparative benignity of bullet wounds of the chest. They had heard of the occurrence of some cases of tetanus in another hospital, but had seen no instances of it themselves, and though a very large proportion of all the wounds they had dressed were very septic actual gangrene had occurred in none of them. They were greatly impressed by the patient courage of the Belgian soldiers, by their uncomplaining endurance of pain, and the remarkable way in which they recovered from injuries which at first sight seemed to them inevitably fatal. Iodine was the chief antiseptic used and by some surgeons was employed so freely and in such strength that excoriation of the skin was quite common. What had struck them, however, more than anything else was the state of nerve exhaustion in which many of the patients arrived. Some who had serious and what had seemed to them very painful wounds, appeared to suffer not at all for some days after admission; others were brought in from the trenches without any wounds at all; they were simply semiconscious and remained so for days and days. It was difficult to get these patients to take either food or drink and their temperatures remained subnormal.

A Dresser's Experience.

We are indebted to Dr. T. Warner Lacey, of Woolwich Common, for the following letter from a dresser in the hospital in the Hôtel Majestic, organized by Dr. Haden Guest:

This hotel, with some 800 rooms, has been almost entirely taken over by the French Red Cross. We have two large ground-floor rooms fitted up as wards, each accommodating about 30 beds, for private soldiers. More rooms are now in course of preparation. We have two smaller rooms for officers, and also an operating theatre and numerous other departments. A dispensary has been improvised, together with an *x*-ray room, etc.

The cases are, of course, very different from anything one sees in an ordinary hospital. In London one may, now and then, see a man who has been seriously injured in an explosion, or who has had a limb or two crushed in a machine, and he usually dies. But if one can imagine that a hundred men are simultaneously involved in such an explosion or laceration, and half a dozen survive, lie in a ditch for a day or two, then are dragged out and dropped in a cattle truck, carried fifty miles, and taken to a hospital on a stretcher, you will get an idea of what the men are like who are brought here.

The following are typical cases:

1. Driver of an artillery wagon. He, with nine others, were halting by the roadside. A shell hit the wagon, killing seven, and wounding three. This man has wounds in right forearm (three), two in right leg, four in back, one of them reaching down through the scapula, including the pleura, and one on the scrotum. On admission all these were septic. All wounds now doing well.

2. Wounded September 14th. Compound fracture of right femur. Small field dressing applied same day. No attention till four days later, then splint applied. Brought to Paris September 23rd. Operated upon: Septic shell wound 4 in. by 3 in. Comminuted fracture of shaft of femur, just below middle. About twenty large loose fragments removed. Wound irrigated. Counter opening made in the back of thigh. Drainage tube. September 24: Persistent vomiting; exhaustion; died.

3. Wounded by shell. Neglected for two days, then carried to station and wound dressed. After four days arrived at Paris, having only field dressing on wound. Compound fracture of right femur; huge septic wound in thigh, about 4 in. of femur exposed. Foot internally rotated through about 110 degrees. Lower fragment of femur displaced backwards and upwards, and internally rotated. Profuse fetid discharge from wound. On admission, wound thoroughly cleaned up and packed with iodoform gauze; splint applied. Later (October 1st), deformity reduced under anaesthetic, and weight extension applied. Now doing well. On September 28th two large sequestra, 3 in. by 1 in., and 1½ in. by 1 in., extracted under anaesthetic.

4. Wounded Tuesday morning, three weeks ago. First attended to Thursday night. On admission severe compound fracture of tibia and fibula, with much fetid discharge. Gangrene of foot. Foot amputated, and leg wound cleaned up thoroughly. On 24th amputation wound clean and doing well. Leg wound opened for better drainage; two necrosed fragments of tibia removed. October 1st: Wound extremely tender; much discharge; another sequestrum separating. Amputation wound nearly healed.

We have two cases of tetanus, both of which are doing well, under injections of serum and chloral.

MILITARY SANITATION AT HOME.

The Society of Medical Officers of Health.

Dr. Herbert Jones of Hereford, in taking the chair as president of the Society of Medical Officers of Health on October 16th, devoted his address to a consideration of the duty of the public health service in the national crisis. After some preliminary observations, and after commenting on the remarkable improvement in physical conditions to be witnessed in men of the Territorial Force who have been undergoing intensive military

training during the last two or three months, he said that all those engaged in public health work in this country were ever ready to acknowledge their indebtedness to the Army Medical School, first established fifty-four years ago at Chatham, then removed to Netley, and since 1900 embodied in the Royal Army Medical College at Millbank. He went on to consider the sanitary medical service of the Territorial Force, and after sketching the original scheme he pointed out that, owing to unavoidable circumstances, which have already been indicated from time to time in our pages, it had not at once on mobilization fulfilled the functions it was intended to subserve. The principles underlying the scheme were, however, he said, being carried out in another manner to good purpose, and he outlined the steps which have recently been taken by the Army Council to make the services of medical officers of health available in the interests of troops. Instead of quoting Dr. Jones's account of the steps taken it will be preferable to give the actual terms of a letter addressed to General Officers Commanding-in-Chief of Commands instructing them to consult with the medical officers of health of localities in which troops are encamped, and to invite their co-operation in safeguarding the health of troops stationed in their respective areas.

Circular to General Officers Commanding-in-Chief of Commands.

With reference to War Office letters No. 79 Medical 17 (A.M.D.2), dated August 8th and September 12th, 1914, I am commanded by the Army Council to say that it is understood that billets are frequently arranged without reference to the medical officer of health of the district in which the troops are to be quartered, and, as he is in the best position to give the necessary information regarding the existence of infectious diseases, water supplies, drainage, localities where latrines should be placed, etc., the Army Council direct that you are to communicate with him before troops march in, with a view to obtaining his expert advice and co-operation in billeting the incoming troops under the best sanitary conditions available.

In the case of towns a telegram should be sent in advance addressed to the medical officer of health of the town in which the troops are to be billeted, appointing a time and place of meeting with the billeting officers, who are sent in advance, to arrange for the housing of troops. In the case of rural districts, that is, areas outside townships, similar telegrams should be sent, addressed to the medical officer of health of the county in which the troops are to be billeted and giving the same information.

As regards Territorial Force Head Quarters, the local medical officer of health is similarly to be consulted before men are furnished with billets.

When camps are formed and maintained the medical officer of health is also to be consulted, and his visits are to be encouraged.

In many cases urgent sanitary work in connexion with the removal of excreta, connexions with sewers, etc., can be most expeditiously performed by making use of local sanitary officials. When these officials are willing to perform this work, their services should be utilized. The question of the adjustment of any expenditure so incurred is under consideration.

When, in the interests of the public health of the troops, the medical officer of health feels compelled to submit written recommendations, these will be forwarded without delay, through the D.D.M.S. of the Command, to the War Office.

The medical inspectors of the Local Government Board will continue to visit billeting areas and camps, with a view to co-ordinating the work of the military and civil sanitary officials.

Dr. Jones believed that, bearing in mind the timely action of the Local Government Board on the one hand, and the Army Council on the other, there was a probability that the co-operation between civil and military authorities will in future be on a satisfactory footing. Medical officers of health, however, must, he said, remember that they are merely advisers.

It may not be possible, he continued, to act upon the advice given for military reasons, however correct it may be from a sanitary point of view. This aspect of the duties of a sanitary adviser is too often overlooked by medical officers of health, and may account to some extent for the reluctance of certain military officers to consult them. The recommendations of the medical officer of health must be reasonable, and when he is considering their reasonableness he must be guided, not by ordinary civil conditions, but by the special military circumstances prevailing at the time.

Future of the Civil and Military Sanitary Services.

I now come to the question of the future development of a civil sanitary service, which shall be closely associated, when necessity arises, with the military service. It has been suggested in some quarters that the existing *a la suite* corps should be reorganized, but that its members should be drawn exclusively from the ranks of the medical officers of health of counties and county and metropolitan boroughs, each one of whom should be given a commission. The fatal objection to this proposal is that among the fourteen sanitary officers of the Territorial divisions ten are medical officers of health of those districts, and they are certainly better employed than they would be in the *a la suite* service. A better plan, in my opinion, would be to reorganize the service on a geographical basis, and no longer restrict the duties of the officers to the areas of their civil activities. In this way there would be comparatively little upheaval of, or alteration in, the scheme as propounded to us by Sir Alfred Keogh, and those members of the service who are not medical officers of health of counties but who have in the past few years been paying particular attention to the duties likely to fall upon them on mobilization would be retained in the service to the advantage of the troops.

There is another direction in which it appears to me the public health service, and especially the whole-time members of the service, might be more closely associated with the Territorial Force than is at present the case. In the term public health service I include not only medical officers of health, both chiefs and assistants, but also school medical officers, assistant school medical officers, and tuberculosis officers. The R.A.M.C.(T.F.) includes nearly a thousand medical practitioners, the majority of whom are in private practice. They have to make large sacrifices both of leisure and of money in order to make themselves proficient in their military duties, and at a time such as the present, when the whole Territorial Force is mobilized, there must be considerable dislocation of practices all over the country through the absence of practitioners on military duty. There would, however, be a minimum of disarrangement if the officers of the R.A.M.C.(T.F.) were largely recruited, as I think they should be, from the whole-time public health service. In the case of medical officers of health two or more districts could be placed temporarily under the charge of one officer, who on account of age or for some other justifiable reason was not connected with the Territorial Force. The work of whole-time school medical officers, or of their assistants, and of tuberculosis officers could be carried on temporarily by private practitioners, an arrangement adopted in some districts at the present time, which has in it the elements of simplicity and success. I cannot help referring to the advantage it would have been to us had there been in operation in the past years the scheme of superannuation so long advocated by this Society. We should by now have had available a reserve of public health officials ready to return for a time to their former duties, and so release junior members of the service for active military duty.

THE LOCAL GOVERNMENT BOARD.

Mr. Herbert Lewis, Parliamentary Secretary to the Local Government Board, speaking last Monday at Buckley, in Flintshire, which county he represents in Parliament, said that, speaking generally, the health of the troops in the United Kingdom, including recruits, was excellent. One of the greatest dangers to be apprehended from the massing together of a large number of men, for whom temporary provision had to be made, was, he said, the spread of typhoid fever. He was therefore glad to be able to state that, out of some 600,000 men, only 5 cases had been notified in the week ending September 26th, 12 cases for the following week, and 10 cases for the week ending October 10th. This reflected the highest credit upon the sanitary arrangements made by the Army Medical Department, which was the responsible authority. The Local Government Board had lent the whole-time services of twelve of its medical inspectors for the purpose of co-ordinating the work of local sanitary authorities and of the military authorities of the camps. Medical officers of health and sanitary inspectors throughout the country were also giving the benefit of their local experience. A system of inspection of all camps and other military premises by these civil

officers had been arranged, and there was no doubt that this would ensure that any earlier defects, which might have been associated with the inauguration of immense new arrangements, would rapidly disappear. There was the closest and most cordial co-operation between the civil and military authorities. No doubt there would be further dangers to guard against, and it was likely that, with the advance of time, sickness arising out of the continued occupation of camps might increase; but, with the hearty co-operation of the civil and military authorities, there was every reason to be confident that disease would be kept within the narrowest possible limits.

SANITATION OF CAMPS.

An American View.

Our attention has been drawn to an address delivered at the annual meeting of the Medical Society of the State of California four years ago (June, 1910) by the president, Dr. James H. Parkinson (Sacramento). The title of the address was "The Physician in his Relation to Public Life," and it was concerned largely with the contrast between the results obtained by Japan in the prevention of disease among her troops during the Russo-Japanese war, and the results in the campaign of the British in South Africa, and the expedition of the United States to the West Indies (Cuban war). There was, he said, little to choose between the achievements of the Anglo-Saxon race, and less to be proud of. He discussed the disease record of the United States camps during the Cuban war, a subject of which we gave some account a few weeks ago (September 19th, p. 510). "If," he said, "the results on battlefields were disastrous from the modern standpoint, what can be said of the ghastly record of the reserve camps? Here were normal healthy young men assembled in peaceful camps in their own country to fall victims by thousands to a preventable disease." "Was it," he asked, "possible to imagine such results happening in any American city with a fairly equipped health department as lay at the door of the Medical Department of the United States Army, regular and volunteer?" "Far be it from me," he said, "to question the character and attainments of the medical corps of the United States Army; its personnel is of the highest. It is the fault of the system, not of the profession." It must rest, therefore, with the profession to remedy the system, by insisting upon the control of purely medical considerations being placed in the hands of those who understood their far-reaching and life-saving results.

"With all our progress in the healing art," Dr. Parkinson went on, "the opprobrium of centuries still remained; disease and pestilence slew more than the bullets of the enemy. This patent and obvious fact stands forth on army records everywhere, yet with its very obviousness, why could not the lesson be learnt? It was not the bullets of the enemy that decimated the armies; it was the bacilli of disease. At times his brigades worked havoc with the ranks, but the bacteria of pathogenic processes conducted a twenty-four hour campaign on every day of the year. How are these ravages to be met? By the trained medical officer, who can give force to his knowledge in an authoritative order."

Dr. Parkinson was Chairman of the State Board of Health at Sacramento when the earthquake at San Francisco occurred, and as the two cities are only ninety miles apart it was at once realized that a large number of unfortunate persons, many of them in a destitute condition, would reach Sacramento. A relief committee was instantly formed and raised 50,000 dols. in an hour, and the Board of Health at a special meeting agreed to work with the relief committee. A refugee camp was organized at head quarters with a medical man and trained nurse in charge, while the general administration was turned over to one of the inspectors of the board who had seen service, and held the rank of colonel in the State militia. The result was complete success; all relief demands were promptly met, and more than one-third of the relief fund was returned to the subscribers. The success was undoubtedly due to the fact that there was in existence an organization dealing with public health work and familiar with preventive medicine, and that this organization was given ample funds and ample authority to carry out what was considered essential to attain this end.

We would venture to invite those who have not had the opportunity to read Dr. Livingston Seaman's work on *The Real Triumph of Japan and the Conquest of the Silent Foe* (1906) to do so, as a further testimony that the American view supports the opinions expressed in recent issues of this Journal in connexion with the health of our New Army and Territorial Forces.

THE BRITISH RED CROSS SOCIETY.

Reception of Wounded at the Ports.

A new departure has been made by the British Red Cross Society in its work of supplementing the military provision for the sick and wounded. When a large number of wounded are landed at an English port the task of transferring them to the trains is no light one, and often severely taxes the available R.A.M.C. staff. A staff of six surgeons and a number of nurses is now maintained at head quarters in 83, Pall Mall, ready to be dispatched at a moment's notice to Southampton, Harwich, or any port where the wounded are being landed in large numbers. The work done in this way has already proved of the greatest value.

Change of Base in France.

Owing to the desire not to concentrate the wounded in large numbers in Paris, the military authorities are sending patients further north, and the British Red Cross head quarters have been moved from Paris to Boulogne. The removal of hospitals or the setting up of new ones in the more northerly area may be shortly expected.

The Supply of Trained Nurses.

Sir Frederick Treves informs us that rumours are abroad that sick and wounded British soldiers are being nursed by unqualified nurses, and he emphatically repeats that no women are engaged by the Red Cross Society as nurses except those who are fully trained hospital nurses with a three years' certificate. The statement that there is a shortage of trained nurses is untrue as far as Red Cross work is concerned, whatever may be the case in civil affairs. The Society has received considerable accessions to the roll, and still has 1,500 fully trained nurses on its waiting list. In addition, there is a reserve consisting of a large number of nuns, who have had a complete hospital training, but who have not yet been called upon. There is an ample supply of fully trained nurses for all the wounded who are likely to reach this country or are under treatment abroad.

The following letter emphasizing this point has been received by the Medical Secretary of the British Medical Association:

British Red Cross Society.
83, Pall Mall, London, S.W.,
October 19th, 1914.

Sir,—It has been brought to the notice of the Committee of the British Red Cross Society that doctors in various parts of the country are complaining that wounded soldiers are, as they allege, being nursed by members of Voluntary Aid Detachments who are not fully trained and certificated nurses.

On behalf of this Society I desire to point out that no offer of hospital accommodation which has been submitted to us, and has been approved of by the military authorities, is ever accepted unless fully trained and certificated nurses are in charge. In these hospitals the services of Voluntary Aid Detachments are utilized as probationers, cooks, and in other general ways.

If hospitals are started and utilized by the military authorities without reference to this Society, the doctor who is asked to take medical charge should, if he finds lack of skilled nurses, apply to the authority responsible for starting such a hospital.

I may mention that we have upon our books the names of some 1,500 trained and fully certificated nurses whose services could be called upon at any time in case of need, and without expense to the hospitals for which they are required.

I am, yours obediently,
Arthur Stanley,
Chairman of Executive Committee.

Pressure of Work in France.

The personnel of a large ambulance train in France is now being got ready. Twelve dressers have been sent to Boulogne, and surgeons have been sent to Biarritz and Dinant to relieve the pressure of work at those centres.

The Red Cross Hospital at Netley.

The British Red Cross Hospital at Netley has been supplied with full equipment for 500 patients, and is now open.

Enormous quantities of stores continue to be sent out. During the week as many as 100,000 garments were dispatched. The total number of motor ambulances promised has now reached 458.

Scottish Motor Ambulances.

The Scottish branch of the British Red Cross Society shipped four motor ambulances and three transports from Glasgow to France on October 15th. Two, the cost of which has been defrayed by public subscription, are named "Lord Lister" and "James Young Simpson." The third, presented by a Glasgow merchant, is called "The Glesca Keelie"; while the fourth, the cost of which has been defrayed by the women of Selkirk, has been named "The Selkirk Car." Mr. T. Craig-Brown, a former provost of Selkirk, has given £400 to provide another ambulance motor car to be called the "Ettrick Forest Car," on the understanding that at the end of the war one of the two cars shall be given to the burgh of Selkirk to be used for the county burgh and the immediate neighbourhood.

ST. JOHN AMBULANCE ASSOCIATION.

HIDDEN from observation in a district of large warehouses and factories, the picturesque mediaeval head quarters of the St. John Ambulance Association in Clerkenwell are the centre of much activity at the present time. Upon the outbreak of hostilities the association was able to render valuable service in supplying trained orderlies. Having been in existence for more than forty years and having issued certificates to a million people practised in first aid the association was able effectively to meet the demand. There were over 20,000 volunteers for the first 4,000 positions as orderlies in hospitals near the fighting line, at the base, or in various parts of England and France, which were filled through the association's organization. In all 5,000 orderlies were supplied. Reports from the front note with admiration the work of St. John Ambulance orderlies at the hospitals. Many of them are drawn from Lancashire and Cheshire; they look rather rough fellows (it is said), but the gentleness of touch and consideration they show, as well as their great strength, make them ideal ambulance men. Some are miners, and experience in pit accidents has served them in good stead. The association has supplied 44,000 men's garments and many tons of medical stores and supplies. The whole of the supply of medical stores and comforts for the Indian contingent is in the hands of the association, and many small hospitals established in buildings privately lent, have been organized and their staffs provided. No nurse has been sent out who has not had a three years' certificate. Marconi House, Strand, has been lent to the association for the purpose of organizing a fund to which regular contributions from the less well-to-do will be invited.

DUBLIN.

Under the auspices of the St. John Ambulance Brigade, a lecture was delivered in the Lecture Theatre of the Royal Dublin Society last week by Dr. Conway Dwyer, President of the Royal College of Surgeons, Ireland, on the treatment of wounds, more especially those received in action. He paid a special tribute to the zealous and intelligent manner in which not only the ladies of Dublin, but those in every part of Ireland, had been attending the various lectures and ambulance classes arranged by the St. John Ambulance Brigade. This attendance and interest was most admirable, and had brought to light energies that, in less strenuous times, might have remained dormant. Dr. Dwyer then said that wounds might be classified as infected and non-infected, and indicated the general principles of treatment. At the close of the lecture Dr. Lumsden announced that Ireland had been made an official district of the St. John Ambulance Brigade, with head quarters at his house, 4, Fitzwilliam Place, and that he would act as Deputy Commissioner.

THE HOME HOSPITALS AND THE WAR.

4TH NORTHERN GENERAL HOSPITAL, LINCOLN.

As was mentioned in the JOURNAL of August 15th, p. 339, the 4th Northern General Hospital was mobilized on August 5th. The first patient was admitted on August 18th, and since then there have been admitted 602 from the home troops, 213 from the expeditionary forces, and 216 Belgian wounded and sick, a total of 1,031 patients. On October 19th there were under treatment 159 from the home troops, 111 from the expeditionary force, and 216 Belgians, a total of 486, of whom about 100 are in the various convalescent homes connected with the hospital. The operations performed under a general anaesthetic number 56, and 29 of these were for damage caused by shrapnel and rifle bullets, of which the former largely preponderated, rendering necessary in 2 cases amputation of the leg and of the forearm respectively. Badly united fractures necessitated wiring the olecranon in one case and the forearm in another. Three cases of appendicular abscess have been operated on, and operations have been done for radical cure of hernia, varicose veins, cervical abscess, haemorrhoids, and loose cartilage of knee-joint. The mastoid operation has also been required, and among the others were operations in eye cases and amputations of toes and fingers.

There have been five deaths due to pneumonia, and one to tetanus after removal of a large piece of shrapnel shell from the thigh. The fifth was due to mastoid disease; the patient, who died four days after the operation, was in a very critical condition when admitted.

A number of venereal cases have been under treatment, amounting at one time to over sixty, but these are now being attended to elsewhere. Two cases of typhoid fever were transferred to the City Hospital, and there have been many cases of pneumonia. They have all occurred amongst the home troops.

The surgical cases have necessitated the taking of nearly 200 *x*-ray photographs. Most of the wounds were in a septic condition, and in many the bones were smashed up by shrapnel shell or bullet, and amputation seemed inevitable, but rest, food, and drainage of the wound worked marvels, and the men were soon able to be up and about.

In many of the cases of rifle bullet wounds in close proximity to important nerves acute neuralgic pains occurred sooner or later below the seat of injury. They lasted for a day or two, and were considered to be the reaction from nerve concussion.

The case of tetanus for a time seemed to respond to the treatment by the injection of antitetanic serum. Many of the cases were of great interest, especially one of shrapnel wound in the centre of the forehead; when the depressed inner plate of the frontal bone was partly elevated and partly removed, nearly two ounces of blood clot and broken down brain matter escaped; a drainage tube was passed backwards beneath the cerebrum for over four inches. The patient is making an excellent recovery.

The Belgian cases were in a pitiable condition—in some the wounds had not been dressed for three weeks; although it was after midnight when the last of them were warded, all the wounded needed immediate dressing. These cases were only admitted on October 16th, but many of them will soon be going to convalescent homes.

ST. GEORGE'S HOSPITAL.

St. George's Hospital has offered accommodation for fifty sick and wounded, and a first batch of twenty-eight was received recently. Of these four are medical cases—including a man who received a bullet wound in the liver. The remainder consist to a great extent of wounds of the arms, caused in a majority of cases by shrapnel. There are also several sufferers from injuries not the result of fighting—for example, a crushed hand, fractured shoulder, and septic thumb.

The arrangements at St. George's Hospital were at first somewhat disturbed, because a message was received from the War Office to prepare to receive fifty cases, and then a fortnight elapsed before any patients arrived, only twenty-eight being sent even then. Now, however, two wards have been shut off from the others to serve as a military unit, and here accommodation is available for fifty soldiers under conditions and rules varying from those prevailing in the hospital as a whole. The men have special diet, are given greater freedom as to visitors, and are allowed to smoke. Most of them are nearly recovered, but as they are under military regulations they remain at the hospital. For military purposes St. George's is a

branch of Queen Alexandra's Hospital, Millbank. Probably because of its prominent position at Hyde Park Corner the hospital has received a great many presents of fruit, games, and tobacco for the soldier patients, and offers of motor car drives in the park. A supply of tobacco sufficient for fifty men for six months has been guaranteed, and arrangements will be made if St. George's gets an overplus of good things to share with other institutes less fortunately situated.

Fifty beds at the convalescent home at Wimbledon have also been placed at the disposal of the authorities, and by drafting patients there it is hoped that 100 soldiers will be receiving the benefits of St. George's Hospital at one time.

Royal National Orthopaedic Hospital.

Seventy-nine wounded soldiers from Antwerp were received at this hospital last week, the majority being Belgians. Although the army medical authorities do not appear to have made a special selection of the cases, it so happened that many were fractures of the foot or leg. One or two men had bad smashes of the arm; one had comminuted fracture of the humerus. The wounds were remarkably clean and are doing extremely well. A man whose arm was amputated by a woman surgeon at Ostend is doing well. Several patients have been discharged already. In a few cases bullets have still to be extracted. Some of the Belgians have evidently undergone severe hardships; one man, who was at Liége, has hallucinations. There are no cases of tetanus; on the medical side are sufferers from sciatica, rheumatism, and bronchitis.

Edinburgh.

On October 17th a hundred wounded soldiers were admitted to the Edinburgh Royal Infirmary. They came up by special train, and through the exertions of the British Red Cross Society, were all in bed within an hour of their arrival, as Dr. McKenzie Johnston was able to inform the managers of the institution at their meeting on October 19th. In doing so he paid a tribute to the Edinburgh Red Cross staff and to the work done by the staff of the infirmary in preparing at rather short notice for the latest influx. The Red Cross, he said, removed both parties of men comfortably and expeditiously, and actually brought the patients to the places allocated to them in the wards. When they removed the 100 men from the special train everything went like clockwork, and the men were all in bed within an hour after the arrival of the train. The men were drawn from various regiments at the front —from the 2nd and 3rd Royal Scots, from the 2nd and 3rd K.O.S.B., from the 1st Gordon Highlanders, from the R.F.A., and from a considerable number of English and Irish infantry regiments.

About 170 sick and injured sailors arrived at South Queensferry on October 14th, most of whom were taken to the Royal Naval Hospital there, but some were sent to the Royal Infirmary at Edinburgh. Another large detachment of ninety wounded soldiers arrived at Edinburgh early on the morning of October 19th, and were taken to the Craigleith Military Hospital, where they were received by Sir Joseph Fayrer, the commanding officer, by Lieutenant-Colonel Cotterill, the senior surgeon, and by Major J. D. Comrie, the senior medical officer. They were drawn from a great variety of regiments.

In a Country House Hospital.

H. S. C. writes under date October 17th: It was my privilege to visit yesterday one of the many mansions of this county (Hampshire) which have been converted into military hospitals, and to be present at four operations done by a surgeon of the local Cottage Hospital. It is with pride and pleasure that I feel myself able to praise everything I saw. The admirably adapted wards and offices—luxurious beds and other fittings, the capable staff of professional nurses and the intelligence and usefulness of the Red Cross auxiliary helpers, while the technique of the operations was in my judgement without flaw.

To write such pleasant words would not be an excuse for sending you this letter, but at the close of the operations —all of which were for extraction of bullet or shell fragment—I found myself calling to memory the operations of extraction of bullets and the like which were done by me while still on the staff of a London hospital. The cases were neither brilliant nor numerous; the only use I can make of them is to express the following opinions:

1. Even when the foreign body can be localized without *x* rays, these should always be employed because it may be fragmented, or bone splinters may be present and require removal.

2. Fallacies of screen and pictures may be guarded against in many cases by a consideration of physical and rational signs.

3. A single *x*-ray picture by itself is not a guide but a dangerous misguide in most cases.

4. The presence of a colleague at the operation, unless he has seen the case under the screen, cannot relieve the operator from any part of the responsibility. It is unwise to operate without the *x*-ray apparatus and without the presence of someone acquainted with its working. Indeed, the *x*-ray expert is almost a necessary assistant.

SIR JOHN FRENCH'S DISPATCHES.

Sixty-six medical officers are mentioned in Sir John French's dispatches of September 17th and October 8th, dealing with the operations of the Expeditionary Force from August 28th to October 8th. In concluding his dispatch Sir John French wrote:

The fact that between the 12th September to the date of this dispatch the total numbers of killed, wounded, and missing reached the figures amounting to 561 officers, 12,980 men, proves the severity of the struggle.

The tax on the endurance of the troops was further increased by the heavy rain and cold which prevailed for some ten or twelve days of this trying time.

The battle of the Aisne has once more demonstrated the splendid spirit, gallantry, and devotion which animates the officers and men of His Majesty's forces.

The following are the names of the medical officers mentioned:

General Head Quarters Staff.

Surgeon-General T. P. Woodhouse.

Colonels E. H. L. Lynden-Bell, T. J. O'Donnell, D.S.O., H. S. Hickson, R. Porter, and R. H. S. Sawyer.

Lieutenant-Colonels J. H. Barefoot, W. W. O. Beveridge, D.S.O., S. F. Clark, G. Cree, C. Dalton (killed), J. J. Russell.

Majors M. H. Babington, E. A. Bourke, B. B. Burke, A. Chopping, S. L. Cummins, M. H. G. Fell, J. V. Forrest, J. S. Gallie, G. A. Moore, C. D. Myles, E. Ryan, E. B. Steel, F. A. Symonds, A. H. Waring, A. L. A. Webb, A. B. Smallman.

Captain A. C. Amy.

Also Principal Matron Miss E. M. McCarthy.

Regiments.

1st Battalion Irish Guards, Lieutenant H. J. S. Shields, R.A.M.C.

3rd Battalion Coldstream Guards, Lieutenant J. L. Huggan, R.A.M.C. (killed).

1st Battalion Northumberland Fusiliers, Captain M. Leckie, R.A.M.C.

1st Battalion Lincoln Regiment, Captain G. A. Kempthorne, R.A.M.C.

1st Battalion King's Royal Rifle Corps, Captain H. S. Ranken, R.A.M.C. (killed).

2nd Battalion Royal Irish Rifles, Captain S. E. Lewis, R.A.M.C.

Royal Army Medical Corps.

Lieutenant-Colonels L. A. Mitchell, J. C. Morgan.

Majors E. T. F. Birrell, S. G. Butler, R. V. Cowey, H. Ensor, D.S.O., T. E. Fielding, R. L. V. Foster, T. H. J. C. Goodwin, D.S.O., J. Grech, H. A. Hinge, O. W. Lloyd, C. W. Profeit.

Captains E. D. Caddell, E. B. Lathbury, J. T. McEntire, J. F. Murphy (Special Reserve), W. M. Nimmo (attached 1st Battalion, Loyal North Lancs. Regiment), C. P. O'Brien-Butler (attached 5th Lancers), A. C. Osburn, F. C. Sampson, H. Stewart, G. W. W. Ware.

Lieutenants L. G. Bourdillon, R. V. Dolbey, C. Hairsine (Special Reserve), C. Helm, H. L. Hopkins (Civil Surgeon), W. M. Howells, R. A. Preston, W. Wyler (Civil Surgeon).

NOTES

OVERSEAS DOMINIONS.

CANADA.

[From our Correspondent.]

The McGill Regiment.

A regiment is being recruited from the students and graduates of McGill University; the organization is proceeding rapidly under the direction of Dr. Geddes, and already over 300 are in training. McGill has had a contingent of the Canadian Officers' Training Corps for three

years, and five men from it have already received commissions in the British army. It is the intention that the contingent now being recruited shall consist of 500 men, and shall be attached to one of the British regiments and commanded by an officer of the British army. The necessary funds are to be raised by the Graduates' Society, which is prepared also to issue from time to time statements concerning the war, with the object of encouraging graduates to take some active part in assisting the Motherland, by themselves volunteering, by giving financial assistance, or by public speaking.

Canadian Hospitals in Paris.

It is announced that the French Government has accepted the offer made by the Canadian Government to give $100,000 towards a hospital in Paris, to be known as the "Hospice Canadien." A fund for the relief of Belgian refugees has been opened, and up to the present the contributions amount to $101,794.50. Clothing and foodstuffs have also been given.

The municipalities in the province of Quebec are contributing towards the maintenance of a hospital which has been established and equipped at the Rue de la Chaise, Paris, and which bears the military number 47. Each bed will cost about 5 francs a day, and, on the basis that the hospital will be required for five months, each municipality is asked to contribute 750 francs. It is the intention that each bed shall bear the name of the parish that contributed towards its maintenance. A sufficient sum has already been subscribed to maintain 15 beds for the period mentioned, and it is probable that the Quebec Government will give 10,000 dollars for the maintenance of a complete ward of about 70 beds with attendants, the ward to be named the Provincial Government of Quebec Ward.

The Expeditionary Force.

The first Canadian expeditionary force left Quebec recently. Arrangements are already being made for a second contingent of 22,000 troops, 2,000 being intended to fill vacancies. It is probable that these troops will not be trained at Valcartier, as the severe weather is coming on, but will be mobilized in sections in the various military districts, and will come together at the point of embarkation.

Medical Students on Active Service.

The McGill University is prepared to give students who go to the front every consideration both as to fees and time allowance, and in the case of medical students credit will be given for clinical experience gained on active service. Similar action was taken at a recent meeting of the Quebec College of Physicians and Surgeons, when it was decided to allow students in their final year of medicine to be exempted from study while on active service, the time to count as though they were attending regular college duties. It was resolved also that $1,000 should be given to the Patriotic Fund, which now amounts almost to five million dollars.

The late Colonel J. H. Burland.

The announcement of the death of Colonel Jeffrey Hale Burland has been received with the greatest regret in Canada. Colonel Burland left Montreal, apparently in good health, on September 28th last, to direct the work of the Canadian Red Cross in England and at the front. His death from angina pectoris occurred in London on Friday, October 9th. Colonel Burland was born in Montreal on March 19th, 1861; he was educated at the Montreal Academy and at McGill University, where he graduated in science in 1882. Closely identified with the business life of Montreal, devoted to all manner of charitable and philanthropic work, Colonel Burland was a man of great activity. He was in command of the 6th Fusiliers, and was president of the Dominion Rifle Association, but still found time to take an active part in the campaign against tuberculosis, and was one of the founders of the King Edward Institute. For several years he was closely connected with the work of the Red Cross, and it was due to his efforts that the Quebec branch of the society was established in 1912. In short, Colonel Burland was a man of boundless energy and enthusiasm, a splendid organizer, and a generous giver; he was held in the highest esteem by rich and poor alike, and his loss will be very keenly felt.

Attendance on Dependants: Interests of Practitioners with the Colours.

The members of the Montreal Medico-Chirurgical Society have decided to give to the Red Cross Society the sums usually expended in supplying tobacco at their smoking concerts, and members are requested to bring their own smoking materials. It was resolved, also, that members should give their services free to the dependants of those who have gone to the front, and it was decided that each member should attend to such cases within his own district. It was further agreed that members who had volunteered for active service should be exempted from the dues payable to the society, but that their names should be retained on the membership list.

Throughout the country the profession has expressed itself willing to protect in every way possible the interests of medical men who have volunteered for active service, and to look after their practices during their absence. It is also prepared to give medical aid free of charge to the dependants of those who have gone to the front.

Queen's Canadian Military Hospital.

Canadians resident in this country and on the other side of the Atlantic have combined to equip a hospital for the wounded, which, by permission of Her Majesty, is known as the Queen's Canadian Military Hospital. It is situated at Beachborough House, two miles from Shorncliffe, which has been lent by Sir Arthur Markham, Bart., M.P. The hospital has been organized by the Canadian War Contingent Association, and does not form part of the military scheme of hospitals in connexion with the Canadian contingent, of which particulars have already appeared in our pages. While it is hoped that as often as possible Canadians will be drafted to the hospital, the establishment has been placed unreservedly at the disposal of the War Office, by whom it has been approved. Sir Arthur and Lady Markham have given up the whole of their house for the purposes of the hospital. The largest apartment contains 10 beds, and the total accommodation is 60. In addition they have presented a complete *x*-ray apparatus and two motor ambulances.

The staff of the hospital is as follows: Principal physician, Sir William Osler; principal surgeon, Mr. Donald Armour; assistants, Dr. Fraser and Dr. Wallace; principal nurse, Miss Macmahon. The whole of the nursing staff is composed of Canadians; Lady Markham is the superintendent of the commissariat. Subscriptions already promised amount to upwards of £17,000, and Canadians and others interested are asked to communicate with the treasurer at the Bank of Montreal, Threadneedle Street, E.C. The Canadian War Contingent Association, in co-operation with the Canadian Y.M.C.A., also has in hand arrangements for the comfort of the troops from Canada now in training in this country.

At present the hospital is filled with wounded from Antwerp, principally officers and men of the Belgian army. Mr. Donald Armour kindly gave a representative of the JOURNAL some particulars of these cases. Many of the wounded had been almost constantly under active service conditions since the outbreak of war, and the effects of the terrible strain they had undergone were plainly visible. There were one or two heart cases and all were suffering from severe exhaustion. It seemed as though their wounds were not, in many cases, the chief concern of the men. More than anything, they wanted food and rest and to be quiet, away from the sound of firing. The condition of those suffering from bullet wounds confirmed the experience of the South African war as to the small extent of the injury done by the penetrating bullet as compared with the effects of shrapnel. Two men had bullet wounds through the lungs, but they seemed none the worse. Bad wounds were usually the result of shrapnel. One man was hit by a bullet just below the clavicle; it did not touch any vessels or nerves, went through the lung, and came out in the middle of the scapula. The wound of entrance was open, but the wound of exit had healed. Most of the wounds were septic. Some of the cases had already received attention in an Antwerp hospital and were removed before the entry of the enemy.

INDIA.

The *Pioneer Mail* of September 25th, received by the last Indian mail, gives the names of the medical staff

selected for the hospital ship presented by Madras. The vessel chosen is the British-India liner *Teuda*, a new twin-screw boat of nearly 7,000 tons. Lieutenant-Colonel G. G. Giffard, in medical charge, joined the Indian Medical Service on March 31st, 1890. He holds the M.R.C.P.Lond., and is Professor of Midwifery and Principal of the Madras Medical College. He received the C.S.I. on June 3rd, 1913. Major T. H. Symons entered on January 29th, 1896; he is Professor of Anatomy in the Medical College and second surgeon of Madras General Hospital. Major Diwan Ganpat Rai, a Punjabi by birth, entered on January 29th, 1902; he is district sanitary and medical officer of Nellore. Captain E. W. C. Bradfield joined on August 31st, 1903. He is an M.B.Lond. and F.R.C.S.Edin., was recently medical officer of the 31st Lancers, and is now third surgeon of Madras General Hospital. Captain Scott, the most junior, is surgeon to the Governor of Madras. The sixth, the Hon. Dr. T. M. Nair, is a private practitioner of reputation in Madras, better known, perhaps, as a public man than as a doctor, a member of the Madras Municipality and of the Madras Council. He served on the Indian Factory Commission in 1909.

Gift of Motor Ambulance by London Panel Practitioners.

The motor ambulance presented by the practitioners on the panel in the County of London was handed over to the British Red Cross Society on October 20th and will be sent to France for use in bringing wounded soldiers from the front to the base hospitals. The chassis of the ambulance is a 1915 model, 25-h.p. Berliet. The ambulance body, which is of the pattern approved by the British Red Cross Society, is capable of accommodating four persons lying down, or two lying down and six sitting, or twelve sitting. A special point about the body is the speed and efficiency with which it can be loaded. It has a door in the front and a narrow gangway between the tiers of stretchers which permit the attendant not only to assist in loading and unloading, but to give assistance to the wounded without having to stop the vehicle. The ambulance will form one of a number of ambulances which will parade at Regent's Park on Saturday next at 3 p.m., when detachments of the City of London Branch of the British Red Cross Society will assemble under the command of Colonel P. Broome Giles, C.B.

A Gift from Oxford.

Immediately after the publication, in the British Medical Journal of October 3rd, of the appeal by Sir Frederick Treves for motor ambulances for use in France, when he stated that no greater service could be done to our wounded troops than by the provision of motor ambulances, a circular letter was issued by Sir William Osler and Dr. William Collier of Oxford, to a few friends, which resulted in the receipt of over £500 in three days. A more public appeal was then made; over £1,200 has been received, and at least two well-equipped motor ambulances are being sent to the front. This ought to be a good example to other towns; probably there are many people who would be more willing to give to a local fund than to a general one.

CASUALTIES.

Royal Navy.

The Loss of the Hawke.

By the sinking of the cruiser *Hawke*, by a submarine, on October 15th, over 400 lives were lost, only some 70 being saved. The *Hawke*, it will be remembered, was in collision with the White Star liner *Olympic* in the Solent on September 20th, 1911. Among those lost, all three of her medical officers appear to be included.

Staff Surgeon George Charles Cumberland Ross was educated at Trinity College, Dublin, where he took the B.A. in 1897, the M.B., B.Ch., and B.A.O. in 1899. He entered the navy in 1901, became staff surgeon on August 11th, 1909, and joined the *Hawke* on August 1st last.

Surgeon Gustavus William Musgrave Custance was educated at St. Thomas's, took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1907, and entered the navy on May 12th, 1908, joining his ship on July 15th.

Temporary Surgeon James Henry Digby Watson was aged 23. He was the son of Engineer-Captain Watson, R.N., of Devonport Dockyard, and was educated at Edinburgh Academy, King's School, Canterbury, Edinburgh University, and the London Hospital; he had only recently qualified, joining the navy and the *Hawke* in August last. He was well known as a Rugby international football player, representing London Hospital and Blackheath, and specially distinguished himself playing three-quarter back for England in last year's international matches.

Surgeon B. A. Playne (temporary), R.N., 3rd Battalion (*Hawke*) 1st Brigade, is among the officers interned in Holland.

Army.

Prisoners of War.

Cahill, Captain R. J., R.A.M.C. (previously reported missing).
Thompson, Captain W. I., R.A.M.C. (previously reported missing).

Missing.

Fraser, Captain A. D., R.A.M.C.
Captain T. B. Moriarty, R.A.M.C., previously reported missing, has now rejoined.

Mr. F. F. Burghard, surgeon to King's College Hospital, London, has been appointed consulting surgeon with the British Forces overseas, and has already left for France.

Universities and Colleges.

UNIVERSITY OF EDINBURGH.

Graduation Ceremony.

The winter graduation ceremony in Edinburgh University has been remarkable for its quietness, and for the small attendance both of undergraduates and general public. The shadow of the great war has fallen on it, and dashed the usual rather too exuberant spirits of the students. It took place on October 16th in the McEwan Hall. Principal Sir William Turner was in the chair. After the presentation of the graduates in law, medicine, arts, and science, he said that he was happy to see that among them there were several who had already assumed the King's colours, who had already taken upon themselves duties which were additional to those of their degrees because they had pledged themselves to do honour to their country in the great contest that was now going on. There were among them several who had not as yet assumed the King's uniform but whose intention it was to do so; and when the time came—which he hoped would be a happy time for them—they would look to them also to go through the new duties imposed upon them, doing honour to the university of which they had become graduates. To all of them, graduates of both sexes, he heartily wished—and his colleagues joined him in the wish—success in their respective careers. The assembly then united in the singing of the National Anthem.

The following is the list of the graduates in Medicine (M.B. and Ch.B.):

C. W. Aikman, J. G. Anderson, T. H. S. Bell, P. N. Berry, T. C. Britton, E. L. G. Brodziak, W. T. Buchan, P. W. Carruthers, F. C. Chandler, J. S. Crichton, J. Dale, D. J. Danth, J. Dunlop, W. F. Dunlop, H. H. Gellert, D. C. Graham, W. W. Hallehureh, F. W. Hird, S. C. Huddlestone (*in absentia*), M. P. Inglis, L. F. E. Jeffcoat, L. Lappin, G. MacL. Levack, J. Loftus, E. W Louw, P. T. T. Macdonald, W. H. M'Granahan, F. G. Milne, W. W. Phillips, A. R. Ross, H. P. Rudolf, A. H. Shaikh, C. H. K. Smith, P. A. Strasheim, S. W. H. Stuart, K. A. M. Tomory, J. M. Verster, G. T. van der Vijver, J. F. van der Westhuijzen, H. W. Weir, J. A. Young.

Kavalam Padmanabha Panikkar, M.B., Ch.B., obtained the Diploma in Tropical Medicine and Hygiene.

German Lecturers.

In connexion with the action taken by the university authorities some weeks ago (vide Journal, p. 523, for September 19th), we learn that Dr. Otto Schlapp, University Lecturer on the German Language, Literature, and Teutonic Philology, being now a naturalized British subject, is continuing his teaching work, whilst the resignation of Dr. W. Cramer, Lecturer on Chemical Physiology, has been accepted. At the same time, we understand that the latter gentleman has either received, or is just about to receive, letters of naturalization.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

At the annual stated meeting of the President and Fellows of the Royal College of Physicians of Ireland, held on Monday, October 19th, the Morrow of St. Luke's Day, the following officers were elected for the coming year:

President.—Dr. E. MacDowel Cosgrave.
Vice-President.—Dr. Joseph O'Carroll.
Censors.—Dr. J. O'Carroll, Dr. S. T. Gordon, Dr. S. C. Drury, Dr. Gibbon Fitz-Gibbon.
Representative on the General Medical Council.—Sir John Moore.
Treasurer.—Dr. Bewlay.
Registrar.—Dr. Kirkpatrick.

Professor W. H. Thompson, M.D., of the School of Physic in Ireland, Trinity College, Dublin, was elected a Fellow of the College.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

WALES.

THE WELSH MILITARY HOSPITAL.

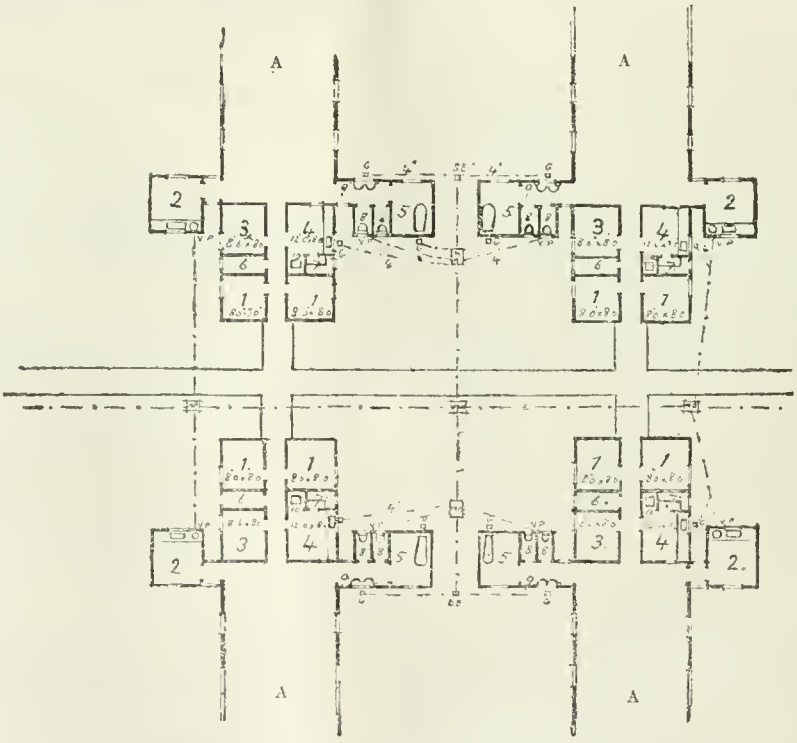
THE Welsh Hospital came into existence as the result of a public meeting held at Cardiff on August 11th, under the presidency of the Lord Mayor, Dr. Robinson. In response to the appeal for £25,000 signed by the Lord Mayor of Cardiff, and Sir W. J. Thomas, Honorary Treasurer of the Hospital, over £10,000 was subscribed in a week, and the total has now nearly been reached; £250 is regarded as endowing a bed to be named after the donor, and already there are 62 such endowed beds. All Wales has taken part in the movement, and many beds have been endowed from North Wales. Sir William James Thomas, always foremost in good works, endowed 10 beds, and other large subscribers are: Mr. David Davies, Llandinam (4 beds); the Earl of Plymouth (2 beds); and the Marquis of Bute (2 beds). Through the medium of the British Red Cross Society the hospital was offered on behalf of the Principality to the War Office, for service with the Expeditionary Force, by H.R.H. the Prince of Wales. The offer was accepted, and it was requested that the hospital should be located in the first place at Netley, to go overseas later when required.

It is situated on the recreation ground on the north side of the Royal Victoria Hospital, and will be ready to receive patients on October 26th.

The honorary architects are Messrs. E. T. and E. Stanley Hall of London, the architects of the Manchester Royal Infirmary and the Welsh National Memorial. The present hospital provides for 104 patients, but a further 100 beds can be added if required. The general plan of the hospital is shown in the sketch plan of its central part. The administration block is at the south end, and next in order is the residence for the medical staff. This consists of 11 rooms with a common room, lavatories, water closets, and bath rooms. Opposite this, on the west, are the quarters for sergeants and orderlies.

The theatre block, to the north of this, contains a theatre (20 ft. by 16 ft.) with an anaesthetizing room and sterilizing room, while an opposite building contains *x*-ray room, dark room, dispensary, and pathological laboratory. There are four long wards for 24 beds each, two single bed wards, a nurses' room, a pack store with cut-off annexes, a bath room and closets on one side and a nurses' sink room on the other.

Beyond the wards on the west are mess-rooms for the staff (male and female), and opposite these, on the east, the kitchen and general stores. Further north still is the residence of the matron and nurses on the west, and a separate residence for the maids on the east. At the northern extremity is a small laundry for casual use, the intention being that the general laundry work shall be done elsewhere. There is at the south-east end another small block containing the ambulance, the mortuary, and *post mortem* room, a workshop, and drying-room.



The Welsh Military Hospital, Netley.—1, Single-bed wards; 2, Sink room; 3, Pack store; 4, Nurse; 5, Bath; 6, Linen; 7, Larder; 8, W.c's.; 9, Lavatory; 10, Gas stove; A, Long wards for 24 beds.

The buildings are erected of timber framing covered with felt and iron outside and lined inside with asbestos sheeting which is of pleasing colour. The paintwork throughout the patients' and residential blocks is white internally; the exterior is being painted green. The floors generally, except that of the theatre block, are of wood. The fittings are complete in every respect. The buildings are lighted throughout by electricity and the heating and hot-water supplies are by gas.

The hospital is designed as a temporary building which could be removed if desired to France or elsewhere. The furniture and equipment could be packed up at short notice. The rooms have been kept as compact as possible, having regard to efficiency and the essentials of ventilation have been carefully considered.

The hospital was commenced on September 9th and will be completed by October 31st.

The total staff numbers forty-eight. The commanding officer and senior surgeon is Lieutenant-Colonel A. W. Sheen, R.A.M.C.(T.), surgeon to King Edward VII Hospital, Cardiff. The other medical officers are Mr. Fergus Armstrong, M.D.Edin., F.R.C.S. Edin., Mr. T. Garfield Evans, M.D. Lond., Mr. Sydney J. Rowlands, M.D. Liverp., and Mr. Bernard G. Klein, M.D.Oxon. The quartermaster is Mr. E. J. August. All these officers have been given temporary commissions in the Royal Army Medical Corps. Four senior medical students are engaged as dressers, and the rest of the male staff consists of a sergeant-major, two sergeants, and twelve orderlies. The matron is Miss M. Martin, who served with the Welsh Hospital in the South African war, and there are twelve nursing sisters, a housekeeper, and domestic staff.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

OPENING OF THE SESSION.

Royal Victoria Hospital, Belfast.

THE opening lecture of the present session was delivered by Dr. Fielden, principal anaesthetist to the hospital, on October 16th. The lecturer welcomed the students, and immediately proceeded to discuss the subject of his lecture, "Suggestion." He gave numerous illustrations from the physiology of everyday life. Tracing the history from early times, he then enlarged upon the views of Charcot and other more recent authorities, and showed that it was by no means the offspring of recent quackery, but was a means of treatment found not merely in the higher fiction but also in science. Hypnotism was suggestion to the subliminal consciousness, and its effects were different from suggestion to ordinary consciousness which was switched off in the patient and that of another switched on. A brief account of Christian Science, of Lourdes, of holy wells,

and healing places was given; all these deserved careful study on the part of the medical man, which would amply repay the work.

Royal College of Surgeons in Ireland.

The opening meeting of the winter session 1914–15 was held on October 15th in the Royal College of Surgeons, when the prizes were distributed by the President (Mr. F. Conway Dwyer). The President, in an address to the students, offered them a hearty welcome to the Medical School of the College. He admitted that the course of studies and the number and variety of the subjects was calculated to produce an impression of dismay: but the course was not so formidable as it looked, at the same time it made no allowance for slackness. He advised them to spend as much time as they could in the dissecting room, as any really useful knowledge of anatomy was only to be acquired if they made a proper use of their time there. He wished also to impress upon them the importance of attending to hospital work, as there was no other way of acquiring habits of observation, and that familiarity with the stigmata of disease which gave confidence and decision when confronted with disease in practice. Case-taking—a most important duty—was, he feared, somewhat neglected in the hospitals, through no fault of the students. Careful case-taking cultivated habits of precision, developed the faculty of observation, and enabled the student to systematize his work. It was well known that many of their men who sought to enter the army and naval medical services compared badly in this respect with candidates from the other side of the Channel.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

Medical Teaching in Edinburgh and the War.

Inquiry at the university reveals the fact, as was anticipated, that the number of students this winter as compared with last is considerably smaller. It is understood that the total number of undergraduates of all faculties is about a third less, and that, of course, medicine shares in the drop; at the same time, it is said that neither the first nor the final year in medicine is affected, a circumstance which is presumably to be explained by the advice given to the fifth-year men to complete their studies so as to be ready for service as qualified men next year, and to the fact that the first-year students are less eligible in the matter of age, etc., for volunteering for military work. It is in the intermediate years that the shortage is more evident. With regard to the teaching staff, we are informed that the professorial ranks are unbroken, but that some of the lecturers and assistants are absent on active service, and that their duties are being undertaken by others. In the extramural school there is also a falling off in the number of students; it is not thought to be large, but in the meantime, until the session is further advanced, it is impossible to gauge its extent. With the single exception of surgery, the lecturers in the extramural school are little, if at all, affected, and the classes are going on as usual. All the surgery teachers, however, with one exception, are away on active service connected with the war. As a matter of fact, this occurrence could not have happened at a less inopportune time, for, as was indicated in the Journal for May 9th of the present year (see pp. 1040, 1041)), there has just been completed a large rearrangement of the classes by which the taking of the surgery lectures was put back a year whilst that of the medicine lectures was advanced. The result has been that scarcely any students wish to attend surgery lectures this session, whilst there has been a rush upon the medicine classrooms. In the School of Medicine for Women, where, by the way, there is a remarkable increase in the first-year students, the lecturer on medicine (Dr. W. T. Ritchie) is absent on military duties, and Dr. G. D. Mathewson is taking his place; the lecturer on surgery is also absent, but there was only one woman who required lectures on this subject this session, and an arrangement has been made whereby she shall not suffer through the lack of teaching during the winter. The other lecturers, including the veteran "father of the extramural school," Dr. William Craig, who began to teach materia medica as far back as 1874, are all in their places.

Correspondence.

TO SAFEGUARD THE ACCURACY OF THE "MEDICAL REGISTER."

Sir,—May I once more ask you for your valuable assistance in reminding members of the profession that, unless their names appear in the *Medical Register*, they are not "legally qualified medical practitioners" (Medical Act, 1858, Section 34), and that the duty of notifying changes of address rests with them?

> No person can "hold any appointment as a physician, surgeon, or other medical officer either in the military or naval service or in emigrant or other vessels, or in any hospital, infirmary, dispensary, or lying-in hospital, not supported wholly by voluntary contributions, or in any lunatic asylum, gaol, penitentiary, house of correction, house of industry, parochial or union workhouse or poor-house, parish union, or other public establishment, body or institution, or to any friendly or other society for affording mutual relief in sickness, infirmity, or old age, or as a medical officer of health, unless he be registered" (Section 36); and
>
> "no certificate required by any Act now in force, or that may hereafter be passed, from any physician, surgeon, licentiate in medicine and surgery, or other medical practitioner, shall be valid unless the person signing the same be registered" (Section 37).

The *Medical Register* is the only official publication, and should not be confused with any of the various directories which issue circulars annually.

No one who is not familiar with the work of this office would believe the amount of trouble which is taken to keep in touch with practitioners and to find them when touch has been lost, but unless we are assisted by members of the profession themselves our efforts are often fruitless.

In consequence of cases which have recently occurred it becomes increasingly important every year that the Registrar should carry out the duty laid upon him under Section 14 of removing from the *Register* the names of practitioners with whom he cannot communicate. It is done with reluctance, but only by this means can the public and the profession be protected against impostors. No doubt cases of hardship do sometimes arise in consequence of this removal of names, but every possible source of information is made use of to save practitioners from the results of their own forgetfulness, and if they are inconvenienced by finding that their names are off the *Register*, the blame does not rest with this office.

Perhaps I may add that, by a recent regulation, practitioners possessing medical and dental qualifications, if already on the *Medical Register*, may register in the *Dentists Register* (or vice versa) for a reduced fee of £2 1s. instead of £5 1s.

I should also like to take the opportunity of drawing attention to the following resolution, adopted by the Council on November 30th, 1911, and re-drafted on June 1st, 1914. It cannot be too strongly urged upon practitioners that, in giving certificates, they are recognized by law as members of a trusted profession, and that it behoves them to exercise the greatest possible care in the matter:

1. *Certificates, Notifications, Reports, etc.*

Registered practitioners are in certain cases bound by law to give, or may be from time to time called upon or requested to give, certificates, notifications, reports, and other documents of a kindred character, signed by them in their professional capacity, for subsequent use either in courts of justice or for administrative purposes.

Such documents include, among others, certificates, notifications, reports, etc.:

(*a*) Under the Statutes relating to *births, deaths, or disposal of the dead*.
(*b*) Under the Acts relating to *Lunacy* and *Mental Deficiency* and the rules made thereunder.
(*c*) Under the *Vaccination* Acts and the Local Government Board Orders made thereunder.
(*d*) Under the *Factory* Acts and the Home Office Regulations made thereunder.
(*e*) Under the *Education* Acts.
(*f*) Under the *Public Health* Acts and the Local Government Board Orders made thereunder.

(*g*) Under the *Workmen's Compensation* Acts.
(*h*) Under the Acts and the Local Government Board Orders relating to *the notification of infectious diseases*.
(*i*) Under the *National Insurance* Acts and the Regulations made thereunder.
(*j*) Under the *Old Age Pensions* Acts and the Treasury Regulations made thereunder.
(*k*) Under the *Merchant Shipping* Acts.
(*l*) In connexion with *sick benefit, insurance and friendly societies*.
(*m*) For procuring the issue of Foreign Office *passports*.
(*n*) For *excusing attendance* in courts of justice, in the public services, in public offices, or in ordinary employments.
(*o*) In connexion with *naval and military* matters.

Any registered practitioner who shall be shown to have signed or given under his name and authority any such certificate, notification, report, or document of a kindred character, which is untrue, misleading, or improper, *whether relating to the several matters above specified or otherwise*, is liable to have his name erased from the *Register*.

—I am, etc.,

A. J. COCKINGTON,
Acting Registrar.

General Medical Council Office,
299, Oxford Street, London, W.,
October 15th.

A PLEA FOR AN AMBULANCE CHASSIS.

SIR,—While so much is being done to increase the number of motor ambulances at the front, almost all attention, as regards construction, seems to be centred on the coachmaking. It is quite time that the chassis itself were constructed specially for ambulance work. To this end the back (driving) wheels ought to be at least 4 or 4½ ft. in height, including the tyres, since a high wheel runs far more smoothly over a bad road than a low one. The tyre on a high wheel will carry a much heavier load than an equally wide tyre on a small one as it has a longer ground contact. It also fatigues less and lasts longer. Small driving wheels were introduced to make room for side doors and to keep down expense in building, neither of which is essential when preparing an ambulance car.

The car should be chain driven, and the cogged drum on the driving wheel should, of course, have a diameter proportional to that of the wheel. This would make the propulsion of the car as easy for the engine as if the wheels were low. The driving drum, which contains the brake, is bolted on the spokes, and so strengthens the wheel that it scarcely needs to be more heavily constructed than a low wheel. This I know from experience, as I possess such a car. The frame might be underslung to bring the coachwork to a suitable height, and the ambulance should open at the front, as shown in Mr. Massac Buist's article in the BRITISH MEDICAL JOURNAL of October 10th, page 642. The back axle should, if possible, be behind the ambulance proper.

The only structural difficulty is to find room for the chain and brake drum and the radius rods. The wheels might have to be well clear of the side of the body to allow this, though a little ingenuity on the part of the builders would get over this difficulty, as it did in the early days of motor cars when they were constructed with high driving wheels.

Many of the ambulance wagons now supplied are a mechanical disgrace, with half the body overhanging behind low back wheels, thus providing a maximum of discomfort for the unfortunate occupants.—I am, etc.,

Clyst St. George, Devon. D. W. SAMWAYS.

NUTRITION AND MEAT EXTRACTS.

SIR,—If Mr. Sohn will be good enough to refer to my letter again (JOURNAL, September 26th) he will find there is no protest in it and nothing to admit. There is a statement of the published deductions which my colleagues and I had drawn from our experimental investigation of the nutritive value of beef extracts, with reasons for not accepting his suggestion that the effects we observed were due to a retention of mineral salts. Incidentally, some of the many inaccuracies in Mr. Sohn's book on nutrition were pointed out.

Our conclusions were drawn from a consideration of the whole facts and not from a small minority of deviations which do not modify the main inferences.

The effects of the extracts we used were, as I stated, an increase of weight, a better assimilation of other food, a retention of nitrogen, and, I may now add, a general improvement of nutrition. This latter, which many would regard as the most important outcome of the whole, was apparent to the eye in the condition of the animals, and was consciously felt by the human subjects, but being immeasurable was kept out of our published papers.

It is open, however, to any one to repeat the investigations, and if Mr. Sohn will spend eighteen months in doing so, and publish his results, with protocols giving details of the experiments, as we have done, he will have made a contribution to the subject which will be of value. Nor will any one welcome his findings more sincerely than I, whether they be in harmony or not with those obtained in my own laboratory.

As I stated in a letter which appeared in this JOURNAL on November 26th, 1910, "I have no interests to serve in the matter other than those of science," nor do I suppose Mr. Sohn has. There ought, therefore, to be no difficulty in finally settling the questions at issue if, as he thinks, our conclusions are unwarranted or untenable.

Meanwhile theoretical considerations are only of value as working hypotheses to be put, without bias, to the test of experimental proof.—I am, etc.,

Dublin, Oct. 17th. W. H. THOMPSON.

INSECTS AND WAR: FLEAS.

SIR,—With reference to the letter by Mr. Trevor M. Smith in your last week's issue, I would like to say that my informant was Mr. C. A. Barber, Sc.D., Sugar Expert for India. Mr. Barber was born in South Africa and has lived there a long time, and indeed in many parts of the world. I confess when he told me that rooms plastered with cow-dung kept away flies I was sceptical, but he was perfectly clear on the point and is a trained and accurate observer.—I am, etc.,

Cambridge, Oct. 20th. A. E. SHIPLEY.

Medical News.

BEGINNING with the October issue, the *American Journal of Surgery* will publish a thirty-two page supplement wholly devoted to anaesthesia and analgesia.

AT the annual meeting of the Society of Medical Officers of Health, held on October 16th, Sir Arthur Whitelegge, K.C.B., and Dr. E. C. Seaton, who had been Fellows of the Society for many years, were elected Honorary Fellows. Dr. Seaton was President of the Society in 1897.

THE Huxley Memorial Lecture on recent advances in science in relation to medicine and surgery will be delivered at Charing Cross Hospital on Monday, November 2nd, at 3 p.m., by Sir Ronald Ross, M.D., K.C.V.O., F.R.S., Sir Thomas Barlow, Bart., President of the Royal College of Physicians, in the chair. The lecture is open to all members of the profession.

AT a meeting of the Bath City Council on October 20th it was resolved to alter and improve or extend the baths; that the work should be put in hand at as early a date as possible; that any new baths should be first class in style and equipment; and that the chief aim should be to develop the use of the hot springs; but that, in view of the grave national crisis, the strictest economy should be observed. A proposal to enter on an expenditure of £87,000 was deferred.

THE next meeting of the Life Assurance Medical Officers' Association will be held at 1, Wimpole Street (Royal Society of Medicine), on Wednesday, November 4th, at 5.30 p.m., when Dr. H. J. Cardale and Dr. J. Fletcher Porter will initiate a discussion on The Certification of Invalidity under the National Insurance Act. Tea and coffee at 5 p.m. The association will welcome the presence and participation of any medical man interested in the subject.

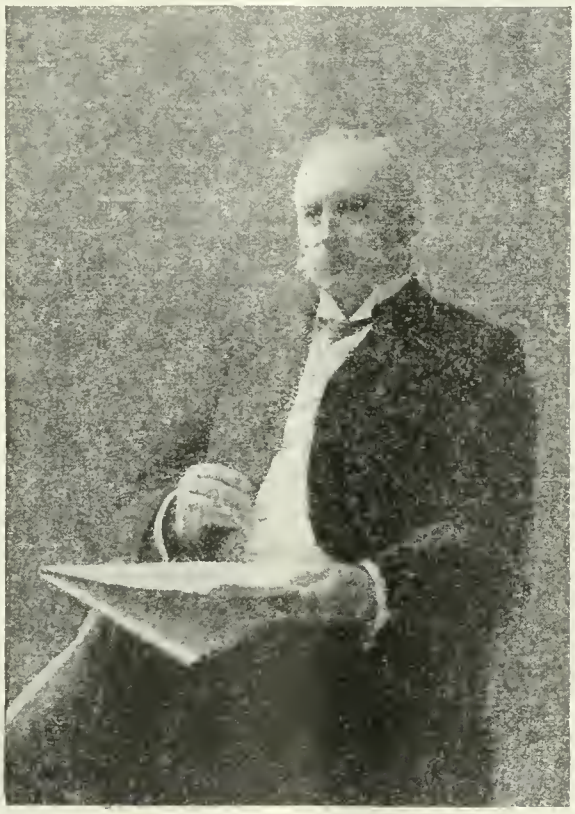
THE London County Council on October 20th approved the action of the Education Committee during recess, in opening, upon the outbreak of war, in various parts of London, 146 classes in first aid, 111 classes in home nursing, and 32 in cookery for the sick. These facilities were provided in response to many applications from persons wishing to qualify themselves to join detachments of the British Red Cross Society or otherwise to be able to render service in connexion with the war. The classes are estimated to cost £4,000.

Obituary.

THOMAS HOBBS CRAMPTON, L.R.C.P.I., L.R.C.S.I.,
ISLINGTON.

The death of Dr. Crampton, which took place after a very short illness at his residence in Islington on October 13th, will be mourned by a very large circle of personal friends, as well as by his brother practitioners in the neighbourhood where he practised, for his was a character that won respect and esteem bordering on affection.

He was born in the county Kildare in 1857, and studied medicine at the Carmichael School, Dublin. He obtained his diplomas in 1880, and shortly afterwards went to London, attracted by the advertisement for an assistant to a West-End practitioner ending with the note, "None but Irish need apply." The introduction thus obtained led finally to his putting up his plate in Islington, where he soon established for himself a good general practice. His steady attention to work, his constant acquisition of the most recent methods of treatment, coupled with his geniality and keen sense of humour, laid the foundation for his remarkable success, and the high esteem in which he was held by his brother practitioners in Islington, who had the greatest confidence in his judgement. In the recent efforts made by the profession to obtain better terms under the Insurance Acts, Hobbs Crampton was frequently put forward by his neighbours as their spokesman. He maintained to the last his unswerving opposition to the panel system.



Thomas Hobbs Crampton.
(Photograph by Lafayette, Limited, London.)

Dr. Hobbs Crampton was Chairman last year (1913–14) of the City Division of the Metropolitan Counties Branch of the British Medical Association, and at a meeting of the Division held a few days after his death Dr. J. W. Hunt, on behalf of the members, expressed the great appreciation all felt at the exemplary manner in which the duties of the chair had been sustained by Dr. Hobbs Crampton throughout a trying year of office; the unfailing courtesy, unswerving impartiality, and unwearying assiduity in the despatch of business having won universal admiration.

Dr. Crampton was one of the oldest members of the Irish Medical Schools' and Graduates' Association, at the functions of which for the last twenty years he was invariably present. In fact, an Irish graduates' banquet without Hobbs Crampton would have been shorn of half its charm. His fellow members of that society showed their appreciation of his qualities as a wise and capable administrator by electing him to every honorary office, one after the other, for which he was eligible. He would probably have been the next metropolitan member elected to the presidential chair. The Council mustered in large numbers at his funeral, which took place on October 16th at the Great Northern Cemetery, New Southgate, and was attended by nearly every medical practitioner within a circuit of several miles of Myddelton Square, where he had resided for over twenty years. He has left a widow, one son, now a student at Cambridge, and one daughter, to whom the sympathy of many scores of friends will go out, for Hobbs Crampton was essentially a man fond of his home, and in his case it was very true that—

> Home's not merely four square walls
> Hung with pictures framed and gilt;
> Home is where affection calls
> To the shrines itself hath built.

ANTHONY TRAILL, M.D., M.Ch., LL.D.,
PROVOST OF TRINITY COLLEGE, DUBLIN.

We regret to announce the death of Dr. Traill, the provost of Trinity College, Dublin, which took place on October 15th. For some time past he had been in bad health, and for several days before his death he had been practically unconscious.

Anthony Traill was born on November 1st, 1838, being the eldest son of William Traill, of Ballylough House, co. Antrim, and Louisa, daughter of Robert Ffrench, of Monivea Castle, co. Galway. He came of a sturdy stock, his first Irish ancestor being Colonel James Traill, who came over with the Parliamentary Army in 1660, and married the niece of the first Viscount Clandeboye, subsequently settling down at Tullaguim, co. Down. Anthony Traill entered Trinity College in July, 1855, at the age of 16, and had as fellow signatories of the students' roll Lecky the historian, Lord Justice Fitzgibbon, Lord Ashbourne, and Professor Mahaffy. He obtained a mathematical scholarship in 1858 and a studentship two years later, when he graduated B.A. with two senior moderatorships and two large gold medals. In 1864 he advanced to his degree of Master of Arts, and was elected a Fellow in the following year, in which he also took the degree of LL.D. In 1870 he took out the degrees of M.Ch. and M.D., and it was a subject of pride to him in later years that he was the first medical graduate of Trinity who had ever been called to the provost's chair. In 1875 Dr. Traill made an unsuccessful effort to enter Parliament as one of the representatives of the university. In 1888 he was elected a member of the Council, and in 1890 became assistant professor of natural philosophy. In 1899, on the resignation of Dr. Kells Ingram, he was co-opted a senior Fellow, and a little later filled the office of bursar of the College.

On January 23rd, 1904, Rev. George Salmon, who had been Provost since March, 1888, passed away at the advanced age of 85 years, and it was in succession to him that Dr. Traill was nominated a few months later by King Edward. A strong and stalwart character was needed at that time to face the disputes which were going on outside the College walls, and to meet those who might seek to lay hands on the rights and privileges of an envied seat of learning which had insisted on remaining true to her traditions and the principles of her original foundation. The late Provost was always a warm friend of technical education and concerned himself chiefly with the work of the University Engineering Students' Society; he was also a hard working member of the Medical School Committee, of which for a considerable time he acted as Vice-President. He was also President of the University Experimental Science Association, and of the University Choral Society: patron of the T.C.D. Church Musical Association and of the University Chess Club.

Many distinctions and honours came his way, including the degrees of LL.D. (*Honoris Causâ*) from the Universities of Glasgow, Aberdeen, and St. Andrews. In 1904 he became an honorary Fellow of the Royal College of Surgeons, and in 1905 an honorary Fellow of the Royal College of Physicians in Ireland.

He was all his life devoted to the welfare of the Church of Ireland, and as a member of the Representative Body since its incorporation, it was his privilege annually to

bring in the Church budget at the meetings of the General Synod. He was also one of the leading lay members of the Diocesan Council of the United Dioceses of Down, Connor, and Dromore, and as one of the diocesan trustees was a familiar figure at the Synod. His valuable services in connexion with the Church Auxiliary Fund, raised within recent years, will also always be remembered as an instance of the unwavering industry and ceaseless advocacy which he was able to bring to bear on any project that commended itself to his mind. From 1885 to 1892 Dr. Traill was one of the most useful and energetic members of the Educational Endowments (Ireland) Commission. In association with his brother and the late Lord Kelvin and Sir William Siemens, he was one of the pioneers in the construction of the Portrush and Giant's Causeway Electric Railway, which for many years enjoyed the unique distinction of being the only electric railway in the world.

The leading incidents of Dr. Traill's provostship are well within recollection, and need not, therefore, be recounted in detail. Trinity College found in him one of the shrewdest and most business-like of a long line of administrators. He was largely responsible for the admission of women to the privilege of university training and graduation. Dublin was the first of the three great residential universities in the United Kingdom to open its doors thus to womankind. Another departure in which Dr. Traill took an active interest was the formation of the Officers' Training Corps, which has fostered such a spirit that a few weeks ago 45 per cent. of the male undergraduates had applied for commissions in the new army. He has left a permanent mark on the history of Dublin University, not as a distinguished scholar, but as a very able administrator. As for the man himself, he was one who compelled the respect even of those who loved him least. He was, as the very barest recapitulation of his activities shows, a hard worker in many different causes. His great industry lasted as long as his health. The achievements of Dr. Traill were due to his immense strength of character. Any task which he set before himself he attacked with a determination and courage which was indomitable and almost irresistible. These characteristics, combined with a sturdy independence, which prevented him from taking opinions at second hand, made him at once a remarkable and formidable figure in Irish life. He never conformed to the academic ideal of the head of a learned university; but the work which he did for Trinity College will not soon be forgotten.

In the realm of sport Dr. Traill exhibited strenuous energy. In his undergraduate days he captained the University Cricket Eleven, and for fourteen years he held the University Racquet Championship, losing it for the first time at the age of 50, only to recapture it the following year. Of late years he was a keen golfer and was president of the Royal Portrush Golf Club. Rifle-shooting and fishing were also favourite pastimes. He was a member of the Alpine Club, and for many years spent his vacation in Switzerland. He was amongst the earliest of those who made the perilous climb of Monte Rosa; he made a second ascent on his wedding tour in 1867. In 1867 Dr. Traill married Catherine Elizabeth (who died in 1909), daughter of Captain Stewart Moore, of Ballydivity, co. Antrim, a Waterloo veteran. There were five sons and three daughters by the marriage.

Medico-Legal.

DEFINITION OF A "PROVIDENT DISPENSARY."

In Coventry County Court, on Tuesday, October 20th, Judge Cann gave judgement in the case of Dr. David Holmes, one of the medical officers of the Coventry Provident Dispensary *v.* the Corporation, a claim of 1s. 6d., balance of fee for notifying a case of tuberculosis to the medical officer of health (Dr. Snell). Defendants contended that plaintiff was so acting as medical officer of a hospital as defined by the Public Health (Tuberculosis) Regulations, 1912, and therefore entitled to only 1s.

His Honour said plaintiff was paid out of the society, and not by the members individually, and his remuneration fixed according to the number of cases treated. He came to the conclusion that this provident dispensary was included in the definition of the word "hospital" as defined by the regulations of 1912; the claim therefore failed, and the action was dismissed with costs.

ANSWERS.

W.B.F.—In Martindale and Westcott's *Extra Pharmacopoeia* gonosan is said to be a special preparation of kava resins in santal wood oil in capsule form. The same book gives the formula for liquor santal cum kava, stated to consist of yellow santal wood in powder 4, alcohol 60 per cent., q.s. to 15 liquid extract of kava-kava 5. Kava-kava is the root of *Piper methysticum*, a shrub indigenous to the Sandwich Islands. The *Indian and Colonial Addendum*, 1900, to the *British Pharmacopoeia*, 1898, contains kava rhizome and a liquid extract of kava, both of which are official in the Australasian colonies (dose to 30 to 60 minims). The *British Pharmaceutical Codex*, which mentions also a solid extract of kava for use in pills (1 to 5 grains), states that the active constituents of the drug appear to be two resins—alpha-kava and beta-kava resins—and that an alkaloid kavaine is also said to be present. Kava-kava is used in the South Sea Islands for preparing an intoxicating drink; it is said to affect the power of movement, while leaving the intellect clear. It is given in gonorrhoea on the supposition that it acts as an anaesthetic to the urethral mucous membrane, reduces congestion, and acts as an anaphrodisiac.

SUITABILITY OF ALPINE CLIMATE FOR BRONCHITIC.

A LATE medical officer (British) to a sanatorium in Switzerland writes, in reply to "Indian": If the bronchitis is uncomplicated with emphysema or weakness of the heart muscles or other grave complication, such as advanced renal or arterial degeneration, the probability is that the dry mountain air would exercise a beneficial influence on the pneumococcal infection. The freedom from dust and relative sterility of the air would tend to prevent the onset of secondary infection and to minimize the effect of organisms already present in the upper air passages and bronchial tubes. Some emphysema is undoubtedly a contraindication to high altitudes, and the writer has had the unfortunate experience of seeing a patient with extensive emphysema and chronic bronchitis die on the day after arrival at Davos-Platz. Hence it is probable that if the symptoms comprise marked dyspnoea, marked and persistent tachycardia, and troublesome insomnia, a trial of the Alps should be made cautiously or not at all.

*** As the inquirer is now resident in Great Britain it will be necessary to make careful inquiries before starting as to how he is to reach Switzerland quickly and comfortably. Routes via Bordeaux and via Genoa have been mentioned, but we are informed that it is possible to travel by way of Paris, Lyons, Geneva, and Zürich; passports with French and Swiss consular visés are required. We are also informed that it is expected that the electric railway from Coire to Arosa will be open for passenger traffic early in November. From the *Davoser Blätter* of October 3rd it appears that at the end of September there were 1,630 foreign residents in Davos, of whom 552 were of German or Austro-Hungarian nationality. The British, French, Russians, and Belgians numbered 460, of whom 67 were British. The total was made up by various other nationalities, including 67 Americans.

ON THE TREATMENT OF ARTHRITIC DEFORMITIES.

Being the Introduction to a Discussion in the Section of Surgery of the Annual Meeting of the British Medical Association, 1914.

By ROBERT JONES, Ch.M., F.R.C.S.E., F.R.C.S.I.(Hon.),

lecturer on orthopaedic surgery, university of liverpool.

Many cases of arthritis hitherto classified as tuberculous belong really to other groups, but although these present manifold and often easily diagnosed variations in their clinical course, they nearly all present similar deformities. In some these deformities appear early, in others they appear late, but whenever and wherever they appear they reflect discredit upon somebody—the parent for not seeking advice, or the practitioner for failing to appreciate the fundamental principles of treatment.

The prevention of deformity is therefore a much more important matter than its correction, but except indirectly this phase of the subject will not be discussed. Certain symptoms are common to every variety of arthritis, but the essential symptom is that of limitation of movement of the joint in each of its normal directions. It is difficult to prevent deformity unless we know the types which occur in the natural course of disease. In arthritis of the big toe we must expect plantar flexion; of the ankle, extension; of the knee, flexion, accompanied in the more pronounced cases by rotation outwards and displacement backwards of the tibia; in the later stages of arthritis of the hip, flexion, adduction, and internal rotation; in that of the wrist, palmar flexion; in the elbow, extension to about 110 degrees, and in arthritis of the shoulder, adduction. In cervical caries the malposition of the head depends upon the location of the disease. If the upper two or three vertebrae are diseased the head is twisted to one side into the position of wry-neck. If the disease be lower the chin is advanced and dropped towards the chest. If the disease is yet lower the chin is elevated and somewhat advanced, the head being thrown backwards towards the shoulders, which are raised to meet it. In view of the possibility of ankylosis the surgeon should ascertain from the patient what position he would desire his joint, in order to obtain most use from it. In the case of the elbow this will depend largely upon occupation, and to a lesser extent also in the case of the hip. The hip is usually best fixed fully extended, as is also the knee; if bony ankylosis should occur a little flexion at both joints is no disadvantage. The ankle should be fixed at right angles, and the elbow slightly below the right angle. The wrist should be kept hyperextended.

Fig. 1.—Abduction frame applied for right tuberculous hip.

I need say no more in regard to preventive measures. When we realize the deformity of the untreated case we can always be prepared for its prevention.

To simplify the subject take first tuberculous deformities in the young. At the outset it may be asked, "At what stage of the disease should we correct deformity? Should we alter the malposition of a joint in the stage of its activity, or wait until recovery has taken place?" It is perfectly safe to correct deformity during the active period, and comparatively simple. My experience does not favour the view that by this act a general dissemination of tubercle will be caused.

In the hip-joint, therefore, when a case presents flexion, adduction and elevation of the pelvis, I apply a frame so constructed as to govern the triple deformity (Fig. 1). The splint should never be fitted to the deformity, but the deformity should be moulded to the splint. The limb is then retained rigidly at rest both to recover from the manipulation and in obedience to the principles according to which we treat such joints. It is obvious that the manipulation should be practised without excessive force, slowly and gently, never rapidly or roughly.

In the case of the knee, flexion and tibial displacement are corrected together, and the limb placed in a Thomas's bed knee splint. The correction is not necessarily completed at the one sitting. The deformity may be only partially reduced and then the treatment be completed by extension in the splint.

Palmar flexion at the wrist should be changed to dorsiflexion, in order that a good grip should be secured if ankylosis should become permanent (Fig. 1a). The power

Fig. 1a.—Showing wrist held in dorsiflexion by "cock-up" splint.

of grasp, as we know, diminishes in proportion to the amount of flexion, at the wrist. The shoulder should be kept abducted, held somewhat forwards, and slightly rotated inwards, so that if ankylosis occur the range of movement will be materially assisted by the muscles of the scapula. Deformities of the spine may always be diminished by appropriate padding while the patient lies upon a convex frame.

These deformities, obviously fibrous in character, are thus corrected during the presence of active disease, and this correction is maintained until the joints recover. Such methods, however, are of avail only when the deformities are fibrous. If bony fixation has occurred, more radical measures are needed. Bony ankylosis in children is a comparatively uncommon ending, so that osteotomies, removal of wedges of bone, and similar radical measures are very rarely called for in the very young.

A fibrous ankylosis has one serious clinical drawback—it goes on contracting and adding to deformity for a considerable time, until at last it becomes quiescent. H. O. Thomas introduced a nomenclature of ankylosis which was of considerable clinical value. He spoke of sound and unsound ankylosis. The distinction is that in unsound ankylosis the angle of flexion will be increased by use, and that in sound ankylosis the angle will not be altered by use. This is a useful classification, more especially when we deal with the adduction deformity in arthritic affections of the hip.

In those cases of hip disease in patients more advanced in age with typical deformity, where the disease has nearly run its course, we have to consider whether it may not be wiser to perform an osteotomy below the affected area in order to correct the flexion, pelvic obliquity, and internal rotation of the limb. This is often a time-saving measure, as we avoid the renewed deforming effects which would result from an attack upon an unsound ankylosis. I will endeavour to make this more clear. In a small child where disease is active and the diseased structures are soft, by placing a hip in abduction with extension we allow it to run its course until the ankylosis is sound, until, in fact, the angle at the joint will not be altered by use. In the more advanced case, where the deformity has been allowed to take place and the patient has nearly recovered, one might perform a subtrochanteric osteotomy and place the limb in abduction, rather than force the joint into abduction with the knowledge that the deformity would partially recur. A sound fibrous ankylosis at the hip, therefore, is best left alone, and the operative attack should be made below the joint.

Tuberculosis in the young I have always looked upon as benign and tractable; in the adult it is a very different

disease, requiring early and radical attack. The deformities presented are similar in both.

For the correction of deformity in the short fibrous and in the osseous types, the possible procedures consist of manipulation with or without extension, osteotomies, wedge exsections, exsections of joints, pseudo-arthroses, and arthroplasties and transplantations.

Manipulation with extension should always be our method of attack, in young children, where the disease is active, and in patients, of whatever age, where the fixation is soft and fibrous, and where operation is disallowed. It should never be advocated in the adolescent, where the ankylosis is sound, be it fibrous or bony. Osteotomy is employed with best effect on the femur to correct deformities at the hip, and sometimes to correct faulty lateral alinement in connexion with arthritis of the knee. Where ankylosis is bony the operation is most successful, and I have often, in the case of pelvic obliquity, corrected four and five inches of practical shortening (Fig. 2). If the adduction and flexion are marked and the neck of the femur is not absorbed and the ankylosis is bony, I prefer a trans-trochanteric section. To do this safely, no matter how pronounced the flexion and adduction, it is advisable to make the section through the bone parallel to Poupart's ligament, and the operation should be completed by subcutaneous division of the adductors.

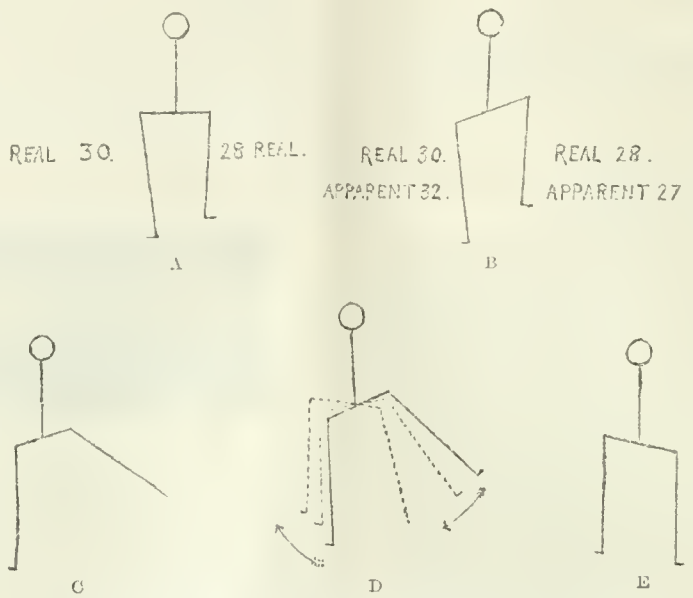

Fig. 2.—A, Showing 2 in. real shortening. B, Tilting of pelvis; showing real and practical shortening from pelvic obliquity. C, Position of leg after trans-trochanteric osteotomy. D, Showing elevation of pelvis on sound side by bringing abducted leg into position. E, Showing final result with adduction of leg and elevation of pelvis of sound side.

If the neck and head of the femur be absorbed and the trochanter raised, it will be necessary to remove a wedge from the base of the trochanter, as a simple osteotomy will not secure sufficient abduction. A subtrochanteric division should never be done if the flexion is acute, otherwise when the limb is straightened the upper end of the femur will project in Scarpa's triangle.

The subtrochanteric division should be reserved for cases of unsound fibrous ankylosis where flexion is not so marked a feature as adduction and rotation. In the adult this section is sometimes made by open incision, as the bone is very apt to splinter, and, if a wedge be removed with its base to the outside, the severed ends will remain in excellent apposition. Although the Gant operation done subcutaneously can scarcely be defended upon artistic or mechanical grounds, I have never yet met with a failure of union. The trans-trochanteric route should be that selected where the essential condition renders it possible. After the osteotomy the limb should be kept for six weeks well abducted, and at the end of that period the leg is brought to the middle line, the pelvis follows it, and in this way the practical length of the short limb is increased, the amount of lengthening being proportionate to the abduction at which it was placed.

In bony ankylosis of the knee a wedge is removed anteriorly, the shape of the wedge depending upon the degree of flexion and the presence or absence of lateral deviation. The fit should be very accurate to ensure a firm ankylosis.

In performing this operation it is better not to allow the apex of the wedge to reach the popliteal space; it should end half an inch anteriorly. The wedge of bone is then removed and the remaining bone is cautiously divided by means of the saw. The knee is then completely flexed, the posterior sharp ends trimmed, and the limb extended. In this way the vein and artery are secure from danger.

In cases where moderate flexion persists with otherwise free movement, an oblique osteotomy should be performed, and the limb straightened. In this way the joint mobility is transferred to a more useful sphere of activity.

In bony ankylosis of the shoulder, more particularly in young children, an osteotomy of the neck of the humerus may be advantageously employed in the young. The arm is rotated inwards and abducted forwards, and when union has taken place the arm can be lifted high.

Within comparatively recent years there has been a growing dissatisfaction felt towards the ankylosed joint, and in fields wide apart experiments and operations have been performed with a view of mobilizing ankylosed joints. Most of us who have dealt largely with colonies of tuberculous children have preferred a firm ankylosis as an end-result to the restricted movement which sometimes occurs. There is apt to be recurrence where movement remains, and through the years, if a true recurrence does not take place, there are frequent alarms, the consequence of strain. These recurrences are more likely to take place in tuberculous joints than in those of septic origin.

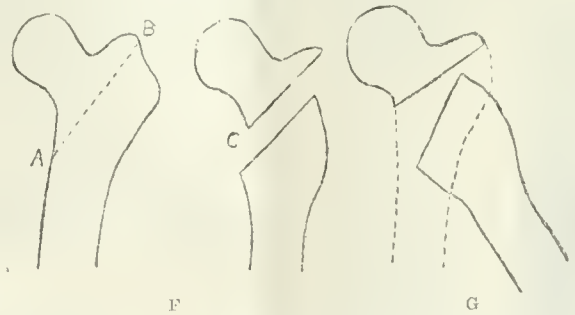

Fig. 3.—F: A, B, Line of section through trochanter; C, lengthening after traction. G, Position of fragments when limb is abducted.

But to obtain movement in joints without adding to the risks of recurrence of disease has been a very fascinating study and achievement during the last few years. We are in danger, perhaps, of underestimating the work done by older surgeons if we do not hold our enthusiasm a little in check. Very excellent results were obtained by our ancestors by the ordinary excision of the hip and elbow, and, though we hear very little of these successes now, there are vast numbers of men doing hard manual labour whose excisions have been performed without the intervention of muscle or fascial flap. There were, of course, the failures—the elbows, which did not confine their movements in normal directions, and the hips, which often ankylosed at divers angles.

The modern operation of arthroplasty requires the exposure of an ankylosed joint and the separation of the bones by manipulation and chisel at the site of the old articulation. The bones are then modelled or resected and covered with a flap of tissue either pedunculated or free, or by the interposition of some foreign body. These modern methods aim at greater precision of result and at

greater stability. In my early days most of the pseudo-arthroses I performed were in cases of ankylosis of both hips, and for some years following 1895 after excising the head and neck, sometimes neck and trochanter, I covered the stump with gold-foil, and, failing that, with any material in the vicinity of the bone that came to hand. The results on the whole were good, and when I

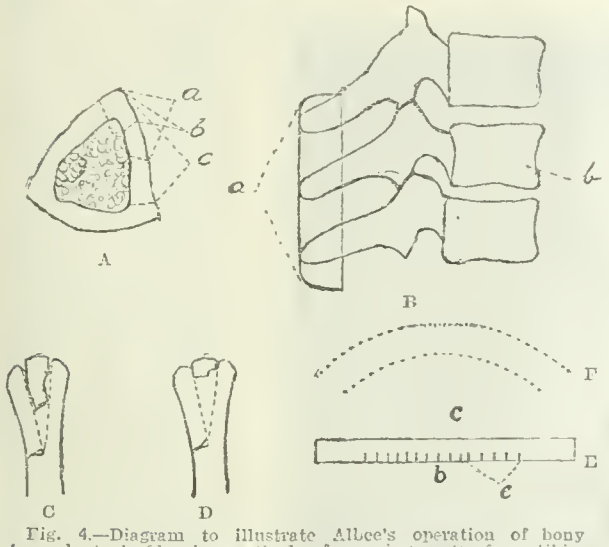

Fig. 4.—Diagram to illustrate Albee's operation of bony transplant: A, Showing methods of securing grafts from tibia. B, Showing splint-like action of transplant: *a*, Splint of bone; *b*, Diseased vertebra. C, D, Showing transplant in split spinal process. E, Showing cross incisions in graft to allow it to bend. F, Graft curved.

learnt the secret of the free removal of bone, the results were consistently better.

When a difficulty arose in securing a flap, one easily got over it by thinning and gouging the compact tissue at the reversed end of the femur and hammering the sides over the medullary cavity. In this way callus exudation was prevented. Until recent years I never performed a flap operation on the elbow, but for very long I have used masses of free fat in trying to obtain mobile ankles. All over Europe and America various procedures have been advocated, but I think the honour of priority of using tissue flaps should be given to Verneuil, who as early as 1865 recommended that after removing bone for temporo-maxillary ankylosis the capsular soft parts should be inserted between the bones.

Among the most ingenious and active workers of the present day we would place J. B. Murphy. He is the great apostle, and to him undoubtedly belongs the credit of systematically attempting to restore a joint to its normal shape and function, and of drawing our attention to the value of fat and fascia as a lining to a joint because of its hygromatous transformation. As I have on other occasions pointed out, it is rare in old tuberculous conditions where bony ankylosis has resulted, to find hips which can with any success be modelled into shape. The head is usually absorbed and the neck has travelled a varying distance above the acetabulum. It is quite impossible to bring such femora, often ankylosed to the ilium, into an approximately normal position. The application of pulleys after division of the bone I know from experience to be futile.

Such cases demand the free removal of bone, as in the case of a lady of 36 upon whom I operated in 1903. Her hip was flexed and adducted, and she presented 6 in. of practical shortening. As a first stage, in order to add to the length of the limb, I performed an osteotomy and placed the limb for six weeks in abduction. Four inches of practical lengthening were gained in this way. Some months later I removed the greater part of the trochanter and neck and interposed a muscular flap. The patient now has free movement, is on her feet most of the day, and can walk many miles.

I really do not think that it makes much difference what material is used for a flap. Most tissues, whether fat or muscular, seem to turn into connective tissue, and that is exactly what is required, if we are to place reliance upon the experiments made regarding the embryology of joints and the theory of bursa formation. For this reason I use entirely free fascial flaps derived from the fascia lata—operation is thus much simplified. Some of the most successful results are those reported by Baer of Baltimore, who uses sterilized pig's bladder. From a study of the records I should lay more stress upon the cleanliness and competence of the surgeon than upon the character of the interposing flap.

The elbow-joint offers a very favourable field for arthroplasty, whether we utilize a flap from the triceps, brachialis anticus, or any of the accommodating muscles in the neighbourhood of the joint, or in the transplantation of free or pedunculated fascial flaps. I have only performed one pseudo-arthrosis of the wrist, and I then filled the space with free fat. The operation was a success, and secured permanently about 40 degrees of movement. In bony ankylosis, where the wrist is flexed and the grip consequently poor, I have often removed a wedge from the carpus in order to obtain dorsiflexion.

Undoubtedly the knee-joint is the most difficult problem in connexion with arthroplasty. In complete bony ankylosis involving patella, femur, and tibia, it is difficult to conceive a mobile joint with stability. The stability of the knee-joint is not altogether maintained by bone, but chiefly by intra-articular ligaments and capsule. If these be destroyed, as is usually the case in complete bony ankylosis, the result cannot be as satisfactory as a good firm ankylosis. Baer, who gives a very judicial presentment of his results—and he has had a large experience—tells us that of eleven cases where the ankylosis was between the three bones, five cases gave no motion, four cases gave 20 per cent., and they were of gonorrhoeal origin. Two gave useful motion, but nothing is said as to the stability of the joint. The results are very promising in cases of fibrous ankylosis where ligaments can be saved, and in those cases where the only bony fixation is between the patella and the femur. The collected results of arthroplasty of the ankylosed tuberculous knee are by no means encouraging. There is no doubt that arthroplasty has come to stay, but we should proceed warily, learning all we can from our failures and recognizing the obvious fact that so far we are only on the threshold of the subject.

May I venture to suggest that the operation is contra-indicated in the presence of disease, in the young because of the growth centres—in cases where from prolonged ankylosis and infiltration the muscles are partially destroyed, or where scar tissue surrounds the joint in such a way as to threaten the vitality of the flaps?

It is not so easy to correct the deformities of spinal caries as to avoid them, but the work of Lange, Hibbs, and Albee have added interest to this type of case. Lange of Munich introduced metal rods along the spine and stitched them in position in order to secure fixation.

A distinct advance was made by Hibbs, who utilized the spinous processes in order to bring about a bony fixation. He split each spinous process longitudinally over the area of disease, turning one half upwards and the other downwards, so that the spinous processes became

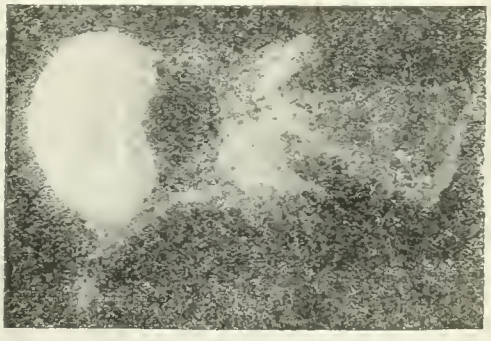

Fig. 5.—Section to show union of transplant to spinous process.

ankylosed, and supplied a firm support to the column. Albee brought about the same result by transplanting a portion of tibia into the cleft of the split spinous processes (Figs. 4 and 5). Bony spinal fixation is an ideal operation in the adult, especially in the lower lumbar region, where ambulatory fixation by apparatus is impossible. We have yet to solve the problem of growth of the transplant in the case of children. Will the transplanted

bone grow as the child grows, and at the same rate? If not, what then? So far the reports are favourable. After a conversation I held with Sir William Macewen I performed several operations affixing my graft against the bared laminae, and not disturbing the integrity of the spinous processes (Fig. 6).

The muscles are separated from the laminae and the base of the spinous processes, and then layers of bone are chiselled off and preserved. The transplant is laid upon the bed thus formed, and snugly covered by muscle and the preserved layers of bone.

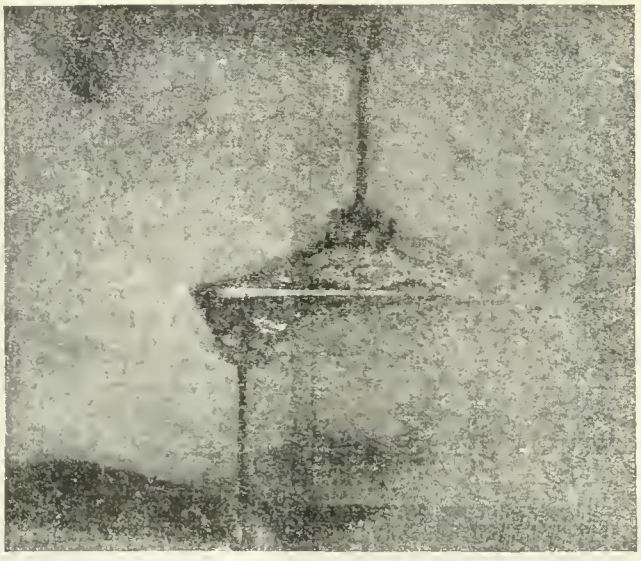

Fig. 6.—Photograph to show transplant lying on laminae.

The deformities of the rheumatoid or septic group are amenable to radical measures once the disease has ceased. The relation of such a case may be an encouragement to some.

A young woman of 30 presented two acutely flexed hips and knees and an ankle fixed by bony ankylosis. The joints stiffened five years before with very acute symptoms following typhoid fever. The left hip lay upon the abdomen bound down by firm fibrous ankylosis. The right knee was ankylosed at an angle of 90 degrees, both knees were badly flexed and fixed, while the ankle looked glazed and remained synostosed in extreme equino-varus. No attempt at walking had been made. In four months I operated upon her five times. The deformity at the ankle was rectified by the removal of a large wedge. Then a wedge was removed from the left knee. Later a pseudo-arthrosis of the left hip was performed, the head and neck of the femur being removed and a muscular flap interposed. The right knee was next straightened by a similar operation as the other knee, and finally a trans-trochanteric osteotomy of the right femur. In six months the patient was walking short distances painlessly, aided only by two sticks.

Surgeons rarely enthuse at the visit of a case of so-called monarticular rheumatoid arthritis of the hip in an elderly person. I shall not deal with its early treatment. What are we to do when a patient with this affection comes hobbling on two sticks or crutches, with a flexion deformity of 50 degrees and unendurable gnawing pain? We know that in such a case friction is the cause both of the pain and of the increase in bony excrescence. Relief from friction may be brought about in early cases by operations for the removal of bony outgrowths, such as those devised by Wheeler and Sampson Handley, or in more severe cases by bony fixation of the head of the femur to the acetabulum, as suggested by Albee, or in the still more advanced cases by the operation of pseudo-arthrosis without disarticulation, which I suggested and have practised for many years. The shock which disarticulation of the femur produces in the old is very great. I feel, therefore, that a relief from friction and a restoration of movement without the shock of disarticulation is a judicious proceeding. I devised, therefore, an operation which consisted of chiselling the trochanter from the femur and preserving it with its muscular attachments; and removing the neck of the femur and nailing the trochanter over the acetabulum, which contains the severed femoral head (Fig. 7). In this way callus exudation is avoided and movement practised without friction. This operation is rapidly done and involves but little shock.

Transplantation of joints from the cadaver has been performed on several occasions, and was first practised by Lexer. I have never had an opportunity of examining such cases after operation, and cannot give an opinion as to the results. Auto-transplantations of portions of living joints have frequently resulted in success. If time permitted one would like to dwell on some of the difficulties and dangers of operative procedures, upon the grave collapse and abdominal distension which not uncommonly follows an attempt at extending the flexed thigh of elderly folk.

I would urge, however, the importance of anticipating deformity, and of carefully choosing safe and effective methods to restore the stability and functions of the joints.

We should give careful thought to the relative functional values and disadvantages of the stiff and mobile joints. We should not allow ourselves to be mesmerized by the mere glamour of mobility, unless movement is associated with stability. It is obvious that, however skilfully performed, no arthroplasty can produce a normal joint, and it depends largely upon the surgeon's temperament as to how he estimates his canons of perfection. I have seen a knee-joint so efficiently mobilized that the patient could perform an extensive circumduction, and yet the surgeon thought the result a promising one.

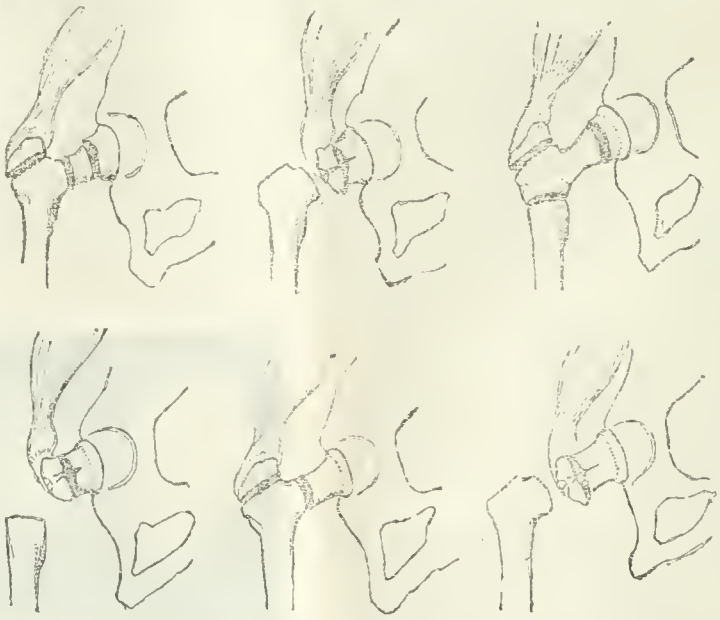

Fig. 7.—Diagram to illustrate operation of pseudarthrosis of hip.

To briefly sum up, I would affirm—

That deformities are preventable if a surgeon be acquainted with the natural course of disease.

That in view of ankylosis the joint should be allowed to become fixed in the position of greatest usefulness as regards function.

That in children most deformities can be corrected by manipulation, and that osteotomies and exsection of bone are very rarely required.

That the reduction of deformity in a septic or tuber-

culous joint during the existence of disease can be safely undertaken if it be immediately followed by fixation.

That in sound fibrous ankylosis of the hip an osteotomy should be preferred for the correction of adduction, as some recurrence of deformity would follow reduction by manipulation.

That the site of osteotomy will depend upon the nature of the ankylosis and upon the extent of the deformity. Trans-trochanteric osteotomy gives the most accurate mechanical result. It should be practised in all cases of bony fixation where the femoral neck is not absorbed and where there is no marked pathological dislocation. Where destruction of the head and neck have occurred and the femur lies close upon the pelvis, a wedge should be removed from the neighbourhood of the trochanter. In cases of fibrous ankylosis in the process of becoming sound a sub-trochanteric osteotomy is indicated to prevent strain upon fibrous bands. All osteotomies require subcutaneous division of the adductors. Subtrochanteric osteotomy is contraindicated where flexion is extreme.

Arthroplasty of the hip-joint in any of its many forms may be looked upon as a valuable and successful procedure. The character of the intervening substance—whether bone, free or pedunculated fascial flap, fat, or muscle—is not so important as a good technique and a sound judgement.

It should not be performed upon children nor in the presence of active disease. It should be reserved for adult life, and has proved more successful after recovered septic than after tuberculous disease, and in the case of septic disease it should be postponed for one or more years until the periarticular structures have become more normal.

The results of arthroplasty of the knee are not too encouraging. In bony ankylosis of the femur and tibia the results are distinctly discouraging. In those instances where the ankylosis is fibrous, with perhaps bony fixation of patella, results are often good. We must recollect, however, that in such conditions mobility may often be secured without operation.

Finally, we have in painful and progressive deformities, such as in osteo-arthritis of the hip, many procedures destined to give relief by preventing the friction of tender joint surfaces.

DISCUSSION.

Mr. H. M. W. Gray (Aberdeen) said he wished to speak only about Albee's operation for spinal caries. The speaker's practice was to place the long grafts from the tibia on each side, resting on the spinous processes and on the laminae, from the surfaces of which the periosteum had been loosened in flaps, so that it would come into contact by its raw surface with the grafts. When the aponeurosis of each side was united across the apices of spinous processes—which was very easy—the pressure thereby produced kept the grafts closely applied to the denuded laminae and spines, and thus ensured solid fusion and fixation. In removing the grafts he drilled holes, ½ in. apart, along the lines where the tibia was to be incised. The drill holes caused the bone to split in the desired direction when the chisel was used. He preferred this method to using a circular saw. In drilling a considerable amount of bone "dust" was obtained, and was carefully collected and spread in the interstices in the depth of the bed where the grafts were to lie, so that new bone might be formed from this source also. After observation in many cases of bone grafting, he regarded it as essential to remove its periosteum with the graft, and to approximate the periosteum of the graft to that of the laminae, etc. With regard to the growth of the graft subsequently and the possibility of deformity occurring if it did not do so, he had operated on several cases so long ago that enough time had elapsed to allow sufficient growth of the child to enable it to be said that the graft developed *pari passu* with the growth of the child. Local anaesthetic, with plenty of adrenalin, prevented shock and gave a bloodless field.

Mr. Max Page (London) directed attention chiefly to tuberculosis of the shoulder in children; he urged that the arm should be placed in position of abduction. He thought that manipulative reduction of deformity of hip was feasible in those cases in which destruction of the neck and head of the bone had not proceeded very far. He had used spinal anaesthesia as a preventive of shock.

Professor Marnoch (Aberdeen) said that in performing arthroplasty of the elbow he had experienced difficulty in obtaining flaps of fascia in the neighbourhood, and his practice was to take a flap of fascia lata to cover the end of the humerus.

Mr. Hey Groves (Bristol) asked if it were justifiable to leave the limb in position of rest till the tuberculous process had come to an end, and then to proceed to restore the position of the joint. He referred to the difficulty of operating in ankle-joint cases, and recommended astragalectomy. He described a method of strengthening the excised knee by using a bone graft cut from the upper end of the tibia as an intramedullary peg in the lower end of the femur. He desired information as to the fate of bone grafts of small size, and expressed the opinion that many of these, if thrown more or less loosely into the hip, were more or less indolent.

Mr. McAdam Eccles (London) said that after wrist operations dorsiflexion was the position to be maintained. He recommended membrane from a prepatellar bursa as a suitable interposing membrane. The direction of section of the femur in cases of unsound ankylosis should be parallel to Poupart's ligament.

Professor J. T. J. Morrison (Birmingham) thought that the shock of these operations was minimized by the employment of spinal anaesthesia with tropacocaine.

Mr. de C. Wheeler (Dublin) said that he had operated upon a girl about two years ago who had consulted him for crippling rheumatic arthritis of the right hip and left knee joint. She had been on crutches for seven years and could bear no weight without pain on the side of the affected hip. The operation of "cheiletomy" (the first recorded) was performed with a perfect result. The knee was strengthened and some bony outgrowth chiselled off the upper end of the tibia. In a fortnight's time the patient was allowed up, and as soon as she was "taught" to walk was able to discard her crutches, and now, two years after operation, walked without limp and was free of pain.

Mr. Robert Jones, in reply, said he agreed with Professor Marnoch that local flaps in the neighbourhood of the elbow were difficult to secure, and he used free fascial flaps instead. In the case of pseudo-arthrosis of the ankle where possible removal of astragalus was practised; frequently, however, this was not possible. In attacking ankylosis of the knee where union was questionable, he performed an operation similar to Mr. Hey Groves, transplanting a slice of the upper end of the tibia into the femur.

The medical school of the University of Pennsylvania has admitted women to the regular course this year for the first time.

The Chadwick Trust (8, Dartmouth Street, Westminster) has arranged courses of public lectures on military hygiene, to be given in various places during the next three months. Dr. Naukivell, M.O.H. Poole, Dorset, will give three lectures at Bedford College, Regent's Park, on "Camp, Ship, and Hospital Hygiene," on Saturdays, November 14th, 21st, and 28th, at 3 p.m. on each day. Sir Ronald Ross, K.C.B., F.R.S., will give two lectures on "Government and Military Sanitation in the Tropics," at the London School of Economics, Clare Market, Kingsway, W.C., on Fridays, December 4th and December 11th, at 8.15 p.m. Dr. F. M. Sandwith, Gresham Professor of Physic, and formerly Physician to the Imperial Yeomanry Hospital, South Africa, will give three lectures at the Royal Society of Arts, Adelphi, W.C., on "War and Disease," on Fridays, January 15th, 22nd, and 29th, 1915, at 5.15 p.m. Professor W. J. Simpson, C.M.G., will give three lectures on "Naval Hygiene" at the Town Hall, Portsmouth, on Fridays, November 27th, December 4th and December 11th, at 9 p.m., and at the Royal Naval Hospital, Plymouth, on Saturdays, November 28th, December 5th and December 12th.

MECHANICAL CONSIDERATIONS OF THE HUMAN FOOT,

*WITH SPECIAL REFERENCE TO FLAT FOOT.**

BY

H. S. ROWELL, A.R.C.Sc.LOND., B.Sc.LOND., WH.SCH., A.M.I.MECH.E.,

ASSISTANT LECTURER AND DEMONSTRATOR IN THE UNIVERSITY OF LEEDS (ENGINEERING DEPARTMENT).

SOME time ago a man came to me with what he called a problem in mechanics. He was troubled, he said, with flat-foot, and had found great relief on making the heels of his boots higher by means of ordinary rubber heel pads. I asked him if the value of the rubber heels might not be due to the shock-absorbing qualities of rubber, and suggested experiments with leather heels of equal height. But he declined the experiments, and said he was quite certain that the elevation of the heel was the important factor, because one or two hours on his feet in low-heeled slippers brought back to him the pains of flat-foot. He asked me to investigate the mechanical conditions of the foot in order to see if raising the heel might give some mechanical advantage to those parts which maintain the arch of the foot. What I have been able to do will be seen below.

From the mechanical point of view the human foot is a structure of great complexity, so complex, in fact, as to be, in its complete form at any rate, quite beyond the power of exact mathematical treatment; mathematicians would call it a statically indeterminate structure.

By making one or two legitimate assumptions, results at least qualitative may be simply deduced. The foot may be considered replaced by a simple structure like an unsymmetrical roof truss (see Fig. 1): A B and A C represent the anterior and posterior limbs of the pedal arch, and B C is the tie of the truss which may be regarded as the resultant of the various ligaments and muscles which have a similar function in the foot. The points B and C represent, of course, the centres of pressure under the toes and heel respectively. Thus we replace the foot, with its numerous bones, muscles, and ligaments, by a virtual arch or truss supported against collapse by a virtual tie. It is now a matter of simple statics to calculate the variation of tension in B C as the heel of the truss is raised or lowered. The downward force at A is, of course, regarded as a constant and proportional to the weight of the man.

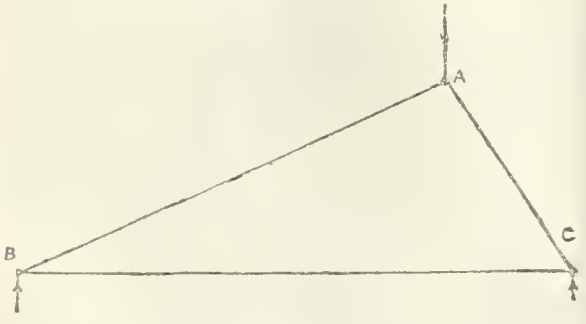

Fig. 1.

In the first place there are two limiting positions of the foot to be considered—the one, entirely suppositious, when the toes are raised until the posterior limb A C of the arch becomes vertical, the other, a case exemplified by many professional dancers, when the heel is raised so that the anterior limb A B becomes vertical. In both of these extreme positions there is no tension in the virtual tie of the arch. For any intermediate position there is a tension in B C, and the variation of this is shown graphically in Fig. 2. The abscissae of points on the curve in Fig. 2 represent in degrees the inclination of the sole of the foot to the horizontal; the angle of inclination being positive when the heel is higher than the toe and negative when lower. The ordinates of the curve represent the tensions in the virtual tie at the various angles of inclination. The scale of the ordinates is clearly quite immaterial, since the absolute tension is proportional to the weight of the man.

* Read in the Section of Surgery at the Annual Meetin of the British Medical Association, 1914.

The important point to be observed from Fig. 2 is that the tension (what would be popularly and erroneously termed the strain) is greatest when the sole of the foot is inclined

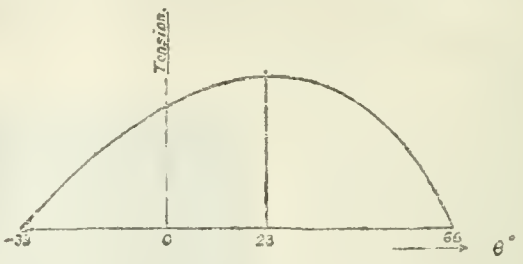

Fig. 2.

at 23 degrees to the horizontal. (In this position the tension is about 58 per cent. of the vertical load on the foot.) When the heel is raised or lowered from this position the tension is decreased. Thus, if the normal inclination of the foot were 23 degrees, then raising the heel would lessen the tension; but so also would lowering the heel, and this is distinctly inconsistent with the opening sentences of this paper.

It is to be remembered that the curve of Fig. 2 is deduced from a simple structure very different in detail from the foot which it is assumed to represent, and it might be supposed that the inclination of 23 degrees is not the exact angle of maximum tension in the actual foot. I have considered the chief elements which render the foot mechanically different from our simple roof truss model, such as a slight shifting of the astragalus and the finite curvature of the ends of the metatarsals and of the inferior surface of the os calcis. But these factors do not produce any material alteration in the results shown by Fig. 2. Thus the angle at which maximum tension occurs in the foot must be about 23 degrees. In Fig. 3 a boot is drawn in which the foot sole is at 23 degrees to the ground, and it will be seen to have a much higher heel than any ordinary man's boot. Thus raising the heel of the ordinary man's boot would have the effect of increasing instead of decreasing the tension in the supporting tissues. It is fitting to remark here that the boot shown in Fig. 3 is quite an average woman's boot, and we are led to wonder if women ordinarily wear boots which impose the maximum tension in the supporting tissues.

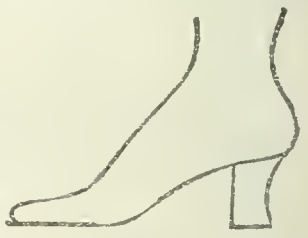

Fig. 3.

From the two preceding paragraphs it would appear that raising the boot heel could not in general have a beneficial influence in cases of incipient flat-foot. This conclusion is, however, only partly justifiable because our investigation has been purely statical and cannot take account of the foot in motion. On the other hand, flat-foot mostly occurs in people who do a great deal of standing, so that it might seem rational to suppose that the causes producing the trouble are statical. These results are in nowise affected by considerations of muscular tone except in the sense of corroboration. For if the muscles become flaccid the effect would be to increase the stress in the large ligamentous fascia at the sole of the foot and in fact to approach more nearly the statical conditions of the roof truss model.

So much, then, for statics. When we consider the foot in motion there are reasons why raising the heel might be advantageous. In the first place raising the heel must bring a greater proportion of the load on the anterior limb of the arch (see Fig. 4, where the maximum force in the anterior limb occurs when the inclination is 66° and is then equal to the vertical load—the ballet dancer condition). Now since the anterior portion of the foot is much more resilient than the other, there is every reason to believe that the dynamical stresses in the other parts of the foot would be reduced; speaking generally the momentum of the descending masses is destroyed in a longer time and thus the impulsive force is less. There

is also another consideration: anyone who observes pedestrians in a city thoroughfare will see at once a difference in the gait of those wearing high heels and

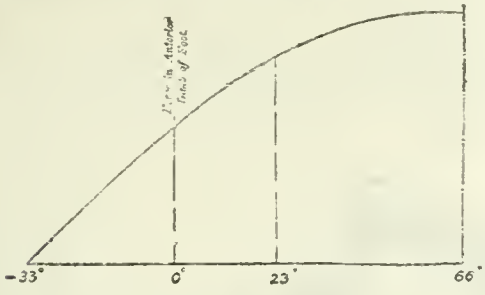

Fig. 4.

those wearing low; the high-heeled person seems to the eye to step more lightly, and this is confirmed by the ear of one who sits at a window in a quiet street and listens to the steps of the passers-by. This lightness of step artificially induced by the high heel involves a greater proportional stress on the anterior parts of the foot, which are, of course, supported by some of the calf muscles (tibialis posticus, etc.), and this would probably tend to maintain a degree of tone in these muscles, and almost certainly lessen the stress in the ligamentous fascia. Yet further, in the action of walking, the heel is raised largely by the action of the gastrocnemius. This muscle pulls on the os calcis, which in turn pulls on the ligamentous fascia. If the lifting action begins from a high heel, it is obvious that the stress in the ligamentous fascia due to this part of the motion must be less, for the weight of the body has then less moment about the toes, or, in less technical language, a smaller leverage.

Why the modern boot has been evolved with a heel thicker than the sole is a matter for speculation. The vanity of increased stature cannot be alone responsible, nor the advantages in raising the wearer out of the wet. The obvious advantage of a high heel in ascending a hill is more than neutralized in descending. Probably the reduction of jar on the heel and spine is an important factor; a high heel is capable of storing more strain energy than a low one. Thus it should not only lessen the shocks on the human frame, but, other things being the same, it will not be so highly stressed, and should thus last longer. This will be clearly grasped by those who understand why a wax candle may be projected through the panel of a door. The jarring action on the heel is easily perceived by walking on hard pavement in thinly-soled gymnasium shoes, taking long strides, so as to bring the heel down first.

An interesting paper by Mr. Dennis Cotterill on the treatment of flat-foot appeared in the *Edinburgh Medical Journal* of 1912.* In this paper the method described and recommended is that due to Mr. Robert Jones, of Liverpool, who, following Mr. Thomas, modifies the boots of the patient, making the soles and heels inclined transversely and in opposite directions. By this means and general exhortation the patient is induced to walk with his feet parallel, or nearly so. The argument for this method is practically entirely statical—namely, that by wedging over the boot a greater proportion of the load is thrown on to the shorter and stronger arches at the outside of the foot, and by inclining the toes inwards the resultant or virtual anterior limb of the pedal arch is shorter. These notions are, as far as they go, quite correct, but it would be irrational to suppose that the great majority of civilized people walk with out-turned feet for no good reason. By splaying the feet to a reasonable extent the base of support is widened, lateral stability is increased, and the control is much better; that is why a Swedish gymnastics instructor always recommends his pupils to land from a high jump with the feet inclined at 90 degrees so as to lessen the liability to spraining the ankle.

It is extremely difficult to see how purely statical effects could produce any appreciable benefit with the system recommended by Mr. Cotterill. The changes of stress consequent on such small changes of form would be very small indeed. Thus, as in the method of raising the heel, one is compelled to reject a statical explanation as insufficient. In the method of the high heel there are plausible dynamical considerations which might account for appreciable benefit to the patient, but the method of wedging the foot over is hard to justify dynamically. The only factor to account for the admitted efficacy of the method seems to be that of induced muscular tension, and this, if tenable, supports the employment of high heels too. Wedging the foot over and turning the toes in would induce a contraction of the tibialis posticus, and this would support the astragalus and the arch of the foot. Similarly, since by raising the heel the angles between the foot sole and the toes and between the foot sole and the tibia are both increased, the flexors of the foot would be brought into more active employment, and liability to flat-foot lessened.

It must not be thought that this article recommends the use of high heels universally. For long distance walking or rough country walking high heels would be absurd, because of the short strides which must be taken if the balance is to be convenient and sure. There is also the undoubted difficulty of avoiding undue pressure and constraint on the anterior part of the foot, but that is the bootmaker's problem. Our main conclusion is this, that for the ordinary inactive life of the drawing-room, office, and shop, high-heeled boots and shoes may be advantageous in giving to the feet a pleasant, braced-up feeling, quite different from that enjoyed or suffered by those who slither about in heel-less slippers.

Migrations from one to another branch of science are usually very difficult unless one has the advantage of expert help in those departments not one's own. In connexion with this inquiry I have been especially fortunate. To Mr. A. H. Miller, M.A., M.D., I am indebted for the suggestion of the problem, and to Mr. R. Cattley, M.B., B.Sc., for many instructive and interesting conversations. Mr. J. Kay Jamieson, M.B., C.M., Professor of Anatomy in the University of Leeds, took great trouble in making clear to me the essential structure of the foot, and Mr. J. C. Brash, M.A., M.B., B.Sc., Demonstrator of Anatomy in the University of Leeds, not only discussed the matter on every occasion most willingly, but dissected a foot for my especial benefit and instruction. These gentlemen I heartily thank.

DISCUSSION.

Mr. ROBERT JONES stated that the problem of flat-foot could not be solved merely by attention to the height of the heels. Undoubtedly certain cases of painful feet were alleviated by wearing high-heeled boots, and, furthermore, the use of sandals had been a factor in the production of flat-feet in children. High heels, however, tended to flatten the transverse arch, and to produce metatarsalgia, and failed in supplying the development of the muscles of the sole. The pain complained of by people changing suddenly from wearing high heels to wearing low ones was real, but it was equally true that pain was as marked when the low heels were suddenly substituted by high ones. Mr. Jones doubted the improvement in walk spoken of by Mr. Rowell as brought about by high heels. Nor did he agree that the abducted foot gait should be encouraged. Valgus could be artificially produced by training children to walk with their toes out-turned, and for this error the dancing mistress was largely responsible. The eversion of the foot was a complication which could only be met by so altering the footgear that body weight became transferred from the inner to the outer side of the tarsus. This relieved the ligaments and muscles of the sole from strain, and relaxed the internal lateral ligament of the ankle. In a condition such as flat foot it was impossible to work out a code of treatment by dynamics without studying the variants that played a part in the problem. For the cure of the condition it was fundamental that the feet should be parallel when walking, that the walk should be heel and toe; that body weight should be deflected from the inner side, and that exercises should be practised, designed to strengthen the invertors of the foot.

* Tilting the Soles of the Boots and its Use as a Means of Treatment in various Common Conditions. *Edinburgh Medical Journal*, N.S., viii. 1912, p. 111, et seq. My best thanks are due to Mr. J. C. Brash for having brought this paper to my notice.

THE SOLDIERS' FEET AND FOOTGEAR.

BY

CECIL WEBB-JOHNSON, M.B., CH.B.,

CAPTAIN R.A.M.C.(T.F.),

HONORARY SECRETARY OF NAVAL AND MILITARY MEDICINE AND SURGERY SECTION, ANNUAL MEETING, BRITISH MEDICAL ASSOCIATION, 1914.

THE SOLDIERS' FEET.

THE soldier's foot has not only to support the whole weight of the body, but also to act as a buffer, and prevent shocks being transmitted to the knee and hip joints when jumping or doubling over rough ground. The Germans found that lifting the foot high when marching made the troops more surefooted, and that while before its adoption, 25 per cent. of the men stumbled, and 10 per cent. fell in a charge over rough ground, the new method practically eliminated such misfortunes. Any horseman will recognize this, for not only is it safer to canter than to trot on rough ground, but a horse that does not lift its feet is a danger anywhere, not only to himself, but to the rider.

The soldier's foot must be capable of standing the strain of long marches without becoming incapacitated by pain and loss of power. The medical officer should reject as unfit any recruit who suffers from the following conditions in a bad form:

1. Flat-foot.
2. Hallux valgus.
3. Hammer toe.
4. Ingrowing toenail.
5. Corns.
6. Bunions.

Some of these conditions can be cured so as to give a man a serviceable foot, but with others it is quite impossible. In the former case a recruit should not be accepted *until* he has undergone treatment, and been cured, while, in the latter, he should be unconditionally rejected.

1. *Flat-foot*, if of a slight degree, may be disregarded, as in many cases it does not get worse with long marching. Some medical officers refuse all cases of flat-foot, but in my opinion this is too drastic. I knew a well-known quartermaster, rejected twenty-nine years ago by the 17th Lancers on account of a slight degree of flat-foot, who was accepted next day by the Grenadier Guards, and who assures me that he has never had any trouble with his feet from that day to this. In a great number of cases the healthy outdoor life of a soldier, coupled with the physical exercises and marches, tones up the muscles which support the arch. The formation and maintenance of the arches was fully discussed earlier in this paper; when the muscles and ligaments have yielded, the head of the astragalus and scaphoid may even rest upon the ground, on standing. The flat-footed person walks with the toes turned out, and the heels do not leave the ground, so that all elasticity in walking disappears. In a bad case a man complains of pain along the inner side of the foot, and in the calf on marching, and gets tired very quickly. I make it a rule to reject a man with flat-foot if he is quite unable to raise himself on his toes and restore the arch by the action of the muscles of the calf. If the flat-foot is only slight, tip-toe exercises, combined with massage of the deep muscles of the calf and sole of the foot, improve the condition. Mechanical supports are not to be encouraged in the soldier, though they may be of use in civil life. I am of opinion that careful lacing of the boots, so as not to retard too much the increasing convexity of the tarsus in the act of rising when walking, considerably helps matters, and a good plan is to tell the men to knot their laces low down (as for a shoe) and then to continue to lace less tightly in the upper holes. The heel and sole of the boot may be made continuous on the inner side, or the inner border may be raised so as to throw the foot on to its outer border.

Fig. 5.—Hallux valgus, showing bunion and deformity; A, bunion.

2. *Hallux valgus*, if in an advanced state, incapacitates a man for marching, for the great toe, being abducted at the metatarso-phalangeal joint, is compelled to pass either above or below the second toe, thus crowding the other toes together and making them liable to cross. The head of the first metatarsal bone is pressed upon by the boot and gives rise to a bunion.

It is not within the province of this paper to discuss the operative treatment of this deformity, but one may unhesitatingly say that a man with such a foot should be rejected. Slight cases may be treated by giving a boot with wide toes and a straight inner border, and by keeping the great toe in a straight line by mechanical means.

3. *Hammer Toe.*—In this condition the toe is flexed at the proximal phalangeal joint, on the top of which there is generally a corn. At the end of the toe, where it presses on the boot, another corn is often found, and these corns become exquisitely painful and prevent a man from marching.

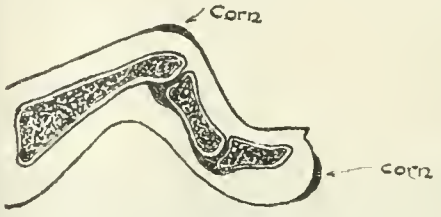

Fig. 6.—Hammer toe, showing deformity and favourite situation of corns.

Formerly the toe was amputated, but to-day the proximal phalangeal joint is excised or the toe straightened by section of the flexed tendon and the lateral ligaments at the first interphalangeal joint. If either of these treatments be adopted successfully there is no need to reject a man, but if operative treatment be refused he should be found unfit for service.

4. *Ingrowing Toenail.*—This is an extremely painful condition, caused by wearing boots with narrow toes. In a slight case the boots having been corrected, the nail should be cut square and a wedge-shaped piece taken from the centre, or the centre of the nail should be scraped and filed down and the pressure relieved by packing plugs of cotton-wool under the free ends and sides of the nail. If this does not relieve the symptoms, the nail should be removed by one of the recognized methods.

5. *Corns.*—Hard corns, caused by the pressure of tight boots, are most commonly found on the sides of the toes, under the tread, and on the heel. Soft corns, caused by dirt and sweat, are usually found between the toes. Corns are more painful in wet than in dry weather, and are said to "shoot," a condition due to a sudden increase of activity in the vascular and sensitive papillae, on the approach of damp weather. The treatment of corns may be divided into palliative and radical, but it should be remembered that if the boots fit properly without undue pressure the soldier should be free from them. If no chiropodist is at hand the corns may be rubbed down daily with pumice stone, and if tender, protected with a piece of stockingette plaster, stretched over the corn with a good margin. For the radical cure the area of corn is painted with tincture of iodine, and all the thickened epidermis is cleared away with a scapel, this being facilitated by making the skin tense with the left fingers. Then the concentrated apex or ridges, which are the actual cause of the pain, are lifted out with a sharp-pointed straight scalpel. Often there is a small adventitious bursa, which should also be removed, and an antiseptic dressing placed in the cavity. Circular plasters are seldom effective, as the portion on the distal side of the corn may press back in walking, and irritate, but it is advisable to pad with a crescent-shaped piece on the posterior aspect of the wound, and cover with a stockingette plaster.

6. *Bunions* are generally associated with hallux valgus, and, if accompanied by synovitis, prevent marching. To alleviate the pain a wedge-shaped felt pad should be worn between the great and second toes at the base, and, in addition, a crescent-shaped adhesive felt pad on the metatarsal aspect, posterior to the joint. This condition is greatly helped by a 1-in. zinc oxide strapping round the shafts of the metatarsal bones, sufficiently tight to hold them a little closer together, as with a bunion there is

Fig. 7.—B, Wedge-shaped piece of felt; C, bunion.

always a lateral expansion of these bones. This strapping should be put round slightly diagonally, encircling the foot twice and overlapping, so that the total width is 1½ in. Elastic's zincoplast is the best for this purpose, as it causes no irritation and can be worn for a fortnight without discomfort. Incipient bunions may be painted with iodine or rubbed with iodex; if there is much inflammation the joint can be quickly reduced by an application of antiphlogistine.

Sore Feet.

The disabilities of the foot already mentioned, although coming under the general heading of sore feet, as used in military parlance, do not constitute the ordinary variety met with after a march. Sore feet are of several varieties and degrees of severity, and, if promptly and properly treated, may be quickly cured. When the skin of the foot is irritated by the boot or sock either pressing or rubbing on it, or when, through lack of cleanliness, sweat and various germs collect on it, the foot becomes hot, swollen, and tender. If the condition is not suitably and quickly treated, blisters form, especially under the heel and above it, at the sides of the feet, between the toes, and at the anterior roots of the toes. If this in turn is neglected, there is a danger of the hard, horny skin being rubbed off, and the tender deep layer of the true skin being exposed, and if this is not treated there is every possibility of the deeper tissues being involved, and of an ulcer forming. The causes of sore and blistered feet after a march are:

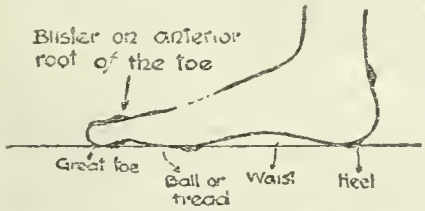

Fig. 3.—Common situation of Blisters.

1. *Boots.*
   (*a*) Too tight, causing pressure.
   (*b*) Too loose, causing friction.
   (*c*) Too hard, through lack of oil or dubbin.
   (*d*) Shrunk, through getting wet.
   (*e*) Nail or seam inside boot.
   (*f*) Improperly laced boot.
2. *Socks.*
   (*a*) Too tight, causing compression of toes, or heel of sock getting under sole of foot.
   (*b*) Too loose, causing wrinkles.
   (*c*) Dirty socks.
   (*d*) Socks with holes.
   (*e*) Too thin and non-absorbent socks.
   (*f*) Badly darned socks.
3. *Feet.*
   (*a*) Dirty feet.
   (*b*) Sweaty feet.
   (*c*) Deformed feet.
4. *Accidental.*
   (*a*) Grit or foreign matter in boot.
   (*b*) Burn or scald when cooking.
   (*c*) Punctured wound from external object.
   (*d*) Weight, such as rifle, falling on foot.
   (*e*) Kick or stumble.
5. *Vasomotor.*
   (*a*) Frost-bite.
   (*b*) Chilblain.

Practically all these causes can be avoided if a little care be exercised, and it is seen that:

(*a*) The boots and socks fit properly.
(*b*) They are periodically inspected.
(*c*) The boot is kept soft and supple.
(*d*) The sock is kept clean and well darned.
(*e*) The feet are washed and thoroughly dried daily.
(*f*) There is a regular foot inspection.
(*g*) The chiropodist is consulted early.

In the paper on "Common Ailments in Camp" which I read this year at the annual meeting of the British Medical Association,[1] I said: "One of the greatest troubles in camp is blistered feet, and a large percentage of men is rendered unfit for duty for one or more days on this account. The men should be taught to see that their feet are washed and thoroughly dried every day after work is over, and if this is found to be impracticable, the feet should be thoroughly wiped with a wet towel, especially between the toes, and then dried. The socks should be greased on the outside with soap, and when they show a tendency to shrink they should be stretched and worn on the opposite feet. I would suggest that a regular foot inspection be conducted by the medical officer in conjunction with the company officers, so that all feet requiring attention can be treated and at the same time the boots and socks inspected." I have little to add to this except to put forward a few suggestions as to the best means to adopt to prevent the tender feet from blistering.

It cannot be denied that some men's feet blister more readily than others, and it is wise in such cases to try to harden the skin and make it less susceptible. When a man's feet are sore and inflamed, but not blistered, it is advisable for him not only to carry out all the rules laid down in this paper, but also regularly to do one of the following:

(*a*) Rub the feet night and morning with spirit, to which may be added 1 to 2 per cent. of salicylic acid.

(*b*) Paint the tender parts once or twice a day with either a saturated solution of picric acid, or a solution of chromic acid (2 to 3 grains to the ounce).

(*c*) After drying the feet, sprinkle with a powder composed of talc and salicylic acid (salicylic acid 2 grains, talc 1 oz.).

(*d*) Soak the feet in a bucket of cold water to which potassium permanganate, salt, alum, tannic acid, or saltpetre has been added.

Men who complain of excessive sweating of the feet should soak them daily in a solution of formalin and water (1 to 800), dry them, and dust them with zinc oxid or some other powder. Tender feet may be well greased with zinc or boracic ointment, or the soles of the feet may be soaped. When a man's feet are normally fatigued at the end of a long march, after he has washed and dried them, he will find great relief if he lies down and raises the feet by resting them against some firm object.

If, in spite of all these precautions, a blister forms, the fluid should be evacuated aseptically and the surplus skin, liable to cause pressure, cleared away. An antiseptic ointment should then be applied and the blister covered with stockingette plaster. As, after the heel, the most common situation for a blister is the plantar aspects of the fourth and fifth toes, it is in this case advisable to use animal wool round and under the toes to counteract the flexion which causes the pressure on these parts.

The commonest cause of *chilblains* is sitting over the fire with wet, cold boots, and these are best treated by restoring the circulation by gentle massage and by wearing warm footgear. Lead and opium plaster may be applied, or the internal administration of tincture of opium may act as a charm in some cases.

Frost-bites, caused by exposure to cold, have given the soldier trouble in the past, and will do so in the future if the circulation is not kept in a vigorous condition and the foot warmly clad. In treating any case of frost-bite a great amount of patience is necessary to restore the circulation gradually. If the toes are frost-bitten, it is advisable to do this before taking the soldier into a warm place, and on no account should he be brought near a fire until the circulation has been restored. Begin by rubbing the affected part gently with snow, and bathe the feet with water, increasing the temperature gradually until the circulation is fully restored, when the affected parts may be wrapped in cotton-wool or flannel.

One cannot leave the question of the soldiers' feet without mentioning the fact that the gonococcus is responsible for many foot disabilities in the army. The *fons et origo* of the trouble should be drastically treated and the serum injections resorted to, but a man with gonococcic arthritis or flat-foot should be *rejected*, as he will always be a danger to his unit. In no small measure the question of the marching power of a soldier depends upon the medical officer, for not only has he the power of rejecting an unsuitable man, but also he has the responsibility of seeing that the soldier keeps his feet in good order, and ready for efficient service. To do this means constant supervision and advice, and he should remember that there is no *deus ex machina* to remedy the disability immediately, when it occurs.

Summary.

To make the soldier as perfect a marcher as is consistent with the human foot, I would, in addition to what is being done at present, suggest the following:

Feet.

(*a*) No recruit with any bad degree of foot deformity should be accepted as medically fit until the condition is cured.

(*b*) Every soldier, on enlistment, should be given a printed pamphlet explaining the importance of foot cleanliness, and he should be periodically lectured on it by an officer.

(*c*) Foot parades should be more thorough and more frequent.

(*d*) The battalion chiropodist should be more often and sooner consulted.

(*e*) It should be made *compulsory* for the feet to be washed after every long march.

(*f*) No medical officer should find any difficulty in obtaining adequate supplies of chromic and picric acids, formalin, and dusting powders, or any other drugs he considers necessary.

Boots.

(*a*) The army boot might be improved by allowing more depth over the toes. This could be accomplished by boxing up the anterior part of the vamp and having the end more rounded.

(*b*) Printed instructions and lectures should be given on the best means of keeping the boots in good condition.

(*c*) No man should be allowed to wear new boots until they have been well softened.

(*d*) The proper fitting of a boot should be considered an art and not a nuisance. Fully one half of the foot troubles are caused by careless or too rapid fitting.

(*e*) The boot should allow more ventilation of the feet. It is a debatable point which is the worse of the two evils, namely, the possibility of a little water percolating into the boot or the continuous saturation of the foot and sock with stale sweat. In my opinion a wet foot in free communication with the air is less likely to cause trouble than one which is rendered sodden, soft, and offensive by being bathed in its own sweat, without aëration. To give more ventilation, the tongue of the boot should not be attached to the uppers to the exclusion of all air, and the quarters should be perforated by ventilating holes so as to admit fresh air and allow the escape of foul emanations and gases arising from the heated and fatigued state of the foot.

Socks.

(*a*) These should be fitted as carefully as the boots.

(*b*) They should be issued *after* having been shrunk.

(*c*) They should be washed after a long march, and different pairs should be worn on alternate days. This should be compulsory.

It may be argued that many of these points are already known to the men, who have been lectured on them by their officers. Even so, it does not follow that they carry out what they are taught and know to be correct, any more than when a man is taught to be good he becomes a saint, or a gouty subject abstains from port because his medical adviser told him to do so. Further, we must remember that we are discussing the feet not only of the regular army but those of the Territorial Force and Kitchener's Army. If every soldier were taught to take as much care of his feet, boots, and socks as his rifle, and, in addition, were compelled to do so, sore feet would cease to give trouble. The civil surgeon may inquire, "Why all this toil for the triumph of an hour?" and my answer is "*Finis coronat opus.*" The crowning hour of success may be gained by men whose feet can carry them to victory, but can never be won by those who cry in despair, *Volo, non valeo.*

Dr. H. P. Pickerill, Professor of Dentistry in the University of Otago, informs us that with the New Zealand Expeditionary Force coming to Europe are two dental lieutenants. These gentlemen were senior students at the Otago University, but on the outbreak of war were given special examinations, and thereafter granted special dental commissions.

INSECTS AND WAR:

VII.—*MITES: THE HARVEST MITE (Trombidium).*

By A. E. SHIPLEY, Sc.D., F.R.S.,

Master of Christ's College, Cambridge.

Natura in minimis maxime miranda.

Linnaeus.

We do not know what life is, but we can at any rate record its manifestations, and we know that it is always associated with an extremely complex substance called by Purkinje "protoplasm." This substance Huxley described as "the physical basis of life." Protoplasm, though we know of what elements it is composed, defies accurate analysis, and, indeed, is never the same for two minutes together. It is constantly changing, it is in a state of flux, and is, in effect, a stream into which matter is continuously entering and continuously leaving.

Protoplasm may be living, or it may be dead, and when dead it soon undergoes dissolution; but there is no life without protoplasm. Somewhere or other Dr. David Sharp has stated that out of the total amount of protoplasm "in being" in the world, the real volume of the life-material, at least one half is wrapped up in the body of insects. But insects only form one group out of the several which make up the Phylum *Arthropoda*, or those animals which are distinguished from others by possessing externally jointed legs—that is, jointed appendages. This phylum includes also the Crustacea, the multi-segmented Centipedes, and the Arachnids or spider-like animals.

Insects, like aeroplanes, dominate the air; the crustacea, like submarines, inhabit the water; the poet has passionately asked:

> Ah! who has seen the mailèd lobster rise,
> Clap her bread wings and soaring claim the skies?

But the answer is, in the language of those curious creatures the politicians, "in the negative." Crustaceans are essentially aquatic. On the other hand, centipedes and spiders are earth-loving animals, and some have unhappily developed parasitic or pseudo-parasitic habits.

The last-named subgroup, the Arachnids, comprise many subdivisions. There are the spiders, the harvest-men, the scorpions, the king-crabs, and so on. But one of the most numerous of the subdivisions of the group are the mites and ticks (*Acarina*). I have for years been trying to find some organ or structure shared by insects and mites and ticks, and not found in any other group of arthropods. If I could do this I would invent a long polysyllabic word—with lots of Greek in it—which would replace the word "insect" at the head of this article; it is, of course, hopelessly bad zoology to class Mites with Insects. These Acarines are for the most part small, and they differ from spiders in having no waist. In fact, the three divisions in which the body of an arachnid is divided—head, thorax, and abdomen—are indistinguishable in mites, the body forming an unconstricted whole. As a rule, these little creatures breathe, as do Insects, by tracheae, or, if these be absent, by the general surface of the body. They live for the most part on vegetable and animal juices, and their mouth parts are, as a rule, piercing and sucterial; but in some species the appendages of the mouth are capable of biting as well as piercing. The adults have typically eight legs. The larval stages are very numerous, and at times six distinct moults of the skin are recognizable. With few exceptions the larva emerges from the egg as a six-legged creature. In fact, mites undergo a metamorphosis

Fig. 1.—*Trombidium holosericeum.* Female, dorsal view. × 20.

which varies in complexity and in completeness in different groups, and it is often one of the larval stages which causes the greatest trouble to man.

One of these six-legged larvae has been long known as the harvest mite, under the name of *Leptus autumnalis*. But this is not a real species, and there is still considerable confusion as to what the exact status of *Leptus autumnalis*, the harvest mite, is. Probably the larvae of several species are involved, but it seems pretty certain that in many cases the larvae will grow up into a species of the genus *Trombidium holosericcum*, though a certain and at present unknown percentage of the larvae will grow up into *Trombidium something or other else*.

Fig. 2.—*Leptus autumnalis* = larva of *Trombidium holosericcum*. Ventral view. × 100.

They are minute bright-red little creatures of a beautiful satiny red, decorated here and there with blackish spots. The body of the adult is somewhat square, tapering slightly to the hinder end. Both legs and body are covered with red hairs. The eyes are borne on little pedicels—like lighthouses. The legs have six joints and end in two little claws. The male is usually smaller and more feeble than the female, the latter reaching a length of 3 to 4 mm. The adults are commonly met with in the spring or commencing summer. Apparently they nourish themselves on vegetable sap. The larval form of this species is undoubtedly one of the forms confused under the discarded name of *Leptus autumnalis*. When starving, the body is orbicular in outline, but it becomes oblong when it is fed, and in this case it may attain a length of ½ mm. Its colour is of a deep orange.

This harvest mite, or, as it is called in France, *le rouget*, is most troublesome at the end of summer or at the beginning of autumn, when it is found in enormous numbers in grass and amongst many other plants—gooseberries, raspberries, currants, haricot-beans, sorrel, and elderberries. From these plants it passes on to any warm-blooded animals; particularly it attacks small mammals, hares and rabbits; moles are often covered with them, but they leave their victim, should it be shot, so soon as the body chills. They are particularly common in Great Britain and in the centre and west of France, and in certain parts of Germany. These irritating little semi-parasites may be dislodged by the application of petrol or benzine, both very inflammable, and the itching they cause allayed by the application of acid or alcoholic lotions.

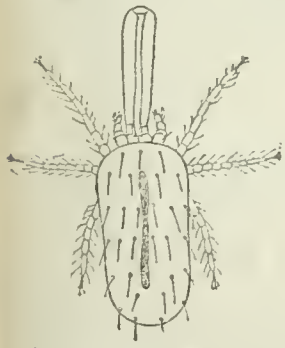

Fig. 3.—*Leptus autumnalis*, with the so-called proboscis. (After Gudden.) Magnified.

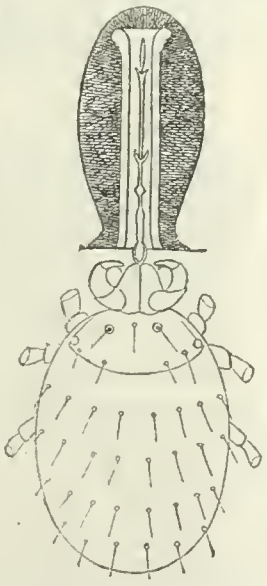

Fig. 4.—*Leptus autumnalis*. × 100. The so-called proboscis is formed around the hypopharynx sunk into the skin. (After Trouessart.)

Fig. 5.—*Pediculoides ventricosus*. Male; ventral view. × 250.

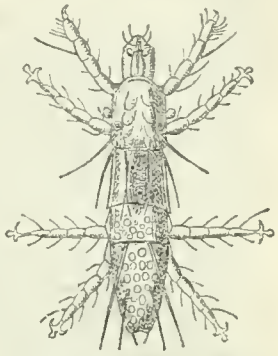

Fig. 6.—*Pediculoides ventricosus*. Female, before fertilization. × 225.

Men working in the fields are frequently attacked. During September the soldiers of the Sixth Division, stationed in and about Cambridge, suffered severely from their "bites." They mostly attacked the ankles, the wrists, and the neck, but they rapidly extend over the body. If they be checked by the presence of any stricture, such as a garter or wrist-band, they accumulate behind it, and the irritation is accentuated. The presence of their proboscis in the skin causes the surrounding tissues to harden and form a cylindrical tube.

The amount of trouble they cause varies very greatly in different people. Children and women with soft skins suffer as a rule most, but as happens in the case of other biting insects, certain individuals seem to be almost immune, whilst others suffer very considerably. The trouble is caused by the mite implanting its mouth parts in the skin, preferably in hair follicles or sweat glands. When it is once fixed it rarely moves. The body remains, of course, on the surface of the skin as a little reddish-orange point, scarcely perceptible unless many of them are congregated in the same position. The effect of their presence is to produce a swelling in the skin which may be as large as a split pea, accompanied by an intense itching and a smarting which banishes sleep. This leads to the patient's scratching, and this scratching is the departure-point of many troubles. Scoriated papules appear and eczematous patches, and when the mites are very numerous an erythema, named by Rubies *Erythema autumnale*, supervenes. The skin near the point of puncture swells, becomes red, sometimes almost purple, and irregular patches, which may be confluent, appear a centimetre in diameter.

These skin troubles, which may end in a kind of generalized eruption, are accompanied by a rise of temperature and a certain, sometimes a high, degree of fever. Besides men, dogs and cats suffer from these pests, and in these domestic pets the parasites give rise to a miliary eruption.

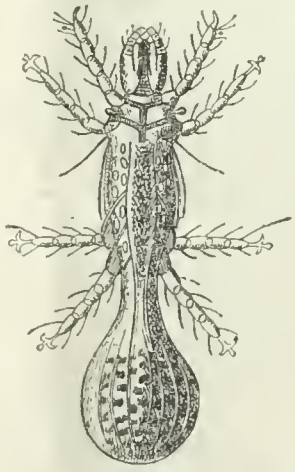

Fig. 7.—*Pediculoides ventricosus*, after fertilization; the abdomen has begun to swell. × 250.

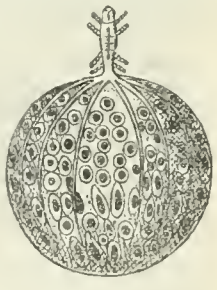

Fig. 8.—*Pediculoides ventricosus*, with abdomen fully swollen. × 40.

Domestic cattle—sheep and horses—are also attacked. But, according to some authorities, poultry are not only attacked but killed by these parasites. The larvae apparently can only live a few days in the skin of the victim.

As far as is known at present the larvae of *Trombidium* convey no protozoal disease, but there is a terrifying little creature, known as the Kedana mite, which in some districts of Japan causes a serious illness, with a mortality of some 70 per cent. Apparently it does not act as an inoculating agent itself, but the papule surrounded by the red area which forms as a result of its bite changes to a pustule, and the lesion becomes the point of entrance of bacteria which produce the so called "river" or "flood" fever. If these mites be carefully removed the patient suffers no harm.

Another species of mite, *Pediculoides ventricosus*, lives in stalks of serials and is very apt to attack labourers who are dealing with grain. Their bites cause severe irritation, local swellings, reddening of the epidermis, and fever. In this particular species the female before she is fertilized has an elongated form 0.2 mm. in length and 0.07 mm. in breadth; but when fertilized the ovaries increase to such an extent that the posterior end of the body becomes spherical. In this respect it resembles that remarkable flea, the chigo or jigger. The larva is born with four legs and pairs almost immediately after emerging from the egg-shell.

A SIMPLE AND RAPID METHOD OF LOCALIZING BULLETS.

By FRANCIS HERNAMAN-JOHNSON, M.D.,

MEDICAL OFFICER AT PRESENT IN CHARGE OF X-RAY AND ELECTRICAL DEPARTMENT, CAMBRIDGE HOSPITAL, ALDERSHOT.

A MEANS of localizing bullets which does not require the use of any special apparatus, nor involve the taking of radiographs, is often of value. A method of which I have made considerable use is the following. So far as I am concerned it is original, though it may, of course, have been described by others without my knowledge.

Suppose a bullet has lodged somewhere about the middle of the thigh. The patient is placed on an ordinary examination couch having the tube beneath. His feet are placed together, with toes pointing directly upwards. The *x* rays are turned on with a widely open diaphragm, and the general position of the bullet ascertained by the fluorescent screen.

The aperture is now gradually narrowed, and the tube moved about so that the image comes into the centre of the field, which, if the anticathode has been correctly centred, will be a perfect circle. This process is continued until the illuminated patch is not more than 1 in. in diameter. The image of the bullet is now vertically above the bullet itself.

The only special device necessary is now used. It consists of a metal ring having an internal diameter of about ¾ in., fixed to the end of a flat wooden handle 1 ft. in length (Fig. 3). The ring is slipped under the screen, and moved until its shadow encircles that of the bullet. A mark is made on the skin with silver nitrate in the centre of the ring, the screen being first removed, but care being taken not to displace the "ring-localizer."

Next, the screen is readjusted, and the ring is now slipped between the patient and the couch. The encircling position is again found, and a second mark made, this time on the skin of the lower aspect of the limb. If everything has been carried out properly, this second mark will be found vertically below the first.

I have tried to illustrate this diagrammatically in the accompanying figures, which represent a vertical section through the patient's limb, couch and tube, at right angles to their long axis. Z B (Fig. 1) is the vertical beam of rays passing through the narrow aperture X and casting a shadow of the bullet B, which is marked at C; A is the mark below the limb, obtained as above described. An incision commenced at C, and carried downwards at right angles to the surface along the line C A would eventually strike the bullet, but it is not yet possible to say at what distance below the surface it will be found.

To ascertain this the patient is rolled over on his side, so that the line A C is parallel with the plane of the couch—that is, B is made to move through an arc of 90 degrees. The original procedure is now repeated and two other marks are obtained, a line joining which, E D, cuts A C at right angles (Fig. 2).

The patient is now returned to his former position, and an inspection of the marks will enable one to judge within half an inch the distance at which B lies below the surface along the line C A.

Should the surgeon desire an exact quotation in inches, a strip of lead, thick enough to retain the shape into which it is bent, is moulded to the surface of the limb from E to D. A nick is made in it corresponding with the mark C. It is then placed on a flat surface, so that a line joining its extremities represents the chord E D. A vertical measurement with a ruler from the nick (C) gives the distance C B.

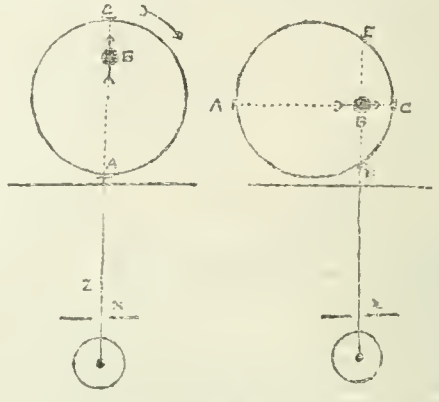

Fig. 1. Fig. 2.

Fig. 3.—Ring-localizer; scale ½.

The above method is not readily applicable to foreign bodies in the neighbourhood of the pelvis, as the transverse line is difficult to obtain. Here I find the simplest thing is to ascertain the vertical line as above, and then to take stereoscopic negatives. These, as a rule, enable one to get a sufficiently good idea of the depth for practical purposes.

Points essential to the success of the method are:

1. The beam of *x* rays must be vertical, and the shadow of the bullet must be manœuvred into the centre of the small illuminated field.
2. The "ring-localizer" must accurately encircle the bullet shadow.
3. The nitrate of silver marks must be placed at the centre of the ring. It is better to make dots for the vertical marks, and crosses for the horizontal, in order to avoid subsequent confusion.
4. Whenever the nature of the case permits, the patient should be operated on in one or other of the positions in which the localizing was carried out.
5. Lastly, wherever possible, the patient should be taken directly from the examining couch to the operating theatre. Bullets sometimes alter their position to some extent even in twenty-four hours, and undeserved discredit is thereby brought upon the art of the radiographer.

Although the procedure described depends entirely on screen examination, it is not dangerous to the operator. The small field makes it unnecessary for him to expose his eyes to a direct *x*-ray beam, and the handle of the "ring-localizer" does away with all risk to the fingers.

THE Registrar-General, Somerset House, London, W.C., has been entrusted with the duty of compiling a Central Register of all Belgian and other war refugees who have been received in the United Kingdom, and the secretaries of local committees formed for providing accommodation for refugees are asked to apply at once to him for a supply of forms upon which to record the particulars required. Letters sent to the Registrar-General, Somerset House, London, W.C., do not require to be stamped. The envelopes should be marked "War Refugees" in the top left-hand corner.

THE MEDICAL CARE OF LINES OF COMMUNICATION AT HOME.

By C. BREHMER HEALD, M.D.Cantab., D.P.H.,
TEMPORARY SURGEON, R.N.

Various extremely interesting contributions have recently been appearing in the pages of the British Medical Journal from the pens of both Regular and Territorial officers of the Royal Army Medical Corps dealing with different aspects of hygiene and health among troops. Several writers, notably Mr. Basil Hughes, have insisted on the necessity for taking simple but active steps to prevent minor ailments—such as constipation, diarrhoea, sore feet, etc. It is in connexion with these lesser conditions that I think perhaps my experience may be of interest to some and of use to others.

Shortly after the outbreak of war I found I had a week or two to wait before being appointed to a hospital ship, the fitting out of which had become delayed, and I happened one day to be standing on the station at home when someone addressed me as "Dr.," and the sergeant of the picket overhearing, asked if I would look at a man who had sprained his ankle. I of course did so. It then occurred to me to ask who was looking after the health and sanitation of the various pickets all down the line; and I was told that the only surgeon then working with the battalion, which had to cover fifty miles of line, was the Major R.A.M.C.(T.) at the battalion head quarters, and that he had more than he could do there, so that anything like regular visits was impossible. Recognizing that these Territorials, coming as they did from a densely populated district in London, would need careful preventive treatment if they were to be "hardened without cracking," I applied to the senior medical officer of the battalion for leave to visit each day as many of the isolated tents and huts as I could, until such time as I was called to my ship. This offer was most gratefully accepted, and I commenced work the following day, and for the first few days went only on foot with the officer of the different sections; later I was able to borrow a car, and more than doubled the distance of line looked after. I carried a rucksack, and it took several days to find out what was and what was not needed when visiting far from either hospital or chemist. As a matter of interest I have appended a list of the contents of the rucksack.

The day's work consisted in visiting, with the officer of the section, the tent or hut used by the picket guarding each bridge and culvert; when he had done his work the various points of medical interest were gone into, and gradually a definite scheme of inspection and questions built up. The average number of posts were about two to the mile.

At first, however, we found:

(*a*) Badly prepared latrines, either too shallow or with countless flies swarming over improperly covered evacuations; or too near the tent, or—and this was very common—in ditches leading directly to the bathing or drinking water; or the same pit being used both for evacuation and urination.

(*b*) Badly kept food, that is, meat exposed to flies or in close proximity to fires and sleeping places; dirty food boxes, refuse and rubbish hidden but not destroyed.

(*c*) Water kept where anything could fall into it, and water bottles never scalded out.

(*d*) Dishes and utensils cleaned in sand and with grass, and neither these nor the cloths for drying them ever boiled.

We found constipation, sore feet, minor injuries, sore throats and diarrhoea the most common cases for treatment; the first two accounting for about 60 per cent. of the whole.

The teeth were troublesome after the first week when there had been a considerable change in the weather. The cause of sudden inflammation in teeth which had probably been chronically septic for years was, I considered, due to a summation of changes in the life of these men and not to any one factor such as the weather. The men were made to purchase toothbrushes and tooth-powder and the non-commissioned officer of the tent made responsible for seeing that every one used them.

The following points were insisted on, one by one, to remove the dangers inherent under such conditions; thus the men were gradually trained without being muddled.

A Proper Latrine Scheme for Each Picket.—The instructions with regard to these varied widely; the railway might be running on an embankment or through a cutting, or the picket might be small or large; or, again, they might be in a station with regular sanitary arrangements. These instructions were based on the section on camp sanitation in Notter and Firth's *Hygiene*, and were found to work satisfactorily, especially when each man built his own latrine trench and was made responsible for it.

Meat safes were provided by voluntary workers; they were made of two rings of wire, an "S"-shaped meat hook, a cheap fly-proof cloth which allowed air to pass freely, and a running cord. These could be made for about half the price paid in shops, and were found effective in keeping the flies off and providing means for hanging the meat in a cool place. Food boxes were ordered to be scrubbed out and an incinerator built. It always remained necessary to probe the tent or hut for hidden débris, as also for signs of the men not using the latrines at night. All water was ordered to be boiled and set aside to cool with a cover on it; this precaution was partly taken on account of the certain knowledge one of the officers possessed of attempts to poison water supplies. Dishes were allowed to be cleaned in sand and grass, but then had to be boiled and the sand and grass thrown on the incinerator. Where this was not done cases of diarrhoea occurred, and I think that Mr. Basil Hughes is probably correct in his suggestion that the Gaertner bacillus was the responsible organism.

The men were asked the following questions, each separately, as it was found that less careful questioning resulted in unsatisfactory answers: (1) Were your bowels open this morning? Were they open yesterday? What time? (2) Are your feet sore? Foot inspection was taken every alternate day, and on this day teeth also were looked at. (3) Are you sleeping and feeding well? (4) Do you change your socks every night? (5) Are you getting a swim or bathe?

Then to the non-commissioned officer of the picket:

(*a*) Has anyone been complaining of anything?
(*b*) Are you satisfied with their health?

It may be noticed that the question "Have you anything to complain of?" was not asked. This was done purposely, as the majority of the men in the first flush of the war would have done anything rather than complain.

I want to make it clear that this routine was not built up in one or even two days, nor did the methods employed for treating cases at isolated and distant posts spring into being at once.

Constipation was treated by leaving with the non-commissioned officer about an ounce of magnesium sulphate and some strong pills and making him responsible for giving these at the proper time and in the proper quantity.

Sore Feet.—The care of the feet is so important that I propose giving a separate paragraph to this complaint, detailing the method that was found to give the most satisfactory results. The most important point is to treat for sore feet before the feet are sore. Feet that are unaccustomed to long marches but must endure them in the near future need air, suitable socks, and suitable boots. To secure these:

1. Wash well and dry carefully.
2. Leave feet exposed to open air for at least half an hour. (Both the above should be at first compulsory routine every day.)
3. Paint all feet with picric acid in alcohol when the skin flakes easily. Ten grains to the ounce can be used over blisters and open sores with remarkable effect, and I am indebted to one of the officers for suggesting its use. The further advantage picric acid has besides being hardening and antiseptic is that it shows clearly at the next foot inspection how thoroughly the feet have been painted.
4. Insist on the socks being changed before turning in; this point is of the greatest importance, as a sock damp from perspiration is certain to cause sore feet sooner or later, owing to its softening the skin like a fomentation. (Captain Scott and his party considered this one of the essential details for a successful march.) The majority of men when under canvas sleep in their socks, and there is no objection to this provided they change them.
5. Inspect the socks worn; many socks full of dye were used at first. See that every man has loose enough and heavy enough boots.

6. If the boots are hard they can be made fairly waterproof and quite soft in twenty-four hours; the suggestion of Mr. Basil Hughes that hard boots should be kept in castor oil for six days is hardly practicable. The following method was taught the writer by a Canadian game guide and was employed with great success:

Steep the boots for twelve to eighteen hours (less will do) in cold water completely covered. Take out, shake, and wipe off the superfluous water: do not attempt to dry at all. With some tow soaked in neatsfoot oil paint inside and out and on the soles, and particularly along the welts, and as soon as one layer has disappeared paint on another; the more often this painting process can be done the better. The boots should be smeared every two days to keep them pliable and waterproof. Should they commence to leak, another soaking in water is indicated, followed by more oil. It is unnecessary to use either powder or soap on the feet if the above instructions are carried out. The boots feel unpleasant at first, but do not chill the wearer. Small supplies of picric acid solution were left, when necessary, with the non-commissioned officer of the picket.

Minor injuries were treated chiefly with tincture of iodine and strapping used where possible.

Sore throats and *diarrhœa* were treated in the ordinary way—glycerin. hydrarg. perchlor. (1 in 500) being used for the former and hyd. cum creta for the latter. Owing to the kindness of a local dental surgeon we were able to have one good "tooth field day," carrying sterilizer, forceps, mouth lotion, cotton-wool, etc., round with us in a car and removing septic stumps only from the younger men. Even this limited field gave us more work than we could cope with. Those who refused this chance will probably regret it as the winter comes on.

Bathing.—One of my questions, it will be seen, was whether the man had had a swim. Places for swimming were within easy reach of the majority of the pickets, and getting the men to go meant that they had some free time, they got away from the line, they got a different kind of exercise, and they kept clean; all these points I considered of prime importance at that time.

Rest Stations.

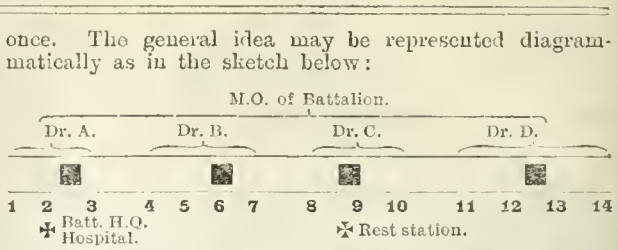
After about ten days the effects of this constant supervision began to show themselves in the men, and their gratitude and the kindness of the officers in assisting me makes me look back on these rounds as some of the most pleasant days I have ever spent. Even though starting at 9 a.m., one frequently did not return until 10 or 11 at night.

There remained, however, two gaps in this scheme: there was no provision for acute cases and for cases needing minor operations; nor was there any one immediately available to replace me as soon as I was called up to my ship. With the approval of the senior medical officer at head quarters I was able to devise and initiate a scheme for filling in these two gaps.

For the cases needing observation, minor operations and difficult dressings, a rest station was equipped and fitted; this was in close proximity to one of the stations on the line, and was intended to drain all cases for about nine miles either side of it. The patients were to arrive and return by train, the maximum stay in the rest station was to be two days, and if return to duty was still impossible, proper hospital accommodation was to be found for the patient. All cases likely to need prolonged treatment were to be transferred, immediately after being seen by the medical officer, to the nearest suitable hospital.

Sanitary Supervision.

The sanitary supervision and general health at each picket was to be carried out as follows: The line under consideration passed through villages and towns at frequent intervals, and in the district I am speaking of each of these had a Volunteer Aid Detachment. The commandants were communicated with, and their doctor visited and asked (1) to take over a definite piece of the line; (2) to put himself in touch with the senior medical officer and with the officer commanding the piece of line in his district, and to act under his orders; (3) to visit all tents and sheds occupied by the men, doing this with the officer commanding at times convenient to both; (4) to let each picket know at what hours he could be found in case of sudden illness; (5) to send minor cases to the rest station. All the doctors seen considered the scheme simple and workable, and were ready to put it into operation at once. The general idea may be represented diagrammatically as in the sketch below:



The figures represent the various pickets at bridges and culverts; the black squares, station with town or village.

It should be noted that I have no accurate information as to how far the above scheme has been successful, as I was appointed to my ship before the final details were in working order, and I have consequently been out of touch for some weeks, but I hear that the rest station has been working satisfactorily, and also some sections of the line.

It may be asked what are the advantages of such a scheme. They appear to me to be many: First, it provides a permanent organization with local knowledge, which can be used during the stay of each contingent, and dropped without expense when it leaves. Secondly, it makes it possible for a constant watch to be kept on the health and sanitation of all men, which, where the lines of communication are long, is impossible for the ordinary medical staff of a battalion. Thirdly, the regular detailed inspection puts the men into the way of looking after their own health, and protects them during the hardening process. Fourthly, the sanitary arrangements of successive pickets can be watched over both in the interests of the men and the neighbourhood, and, speaking from my brief experience, this watch cannot be too frequent or too careful. Fifthly, it puts a local society in touch with the officer of that particular section, and through him extras and comforts not supplied by head quarters can be given out; and promiscuous, and frequently harmful, presents stopped.

A medical officer of a battalion coming to guard long lines of railway or road communications in England would, I feel sure, be wise if he put himself in touch with the commandants of the Volunteer Aid Detachment, and set up some such organization working under his directions as long as the battalion remained there. The men who came under this scheme will become hardened sooner than those not so regularly inspected, and, moreover, will have learnt elementary but highly important lessons in the care of isolated sentry posts.

The Contents of the Rucksack.

1. The usual pocket case of instruments and thermometer.
2. A largish bottle of tincture of iodine.
3. A largish bottle of picric acid (10 grains to the ounce).
4. Some small empty bottles with labels for leaving in charge of the non-commissioned officer with either of (2) or (3) in them.
5. Best roller adhesive plaster.
6. Compressed bandages, dressings, and cotton-wool.
7. Bottles of hydrogen peroxide and glycerin. hyd. perchlor. (1 in 500).
8. Pills and magnesium sulphate, with spare boxes for leaving with non-commissioned officer.
9. Lead lotion, tape measure, triangular bandages.

PINEWOOD SAWDUST AS A SURGICAL DRESSING.

I.—By RUSHTON PARKER, M.B., B.S., F.R.C.S.,
PROFESSOR OF SURGERY, UNIVERSITY OF LIVERPOOL.

I AM glad to confirm the good opinion of this material so well expressed by Mr. Cathcart in the JOURNAL of October 17th, 1914. Soon after it was originally proposed a development of it was the sublimated wood wool so much used since. But the latter substance, supposed to be a refinement on the sawdust, though it has its convenient uses as an absorbing mild antiseptic, is far inferior in efficacy and variety of use. As Mr. Cathcart truly says, the late Mr. Hugh Owen Thomas took it up, and I well remember the eagerness with which he first applied it, in

a perchloridized form, to many varieties of wound and open sore, and I have followed his example very often since. In recent wounds its utility is almost infinite, but to be convenient it must be applied properly. It may, of course, be enclosed in bags of muslin; but I have preferred to put it loose in a sheet of rag, and pin the latter round the part so as not to shed the sawdust. I have always used it thus perchloridized, and mention briefly three cases in which its value was most striking:

1. One of these occurred in 1887, a case of perineal lithotomy in a boy of 11. A large drawsheet, folded several times into a triangle, was pinned round the hips and between the thighs, as is done with a baby's napkin, enclosing plenty of the loose sawdust against the buttocks and genitals. The urine drained, without tube, into the sawdust, which was changed before it became wet enough to soak into the bed. It is only the wet or soiled portion that requires to be changed, and no washing of the part is needed.

2. The second, a most difficult case occurring in private practice in 1906, was one of gangrene beginning in the toe of a diabetic male patient aged 62, spreading eventually up the leg. At first I failed to keep down the overpowering smell, even with sublimated wood wool, which I used after other conventional dressings had been unsuccessful. The perchloridized sawdust immediately stopped all offensive odour. As the disease spread I laid open the integuments freely, and rubbed the sawdust into the exposed tissues. Here, also, a towel was pinned round the leg, and enclosed plenty of the material, which was changed where saturated—about once a day. There was no question of amputation in this case, and the patient passed, as expected, into fatal coma. But although no arrest of the gangrene was possible, the room and the diseased leg became sweet, and so continued till the patient's death.

3. The third I met with in August, 1909, when I was called by a medical friend to his mother, aged 92, who had had an ulcer of the right leg thirty years. She had been in bed three weeks, and the ulcer was 6 or 7 inches long by 1½ wide. It was being dressed frequently without benefit; but she had become delirious, and was supposed to be dying. The only intelligent interference I could suggest was the arrest of any possible septic absorption, in case the delirium was due to that. A towel containing plenty of the perchloridized sawdust was pinned round the leg, and examined once a day to remove the small soiled portion. No washing or wiping was done, and the greater portion—that unsoiled—was used as before, slight fresh additions being made over the ulcer. In a couple of days she became conscious; the sore gradually became clean, and after four or five months healed entirely; and she continued as well as her feeble old age permitted. In the last week of 1910 she had a stroke, followed by two others, and died on January 19th, 1911.

I do not know of any other dressing or conventional line of treatment by which the desired result could have been attained so quickly, easily, and cheaply, or, in fact, at all.

The crude sawdust should be sifted, as Mr. Cathcart says, through a riddle with ¾-in. mesh, and dealt with as follows: Take of tar oil 2 quarts, hydrarg. perchlor. 120 grains, turmeric 2 oz., 4 gallons of water, and mix thoroughly with 4 pecks of the prepared sawdust. The turmeric gives an agreeable yellow colour, and the tar oil a fragrant odour. Any one can prepare the material for himself, but Messrs. R. Sumner and Co., wholesale druggists, Lord Street, Liverpool, keep it in suitable packets ready for use.

II.—By F. D. BENNETT, M.R.C.S., London.

I should like to corroborate Mr. Charles Cathcart's experience of pinewood sawdust as a surgical dressing. My experience of its merits was obtained when medical officer of a hospital on the works during the building of the Manchester Ship Canal, Mr. Robert Jones and Mr. G. P. Newbolt being consulting surgeons. The severe nature of the injuries, owing frequently to accidents caused by high explosives when blasting, would, I should imagine, resemble in many cases the severe wounds caused by shrapnel one now hears and reads so much about. Many of the wounds when treated with sawdust yielded excellent results, limbs being saved which at the time of admission to hospital seemed hopeless.

This treatment seems especially suitable when time must be of such importance in dealing rapidly with a large number of wounded as must happen at the front. In the hospital mentioned sometimes as many as twenty-five cases were admitted, after a bad accident, at the same time. These were run up to the hospital surgery on a branch railway. One of the difficulties was to deal single-handed (assistance taking time to obtain) with so many at once, and this method of treatment proved most effectual and rapid. It gave immediate relief to the patient, and could be very easily removed for a more thorough examination when necessary.

For limbs where there was no fracture a gauze dressing, with ample sawdust in a towel to support it, provided immediate rest and comfort, as well as an absorbent and deodorizer for the injured part.

For cases of fractured limbs, primitive box splints with loose sawdust were supplied, and afforded immediate rest in position for the limb. The box splints and sawdust were easily changed when necessary, and the patient saved the pain and shock of the removal of adherent dressings, for the sawdust was easily removed by a stream of sterilized warm water.

Memoranda:
MEDICAL, SURGICAL, OBSTETRICAL.

TREATMENT OF ACUTE GONORRHOEA IN THE MALE.

The interesting articles on this subject appearing in the British Medical Journal have made one point quite clear—that is, that there is still a difference of opinion as to the best method of treating this disease.

I think that much of this difference of opinion is due to the standard of cure adopted by the surgeon. It is a most dangerous practice to consider a patient cured because his discharge has been quickly stopped or obscured. Such a patient frequently has several attacks (cured, as he thinks) in the course of a year or two! Was he ever cured at all? In my experience the best treatment for gonorrhoea is for the surgeon to cleanse the urethra daily (twice daily at first) by irrigation with a weak permanganate solution, and then to administer an injection of argyrol himself. The patient should be seen daily, so that the effect of the treatment can be closely watched and modified or altered as desired. If all cases were so treated, I am convinced that there would be fewer "so-called cured" carriers of the disease at large.

London, S.W. Frederick H. Pickin.

STOMATITIS IN RELATION TO DIPHTHERIA.

Although primary diphtherial ulceration of the mouth is very rare, the importance of its recognition as a focus of infection may be illustrated by the following cases:

A schoolgirl, aged 9, was seen by me at the end of March for a condition of the mouth which had been persistent for two to three weeks since her return from home. The right cheek was much swollen, the skin glazed and shining, and a diffused purplish flush was obvious from the angle of the jaw to the corner of the mouth over the lower part of the face. The buccal mucous membrane showed extensive ulceration from the right anterior fauces to the middle line of the under lip. The ulcers were irregular in shape, the largest being the size of a half-penny. Their edges were not particularly undermined, but sloping, the surface covered by a bluish-white film, which also extended very slightly to the right tonsil. Removal by a swab left a raw bleeding surface. Microscopical examination showed numerous streptococci and staphylococci, spirilla, and rod-shaped bacilli, some showing polar staining. Numerous club-shaped involution forms were present, and mycotic organisms. The temperature and pulse were normal and the tongue coated, but the general condition was otherwise good. I was disposed to consider the possibility of diphtheria, and treatment consisted in touching the ulcers with 5 per cent. solution of silver nitrate, hot mouth washes of borax and permanganate alternately, and calomel internally. The ulcers healed in five to ten days. The case was isolated. There was no source of infection traceable.

Two days after the first examination I was called to see her room companion, aged 13, suffering from headache, vomiting, and sore throat. I found her looking extremely ill, with a temperature of 104°, frontal and occipital headache, much tenderness and swelling of the cervical glands,

and rigidity of the neck; the pulse was rapid and strong. Examination of the throat showed redness and swelling of the fauces, with a suspicious yellowish-white membrane on the right tonsil not detachable except by force. She was isolated, and the following day the membrane had spread to the soft palate, pharynx, and left tonsil; the throat was almost completely closed, a croupy cough was present, she vomited on any examination, and persistently hawked up quantities of viscous blood-stained sputum. Microscopical examination of a swab from the throat showed diphtheria bacilli, but I had no means of making cultures and had to depend on this and clinical evidence; 4,000 units antitoxin were given immediately, followed by 4,000 more in sixteen hours. Recovery was complete, despite threatened cardiac failure on the seventh day and somewhat abundant albumin in the urine in the second and third weeks. As she had been at school some weeks before developing diphtheria and the only possible known source of infection was her room companion, I considered the latter as responsible for carrying the disease, though remarkably free from toxic symptoms herself.

The importance of such cases, both in school inspection and general practice, seems to me to be necessary of emphasis.

IONIZATION FOR BILHARZIOSIS.

As the condition of vesical and rectal bilharziosis is so intractable, and virtually unaffected by any generally practised treatment, anything promising relief from this troublesome condition is to be welcomed. Owing to the embedded situation of the parasite, and consequent difficulty of penetration of efficacious therapeutic agents that will not, by reason of their potency, at the same time prove harmful to the mucous membranes, it is not surprising that here, as in the somewhat analogous case of ringworm, the results of ordinary treatment are so hopelessly disappointing. By the modern device of causing chemical penetration through the agency of the constant current, I would suggest that a valuable and satisfactory means for dealing with bilharzial infections may be found by means of ionization; and I think this procedure might be given a fair and extended trial in this condition. The ionizing fluid having been introduced into the bladder or rectum and a suitably insulated electrode inserted, the ordinary technique is employed. The results of ionization for ringworm are also likely to improve so much with the advance of technique as to cause this method ultimately to supplant all others.

Reports
ON
MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

HOSPITAL FOR WOMEN, SOHO SQUARE.

TWO SIMPLE OMENTAL CYSTS AND ONE SIMPLE OVARIAN CYST IN THE SAME PATIENT.

(By JAMES OLIVER, M.D., F.R.S.Edin.)

THE patient, aged 65, was sent to me by Dr. Percy Elliott, of Walthamstow, on June 24th last. She had that morning consulted Dr. Elliott on account of abdominal discomfort, which she had been told was indigestion, and from which she had suffered for years. Unlike some of the practitioners whom the patient had consulted, Dr. Elliott examined the abdomen and detected the tumour.

Palpation of the abdomen revealed in the right lower half a swelling of about the size of a fetal head; this swelling was fairly freely movable, but became tender when pushed into the left abdomen. The vaginal roof was markedly puckered, but through this there was felt in the pelvis what appeared to be a portion of the abdominal swelling.

On opening the abdomen in the mid-line there presented a thin-walled glistening cyst the size of a fetal head. With a few snips of the scissors this cyst was enucleated intact from the lower border of the omentum. When this cyst was removed there presented another, similar but rather smaller, which with a few snips of the scissors was enucleated from a stretch of omentum attached to the bladder and the fundus uteri. After ligaturing and removing the portion of adherent omentum another cyst the size of a cocoa-nut was found in the right pelvis. This cyst was ovarian, and was removed after ligation of the mesovarium. The left ovary, which was cirrhotic and adherent in the pelvis, was also removed after ligation of the mesovarium. All three cysts were unilocular.

Reports of Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNAECOLOGY.

AT a meeting of the Section of Obstetrics and Gynaecology on October 8th Mr. J. D. MALCOLM read a paper on *Intestinal fistula after abdominal operation upon the abdomen*. He discussed the condition sometimes arising after an abdominal section in which the surgeon believes that if the patient's bowels will move recovery will follow, but if the bowels will not move the patient will die. The symptoms were usually attributed to paralysis or paresis of the intestine, and this in turn was commonly believed to be due to septic peritonitis. Mr. Malcolm expressed the opinion that in many of these cases the cause of trouble was not a septic peritonitis but that the symptoms were due in part to a feebleness of peristaltic force, in part to some more or less definite obstruction of the intestine, and that the condition might be correctly described as one of acute intestinal stasis. When opium was given in full doses after every abdominal section most of the cases did well, but if no gases escaped from the anus the patient always died not later than the fifth day, and a slight spreading peritonitis was found after death. If in one of these cases a second operation was performed in the hope of finding an obstruction early on the fourth day or sooner, but when the symptoms were well developed, there was never any sign of spreading peritonitis in a typical case. Moreover, sometimes, if no second operation was undertaken, a patient, immensely distended and apparently moribund, would, without apparent cause, begin to pass gases from the rectum, and all the symptoms would be completely and rapidly resolved. It was argued that the peritonitis found after death, when death occurred, could not be the cause of the symptoms and that it was a consequence of the mode of death. The effect of modern treatment by substituting stimulation of the bowel and rational feeding for continuous administration of opium and starvation was pointed out, and records of cases were given in support of these views. The importance of not making a fistula unnecessarily was insisted upon, but the fact that this treatment would occasionally save a life was shown by the records given. The making of a fistula for the relief of distension was not likely to be successful in a case of septic peritonitis. If an early diagnosis could be made in a strong patient an immediate release of adhesions might give the most satisfactory results, but after the third day, if the patient was weak and if there were many adhesions, an extensive operation would almost certainly prove fatal, whereas a simple formation of a fistula might bring about a cure. The paper was discussed by Dr. TATE, Dr. BRIGGS, Dr. HUBERT ROBERTS, Dr. GILES, and Mrs. SCHARLIEB. Dr. H. RUSSELL ANDREWS recorded a case of severe bleeding after the menopause due to *Rupture of a vein in the endometrium*. Dr. ARTHUR GILES and Dr. CUTHBERT LOCKYER showed a case of *Pregnancy occurring within the ovary*. Mr. DONALD ROY communicated a case of *Puerperal eclampsia*, fatal from rupture of a large subcapsular haematoma of the liver into the peritoneal cavity. Other cases and specimens were shown.

THE Right Hon. Sir Christopher Nixon, a former President of the Royal College of Physicians in Ireland, left personal estate in the United Kingdom valued at £41,087.

Reviews.

GAS POISONING IN MINING AND OTHER INDUSTRIES.

In the past, before working miners knew anything of the composition of the air of mines, experience had taught them that varying atmospheres had different effects upon the men and different actions upon the flame of their lamps. They called these atmospheres "damps"—hence the term "fire damp," an inflammable atmosphere; "choke damp" or "black damp," which when inhaled causes a choking sensation; "sweet damp," when CO is breathed, partly on account of its sweetness; "white damp," the poisonous fume met with in underground fires; and "after damp," the poisonous air found in mines after an explosion.

As currents of air are driven through a coal mine the air becomes contaminated by the products of the respiration of men and ponies, by the unconsumed carbon of the lamps, by the use of explosives, and by emanations from the coal itself, so that the return air from a mine always contains eight to ten times more CO_2 than the intake air. Usually the amounts of CO_2 are uniformly and evenly added to the air, but occasionally there are sudden outbursts of the gas from the coal itself, so that men have been asphyxiated by the gas before they could reach the bottom of the shaft. Professor Glaister and Dr. Dale Logan, in *Gas Poisoning in Mining and Other Industries*,[1] deal with the various forms of "damps," and give in detail the symptoms caused by each. Miners when ill are prone to attribute their indisposition to working in bad air. Doubtless in many instances the indisposition may be the result of working in atmospheres deficient in oxygen. In such cases the symptoms are often slowly developed, and a warning is thereby given, but on other occasions the action of the poison is rapid, and the men are suddenly and fatally overpowered by gas. This is especially the case in the opening up of old workings. There is therefore necessity for great caution on the part of miners about to descend into old workings, disused shafts, and wells. Although methane or fire damp has of itself little or no injurious effect upon man, and is only harmful through lack of oxygen, yet there are instances on record of death having occurred through men breathing the gas in the mine. It was Thomas and Meyer who first showed that in the wake of explosions in coal mines CO is generated, so that when miners escape from the violence of an explosion they may yet be overcome by CO and fall victims to it.

One important requirement of mine ventilation is that the air shall be kept circulating. Cool air and movement of it favour the conditions of work for the men. The spontaneous firing of coal mines is discussed, and also its relation to oxidation of small coal. After a colliery explosion, miners who have survived the shock may suffer from laryngitis, bronchitis, and pneumonia. The nervous phenomena observed in chronic carbon-monoxide poisoning are detailed at length. The chapter devoted thereto forms a valuable contribution to the literature of the subject. Glaister and Logan's monograph ought to be extremely helpful to all persons whose duties bring them into contact with dangerous gases.

SURGICAL PHYSIOLOGY.

Few books on the relationship of surgery with cognate sciences aroused such interest as Mr. Rendle Short's volume on *The New Physiology in Surgical and General Practice*. It is evident that that interest showed itself in the practical manner of purchase, as we have now before us a third edition[2] only three years after the publication of the first. There are some changes to note. The first is the change in title to *The Newer Physiology*, hardly called for, we think, though the author makes it as "approximately half of the present volume is new." In this edition there are new chapters on vitamines and the genital glands; and "the articles on surgical shock, the digestive apparatus, the pituitary and pineal glands are largely rewritten." The chapter on vitamines is exceedingly interesting and well worthy of its place. Vitamines are bodies which appear to be essential constituents of a healthy dietary; their chemical constitution is unknown, but the recognition of their existence has opened up a new and very wide field of investigation. It seems probable that it is their absence that gives rise to beri-beri, scurvy, rickets, and all diseases of deficiency; even ordinary growth cannot proceed without them, though the constituents of the food be scientifically accurate in quantity and material. The social bearing of this question in Japan, China, Siam, the Malay States, the Philippines is pleasantly indicated in this chapter.

Surgical shock presents a never-ending problem. The chapter on this subject discusses the strictly modern theories of Crile and Mummery, Yandell Henderson, Cobbett, and Vale. The author does not venture to formulate a cut-and-dried theory. He suggests that the nociceptive impulses which bring about surgical shock do so by inhibiting or paralysing the nuclei in the fourth ventricle, and possibly in the cerebellum, which are continually sending impulses down the spinal cord, maintaining its functional activity and increasing muscular tone. When this inhibition or paralysis takes place blood pressure may fall, and the respiratory and perhaps also the vasomotor centre share in the depression of function. The chapter on the growth of bone is virtually a recognition of the truth of Macewen's theories on the function of periosteum; that on studies in digestion and absorption summarizes the work of the Pawlow school; those on haemorrhagic diathesis, acidosis, nerve injuries, cerebral localization indicate clearly the latest knowledge on all these subjects.

To many practitioners knowledge of physiology is a remote accomplishment, and their knowledge of the newer physiology is often fragmentary. This most excellent book will help greatly to revive practitioners' interest in the physiological foundations of their everyday work. Mr. Rendle Short has done the profession a real service in presenting it with this little volume. It is written with delightful freedom from textbook rigidity, and we strongly recommend its possessio to even the busiest, with the suggestion that it be perused as a book of pleasure and not as a task.

AMBULANCE HANDBOOKS.

The fact that Mr. Scott Riddell's *Manual of Ambulance*[3] has now reached a sixth edition is a sufficient tribute to its worth and a guarantee that its usefulness has been appreciated. It provides a complete course of ambulance instruction arranged by one of long experience as lecturer and examiner. After an introductory chapter on anatomy and physiology, bandages are discussed, then fractures, dislocations and sprains, haemorrhage, and wounds are treated of. Important chapters are those on ambulance transport and stretcher drill, and the after-treatment of ambulance cases. Those who have to organize and conduct ambulance classes will find ready assistance in the final chapter. The book is written in a eminently clear, terse style, and the headings are arranged so as readily to catch the eye. The pictures, however, are of unequal merit; some are excellent photographs, many are rather crude drawings which might easily be greatly improved. Even amateurs are disposed to be critical of illustrations, and may not accept the excuse occasionally bracketed "highly diagrammatic." But the pictures are very numerous—a commendable feature in such a work. We feel assured that the new edition will meet with the success of its predecessors.

First Aid in Accidents and Sudden Illnesses[4] is a new handbook, written by Dr. Duncan Macartney, surgeon to the Western Infirmary, Glasgow, for the St. Andrew's

[1] *Gas Poisoning in Mining and Other Industries.* By J. Glaister, M.D.Glasg., D.P.H.Camb., F.R.S.E., etc.; and D. Dale Logan, M.D.Glasg., D.P.H. Edinburgh: E. and S. Livingstone. 1914. (Demy 8vo, pp. 482; 2 plates, 36 figures, 2 plans. 10s. 6d. net.)

[2] *The Newer Physiology in Surgical and General Practice.* By A. Rendle Short, M.D., B.S., B. e.Lond., F.R.C.S.Eng. Third edition, revised and enlarged. Bristol: John Wright and Sons, Ltd. London: Simpkin, Marshall, Hamilton, Kent and Co. 1914. (Cr. 8vo, pp. 266. 5s. net.)

[3] *A Manual of Ambulance.* By J. S. Riddell, M.V.O., M.A., M.B., C.M. Sixth edition, much enlarged and specially prepared for the use of Voluntary Aid Detachments. London: C. Griffin and Co., Ltd. 1913. (Demy 8vo, pp. 270; 212 figures. 6s. net.)

[4] *First Aid in Accidents and Sudden Illnesses.* By D. Macartney, M.A., M.D. Glasgow: St. Andrew's Ambulance Association. 1914. (Fcap. 8vo, pp. 225; 24 plates, 90 figures.)

Ambulance Association. The author says that it is intended as an introduction to more advanced books, and especially to Sir George Beatson's; but it will be found very useful not only by pupils, but also by medical men who may be called upon to give lectures on first aid for the first time. The book is well written, and well illustrated by photographs and drawings, which are all really helpful. The photographs in particular are very well reproduced. A novel feature, so far as we are aware, is the introduction of a section on rescue work in mines, where the special precautions to be taken are mentioned, various forms of rescue apparatus are described, and a set of instructions for the guidance of a rescue corps given. For information on these subjects the author acknowledges his indebtedness to Mr. Kerr, consulting engineer for the Scottish Mineowners' Association. The volume has an indifferent table of contents, but a good index.

Dr. Finny's First Aid[5] is a much smaller volume, which has no table of contents, but again a good index. It is intended to be used as a handbook by ambulance students, and has blank pages interleaved. After a chapter on anatomy and physiology follow seven on injuries of various parts and organs, one on stretchers and transport of the injured, another on preparation for receiving the injured, and a final note on Esmarch's triangular bandage.

NOTES ON BOOKS.

The Secrets of the German War Office[6] reads like a collection of short stories founded on fact and strung together in the form of the reminiscences of a secret service agent of the German Government. How much is fact and how much fiction the reader must decide for himself. In July, 1912, a person stated to be a doctor was tried in Edinburgh under the name Armgaard Karl Graves, and sentenced to eighteen months' imprisonment as a spy. He had been arrested in April, and was eventually liberated in December, so that he was only in custody about nine months. The book is professedly written by him, but it is odd that he should apply an incorrect term to the presiding judge. The last two chapters are essays on the military machinery and foreign policy of Germany. The whole may be an example of the German press propaganda, of which so much has recently been heard. If so, it is a good deal more ingenious than most of their efforts. The publishers state that the manuscript was in their hands on June 1st last.

The Encyclopaedia Britannica Company[7] has issued the three remaining volumes of the set in which, as mentioned last week, it is reprinting certain historical articles published in the eleventh edition of the *Encyclopaedia Britannica*. The first of the new volumes contains the articles on the history of *Russia and the Balkan States* by Sir D. Mackenzie Wallace, Prince Kropotkin, Mr. C. Mijatovich, formerly Servian Minister in London, and Mr. J. D. Bourchier, correspondent of the *Times*; and the second, the *History of Austria-Hungary and Poland*, the articles on these subjects by Mr. H. Wickham Steed, Professor W. A. Phillips, and Mr. David Hannay. The sixth volume contains the articles on the *Wars of the Nineteenth Century* by Major-General C. W. Robinson, C.B., Colonel Maude, C.B., and Lieutenant-Colonel J. H. Verrinder Crowe. In addition to the history of the French revolutionary wars, the Napoleonic campaigns, and the Italian wars, it contains accounts of the Austro-Prussian war, the Franco-German war of 1870–71, the Russo-Turkish war of 1877–78, the Servian-Bulgarian war of 1885, the Spanish-American war of 1898, the South African war of 1899–1902, the Russo-Japanese war of 1904–5, and the Balkan war of 1912. The volume is adequately illustrated by maps and plans, and is perhaps the most immediately interesting of the series. The first article in it describes fighting over the same ground as is now the scene of conflict, and this is true also of the account of the later part of the campaign of 1814. The articles in the series of six volumes are all written by acknowledged authorities on the subjects treated, and they supply trustworthy information elucidating many points touching the great topic which is now the paramount interest in all our minds

THE BRITISH PHARMACOPOEIA, 1914.

(Continued from page 721.)

STANDARDS FOR DRUGS AND CHEMICALS.

MOST of the changes that have been made in the pharmacopoeial standards of strength and purity have been in the direction of greater stringency. In a few cases the standard has been raised; in nearly all the requirements have been made more definite and precise, while quantitative tests have been extended to a good many articles for which they were not previously ordered. Taking original drugs first, assay processes for showing the presence of a definite minimum or a definite quantity of the principal active constituent or constituents, or some substance to which their value is chiefly due, are now required in sixteen more instances than formerly. These are as follows:

ORIGINAL DRUGS.

Aconite Root.—This is no longer limited to the root of plants cultivated in Britain; as no such root has been commercially obtainable for a long time, root grown in or imported through Germany has been regularly used, and this alteration merely legalizes the state of things that existed before the war. The new requirement is that the root shall yield not less than 0.4 per cent. of ether-soluble alkaloid when assayed by the process which is described. The exact determination of aconitine, the true active principle, is a matter of so much difficulty as to be scarcely practicable; on the other hand, the determination of the total alkaloid is of no value as an indication of activity, as the alkaloid may consist principally of the nearly inert aconine. Since the latter is not soluble in ether, the percentage of ether-soluble alkaloid is an approximate indication of the amount of aconitine probably present, but it is by no means a certain index of the activity of the drug. Since the preparations of aconite are standardized, and the root itself is never administered, the standardization of the latter does not appear to be of much importance; its chief effect is to secure that in the preparations there shall be something like a normal or average ratio between the amounts of ether-soluble alkaloid and extractive, since it is not permissible to use a root that is very low in alkaloid while probably containing the usual amount of extractive.

Belladonna Leaves.—It has already been noted that this drug now consists of the dried leaves, instead of the fresh leaves and branches; it is now required to be assayed and to yield not less than 0.3 per cent. of total alkaloid by the process described.

Cannabis Indica.—No definite active principle has yet been satisfactorily isolated from this drug, but its activity is approximately proportional to the amount of resin it contains. The amount of extract yielded to alcohol is now to be determined, and the drug is required to yield about 12½ per cent. in a single extraction by maceration for twenty-four hours. It is also required to contain not more than 15 per cent. of ash.

Gentian Root.—No assay of a definite active principle is practicable; the drug is now required to yield not less than about 33 per cent. of extract to cold water when macerated for twenty-four hours. It is also required to contain not more than 6 per cent. of ash.

Liquorice Root.—The value of this is roughly proportionate to the amount of extract which it yields; the drug is now required to yield about 10 per cent. of extract (dry) when extracted once with chloroform water by maceration for twenty-four hours. It is also required to contain not more than 6 per cent. of ash.

Ipecacuanha.—The preparations of ipecacuanha have been standardized since the last issue of the *Pharmacopoeia*; the drug itself is now required to be assayed and to contain not less than 2 per cent. of alkaloids. In this case there is the further requirement that the powdered drug, when used for other purposes than the production of standardized preparations, shall not contain more than 2 per cent. of alkaloids, a stronger powder being reduced to this strength by the addition of sugar of milk. The Cartagena root is still excluded. The limit for ash is 5 per cent.

Nux Vomica.—This is treated on the same principle as ipecacuanha—that is, the drug is required to contain not less than 1.25 per cent. of strychnine, and if its powder is

used for other purposes than the production of standardized preparations, it must not contain more than that proportion, being reduced in strength, if necessary, by the addition of sugar of milk.

Oil of Cajuput.—This is now required to contain not less than 45 per cent. of cineol, as shown by the prescribed test. The former requirement was merely that it should become semi-solid on being stirred with a third or half its volume of phosphoric acid, which allowed considerable variation in the cineol content.

Oil of Eucalyptus.—This is now required to contain not less than 55 per cent. of cineol, and the remarks made with regard to oil of cajuput apply here also.

Oil of Cloves.—Now required to contain not less than 85 per cent. of eugenol, as shown by the prescribed test. This takes the place of the statement that it forms a semi-solid yellowish mass when shaken with its own volume of strong solution of ammonia.

Oil of Lemon.—Required to contain not less than 4 per cent. of aldehydes calculated as citral, as shown by the prescribed test.

Oil of Peppermint.—Required to contain not less than 50 per cent. of total alcohols calculated as menthol, and not less than 5 per cent. of esters calculated as menthyl acetate.

Oil of Rosemary.—Required to contain not less than 10 per cent. of total alcohols calculated as borneol, and not less than 1.8 per cent. of esters calculated as bornyl acetate.

Oil of Sandal Wood.—Required to contain not less than 90 per cent. of alcohols calculated as santalol.

Volatile Oil of Mustard.—Required to contain not less than 92 per cent. (%) of allyl isothiocyanate, as shown by the prescribed process.

Prepared Storax.—Required to yield not less than 20 per cent. of cinnamic acid by the prescribed test.

Galenical Preparations.

Besides the various extracts, tinctures, etc., previously standardized, assay processes and a standard strength are now ordered in seven new cases, which are as follows:

Extract of Belladonna.—This dry extract is required to contain 1 per cent. of the alkaloids of the leaves. This is only a new requirement to a limited extent; the extract replaces the soft alcoholic extract, made from the root, which is standardized to 1 per cent. of alkaloid, and the green extract made from the leaves and not standardized. As the new extract is made from the leaves, it more nearly represents the latter.

Liquid Extract of Male Fern.—Now required to contain not less than 20 per cent. of filicin, as determined by the process described.

Liquid Extract of Hydrastis.—Required to contain 2 per cent. of hydrastine, as determined by the process described. The liquid extract is made with 60 per cent. alcohol instead of 45 per cent.

Extract of Henbane.—Now required to contain 0.3 per cent. of alkaloids.

Liniment of Aconite.—Now required to contain 0.2 per cent. of ether-soluble alkaloid.

Tincture of Aconite.—Required to contain 0.04 per cent. of ether-soluble alkaloid.

Vinum Ferri.—This is now made by macerating iron in sherry until the liquid, after filtering, contains not less than 0.125 nor more than 0.300 per cent. of iron, the limits being thus very wide.

Other Quantitative Tests.

Apart from standardization in regard to active constituents, there is a great extension of the use of quantitative tests for securing the requisite degree of purity. These need not be discussed here in detail, but a few examples will suffice.

Crude Drugs.

In a large number of cases limiting figures are given for the amount of ash that is permissible. All vegetable drugs, of course, contain some mineral matter, consisting of those elements absorbed from the soil by the plant in its growth; besides this, roots and rhizomes can never be obtained perfectly free from adherent soil, while gum resins which exude from incisions near the ground are very apt to be contaminated with earthy matter. It is necessary, however, that such care should be exercised in collection that the ash derived from this source shall not be excessive; and, in the case of drugs which are used in powder, an ash limit is also desirable for excluding adulteration with mineral matter.

The umbelliferous fruits are instances of drugs which should only contain the mineral matter naturally within them. The ash of anise is required not to exceed 11 per cent., of caraway 9 per cent., but no ash limit is given for dill fruit. The ash of senna leaves is not to exceed 12 per cent., but no limit is given for senna fruits or for digitalis leaves, although the latter are not infrequently used in powder as an ingredient of pills, and there is no assay for active principles. Among roots and underground stems the ash of hydrastis is not to exceed 11 per cent., jalap 6.5 per cent., rhubarb 15 per cent., ipecacuanha 5 per cent., serpentary 10 per cent., and other limits are given in other cases; but no figures are given for senega, taraxacum, and many others. Ammoniacum is not to contain more than 7 per cent. of ash, asafetida 15 per cent.; the latter is an instance of relaxation of stringency, the present limit being 10 per cent.; the same drug is only required to contain 50 per cent. of matter soluble in alcohol, against 65 per cent. at present demanded.

The absence of uniformity in the imposition of an ash limit for crude drugs is probably due to the compilers having incorporated such published figures as have been shown to be reasonable, without making an investigation as to what is a fair limit in those cases for which figures have not been published.

Fats and Oils.

The characters now given for these include in nearly all cases the acid value, saponification value, iodine value, and refractive index, besides the specific gravity which is usually given at present. The acid value is chiefly of use in showing the absence of rancidity, while the three other characters afford useful evidence of the identity and purity of the article in question. Substances of this class are therefore far more adequately characterized than hitherto.

Volatile Oils.

The characters now given for these include the optical rotation, and in many cases also the refractive index, as well as the specific gravity; special tests are also given in many cases. As a whole, volatile oils are far more adequately characterized than hitherto.

Other Organic Substances.

Acetic ether is now required to contain 90 per cent. of real ethyl acetate, as determined by the test which is described. Amyl nitrite is required to be of a higher standard than before, 7.9 volumes of nitric oxide being yielded by the same quantity which was formerly required to yield 6 volumes. Aloin is now required to leave no appreciable ash, and tests for its identification are given. A quantitative test for caffeine citrate is given, to show that it contains the proper proportion of caffeine. Many other cases occur in which the tests are extended, the new tests being either fully quantitative or of the nature of limit tests for particular impurities.

Chemicals.

Definite chemical substances, such as metallic salts or acids, are from their nature capable of being more accurately and definitely specified in regard to purity and strength than drugs or galenicals, and in this class of substances there is a considerable increase of quantitative tests. Certain widespread and important impurities, notably lead and arsenic, are to be tested for quantitatively in nearly every case, and figures are given for the limiting quantities permissible.

The fifth and sixth appendices, occupying together some twenty-three pages, are devoted respectively to detailed descriptions of the processes to be employed in testing for lead and for arsenic, together with the limits for the various official chemicals. This is a very great advance on what has been done before; the processes adopted for the tests are simple, and require no elaborate apparatus, but if carefully carried out they are capable of great accuracy. In the case of many other impurities, definite limit tests are given in the monograph on the appropriate substances. As a rule, under any chemical substance, a list is given of

impurities which are to be proved absent, or not present in more than slight traces; in addition, a definite percentage (commonly 99 per cent.) of the pure substance is required to be present. In some instances the quantitative test ordered only proves the proper proportion of one radicle, the acid or the basic, of a salt; and the proper proportion of the other is then secured by the requirement that a certain percentage of the pure substance must be present, the analyst being left to prove this by such other tests as his experience may direct.

On the whole, it can be said that the standards of strength and purity of the new *Pharmacopoeia*, and the tests ordered for securing them, mark a substantial advance, and are not unworthy of the authority of the work.

The pharmacy of the *Pharmacopoeia* will next be briefly discussed.

(To be continued.)

THE CULTIVATION AND COLLECTION OF MEDICINAL PLANTS IN ENGLAND.

THE Board of Agriculture has issued an interesting leaflet on the cultivation and collection of medicinal plants in England. It points out that medicinal herbs have been cultivated in this country for centuries, and in the Middle Ages were grown in kitchen gardens attached to monastic establishments and the mansions of noblemen. At the present day materia medica (or drug) farms exist at Mitcham, Carshalton, Hitchin, Ampthill, Long Melford, Steppingley, Market Deeping, and Wisbech, but for many years the main source of British drugs has been mid-Europe, particularly Germany and Austria-Hungary. During recent years the acreage devoted to drug cultivation in Britain has been more and more restricted by competition with wild foreign products, and the result has been a slow but sure ousting of British grown drugs from the market.

The advent of a European war (the leaflet continues) has completely changed the situation, and an effort on the part of growers and drug merchants may largely secure for England the collection and cultivation for the future of medicinal plants which can for the present no longer be imported from Central Europe. Supplies of drugs, especially of belladonna leaves and root, are much in demand, but in the case of other Continental drugs grown in England the shortage is not so serious. The price of belladonna has risen seriously (more than 100 per cent.) since the outbreak of war, and as it takes at least two years to grow this drug in quantity the drug grown next year is likely to realize high prices. This applies in lesser degree to chamomile, dill, dandelion, and valerian, and it is believed that the prices of colchicum, digitalis, fennel, henbane, and stramonium must also be considerably affected.

The leaflet, however, points out that the limited outlet for most drugs makes overloading the market a comparatively easy matter, and any grower who proposes to devote attention to the cultivation of medicinal plants should give the matter careful consideration before embarking on it to any serious extent. By a number of growers, however, who can successfully raise good crops, handsome profits should, it is thought, be made in the near future.

The leaflet, No. 288, can be obtained free of charge and post free on application to the Secretary to the Board of Agriculture, Whitehall Place, London, S.W. A few notes taken from it will indicate its general character. In each case directions for cultivation are also given.

Aconite.—It is stated that the chief collecting centres for foreign aconite root are the Swiss Alps, Salzburg, North Tyrol and Vorarlberg. Swiss supplies (which have come via Germany) may be cut off as well as the others. Supplies of Japanese aconite root are plentiful, and Spanish root is also coming into the market, so that the demand for English aconite will probably be restricted. The price of the Continental root is about 50s. per cwt., and Japanese (usually ascribed to *A. Fischeri*, Reichb.) about 35s. per cwt., while English is ordinarily worth 2s. per lb. Cultivation of aconite has not paid in recent years, even with cultivated root four times the price of wild.

Belladonna.—The bulk of the world's supply of belladonna, it is stated, is derived from wild plants growing in quantity on waste stony places in Southern Europe. Only a little belladonna root is dug in England, the large supplies used being derived from the Continent. The Balkan war of 1912–13 interfered with the continuity of belladonna exports from Croatia and Slavonia in South Hungary, the chief centres for foreign belladonna. Stocks of roots and leaves made shorter supplies eke out until 1914, when prices rose owing to increasing scarcity. The root, which realized 45s. per cwt. in January, 1914, sold for 65s. in June, and on the outbreak of war the price immediately rose to 100s. per cwt., and before the end of August 150s. had been paid. Belladonna leaves from abroad sell at normal times for 45s. to 50s. per cwt., but at the end of August they were unobtainable at 1s. per pound.

Digitalis.—It is stated that the Continental supplies of digitalis leaves from Thuringia and the Harz mountains are stopped, but that there should be enough of the wild plant in England to satisfy home requirements if it can be collected. Dry wild leaves would be worth 35s. per cwt. and upwards. Unless these are gathered in considerable quantity there will be a shortage next year. The leaves are hand picked in the second year, from flowering plants, the yield being about one to two tons of fresh leaves per acre. Great care is necessary in collecting and drying quickly, and a reputation for care is necessary if the crop is to be sold at remunerative prices.

Hydrastis.—The leaflet states that the price of golden seal (*Hydrastis canadensis*) has risen from 5s. per lb. in 1905 to 20s. or more in September. Such a high price enables cultivation to be practised on a commercial scale both in America and in England, even with the great expense of artificial shading in order to simulate natural conditions. Cultivation of this drug might become a paying proposition to any one who could solve the problem of the correct conditions of shade and moisture. Several times the amount of drug now used would be absorbed for making fluid extract of hydrastis and the alkaloids hydrastine and hydrastinine.

Hyoscyamus.—The Board considers that the established drug farms will probably be able to meet the demand for henbane (*Hyoscyamus niger*). The official henbane leaves of the *British Pharmacopoeia* are the leaves and flowering tops of second year plants of biennial henbane, but the dry commercial leaves imported from Germany and Russia are derived from the wild annual. The plant might be grown next year to make good any shortage, if good germinable seed can be obtained. There will be a demand for dry leaves at enhanced prices next year.

THE ORIGIN AND DEVELOPMENT OF THE RED CROSS.

(Continued from p. 722.)

REVIVAL OF THE ORDER OF ST. JOHN.

ACCORDING to General Porter,[1] the fall of Napoleon and the restoration of the Bourbons in 1814 gave the suppressed French Knights of Malta the opportunity of a revival of which they at once took advantage. They assembled in chapter in Paris, and, "forming, as they did at that time, the most powerful branch of the Order still surviving, elected a permanent capitular commission, in which was vested plenary power to act as might seem best for the general interests of the fraternity. The creation of this capitular commission was confirmed by a Pontifical Bull issued by Pope Pius VII on the 10th August, 1814." It was also recognized by Louis XVIII. This commission was very active in stirring the Order into new life. Among other things, it considered the question of reviving the English *langue*. The commission placed itself in communication with Sir Robert Peat, D.D., Chaplain Extraordinary to George IV, and other Englishmen of position. The negotiations were successful, and articles of convention were executed on June 11th, 1826, and on August 24th and October 15th, 1827. In these the English people is referred to as follows:

> This brave and generous nation furnished formerly illustrious subjects who made part of the most formidable, the most valiant and the most renowned Chevaliers of this ancient sovereign order, and whose successors are now invited to raise that Christian and famous banner which was in former times the pride and glory of their ancestors, and who can again form part of this Order in climates and in countries the most fortunate and the most celebrated.

The articles of convention set forth that in the revival the French *langues* were acting with the concurrence and

[1] Whitworth Porter, Major-General, Royal Engineers: *A History of the Knights of Malta or the Order of St. John of Jerusalem.* Revised edition. London, 1883.

approval of those of Arragon and Castile, representing five out of the eight divisions of the Order. The French Knights decided that the business of the English *langue* should be conducted independently, and in particular that the funds of the English brethren should be under their own control. They further declared that, "to revive so honourable an institution, it is most necessary to act legally and according to the existing statutes, otherwise the Order would not be esteemed and respected; that the statutes must be taken by the Committee as its guide and direction in the work, and that from this foundation no departure could take place except as regards the modifications necessary owing to the religion of the United Kingdom." The Chevalier Philippe de Chastelain and Mr. Donald Currie were appointed delegates for formally inaugurating the revival, by deed dated December 14th, 1827. On January 24th, 1831, the Chevalier de Chastelain attended a meeting in London when the English *langue* was formally reorganized, and the Rev. Sir Robert Peat, D.D., Knight Grand Cross of the Royal Order of St. Stanislaus of Poland, and Chaplain Extraordinary to George IV, was invested with the functions and authority of Grand Prior of the revived English *langue*. The names of many English noblemen and gentlemen were then inscribed on the roll of the *langue*.

In 1834, acting under the advice of the Vice-Chancellor of England, Sir Launcelot Shadwell (who himself shortly after joined the Order), Sir Robert Peat sought to qualify for office, and at the same time to revive the charter of Philip and Mary, by taking the oath *de fideli administratione* in the Court of King's Bench. A copy of the oath, authenticated by the signature of the Lord Chief Justice, is in the archives of the *langue*. The following is the text:

"In the King's Bench I the Right Reverend Sir Robert Peat Knight Vicar of New Brentford in the County of Middlesex and Prior of the Sixth Language of the Sovereign Order of St. John of Jerusalem in London do make oath and say that I will faithfully truly carefully and strictly perform fulfil keep and obey the ancient Statutes of the said Sovereign Order as far as they are applicable to the government of the Sixth Language and in accordance with the other seven languages and that I will use the authority reposed in me and my best endeavours and exertions amongst the Brethren to keep the said Statutes inviolable, this deponent hereby qualifying himself to govern the said Sixth Language as Prior thereof under the provision of the Statute of the 4th and 5th of Philip and Mary in the case made and provided. (Signed) Robert Peat. Sworn at Guildhall in the City of London, this 24th day of February, 1834, before me (signed) T. Denman."

We have told the story in some detail because we think it is little known, and it has been too hastily assumed that the modern Order of St. John is merely a decorative body masquerading under a great name. The documents quoted show that there is a trickle of continuity between the old order and the new.

From the time of its revival, says Porter, the English *langue* has continued to grow in numbers and prosperity and has followed in the footsteps of the parent Order by the promotion of works of usefulness and mercy. Among other objects for which it has striven are the provision of nourishing diet under medical orders for hospital convalescents without regard to creed; the original institution in England of what is now known as the National Society for Aid to Sick and Wounded in War; the foundation and maintenance of cottage hospitals and convalescent homes; the provision of means of opportunities for the training of nurses for the sick poor, and the foundation of what is now known as the Metropolitan and National Society for training and supplying such nurses; the establishment of litters for the conveyance of sick and injured persons in the colliery and mining districts and in all large railway and other public departments and towns; the institution of the St. John Ambulance Association for instruction in the preliminary treatment of the injured in peace and the wounded in war; and the establishment of the British Hospice and Ophthalmic Dispensary at Jerusalem.

On May 14th, 1888, in recognition of the charitable work done by the fraternity along these various lines, Queen Victoria granted to them a Royal Charter of incorporation under their old style and title of "The Grand Priory of the Order of the Hospital of St. John of Jerusalem in England." Her Majesty became the Sovereign Head of the Order, and in July of the same year the late King Edward VII, then Prince of Wales, was installed Grand Prior. The ceremony took place in the Grand Hall in the old Gatehouse at Clerkenwell. This is the room in which Samuel Johnson had worked—too often, it is to be feared, *impransus*—for Cave, publisher of the *Gentleman's Magazine*.

The St. John Ambulance.[2]

In 1877 the St. John Ambulance came definitely into existence.

The first step towards a genuine revival of Hospitaller work in England was taken when the members of the Order removed their head quarters to the Gatehouse of the ancient Priory of Clerkenwell, which had been secured for their use by the foresight of Sir Edmund Lechmere. As a dilettante charitable association with chivalric traditions indeed, but only occupying temporary apartments under a roof which was not its own, an element of uncertainty pervaded both its inner organization and its external work; but the very *genius loci* of the old headquarters of the English *langue* seemed to breathe its inspiration into the proceedings of the Council under its own roof, and steady progress has since marked its history.[3]

In old days many of the distinguished guests of the Prior were lodged in the Gatehouse. Holbeache says:

The business of the great ambulance work of to-day may be actually proceeding in apartments where L'Isle Adam stayed on his memorable visit to King Henry VIII, and where most of the home concerns of the English *langue* with their tenants or dependants were transacted.

The progress of the association was largely helped by the medical profession. Sir Edward Sieveking, a Knight of Grace, was one of the most earnest supporters of the Order of St. John from his admission as an honorary associate in 1869. In 1887 he presided at a meeting of hospital physicians and surgeons at St. John's Gate, where approval of the objects of the Order was expressed, and resolutions unanimously passed that every effort should be made to make the work known.

The first centre of the St. John Ambulance was established at Woolwich; others were quickly formed in various parts of the country. Instruction in first aid to the injured was given, and certificates were issued after examination. Ambulance stations were established at exhibitions and in places where large crowds were gathered together. The great development of the Ambulance Department of itself was sufficient to justify the resuscitation of the Order of St. John in England. The institution became a national one, and branches were founded in India. When Queen Victoria granted a charter to the Order of St. John, the Ambulance Association was incorporated with it as one of the principal departments and was made subject to its laws and regulations, the management and finances, however, being kept independent.[3] On the outbreak of the South African war in 1899, Lord Knutsford and Sir John Furley represented the St. John Ambulance Association on the Central British Red Cross Committee. By the regulations of the Committee the Association was entrusted among other things with two special branches of work, the collection and dispatch to the seat of war of ambulance material, and the organization of the personnel. Vast quantities of material of all kinds were sent out for the use of the sick and wounded, and distributed first by Colonel Young, and later by Sir John Furley. The various centres of the Association vied with each other in the quantity and excellence of the comforts and so forth sent out. The Association also forwarded a sum of seven thousand three hundred and seventy pounds in cash, collected from its centres, branches and supporters.

The St. John Ambulance Brigade is an offshoot of the parent association, its distinguishing feature being that it is a voluntary organization for rendering first aid to the public in a systematic manner by members holding the certificate of the St. John Ambulance Association. The approximate number of men in the brigade at the end of June, 1901, was 6,500, and of these 1,313 were at that time serving in South Africa or on their way there.

SATURDAY, OCTOBER 31ST, 1914.

GERMAN "CULTURE" AND SCIENCE.

FREDERICK THE GREAT said: "When I want a thing I take it, and find hosts of pedants to justify my action." Carlyle's questionable "hero" evidently knew the value of German culture. Bismarck, too, lost no opportunity of expressing his contempt for "professors." Of Treitschke, the preacher of the gospel of hatred for England, we are told by Norman Hapgood in *Harper's Weekly*, that "he had a natural tendency toward learning, but a natural tendency also toward using his facts to prove what he liked to believe." This characteristic is strikingly illustrated in the manifesto on the war which has been issued by ninety-three of the leading "intellectuals" in Germany. Among the names appended to this document are those of Professors von Behring, Czerny, August Bier, Haeckel, Ehrlich, Weismann, W. Wundt, and others who have been looked upon as leaders in medical science. If this kind of effusion is the product of "culture," it seems to us to be an exhibition of the German spirit even more deplorable than the burning of Louvain or the shelling of Rheims. These crimes of savagery may be partly explained as the acts of a brutalized soldiery. But that German learning in its highest development should lead men to ignore and misrepresent plain facts and insult the intelligence of the world by asking it to believe statements which can only be described as, like Falstaff's lies, "gross as a mountain, open, palpable," throws a fierce light on the mentality of the nation of which they are the intellectual leaders.

As the documents are of a political character, we do not propose to discuss their text. It is of importance, however, to point out that the authors do not seem to have taken the slightest trouble to make themselves acquainted with the facts as to the origin of the war; indeed, some of their statements are in direct conflict with the German case as presented in the official White Book. This being their method of controversy, it is natural that they should simply ignore the German Chancellor's confession of wrongdoing and his illuminating reference to a solemn treaty as a "scrap of paper." What interests us is the revelation afforded by the manifesto of the value of "culture." Either the professors know that they are putting forward untruths or they do not. If they do know this, how can we trust any other statements they may make? If they do not know it, then German "culture" as an instrument for the discovery of truth is utterly worthless—or worse, for it is a machine for the production of falsehood. We are more disposed, however, to believe that the German "intellectuals," like their master, Treitschke, have a natural tendency to use their facts to prove what they like to believe. Whether they are in good faith or not, the result of their amazing deliverance must be to discredit German science.

Dr. Victor C. Vaughan, President of the American Medical Association and Dean of the Department of Medicine and Surgery of the University of Michigan, has recently deplored in the New York *World* the loss to the world since German laboratories were exchanged for battlefields whence few will return. "The greatest scientific discoveries of the world," he says, "have been made in German laboratories." We venture to think that Dr. Vaughan exaggerates. It was not in German laboratories that vaccination, anaesthesia, or antisepsis was discovered. Bacteriology we owe to Pasteur, radium to Madame Curie. The list might be indefinitely extended. The German talent lies largely in applying discoveries made in other countries.

A reply to the German manifesto, at once dignified in the restraint of its tone and crushing in its plain recital of facts, has been made by a number of scholars and men of science representing different sides of British learning. It was drawn up by Professor Gilbert Murray, of Oxford, and among the signatories are Sir Clifford Allbutt, Sir Charles B. Ball, Sir Thomas Barlow, Sir William Watson Cheyne, Sir James Crichton-Browne, Sir Rickman Godlee, Dr. J. S. Haldane, Sir Wilmot Herringham, Professor J. N. Langley, Sir Donald MacAlister, Sir William Macewen, Sir Patrick Manson, Professor F. W. Mott, Sir William Osler, Sir Isambard Owen, Sir William Ramsay, Sir Ronald Ross, Professor C. S. Sherrington, Sir William Turner, and Sir Almroth Wright. It may be interesting to add M. Anatole France's opinion of the German professors' protest. "This manifesto," says the leading writer of France, "is a monstrous crevasse between Germany and the whole civilized Europe, an unbridgeable abyss. The only reply to make is to fire on the mass without scruple. These 'intellectuals,' glorifying and exulting Prussian militarism, show themselves to be more odious than the brutes whom they defend. The apologists for a crime are more culpable than the criminals. We must now make a new Europe, a harmonious Europe. It will be necessary to destroy the last army, the last fortress of the Hohenzollerns. After the defeat of the Germans we shall see, but for the moment our business is to conquer."

FRENCH SURGERY IN THIS WAR.

M. TUFFIER, the distinguished surgeon to the Beaujon Hospital in Paris, who was commissioned by the French Minister of War to inspect the medical arrangements of the French army, read his report to the Académie de Médecine in Paris on October 13th. The period covered was from the last week of August to the end of September, and he discussed the conditions existing from the firing line, through the clearing hospitals, the railway stations where the wounded were entrained, or the junctions where the trains were marshalled to be sent to their final destination at some place—it might be very distant—where the particular base hospital into which the wounded were to be admitted was established. The general conception of the French plan for handling the wounded resembles that followed in the British, and, indeed, all other armies, but it will, of course, be understood that M. Tuffier's observations apply only to the French army.

Dealing with the first stage of the wounded man's *via dolorosa*, M. Tuffier paid a high tribute to the skill and conscientiousness, courage and endurance of the surgeons at the fighting front. He saw them at work within a few hundred yards of the firing line in barns and hay sheds, often roofless, into which the wounded had been collected. Tincture of iodine "parsimoniously" applied, an aseptic compress, a little cotton-wool, and a bandage were often sufficient to ensure the healing of simple wounds, and this first

dressing might not need to be renewed. Between August 24th and 29th he saw at the Achères railway station over 6,000 wounded from Charleroi, Namur, Catelet, and Mons—men, that is to say, who had travelled from the frontier to within a few miles of Paris, a three days' journey; two-thirds of them were sitting-up cases, and the excellence of the dressings and of the improvised splints for fractures was, M. Tuffier says, striking. In less than 1 per cent. was it necessary to adjust or replace them. Comparing the iron wire troughs and zinc splints used by the French with the padded wooden splints used by the Germans and in the British hospitals, he gave his preference to the latter, because they were simpler and smaller, and because a leg or an arm could be really immobilized with them, much better than with troughs.

In discussing clearing hospitals, M. Tuffier deals with a matter of principle which many surgeons attached to base hospitals at home have brought privately to our notice, and we therefore translate M. Tuffier's observations on this head. "The clearing hospital," he said, "is the first sieve; it sifts out the cases not fit to be moved—abdominal and chest wounds, fractures of the upper third of the femur, and haemorrhagic cases, that is to say, all the serious cases. . . . Such a hospital is a point of capital importance, and should have a special staff (*un personnel de choix*) of experienced operating surgeons capable of rapidly appreciating and carrying out every indication for operations which its equipment and organization justify. Delicate adaptation of individual capabilities, and judicious division of the work according to aptitude is necessary here, but unfortunately it is hardly possible to fulfil this desideratum. The hospital is close to the fighting line, and consequently is constantly liable to be abandoned or captured. If the line advances, the hospital becomes useless for its special purpose; if it retires, the hospital becomes untenable or is captured by the enemy. These conditions, of course, are not favourable to a great surgical organization. Yet what actually happens is most distressing; minute by minute men arrive suffering from wounds of every degree which must be examined and treated. To meet these imperious demands you have only a small hospital with an operating room often chosen at haphazard, and a very small number of surgeons."

Coming next to the transit by railway, M. Tuffier dismissed the luxurious ambulance trains with dressing rooms, pharmacies, and kitchen with the remark that they were only to be seen at international exhibitions. The choice during the time covered by his report really lay between trains made up of ordinary third class passenger carriages or of freight wagons; the latter were generally used because they could carry twice as many as the former. The conditions have since, we learn, been very greatly improved. Ambulance trains made up of ordinary passenger carriages ingeniously converted, and good trucks filled with cots, are now available in sufficient number, and, if not luxurious, provide the essentials of comfortable transit. They carry medical officers and nurses.

During the artillery duels in the early part of the campaign in the Vosges 400 or 500 wounded might come through the station at Épinal, but during the close fighting 4,000. It was essential to empty the clearing hospitals to be ready for the next day, and a single line of railway had to take up food, material, and ammunition; supply had to take precedence of the wounded, so that the only way to bring them down was in the empty freight trucks. He had ascertained that the medical service was not responsible for the make-up of the trains, but was responsible for the selection of base hospitals to which the wounded should be sent. But this responsibility had to be exercised under special conditions; the scene of operations and all the fortified towns had to be kept free from wounded, and often, therefore, they had to be sent long distances. He urged that canteens and nurses should be established at the railway stations all along the road to the base hospitals, but that the nurses in the stations should have strict injunctions not to yield to the request of patients to have their dressings removed and replaced.

With regard to tetanus, which, he said, is one of the most important complications of wounds in this war, he dismissed the suggestion that it was due to bringing the men down in trucks which had been used for horses, and agrees with the opinion which has already been expressed in this Journal that it is in wounds soiled by earth, especially wounds of the extremities, that the infection most often establishes itself. He had observed some fifty cases, and the symptoms first appeared at varying dates—some as early as four or five days after the wound, others much later, after the patients had reached the auxiliary hospital at St. Germain, close to Paris. The proper treatment was preventive—by antiseptics at the earliest date, and the early removal of foreign bodies wherever possible, though in irregular and anfractuous wounds it might be very difficult to do this in the clearing hospitals. He therefore urged the early employment of antitetanus serum. Tetanus, he said, had its birth on the field of battle, and it was there that it must be attacked.

Emphysematous gangrene, which had been observed most often after shell wounds in which particles of clothing had been carried into the tissues, was difficult to treat successfully even if taken early. The actual cautery and large injections of hydrogen peroxide too often proved insufficient, and in the five cases he had seen in which amputation was performed, the operations were not successful in arresting the disease. For this reason he urged the earliest possible extraction of foreign bodies in such cases.

M. Tuffier stated certain general conclusions to which he had been brought. The first was that antisepsis was incontestably superior to asepsis; the second was that in the treatment of infected wounds there was nothing equal to drainage, which was the main point to be kept in view. The third was that in the treatment of wounds of the limbs the French Army Medical Service was right in being guided by the principles of conservative surgery provided that they were not carried too far. Each case must be judged on its own merits, for undiscriminating conservatism exposed the patient to the risk of emphysematous gangrene and acute septicaemia. The fourth was that it should be an absolute rule not to close wounds.

With regard to the relation of the gravity of wounds to the nature of the projectile, he arranged them in the order—bullet, shrapnel, shell. So grave were the wounds produced by the last-named, so liable to be followed by gangrenous septicaemias and by tetanus, that the immediate removal of fragments was indicated in every case in which extraction was easy. Otherwise as little as possible in the way of operation should be done at the front, the surgeon there contenting himself with getting the wounds as clean as possible. The chest wounds which reached the hospitals were, he said, remarkably benign, and cases of haemothorax calling for surgical intervention very rare.

M. Tuffier had a word to say about explosive bullets. He says that a large number of cases were shown to him in various hospitals in which large wounds of exit were supposed to be evidence of the use of such bullets. Every case, however, was, he said, an instance in which the bullet had struck a bone, and its envelope or a fragment of bone had been driven outwards. The fact was, he said, notorious among the surgeons on service, and, he added, "I saw a number of terrible examples among the wounded Germans." In order to prove the existence of prohibited bullets they must be found, he maintained, in the bandolier, or in the rifle magazine of the combatant.

TRANSPORT OF BRITISH WOUNDED IN FRANCE.

WE have received during the last few days information which enables us to say that the arrangements for the removal of the British wounded from the fighting line to the base hospitals have now been thoroughly reorganized, and for several weeks have been working in a manner that may be described as satisfactory. The unfavourable conditions of railway transport described by Professor Tuffier in his address to the Académie de Médecine as existing in respect of the French wounded a month ago have also been remedied. Properly appointed ambulance trains have been established, and are now running regularly. Ordinary passenger trains have rapidly undergone a marvellous transformation. Among other alterations first-class compartments of corridor carriages have been converted into two-bed wards for lying down patients. Good accommodation has also been obtained by fitting cots in properly cleaned and disinfected freight wagons. In the north, where the battle of the coast is now going on, ambulance trains are running regularly up to the clearing hospitals, and there is, we are informed on the authority of a very competent witness, no congestion or undue suffering or hardship, although the wounded are arriving in great numbers. The ambulance trains are provided with kitchens and other comforts, and a good nursing staff. Motor ambulances are a great feature of the medical arrangements for the transport of wounded to the clearing hospitals and rail-head, and many of them are also utilized on the lines of communication. Many more could be utilized there, but the chief use of the motor ambulance is the rapid removal of the wounded from the field ambulance to the clearing hospital. It is found that the best and most humane method of transport from the clearing hospitals to the line of communication hospitals, and from the latter to the ships, is the ambulance train. For the work in the advance line—that is to say, between the field ambulances and the clearing hospital—motor ambulances should completely replace horse or hand drawn vehicles, but they should not be used as a rule as a substitute for trains when these are available. The correspondent from whom we have received this information states that he has seen very systematic work for dealing with large numbers of wounded in Manchuria—work quoted as the admiration of the world—but he is able confidently to assert that the work now going on where our fighting is hardest surpasses anything that has before been attempted.

THE BENEFICENT TRIUMPH OF THE MOTOR AMBULANCE.

WE need hardly remind our readers that for many years past we have pleaded for the introduction of the motor ambulance in supersession of wheel-litters and horsed ambulances for the transport of the injured, and we cordially supported Sir William Collins in his efforts to introduce such a service for London, and in piloting through Parliament, for that purpose, his Metropolitan Ambulances Act, 1909. At the end of August we intimated that similar ambulances would probably be required for military service, where their success was likely to be as marked as it had been in civil work in large towns both here and abroad. Since that date it is not too much to say that the motor ambulance has come in with a mighty rush. Its suffering-saving capacities, and the earlier treatment which its prompt transport secures, have been abundantly demonstrated. An ounce of practice has outweighed pounds of theoretical objections which were previously forthcoming. The preferences on the part of police authorities for wheel-litters, municipal reactionaries' enthusiasm for workhouse cabs for the conveyance of victims of accidents, and parliamentary committees' vaticinations as to costly experiments have been blown to the winds. Sir Alfred Keogh and Sir Frederick Treves, on their return from a recent visit to the base hospitals, declare that "the need which transcends all other needs at this moment is an adequate supply of properly fitted motor ambulances." Mr. Massac Buist, in our issues of October 3rd and 10th, has called attention to important points in the adaptation of motor cars for ambulance purposes—the avoidance of overhang, the provision of sufficiently plangent springs, and a comparatively long wheel base; and these matters have engaged the attention of the British Red Cross Society and the Royal Automobile Club, which is co-operating in this good work. The excellent electric ambulances employed by the City Corporation have been the admiration of London citizens during the last seven years, and have given an object lesson in how to deal with the transport of the victims of accidents in streets or public places. On an average, we understand, only eight minutes elapse between the telephone summons and the deposit of the patient in hospital. Where electric power is available, and the gradients to be traversed are low, there is no doubt that such a type of ambulance is for urban districts superior to others. Thanks to the generosity of the Grand Duke Michael of Russia, the North-West of London has for two years been able to witness the beneficent work of a petrol driven motor ambulance attached to the Hampstead General Hospital. It is of 15.9 horse-power, climbs the heights of Hampstead and Highgate with ease, and consumes, we understand, about one gallon of petrol for every fifteen miles run. The motor ambulances tardily ordered by the London County Council, to the number of eight or nine, were to be delivered by the contractors this month. They are, we believe, of a novel and quite up-to-date type, largely devised by Lieutenant Sladen, chief of the London Fire Brigade, and are intended to avoid the use of stretchers. No doubt the motor ambulance, whose virtues have so suddenly found themselves acknowledged, is still in a stage of evolution, and the most serviceable form has not yet been finally determined. We have, indeed, heard recently of a combined electric and petrol ambulance, generating its own electric power and lighting as it goes. It would be necessary only to arrange for the utilization of such power for *x*-ray work and inside illumination in order to provide a true moving hospital. To abbreviate the interval between the infliction of the wound and the ministrations of the surgeon and to anaesthetize this interval as much as possible are the objects to be kept in view as well as the great services rendered by the motor ambulance. In this case "it is the pace that"—saves.

HOSPITAL SHIPS.

THE hospital ship, though in its present form a novelty, has played a part in naval warfare on many occasions. Its history extends back to the seventeenth century. In the *Army and Navy Gazette* of October 10th the Rev. A. G.

Kealy, R.N., shows that the general idea that the *Maine*, which was wrecked some time ago, before the outbreak of the present war, was the first of seagoing hospital ships is erroneous. He gives the following record of the previous use of such vessels: In 1673 William Dampier, serving on board the *Royal Prince*, on falling sick two days before the action of August 11th, was sent on board the hospital ship. In 1692 Richard Allyn, chaplain of H.M.S. *Centurion*, gives in his list of ships engaged in the battle of La Hogue two hospital ships as attached to each squadron, the Red and Blue. In 1701 Sir George Rooke requested that the hospital ship might bring a good supply of Thames water for the fleet, and later ordered Captain Watkins to take aboard the hospital ship all such sick men as should be sent to him. In 1718 a hospital ship accompanied Sir George Byng when he sailed from Spithead, June 15th. In 1793 Cooper-Willyams, chaplain of H.M.S. *Boyne*, in his account of the campaign in the West Indies, in which the army acted with the fleet, says that after the Grenadiers had repulsed an attack in the Isle of Martinique the wounded were sent on board the *Roebuck*, the hospital ship of the fleet. Later on, when speaking of the hospital taken possession of at S. Pierre, Cooper-Willyams says: "This we found of infinite use for our sick and wounded, who were far better provided for here than they could be in the hospital ships." In 1794 a hospital ship was attached to Lord Howe's fleet off Ushant. In 1795 one was likewise attached to Lord Bridport's fleet off Belle Isle. Mr. Kealy can find no record of hospital ships having been used in the Crimean war in connexion with any of the fleets. He adds: "With regard to the *Maine*, with which we commenced, she was bought for naval service sometime after the South African war, and in 1902 Mr. Arnold-Forster said in Parliament that the policy of hospital ships for the navy had been deliberately adopted after a great deal of consideration by the Admiralty. The current *Navy List* contains the names of seven hospital ships carrying nursing sisters, whose presence at sea is a curious reversal of naval discipline."

SIR ROBERT SIMON.

We mentioned last May that Sir Robert Simon had resigned the position of physician to the General Hospital, Birmingham, after having served the hospital for thirty-five years. At a meeting in the board-room at the hospital on October 14th, before a large audience, his portrait by Mr. Edward S. Harper was presented to the hospital, and gratefully accepted by the Lord Mayor, who said that Sir Robert Simon was prominent in the long line of eminent men who through the last 140 years had gradually built up the very great reputation the General Hospital now possessed. Sir John Holder, as chairman of the House Committee, then presented a diamond tiara to Lady Simon as an acknowledgement of the governors' high appreciation of the devoted and distinguished services Sir Robert Simon had rendered to the hospital. Mr. Gilbert Barling, senior surgeon, then asked the Lord Mayor to present to Sir Robert Simon an album containing an illuminated resolution and a list of subscribers, together with the resolution of the Board of Management, which we published last May. The album having been formally presented, Sir Robert Simon said that after so many years' connexion with the hospital he found it a wrench to give up his association with it. He felt especial pride in knowing that his portrait would hang on the walls of the board-room, and concluded by saying that his work at the hospital had been lightened by the co-operation of the whole of his colleagues, than whom it would be impossible to find a set of men more devoted to the hospital, or more closely associated by the common bond of love for the institution they were so proud to serve.

A MEDICAL AVIATOR.

Dr. Emile Reymond, Member of the French Senate for the Loire, was a medical man by profession, and had won distinction as a surgeon. He held the rank of surgeon-major in the French army. But his heart was in aviation, the possibilities of which in military operations he had often defended in the Senate. Before the war he was President of the National Committee which bought aeroplanes, built sheds, and instructed pilots. He was most eager for service with the army aviation corps, and at his own request was attached to it for military service on the outbreak of the war. He was so successful as a flight observer that he was mentioned in dispatches. While making a reconnaissance over the German lines he was hit by a bullet and mortally wounded. He made a final effort to reach the French lines, but, his strength failing his machine fell between the two opposing armies. The Germans made a determined effort to capture him, but were driven off by the French. He was carried back to his own lines in a dying state, but insisted on giving a report of the results of his reconnaissance. Before his death, which took place a few hours later, the general commanding his division pinned on his breast the Cross of the Legion of Honour. The President of the French Republic sent the following telegram to Dr. Reymond's widow:

Please accept, madame, my respectful condolences in the loss which you have suffered. The heroic and glorious death of Dr. Reymond is a cruel blow to all his friends, of whom I was one, but the magnificent example of courage which he gave is an honour to the Parliament of France. I hope that this thought may be some consolation to you in your great sorrow.

Dr. Reymond is said to have had a greater influence than any other man in France on the development of military aviation, to which he first gave the name of "Fifth Arm."

ARMY SANITARY COMMITTEE.

The Army Sanitary Committee which, as we announced a fortnight ago, the Minister for War had decided to appoint to advise the Army Council on all matters connected with the health of the troops at home and abroad, has already held one meeting. It is constituted as follows: Brigadier-General F. J. Anderson, R.E. (chairman), Dr. Arthur Newsholme, C.B. (Medical Officer, Local Government Board), Colonel W. H. Horrocks, M.B., B.Sc. (Expert in Sanitation, Army Medical Advisory Board), Sir Frederick Treves, Bart., G.C.V.O., C.B., Dr. John Robertson (M.O.H., Birmingham), Dr Henry R. Kenwood (M.O.H., Bedfordshire and Stoke Newington, Civil Expert in Sanitation, Army Medical Advisory Board), and Major C. E. P. Fowler, F.R.C.S., R.A.M.C. (late Officer in Charge, School of Army Sanitation, Aldershot), with Mr. Edmond T. Gann, Secretary of the Army Medical Advisory Board, as Secretary.

THE WAR AND THE MEDICAL SCHOOLS.

London.

Inquiries recently made with regard to the number of new students who have entered at the various medical schools in London, and as to the number of senior students who are at present serving with the army, appear to show that the decline in the former has not on the whole been great.

St. Bartholomew's Hospital.

The entry of new students is considered to be as good as could be expected in the abnormal circumstances, but the medical school is about 50 per cent. below strength, owing to the fact that a few of the second year men, a certain number of the third year, and a great many of the fourth and fifth year students have accepted positions as dressers, etc.

Guy's Hospital.

We are informed that at Guy's Hospital the number of new students is well up to the average. For those students who had any clinical experience and were entitled to begin their clinical training special courses have been provided to qualify them for Red Cross work, and a great many of them have gone to the front. It had been generally realized by students and their parents that it

was better for students nearly at the end of their course to complete their training in order to be able to offer themselves, if need be, as fully qualified men. The secretary of the medical school points out that new students are usually received at ages below the minimum age of enlistment, and that consequently the war need not be expected to affect the numbers of new students to any extent. In the dental department the position is different; students begin their two years' clinical training at 21 years of age, and the entry of dental students has been affected by the war.

The London Hospital.

The London Hospital last year had what was considered a poor entry as regards the number of new students, and this was ascribed to the state of uncertainty brought about by the introduction of the Insurance Act and early difficulties in its administration. This year the figures of last year have been improved upon in spite of the fact that at the last moment fifteen whose names had been given in withdrew in order to enlist. Of students in their final years nearly eighty have left for service with Red Cross and similar units. Second and third year students have not gone to quite the same extent. So far the authorities of the medical school have taken no steps to withhold men from active service, although it is realized that the time may come when it will have to be urged that duties at home are more pressing and must have first claim. It has been found possible up to the present to man the hospital with house-physicians and house-surgeons, and it had not been necessary to draw upon men outside. Several teachers are away on active service, but the course of study is normal.

St. Thomas's Hospital.

At St. Thomas's, also, the point is made that new students are too young to enlist, and we are informed that the number of entrants is little, if at all, lower than the average of the last five years. Of late third and early fourth year men a great many have been accepted as dressers, so that the numbers in the school are lower than usual.

School of Medicine for Women.

On inquiry at the London Royal Free Hospital School of Medicine for Women, there is, we are informed, a record entry of students, the number being 56, which brings the total number of students to 212. Many of the more advanced students are taking service for periods of not longer than three months with private corps which are undertaking the care of the wounded. Former students of the Royal Free Hospital are largely represented on the staff of the Women's Hospital in Paris, which is conducted entirely by medical women. The Royal Free Hospital is also represented on the unit which has been in Antwerp and is about to go to the Continent again.

CAMBRIDGE.

We learn that the number of students proposing to study medicine who have come into residence at Cambridge in October is 64; last year the number was 116, in 1912 it was 110, and in 1911, 114. From the list of resident members of the university it appears that almost 50 per cent. are away, the percentage ranging in various colleges from 71 to 26. Those who have the responsibility of advising medical undergraduates have done everything in their power to keep medical students at their studies, and to some extent have succeeded. In this the university accepts the view of the General Medical Council and the War Office that a medical student should fulfil his course and become qualified at the earliest possible moment.

The members of the field ambulance section of the Officers' Training Corps will for the present devote most of their time to learning the necessary amount of infantry drill, proceeding later to the special work of their unit.

PARIS.

The Faculty of Medicine opened its doors for a short time last week for the purpose of holding the final examinations which ordinarily take place in the month of October, and is arranging for the commencement early next month of a certain number of lectures and classes in the school of medicine. These, however, merely cover the subjects of the first two years, the number of senior students able to follow their ordinary pursuits being too few to make it worth while to hold courses in the subjects of the third and fourth years.

THE WAR.

MEDICAL MATTERS IN FRANCE.

(From a Special Correspondent in Paris.)

CONSERVATIVE SURGERY.

In a recent note I made passing reference to certain cases which had left on my mind an impression that the experience of civilian hospitals was perhaps influencing treatment somewhat unduly. It seemed to me possible that the successes of peace time surgery were leading to overventuresomeness in the way of attempting to save shattered limbs. Having given vent to this half-formed view I ought perhaps to cite against it the fact that one of the strongest advocates of conservative treatment that I know is a man whose surgical training has been not civilian, but military. This is Dr. M. E. Delorme, who is a medical inspector general of the French army and a surgeon of such long experience that very great weight must be attached to his opinion. This, as expressed in his treatise on military surgery, is absolutely favourable to the conservative treatment of the kind of cases that most surgeons a decade or so ago would, reluctantly no doubt, but still unhesitatingly, have submitted to amputation. He is, indeed, so keen an advocate of the observance of conservative principles in military practice that on the outbreak of the present war he issued a kind of manifesto in their favour in the form of a communication to the Institute of France under the title of Conseils aux Chirurgiens. In view of his position in the army this statement would seem almost equivalent to an order so far as his junior colleagues are concerned, and he has since justified it in a summary attached to a review of a batch of over 700 cases. The patients in all these cases were prisoners of war, the survivors of a larger number of wounded left on the field when the Germans began their retiring movement after the battle of the Marne. Picked up by the French in circumstances which suggested that they were among the most serious cases and deemed by the German surgeons unfit to be sent to a German base hospital, they were sent to the citadel of Blaye, where Inspector-General Delorme went to organize a hospital for their benefit. The wounds were of all kinds, and most of them serious in themselves and septic to boot. This was not surprising, for though the Germans had not left them unattended and had applied first aid dressings and splints, six or seven days had elapsed since the men had been wounded, and meantime there had been no opportunity for changing the dressings. Dr. Delorme remained in charge for five days and then left after giving his junior colleagues precise instructions as to how each case was to be further treated. Meantime he had done all the operative work that seemed to him necessary, and in the way of amputations this was limited to the removal of a single finger. This fact Inspector-General Delorme holds to justify his previous teaching, namely, that the primary treatment of compound fractures and the like, however serious, should almost invariably be conservative. This may well be true, but it can hardly be said that the foregoing record is very convincing. The disadvantages of amputating become evident at once, those of conservative treatment not as a rule in five days but commonly not for several weeks. It may then be found either that the limb though saved is practically useless owing to nerve lesions or other circumstances, or that the risks of amputation have to be faced in a patient exhausted by long-continued suppuration and surgical fever. It may seem presumptuous for me to appear to oppose in a casual note of this kind the teaching and practice of so great an authority as Dr. Delorme, more especially as he is supported by a large number of distinguished civilian and military colleagues, but I have a valid excuse for pointing out that the possible arguments are not all on one side. Despite the fact that the tendency in favour of conservative treatment is exceedingly strong, I have seen a good many amputations, and certain circumstances have convinced me that when the war is over suggestions to the effect that A. lost his arm because he was under the treatment of B., and that the leg of C., which was equally badly injured, was saved thanks to D., will not be lacking. The real fact is that

the right treatment of severe compound fractures, however caused, is not a matter for safe generalizations. Every case must be treated on its own individual merits, the precise nature of the lesions, the present and future environment of the patient, and the apparent extent of his vital resistance all being taken into consideration.

Sick Transport.

The French have been by no means blind to the preventable evils arising from lack of sufficient ambulance trains and their blockage through other traffic to and from various bases. It was, indeed, partly in the hope of improving matters that until a comparatively short time ago permits to visit the front were freely issued to persons who had converted their automobiles into ambulances, and expressed themselves ready to take part in the work of bringing down the wounded to base and other hospitals. This partial remedy, however, was early seen to be not free from drawbacks—to some of which allusion was made in a previous note—and consequently the whole subject was taken in hand by the Minister of Public Works in counsel with the Director of the State railways of France. The result of their deliberations has been that a new service of ambulance trains has been put into operation. The new rolling stock, though not as thoroughly suited to its purpose as are carriages specially built for carrying sick soldiers, at least represents a very great improvement. The carriages are of two kinds—those intended for patients able to sit up and those for patients who must be kept lying down. The former are, in effect, ordinary corridor carriages, each arranged to accommodate forty wounded men, and the latter covered goods trucks, each capable of holding nine loaded stretchers. It is said that, so far as rolling stock is concerned, there is now provision for the simultaneous transport of over 68,000 wounded, the State lines being able to deal with 20,000, the Paris, Lyons, and Mediterranean Railway with 20,000, the Orleans Railway with 20,000, and the Midi Railway with 8,000. Each train is to carry a medical officer and a nurse, and will be equipped with everything necessary for the renewal of dressings. The Minister of Public Works is stated also to have in hand the question of utilizing on a large scale the canals and rivers of France for the purpose of transporting wounded men either to base hospitals or to their homes. The idea would seem to be to cover in a large number of barges and equip them in the style of the floating ambulances described in a recent note as having been provided by one of the branches of the Union des Femmes de France. Regarding the projects of that society I should correct a statement previously made. Though it is recognized that the use of self-propelling barges would present advantages, it is considered that it will be preferable on the whole to use ordinary barges and link a sufficient number of them together to form a hospital unit of 400 or 500 beds. Such a unit could be placed in charge of one or more medical officers and a staff of attendants and be towed gently along by means of a steam tug.

The Anglo-Franco-Belge Hospital.

Among the temporary hospitals in Paris which seem to me, on the whole, unlikely to move is that known as the Claridge, or Anglo-Franco-Belge. Most of its patients, perhaps, up to the present have been British, but recently it has been inspected by General Février, the head of the French army medical department in Paris, and its general organization and the character of the work it was doing met with his full approval. Consequently, none of its 80 beds are likely to remain empty long so soon as the present practical embargo on the entry of wounded into Paris is removed. General Février's approval of this institution is not surprising, for the whole of its arrangements are of a most workmanlike order. Nominally under the control of the Union des Femmes de France, it is in effect a free-lance institution, organized, officered, and maintained by persons interested in the suffragist movement in England. The principal medical officers are Dr. Flora Murray and Dr. Louisa Garrett Anderson, who have as their colleagues Drs. Hazel Cuthbert, Grace Judge, Emily Lazear, Blundy, and Jobson. On the subordinate staff are a varying number of fully trained nurses, the only males about the establishment, apart from the patients, being four orderlies. The uniform of the staff is a neat brown costume, with small close-fitting bonnets, and its business-like inconspicuousness might well be imitated by other ladies engaged in the same kind of work. If all I hear is true some of the costumes to be seen in the streets of London suggest the stage of a musical comedy theatre. Paris, too, suffered at the beginning of the war from an epidemic of this order but early revolted against it. Paris, indeed, at the present time is a model to London in more respects than one. However, this is not the subject on which I intended to write. The Anglo-Franco-Belge Hospital is commonly called the Claridge Hospital because it occupies the building of the Claridge Hostel, close to the Rond Point of the Champs Elysées. In respect of the airiness and brightness of its wards, it has no reason to envy any of its compeers, and the arrangements have been thoughtfully made to include a feature which, if not peculiar to this institution, I have not seen elsewhere. A large long room in the basement has been converted into a *chapelle ardente*, and presents at one end an altar, at the other chairs for the mourners, and in the middle a space for a coffin. It is kept tastefully decked, and on the day that I visited it looked very peaceful and beautiful, the light falling into the room through coloured glass in a fashion reminiscent of the famous antechamber of the chapel at Les Invalides. On one of the days that I visited this hospital a number of British patients were being sent home, and the fashion in which they bade their farewells left no doubt as to their opinion of the way in which they had been treated. In fact, if this institution were the sole British hospital in Paris the medical profession in Great Britain might still continue to regard itself as well represented. I should add, lest I forget it as I did last week, an observation in regard to the character of the nursing that I have seen at various hospitals. On several occasions I have been present at operations on patients who had only reached the hospital from the trenches a few hours previously; nevertheless, they were placed on the table absolutely clean. British nurses in Paris are, in short, justifying the esteem in which English nursing has long been held abroad.

Enteric Fever.

At the American Hospital I noted a water filter dependent for its operation on some form of electricity. The machinery being all covered in, and my guide through the building unversed in the subject, I was unable to ascertain what was the system employed. From its general construction, however, I concluded it to be a violet-ray sterilizer. If so, it is probably one of the same pattern that a young British airman officer informed me was being used by his corps. I mention the fact since it serves to illustrate the amount of care that is being taken to provide pure water for the troops. I have made careful inquiry as to the number of cases of enteric fever coming down from the front, and am able to state with assurance that there are at present very few, and that the Widal reaction is being applied in all cases deemed in the least degree of a suspicious character. One hopeful factor in the situation is that the British soldier seems thoroughly impressed with the need of abstaining from drinking any water other than that served out to him ready sterilized, or at all events, is much more docile in the matter than was his predecessor of fourteen years ago in South Africa. Those who served in that war will remember that it was practically impossible to prevent the soldiers drinking any and every water that was available when they were overcome with thirst. It is true that South Africa with its intensely dry climate and usually glaring sun was a much more thirst-provoking land than any part of France, but thirst in the present war has been common. A soldier from the fighting line, in fact, told me that he had only two things of which to complain: one was the difficulty of obtaining bread—which he added was lessening—and the other the impossibility of getting any but a very limited supply of drinking water. What he added regarding the latter trouble was rather interesting. He and his comrades, he said, dare not drink ordinary water because it was well known that the Germans had poisoned it. It appears, therefore, that the belief in the unscrupulousness of its methods that the German army has established is not without its advantages.

THE GERMAN INTELLECTUALS.

It is understood that at its next meeting, which will probably have taken place before this letter reaches England, the Academy of Medicine will decide on some definite step in regard to associates and honorary correspondents of German and Austrian nationality. A decision on the point seems to be inevitable, for, though the Academy is not one of the five constituents of the Institute of France, it is the official representative of French medicine, and guards its portals with the utmost care. Although divided into twelve sections, its ordinary members do not aggregate more than 110 all told. Its statutes permit of its electing twenty foreign associates and twenty-five foreign correspondents, and the roll of the former includes the names of W. C. von Roentgen, of Munich; E. von Behring, of Marburg; Emil Fischer, of Berlin; Paul Ehrlich, of Frankfort; and Friedrich Loeffler, of Greifswald, in Pomerania. On the list of foreign correspondents are Jaroslav Hlava, of Prague; Albert Adamkiewicz, Maurice Benedikt, and Ernest Ludwig, of Vienna; G. H. Erb, and A. Kossell, of Heidelberg; Paul Unna, of Hamburg, and W. Oskar Filehne and J. Hirschberg, of Berlin. Individually most members of the Academy of Medicine are overwhelmed with work at the present time, and for this reason, if for no other, they would doubtless have been glad to avoid any question of revising the foreign associates and correspondents roll. Its consideration has been forced upon them, however, by the manifesto addressed by the intellectuals of Germany to their fellows in neutral countries. This document, following as its issue did on the destruction of invaluable buildings and libraries, unnecessary slaughter of hundreds of innocent civilians, and various other exhibitions of German "kultur" in time of war, is viewed with the deepest indignation among the educated classes in France. Newspapers of all types have mentioned it almost daily since its appearance, and have endeavoured to forecast what action the *Institut*, which is the representative of educated thought in France, will take in respect of it. It seems a little doubtful whether the Institute of France as a whole will take any action in the matter, for seemingly it can only do so on the unanimous vote of its five constituent academies. One of these—that of science, which includes a small section representative of medicine—has in the past rather prided itself on standing aside from its fellows, and another—the French Academy—is not directly concerned, since up to the present it has never elected foreign associate members nor appointed foreign correspondents. It is, however, believed, or at all events hoped, that on the present occasion these two academies will fall in with the rest should any joint action be attempted. Meantime, l'Académie des Inscriptions et Belles Lettres, which is concerned with the study of great historic civilizations, the Academy of Moral and Political Science, and the Academy of Fine Arts have already passed resolutions which have been nominated *flétrissures*. This term, so far as it can be translated at all, may be taken as signifying, in the present connexion, a crushing rebuke to the intellectuals of Germany for publishing a totally unnecessary and misleading statement, and thus tacitly approving of the irreparable destruction of objects of immense interest to cultivated persons all over the world, and of numerous cruelties to women and children.

THE ACADEMY OF MEDICINE.

There are several vacancies in the various sections of the Académie de Médecine, and names of candidates for all of them have been put forward. At an ordinary meeting, however, on October 13th, the president reported that it had been decided by the council to defer all elections until the end of the war. At the same meeting it was resolved to give publicity to the fact that so soon as war was declared the Academy, in view of this circumstance, had adopted unanimously a series of resolutions relative thereto. One of these stated that the whole of its members placed their services at the disposition of Government, while the rest were to the effect that in the public interest the danger of a possible outbreak of small-pox as a consequence of the war should be forestalled by increased attention to revaccination; that to prevent any possible shortage of lymph on account of lack of calves the Vaccine Institute, which is under the general control of the Academy, should be taken over temporarily by the medical department of the Ministry of War; and that the general public should be encouraged to seek protection against enteric fever by the use of antityphoid serum.

CHANGES.

During the past fortnight or so there has been a distinct change in the atmosphere of Paris, both physical and moral, but it is not of such a character as to be susceptible of description in a couple of phrases. Meteorologically, the weather has been distinctly autumnal, cold days of drizzling rain alternating in triplets with a few brief hours of springlike sunshine. Autumnal, too—indeed, almost wintry—is the moral atmosphere, inasmuch as that the average Parisian, though he has lost neither his courage nor phenomenal calm, is becoming somewhat subdued. Still confident that there can only be one end to the war, proud of the performances of his own army, and gratefully and fully alive to the assistance that that army has received from the British and Belgian forces, he is nevertheless beginning to recognize that the war will be long, and views with a certain degree of heart-sinking the prospect of being unable to return to his normal existence for many months to come. On the other hand, there is a suggestion of spring in the fact that little by little the number of shopkeepers who think it worth while to reopen their premises is increasing, and that many more people are to be seen in the streets than was the case a few weeks ago. Among these a British soldier is becoming a rare object, and this is due to the greatest change of all. Comparatively few wounded of any nationality have been brought into Paris for a week or two past, and of British wounded practically none at all. Indeed, the British Red Cross and other hospitals officered and maintained by English-speaking folk are beginning to wonder whether they will not soon be directed to move out of Paris further towards the north, whither the head quarters of the British Red Cross Society have already proceeded. It seems hardly likely, however, that all of them will be moved, or that in the case of any of them a change of station will take place rapidly; though the inflow of new patients has ceased, all of them still have many cases on their hands and in addition to finding a new home for themselves the hospitals must find also new quarters for their present inmates. Besides this several of them are catering quite as much for French as British patients. The American, the Majestic, and the Anglo-Franco-Belge hospitals are cases in point. There would probably also be some difficulty in finding suitable fresh quarters for so large and well elaborated an institution as the Astoria. This was the first of the four hospitals established under the aegis of the Red Cross Society in Paris, and the fact that it was ever established at all is a distinct feather in the cap of Dr. Leonard Robinson, Dr. Jarvis, and others connected with the Paris branch of the society in question. Foreseeing the need of a Paris branch Dr. Leonard Robinson applied, almost as soon as war started, for authority to establish one, and when no reply came from London he and his colleagues practically gambled on the chances of an authorization eventually arriving and set to work to lay the foundation of a hospital organization and provide other necessaries forthwith. They did this despite the fact that little assistance seemed likely to be forthcoming from the natural supporters of a Paris branch. Most of these—namely, the richer members of the British community in Paris—had left when the probability of Paris being invested first loomed on the horizon, and the amount of support on which Dr. Robinson and his colleagues were able to count with certainty was very limited. It was well indeed that they had the courage of their own convictions, for it was largely owing to the pioneer work of the nascent Paris branch that the parent body was able to do effective work on a larger scale immediately it reached the capital. Previously its career had been a series of disappointments, owing to its having been driven from pillar to post by the frequent changes of front and having had to abandon project after project. All supporters of the British Red Cross Society are therefore greatly indebted to those who took part in the foundation of the Paris branch. They have had an immense amount of work of all kinds thrown upon them, and they are unlikely to be able to slacken their efforts for some time to come.

MEDICAL ARRANGEMENTS IN THE NORTH OF FRANCE.

We have been favoured with a copy of a letter referring to the British medical arrangements in the north of France, written by a military medical officer of long experience, and are permitted to take the following extracts from it:

No praise (he says) is too great for the systematic work which is being done both in the field ambulances and clearing hospitals during the heavy fighting which has been going on. Every possible arrangement is being made for the comfort of the wounded. For example, at one of the dressing stations opened in a village estaminet the public room had been very comfortably prepared for severely wounded, a central stove with a cheery fire and hot coffee making a great contrast with the cold, drizzly, dismal weather outside to which the men were being exposed in the attack. In an adjoining house of a well-to-do French family one of the bedrooms had the bed beautifully ready with clean sheets and blankets, the fire lighted, and the whole effect that of a cheery bedroom at home. This was kept for the reception of any seriously wounded officer. I mention these incidents merely to give a picture of the kind of thing that is going on under the R.A.M.C. under the enemy's guns in what is practically an encounter battle. From the dressing stations to the clearing hospitals which were opened about five miles back motor ambulances were constantly running, and the wounded got back almost as fast as they could be dressed. One clearing hospital associated with the field ambulances was opened in an extensive seminary for young ladies. The building was fitted with every sanitary convenience, and had rows of cubicles, each with a neat little cot. The girls had only been turned out of the building a couple of days before, and, in consequence of all this useful equipment, a really bright hospital was ready in no time. I cannot imagine anything more comfortably arranged in a hospital of such a transitory nature and so near the fighting line. You may be satisfied, and everybody at home may be satisfied, that any tales intended to cause anxiety to those who have friends and relatives at the front are wicked and untrue.

General and stationary hospitals at the base are, the writer states, usually housed in luxurious hotels and casinos. In several which he visited he found that though the personnel and equipment had only been there a day or two, all was got ready with great rapidity; most of the buildings were already full of wounded. There appears to be very little sickness.

"Nobody here," he concludes, "seems capable of understanding how the idea got about that there was anything approaching a breakdown of the medical arrangements. The whole system is full of life, zeal, initiative, and vigour. It is capable of bearing a much greater strain than any to which it has yet been put."

A CLEARING HOSPITAL.

We have received an outline of the work of a British clearing hospital established at a small village at the rear of the fighting line on the Aisne. When first established it had five medical officers and the help of a French lady who had had some training in nursing. Its organization steadily improved, and when in full swing it had five special reserve medical officers, or civil surgeons, including a bacteriologist, and three Red Cross nurses. The village church was used as the reception hospital, and cases as received from the front by motor ambulances or lorries were sorted into bad, sitting, and sick, which were placed in different parts of the church. The village hospital of two wards, already properly equipped with beds and bedding, was taken over and used for bad cases. Four houses and certain convenient outbuildings were also taken over and fitted up with beds and other equipment obtained from neighbouring country houses. Altogether fairly adequate provision was made for between 200 and 300 wounded and sick. During the first week nearly 4,000 wounded—British, French and German—came down. The motor ambulances (Wolseley's) were of very good pattern, and were used for bringing down the wounded to the village, and also for transporting them to the rail-head; in some cases they were used for taking serious cases to Paris direct. The ambulances held four lying down and went to Paris in charge of a medical officer, but as the roads were bad, a train was preferred when one could be obtained, as was usually the case later on. A rough rule was made that in cases of wounds of the head and chest or severe wounds of the leg, the patient should not be moved if conditions permitted his detention, as such cases bore the journey badly and did much better in the village.

When the British force removed from the region the clearing hospital was ready to move also, and its departure was hastened by the fact that one afternoon it was shelled for several hours, most of the shells being apparently directed on the church, which, as has been said, was being used for the reception of wounded when first brought down.

At this time, in addition to the ordinary wounded, the hospital had charge of seven women who had been hit while attending the wounded in neighbouring villages. One of these women who had suffered a severe shell wound of the skull, exposing the brain, died. In another case it was necessary to amputate the foot: in a third, a rifle bullet had entered in the back to the right of the vertebral column, and had probably damaged the ureter; the patient developed signs of pelvic peritonitis, but it was found possible to move her to the ambulance train, and it is believed that she eventually did well.

The general line of treatment followed at the front and at the hospital was the application of iodine to the skin followed by dry dressings. Other antiseptics than iodine were not generally used; instruments were boiled. Most of the cases in which amputation was necessary did well, but in some, where the men had lain out long before they were brought to the field ambulance and hospital, malignant oedema had set in and amputation proved useless. There were few abdominal injuries; they did badly. The hospital had the services of a bacteriologist whose assistance was very valuable, particularly in the detection of typhoid fever, of which some 30 cases, chiefly from the British forces, were admitted. After the hospital had been established for some time injections of antitetanus serum became the rule. At the clearing hospitals in the north of France all the wounded, we are informed, are receiving an injection of antitetanic serum as a routine prophylactic measure. A German ambulance, very well fitted up and containing dressings and drugs, was brought into the village, and its supplies utilized to supplement those already available. Among the duties undertaken by the clearing hospital was medical attendance on the ordinary inhabitants of the village, who numbered about 200. A civil surgeon was told off for this duty, and during part of the time had the assistance of a German medical officer who had been taken prisoner.

INDIAN EXPEDITIONARY FORCE.

A British military medical officer in France who has seen a good deal of one of the Indian Divisions tells us that, from what he has observed of the billeting of its field ambulances, he came to the conclusion that the Indians would very soon become experts in making themselves comfortable in the French houses. The building assigned as a stationary and general hospital for Indians should, he thinks, in time become a fairly comfortable hospital, and he expresses the hope that the standard of comfort and brightness will be made equal to that of the British hospitals. One of the Indian hospital ships which he visited he describes as most luxurious, no element of comfort being lacking. It is, he says, "in every respect equal, if not better, than the British hospital ships, one of which I saw alongside the Indian one."

A HOSPITAL YACHT.

The turbine yacht *Albion*, 1,700 tons, Captain Thomas Derham, Lieutenant R.N.R., has been generously placed at the disposal of the War Office after being very cleverly converted into a hospital yacht by the owner, Mr. H. Loeffler, R.T.Y.C. The staff consists of Lieutenant-Colonel A. B. Cottell, F.R.C.S.Edin., R.A.M.C. (retired), as Principal Medical Officer, Mr E. P. Scott, M.R.C.S., L.R.C.P., as operator, and Mr. G. A. Lilly, M.R.C.S., L.R.C.P., B.S.Cantab., as physician and anaesthetist. Miss M. S. Ram is acting matron, and Sister C. R. Millar, of the

Q.A.I.M.N.S., and Miss A. McCulloch, Miss F. M. Steel, from the Royal Sussex County Hospital, Brighton, Miss F. N. Hobbs and Miss I. Pope from the Royal Infirmary, Bristol, and Miss G. Penley, private nurse, and Miss M. H. Cottell, British Red Cross Society, act as sisters, and two privates of the R.A.M.C. as ward orderlies. The crew and stewards assist in cleaning the wards and lifting the stretcher cases.

The yacht had previously been accepted by the Admiralty as a hospital yacht, official number 9, and was employed by them from August 19th to September 14th. She was then placed in reserve, and, as the War Office was anxious to obtain her services, she was placed at its disposal. Her accommodation for wounded and sick consists of 26 beds, and she can take up to 30 cases on deck on mattresses if the weather is suitable, as she is fitted with wooden bulwarks, shutters, and fore and aft canvas screens. She is fully equipped for any operation, and has a commodious dispensary.

Her coal capacity enables her to make ten voyages out and back without the dirt, discomfort, and delay of re-coaling, and, owing to the good arrangements, she can disembark her patients and return for more in two hours.

She left Southampton for Boulogne on her first trip on October 16th, and the first wounded were embarked next day—3 officers and 23 men cot cases and 30 on deck. These were straight from a hospital train, and most were severely wounded and needed re-dressing. There were some minor operations, and one amputation of the arm for malignant gangrene. The next batch of wounded was embarked on October 19th, when the yacht carried 9 officers, 19 men, and 4 Germans; these also mostly required re-dressing or change of splints.

On October 21st 13 officers and 27 men, amongst them the Duke of Teck and the Duke of Roxburgh, were embarked from the same port. There were 5 cases which needed an operation requiring general anaesthesia.

On October 24th the yacht carried 26 cot cases and 6 deck cases—the usual gunshot injuries. All the patients carried, with the one exception of the man with malignant gangrene, have been disembarked in much improved condition. The facilities for operating have been more than valuable, and limbs have been saved by timely surgical interference.

All the staff and the crew have worked ungrudgingly and well.

AUSTRALIAN VOLUNTARY HOSPITAL.

Roentgen Ray Work.

Mr. Herschel Harris, M.B., Ch.M., Sydney, sends us some notes on the work of the *x* ray department of the Australian Voluntary Hospital, under the control of Colonel Eames, C.B., which was early in the field. It was first established at St. Nazaire, where the main part of its work was carried on in a large house which had been occupied by a medical man as a private hospital; a large school building alongside was used as an annexe. Two basement rooms in the house were assigned to the *x*-ray department. Electric current was supplied from accumulators. Within twelve hours the hospital, as well as a tent-hospital pitched on a vacant piece of land adjoining the gardens, were practically filled with wounded. Within seven hours after the cases containing the *x*-ray apparatus were delivered it was set up and ready for use, and several patients were immediately radiographed and operated upon. Two ordinary small kitchen tables were procured in the town which could be placed end to end or separated to allow a stretcher to be placed between them. These were very useful, and quite as convenient as most of the elaborate tables; the tube could be employed above or below, as desired.

With an able volunteer assistant, Mr. Harris was able to do much useful work, sometimes as many as thirty cases being rayed in one day. In only seven of the first 200 cases were rifle bullets found. By far the greater number had fragments of shell varying in size from a pin's head to pieces 2 in. square. In most instances the shrapnel had carried into the wound a piece of the garment traversed by it, and this was usually discovered at the subsequent operation for the removal of the foreign body. A large number of fractures came under observation, and in some cases the shrapnel was present amidst the fragments of shattered bone. The comminution in some cases was appalling, and often large pieces of bone had completely disappeared. The shell fragments apparently caused more havoc than other projectiles.

Some most remarkable cases came under observation. One was that of a man who was hit in the right shoulder by a shrapnel bullet which traversed the right lung, diaphragm, liver, and intestine, and was discovered in the pelvis. It was traced for several hours passing along the intestines, and subsequently the patient passed the fragment, and returned home cured. Mr. Thring, of Sydney, intends to report this case fully later on.

One man who was shot in the thigh found the head of the bullet in his trousers, and the casing was subsequently removed from the wound. The femur was frightfully shattered in this case. Nothing in the shape of Dum-Dum bullets has been met with.

Generally a rough localization was satisfactory, for at operation it was usually found that a large sinus led to the foreign body, which could then be detected by sounding with a steel instrument such as a long pair of forceps. The shrapnel bullets—the size of small marbles—were found at variable distances from the entrance wound. Sometimes they appeared to have travelled for some distance along the planes of cellular tissue. Colonel Eames procured a large horse ambulance to carry the *x*-ray apparatus, and Mr. Harris obtained a small dynamo and engine which will enable the hospital to manufacture its own electricity in future. Thus equipped, it will be prepared to work at practically a moment's notice on the field. In most cases radiographs were taken and printed copies made of all cases of interest.

THE BRITISH RED CROSS SOCIETY.

Severe Pressure upon the Organization.

Pressure upon the organization of the British Red Cross Society has been increasingly severe for several days past, and it is felt that the course of affairs has amply justified the policy of paying regard, first and foremost, to the needs of British wounded. To have embarked, during a period when pressure was less great, upon any extensive plans for aiding the French medical organization would have been extremely undesirable as likely to lead to almost insuperable difficulties. Meanwhile good progress has been made by the French army medical department, much better organization prevails, and the work is less in arrear. Six surgeons and twelve dressers have been sent by the British Red Cross Society to Rennes this week to help with the French wounded. This brings the number of surgeons so engaged to at least thirty, but it is expected that from now onwards the French will require less help from the British society. The society claims that there has been no urgent call to which it has not responded. The need of the moment is for dressers, of whom the supply seems scanty.

Work in France.

There are a great number of British wounded at Boulogne, where, in order to cope with the pressure, 100 orderlies, 12 dressers, and other personnel have been sent. The society's very large fleet of motor ambulances is working in and about Boulogne. The first British Red Cross hospital train is now in readiness, and 5 surgeons and 20 nurses have been sent to take charge of it. Two other hospital trains are being prepared. Mr. Graham White has placed a yacht at the disposal of the society for the transport of stores, etc. A hospital ship is also being prepared for service.

Emergency Corps of Surgeons.

The new departure noted last week of sending a body of surgeons and nurses to assist the R.A.M.C. officers in landing the wounded at the ports continues to be most useful. The corps has done good service already at Dover, Folkestone, and Southampton. An additional service is now provided by the society—namely, an emergency corps of surgeons and nurses to assist the staff of any hospital passing through a period of great pressure during the reception of a large number of wounded. The emergency corps, which remains until the patients are satisfactorily settled in the wards, has been able to render most valuable help.

Help for Servia.

Having received, as we noted recently, an appeal for help from Servia, the society this week dispatched six surgeons and twelve orderlies with large stores to that distant battle area. The unit makes the journey in the Admiralty transport *Dongola*, and is detailed to the port of Salonika, whence it will go up country. The leader of the party is Dr. Barrie, who served in the South African war and the Chinese rebellion.

THE HOME HOSPITALS AND THE WAR.

The 2nd Eastern General Hospital, Brighton.

Two more convoys of wounded have been received at the 2nd Eastern General Hospital, the first—numbering about fifty—from Bethune, near Lille, the second—120 in number, and of Belgian nationality—from the coast fighting now going on. The former were only wounded on a Tuesday, but so rapid was their transport that they were admitted to the Brighton Territorial Hospital sixty hours later. Many of the injuries received by those at Bethune were very serious, but those of the Belgians were, in the great majority of instances, not very bad. The following are examples of cases under treatment:

Shrapnel Wound of Back: Injury to Rectum: Paralysis of Bladder.

This man was struck by shrapnel in the lower part of the back on Tuesday. On admission on Friday, sixty hours later, he complained of bad abdominal pain. The lower half of the abdomen was very much distended, and the distension was clearly due to a full bladder. He had not passed water since he was shot, but urine had dribbled from the over-distended organ. A catheter was passed at once and a large amount of water withdrawn. He still had paralysis of the bladder necessitating the regular use of a catheter, but as he has no sign of paralysis of motion or sensation this is probably due to concussion of the bladder centre and not to any injury of the cord. The wound in the back discharges faeces, showing that it communicates with the rectum, which was evidently wounded by the shrapnel bullet.

Amputations for Severe Gunshot Wounds.

Three amputations have been necessary, one of the arm and two of the leg, all for compound fracture of joints. In the first case, notes of which have already appeared in these columns, the subclavian artery had been ligatured for secondary haemorrhage, but in spite of this repeated losses of blood had occurred, so weakening the man that it was clear that nothing short of amputation gave him a chance. He had been advised this some time before but had declined. The arm was removed at the shoulder, and it was found that the joint was completely smashed, the bone being in pieces and freely suppurating. His condition is still extremely grave. This case is a good illustration of the value of the dictum of the old military surgeons: "Always amputate for secondary haemorrhage from a gunshot wound. If the ligature of the main artery is successful in averting haemorrhage, you get gangrene. If you do not get gangrene, you fail to check the bleeding."

The two other cases were very similar. Both men had smashed knee-joints from bullet wounds. In each case attempts had been made to save the limb, but the wounds had become very septic, and the temperature rose in one case to over 105° F. Nothing was left but amputation, which in each case was carried out at about the middle of the thigh. The two men are doing well.

Rifle Bullet Wound of the Head, Neck, and Chest: Death from Secondary Haemorrhage and Exhaustion.

This patient was shot in the nose, the bullet entering at the left hand top corner of that organ, passing downwards through the hard palate, and then down the right side of the neck. On admission he was haggard, worn, and emaciated, and plainly very ill. He had a sloughing wound of the hard and soft palate, dividing them completely, in fact his mouth looked as if he had had a badly performed operation for cleft palate, which had got very septic. He was coughing up large quantities of thick, purulent expectoration, there was slight surgical emphysema of the top of the right side of the chest, and his right arm was more or less paralysed. He said he was unable to swallow anything. He was treated by frequent hydrogen peroxide spraying for the mouth, and fed by getting him to lie on his side, take fluid into the hollow of his mouth, and allowing it to trickle down. This answered admirably, and he soon began to get quite a quantity of food down. He picked up well after a few days. *X* rays located the bullet behind the sterno-clavicular articulation of the right side, just over the innominate artery. There were no abnormal signs in the lung. As he was improving it was decided not to remove the bullet, but to wait and watch the course of events. The paralysis quickly improved, so much so that there could not have been any very serious lesion of the cords of the brachial plexus. On the eighth day after receiving his wounds a large slough separated from the palate and the parts looked quite nicely. In a few hours there was excessive haemorrhage from the palate which ceased spontaneously. This recurred a few hours later, and was arrested by plugging, but he died from exhaustion a few hours later.

The course of the bullet was evidently as follows: It struck the top of the nose obliquely on the left side, passed through the palate a little to the right of the middle line, then down the right side of the neck, concussing the cords of the plexus, and finally lodged in the upper part of the right side of the chest, slightly wounding the apex of the lung in its course.

Multiple Shrapnel Wounds.

One man had as many as twelve wounds on his body, arms, legs, neck, and chest, from a shower of shrapnel. None of them was very serious; the case is mentioned simply on account of the number of injuries.

Compound Fracture of the Femur.

This man was shot through the leg, the bullet striking the femur, and then passing through the thigh, causing a large spiral fracture of the middle of the shaft of the bone. He arrived with his field dressing on, and his rifle and some trenching tools as splints. He was put up with a long Liston splint and extension, and so far seems to be doing fairly well; but unfortunately the bullet wound is septic.

Compound Fracture of Humerus.

This man, a wounded Belgian from the coast, was found to have two septic wounds of the upper arm, and two of the forearm. The humerus was broken in its upper end and also in its lower. The condition of the arm is so bad that probably it will require amputation, though as the man's general condition is quite good, an attempt is being made to save it.

Two Cases of Bullet Wounds of the Lung.

In both these cases the men were shot through the chest, the bullet remaining in the lung. They both had pyrexia, the temperature reaching about 103° F., and both had a good deal of muco-purulent expectoration. It was decided, in view of the great risk of hunting for bullets in the lung, to watch these cases, and see if improvement ensued, before undertaking any operation.

Wound of Genitals.

This man was struck by a bullet which carried off the end of the penis, laid open one side of the scrotum, and then traversed the inner side of the thigh. The whole wound was sloughy on admission, but is now clearing up nicely.

Bullet Wound of the Brain.

This patient was shot by a rifle bullet, which left a compound fracture of the frontal region of the skull, with a septic wound through which the brain was protruding. It was impossible to do much in this case, but some loose pieces of bone and the protruding brain were removed, and the man is doing quite nicely.

The number of operations performed in the theatre so far is 135. In addition, a good many minor operations were undertaken in the wards. The operations include 27 cases of extraction of bullets, 20 for the radical cure of hernia, 6 for haemorrhoids, 4 for varicose veins, 3 for hydrocele, 12 for appendicitis, 3 for loose cartilage in the knee, 11 for removal of tonsils, 4 cases of trephining, 1 of short-circuiting, 1 for mastoid disease, 2 for secondary haemorrhage, 1 of amputation of the arm, 2 of amputation of the leg, 1 of amputation of the finger, 2 of amputation of the toe, 3 for varicocele, 1 for empyema, 4 of perineal section, 1 of excision of the eyeball, and various others. With the exception of one case trephined for bullet wound of the skull, there has been no fatal case following operation.

NOTES.

Church Army War Fund.

An appeal for £20,000 towards his special war fund was made by Prebendary Carlile at a meeting of the Church Army held at the Hampstead Conservatoire on October 22nd. Lady Jellicoe, who presided, said that our sailors and soldiers were hourly facing hardships and perils at the front, and it would be a great support to them to know that those at home were also trying to play their part by doing what they could for the country in its hour of need. She rejoiced to know that the Church Army was responding to the call, for in addition to a war hospital at Caen it had organized recreation tents and church rooms for the troops, and was looking after a great number of Belgian refugees. A letter was read from Millicent Duchess of Sutherland, stating that what was most needed at the present moment was an adequate organization of ambulances and hospitals both at the front and at home. France and Belgium had suffered terribly from inadequate organization, and what had struck her most forcibly whilst with the Germans was their first-class powers in

this direction. She felt sure that the British, who had done nobly so far, would use the necessary method and perseverance to meet the needs that now faced them, and laid stress on the self-sacrifice of the individual and the power of organization of ambulances and hospitals both at home and abroad. The meeting concluded with an interesting address on the hospital work of the Church Army in the north of France. A speaker, who had gone over to Caen only two or three weeks after the establishment of the Church Army hospital in that town, said that he had been amazed at the efficiency and completeness of its arrangements. Everything worked like clockwork. He had been present at the arrival of a batch of some fifty badly wounded men, some of whom had spent two or three days in a hospital train and were on the verge of collapse from pain and exhaustion. In the shortest possible space of time they were comfortably in bed with their wounds dressed, and within a couple of days were as bright and contented as it was possible for them to be. He had been particularly struck by their uncomplaining endurance and by the touching gratitude they showed for all that was done for them; and if he left France with an increased detestation of the horrors of war he had also left it with a tremendous admiration for the brave men who were upholding the national prestige across the Channel.

Motor Ambulances for the Front.

We published last week the announcement of the gift of a motor ambulance by the panel practitioners of London, and of motor ambulances from a fund raised by an appeal by medical men in Oxford. We now have pleasure in mentioning that the same movement is being carried out in other parts of the country.

The Council of the Surrey Branch of the British Medical Association is making an appeal to the profession in the county to subscribe for a motor ambulance. Promises amounting to £200 were very quickly received, and also an offer from a doctor to act as driver. All doctors in Surrey who wish to subscribe to the gift should send their cheques without delay to Mr. Cecil P. Lankester, Honorary Secretary, Surrey Branch, 1, Rectory Place, Guildford.

An appeal, signed by, among others, the President of the Yorkshire Branch of the British Medical Association and the Chairmen of the Local Medical and Panel Committees of the North, East, and West Ridings, has been made to the medical profession in Yorkshire to contribute £1,000 primarily for the object of supplying motor ambulances where they may be needed, but also for other Red Cross and ambulance work designed to lessen the sufferings of those who are fighting the nation's battles.

Field Ambulances (Reserve).

1st East Anglian Field Ambulance (Reserve.)

Captain Francis Ward, R.A.M.C.T., Drill Hall, Woodbridge Road, Ipswich, states that there are three vacancies for officers in the 1st East Anglian Field Ambulance (Reserve). In addition to the usual training, each section is being trained to work as a motor ambulance and cycle section. Only competent medical men possessing motor bicycles need apply.

1st Reserve Welsh Field Ambulance.

Major Howard Jones, 1st Reserve Welsh Field Ambulance (Ebbw Vale), states that there are vacancies in that unit for lieutenants.

Field Ambulance Officers and Civil Practice.

The following correspondence, following on a suggestion of the Dundee Division that medical officers while stationed in Dundee should be permitted to attend to their civil practice when not required for military duty, may be useful to other districts where practitioners have difficulty in accepting commissions in Field Ambulance Reserve units. As the commanding officer is primarily concerned with the efficiency of his unit, it will be well to form a cautious estimate of the amount of time available for civil work.

From the City of Dundee Territorial Force Association,
To Head Quarters, Scottish Command.

October 13th, 1914.

Sir,—I am directed to forward attached correspondence for your favourable consideration and necessary action. The Association is of opinion that medical officers could well attend to their practice while stationed in Dundee, and strongly recommend accordingly.—(Signed) Jno. Vair, Major (Secretary).

[Reply.]

October 14th, 1914.

I see no reason why the medical officers who join the reserve unit of the 3rd Highland Field Ambulance (T.F.) should withdraw from all civil practice. The medical needs of the civil population must be attended to. When not required for duty they can attend to their civil duties.—(Signed) G. O. Bourke, Surgeon-General, D.D.M.S. Scottish Command.

[FROM OUR SPECIAL CORRESPONDENTS.]

MANCHESTER AND SALFORD.

The Insurance Act: Medical Benefit.

In April last the Manchester Insurance Committee appointed a special subcommittee to inquire into the working of the Manchester system of medical benefit. It will be remembered that under the Manchester system the panel doctors receive payment from the pooled sums available for medical benefit in proportion to the number of attendances actually rendered, and the Panel Committee holds itself responsible for the efficient treatment of the insured. During last year and the earlier part of the present year there were numerous complaints that the Manchester system lent itself to a number of abuses which were less liable to occur under the capitation system, the principal charges being that, in order to raise the number of their visits and consultations, the panel doctors encouraged patients to remain on sick list longer than was necessary, giving certificates for sickness benefit without sufficiently strict examination, and prescribing so lavishly that the drug fund was not adequate to meet the chemists' bills.

Mr. W. Davies, Chairman of the Insurance Committee, was elected chairman of the committee of inquiry, and, after holding seventeen meetings and hearing a number of witnesses, the committee has now issued its report. The committee expresses regret that in spite of the number of complaints which had been made by approved societies, more witnesses representative of the societies had not offered to give evidence, but from the material at its disposal the committee concludes that the allegations of slipshod diagnosis owing to large practices induced by the system were "practically unsubstantiated." It believes that in the earlier months, soon after medical benefit commenced, the antagonistic attitude of the doctors towards the approved societies and the absence of checks on over-attendance had led to lax certification and excessive sickness claims, but for some time past now these abuses have been diminishing, and are likely still further to diminish in the future. The committee expresses the hope that there is no ground for the complaint that insurance patients are treated differently from private patients, as it would view with marked disapproval any invidious distinction of patients or differentiation of treatment. On the whole, the committee believes that the Manchester system provides an adequate medical service, and that insured persons receive adequate attendance and treatment, that the system is more satisfactory than the capitation system to the insured, and, owing to the greater

influence of the Local Medical and Panel Committees, can be made more advantageous to approved societies. It is also of opinion that the establishment of a whole-time or salaried service is not at present practicable, though the appointment of a few whole-time officers with the requisite facilities for specialized treatment would improve the present system.

The report was presented to the Insurance Committee at a special meeting held on October 20th, and after some discussion an amendment was proposed recommending the adoption of a whole-time salaried service. This, however, received but little support and it was eventually resolved to recommend the continuance of the present system for the year 1915, the resolution expressing the opinion that insured persons under this system are receiving adequate medical treatment.

At the monthly meeting of the Salford Insurance Committee it was stated that the Salford committee of enquiry on the lines of the Manchester Committee was not yet prepared with any report, but it was understood that there had been the same difficulty as in Manchester, as very few of the approved societies which were loud in their complaints some months ago had seen fit to offer any evidence on which a reliable judgement one way or the other could be based.

With regard to the dispute between the Salford Panel and Pharmaceutical Committees about the charges of over-prescribing against about sixteen of the panel practitioners, the Insurance Committee expressed its regret that it had not up to then received any official report since the matter was referred back to these two committees, though it is pretty well understood that the two committees have not been able to arrive at any agreement.

The Manchester University and the Belgian Refugees.

The Senate of the Manchester University has recently sent through the Belgian authorities an address of sympathy to the University of Louvain. The address, which was in Latin and English, reminds the University of Louvain that three years ago the Manchester University had congratulated it on the seventieth anniversary of its second foundation, and though at this moment the enemy is still trampling on the ruins of its buildings, the time is not far off when they will pay the penalty which they have incurred. After complimentary reference to the past history of the Louvain university, the address proceeds to say that "if you, our colleagues of Louvain, or other teachers also banished from Belgium, will come with your families and accept the hospitality which we are proud to offer, be sure that we shall count it an honour." In order to carry out in a practical manner this offer, a meeting of members of the senate has been held, and a "Manchester University Committee" was constituted for the purpose of receiving Belgian professors and teachers. Mrs. Weiss, wife of the Vice-Chancellor, was appointed chairman, with Professor Conway, chairman of the executive committee, Mr. E. Fiddes, treasurer, and Professor Unwin and Mrs. Lapworth, honorary secretaries. In addition to the Vice-Chancellor, Professor Weiss, a large number of the university professors are members of the committee, which hopes to work in friendly co-operation with the general Manchester and London committees. Its immediate object is to find out those of the exiles who would like private hospitality and to secure it for them as guests, and secondly to fit up a house or houses for those who wish to live together, and to make reasonable provision for their needs. The secretaries of the committee will be pleased to hear from any Belgian exiles who belong to the teaching profession.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

Presentation to Dr. William Bartley.

Last week, in the Temperance Hall, Ballybay, Dr. Bartley met a committee representative of his friends in the neighbourhood, and received an expression of good will on the occasion of his marriage, accompanied by a canteen case, silver salver, an illuminated address, and a cheque. The Chairman bore testimony to the regard and esteem in which Dr. Bartley was held by the whole community. Dr. Bartley made a suitable reply, in which he referred to the invariable kindness he had received from the people of Ballybay and surrounding districts.

Royal College of Physicians.

Dr. E. MacDowel Cosgrave, who has just been elected President of the College of Physicians, has been a Fellow of the College since 1887. He graduated M.B., Ch.B.Dubl. in 1876, and M.D. in 1878. For many years past he has been Professor of Biology in the Royal College of Surgeons in Ireland. He is the author of the St. John Ambulance textbook, *Hints and Helps for Home Nursing and Hygiene*.

Vaccination.

At the last weekly meeting of the board of guardians of the South Dublin Union the following letter was read from the Secretary of the Local Government Board:

> I am directed by the Local Government Board for Ireland to state that the board of guardians should at the present juncture pay special attention to the carrying out of vaccination in their union, so as to be in a condition of preparedness to meet an epidemic of small-pox should that disease unfortunately be conveyed to this country. The Board are of opinion that there is now a very real and imminent danger of an outbreak of the disease, and they have to inform the guardians that the outbreak which followed the Franco Prussian war of 1870 was not only of practically world-wide diffusion, but was also of marked intensity and malignity. Successful infant vaccination and successful revaccination are the precautionary measures that can be taken to guard against a visitation of the disease, and the guardians are the authority in each union entrusted by Parliament with the duty of promoting the vaccination of the people.

It was proposed and seconded:

> That the provisions of the Vaccination Acts, revaccination and the importance of revaccination, be put into force without further delay, and that the relieving officers be instructed to prosecute in every case of neglect to carry out same.

One member of the board mentioned that both her parents had died during the epidemic which followed the Franco-Prussian war because they had not been revaccinated. The resolution was carried on a division by 21 votes to 12. A notice of motion was handed in to rescind the resolution.

India.

[FROM OUR SPECIAL CORRESPONDENT.]

Bengal Council of Medical Registration.

The *Calcutta Gazette* of September 23rd notifies the appointments made by the Bengal Government to the newly constituted Bengal Council of Medical Registration as follows:

President: Surgeon-General G. F. A. Harris, Inspector-General of Civil Hospitals, Bengal. *Members:* Lieutenant-Colonel W. J. Buchanan, C.I.E., Inspector-General of Prisons, Bengal; Lieutenant-Colonel E. A. R. Newman, Civil Surgeon, 24th Parganas; Lieutenant-Colonel F. O'Kinealy, Surgeon-Superintendent, Presidency European General Hospital; Lieutenant-Colonel J. T. Calvert, Principal and Professor of Medicine, Medical College, Calcutta, and first physician, Medical College Hospital; Lieutenant-Colonel C. R. Stevens, Professor of Clinical and Operative Surgery, Medical College, and surgeon to the College Hospital; Major D. McCay, Professor of Physiology, Medical College; and Rai Upendra Nath Brahmachari, Bahadur, Teacher of Medicine, Campbell Medical School, Calcutta. All except the last named, who is a member of the Provincial Medical Service, are officers of the Indian Medical Service. The names of the elected members of the council are not given; presumably they have not yet been chosen.

The Health of the Punjab.

The report of the Sanitary Commissioner of the Punjab for 1913 shows a rising birth-rate, but not, unfortunately, a falling death-rate. All the same, there were three births for every two deaths, but the rate of infant mortality was very high—about 230 per 1,000 births. This waste of life is receiving serious attention, but it is mainly a question of education—education of midwives, education of mothers in the principles of hygiene, and education of the public

at large, so that prejudices may be removed. The rural death-rate still remains considerably below the urban, but it is noteworthy that the urban rate has fallen markedly in the last decade or so, and there seems justification for the conclusion that improved drainage and water supply, better facilities for medical advice and treatment, and growing enlightenment and knowledge of hygienic principles have had something to do with the result. It is not possible to assume that the last named factor has yet become a very powerful agent for good when we learn that efforts to combat a cholera epidemic were impeded by the opposition of the people, especially in the towns: that vaccination, even where compulsory, is not vigorously enforced; that plague preventive measures are rarely acceptable, except in time of severe epidemic. Progress has, however, been made in recent years, and with the larger financial grants that are now possible, and the development of organized programmes of work, it is hoped that the spread of enlightenment will be more rapid in the future than in the past. The Lieutenant-Governor, in his remarks on the report, emphasizes the fact that the sanitation of a town or village does not depend merely on improved drainage and purer water, and by efficient conservancy and scavenging; the voluntary co-operation of the people themselves is essential for any radical improvement in the health of the province.

Correspondence.

TREATMENT OF TORTICOLLIS.

Sir,—In your issue of October 17th, 1914, Mr. Paul Bernard Roth, writing on the subject of scarring after the open operation for section of the sterno-mastoid just above the clavicle, says, "a writer on this subject makes light of the annoyance of a resulting scar, and then describes a new incision of his own for avoiding it." It was only when I referred to the list of references at the foot of the article that I discovered the writer was myself. If Mr. Roth will refer to *Deformities*, second edition, vol. i, pp. 69 and 70, he will find that so far from making light of scarring after the horizontal incision, I said:

> As the patient grows, the cicatrix grows too; so that what is quite a small mark in the child is considerable in the adult, and keloid is apt further to complicate matters. The broadening of the horizontal scar made in childhood is often very extensive, owing to the pull on the parts, especially in carrying out manipulations, and the suture-scars are very prominent.

The second remark made by Mr. Paul Bernard Roth, to which I wish to refer, is as follows: "and then he [the writer] describes a new incision of his own for avoiding it. Probably, when the new incision has been tested by time, the resulting scar will be as bad as ever." On the subject of this oblique incision I have remarked in the same work that "prolonged observation of a scar (following the oblique incision) shows that it becomes a thin line and does not widen." The word "prolonged" here refers to cases which have been seen as long as ten years after the operation.

It is a pity that Mr. Paul Bernard Roth, if he desired to criticize my writings, should not have put my name in the body of his article; and further, that he should have not only failed to follow the text in *Deformities*, but also have suppressed my statements on the subject at issue.—I am, etc.,

London, W., Oct. 21st. A. H. TUBBY.

RHEUMATOID ARTHRITIS.

SIR,—I have read Dr. Durward Brown's article on rheumatoid arthritis in the BRITISH MEDICAL JOURNAL, October 17th, 1914, p. 666. I am delighted to find that he has adopted the methods of treatment Drs. P. W. Latham, R. Jones Llewellyn, and I, as well as many others, have advocated for many years. I refer particularly to blisters near the cervical and lumbar enlargements of the spinal cord and the administration internally of thyroid extract. These are very powerful remedies and as their action is general and not specific they may be used in other ailments as well.

Dr. Brown, I notice, put blisters on the dorsal region, but says nothing about the cervical. I am of opinion that it is most important to treat the cervical region before the lumbar.

He very justly asks why separate infection and affection of the spinal cord when the one is the result of the other? I am most strongly of opinion that there can be no degeneration of the cord apart from infection. Even when traumatism is a factor germs attack the weak spot. Also that in all cases of arthritis there is some degeneration of the spinal cord. Slight in some cases I admit, but enough to be a factor.

He asks why one should blister when one can ionize. One cannot always ionize because one may not possess the necessary apparatus. Then there is the exudation that results from blistering. This is a most important point, the value of which few seem to realize. Also the hyperaemia produced by blistering is greater than of ionization, unless the latter is pushed to the point of burning the skin. I am quite sure that if Dr. Brown will persevere with spinal counter-irritation and the administration of thyroid extract he will find he has stolen a long march on those medical men who do not use them.—I am, etc.,

Bournemouth, Oct. 24th. W. J. MIDELTON.

Medico-Legal.

THE SALVARSAN PATENTS.

FURTHER proceedings have taken place at the Patent Office, London, with reference to applications to avoid or suspend the German patents in respect of salvarsan, under legislation passed on the outbreak of the war. We noted in the JOURNAL of September 26th, p. 558, an application by Messrs. Burroughs, Wellcome, and Co., for the suspension of the salvarsan patents in their favour, and the request has since been granted.

On October 12th Mr. Ellis applied, on behalf of Messrs. Bresillon and Co., for the suspension of the patents in their favour. It was explained that the firm obtained its supplies from Paris, where a considerable quantity was made at two separate laboratories, and could be obtained immediately permission was given to import. Messrs. Bresillon would agree to the payment of royalty out of the net profits on a basis fixed by the Board of Trade. It was not desired to use the name salvarsan or neo-salvarsan, but to sell the product under the names "ampsalis" and "soupsalis." Supplies could be provided at the price at which salvarsan was sold before the war. The two French makers were well-known firms, and their names would be a guarantee of proper manufacture.

In reply to the Comptroller (Mr. W. Temple Franks), Mr. Ellis said the product could be tested in this country from a sample of a quantity imported.

The Comptroller: We were told that the product was tested by Ehrlich as a security of safety.

Mr. Ellis: We should be prepared to submit the samples to any test to which salvarsan is subjected in this country. He added that he was not clear whether, as it was desired to sell a product made outside the United Kingdom, the application could be entertained.

The Comptroller replied that it was not an absolute bar in this case, because, although it was desired to encourage trade in this country, it might be necessary to secure supplies from anywhere.

Mr. Gray, K.C., on behalf of Messrs. Meister, Lucins and Bruning, the holders of the salvarsan patents, submitted that there was no evidence that the Paris firm was competent to manufacture. The law required that applicants should themselves manufacture the patented article. A licence to import would prevent the substance being made in this country. On the question of price, he remarked that the infringer of a patent was always able to make a cheaper product, as he was not saddled with the heavy initial expenses of invention.

In reply to the Comptroller, who remarked that in the public interest it was hardly desirable that the manufacture should be in the hands of monopolists who might fix any price they pleased, Mr. Gray said that the present price was not excessive; there had been no increase since the war.

On October 23rd the proceedings were continued, when Messrs. Poulenc Frères, of Paris, made application for the suspension of the patents in their favour. Mr. Potts (of Messrs. W. P. Thompson and Co., patent agents of Liverpool), who appeared on their behalf, stated that the firm were French manufacturing chemists of repute. As a patent for a pharmaceutical product was not granted under French law Messrs. Poulenc Frères had been engaged in the manufacture of salvarsan since its discovery and claimed to have made various improvements in the mode of preparation. The firm supplied the Paris hospitals, L'Institut Pasteur, and the Ministry for War and Marine, as well as many provincial hospitals. The preparation was known in France as "dioxyarseno-benzene." Extracts were read from several French medical journals, purporting to show that the preparation had a toxicity exactly equal to that of salvarsan, while its therapeutic value was even superior. The plant at Messrs. Poulenc Frères had a large output, and the quantity could be doubled if necessary. At the final stage the preparation was only

worked up in very small quantities and a sample sufficient for a dose for a human being was injected intravenously into a rabbit. If the rabbit did not live forty-eight hours the whole sample was rejected. The firm was ready to submit the product to any further test.

In reply to the Comptroller, who remarked that the fact that the firm did not propose to manufacture in this country created a difficulty, Mr. Potts said it was proposed to manufacture here when times were quieter. Every consignment passed at one important stage through the hands of one man, so that at present it was more satisfactory to manufacture in one place.

Letters were read and evidence was called to show that there was a shortage of salvarsan in this country and that the price had risen considerably.

In reply to the Comptroller, Mr. Potts said Messrs. Poulenc Frères would be prepared to pay a reasonable royalty. He urged that the licence should be for the whole length of the patent. Messrs. Poulenc Frères's alternative process of manufacture would be a good ground for a compulsory licence for the whole term of the patent. They asked for a licence to sell in this country and to manufacture here later.

Mr. Gray, on behalf of Messrs. Meister, Lucius, and Bruning, said that the firm was prepared to supply salvarsan in sufficient quantity, but if the Board of Trade was in any doubt as to whether the firm was in a position to do, it was not for him to say that some one else should not be given permission to manufacture. Enormous harm might be done by having an impure supply of the preparation or by having variations in dosage. A licence to manufacture abroad must be determined at the end of the war, otherwise the rights of the patentees would be unfairly affected. He asked that, in view of the merits of the invention, the royalties should be made as high as possible. He could not see why Messrs. Bresillon and Co. wanted a licence when they proposed to buy from Messrs. Poulenc Frères.

Mr Ellis intimated that if Messrs. Poulenc Frères obtained a licence Messrs. Bresillon would withdraw their application.

Mr. Potts said his clients were prepared to sell at the price obtaining before the war—namely, 10s. a dose, and to pay a royalty at the rate of 10 per cent.

The Comptroller thought that the product should be submitted to a test in this country, and, Mr. Potts agreeing, the Comptroller remarked that perhaps arrangements could be made with a public body.

The court stated that it would make a recommendation to the Board of Trade.

HYOSCINE AND MENTAL HEALING.

Mr. Justice Rowlatt, in sentencing Orland Edgar Miller, a lecturer on "higher thought" and "faith healing," sometimes erroneously described as a Christian Scientist, to three months' imprisonment in the second division, said, according to the report in the *Times*: "This conviction, in my judgement, is a very important one, because it shows, and I hope it will show to all others who, with no knowledge or with a little knowledge which is more dangerous than complete ignorance, undertake to deal with dangerous poisons, that in spite of the rhetoric which may be brought to bear on these occasions and all the tall talk about other cures and a wonderful system of mental treatment and the unity of the infinite and all that sort of stuff, when a British jury finds that people have been subjected to the influence of deadly poisons by incompetent people it will go straight to the business mark and say it is manslaughter." The medical evidence in the case was to the effect that death was due to paralysis of the stomach set up by the administration of hyoscine (British Medical Journal, July 18th, p. 156, and October 3rd, 1914, p. 697). The defendant called a number of witnesses to testify to the efficacy of the treatment; several former patients stated that they were cured of consumption and tuberculosis by it.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

The following degrees have been conferred:

M.D.—R. F. Higgin.

M.B., B.C.—L. E. S. Sharp, C. G. H. Moore.

The following candidates have passed in the examination indicated:

D.P.H. (*Both Parts*).—E. Bach, J. L. Bocarro, J. M. Davidson, L. L. Fyfe, H. D. Gimi, I. J. Khaw Oo Kek, J. McC. Laug, R. C. Malhotra, B. P. Mozoomdar, *W. H. Peacock, R. N. Roy, †A. G. G. Thompson.

* Distinguished in the practical application of Sanitary Science and Pathology. † Distinguished in Bacteriology.

UNIVERSITY OF GLASGOW.

The following candidates have been approved at the examinations indicated:

Final.—*A. D. Brown, *D. MacC. Blair, *D. C. Bowie, *A. M. Davidson, J. Donald, *A. G. Letters, *W. B. M'Queen, *A. W. M'Rorie, *A. S. Strachan, Lydia I. H. Torrance, *W. G. W. Harrison, *J. G. Harrower, M. Hyman, Alice M'Glashan, *J. Stewart, J. S. Young, A. F. M'Millan, N. Morris, *J. C. Knox, *J. M. Maffin, *W. P. Shanks, *J. S. Martin, *W. Adams, *H. Stuart, F. C. Logan.

* Passed with distinction in one or more subjects.

† Under old and new regulations.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH. At a meeting of the College held on October 21st Mr. J. W. B. Hodsdon was elected President for the ensuing year. Mr. Hodsdon has been a member of Council and the Representative of the College on the General Medical Council for a number of years.

The following gentlemen having passed the requisite examinations were admitted Fellows:

T. S. Allen, A. J. Ballantine, N. H. Bolton, H. H. Davis, H. E. K. Fretz, W. G. Goudie, D. L. Graham, J. D. Gunn, D. J. Guthrie, A. J. G. Hunter, J. B. D. Hunter, F. G. Lloyd R. M. Manwaring-White F. L. Nash-Wortham, J. W. Pell, G. A. Platt, E. L. Reid, J. W. Richardson, S. J. Simpson, L. J. Thompson, D. B. Walshe, R. E. Walker, and W. Q. Wood.

Obituary.

Dr. William Haldane, of Bridge of Allan, Stirlingshire, who has recently died, was born at that place in 1847. He received his school education in Stirling, and then proceeded to the University of Edinburgh, later migrating to Glasgow, where he graduated M.B. and C.M. in 1872. Afterwards he held the office of resident physician in the Glasgow Royal Infirmary under Sir Thomas M'Call Anderson, and was subsequently assistant to the Professor of Clinical Medicine in that university. He was also house-surgeon to the Glasgow Lock Hospital. Becoming M.D. in 1876, he was admitted to the Fellowship of the Faculty of Physicians and Surgeons of Glasgow in the same year. He became a Member of the Royal College of Edinburgh in 1894, and a Fellow in the following year. Dr. Haldane commenced practice in Braemar, where he enjoyed the confidence of the late King Edward VII, then Prince of Wales. More than thirty-five years ago he returned to his native place, where he soon got a large practice. He was Vice-President of the British Balneological and Climatological Society. In Bridge of Allan he took a great interest in local affairs. He was a J.P. for the county of Stirling, and was for many years chairman of the school board, of the water company, and other public bodies. He acted as surgeon-major in the volunteers. He was the author of a paper on Bridge of Allan as a health resort which appeared in the *Scottish Medical Journal* in 1893, and of other contributions to medical journals. Dr. Haldane was held in the highest esteem both by the public among whom he worked and by his professional brethren. He leaves a widow and family.

The death of Archibald Mitchell, M.B., C.M.Edin., on October 18th, at the early age of 42, has caused profound sorrow to his brother practitioners and many friends. A slight attack of influenza paved the way for acute lobar pneumonia, which caused his death. During the thirteen years in which he was in practice in Ilford he upheld the best traditions of the profession. Without being brilliant in any particular branch of medicine he combined sound knowledge and well-balanced judgement, which made his opinion much valued by his fellow practitioners. A truly charming character, his Scottish upbringing perhaps helped Nature to endow him with the absolute unselfishness which characterized him. No petty or personal motives ever influenced his judgements. During the unhappy weeks preceding the launching of the Insurance Act this singleness of purpose and devotion to others had full scope and won the gratitude and respect of all the medical men in the district. With these characteristics he combined a charm of manner, a quiet humour, and a keen interest in things outside his profession which made him beloved by his friends. His work was always thorough. The Ilford Emergency Hospital owes him much, as also does the Ilford Scottish Association. The profession in Ilford is poorer for his death.

Lieutenant-Colonel Andrew Arthur Macrobin, R.A.M.C. (retired), died at Kensington on October 14th, and was buried at Kensington Cemetery, Hanwell, on October 17th. He was educated at Aberdeen, where he graduated M.B. and C.M. in 1866, and entered the army as assistant-surgeon on March 31st, 1863. In March 1873 he became surgeon, in 1880 surgeon-major, and in 1888 attained the rank of lieutenant-colonel, retiring on April 13th, 1898. He served in the Franco-German war of

1870-71, in a British ambulance with the German armies, and received the German steel war medal. He served also in the Ashanti war of 1874, when he was present in the battles of Amoaful and Ordahsu, and at the capture of Kumasi, receiving the medal and clasp.

Medical News.

OWING to the necessary curtailment of the number of pages in the weekly issues of the BRITISH MEDICAL JOURNAL and SUPPLEMENT, all correspondents are particularly requested to write as succinctly as possible.

WE are asked to state that thermogene is not a German product. It was invented by a Belgian chemist, Mr. Charles Vanderbroeck of Brussels, and was acquired fourteen years ago by the present proprietors. It is entirely British owned, and British made by British labour at the company's factories in Sussex.

OWING to the war, it has been decided to postpone the dinner of the London (Royal Free Hospital) School of Medicine for Women usually held on the second Wednesday in December.

A MEETING in aid of the Army and Navy Male Nurses' Association will be held by the kind permission of Mr. and Mrs. Donald Armour at 89, Harley Street, on Wednesday next at 3 p.m.

SIR W. WATSON CHEYNE, President of the Royal College of Surgeons, will open a discussion on Surgical Experiences of the Present War, at the meeting of the Medical Society of London on Monday, November 16th. The paper by Mr. Austen, announced to be read on that day, has been postponed owing to his absence on active service.

THE Bradshaw Lecture before the Royal College of Physicians of London will be delivered by Dr. Nestor Tirard on November 3rd, and will consist of clinical contributions to the study of glycosuria. The FitzPatrick Lectures, on leper houses and mediaeval hospitals, will be delivered by Dr. C. A. Mercier on November 5th and 10th.

THE Master of Christ's College, Cambridge, states that the University is taking in Belgian students from all Belgian universities, and a committee is endeavouring to organize systematic teaching in French and Flemish, and also hospitality. There are already some fifty students and more than twenty professors in residence. Though the resources of the committee are limited, no student need be kept away by want of means. The Master of Magdalen states that there are a number of Belgian professors at Oxford, including nine from Louvain, that a Belgian Students' Committee has been formed, and that it is intended to give facilities to professors and students for free admission to University institutions and lectures.

IN consequence of the war the Council Club of the Royal College of Surgeons decided not to hold its usual dinner this quarter, but sent instead a cheque for 30 guineas as a contribution to the Royal Medical Benevolent Fund. Many dinners and festivals of the kind will be abandoned, and it is hoped that as far as the medical profession is concerned this generous and thoughtful example will be followed. The medical profession will certainly be hit hard by the war in many ways, and already special demands upon the Fund are being made, of which the following is but one example: A young doctor, only seven years in practice, volunteered. He was killed in the field within the first week of the war, and has left a widow and two children in great temporary distress.

WE are informed that a special exhibition of objects and relics associated with naval and military surgery, nursing and ambulance is being arranged at the Wellcome Historical Medical Museum in Wigmore Street. The collection will include miniatures, portraits, prints, autograph letters, commissions, and relics of famous naval and military surgeons, surgical instruments and appliances used in naval and military surgery in bygone times, and medical and surgical chests, cases and cabinets used in war time. Pictures, prints, and drawings of field ambulance work, military hospitals, appliances, and equipments will also be on view. The curator will be glad to hear from medical practitioners who may be willing to lend relics, instruments, or objects of a similar character. Any objects lent will be treated with the greatest care, and insured against loss or damage. Particulars and descriptions of loans should be addressed to the curator, the Wellcome Historical Medical Museum, 54A, Wigmore Street, London, W.

Letters, Notes, and Answers.

☞ *Queries, answers, and communications relating to subjects to which special departments of the* BRITISH MEDICAL JOURNAL *are devoted will be found under their respective headings.*

QUERIES.

J. A. asks for advice in the treatment of a woman, aged 38, whose fifth child is 12 months old. Six months ago oedema of the legs came on suddenly and has increased since in spite of treatment by, among other substances, suprarenin, thyroid extract, hexamethylene, pituitary extract, digitalis, diuretics, and an autogenous vaccine. It now invades the buttocks and there is ascites. The heart sounds are feeble. The urine (2½ pints in twenty-four hours) is strongly alkaline and contains 1.7 per cent. of albumin (serum albumin and serum globulin) associated with large quantities of basic sodium phosphate and calcium carbonate; no sugar; urea 2 per cent. Cultures of urine show the presence of staphylococci and *Bacillus coli*. There are no casts.

ANSWERS.

T. J.—Under the agreement our correspondent is precluded from all professional practice within the borough. In the circumstances, however, it is improbable that his late partner, if approached on the subject, would refuse him permission to act as honorary surgeon to the hospital for Belgian refugees.

LETTERS, NOTES, ETC.

SURSUM CORDA.

To Those who guide the destinies of Earth
Let us give thanks and praise to-day
That on this realm we love They have imposed
A task tremendous and sublime.

O royal privilege, immortal boon
To hazard all upon the faith we share.
Secure of honour, doubtful all beside,
To give ourselves, our lovers or our sons
For England, Belgium, France, the World!

What have we done to merit this award?
It seemed that we had lost our ancient might,
Our ancient manhood, lapped in Plenty's bower.
But we were not abandoned by the Gods,
All things conspired to prove us delicate,
Britannia's brow predestined to achieve
This crown of anguish and of chivalry.

If we must fall, how otherwise than thus
Would we have chosen that our sun should set?
What prouder pageantry of doom than this
That fills the world with flame could heart desire

Only we shall not fall, we shall prevail,
Marching with our allies to victory,
Trampling the fierce aggressors underfoot,
Sweeping their stealthy commerce from the seas,
Aye and their battleships, presumptuous grown
Since all too long their menace we endured.

We must prevail, however huge the cost
In maimed and mangled bodies, broken hearts.
Demolished shrines, burnt homesteads, ravaged fields.
These are the currency of warfare. See!
Invisible Watchers tier on tier arrayed
Hang on the issue, knowing here at stake
The priceless gains of toilsome centuries
In all that lifts us nearer to Themselves.

Hail hallowed Sword, ploughshare of Destiny!
Without thee nothing prospers long on earth,
Nor can our heaven-aspiring dreams take root
Until the blood of heroes waters them.
Therefore we know that when the war-clouds lift,
Out of the carnage, wreckage, wrath, despair
The soul of Man shall rise with strength renewed
To assail the ramparts of Divinity.

CHARLES J. WHITBY (Bath).

SOME OBSERVATIONS ON THE SIGNIFICANCE OF BLOOD-PRESSURE READINGS IN MAN.

BY

J. A. MacWILLIAM, M.D.,

PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF ABERDEEN;

AND

G. SPENCER MELVIN, M.D.,

LECTURER ON EXPERIMENTAL PHYSIOLOGY, UNIVERSITY OF ABERDEEN.

(From the Physiological Laboratory.)

Different opinions are held as regards the practical value of blood-pressure estimations in elucidating the actual conditions of the circulation. It may be stated with confidence that a single estimation of systolic or obliteration pressure, using the first reading obtained, is in some cases open to serious fallacy—apart altogether from psychical disturbances, etc.—even as an estimate of the maximum (systolic) pressure obtaining at that time in the artery under examination.

In former communications we urged the importance of using *continued* local pressure as an aid to correct estimation of the systolic pressure in certain abnormal conditions of the arterial system, an addition to the usual method.[4 5]

But the systolic pressure, even if accurately gauged, gives very insufficient evidence as to what is going on in the circulation. For example, in cases of complete heart-block, where very high systolic readings may be obtained, the mean blood pressure is low and the blood flow is very defective, as shown in various ways, including manifestations of cerebral disturbance from cerebral anaemia, etc. Here the systolic estimation would fallaciously rate the "blood pressure" as being above normal. Again, in cases of slow cardiac failure the systolic pressure may be about the normal level, while the circulation is very inadequately carried on, as evidenced by obvious signs (cyanosis, dyspnoea, etc.).

Diastolic Pressure.

The importance of estimating the minimal or diastolic pressure is now becoming more generally recognized, and with the easy applicability of the auditory method there is no difficulty in the way of its routine use.

Apart from the influence of aortic diastolic pressure in determining (*a*) the strain upon the closed aortic valves, and (*b*) the resistance to the opening of these valves by the ventricular systole, the distending force of load which it imposes on the arterial tube is of prime importance. The properties of the arterial wall are such as to show relatively great effects from long-continued tension as compared with the transient application of distending force, as in the brief rises of pressure that constitute the systolic waves. Experiments upon excised surviving arteries demonstrate very strikingly the different degrees of yielding of the vascular wall in the two cases, especially in a tonically contracted artery.[3]

As long as the diastolic pressure remains low, even with very high systolic readings, the tendency to the giving way of vessels (cerebral haemorrhage, etc.) seems to be relatively slight—for example, in aortic regurgitation.

The greater proneness of the leg arteries to degeneration is especially associated, in all probability, with the high diastolic pressure in the erect position, rather than with the concomitant increase in the systolic level, which is also induced by the influence of gravity.

The evidence available at present is insufficient to show in what measure the injurious effects of an excessive diastolic pressure are to be attributed (*a*) to the influence of mechanical strain upon the tissue elements of the arterial wall, and (*b*) to the influence of a high distending pressure on the flow of blood and lymph in the walls of the arterial tube.

Much requires to be done to elucidate the relations of increased or diminished expansion, depending either on alterations in the tone of the arterial muscle or in variations in the intra-arterial pressure, on the blood flow in the capillaries of the vasa vasorum and on the lymph flow; also the relations of hypermyotrophy and atrophy of the media and hypertrophy of the intima to the intra-arterial pressure, as well as to the various toxic influences that are known to affect the nutrition of the vessels.

Is hypermyotrophy a response to increased internal pressure, comparable with some forms of cardiac hypertrophy developed in certain conditions? Is the diastolic pressure the one that is of primary importance in this connexion?

In regard to various conditions which may exercise a special influence on the diastolic pressure, variations in peripheral resistance are most important, a low diastolic pressure naturally resulting from defective peripheral resistance, and vice versa, unless the heart action is much altered. Apart from alteration in peripheral resistance, quickening of the heart rate *tends* to raise the diastolic pressure by diminishing the time for outflow through the periphery between the pulse beats, and the converse holds with a slowed heart; that is, the diastolic pressure is lowered, with an increase in the range between the systolic and diastolic levels (pulse pressure). It must not, however, be assumed that a slow pulse rate is necessarily associated with a low diastolic pressure. Compensating adjustment in the vascular mechanism often keeps the diastolic pressure quite up to a normal or even heightened level with a slow heart beat, in spite of the lowering tendency of the latter. And the diastolic pressure may be very low with a very quick heart beat, for example, with very defective peripheral resistance, lessened inflow into the heart, etc.

In doing blood-pressure estimations we find it desirable to determine the diastolic index while the armlet pressure is being raised; in some (rare) cases where arm compression leads to a marked rise of blood pressure, the diastolic reading taken with a rising armlet pressure may differ from that obtained during the lowering of the armlet pressure (after determining the systolic index) by as much as 20 mm. This was especially the case when simultaneous estimations were made in the two arms. But a decided effect was sometimes observed when only one arm was tested. Comparison of the diastolic values with rising and falling armlet pressures may thus give important indications of the liability of the arterial pressure to vary in an abnormal way, when a large artery is closed, as in the process of systolic estimation.

As regards the impressions derived from *digital* examination of the pulse, we have found the impression gained as to (*a*) the tension in the vessel within the beats (diastolic pressure), and (*b*) the extent of the change at systole (pulse pressure) to be specially fallacious in some cases—apparently more deceptive than the impression as to the compressibility of the pulse (systolic pressure). An enormous pulse pressure (for example, 120 mm. in a case of aortic regurgitation) may be present, as shown by measurement of the systolic and diastolic pressures, when the finger fails to give any adequate conception of such a pressure wave along the artery. And the measured diastolic pressure may be very high when the impression given by digital examination is that it is rather low.

Some Points in Relation to the Auditory Method.

In former papers we urged the importance of the auditory (auscultatory) method as a simple and accurate means of estimating the diastolic or minimum pressure as well as the systolic or maximum pressure, and our further experience of this method has entirely borne out all that we have said in this connexion.[6] It is clear that if the study of blood pressure is to be successfully applied to elucidate the circulatory conditions in man in health and disease, the examination must include routine estimation of systolic and diastolic pressures with computation of the pulse pressure; such estimation by the auditory method is easy and expeditious, and must replace the very inadequate procedure of systolic estimation alone, as well as the use of the oscillatory method for diastolic estimation.

The term "diastolic" pressure is used in the same sense as "minimum" pressure, to indicate the pressure at the deepest part of the trough between the systolic waves. Of course the arterial pressure varies much at different phases of the period of cardiac diastole, so that there are different levels of pressure at different points in the diastolic interval. The same applies to the period of systole. But, as by common consent the term "systolic pressure" is applied to the highest level resulting from

the cardiac systole, so the term "diastolic" pressure designates the lowest point to which the pressure falls between the pulse-beats.

In regard to the *rationale* of the auditory method to the recognition of systolic pressure, no difficulty arises. But in regard to the use of this method for diastolic pressure estimation, the question may be raised as to how the sound produced in the systolic phase and depending upon the systole can serve as an index of diastolic pressure. The answer is that, though the sound is actually elicited by the systolic wave, its occurrence or non-occurrence and its character when present, are determined by the intra-arterial pressure existing during the diastolic phase and its relation to the external or armlet pressure. If the intra-arterial diastolic pressure stands in such a relation to the armlet pressure that some distortion of the arterial tube from the circular form—that is, some flattening—occurs during diastole, then the loud clear tone is heard. On the other hand, when the relation is such that the intra-arterial diastolic pressure is not sufficiently below the level of the armlet pressure to ensure some flattening between the pulse beats, the sound, if audible at all, is dull in character. The change (during the lowering of the armlet pressure) from the clear to the dull and weaker sound, occurring as soon as the external and internal pressures are approximately equal, constitutes the index of diastolic pressure. In addition to the lines of evidence (as to the correctness of this index) stated in our former papers (study of circulatory schema, comparison with oscillatory method, etc.), we may add the direct experimental test carried out by us in conjunction with Dr. J. R. Murray.[6] Using anaesthetized large animals (sheep), we measured the systolic and diastolic pressures in one carotid artery by means of valved manometers (maximum and minimum) connected with a cannula inserted into the artery at the root of the neck on the proximal (cardiac) side of an armlet which was placed round the neck. The armlet being inflated in the usual way, the actual intra-arterial pressures were read off by one observer on the valved manometers, while simultaneous estimations were made by the auditory method by another observer; the auditory tambour (phonendoscope) was placed over the other carotid on the distal side of the armlet. These simultaneous readings by different observers (changing places from time to time) showed remarkably close correspondence; the auditory indications proved a strikingly accurate guide to the actual intra-arterial pressures as measured by the valved manometers. Such observations were carried out while the levels of blood pressure (systolic and diastolic) were made to vary widely—raised by compression of the abdomen, lowered by amyl nitrite, excess of chloroform, etc., also at very different rates of heart beat, etc. In all such conditions the accuracy of the auditory indications remained unimpaired.

Relation of Systolic and Diastolic Values to Efficiency of Circulation.

When systolic and diastolic pressures have been estimated and found to be at normal or approximately normal levels, with a normal rate of heart-beat, is this sufficient to prove that the circulation is proceeding in normal fashion? In the great majority of cases presenting the normal features referred to, it is the case that the blood flow is proceeding normally. But there are exceptional conditions where, with normal systolic and diastolic pressures, the mass movement of the blood is gravely defective, and the results are evident in the patent signs of circulatory defect—dyspnoea, pallor, or lividity, etc. Though the pressures may be normal, the volume of the arterial stream may be abnormally small, giving rise to circulatory defect. A small output of the heart with a suitable adjustment of the peripheral resistance by constriction of arterioles (necessary to maintain the aortic pressure in presence of the small output of the left ventricle) may establish a condition in which normal or not far from normal pressure readings may be accompanied by very deficient mass movement of the blood. The circulation has in this case been reduced to a smaller size than is compatible with the needs of the animal. The arterial stream may be seriously lacking in volume while showing readings of systolic and diastolic pressure that are not far from normal. With such defective volume the capillary flow is seriously reduced on account of the deficient mass movement of the blood, the small cardiac output being associated with narrowing of the peripheral outlet from the excessive contraction of arterioles which is necessary to maintain the aortic pressure in presence of the small output of the left ventricle.

In children and in small animals the volume of the arterial stream is, of course, very small as compared with the adult man, while the normal relation of peripheral resistance is related to the cardiac output in such a way that the aortic pressures may be pretty similar. The latter pressures in the aorta being maintained without any undue constriction of arterioles, the capillary circulation is a perfectly efficient one, and the mass movement of the blood is rapid. The smaller volume of the arterial stream is adapted to the smaller capillary field to be supplied. With the enormously large capillary field of the adult person a great reduction in the volume of the arterial stream, even with pressures up to the normal, means a serious defect in the capillary stream and the mass movement of the blood in the circulation—hence, signs of circulatory inadequacy. On the other hand, the volume of the arterial stream may be normal, while the circulation is still inadequate; in this case a pressure defect will be evident—abnormally low systolic or diastolic readings or a small pulse pressure. With deficient pressure values a reduced volume of arterial stream would of course imply a still more serious deficiency in the circulation.

Common Readings in Defective Circulations.

The more common conditions, when the circulation is defective, are: (*a*) Low systolic and diastolic readings (as in haemorrhage, shock, etc.), or (*b*) a systolic pressure which may be normal or even higher, attended by an abnormally high level of diastolic pressure, as in some cases of slow cardiac failure. Here the peripheral resistance is increased, keeping up the systolic pressure, notwithstanding a poor cardiac output, but this involves a high diastolic pressure—that is, a small pulse pressure and associated defective movement of the blood. The rate of the heart beat has, of course, to be taken into account in connexion with the pulse pressure. The defective pulse pressure is here of great significance and at once shows the true state of the circulation, whereas the systolic reading taken alone would give an entirely false indication.

It is clear that estimation of the systolic and diastolic pressures with the concomitant determination of the pulse pressure yields data of great importance and value, the precise significance of which in different conditions will, no doubt, become much greater with increasing knowledge. But while this is the case, such estimations must on no account be regarded as superseding or rendering unnecessary the use of other sources of information regarding the condition of the circulation—for example, obvious signs such as pallor, lividity, defective volume of arterial pulse, venous turgescence, dyspnoea, etc. Error from misuse of the results of blood pressure estimation, by blind adherence to mechanical standards, is easily avoided by common-sense application of other obvious signs taken in correlation with the blood pressure data.

Discrepancies in Systolic Readings from Different Limbs.

In a former paper we described the occasional presence of large discrepancies between the systolic readings obtained from different limbs, apparently due to abnormal local conditions.* The higher readings may be greatly reduced by the application of continued local compression, as already described, and in this way the divergent readings may be harmonized, the same readings being then obtained from all the limbs; further local compression may then cause no further lowering of the systolic values. As already stated, it is only in *some* abnormal arteries that such results are obtained; in the majority of thickened arteries practically correct readings are obtained without the preliminary use of continued local compression. The effects of local compression are not dependent on the production of an ischaemic condition of the limb. The closure of the brachial artery—by digital pressure as employed—leads, of course, to

* In this connexion we specifically exclude the cases of arm-leg differences associated with aortic regurgitation.

more or less pronounced stasis in the limb, but not to ischaemia. The latter condition, induced by the application of an Esmarch bandage, was found by Hill[1] and his collaborators to lead to reduced systolic readings for some time after the obstruction to the arterial flow was removed. This holds good in a normal limb as well as under abnormal conditions.

This observation deals with very different conditions from those present in the use of local compression. Local compression, as we employ it, leads to no alteration in the subsequent systolic reading either in normal persons or in the majority of pathological conditions. We have repeated this observation very frequently and with constant results. A pressure reading was first taken from the two arms. One arm was then subjected to repeated compression (for example, twenty times), or, as is preferable, closure of the brachial artery by digital pressure was maintained for three minutes in the area of application of the armlet, the latter being loosened and slipped down on to the forearm or removed altogether. At the end of the period of closure the armlet, reapplied to the upper arm, gave, in the normal subject, a reading which, when compared with one made from the other arm, showed no discrepancy. Comparison with a (second) reading from the other arm which has not been subjected to continued or frequently repeated compression is, of course, essential, as the actual pressure in the arterial system might have undergone some alteration during the period occupied in the observations. The procedure of local compression clearly induces no change in systolic readings in ordinary conditions of the vascular system; this is also true of the great majority of abnormal conditions.

It is only in a small minority of cases with thickened and contracted arteries that a notable reduction of the systolic reading is induced by local compression as described. We have not observed such reduction in any case where there was not evidence of abnormality in the arteries. In cases where divergent readings have been obtained from different limbs, local compression has an equalizing effect. Repetition of the local compression does not induce an indefinite reduction of the readings—not below the level found in a normal or soft artery.

Parallelism between Results from Excised Arteries and Human Limbs.

A long series of experiments (conducted in association with Dr. J. E. Kesson[4]) on excised arteries tested in different conditions in a circulatory schema showed a remarkable parallelism as regards the results of continued compression with those described above. With relaxed arteries (normal or thickened) the "systolic" reading was practically the same before and after continued compression, whereas with powerfully contracted and thickened arteries the subsequent reading was greatly reduced—down to the level of that obtained with relaxed vessels. The continued compression induced relaxation at the compressed part, as was evident on direct examination of the artery, which was soft and easily distensible at that part, in marked contrast to the firm and resistant adjoining parts which had not been subjected to compression. This reduction in the resistance of the arterial wall was temporary; after a time, varying according to circumstances, recovery occurred more or less completely; the contraction and resistance to compression returned, causing the external (obliteration) pressure to be again an over-estimate of the systolic pressure within the artery by the amount of the resistance to compression offered by the arterial wall. Similarly, in the human subject, when the systolic reading had been reduced by continued local compression of the thickened artery, recovery occurred after a time, and the original systolic value was restored; in some cases this restoration was watched and found to occur with remarkable precision in observations repeated from time to time on the same patient over a period of many months. But in most cases the extra resistance, as indicated by the result of local compression, varied considerably from time to time in the same person.

The striking resemblance in the results got from resistant excised arteries and those sometimes obtained from human limbs naturally suggested the possibility or probability of a similar explanation being applicable in the two cases. But it is to be noted that while the parallelism between the results from excised arteries and from the living subject is a perfectly definite and very striking one as regards the nature of the changes in pressure readings, the actual amounts of the alterations in the readings differ widely in the two classes of observations; in other words, there is a very close correspondence in the *kind* of change which occurs in each case, but a great difference in the *degree* of such change.

The alterations induced by continued compression in the human limb are, in some cases in which they are very extensive, very much greater in amount than could be predicated from the study of excised arteries. We have always borne this consideration in mind; in the first paper on the subject from this laboratory we adverted to this, and pointed out that it was impossible to account for the extensive variations in the systolic readings from different limbs sometimes met with, unless one assumed the existence of such enormous resistances as are to be met with in the powerfully contracted thick-walled arteries like the carotid of the ox or the metacarpal or metatarsal of the horse, examined under abnormal conditions calculated to give the maximum resistance, at room temperature, or under the influence of barium chloride, etc. Palpation of arteries in the living subjects under examination has not in our experience given evidence of such extremely resistant characters as were present in the excised arteries above referred to; we have never believed that the great differences in pressure readings in different limbs depended simply on the extra pressure required to distort the circular tube and bring it into a flattened position. There is, we believe, another factor which we have not so far described—resistance, due, as far as is known, to contraction of the arterial muscle acting in another way than simply by opposing the flattening of the circular tube, but in effect constituting a local resistance to the obliteration of the pulse in the artery compressed by the armlet; this depends on certain special features in the form of closure of the vessel when compressed by external pressure.

Resistance to Compression in Excised Arteries.

In an artery like the sheep's carotid, comparable in size and thickness of wall with the human brachial, contraction of moderate amount made very little difference to the pressure readings: this accords with evidence derived from other sources in showing that the normal tone of the brachial artery, and even a markedly increased tone, have no appreciable disturbing effect on blood pressure estimation. Even with extreme contraction, induced by mechanical stimulation at room temperature, use of barium chloride, etc., the resistance offered by the carotid of the sheep in these abnormal conditions, widely removed from those present in the human body—for example, 35 mm.—has not reached anything like the values sometimes observed in the differences between the human limbs in certain conditions (cases of aortic regurgitation are excluded). We conclude, then, that variations in the amount of contraction, such as occur in the normal brachial artery of man, are of no serious import in regard to blood-pressure estimation.

Janeway and Park[2] conclude that resistance of the arterial wall due to muscular contraction may be a source of error in blood-pressure estimations, so far supporting the view long held by Russell[3] to this effect. Janeway and Park think that such error should not be more than 30 mm. in the human brachial artery.

Higher resistance values were naturally obtained from such large thick-walled tubes as the carotid of the ox with its powerful muscular coat. The values obtained from a vessel so different in dimensions from the human brachial could not be applied without qualification to the latter. And even with the ox carotid, differences (apparently due to local causes) as large as those sometimes found in the human limbs were observed only under extremely abnormal conditions; application of these results without qualification to the human vascular system would be wholly unwarrantable.

But these observations refer to normal arteries, and, as has been already stated, the differences in man have been noticed by us only in the presence of abnormal conditions of the arterial system.

In pathological arteries from the legs of old horses we recorded very high degrees of resistance to compression, the resistance depending on the presence of enormously

powerful contraction of the thick muscular coat. But the characters of such arteries on palpation are very different from anything we have felt in human limbs, and it is obviously not permissible to assume the presence of any such amounts of contraction in man.

Mode of Closure of Artery under External Pressure.

A good many years ago von Recklinghausen [7] suggested a different form of closure under external pressure in sclerosed arteries as compared with normal ones, the latter being evenly flattened by external pressure and completely occluded (see the figure c), while in the former the walls of the tube become apposed at the middle part, while chinks still remained open at the sides (B). The fact

A B C

A indicates the circular form of the uncompressed artery; B represents the peculiar form of closure (with chinks at the sides) described in the text; C shows the ordinary form of closure.

that different kinds of tubes may undergo one or other form of closure is a fact that is very easily demonstrable. This hypothesis has, however, not gained currency as accounting for differences in pressure readings. It does not explain why *all* thick sclerosed arteries do not give different readings as compared with others in the same individual that are relatively normal. And it would not account for the effects of continued compression already described as occurring in some sclerosed arteries while absent in the great majority.

There is evidently another factor concerned, and we find reason to believe that muscular contraction constitutes such; that is, that the determination of the peculiar form of closure above referred to depends on an influence exercised by contraction of the muscular coat of a sclerosed artery under certain conditions. Powerful muscular contraction is not at all necessary. An amount of contraction that is soon overcome by external pressure of an extent sufficient to flatten the tube and bring its walls in apposition is able to determine the persistence of chinks at the sides through which the pulse can still be transmitted; a more or less considerable amount of additional external pressure is needed to close the chinks sufficiently to obliterate the pulse.

The occurrence of different pressure readings in different limbs and variations in the amount of such differences at different times are capable of explanation as being due to variations in the contraction present. The effects of continued or repeated compression—reduction of the readings with subsequent recovery, etc.—are similarly explicable as depending on the demonstrated influence of compression in temporarily removing the tonic contraction, which is again restored after a time, with concomitant restoration of the pressure values. The same explanation applies to the facts that local compression tends to equalize the diverse values which may be obtained from different limbs at the first test, and that local compression (even if repeated) does not reduce the reading below the level obtained with a soft artery.

The view here stated differs from that of von Recklinghausen in postulating activity of the arterial muscle as an essential factor, in addition to the presence of certain structural alterations in the sclerosed artery; it differs from that of Russell (who has long urged the importance of hypertonus in normal and sclerosed arteries), inasmuch as the latter seems to regard the muscular resistance as simply opposing flattening, not as determining a special form of closure.

An Illustrative Case.

If the pressure readings from two limbs differ markedly on account of the occurrence of a special form of closure in one artery as compared with the other, the pulse persisting much longer in one than in the other, it might be possible to elicit special evidence bearing upon the different conditions. Such we have sometimes observed definitely; indeed, it was the encountering of certain facts in comparative and simultaneous estimations on different limbs, in some cases giving widely different systolic readings, that led us to regard the above-described mechanism as an operative one; the way in which it harmonized with other facts was sufficiently obvious.

In the following case, examined with Dr. J. R. Murray, these phenomena were very striking. The patient had no aortic regurgitation, but the arm-leg difference in the systolic readings was very marked. At the first test the (simultaneous) obliteration values were 115 for the upper arm and 198 for the leg. But a very marked change was recognizable in the leg artery at 116 mm.—that is, at the obliteration level in the arm. The pulse in the leg, though not abolished, was very notably cut down in volume; it persisted as a pulse of small volume with very little alteration till it became obliterated—at a much higher level.

Repeated compression was tried and was found to give marked lowering in the leg readings at successive tests—namely, 198, 186, 168, 149, 148 mm. A similar change occurred in the relation of the points of disappearance and reappearance of the pulse in successive observations. At first, when the armlet pressure was raised sufficiently to obliterate the pulse, kept at this level for some time and then lowered, the pulse did not reappear until a very much lower level had been reached—154 mm.—as compared with 198. The armlet pressure, run up again, gave disappearance of the pulse at 182 and reappearance at 152. The armlet pressure was then lowered to zero for some time; the next compression gave disappearance at 186 and reappearance at 155. At a later compression the pulse disappeared at 168 and reappeared at 166. There was thus a progressive diminution of both the actual obliteration level and of the difference between the points of disappearance and reappearance.

The arm readings behaved in a strikingly different way. There was no appreciable difference (a very few millimetres) between the points of disappearance and reappearance of the pulse, and the readings remained steady at about 115 to 116 throughout the series of observations, while the leg readings were showing extensive changes; this indicates that the aortic systolic pressure remained unchanged. It was easy in repeated observations to predicate the arm values by noting the very definite change in volume in the leg artery, as already described.

In this case diastolic pressure estimation by the auditory and oscillatory (Pachon) methods gave similar values—75 to 85 mm.—in arm and leg, varying little at the beginning and end of the series of observations.

It is noteworthy that the systolic readings were much higher with the armlet on the calf of the leg than when on the thigh; the latter often nearly agreed with the arm.

We conclude from such results that the systolic pressure was really the same in the arm and leg, despite the fact that a very much higher armlet pressure was required to obliterate the pulse in the leg, though the latter pulse was strikingly cut down—to one of very small volume, which persisted until the compressing armlet pressure had been raised much higher. We interpret this result as being due to a different form of closure in the arm and leg arteries respectively, and we regard the leg arteries as the ones in which the behaviour of the tube under compression was peculiar. There is, of course, the question as to whether the abnormality is in the arm or the leg—that is, whether complete occlusion is abnormally difficult in the leg or abnormally easy in the arm; either of these would obviously cause a discrepancy in the readings, the intra-arterial pressure being similar in both arm and leg.

There is clear evidence that the abnormality is in the leg. The arm readings remained constant, being unaffected by repeated or continued compression, while the leg readings changed very strikingly, being enormously reduced by repeated or continued compression; the leg readings could thus be brought down towards equality with the arm readings, but showed no further reduction—below the arm value—on further compression. And after a time the leg readings recovered their great predominance over the arm values.

These phenomena fit in exactly with the conception of a peculiar form of closure of the leg arteries when compressed by the "armlet," central parts being brought into

apposition a considerable time before the lateral chinks are closed; the pulse continues to be transmitted until a more or less considerable excess of external pressure has been applied, over and above what is needed to stop the transmission of the pulse in a normal artery. The effects of continued or repeated compression in reducing the readings in such an artery find an obvious explanation in their demonstrated influence in reducing the resistance of the arterial wall by temporarily diminishing or annulling the contraction present, and so removing a factor concerned in inducing the peculiar form of closure above described in a sclerosed artery.

Resistance to Compression of Excised Arteries.

In view of the foregoing results, it may be asked whether the high resistance to compression recorded in strongly contracted surviving arteries, possessing thick muscular coats, is associated with a similar peculiarity in the mode of closure under external pressure or whether it is simply due to the direct resistance presented (by the rigid muscle) against distortion of the tube from the circular form.

The excised arteries in which very high resistances were encountered were always powerfully contracted, with rigid muscular coats and a very small lumen. The use of the term "contraction" in this connexion may be ambiguous; it may mean that the action of the (shortened) muscular fibres may be such as to reduce the lumen to very small dimensions; or, on the other hand, the muscle may be "contracted" and rigid while the lumen is not very small—for example, in presence of high internal pressure, under the influence of cold, etc.; in the latter case, the muscle may be firmer and more resistant without being much shortened.

In the case of a strongly contracted artery with a very small lumen, there is no evidence that the peculiar form above described ever occurs in such a way as to allow persistent passage of the pulse wave through lateral chinks. The small lumen seems always to close by a simple apposition of the walls of the tube.

We conclude that the excess of external pressure over internal pressure which is necessary to obliterate the pulse under those conditions is due to the direct resistance to distortion of the rigid muscular walls of the tube. But, as already stated, we find no ground for assuming the existence of anything resembling this degree of muscular rigidity in the vessels of the living subjects. At the same time, the presence of contraction — that is, muscular resistance — is very important in human arteries when associated with certain abnormal structural conditions, determining the occurrence of special features in the process of closure of the vessel by external pressure, and thus leading to different readings of obliteration pressure that do not correspond with differences in the actual systolic pressure.

* By "closure" is meant such a degree of occlusion as is necessary to stop the transmission of the pulse wave as tested on the peripheral side.

Ed. Sergent and L. Nègre have reported to the Society of Biology the results of the examination of the stools of sixty-seven pilgrims returned to North Africa from Mecca; they included thirty-six returned to Algiers and thirty-one to Morocco. Thirteen (10 per cent.) had dysenteric bacilli of the Flexner type in their intestines. The examination of the stools of a certain number of natives resident in the neighbourhood of Algiers who had not been to Mecca gave a negative result. In three of the returned pilgrims (4.5 per cent.) cholera vibrios were found in the intestines, and in two instances the vibrios presented all the true characters of the cholera vibrio. The pilgrims were all in good health, and the observations show that among those returning from Mecca there are carriers who escape existing sanitary measures. An abstract of the paper is published in the *Bulletin de l'Office International d'Hygiène Publique* for August, 1914.

THE BARBER-SURGEONS' COMPANY.

An Address delivered to the Hunterian Society of London.

By THOMAS GLOVER LYON, M.A., M.D.,

President; Second Warden to the Barbers' Company, 1914.

Arms of the Company.

By the kind hospitality of the Worshipful Company of Barbers, the Hunterian Society is now privileged to hold its meetings in a place associated for centuries with the medical profession.

In the year 1461 a corporation which had been solicited by Thomas Morsted, Chirurgien to Henry IV, was granted to Jacques de Fries, his physician, and John Hobbes, his surgeon, by Edward IV, in the names of St. Cosmo and St. Damianus, brothers, physicians and martyrs. This corporation was called the Company of Barber-Surgeons of London, and received authority over all practising the same arts in and about the metropolis.

In spite of this charter, however, many unqualified persons continued to practise. There is an interesting account of how quacks were punished in the minutes of the Company. In the fifth year of the reign of Richard III one Roger Clark was prosecuted for quackery, having given a piece of parchment rolled up and said to be inscribed with the words of a charm, to be used round the neck against fever. The culprit was convicted and sentenced to the following peculiar punishment: He was "led through the middle of the city with trumpet and pipe, he riding on a horse without a saddle, the said parchment and a whetstone for his lies being hung about the neck, and an urinal being hung before him and another behind."

Up to the reign of Henry VIII barbery and surgery were practised by the same individual, but even during this period members of the Company specialized in one branch or the other. Many of those favouring surgery went to the wars either in England or on the Continent. These were often financed by the barbers, who received a share of the large fees paid by the nobles and other wealthy men for surgical attendance. One can imagine how competent men were sought after, and how great were the sufferings of those who were unable to secure their services, by the following quotation from Gale:

> I remember when I was in the Wars at Muttrel (Montreuil), in the time of that most famous prince Henry VIII, there was a great rabblement that looked upon themselves to be surgeons, some were sow gelders and some horse doctors, with tinkers and cobblers. . . . But when the Duke of Norfolk, who was the General, saw how the people did die and that of small wounds, he sent for me and certain other surgeons, commanding us to make search how these men came to their deaths, whether it was by the grievousness of their wounds or by lack of knowledge of these so-called surgeons. . . . In the end this rabblement were committed to the Marshalsea, and threatened by His Grace to be hanged for their worthy deeds except they would declare the truth who they were and of what occupation, and in the end they did confess themselves to be as I have declared to you.

In the third year of Henry VIII's reign (1512), a licensing body was created, whose approval was necessary before anyone could practise as a physician or surgeon in the City of London or within seven miles of it. This consisted of the Bishop of London, or Dean of St. Paul's, aided by four doctors of physic, and for surgery other persons of discretion "experts in this faculty." In spite of the existence of this body, in the thirty-second year of Henry VIII's reign (1541), the Barber-Surgeon Company was united to another company, the Company of Surgeons, by Act of Parliament. This Act divided the members of the Company into barbers and surgeons; the barbers were not allowed to practise surgery except bleeding and drawing of teeth, and the surgeons were not to practise barbery or shaving. The art of surgery to which the charter of 1541 refers comprised the care of "bruises, hurts, and other infirmities, the letting of blood and the drawing of teeth." There has always existed an antagonism

between physicians and surgeons, and we can imagine the words "other infirmities" led to frequent disputes. The same charter gives power to the governing body of the Company to make "statutes and ordinances for the wholesome government, superintendence and correction of the said mysteries, according to the necessities of the case." Power still remains in the Master of this Company to order to prison members who may have misbehaved themselves. The following appears in the minutes of the Company:

17th November, 1635. This day Wm. Kellett, being called here in Court for not makeing presentacon of one Mr. Kinnersleys maide that died in his charge, he saied here in Court that Mr. Doctor Harvye being called to the patient did upon his vew of the patient saie, that by the meanes of a boulster the tumor on the temporall muskle would be discussed and his opinion was that there was no fracture but the vomiteing came by reason of the fouleness of the Stomacke, and to that purpose p'scribed physick by Briscoe the Apotheearye, soe the patient died by ill practice, the fracture being neglected and the Company not called to the vew.

The Mr. Doctor Harvye here mentioned appears to be no other than the discoverer of the circulation of the blood. If a severe case was "presented" to the authorities of the Company, the Master and Wardens visited the case without fee and arranged the treatment in consultation with the surgeons who had presented the case. Supervision and inspection is also given to the Company of "all kinds of instruments, plaisters, and other medicines and their recipes, by such barbers and surgeons given and applied and used for our liege men and curing and healing their wounds, bruises, hurts and such kind of infirmities." Here we get the words, "such kind of infirmities," still a somewhat indefinite expression. This charter also exempts practitioners from serving on juries and other like duties.

Grace Cup presented by Henry VIII.

The method of procedure required of those wishing to become surgeons was as follows: The candidate was first apprenticed to a surgeon, a member of the Company, for five or seven years, and took up the freedom of the Company. Then, after a *viva voce* examination at the Hall, a preliminary certificate to practise for three years was granted. After three years of practice to the satisfaction of the authorities, a final certificate was granted, which enabled the Bishop's Seal confirmatory to be obtained. A silver spoon, engraved with the donor's name, was presented to the Company by all persons passing the examination, but out of many hundreds which must have been presented, only one—given by Jonathan Cheynell—remains. It is interesting to note that an apprentice undertook to devote the whole of his time to his master's service, except such as was given to Divine worship.

The charter of Henry VIII allotted the bodies of four criminals to the Company for dissection, but other bodies were purchased privately. The beadles of the Company used to proceed to the gallows to claim the four bodies, and often had to fight the relations of the culprit for possession. Sometimes in these unseemly brawls the clothing of the corpse was torn, and the Company possesses receipts by the hangman for sums in compensation for the damage done.

Regarding the possibility of resuscitation after hanging, we find records relating to two cases. In Stow's *Annales* there is a story to the following effect:

A man hanged at St. Thomas Watering on February 20th, 1587, was cut down, stripped of his apparel, laid naked in a chest, thrown in a car, and brought through Southwark to the Barbers' Hall. The chest being open to the weather, extremely cold, he was found to be alive, and lived till February 23rd, and then died.

Apparently arising out of this incident, the following minute occurs in the Company's books, July 13th, 1587:

If any body shall revive and come to life, the charges about the same body shall be sustained by the person or persons who shall happen to bring home the body.

The second instance is recorded as follows by Mr. Joseph Wheeler, Clerk to the Company, in a rough minute:

November 23rd, 1740. This day Will Duell, who had been indited at the Old Bailey for a Rape and had received sentence of death for the same, was carried to Tyburn in order to be executed, where having been hung for some time was cutt down, and brought to the Company's Hall in order to be dissected, where he had not been five minutes before life appeared in him, and being let blood and other means used for his recovery, in less than two hours he sat upright, drank some warm wine, and looked round him before he was carried back to Newgate, which was about twelve of the clock at night. He several times pronounced distinctly the word Don't when anybody touched him, though was thought to be mostly insensible of ought but pain, which in great measure he endured by his most violent moanings, and was after in strong convulsions in the bowels which he then expressed by applying his hands to this part. The Sheriff, having ordered him back to Newgate, he was carried in a blanket, putt into a coach, was seemingly much composed and quiet, not making any manner of noise. Within three days time he recovered sufficiently to converse and eat and drink very freely, but never could give any reasonable account of what had passed. He afterwards obtained a reprieve in order to be transported for life, which he was accordingly in his 16th year.

The "Royal Oak" (Boscobel) Cup, presented by Charles II.

It is alleged that Duell changed his name to Deverel, and becoming a prosperous man, gave to the Company a handsome screen.

When we consider the limited scope of the "mystery" over which the Company had control, it is not surprising to find that with the growth of surgery there arose the necessity for a body which would take a more comprehensive attitude towards this branch of the profession. Why the barber-surgeons did not reconstitute themselves according to the needs of the time I am unable to say, but as surgery advanced any alliance with barbery would naturally become strained. Moreover, municipal institutions, for some reason or other, have never succeeded in controlling and developing the higher branches of education. Sir Thomas Gresham intended to found a university connected with the corporate life of the City, but this object was never attained. It thus came to pass that in 1745 the control of the surgical practice of London and the education of practitioners, together with endowments attached to the latter, were alienated from the Barber-Surgeons, and vested in a new corporation, the College of Surgeons of London, which body in 1843 was styled the Royal College of Surgeons of England. In spite of the circumstances under which the new body was founded, the most cordial relations have existed between the old Company and the College of Surgeons. Many members of the College have joined the livery

of the Company, have been elected to the Court of Assistants, and passed the Chair, and at the Company's banquets the President of the Royal College of Surgeons, when present, is always the most honoured guest. The old Company, thereafter called the Company of Barbers, retained the Hall, together with the records and the works of art contained in it. The members of the Barbers' Company regard the custody of these treasures to be their special privilege and duty. Every opportunity for inspection is given to those who are likely to be appreciative, and probably no works of art receive more serious attention. Visitors have often expressed their satisfaction at being able to examine the pictures away from the chilling atmosphere of a public gallery, and to handle the cups instead of gazing at them in glass cases.

The site of the Hall, which originally included an extensive herbal garden, is chiefly interesting on account of its proximity to one of the residences of William Shakespeare, who lived, between 1598 and 1607, at the corner of Monkwell Street and Silver Street, and there wrote seven of his plays. He appears as a witness in the Court of Chancery in favour of his landlord's daughter, who had married an apprentice of her father's, the suit being for payment of a promised dowry. The present hall is part of a pile of buildings which included a large banqueting hall and lecture theatre, designed by Inigo Jones, whose portrait by Vandyck hangs in the hall. The lecture theatre was elliptical in shape, and the ceiling was decorated with the signs of the Zodiac. Against its walls hung the skeletons of two murderers. The table, of peculiar shape, used in this theatre for the display of anatomical specimens is preserved. The building survived the Great Fire of London in 1666, owing to the fact that it was surrounded by a large garden. The large hall and theatre were demolished only recently to make way for warehouses. The hall in which the Society is permitted to meet was the council chamber, and in it examinations were held. The ceiling is adorned with—or shall we say disfigured by?—several anatomical objects, and is a good specimen of the heavy decoration of the period.

The Company's coat of arms was granted by Elizabeth, and is a modification of a former grant by Henry VI. The actual grant of arms is a fine specimen of heraldic emblazonment. The interesting points of this coat from our standpoint are the flewmes or scrapers in two of the quarterings, representing the barbers, and the so-called spatter or spatta, encased in a rose and crown in two other quarters. This spatter is said to be a spatula, but I should say that it is a knife with a spearhead-shaped blade to represent the surgeons. The supporters are two lynxes, to typify the observant acumen which should be a characteristic of a surgeon. The granting of arms to a body of men who were exempt from military service must have presented to the King-at-Arms a humorous aspect, which I cannot help thinking he has slyly indicated in the crest or sign to be worn on the helmet in battle. He describes this as an Opinacus, but others have irreverently referred to it as the Barbers' Flying Jackass. It has the body and legs of a lion, the neck and head of an eagle, the wings of a griffin, and the tail of a camel. Truly, in Trinculo's words, "a most ridiculous monster."

Amongst the numerous treasures possessed by the Company is the gilt silver cup presented to it by Henry VIII. It is said by Mr. Stanley Gardiner, an authority on such subjects, to be the only personal relic of this monarch existing. It is a most beautiful specimen, graceful though simple in design, and of exquisite workmanship. It is ornamented with heraldic designs connected with the House of Tudor, including the rose and portcullis. Hanging round the bowl are little bells, the use of which was probably to call attention when the cup required replenishing. The picture of Henry VIII granting a charter to the Company in 1541 is a fine specimen of Holbein's work—at least, as far as the King's figure goes, and probably the most true to life of any portraits of Henry VIII. Holbein's portraits are all characterized by a photographic fidelity to life, and in this instance the painter was free from any obligation to please the original. Arrogance, sensuality, and cruelty, combined with high and broad-minded intellectual powers, determination, and generosity, are, I think, all expressed in the face and figure of the King. All the personages in the picture were celebrities, but three, I think, are worthy of special mention. John Chambre, immediately on the King's right, was a man of many parts. He, like the old monks, combined the callings of physician and priest. He was physician to Henry VIII, and as Archdeacon of Bedford was one of the Convocation in 1536, when the Articles of Religion were framed. He was one of the founders of the College of Physicians. Dr. Butts, the second to the King's right, was the Dr. Butts mentioned in Shakespeare's Henry VIII. He attended Anne Boleyn through a serious illness, and was sent by the King to Cardinal Wolsey when the latter was taken ill after his disgrace. Butts preserved to the last the regard of this fickle monarch, who made him valuable grants of land. Thomas Vicary, to whom the King is giving the charter, was Master of the Company five times, and was Sergeant-Surgeon to Henry VIII, Edward VI, Mary, and Elizabeth. He was chief surgeon at St. Bartholomew's Hospital, and was author of the first work on anatomy published in English. It was entitled *The Englishman's Treasure*. Many have tried to acquire this famous picture, amongst others Samuel Pepys, who attempted to buy it for £200, and being told it was worth at least £1,000, remarked, "It is not a pleasant though a good picture." I may add that lately a would-be purchaser has added two noughts to Pepys's offer, and has received the answer, "This picture is not for sale."

A tankard which Charles I, at the instance of Thomas Fothergill, presented to the Company, is a contrast to a flagon of the time of the Commonwealth presented by Thomas Collins, professor of surgery. It always seems to me that the elegance of the Cavalier and the stolidity of the Roundhead are impressed upon the one and the other of these handsome pieces. The famous Boscobel cup was presented to the Company by Charles II at the petition of John Knight, surgeon to the King. This is the gem of the Company's collection, and in its lightness and grace, and even in its appearance of instability, is to my mind characteristic of the early Restoration. Its stem is in the shape of the trunk of an oak, somewhat twisted; the handle of the lid is a crown, and the usual little bells hang round the bowl. To four cups, presented by Edward Arris, founder of the Arrisian lectures, a melancholy history is attached, four men having been executed for a theft of them from the hall. Unpretentious like their donor, they are excellent in their simplicity. Of the pictures on these walls not already mentioned, one by Walker, sometimes called the English Vandyck, shows that remarkable man Sir Charles Scarborough giving a demonstration in anatomy, assisted by Edward Arris. Sir Charles was physician to Charles II, James II, and William III. He was a great mathematician, and applied for the first time the principles of mechanics to explain the action of the muscles. Sir Charles was a physician of the candid school, and is said to have remarked to the Duchess of Portsmouth: "Madame, you must eat less, use exercise, take physic, or be sick."

Scarborough assisted William Harvey in his book *De Generatione Animalium*. He was acting as surgeon in attendance to the Duke of York, afterwards James II, on board the frigate *Gloucester*, when it was wrecked on the Well Sands. He was picked up while struggling in the water, and never recovered from the effects of the cold and exposure. There is a second portrait of Edward Arris, this time a full-length one. When the surgeons parted from the barbers they took with them the endowment connected with the Arrisian lectures, but this money was somehow merged in the general funds of the new society or was misappropriated, and so the lectureship became an honorary one. This being pointed out to the council, the sum of the endowment was once more set aside to re-endow the lectureship. The initiative in this matter was taken by a past master of the Barbers' Company, Sir John Tweedy. A fine punchbowl was given by Queen Anne in acknowledgement of the services rendered by the Company in examining surgeons for the army and navy. A Sergeant-Surgeon of Queen Anne, Sir Charles Bernard, whose portrait hangs in the hall, was instrumental in obtaining this gift.

Amongst other works of art owned by the Company is the beautiful firescreen, a fine piece of ornamental ironwork presented by Sir John Tweedy and designed by Lady Tweedy. The waterman's badge and the banners formerly carried on the Company's state barge are also worthy of note.

During its career the Hunterian Society has had many habitations, but none will compare with our present sumptuous meeting place. I think I cannot more fitly conclude this address than by expressing the gratitude of the Society to our kind hosts the Worshipful Company of Barbers, and by repeating the time-honoured sentiment, "Root and branch, may it flourish for ever."

INSECTS AND WAR:

VIII.—*MITES* (PART II)

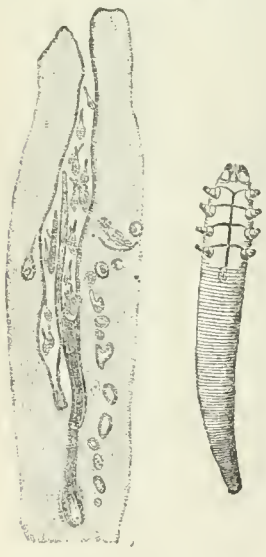
(Demodex; Sarcoptes; Endo-parasitic Mites).

BY A. E. SHIPLEY, Sc.D., F.R.S.,
MASTER OF CHRIST'S COLLEGE, CAMBRIDGE.

Say what the use, were finer optics giv'n,
T' inspect a mite, not comprehend the heav'n.
POPE, *Essay on Man.*

Demodex.

WE have seen that the harvest mite is wont to insert its head into the skin of human beings, but other mites show less restraint and insert their whole bodies. One of these, the well-known *Demodex folliculorum*, is, according to Guiart and Grimbert, "le plus commun des parasites de l'homme et nous en sommes presque tous porteurs." Without taking quite so gloomy a view, *Demodex* is undoubtedly widely distributed in the skin of mankind and of other mammals. There are differences of opinion as to whether this form should be split up into numerous species, or subspecies, according to the genus of the mammals upon which it lives. We, at any rate, will confine our attention to the human kind (Fig. 1) and so avoid losing ourselves in the tortuous maze of synonymy and the arid discussion of a meticulous classification so dear to the analytical German mind. To us a *Demodex* shall be a *Demodex*, and we will leave it at that.



a *b*

Fig. 1.—*(a) Demodex* in hair follicle of dog. *(b) Demodex folliculorum* (highly magnified).

Unlike the majority of mites, *Demodex* is a good deal longer than it is broad. But even for a mite it is very small, and shows signs of bodily degradation associated with its parasitic habit of life. Its shape is adapted to its habitat, which is the sebaceous glands of the skin. The long abdomen appears to be segmented, but the annulations are not true segments. The legs are reduced to conical stumps. The male is 300 μ long and 40 μ* broad across the cephalothorax. The female is, as usual, larger, measuring 380 μ in length by 45 μ in breadth. The minute larvae have, as is so often the case with mites, but three pairs of legs and are 60 to 100 μ in length.

This parasite, which lives on all parts of the skin of the human body, is perhaps most commonly seen on the nose and in the passages leading into the ear. It can be expressed by firmly pressing over the black spot which indicates its presence on the skin of the nose or elsewhere any small cylindrical tube, such as a watch-key. When expressed it is not always easy to see, as coming away with it is a mass of sebaceous matter which can best be dissolved off with oil on the microscopic slide. Whether this particular parasite causes much disease is not known. But in some cases it is certainly associated with acne and other skin disorders, and as it is also found in hair follicles, it may possibly destroy the hair. It is apparently spread by personal contact.

* A μ = 1,000th of a millimetre.

The Itch Mite.

A much more serious trouble is due to *Sarcoptes scabiei*, often called the Acarus, which gives rise to the disease known in England as the "itch" and in France as the "*gale*." *Sarcoptes scabiei* in both sexes is but little longer than broad. The female (Fig. 2) is, as always, larger

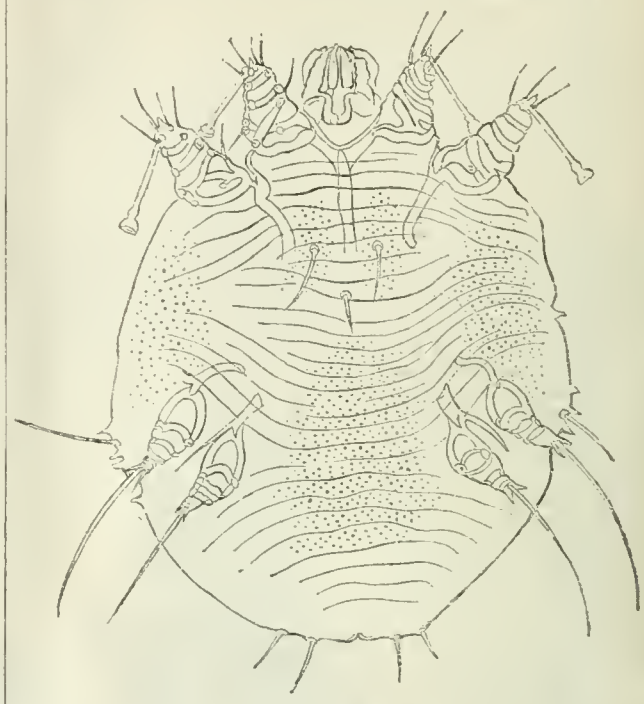


Fig. 2.—*Sarcoptes scabiei.* Female. × 130. Ventral view. (From Bourguignon.)

than the male. These mites are shaped very much like a microscopic tortoise, of a pearly grey colour, passing at parts into a rusty brown. Of the four pairs of legs two run forward close to the head, and two point backwards. The integument is semi-transparent and strengthened by

Fig. 3.—*Sarcoptes scabiei.* Male. × 300. Ventral view. The sucker on the fourth leg on the right is accidentally folded over the third leg. (From Bourguignon.)

parallel folds and bears many little bilateral symmetrical protuberances and scales. There are also certain hairs which have some systematic value (Fig. 3). The male is usually recognized by the fact that its third pair of legs terminates in a long hair, whilst the other legs end in a pedunculated sucker. He measures 200 to 235 μ in

length, by 145 to 190 μ in breadth. By preference he lives under the scales which the presence of the parasite produce on the host. The female is markedly larger than the male, measuring 330 to 450 μ in length by 250 to 350 μ in breadth. Her two anterior legs end in stalked suckers, whilst the two posterior end in hairs. The legs, like Malvolio's, are curiously "cross-gartered" by chitinous bars and rings, as is shown in Fig. 4.

Fig. 4.—One of the legs of *Sarcoptes scabiei*, × about 450, showing the stalked sucker and the curious "cross-gartering."

At first she promenades about with the male on the surface of the human skin. When they have paired the female begins to tunnel in the epidermis. The poor male, having been used, dies. As the mother-mite tunnels she begins to lay eggs, leaving them one by one behind her as she burrows deeper and deeper. Hence those that are nearer the entrance of the tunnel are always more advanced in age and development than those further in. She always works head forward, and as her tunnel is but slightly bigger than the breadth of her body, she cannot turn round, and she is prevented from retreating backwards by the backward hairs or spines of her body (Fig. 5). Hence she burrows always forward until she has dug her own grave at the far end of her excavation.

She is said to live two or three months and to lay one or two eggs a day. Hence one female is enough to infect a single host. The egg is, relatively to the size of the mother, enormous, its length being 150 μ and its width 100 μ. The egg is hatched out after three to six days and the young larva is hexapodous—that is, as is so usual in acarines, six-legged. It escapes from the burrow on to

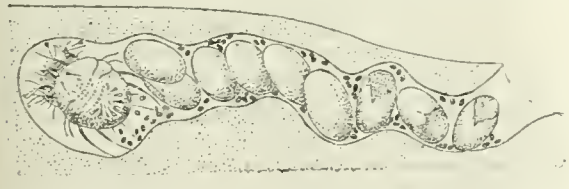

Fig. 5.—A diagrammatic view of the tunnel made by the female of *Sarcoptes scabiei*, with the eggs she has laid behind her as she burrows deeper and deeper. The black lots represent the excrement.

the skin and soon tunnels into the epidermis of its host, where it moults and transforms about the ninth day into a four-legged nymph. At the end of another six days the mites moult again, and at this period one can distinguish nymphs of two sizes, the larger female and the smaller male.

Within a month after hatching the *Sarcoptes* has become adult and the sexes are occupied in seeking each other on the surface of the skin, and it is in this stage that they are easily passed by personal contact from one individual to another.

Many animals suffer from *Sarcoptes*, and the fact that this genus can be transferred to man from the horse, the ox, the sheep, the goat, the dog, the cat, the camel, the lion, etc., is a slight argument in favour of their being one species. There is another undoubtedly distinct species

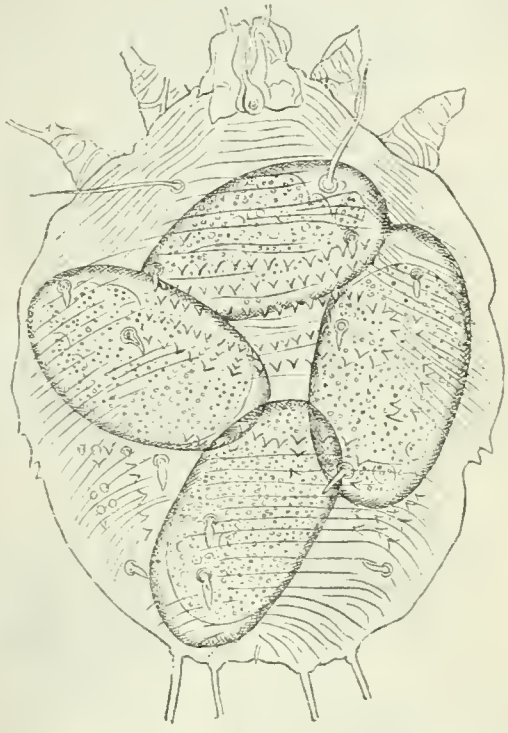

Fig. 6.—A female *Sarcoptes scabiei*, with four eggs in different stages of development; × about 180.

which causes serious epidemics, especially in Norway, but that is hardly likely to enter into the scope of these papers.

Sarcoptes scabiei, the itch mite, is, however, a cause of serious trouble in an army "in being." The tunnel or gallery in which the female mite burrows is the only lesion produced directly by the parasite. To the naked eye it presents a little whitish or greyish line, in which the length varies from some millimetres to one or even three centimetres, the longer ones occurring most frequently on the hands or wrists. It is of course open at one end, and ends in a *cul-de-sac*, which is slightly swollen, and here it is the female has taken up her abode. She is visible as a small white, brilliant spot. Besides the wrist, the inner faces of the fingers, and the interdigital areas are most commonly affected, and the palms of the hands.

If there is any doubt as to the cause of the existence of these tunnels, a diagnosis can easily be verified by extracting the mite. With the point of a needle, held almost parallel with the skin, the tunnel can be slit open, and when the point has reached the inner end the mite is very apt to seize it with its suckers, and can be so withdrawn, and, if not, it can easily be picked out. It can then be examined in a drop of diluted glycerine under a microscope.

I am no doctor, and I am proving but a poor zoologist in writing about mites under the title of "Insects and War," hence I venture to refer the readers of the British Medical Journal to the article on scabies in the *Encyclopaedia Medica* by Dr. G. Pernet and to quote the following paragraphs from Dr. H. Radcliffe Crocker's *Diseases of the Skin*, third edition, vol. ii:

Symptoms and Pathology.—The clinical picture of scabies is made up of two elements: the burrows, or cuniculi, and the attendant inflammation excited directly by the *Acarus scabiei*; and indirectly, the lesions produced by scratching, and the modifying influences of pressure, friction, etc. The result is a great multiformity of lesions, which, combined with their distribution, is in itself suggestive of the nature of the disease, and enables a practised eye to detect a well-marked case at a glance.

When the skin is first penetrated by the acarus, inflammation is often set up, and a papule, vesicle, or pustule is the

consequence. These papules or small vesicles, individually indistinguishable from eczema vesicles, are the most common form of eruption, but the inflammatory symptoms are absent in many burrows. The tract extends and forms a sinuous, irregular, or rarely straight line, which in very clean people is white, but, as a rule, is brownish or blackish from dirt being entangled in the slightly roughened epidermis; the length of these burrows is generally from an eighth to half an inch, but occasionally much longer, Hebra having noticed one four inches long. When a pustule is formed, part of the burrow lies in the roof, but the acarus is always well beyond the pustule or vesicle, or if there is none, lies at the far end, and with a lens may often be discerned as a white speck in the epidermis. The degree and number of inflammatory lesions vary much; there may be no inflammation at all about many burrows, or the whole hand, especially in children, may be covered by pustules, vesicles, or papules, and, indeed, a pustular eruption on the hands is always strongly suggestive of scabies; there is, however, no grouping or arrangement of any of the eruptions, as in eczema, the lesions being scattered about irregularly. It must be remembered that burrows are not always present, from various causes. If the disease is recent it may not have got beyond the papular or vesicular stage, while in washerwomen, bricklayers, or others whose hands are constantly soaked in water or alkaline fluids, or who have to scrub their hands violently, the burrows become destroyed. The eruptions due to scratching have already been described in the descriptions of the "scratched skin," and comprise excoriations, erythema in parallel lines, eczema, impetigirous or so-called ecthymatous eruptions and wheals, and the

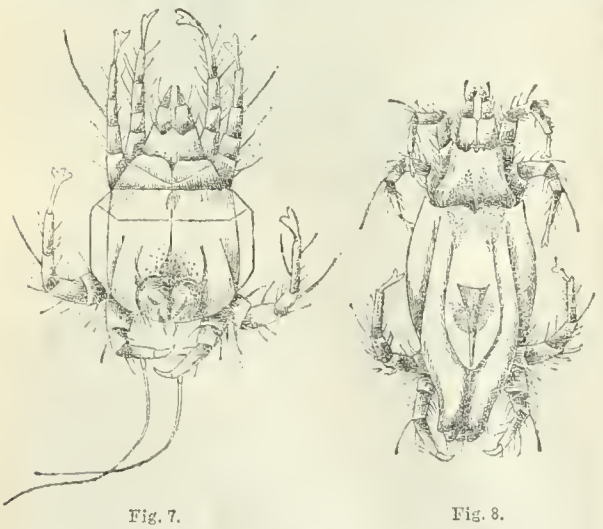

Fig. 7. Fig. 8.

Nephrophages sanguinarius (enlarged). Fig. 7: Male, ventral surface. Fig. 8: Female, dorsal aspect. (After Miyake and Scriba.)

inflammatory scab-topped papules often left after the subsidence of the wheals, especially in children. In carmen, cobblers, tailors, and others who sit on hard boards for hours together, pustular and scabbed eruptions, situated over the ischial tuberosities, are so abundant and constant as to be practically diagnostic of scabies in such people. Similar eruptions may be seen where there is friction from trusses, belts, etc.

Treatment.—I use in private practice, after the preliminary soaking and scrubbing, naphthol 15 parts, cret. prep. 10 parts, sap. mollis 50 parts, adipis 100 parts, as recommended by Kaposi, well rubbed in. For infants it can be used half-strength, and I omit the soft soap. I can speak of it in the highest praise. It is effectual, has no smell, and is not liable to irritate the skin, as sulphur does. It is, however, too expensive for public practice. Nephritis has occurred from its over-use, but I have never seen any bad symptoms. Another remedy less likely to irritate the skin than sulphur is balsam of Peru, of which the vapour alone is said to be fatal to the acari. The balsam is rubbed in for twenty minutes every night, a night shirt impregnated with the drug is worn, and in the morning an ordinary soap-and-water bath is taken. Hallopeau has recorded cases of ulceration of the skin produced by it.

Colonel Alcock says that the best treatment for the itch "consists in the free use of soap and hot water and the liberal application of sulphur ointment, continued for several days. Some prefer baths of potassa sulphurata (1 oz. of the salt to 4 gallons of water). Clothing and bedding should be fumigated with sulphur or baked."

Endo-parasitic Mites.

Certain little mites whose appearance is as repellent as their name, for they are known as *Nephrophages sanguinarius*, were recorded by two Japanese observers twenty years ago as coming away in the urine of a Japanese patient who was suffering from various bladder troubles. As the mites were in all cases dead, the Japanese doctors thought that they must have been endo-parasites of the kidney. They were found day after day for a week or more, and they were found also in the water with which the bladder had been washed out, but always dead. It is, of course, possible that the Japanese doctors were right in their surmise, but the best that can be said for the case is that it is "not proven" (Figs. 7 and 8). These awful-looking little mites are said to have two large eyes, and legs of five segments and of equal length. Their colour is greenish to brownish yellow. Undoubtedly there are many mites which live as endo-parasites; certain members of the group Analgesinae, such as *Laminosioptes gallinarum*, live in the intramuscular and subcutaneous tissue of fowls, and *Cytoleichus sarcoptioides* in their air sacs. I have myself found one of these species in the pigeon, so that it is by no means beyond the bounds of human possibility that *Nephrophages sanguinarius* really lived in the tissues of the Japanese; very strange things live in the tissues of some Japanese.

EIGHTY-SECOND ANNUAL MEETING

OF THE

British Medical Association.

Held in Aberdeen on July 29th, 30th, and 31st.

PROCEEDINGS OF SECTIONS.

SECTION OF STATE MEDICINE AND MEDICAL JURISPRUDENCE.

Professor MATTHEW HAY, M.D., LL.D., President.

OPENING REMARKS BY THE PRESIDENT.

IT must be to many of us a matter of some surprise that the Section over which I have had the honour of being invited to preside should continue to combine within it two subjects on the whole so different as medical jurisprudence and State medicine, as they are usually understood. I grant that both are largely concerned with an endeavour to track and rout or punish the enemies of man—in the one case his human and in the other his bacterial enemies—and I must also admit that the combination of the subjects is still met with in the chairs or lectureships in these subjects in a few of our medical schools, and notably in Scotland. But the two subjects have in recent times drifted far apart, and only a few medical men like myself remain attached to both, in practice and in teaching. I am glad to be able to say, in the interests of both subjects, that the combination will in this university altogether cease when I relinquish my chair, and that in the earlier part of the present month our university court has appointed within the still dual department a full time lecturer in public health, and has thus realized a wish that I have long cherished.

But the Association has at this and the meeting of last year taken a somewhat different method of lightening the combination. They have carved a large slice from a juicy part of the State medicine joint and set it on a plate of its own, and, with the facility in nomenclature peculiar to the table, have named it "medical sociology." I am not going to complain. I would only suggest that perhaps by another year those who control these matters may have contrived to define more clearly which part of State medicine they propose thus to detach. Perhaps the title of "State medicine" might go with the abstracted part, and the more appropriate designation of "preventive medicine" be given to the remanent mother stock. This would, however, still leave the somewhat incongruous conjunction of medical jurisprudence and public health. But medical jurisprudence is, as usually treated at medical meetings, a small subject with rather limited interests, and I fear must continue to shelter itself under the wing of some bigger brother. Which brother is the difficulty.

Familiar as I have occasion to be with both medical jurisprudence and preventive medicine, I cannot help at times contrasting the attitude of the public mind towards, on the one hand, the hunting down and the extermination of the murderer of a single human life, and towards, on the other hand, the discovery and removal of the cause of an epidemic of disease by which hundreds of human lives may be perishing. If some imaginary statistician could be get to count all the words devoted in the public press of the civilized world to the accounts of the beginning, course, and ending of such a murder case as, say, the Crippen case, and similarly to the accounts of the tragedy of some holocaust of human life such as was witnessed in quite recent years in India when some two or three millions of persons died of plague, none of us would be surprised to find that, thus measured, a single murder excited apparently far more human interest and attention than a devouring pestilence. The striking contrast is not greatly to the credit of civilization.

Yet if the particular case in medical jurisprudence, if only tragic enough, appeals more strongly to the ordinary human mind than the particular case in hygiene, we are in these days certainly not without many general appeals and addresses to us in health matters. I feel, therefore, the more free in the limited time at my disposal to devote the remainder of my remarks to medical jurisprudence, and especially to the chief subject in it—the criminal. I am frankly glad that in our time there is a steadily growing desire to see justice done to the criminal, but not quite the kind of justice which such a phrase would have implied 100 years ago. The modern study of lunacy, since lunacy began to be recognized as a disease or a physiological defect and not as some sort of demoniacal possession, has led to an infinitely more humane and just treatment of the ordinary lunatic, and has as a side issue led also to a closer study and understanding of the psychology and genesis of the criminal. I have no wish to be regarded as a fatalist, but I agree with those who hold that each of us, physically, mentally, and morally, is in the main what our parentage and our environment have made us. And if we view the criminal from such a standpoint as I maintain we should, and predict we shall, the more we advance in civilization, then we shall find ourselves becoming more and more accustomed to talk of the treatment of the criminal and less of his punishment. It is largely due to the teachings of medical science in its broadest sense that such views are now being extensively held, and have begun in some measure to be acted on in our legal procedure, although I may be pardoned for saying that the legal profession, through its judicial heads, has accepted such views with much, but perhaps excusable, caution. The public are now becoming alive to this side of the question in criminality, as much from their education by the biologist and the sociologist as from the teachings of medical men. America led the way a considerable number of years ago, and we are now rapidly following, our latest step being the Mental Deficiency Act, which, if whole-heartedly worked throughout the country, cannot fail to introduce a new era in the treatment of defectives, intellectual and moral, and to lessen crime, both directly and indirectly.

In a community of ideal civilization all measures for dealing with crime would aim at its prevention and not at its punishment. If prevention required detention or segregation of the criminal, detention would be practised, and continued in grosser offences for such time, whether months or years, or even a lifetime, as would be necessary for the proper treatment of the criminal or for the public protection; but the detention would be characterized by the humaner treatment now everywhere found in our lunatic asylums, and even now noticeable in our prisons. We have within the last few centuries of the world's progress got rid, in most countries, of nearly all the barbarities of punishment which characterized a long series of preceding centuries. And yet in such countries it is, I believe, true generally to say that serious crime was never less rampant than now. It is a mistake to suppose that the more cruel the punishment the greater will be the deterrent to crime. The one barbarity remaining to us in this and some other countries, in which in other matters the modern humane and scientific view is being increasingly held, is the death sentence. It would not be difficult to show, if time permitted, that it is no deterrent of deliberate murder. Its only justification, in my opinion, is the eugenic one, but the eugenic end could be otherwise attained.

Gentlemen, if you ask me along what lines medical jurisprudence in recent years has made its greatest and most beneficent advance, I answer unhesitatingly that it is in our changed attitude towards the criminal. As with disease, so also with crime, prevention is better than cure. And in this saying the union of State medicine and medical jurisprudence may, after all, find justification.

DISCUSSION ON THE REFORM OF THE VITAL STATISTICS OF THE NATION;

WITH SPECIAL REFERENCE TO DEATH CERTIFICATION.

OPENING PAPERS.

I.—Sir Victor Horsley, F.R.S., F.R.C.S.

The condition of our national statistics as regards life and death merits the earnest attention of every one and naturally the medical profession in the first place. The British Medical Association has always taken a leading and very initiatory part in dealing with this subject, but, unfortunately, the statesmen charged with the duty of providing our vital statistics have never realized their immense significance to public health. Consequently the proposals of the Association have been passed by unheeded. Of course, one reason for official inertia is the oft-recurring one of expense, and here again, until the advent of Mr. Lloyd George, no Chancellor of the Exchequer has ever apparently been cognizant of what health means to a people. But there is another reason, namely, that the medical profession has been exceedingly remiss in not furnishing the Government departments with a classification of diseases of real scientific value. What is called the *Nomenclature of Diseases* prepared by a joint committee appointed by the Royal College of Physicians of London, bearing its imprimatur, and on which unfortunately the Registrar-General relies,[1] is essentially ridiculous in its terminology if it is to be employed as an aggregate of the causes of death, for it is not a nomenclature of diseases but a list of symptoms. For instance, the following are actually put down as diseases:

Hiccough	Vomiting
Hyperaesthesia	Stiff Joint
Trance	Delirum
Vomica	Lumbago

etc., etc.

There is a definitive difference between a "disease" and a "symptom" which apparently has not yet been fully recognized by the College of Physicians. The direct result of the use of this volume is to be seen in the almost useless lists of "diseases" contained in the Registrar-General's returns of deaths in England and Wales,* and also even those agreed upon between the different European peoples, and known as the International Lists. Of course every one recognizes that there is an essential difficulty in this matter owing to the incessant progress of pathological science. Those who have been educated with a certain terminology cannot easily acquire a new one, and yet as pathological science is continually progressing, so of necessity the terminology alters. Scientific discoveries, however, simplify and make more distinct the direct causes of death, which fact is gradually appreciated, and made use of by the profession at large. If it were not so, the subject of the nomenclature of diseases would be in a much more unfavourable state than it is even now. This point is one which I laid before the Venereal Diseases Commission, but it seems to me so essential to the future of public health in this country, and for the matter of that in the empire, that it must be dealt with by our Association. As I have already stated, the responsibility for our false statistics really lies to a very large extent with the authors of the volume *Nomenclature of Diseases* (so called) because by it the profession has been led or encouraged to employ expressions which on the face of it are hopelessly inaccurate.

To give an example out of a very large number, one of the worst instances is a "cause of death" called "hysteria,

* Practically adopted in Scotland and Ireland.

neuralgia, neuritis." These "diseases" are stated by the Registrar-General to have caused the deaths of 160 males and 398 females in 1911—that is to say, no less than 558 persons; of these 57 are stated to have died of "hysteria, neuralgia, and sciatica," however incredible it may appear, and no less than 501 of "neuritis." Of course the "neuritis" cases are really deaths due to alcohol, and, as shown in Table LXVIII (Registrar-General's Report, p. lxxxvi), in some 80 cases the practitioner certifying did venture to risk his professional practice and add the real cause of death—namely, alcohol—to what was essentially an absurd one.

The moral responsibility for the present situation, therefore, would seem to rest considerably on the profession, and a thorough reform of the volume of the College of Physicians must consequently be taken in hand by the British Medical Association. This is no new task for the profession. The late Dr. Sykes, M.O.H. for St. Pancras, insisted on the reform of this *Nomenclature of Diseases* when giving evidence to the Select Committee on Death Certification twenty-one years ago. That Committee (1893), however, reported in a very uncertain manner on the whole subject, and consequently produced little or no effect on death certification and none at all on the preliminary nomenclature or definition of diseases, which has only been slightly altered by the general progress of knowledge and the efflux of time.

My first proposal, therefore, is that our Association should move in this matter and produce a real Nomenclature of Diseases from which all the old loose terms and archaic names are expunged. I am well aware of the great difficulty that will be experienced in getting the help of workers on this point, because the attention of the profession is so fully occupied, and until the great general and social questions affecting us at the present day have to some extent been settled, active reforms in medical scientific terminology will doubtless have to wait. The Public Health Service of the nation will, however, proportionately suffer by such delay.

Let us turn now to the question of direct confidential certification of death. Exactly ten years ago the British Medical Association formulated its views on the certification of death, and drew up specific principles, according to which, in its opinion, certification of death, to be of any real value, should be guided. These principles are contained in a first draft form in the Report on this subject laid by the Medico-Political Committee before the Representative Meeting in 1904 (Minutes, 1904, R.M., p. 76). That draft contained the following clauses:

3. The medical practitioner shall transmit to the Registrar direct the certificate in a sealed envelope.
4. The certificate shall be a confidential document subject to the discretion of the Registrar-General.

In addition the Committee's report provided that not only should the practitioner be required to view the body after death, but that he should be paid a fee for the certificate, and, finally, that in addition there should be an arrangement made for an autopsy being performed (in any uncertain case) at the cost of the State. This last point led in 1904 to the report being referred for further consideration, and at the Representative Meeting in the following year the whole subject was again reported upon, and the report finally approved. This Report of 1905 provided that the certificate of the fact of death and of the cause of death should be separate documents. Thus the British Medical Association's scheme was quite complete. Its principles had been laid fully before the Registrar-General on February 23rd, 1904, by a deputation headed by Mr. Andrew Clark, then Chairman of the Council, and including Dr. Greenwood, Dr. Heron, Sir Victor Horsley, Dr. O'Sullivan, Dr. Whitaker, and Mr. Ellistou; Dr. Bateman attended in representation of the Medical Defence Union. Although the deputation fully explained to the Registrar-General the urgent necessity of altering the system of death certification because the national death statistics were so utterly untrustworthy, nothing was done, the Association's proposals were pigeon-holed and completely forgotten, indeed, there is evidence that nothing would have been done had it not been for the fact of the Royal Commission on Venereal Diseases being appointed. That Commission naturally required to know how many deaths really occurred in the nation from venereal diseases, the certification of which is notoriously as worthless as that of alcohol. Dr. Stevenson, to whom I am obliged for very kindly supplementing the official abstract of his evidence, stated to the Commission that he strongly advocated a general system of confidential certification under which certificates of the cause of death would not be handed over to the surviving relatives.*

I gave evidence to the Royal Commission on March 27th and explained the position of the Association on this point. The evidence of the Commission has of course not yet been published, but the abbreviated official report in the press of that evidence is correct, except that it does not lay sufficient stress on the great primary importance of *confidential* death certification or refer to the fact that the origination of this reform in this country was entirely due to the British Medical Association.[3]

I should like now to make quite short reference to what has been done abroad, and I will take as examples the cases of France and Switzerland. In the history of this subject the most interesting contributions are those of Bertillon and Brouardel in France as follows:

The system adopted thirty years ago by the Municipality of Paris was devised by Bertillon[4] to preserve the confidential character of the certificate of death. The certificate furnished by the medical practitioner is numbered and kept secret by the Registration Office as follows. On notice of a death the civil authority sends to the practitioner a form for the cause of death which is denominated by the number only. The *numbered* form giving the facts of the cause of death is then sent to the Statistical Bureau.

Brouardel[5] in 1888 found two sources of gross errors in the national vital statistics of France.

1. Apathy of many medical practitioners towards vital statistics, and therefore carelessness in certification.
2. Impossibility of attaining accuracy owing to risk of revealing professional "secrets," for example, alcoholism, syphilis, etc., in filling up existing certificates.

The Association des Médecins de France, on May 3rd, 1886, adopted a scheme of regulations by which the certificate of death is transmitted by the medical practitioner who attended the deceased in a sealed envelope to the chairman of the Health Committee of the district. All the records are then preserved in the office of the medical officer of health for the whole department (county). In this way the confidential character of the registration has been secured for many years in France.

The other example I would quote is that of Switzerland; for the simplest and at the same time the most complete is the Swiss system. The practitioner is furnished by the civil authorities with a form the upper part of which is detachable, and contains only the name of the deceased and a series number. This part is torn off and placed in a distinctive envelope by the practitioner in attendance, and must be delivered to the local registrar within forty-eight hours. The rest of the serially-numbered form contains spaces for the details of the cause of death, with a space wherein the practitioner can note the sanitary and social conditions of the dwelling of the deceased. This part is placed in a separate coloured envelope and sent with the other to the local registrar, who, however, forwards this second one unopened to the Central Health Statistical Bureau. The practitioner is remunerated for his certification.

There is no doubt that the Swiss system is in every respect worthy of our imitation, and none the less that it has for a number of years successfully carried into practice the principles agreed to by the British Medical Association ten years ago.

The next direction in which our vital statistics can be improved is the completion of certain legislative reforms, which are partly accomplished, but to perfect which a good deal remains to be done. One of the most important of these is certainly the notification of births. Unfortunately this fundamental principle of public health has been to a large extent hindered by two administrative errors, against both of which the British Medical Association protested, but, as usual, its protestations were not heeded by the Government officials. Thus, in the first place, the Act was only permissive, not compulsory; and in the second place, it made no provision for the

* Since this paper was read the said evidence has been published, namely, Cd. 7475.

remuneration of the practitioner who was called upon to do the work of the State. Where it has been adopted it has proved of the utmost value in assisting to reduce infantile mortality; therefore its operation ought to be made universal. If this is done, then the question of a proper fee for such notification would naturally be settled at the same time.

Closely associated with this reform of the notification of births is that of the certification of stillbirths, which the British Medical Association pressed for in 1905 through the Representative Meeting (Minutes, 1905, p. 110). This would secure for the nation national statistics on a subject on which it has practically no information—namely, antenatal conditions, which are to a large extent responsible for the high infantile mortality, and in any case are of immense importance in the difficult subject of national deterioration and its prevention.

Summary.

A study of this whole subject shows that very fundamental reforms are immediately necessary in our system of national statistical administration, quite apart from the item of certification of death. In the first place, the office of the Registrar-General ought to be completely reconstituted as a sub-office of a Ministry of Public Health. At the present moment it is in effect a sub-office of the Local Government Board, but it cannot be said to be sufficiently co-ordinated with that Department; in fact, it never can be an adequate part of the public health system of our country until it is an essential portion of a Ministry of Public Health, which will unite the three existing and inco-ordinate branches of public health work—namely, the Local Government Board branch, Public Health and Poor Law just referred to, the Board of Education branch, and the Home Office (Factories, etc.)* branch. In the second place, the Registrar-General must be some one who has received a medical education and thoroughly understands the biological problems of vital statistics.

In spite of the rebuffs of its work and the studied neglect of its proposals, the British Medical Association will, I believe, accomplish this national work, and thereby add another to the many benefits it has conferred on an apparently non-appreciative public.

II.—William Bruce, M.D.,

M.O.H. Dingwall.

Dr. Bruce said that, though he had carefully perused the evidence as given in the Report of the Foster Parliamentary Committee (1893) on medical certification of the cause of death, he did not propose to enter at any length into the criminal side of the subject, which was there dealt with as the main reason for reform. He would limit himself chiefly to the public health aspect of the question. He thought it might be taken as granted that every one qualified to discuss the question of the reliability of medical death certificates knew that these certificates were not at present absolute proof of the fact that death had actually occurred. Such a certificate was, legally speaking, useless. It was valuable only for statistical purposes as showing the mortality of certain diseases incident to certain ages, occupations, etc., in certain localities compared with the results of a like nature in other registration districts. If these figures were to be of substantial value from the point of view of public health every effort should be made to make sure they were as correct as possible. Was any attempt made, except, perhaps, in notifiable infectious diseases, to secure perfect accuracy? To compel the medical attendant without fee or even thanks to fill up the usual certificate might well be little more than a farce in too many cases. He did not accuse his medical brethren of moral delinquency, but it could not, he thought, be disputed, that a considerable proportion even of British certificates were granted on insufficient grounds. As to the means by which the character of these documents could be improved, he suggested that if the blank certificate with the name and address of the medical attendant were sent in the first instance to the medical officer of health of the district and through the medical officer of health, for particulars of the cause of death, transmitted to the medical attendant with instructions to be returned to him (and not to the local registrar), it would be open to the medical officer of health to get further information from the medical attendant, if he deemed it to be necessary, before finally deciding as to the real cause of death to be entered in his register. A copy of the entries in this register would be sent periodically to the Registrar-General for statistical purposes. The course suggested offered the following advantages:

Increased value of facts as ascertained.
Secrecy.
Certification of death having actually occurred.
Information of non-notifiable infectious disease having made its appearance in his district.

Where the medical attendant had reason to believe there might have been foul play, he could explain his suspicions to the medical officer of health (with whom he should be on the most confidential footing), and in this way save himself from the odium of interference by letting the medical officer of health decide whether he should communicate his suspicions to the proper legal authorities or not.

The statistical value of certification would be increased if vague terms such as "debility," "old age," "failure of heart's action," "alcohol," "peritonitis," "heart disease," "bronchitis," were amplified. In this connexion he referred to the parallel case of pulmonary tuberculosis notification, where the bald certificate needed in practice to be supplemented if it was to be of much value. With regard to secrecy, practitioners were often afraid to trust local registrars, who were in a position to give, and indeed might be compelled to give, practically to the public at large, copies of the cause of death as certified. Doctors accordingly avoided the use of such terms as "cancer" "puerperal fever," "tuberculosis," and most certainly specific diseases such as "syphilis." Were the medical man assured that his certificates would be confidential it would be much more trustworthy. Early notice of death and its cause would often prove of much value to the medical officer of health by giving him the chance of isolating contacts and disinfecting premises in non-notifiable diseases.

Non-certified cases of death ought to be followed up by the medical officer of health, as in Glasgow and, he believed, in Edinburgh.

Dr. Bruce concluded by presenting the following table showing the present mode of certification and his suggestions for reform. Aware of the difficulty of carrying out changes in a long-established system, he had made the procedure to vary as little as possible from that now in use.

Present Mode of Procedure.	*Suggested Mode of Procedure.*
1. Registration of a death must take place within 7 days of death.	1. Registration to be effected within *24 hours* of death.
2. On the statement of a "qualified informant" given to the local registrar he enters the name of the dead person with particulars of age, sex, etc., and residence in his register.	2. No change.
3. A blank medical certificate of the cause of death is forwarded by the registrar to the medical attendant.	3. No change.
4. The medical attendant returns the completed certificate (under penalty) to the local registrar within 14 days of its receipt, who enters a copy of it in his register.	4. The medical attendant fills up the cause of death and returns the completed certificate to the M.O.H. within 24 hours of receipt.
5. Where there is no medical attendant the local registrar makes the best of any information he can get and enters it in his register. Failing evidence he sets the case down as uncertified. If he suspects foul play he directs the attention of the coroner in England or the procurator-fiscal in Scotland to the case.	5. The M.O.H. instructs the sanitary inspector to visit the residence of the dead person (*a*) to ascertain to the fact of death having taken place; (*b*) to report as to environment, and send report forthwith to the M.O.H.

* See also the *Times*, April 13th, 1914.

6. A copy of entry in his register is supplied by the registrar on payment of a fee.

6. The M.O.H. may refer to the medical attendant for further information on payment of a fee of 2s. 6d.

7. Where there is no medical attendant the M.O.H., after inquiry, if he suspects foul play, refers further investigation to the coroner in England or the procurator-fiscal in Scotland.

8. The M.O.H. shall keep a register of the causes of all deaths, so far as ascertained by him, and make such returns as may be required by the Registrar-General.

9. The M.O.H., on payment of a fee of 2s. 6d., shall hand copies of registration to the informant or other party interested in the fact of death.

BURIAL CERTIFICATES.

Present Rules.

1. The local registrar grants orders for burial on production of a medical certificate of cause of death or in default of such certificate, after inquiry he allows burial to take place, reporting such cases to Registrar-General.

Suggested Rules.

1. The local registrar shall furnish the informant with a blank order for burial, which must be signed by the M.O.H. in order to be effective when produced to the cemetery authority for interment.

2. This order shall be returned after burial to the M.O.H. by the cemetery authority.

III.—JAMES C. DUNLOP, M.D.,

Superintendent of Statistics, General Register House, Edinburgh.

I HAVE listened with great interest to the communications made by Sir Victor Horsley and Dr. Bruce, and while in agreement with some of what was said by them, I am in disagreement on several points. Sir Victor Horsley severely criticizes the *Nomenclature of Diseases*, a work for which the Royal College of Physicians of London is responsible. That work is no doubt imperfect, and as one engaged in the work of the classification of causes of death I would welcome a more perfect volume. But such perfection is hard to obtain. The description of the cause of death in death certificates, though on the whole wonderfully good, is often faulty, and very considerable improvement is possible. As instances of bad certificates, bad in various ways, I may submit the following:

Shock, result of hard labour.
Pulmonary bronchitis.
Asthenic exacerbation, heart failure.
Affection of stomach and bowels.
Senile decay, duration six years, five months, and twenty-two days.
Inward convulsions.
Natural causes, supposed.
Intestinal hydrocephalus.
Pneumococcal poisoning.
Pneumonia seven days, congestion of lungs four days.
Natural causes, or the result of falling into a ditch at the side of the railway.
Probable cause of death asphyxia, the usual result of drowning.
Pneumotyphus (by inquiry found to be a death from typhoid fever complicated by pneumonia).
Asthenia during life.
Typhous pneumonia (subsequently reported as latent pneumonia of typhoid type).
Placenta praevia fifteen years.
Pernicious anaemia, albuminuria.
Apparently spasm of windpipe.
Asphyxia three hours.
Tonsillo-laryngo-trachco-bronchitis.
Probably decapitation.
Phthisis, outcome of cab accident.
Senile decay five days.
Cerebral enteritis.

I give these examples of bad and even absurd certificates as curiosities; they must not be taken as being in any way a fair sample of causes of death as registered. They are merely pickings out of some hundreds of thousands of certificates, and in no way whatever give any reasonable indication of the goodness or badness of the vast majority of the death certificates received. I think I am safe in asserting that 99 in 100 of the certificates received were well and carefully worded and efficiently met the requirements of registration. There are some bad ones, perhaps too many, but they constitute a minority.

Sir Victor Horsley passes on to discuss the difficult question of whether the medical certification of death should be confidential, and makes three suggestions, (1) that the certificate should be sent to the registrar and not given to the informant, (2) that it should be strictly confidential, and (3) that the name of the person and the fact of death should be reported on one schedule while the cause should be reported on another, the two schedules being traceable one to the other by numbering. I may point out that in Scotland the medical certifier is not required to hand his certificate to the informant, but his duty is to transmit it to the registrar. This has been so since registration was instituted in 1855, and no doubt has much to commend it, but it may interest Sir Victor Horsley and others holding his views to know that the majority of medical men in Scotland find the most convenient way of transmitting the certificates to the registrars is by handing them for that purpose to the informants. In considering the question as to whether medical certification should or should not be confidential, one should bear in mind what registration is. It is not an administrative machinery for the production of vital statistics, but an administrative machinery for making and keeping records of the most important events in the lives of individuals, their births, their marriages, and their deaths. Such is the great primary function of registration, and not the preparation of vital statistics. The vital statistics are a by-product of registration, one whose utility and importance cannot be exaggerated, one which simply could not be dispensed with, but, for all that, their preparation was not the only—and perhaps not even the most important—of the functions served by national registration. Bearing that fact in mind, one should consider the other requirements of registration as the preparation of the statistics, and should not advocate radical changes of registration for the purpose of improving the statistics if those radical changes would interfere with the primary functions of registration. Personally I do not like the idea of confidential certification, for I hold that a death register would be incomplete without a statement of the cause of death, and the inclusion of such a statement in what was a public document would be impossible were the certificates treated as confidential.

Sir Victor Horsley advises "certification" of stillbirths. By this I suppose he implies their registration. I disagree with him here also. It is a subject of statistical interest only, and not one calling for public record, and as such would be more reasonably dealt with by notification to medical officers of health than by recording in permanent registers.

One other suggestion of Sir Victor Horsley with which I also disagree is that the Registrar-General should be a medical man. The preparation of vital statistics is only one of his many duties, and though medical knowledge is most desirable for that duty, other special training is very essential for his other duties. For instance, there are points of law, more especially of marriage law, referred to him for decision. In Scotland, by statute the Registrar-General must be an advocate of not less than ten years' standing, and I personally would be very sorry to see that limitation removed.

I disagree with Dr. Bruce's suggestion that the registration of the cause of death should be taken away from the Registrar-General and put on medical officers of health, and fail to see either how death registration or vital statistics would be improved thereby. Whether the registrars' offices should be in closer touch with the public health administration, or even combined with some medical offices—say those of parish medical officers—is a matter which in my opinion is worth consideration, but I am unhesitatingly opposed to the transfer of the registration of the cause of death from national registers to local registers kept by medical officers of health.

IV.—A. K. CHALMERS, M.D.,

Medical Officer of Health, Glasgow.

THE writer of the *Manual of the International List of Causes of Death*, issued by the Census Bureau of the United States, observes in his introductory paragraphs

that the remarkable progress of what is known as the international classification of diseases and causes of death "could only be explained by the fact that there was a wider recognized need for national and international uniformity of classification, and that the system proposed fairly well met the demands . . . and proved capable of progressive development as these demands changed with the advance of medical knowledge.

"As late as 1893," he continues, "no two countries in the world employed precisely the same forms and methods of statistical classification of causes of death, and this lack of uniformity rendered statistical results incomparable. . . . At a session of the International Statistical Institute at Chicago in that year Dr. Bertillon presented, on behalf of a special committee appointed for the purpose, a draft classification for international use. This draft was promptly adopted, and subsequent resolutions suggested the propriety of keeping the classification abreast of scientific progress by means of a decennial revision. Two sessions of the International Commission held in Paris in 1900, and again in 1909, bring the list to the point which it has now reached."

So far the history of the movement, as outlined in the manual to which I have referred, but for our present purpose the interest begins in two recent changes in the method of tabulating the data on which the vital statistics of Scotland are based. These changes may be described as:

(1) The substitution of the public health administrative area for the registration district, or group of districts, as the geographical unit; and
(2) The introduction of a system of transferring births and deaths from the place of their occurrence to that of the usual place of residence of the mother or of the deceased person.

It is at this point that the revision of the *International List of Causes of Death* lends stimulus to the movement for uniformity and emphasis to the need for applying it on some readily understood plan.

According to the Registrar-General of England there are no fewer than 200 "unauthorized, indefinite, and otherwise undesirable terms" more or less commonly used in death certification. In place of this the International List provides 189 separate classes of subtitles arranged in fourteen principal groups in the following manner:

I. General diseases, containing ...	59	classes of subtitles.
II. Diseases of nervous system and of organs of special sense, with ...	17	,, ,,
III. Diseases of circulatory system, with	9	,, ,,
IV. Diseases of respiratory system, with	13	,, ,,
V. Diseases of digestive system, with ...	20	,, ,,
VI. Non-venereal diseases of the genito-urinary system, with	15	,, ,,
VII. The puerperal state, with	8	,, ,,
VIII. Diseases of the skin and cellular tissue, with	4	,, ,,
IX. Diseases of the bones and organs of locomotion, with	4	,, ,,
X. Malformation, with...	1	,, ,,
XI. Diseases of early infancy, with ...	3	,, ,,
XII. Senility, with	1	,, ,,
XIII. External causes, wounds, poisonings, etc., with...	32	,, ,,
XIV. Ill-defined diseases, with	3	,, ,,

Dr. Bertillon's estimate that this list was already adopted by Governments representing 212 millions of people was formed before its adoption in this country, and there seems reasonable likelihood that during the present decade its use will have extended to all countries where registration of vital statistics is systematically carried out.

The importance of this to the progress of medical research, and especially to the progress of preventive medicine, cannot well be over-estimated. It will discount hasty generalization based on limited data gathered from restricted areas. Interest in the geographical distribution of disease will be quickened, and knowledge of fluctuations in prevalence under different local conditions cannot but add to our knowledge of the natural history of disease.

The International Committee of 1900 issued certain rules to guide the selection of the class into which the death should be placed, when, as occurs in about one-half the cases, two or more diseases are jointly stated as the cause thereof. These have not been universally adopted, the reason in England being that they would involve a break in the continuity of the statistical returns without compensating advantages. Following, however, the example of the United States Census Bureau, the English Registrar-General has issued a *Manual* with rules for guidance in the selection of the dominant disease in such cases, so that it may be said that a beginning has been made in the process of adaptation which will in time produce a greater uniformity than now exists.

The order of preference in the selection of causes when two or more are jointly stated as the cause of death is indicated in Rule 3 as: (1) Violence, (2) general diseases, (3) local diseases, (4) ill-defined causes of death. For diseases or conditions associated with early infancy and old age special instructions are given. Difficulty in selection may sometimes arise between a general and a local disease, but the chief difficulties are likely to occur when one of two local diseases must be selected, and the following samples may serve as illustrations. They have not been taken at random, but are selected because of differences in the numbers tabulated under particular groups by the Registrar-General on the one hand, and locally, using the English *Manual* as a guide.

1. *Deaths associated with rickets*, such as bronchopneumonia, bronchitis, or meningitis. According to Rule 5 of the English *Manual* the general disease "rickets" would, in these circumstances, be selected as the group to which the death belongs. Our local figures suggest that in Scotland the local disease is preferred by the Registrar-General.

2. *Valvular Diseases of the Heart; Rheumatism.*—Rheumatism as a term is starred in the rules, and consequently is subject to further inquiry by the Registrar-General. The supplementary information thus obtained would in all probability determine whether the disease is to be included among *general* diseases under rheumatic fever, or allocated to *local* diseases—in this case the diseases of circulation.

3. *Gastro-enteritis, and Meningitis.*—When both diseases are mentioned without duration, the death would, I think, according to the English *Manual*, fall into diarrhoea and enteritis as a local disease of the digestive system, being the first disease shown, while meningitis in Scotland would, I think, be taken in preference to diarrhoea. A similar observation may also, I think, be made regarding gastro-enteritis and pneumonia, the latter being preferred in Scotland. On the other hand, bronchitis and congestion of the lungs occurring in combination with epidemic diarrhoea would, according to Rule 9, Column "A," be regarded in England as a disease of the digestive system, and I am not sure that the same grouping would not be adopted in Scotland in this case.

I should explain that our practice, down to and including 1912, in dealing with certificates containing two causes of death, was to take that which was first stated, save where one of them was an infectious disease.

For 1913 we have endeavoured to follow the rules in use in the General Register Office, England, for the selection of one from two or more jointly stated causes of death, and a few samples of the results will supply illustration of the need for obtaining some definite guide for the construction of local returns.

Cause of Death.	Old Method (Local Classification).	New Method (Local Application of Rules of English *Manual*).	Registrar-General (Scotland).
Influenza	71	92	32
Pneumonia	1,612	1,615	1,777
Bronchitis	1,153	1,092	1,267
Other respiratory diseases	292	295	261
Diarrhoea and enteritis...	753	833	751
Circulatory diseases ...	2,047	1,814	1,496
Cerebral haemorrhage (apoplexy)	744	733	879
Meningitis (not tuberculous)	199	206	236
Cancer...	979	996	1,056

Before considering these in detail it is well to remember that local classifications of causes of death, and more especially of causes of death through affections of the various physiological systems, can scarcely ever agree

numerically with classifications carried out in the Central Register Offices, for the reason that so many of them are starred for reference to the certifying practitioner for further information, and that this information, which may affect the final placing of the particular death, is not communicated to the medical officer of health.

Apart from this, however, the illustrations quoted will serve to show how far we are at present from being able to avoid two sets of mortality figures for the same area. The total deaths will correspond in number, as will also the number of deaths from many of the infectious diseases, but there is something more than a risk that discrepancies in the other groupings will be frequent and considerable.

If, for example, one takes the figures for influenza and pneumonia in the foregoing list there is an excess of 102 in the total, but 60 of those might be explained by a transference from influenza to pneumonia. Similarly, if one compares the relative prevalence of both diseases in Ireland and Scotland and includes other forms of respiratory diseases there would appear to be differences in method of classification which suggest that pneumonia in Scotland is relatively more fatal than in Ireland, while the other diseases of respiration are less so. Taking as illustration the male deaths between 1906–11 in both countries, one finds a fair degree of similarity in their annual numbers ascribed to influenza, pneumonia, and other respiratory diseases taken together; but influenza would appear to be rapidly decreasing as a cause of death in Scotland, while its prevalence in Ireland, as well as England, is fairly maintained. There is more than a passing interest in the question, for pneumonia has been increasing in Scotland during the whole period of active sanitation, and in the last decade had a rate of 145 per 100,000 compared with 90 in the Seventies decade.

In view of this discrepancy, one turns to the International List, where influenza is included among the general diseases of Group I; while pneumonia of all forms, save tuberculous, is grouped under diseases of the respiratory system as a local disease. And among the rules adopted in England for selecting one from two or more jointly stated causes of death is one stating that, with a few exceptions, of which pneumonia is not one, any general disease is to be preferred to any local disease, so that where influenza and pneumonia are both stated death would be ascribed to the former. We know that the term "influenza" is often loosely applied, and there is undoubtedly a good deal to be said for selecting any definitely-stated disease in preference thereto, but the object of the International List is to promote uniformity in tabulation, and a common agreement between central and local authorities as to the application of the list is highly desirable.

I select cancer as the next illustration of discrepancy. The difference here shown is + 69, as returned by the Registrar-General, and probably results from the number of starred forms regarding which further information is sought by the Registrar-General from the certifying practitioner. As in all cases when the subtitle is starred for further inquiry, the result of which may, as here, displace the cause of death from one group of causes to another, the medical officer of health should be informed of the result of the inquiry if it necessitates any change of grouping, such as I have indicated.

Diseases of the organs of circulation and cerebral haemorrhage present difference in opposite directions, the local figure for the former being considerably in excess of the Registrar-General's, while that for cerebral haemorrhage is less. Both are local diseases, but the rule (10) under which they fall is likely to lead to many interpretations. When any form of heart disease and cerebral haemorrhage are jointly stated preference is to be given to the former, and this has been rigidly adhered to locally so that part of the difference may thus be explained.

The object of the International List is to secure a uniform basis for international comparisons. The first step in the process is to secure uniformity in national and local returns. In Scotland we have no manual similar to those I have mentioned as guiding the selection in England and in the United States. If, in addition to such a manual, additional information obtained regarding the starred entries in the list were communicated to the medical officer of health, or alternately the Registrar-General were to obtain such information through the medical officer, many of the discrepancies which seem to me inseparable from the present method would, I think, become rapidly reduced.

DISCUSSION.

Dr. JAMES C. DUNLOP said that the instructions as to the selection of the principal cause of death from two or more stated causes set forth in the *Manual of the International List of Causes of Death as Adapted in England and Wales* differed in some essential details from those in use elsewhere, which may be styled the "International Instructions" (see p. 8 of that manual). In the Scottish tabulation more attention had been paid to the recommendations of the International Commission than to the rulings of the English office. The conference suggested by Dr. Chalmers between medical officers of health and the officials of the Registrar-General's office to discuss this matter would be welcomed by the Registrar-General.

Dr. BOYD (Pretoria) considered that the present system of death certification was most unsatisfactory, chiefly because it was in the hands of laymen—the local registrars. It ought to be in the hands of the medical officers of health, who were in close touch with medical practitioners. Under that arrangement there would be less likelihood of leakage than under the present system, and it would also be easier to deal with cases having a possible criminal aspect.

Dr. MCCOLL (Tamworth) considered that the fact of death only should be returned to the local registrar, and the real cause of death to the medical officer of health, if he was a whole-time officer.

Dr. MURRAY (Stornoway) objected to the term "old age" as a cause of death. It would be as reasonable to speak of "young age" as the cause of death from infantile troubles.

Dr. LAFFAN (Cashel) put in a plea for more frequent *post-mortem* examinations prior to death certification.

Sir VICTOR HORSLEY, in reply, said that he had never taken part in any discussion which proved the truth of what he had advanced more than this one. Dr. Chalmers's paper was a striking proof that the present system of death certification was a complete chaos. He moved the following resolution, which was seconded by Dr. BRUCE, and carried unanimously:

> That the British Medical Association reaffirms its opinion that extensive reforms in the administration of the national statistics of life and death are urgently needed, especially the immediate institution of a confidential system of death certification, and the Association therefore calls on the Government to introduce legislation to effect this essential change in the Public Health Service.

LEGAL INVESTIGATION OF CAUSES OF DEATH IN SCOTLAND.

By W. G. AITCHISON ROBERTSON, M.D., D.Sc., F.R.C.P.E.,
Lecturer on Medical Jurisprudence and Public Health, Royal College of Surgeons, Edinburgh.

THE General Registration Act of 1854 as amended by the Act of 1860 is that under which the registration of deaths is carried out in Scotland.

In ordinary circumstances the medical attendant on the deceased is bound under a penalty of £2 to furnish to the registrar of the district or parish in which the death took place a certificate stating that he attended the deceased, and giving the date on which he last saw him alive and also the date and cause of the death. This certificate must be transmitted to the registrar within seven days of the death. If the registrar has received no certificate by the end of this period, he must transmit to the medical attendant a written or printed requisition, together with a form of the certificate, and the latter must be filled up by the medical attendant and returned within three days. This certificate of death may either be handed by the medical attendant to a near relative of the deceased, or it may be sent directly to the registrar.

In the case of a sudden death, or when death has followed on a long illness, if the medical practitioner

knows that the deceased had suffered from a grave malady, and if he is satisfied that this was the cause of death, he may grant a certificate even though he may not have seen the deceased for a very considerable time previous to his death. On the other hand, the medical attendant may refuse to give a certificate of death if he is not satisfied as to its cause—as, for example, in cases of sudden or unexpected death, and death under what he considers suspicious circumstances, death from violence, etc.

Apart altogether from any medical certificate of death, the registrar may be satisfied with the explanation as to the cause of death as given by the qualified informant or relative of the deceased and may on this information grant an order for burial.

In many cases in which the medical attendant feels disinclined to grant a certificate of death he may refer the case to the surgeon of police, and the latter, after investigation, may give a certificate stating the cause of death. Again, either the medical attendant or the registrar, if not satisfied as to the cause of death, may refer the case to the procurator fiscal.

In every case of suspicious death the police first make inquiries, and these form precognitions of witnesses, which must be handed to the procurator fiscal, who then sets on foot an inquiry and examines witnesses privately to find how the deceased came by his death, and if any culpability exists. If these investigations satisfy him, he may then give a certificate to the registrar stating the cause of death. Generally, however, before doing so he asks a medical practitioner to furnish him with a medical certificate based on an external inspection of the body alone. In cases of graver suspicion, however, the procurator fiscal usually instructs two medical men to make a *post-mortem* examination of the body and to supply him with a report as to the cause of death.

The procurator fiscal then sends either a report of the case or the precognitions themselves to the Lord Advocate at the Crown Office in Edinburgh. The Lord Advocate or one of his deputy advocates goes over these, and either stops further proceedings or, on the other hand, public prosecution may follow.

Many persons die without having had the benefit of medical attendance, and this is especially true in regard to the outlying country districts of Scotland. These are known as *uncertified deaths*, and while in large cities these may amount only to 1 per cent., in counties like Ross and Cromarty or Inverness they may amount to 30 or 40 per cent. If we contrast the Scottish with the English methods we may find points of advantage and disadvantage in both.

Date of Certificate.

First as regards the time allowed for certification of the cause of death. In Scotland this is seven days, with three days extra in cases in which the medical man has forgotten to transmit the certificate; in England the period is five days after death, or five days after the jury have brought in their verdict in cases in which a coroner's inquiry has been held. In my opinion these periods are too long. It would be much better if every case of death were certified within twenty-four hours, It is only before burial that proper investigations as to the cause of death can be made, and we know how seldom the authorities grant orders for exhumation. It is just as easy (or as difficult) to certify the cause of death within twenty-four hours as it is to notify a case of infectious disease, and as medical men comply with the law in the latter case, they would soon be educated to comply with it in the former case. The earlier the information regarding a suspicious death is given, the more likely are we to obtain a true idea of the cause of it. In Scotland there may legally be an interval of eleven days between the death and receipt of the certificate—a period much too long to enable proper inquiries regarding the death to be made.

Transmission of Certificate.

Then as regards the handing of the certificate of death to a relative. This ought not to be the custom. The certificate ought to be a confidential document and should be transmitted by the medical attendant directly to the registrar. If this were done, I think it would conduce to greater statistical exactitude. If the relatives of the deceased have access to the certificate (and we know how inquisitive they are to find out what the medical attendant has put as the cause of death), then in very many cases the certificate will not bear the true cause of death. We would not willingly shock the feelings of the relatives by putting down, for example, that death was due to syphilis or delirium tremens. In order to spare their feelings, or not to turn them away from us as patients, the cause of death may be put down as uraemia or pneumonia, while in reality these may only have been secondary causes. We desire as great certainty as may be in the registration of the causes of death, and this can only be obtained in such cases by non-publicity. As one cannot treat certain cases differently from the whole, then in every case the certificate of death should be a privileged document handed directly by the signatory to the registrar. Only in this way will we obtain a more trustworthy certification of death.

Certificate after Long-past Attendance.

Then as regards the granting of a certificate by a medical man who knew the deceased professionally, but who may not have attended him for a long period previous to his death. Obviously this is very irregular. In many cases the cause of death given must be wrong, and thus grave statistical errors, which are incapable of proof, arise. Such a signed certificate is, in truth, little if at all better than an uncertified death. The illness from which the deceased suffered, and which was known to the signatory, may not have been the cause of death at all. A long chronic illness may have little to do with the death of the individual. People with advanced mitral heart disease may have been confined to bed for long, and yet may die from such a disease as cerebral apoplexy, acute influenza, or even from an accident. Again, such laxity in granting a certificate may allow of crimes being overlooked. Police records show many cases in which false statements have been made to medical practitioners regarding the death of one of their old patients, and a certificate of death has been obtained, so allowing the supposedly dead person to draw insurance money payable at his death.

No medical man should ever grant a certificate of death unless he has been attending the deceased very recently—say within one week—so that he may be able definitely to state the cause of death.

Of course, to refuse to grant a certificate to the relatives of an old patient would in many cases appear a very hard proceeding, but if this time limit were laid down by law, no blame could be put on the medical man, who would only be acting in accordance with the legal enactment. I should think that a certificate of death granted with the added words "as I am informed," would invalidate it altogether; yet I understand many such are accepted by registrars.

Fact of Death.

It is the usual custom in death certification for the medical attendant to grant such without his having seen the dead body. He may have seen the patient one, two, or three days previous to his death, and he may have diagnosed the illness accurately, and so fills in the certificate as to the cause of death. Surely this is not proper. The medical attendant cannot certify to a death which he has not himself witnessed, or to a dead body which he has not seen, and yet such certificates are filled up merely on hearsay evidence of some relative or friend who comes for the certificate. Before we can legally grant a certificate testifying to the death of an individual, we ought to verify the fact. By actual inspection alone can this be done, and the statements of relatives or friends cannot be accepted as proof. If this is true in respect of certificates granted by a practitioner who has been in regular attendance on the deceased, *a fortiori* is it true when many days or weeks have elapsed since the certifier has seen the deceased. Though we may have seen a patient yesterday, and may have thoroughly recognized his disease, he may not really have died from it to-day. I remember a case of this kind: a patient was suffering from pneumonia; his friends came to tell me that he had died suddenly, and I might have granted a certificate of death from pneumonia. On inspecting the body, however, I noted the remarkable pallor, and, examining it, found that death had been caused by cut throat, the patient in his delirium having

get up, seized a razor, and so ended his life. The friends, thinking that their carelessness in attending him was culpable, had tried to suppress the fact of suicide.

Another case I remember to have read of was that of a girl who lived with her invalid father in the country. She was engaged to be married to a dissolute young man. The father suffered from bronchitis, and the girl frequently went to the doctor for medicine. One day she appeared with the news that her father had died, and asked for a certificate of death, which the doctor granted. It was only when the undertaker's men were putting the body in the coffin that they discovered that deceased's head had been battered in. Later it transpired that the young woman had done this in a fit of passion.

I have no doubt in my own mind that many crimes have remained undetected by reason of this negligence in certification.

Before a medical man grants a certificate of death he should himself act the part of the French *médecin vérificateur*, and should inspect the dead body. By this means he will be able to determine that death has really taken place, and so will do away with a danger which is to many an ever-present terror, and one which is exaggerated to a morbid degree by certain individuals—I mean the risk of premature burial. He will also be able in many cases to determine what the cause of death has been, or, if he is not satisfied in his own mind, he may refuse a certificate and refer the case to the authorities.

Uncertified Deaths.

As regards uncertified deaths and the power of the registrar as to satisfying himself as to the cause of death on information given to him by the qualified informer, I cannot but think that there is too great laxity here. His powers of granting a burial order on the unsworn and unverified statement of the informer relative to the death are too wide. In my opinion it puts too great a responsibility on the registrar. We may take it for granted that many of them are men of experience, tact, and acumen, but there must always be a certain number who are careless in their duty or facile and impressionable. The qualified informant narrates a likely story to cover up, it may be, a case of gross neglect, or it may even be of crime, and the registrar may accept it as true without making any inquiry. The vast majority of uncertified deaths occurs amongst illegitimate infants under 1 month old. This in itself would point to a great amount of undiscovered crime, perhaps crime difficult to prove, but none the less existent. Again, a large proportion of uncertified deaths occurs after the age of 80 years, where, again, death may have been hastened by neglect in the way of warmth, food, and general attention.

It is ridiculous to imagine that a man who has had no medical or legal training can find out the most likely cause of death in the case of uncertified deaths. We all know how difficult it may be for us to determine the true cause of death, and yet the registrar is allowed on his sole authority to grant burial orders when he is satisfied as to a death having, in his opinion, occurred from natural causes. The evidence given by certain registrars before the Committee on Death Certification (1893) shows on what shallow and insufficient grounds these deaths were accepted as natural. As there are about 12,000 uncertified deaths every year in England and Wales, these must throw a great additional burden on the registrars, and in many cases only a skilled medical or legal man could determine whether an informant was telling the truth or not.

Suspicious Deaths.

Then, again, the entirely private investigation of the procurator fiscal into cases of suspicious death does not lead to accuracy of diagnosis regarding the cause of death. In many cases the procurator fiscal gives no instruction regarding the medical examination of the dead body. He rests satisfied with what he has found out regarding the death in his precognition of witnesses. He remains the sole judge as to the cause of death, and if he is satisfied the case goes no further, and he gives a certificate as to the death to the registrar.

Mistakes as to the true cause of death must often be made either by the registrar or the procurator fiscal. They have no medical skill, and so cannot cross-examine the informant as a medical man would in order to elucidate the real cause of death. Apart altogether from the risk of crime remaining undiscovered, the errors which must accrue to statistical inquiries into the causes of death must be enormously increased by the certificates granted by either of these two officials. To take, for example, the case of children reported to have died from teething, prematurity, diarrhœa, convulsions, etc., it is in many cases a mere begging of the question to grant certificates on such premises.

Without departing from the privacy of the procurator fiscal's inquiry, it would be desirable, in my opinion, that he should associate himself with a medical man (preferably an expert) in the investigation of any suspicious death. This should be done during the precognition of witnesses and would be altogether independent of the *post-mortem* report, should an autopsy have been performed. The inquiry, after all, has to deal much more with a medical than with a legal question. The object of it is to determine how the individual came by his death, and a medical man is surely at least as well fitted to determine this as a lawyer.

In my opinion, as much, if not a good deal more, information is obtained in a private inquiry conducted as I have indicated than is obtained in a public investigation conducted under more or less disadvantageous circumstances by the coroner. Witnesses often do not conduct themselves nearly so well when giving evidence in public as they do when giving information privately and not on oath. Nor is this difficult to understand; the crowd of eager listeners, the presence of the reporters, and the distracting character of the place, put all but the expert witness out of full control of his faculties, and I feel sure that the contradictory statements often made by witnesses are not nearly so much due to endeavours to conceal the truth as to excitement.

As regards those deaths which under present circumstances are uncertified, I think great benefit, not only to our public health authorities, but to the officers of justice, would accrue if all deaths were duly certified by a medical man. For this purpose in large cities and towns the duty of certifying the cause of death in those cases in which no medical attendant has been present might be placed on the police surgeons, and in rural districts the medical officer of health might undertake it. Should any case appear to these examiners suspicious it could be referred to the police authorities for fuller investigation.

THE NECESSITY FOR REFORMING THE CORONER'S INQUEST.

By J. C. McWALTER, M.D., LL.D.,
Dublin.

DR. MCWALTER, after reviewing the history of the coroner's office and enumerating his duties, dealt with the need for reforms. He said that the following reforms were so manifestly necessary that they needed only to be enumerated in order to receive universal sanction:

1. As regards qualifications, the holder should be a registered medical practitioner, who is also a barrister or LL.B., or a solicitor who is on the *Medical Register*.

2. As regards election—the office being an important non-political post, should not be by popular election, whether by vote of freeholders or by the Municipal Council.

3. As regards payment, this should be, not per inquest, but per annum, subject to revision. Where revision of salary is provided for, periodically, a claim for increment should not rest merely in an increased number of inquests, but regard should be paid to the number of witnesses, and the number of hours engaged, etc.

4. A capable coroner's clerk should always be provided. He should be able to supply shorthand notes.

5. The coroner should have the power, independent of the jury, of having a *post-mortem* examination performed and paid for. He should also be able to get the views of necessary experts.

6. The coroner should have the power in university towns or the like to utilize the material of the inquest for the purpose of teaching medical jurisprudence. This science in England is in a childish and absurd position.

7. Questions of criminal negligence, which now involve several trials, should so be dealt with that a series of inquiries cannot be held on the same question.

8. Where a coroner's inquest tends to resolve itself into an inquiry fixing responsibility for damages, the coroner should have definite powers to confine such inquiry to simple investigations of fact bearing on the immediate cause of death.

9. In no cases are poor and illiterate people so unhappy and unprovided for as in cases of inquest concerning the sudden death of perhaps the chief support of the family, and the coroner should have power, when he thinks fit, to assign a solicitor to look after the interests of the family afflicted if they are too poor to do so.

10. Every uncertified case of death should *prima facie* be the subject of a coroner's inquest, but the coroner should have discretion not to hold the inquest when he thought fit.

11. A legal assessor should be available for every coroner in cases where he thought such help desirable.

12. Where the publication of certain parts of the proceedings might work injustice, the coroner should have power to restrain their publication, subject to appeal.

Reviews.

DISEASES OF THE DIGESTIVE SYSTEM.

A second edition of Professor Saundby's small book on *The Treatment of Diseases of the Digestive System*[1] has recently appeared. It has been revised throughout, and enlarged by an appendix on dietetics containing useful information about test meals, diets, and food values. It is based on the author's personal experience, and contains a great quantity of sensible practical advice. Dr. Saundby is not one of those who feel bound to recommend the latest thing in treatment or the last-published fancies of the experts in disorders of the digestion. He adopts a more conservative line throughout in the treatments he recommends, while at the same time keeping his eyes open for the real advances that are so slowly made in the therapeutics of the alimentary tract and the study of its physiology and bacteriology. A very useful chapter towards the end of the volume gives an excellent but brief description of the chief symptomatic diseases—headache, insomnia, glycosuria, skin eruptions, and the like—that may depend upon affections of the gastro-intestinal system. A couple of dozen serviceable formulae are printed at the end of the book, which may be cordially recommended to the attention of all practitioners of medicine.

We had occasion only eighteen months ago to notice favourably Mr. H. J. Paterson's book on *The Surgery of the Stomach*,[2] so that little requires to be said on the issue of a second edition except to indicate the gratification the author must feel at the rapid absorption of the first. New features and additions are not many. The stereoscopic method of illustrating the pictures of operations has been introduced, and is highly recommended by the author. This method has been employed very effectively from time to time since the pioneering work of Sir J. Mackenzie Davidson, some examples of which were published in our columns a good many years ago. Plates illustrative of the use of *x* rays in diagnosis find a place in the edition, and we could have wished that more had been introduced, as there is much diagnostic value in this method, and there is still a big field for work in correlating symptoms and radiographic findings. Patients find a bismuth oxychloride or barium sulphate meal an easy thing to tackle, whereas a test meal removed by the stomach tube is to many an unpleasant business. Mr. Paterson has made a special study of the physiological effects of gastro-jejunostomy, and it is natural for him to embody in the work his view that the operation does not depend for its success on drainage, but on altered physiological conditions. In the chapter on infantile pyloric stenosis we are surprised to find no reference to the work of J. H. Nicoll, published in 1906. He found that pyloroplasty was eminently suitable for these cases. Mr. Paterson prefers gastro-jejunostomy. We are glad to be able to repeat our praise of this work, which is thoroughly up to date, accurate, and complete.

Judging by the number of textbooks issued, all showing a considerable degree of merit and an adequate knowledge of recent methods of diagnosis and treatment, the diseases of the digestive system are receiving a large amount of attention from our colleagues in the United States. In his volume on the *Diagnosis and Treatment of Digestive Diseases*[3] Professor George M. Niles, of the Atlanta Medical College, has endeavoured to give "concise and intelligible descriptions of the various tests used in studying the gastric contents, intestinal juices and faeces, and of the methods for determining the position, size, and motility of the stomach and other abdominal viscera, a statement of the diagnostic means employed in the recognition of digestive diseases, and finally an exhaustive discussion of their general and special treatment." The first part of the book is devoted to generalities, such as diagnostic methods and the means for local and general treatment, diet and drugs; in the second, which occupies only two-fifths of the whole, special diagnosis and treatment are considered. This method leads to a certain amount of repetition, and is scarcely consistent with the conciseness which the preface lays down as desirable. For example, intestinal parasites are discussed in the former part of the book on pp. 79 to 103, on pp. 370–71, and, finally, on pp. 557 to 569. The first deals with the etiology and diagnosis of parasites, the second with the drugs used against them, and the third repeats all these, although it deals at greater length with methods of treatment. The name of Professor Ewald has been long associated with the test breakfast of rusk or bread and weak tea or water, so that to describe under this name a meal of bread and meat is misleading. It is hardly accurate to say that maltose does not ferment with yeast, as many yeasts contain the necessary enzyme maltase. On p. 103 the author recommends that in examining the faeces for the ova of the hook-worm "a small dose of thymol should be followed by oil," although on pp. 371 and 569 he warns against the administration of oil after thymol, on account of the danger of dissolving the drug, and thereby promoting its absorption; we should suppose a saline purge would be as effective in bringing away any ova present. On p. 111 he recommends glycerine for lubricating a stomach tube, but on p. 175 he says plain water is by far the best for this purpose, "the supremacy of water admits of no argument"—a statement with which we entirely agree. The author's directions and methods are generally good, and his photographs illustrating the method of passing a stomach tube and the position of the physician and of the patient are just as they should be. He is in accord with most physicians in his caution respecting operative interference for gastric haemorrhage, in the use of stomach massage, and his conservative attitude regarding nephropexy. He is right in deprecating the prejudice against drinking water with meals, although condemning the excessive use of iced water. The late Mr. Lowell taught us to be careful in criticizing the use by Americans of unfamiliar words, which are often good but forgotten English, yet when the author speaks of "downcast, complaining, and *sordid* people" we are puzzled, since the word *sordid*, as used here, generally conveys a moral reflection; even in its original meaning of dirty it would not necessarily be appropriate to describe patients who are suffering from mental and physical depression. Is the author quite fair to Professor Chittenden in accusing him of being in opposition to "all the world," when we remember that the diet of the peasantry of Europe, including until recently those in England, Scotland, and Ireland, approximated more closely to the Chittenden standard than to that of Atwater and Voit? Moreover he ignores the evidence which Hindhede has published in support of the low protein diet. We fear English experience does not uphold his opinion that the prolonged use of calcined magnesia is not a cause of intestinal concretions, as when Gregory's powder was a popular domestic remedy these concretions were by no means uncommon. The book is abundantly illustrated and contains many useful tables, but the copy sent us has part of the index interposed among the text.

[2] *The Surgery of the Stomach: A Handbook of Diagnosis and Treatment.* By H. J. Paterson, M.A., M.C., M.B.Cantab., F.R.C.S.Lond. Second edition, revised. London: J. Nisbet and Co., Ltd. 1914. (Med. 8vo, pp. 355; 51 plates, 15 illustrations in the text. 15s. net.)

[3] *The Diagnosis and Treatment of Digestive Diseases. A Practical Treatise for Students and Practitioners of Medicine.* By G. M. Niles, M.D. London: Henry Kimpton. 1914. (Med. 8vo, pp. 609; 1 plate, 86 figures. Cloth, 21s. net; Roxburgh binding, gilt top, 25s. net.)

Professor CHARLES G. STOCKTON, of the University of Buffalo, the author of a volume on *Diseases of the Stomach*,[4] is not a specialist in this department, but he thinks that his experience of twenty-five years as a teacher and practitioner, and the special attention he has given during that time to abdominal diseases, justifies him in writing it, all the more as diseases of the stomach are so intimately connected with other departments of medicine that a general physician is able to take a broader view of the question than one who confines his attention to a narrow speciality. We hardly think it was necessary for the author to spend time in combating supposed views of the inutility of gastric digestion, and we doubt whether such extreme opinions as he seeks to controvert are entertained in any responsible quarters, for it is one thing to recognize that the stomach is not an indispensable organ, but quite another to maintain that it is useless. The book is well written and abundantly illustrated, but there is a certain amount of unnecessary repetition; for example, conditions described in Chapter IX, on functional derangements of digestion, are repeated in Chapters XVIII and XIX, and other subjects dealt with in Chapter VIII are described again later on. We note that the author appears to believe in the value of charcoal as an absorbent of stomach gases, although Ewald pointed out many years ago that charcoal has this action only when it is dry, a condition in which it can hardly continue when it has been swallowed. Professor Stockton's treatment appears to us to be rather excessive, and we doubt whether the use of the stomach tube is really justifiable or useful as a routine practice in either peptic ulcer or chronic gastritis. The author adds to the interest of his book by publishing a good many cases, and we have no doubt it will be greatly appreciated by many readers, among whom we include ourselves, who prefer it to many more rigidly systematic treatises.

NOTES ON BOOKS.

THE little book on *Practical Pathology*,[5] by Dr. J. MILLER, is essentially one for the student of medicine. After an introductory chapter, the author deals with the equipment which a pathologist needs in making an autopsy, and the methods of procedure which he may adopt. The technique recommended is sound, and the best in all but exceptional circumstances. The *post-mortem* appearances to be found in the various tissues and organs in different diseases are next described, and are correlated with the changes occurring in the other tissues and organs of the body. Such an arrangement has the distinct advantage of summarizing the appearances found throughout the body as the result of each particular disease. The size of the book precludes more than a short description of the outstanding features of the morbid anatomy of each. Short accounts are given of the clinical symptoms of some of the conditions found, but these are of necessity so brief, and restricted to so few of them, that it is questionable whether it would not have been wiser to omit them. Very short descriptions of histological appearance are also included. The last chapter deals with points to be remembered in performing autopsies in cases having a medico-legal bearing. This chapter might be more useful if it were extended, for its instructions are insufficient to satisfy the requirements of such an examination. No account, for example, is given of the morbid anatomical conditions found after death from drowning, hanging, criminal abortion, and many other of the common causes which lead to judicial inquiry. A useful appendix deals with such subjects as the treatment of specimens for mounting, methods of staining, making of blood films, and bacteriological and cytological examinations. The illustrations are grouped together at the end of the volume, and, with a few exceptions, are very good. The frontispiece—a coloured plate showing the staining reactions of certain diseased structures—is excellent. The book is the outcome of a praiseworthy endeavour to group all the essential changes found after death—an endeavour which, considering the space available, is highly successful. It should prove very useful to the student.

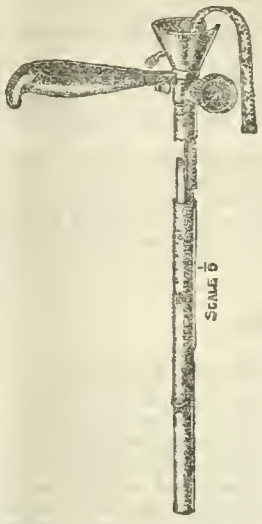
MEDICAL AND SURGICAL APPLIANCES.

Broncho-Oesophagoscope.

SIR WILLIAM MILLIGAN (Manchester) writes that the form of broncho-oesophagoscope illustrated in the drawing is so designed that the inner or extension tube is extended by means of a screw adjustment, on the principle of the coarse adjustment of a microscope, and is constructed in such a manner that its lumen is not interfered with by the mechanism adopted. In this way the inaccurate and clumsy method at present in use of forcibly pushing forward the inner tube is avoided and a smooth, even and gliding motion substituted. The instrument may be fitted to an ordinary handle, as shown, or to the handle of a Brüning's electroscope. A detachable slotted funnel, blackened upon its inner aspect, fixed to the proximal end of the outer tube, is provided when indirect illumination is employed, the object of the slot being to permit of the deep introduction of instruments with handles. To this funnel is attached a small tube, through which an anaesthetic may be administered. Tubes of different sizes are required for use with patients of various ages. The instrument is made by Messrs. Allen and Hanburys.



THE WAR AND THE MEDICAL SCHOOLS.

WE publish below notes of the result of further inquiries as to the effect of the war upon the entry at medical schools this year.

LONDON.

King's College Hospital Medical School.

At King's College the Secretary informed a representative of the JOURNAL that, as regards men due to come to the school for their advanced studies, none had been able to attend, all having entered the service of the country, either as surgeon probationers or in some other capacity. Since the outbreak of the war as many students as possible had obtained qualifications, and the majority of them had joined the Royal Army Medical Corps. The authorities of the school were in accord with the War Office, urging every present student to obtain his qualification at the earliest possible moment, in order that he might be of the utmost service to the country. Students were enlisting to some extent, but such a course was strongly deprecated in the case of those in any degree advanced in their medical studies. Mr. Kelway mentioned the death of one of the King's College Hospital students, Second Lieutenant Sidney Howard Hodges, who was killed in action at Lille. He was an exceptionally brilliant student, graduating B.Sc. before he was 23. Between thirty and forty members of the staff and students of the medical school, we were informed, were at present in the service of the country, either at home or abroad. Of the students some were at the front, some were at Malta, and others were in the naval service.

Mr. Kelway gave it as his impression that the full effect of the present situation would be felt seriously in the course of a year or two. The great shortage of students in the universities would influence some of the London medical schools, and in the long run the population would be affected.

There had been accessions of foreign students which might balance to some extent the shortage of home students; Russians who had begun their education in Germany and had reached a comparatively advanced stage, were endeavouring to complete their education in England, but with very inadequate knowledge of the language. Japanese and students of other nationalities were in similar plight. Mr. Kelway said the school was being carried on upon the usual lines, though necessarily the staff was somewhat curtailed.

King's College.

Professor Waterston, at King's College, informed us that there was an excellent entry of new students in medicine, the number being about fifty, a total about the same as last year or slightly larger. The college contained a number of refugee students, though not many in medicine. There were, however, Russian and Japanese students who had been working in Berlin or Switzerland, and Belgians from Ghent, Liége, and Brussels, also advanced students from Paris. All these were being entertained as the guests of the College. Many could talk very little English, and some of the students acted as interpreters. The experience was a novel one for the teaching staff; he found himself speaking to one group in English and to the next in French, while the Russian students could only be approached through the German language. Professor Waterston said that King's College had now 150 students in the preliminary and intermediate subjects.

University College Hospital Medical School.

The Dean (Dr. G. F. Blacker) reported a definite diminution in new students. There was, he said, a very marked shortage of men to do the work in the hospitals because so many fourth or fifth year students had gone to the front. It was difficult to find clerks and dressers and impossible to get residents. At least one hospital in London was considering the advisability of appointing women as residents, so great was the scarcity of men for any vacant position. Hospitals in the provinces were advertising for residents, and were willing to accept foreign graduates unable to speak English at all readily, men who in ordinary circumstances would not be selected for such positions. A number of Belgian and Russian students had been admitted to the medical school, also some from Paris. During the last ten years the experience at University College Medical School had been a steady increase; this year there had been a definite fall in the numbers. The position could only be attributed to abnormal conditions and must have affected other schools similarly. Seventy of the students had gone to the front and more were going, and for the first time in the history of the hospital the prospect of getting men from outside for resident appointments had had to be contemplated, although this course had not yet been adopted. Dr. Blacker believed the economic factor would be found to have some effect in restricting the entry of new students into the medical schools, and in the college he understood that the numbers of those taking the preliminary course were a little less than the normal.

University College.

This impression was confirmed on inquiry of the Provost, who said the entries were lower than usual. Those embarking upon the medical course numbered about 40, whereas the total was usually over 50. In the whole college nearly 350 men were away; the engineering faculty was most affected, classes having diminished from 40 and 50 members to 7 and 11. The decrease on the medical side was about 20 per cent.

St. Mary's Hospital Medical School.

So many students and members of the staff of this hospital and school offered their services to the country in various capacities on the outbreak of war that those in charge were faced with very considerable difficulties. Now, however, with the help of many substitutes, work is being carried on as usual both in the hospital and medical school. The number of new students shows a decrease, but the entry is 75 per cent. of the average, which, in all the circumstances, is considered very satisfactory. St. Mary's prides itself on the fact that it is represented on three out of the four London Territorial general hospitals, and that the commanding officers of two of them are St. Mary's men. The *Hospital Gazette* publishes a list, extending to several pages, of past and present students who are serving with the naval and military forces.

SCOTLAND.

University of Aberdeen.

Addressing, last week, a mass meeting of Aberdeen students, called to consider the formation of a reserve company of the 4th Battalion Gordon Highlanders, Principal George Adam Smith made a special reference to the position of medical students in regard to enlistment. In the case of those who were in their fifth, sixth, or, it might be, seventh year of study (laughter), he said that a petition had been presented for a final examination at Christmas in order that these students might qualify to take up commissions in the Royal Army Medical Corps. The authorities were under very strict ordinances in the matter, and the General Medical Council intimated that it would look with disfavour on any abbreviation of the ordinary course which it regarded as the minimum. Another reason for not abbreviating the studies of fifth and sixth year students was that the Director-General Army Medical Services stated that he had from 1,000 to 1,200 applications from fully qualified practitioners, and only a small proportion of these were likely to be called upon within the next seven months. Therefore there would be little or no chance, even if arrangements were made for students to qualify by Christmas, of their getting any positions before the following summer. Accordingly the Senatus had decided to take no action with regard to holding a final medical examination at Christmas, and this view was shared by the Universities of Glasgow and Edinburgh.

THE BRITISH PHARMACOPOEIA, 1914.

(Concluded from page 760.)

PHARMACY.

THERE are no very striking changes in the pharmacy of the new *Pharmacopoeia*, though there are fairly numerous alterations of a minor order of importance. It is somewhat surprising to find so few additions which fall under this head; as regards some of the forms of medicines which have come into wide use in recent years, such as capsules, cachets, granules, tablets, ampoules, etc., a paragraph in the preface—nearly identical with a paragraph in the preface in the *British Pharmacopoeia*, 1898—states that it has not been thought desirable to introduce these, but that when such forms are prescribed the drugs themselves must respond to the official characters and tests. It is, of course, obvious that nothing would be gained by putting cachets into the pharmacopoeia; but in the case of capsules and tablets, where some vehicle or excipient or lubricant must usually be added, there would appear to be quite as good reason for a number of formulae being official as for the pills, or the "lamellae" or discs for eye medication. Effervescing granules are official in a few cases, such as caffein citrate, lithium citrate, etc., and the list might well have been somewhat extended.

There is also a considerable and growing class of medicaments the preparation of which belongs to pharmacy in the wider sense, which it is somewhat surprising to find unrepresented in the pharmacopoeia—namely, antiserums and vaccines. Even animal extracts are not included, and the only two official substances prepared from animal glands, apart from the digestives pepsin and pancreatic solution, are dry thyroid and adrenalin.

In regard to the preparation of galenicals, changes are somewhat numerous and indicate a pretty thorough revision. The method of describing certain standard processes in an appendix and only referring to them in the text is again adopted and carried a little further. The percolation process for the preparation of tinctures has been modified somewhat; the material to be exhausted was formerly moistened with the menstruum and allowed to stand for twenty-four hours, then packed in a percolator and the menstruum passed slowly through it; the directions are now to moisten with the menstruum and allow to stand for four hours only, then pack in a percolator, add more menstruum until it forms a layer above the drug, and then allow to stand for twenty-four hours with the orifice closed, after which percolation is allowed to proceed. The object of the first soaking is to allow the drug to swell before being packed, in order that it may not choke the percolator by subsequent swelling, and four hours is no doubt enough for this. The second soaking allows the menstruum to exert its solvent action right into the interior of the particles of drug.

The process of repercolation is now relegated to the appendix; in this process a quantity of drug is divided into five equal parts, which are percolated separately, the percolate from the first being used for the second, the percolate from this for the third, and so on.

The preparation of discs, of which four are official—atropine, cocaine, homatropine, and physostigmine—is now described in an appendix. The basis is made of gelatine, glycerine, and water; the requisite proportion of medicament to base is ordered in the text in each case.

In only one case has a pure active principle taken the place of a crude drug throughout a whole set of galenicals. This case is that of cantharidin, already alluded to. Cantharides has been omitted altogether, and cantharidin is described as obtained from various species of Cantharis or of Mylabris. The tincture, ointment, two plasters, vinegar, blistering liquid, and blistering collodion are all affected by the change. Another change, somewhat of the same nature, is the omission of the gum-resin of scammony, and the use of scammony resin where the gum-resin was formerly ordered, as in compound tincture of jalap.

There has been a general revision of the strengths of alcohol necessary or best for the exhaustion of different drugs, and the alcoholic strengths of ten tinctures have been altered, some very considerably. The bases of the ointments have also been revised, and changes are made in thirteen cases; in many instances the change consists in the use of paraffin in place of some less stable substance, such as oil or lard, but in a few cases the change is in the reverse direction, prepared or benzoated lard taking the place of paraffin, as in iodoform ointment and ammoniated mercury ointment.

Analytical Processes and Tests.

The analytical processes of the *Pharmacopoeia* may be divided into two sections, namely, the assay of drugs and galenical preparations for the percentage of active principles contained in them, and the testing of chemical substances both qualitatively and quantitatively, to ensure the proper strength and purity. In regard to the former, it has already been mentioned that the number of drugs to be assayed and standardized has been substantially increased. A detailed discussion of the assay processes would be out of place here, but it may be said that the processes adopted appear to be in general well chosen. Some processes of the present *Pharmacopoeia* which are unsatisfactory have been improved; for example, in the assay of liquid extract of nux vomica, the present method of separation of strychnine and brucine (since only the former is wanted) is to precipitate the strychnine as ferrocyanide, and wash free from brucine, but this can only be done by also washing away some of the strychnine, and a correct result can only be obtained in this way by chance. In actual practice analysts have long since discarded this method, and decompose the brucine with nitric acid; this method has now been adopted both for the drug itself and its preparations.

In connexion with standardized drugs, besides the percentage of active principle which is required to be present, a figure is given which is called the "limit of error, in excess or defect." A paragraph in Appendix VII is as follows: "Successive assays of the same substance may yield numerical results varying within narrow limits, which are taken to be the range of 'error.' When an average of successive assays shows a deviation from the prescribed standard greater or less than the 'limit of error,' the preparation does not conform to the requirements of the *British Pharmacopoeia*." The meaning of this is not very clear; if the deviation is *greater* than the permitted limit of error, the preparation is clearly too weak or too strong, but it may be *less* than the limit of error, and then the preparation is certainly not outside the requirements. There appears also to be some confusion between the variation of successive assays, which is defined as "error," and the deviation of the actual strength of the preparation from the standard, which is what is concerned in the "limit of error."

The chemical examination of fixed oils and fats and volatile oils involves the determination of a number of constants such as saponification value, iodine value, ester value, percentage of alcohols, refractive index, etc., and adequate directions for making these determinations in a uniform manner are given in Appendices VII and VIII.

In the directions for testing chemical substances for purity and strength there is a great improvement over the present *Pharmacopoeia*. Far more tests are made quantitative, or of the nature of limit tests, especially for the more serious impurities. In particular, in a very large number of cases limits are given for the amounts of lead and arsenic which may be passed. The processes by which these impurities are to be determined are fully described in two of the appendices, and are excellent processes for the purpose. Some criticisms might be advanced in regard to the specification of the impurities to be tested for in particular cases, but details on this matter would not be of interest here, and in general such instructions show a marked improvement on those which they will supplant.

Abbreviated Names.

A new departure is to be found in Appendix XVII, which consists of a list of abbreviations for the names of official substances. The list is put forward simply as showing the abbreviated names adopted in the index, with the full names for which they stand; but it is stated in the preface that it "will probably be found useful to dispensers and others, especially those in foreign countries, who have to interpret the abbreviations occurring in the prescriptions of British practitioners." The majority of those given are such as are commonly employed, but perhaps the abbreviating goes a little too far in such as "emp. res.," "lin. sap.," "zinc. oleost.," while somewhat different syllables would probably be chosen instead of "acid picr.," "liq. pic. carbon.," etc.

Preparations for Tropical and Subtropical Parts.

Appendix XII contains a list of alterations in composition of galenicals which are sanctioned for use in tropical, subtropical, and other parts of the empire. Aromatic waters may be made by triturating the corresponding oil with twice its weight of calcium phosphate and 500 times its volume of distilled water, and filtering; the products are distinguished as aquae olei anethi, anisi, etc. The bases of plasters, suppositories, and ointments may be varied in such a way as to give the necessary consistence in hot climates; liquid extracts and syrupus rhoeados may have the proportion of alcohol increased up to stated limits, where they would otherwise be liable to ferment. Dried lemon peel may be substituted for fresh where the latter cannot be obtained, and in certain specified divisions of the empire arachis oil or sesame oil may be substituted for olive oil in preparations.

Alternative drugs, such as urginea for scilla, kaladana for jalap, etc., with their preparations, are incorporated in the body of the text, and must be ordered under their own official names.

THE ORIGIN AND DEVELOPMENT OF THE RED CROSS.

(Continued from p. 761.)

BRITISH RED CROSS SOCIETY.

THE British Red Cross Society is the result of a combination of several bodies formed for the rendering of voluntary aid to the sick and wounded in war. The movement set on foot by Henri Dunant in the early Sixties gave a great impetus to the development of the work of the revived Order of St. John. In 1868 a few members of that order formed themselves into a provisional committee with a view to the establishment of a National Red Cross Society similar to those which had already been organized in other countries. The members of this committee were General Sir John St. George, Sir Edmund Lechmere, Lord Eliot (afterwards Earl of St. Germains), the Rev. W. B. L. Hawkins, Mr. J. A. Pearson, Sir John Furley, and Captain Burgess. Sir John Furley states[1] that on the outbreak of the Franco-Prussian war in 1870 he asked Colonel Loyd-Lindsay, afterwards Lord Wantage, if he would help in forming a British Red Cross Society. The response was so immediate and emphatic that the British National Aid Society, with Queen Victoria as its patron, at once sprang into existence. Provincial and ladies' committees and subcommittees were formed in every part of the country to work in conjunction with the Central Executive Committee, of which the Prince

[1] *In Peace and War: Autobiographical Sketches.* London. 1905.

of Wales, afterwards Edward VII, was the president. After the Sixth International Conference of Red Cross Societies held in Vienna in 1897, representatives of the National Society for Aid to the Sick and Wounded in War, of the St. John Ambulance Association, and the Army Nursing Service Reserve, were invited by Lord Lansdowne, then Secretary of State for War, to take part in an informal conference to consider the advantages that would arise in time of war if these societies were brought into touch with the Army Medical Service in time of peace. The result was the formation of the Central British Red Cross Committee. Lord Wantage was elected chairman, Sir John Furley honorary treasurer, and Major Macpherson, R.A.M.C., who had represented the British Government at Geneva in 1864, honorary secretary. On January 19th, 1899, the Secretary of State for War notified his official recognition of the committee. On August 10th, 1899, the Princess of Wales, now Queen Alexandra, graciously consented to become its president. On November 27th, 1902, the Foreign Office notified all foreign Chancelleries that the Central British Red Cross Committee was the only body authorized to deal with Red Cross matters throughout the empire.

Central British Red Cross Council.

In May, 1904, the name of the committee was altered to the "Central British Red Cross Council." The Council was finally composed of three representatives of the National Aid Society, with two representatives of the St. John Ambulance Association, the Army Nursing Service Reserve, and the St. Andrew's Ambulance Association respectively, three representatives of the War Office, and one of the Admiralty. The chairman was Lord Knutsford, the honorary treasurer Sir John Furley, and the honorary secretary Major T. McCulloch, R.A.M.C. The work done by the Central British Red Cross Council in the South African war is set forth in an official pamphlet issued in 1902, entitled *Report by the Central British Red Cross Committee on Voluntary Red Cross Organizations in Aid of the Sick and Wounded during the South African War.* In that campaign valuable assistance was also given by the St. John Ambulance Association, the St. Andrew's Ambulance Association, and the Army Nursing Service Reserve, the last named body being under the personal direction of H.R.H. the Princess Christian.

The British Red Cross Society was incorporated on September 3rd, 1908, His Majesty the King being Patron, Queen Alexandra, President; Lord Rothschild, Chairman of the Council; and Sir Frederick Treves, Chairman of the Executive Committee. Now Sir Frederick Treves is Vice-Chairman of the Council, while the Hon. Arthur L. Stanley is Chairman, and Mr. E. A. Ridsdale Vice-Chairman of the Executive Committee. The Admiralty and War Office have granted their official recognition to the British Red Cross Society as the organization responsible for the Red Cross movement throughout the empire, and have agreed that in time of war all voluntary offers of assistance made in Great Britain and Ireland shall reach them only through the channel of the society, other than those coming from, or already arranged with, the Ambulance Department of the Order of St. John and St. Andrew's Ambulance Association for the supply of personnel. It is one of the objects of the British Red Cross Society to examine, systematize, and co-ordinate all offers of help, and, by preventing waste and overlapping, to render them of the utmost possible value. It is essential that all proposals of aid shall be in exact accord with the requirements of those departments of the navy and army which are responsible for the care of the sick and wounded in war. Voluntary aid, it is pointed out in the official pamphlet already quoted, unless it precisely accords in every detail with the requirements of the naval and military authorities, is a doubtful advantage or even an actual hindrance. It should be borne in mind by the charitable public that voluntary aid associations, however perfectly organized, are not entitled to recognition, protection, or neutrality under the terms of the Geneva Convention, and in the theatre of war have only such status as the belligerents may choose to accord them as an act of grace. The work of the British Red Cross at home comprises the encouragement of the formation of Voluntary Aid Detachments, and the training of their members in first aid, home nursing and sanitation, and as stretcher-bearers, sanitary attendants, hospital orderlies, nurses, cooks, etc. It is the body recognized by the War Office for this purpose in connexion with the medical organization of the Territorial Forces, and the County Associations of the Territorial Force are recommended to delegate the formation and organization of Voluntary Aid Detachments to the British Red Cross Society. In June last the British Red Cross Society had registered at the War Office 1,741 Voluntary Aid Detachments with a total personnel of 50,517.

JOINT COMMITTEE.

It was announced on October 23rd that on the recommendation of H.R.H. the Duke of Connaught, Grand Prior of the Order, His Majesty the King, as Sovereign Head, and Her Majesty the Queen, as President of the Ladies' Committee of the Order of St. John of Jerusalem in England, and Queen Alexandra, as President of the British Red Cross Society, had expressed their approval of the immediate formation of a Joint Committee of the two organizations, which shall sit throughout the war, to secure co-ordination and united action in work which is common to both bodies. The committee has been constituted as follows:

Appointed by the Order of St. John of Jerusalem.

Adeline Duchess of Bedford (Chairman of the Special Committee of Ladies of the Order).
Lady Perrott (Honorary Secretary of the Special Committee of Ladies of the Order).
The Chancellor (Colonel Sir Herbert Jekyll, K.C.M.G.).
The Secretary-General (Colonel Sir Herbert Charles Perrott, Bart., C.B.).
The Director of the Ambulance Department (the Earl of Plymouth, C.B.).
The Assistant-Director of the Ambulance Department (Lieutenant-Colonel Sir Richard Carnac Temple, Bart., C.I.E.).
Sir John Hewett, G.C.S.I., C.I.E. (Chairman of the Indian Subcommittee of the Ladies' Committee of the Order).
The Right Honourable Sir Claude Macdonald, G.C.M.G., G.C.V.O., etc. (Chairman of the Foreign Aid Subcommittee of the Ladies' Committee of the Order).

Appointed by the British Red Cross Society.

The Marchioness of Lansdowne.
Georgina Countess of Dudley.
Sir William Edmund Garstin, G.C.M.G.
Sir Robert Arundell Hudson (Chairman of Finance Committee).
Sir Walter Roper Lawrence, G.C.I.E.
Edward A. Ridsdale, Esq., F.G.S. (Vice-Chairman of Executive Committee).
The Hon. Arthur L. Stanley, M.V.O., M.P. (Chairman of Executive Committee).
Sir Frederick Treves, Bart., G.C.V.O., C.B., etc. (Vice-Chairman of Council).

It is understood that the first Chairman of the Joint Committee will be the Hon. Arthur Stanley, and the first Vice-Chairman, Sir Herbert Perrott.

For years there was some friction between the Red Cross Society and the St. John Ambulance Association, and in the early part of the present year the King approved the appointment by the Secretary of State for War of a committee to inquire into their relations.[2] It would be inexpedient to discuss the differences which then existed between the two bodies, especially as the war has brought about an adjustment. In a letter which appeared in the *Times* of October 23rd the Committee of the Red Cross Society says:

> We are seeking in every way we can to perfect our organization at home and abroad in order that we may adequately fulfil our duty to the public as the channel through which their generosity reaches those who are wounded in their country's cause. To this end we have come to an agreement with the St. John Ambulance Association for joint action in common work, which must necessarily increase the usefulness and efficiency of both bodies.

Sir Arthur Sloggett, Director-General of the Army Medical Department, is acting as Chief Commissioner both for the Order of St. John and for the British Red Cross Society. He is assisted by Sir Savile Crossley as Assistant Chief Commissioner.

(To be continued.)

[2] BRITISH MEDICAL JOURNAL, March 21st, 1914.

THE Greenville Board of Health, South Carolina, has decided to include malaria and pellagra among notifiable diseases.

British Medical Journal.

SATURDAY, NOVEMBER 7TH, 1914.

MEDICAL ARRANGEMENTS IN NORTHERN FRANCE.

THE position this JOURNAL occupies as the organ of a great Association is so well recognized that we should scarcely be accused of boasting if we claimed to be exceptionally well informed as to the medical aspects of the present great war. Members of the Association are to be found in every British camp and in every military hospital, whether great or small, both at home and abroad. The result is that we receive a large amount of information from a great variety of sources. Much of it is mainly of medical interest, but not a little of that received during the past ten days has a direct bearing on rumours recently current, of such a kind that they must tend to increase the anxieties of those who have relatives and dear friends at the front, and to disturb all those who are anxious that everything that is humanly possible shall be done to alleviate the suffering and assist the recovery of men and officers wounded while engaged in the service of the country.

Some of these rumours are thoughtlessly set afloat by quite irresponsible persons, and others, though equally groundless, gain currency in a blameless but quite comprehensible fashion. Many persons now in England have on journeys home from abroad passed through towns where base and other hospitals are established and have seen at stations or on quays rows of stretchers, each laden with a wounded man, lying in the open air. Such persons have either not had time or have had no opportunity of taking more than a passing glimpse at them, and have gone off with an impression that they have been left unattended. It is obvious that when wounded men are being entrained and detrained, embarked and disembarked, the work must be carried out in an orderly manner; to attempt to handle all the wounded simultaneously during these transfers would inevitably lead to confusion and cause unnecessary suffering and risk to them.

Other stories relate to events which happened either during the retreat from Mons or in the desperate fighting which took place when the Germans were being driven back towards the Aisne. At that time the British and French troops were intermingled, and the wounded of both countries were either being brought down from the front in the very imperfect rolling stock of the French railways over very long distances and very slowly, or were being carried off from the dressing stations in automobiles by private individuals to their own houses, and thus placed out of the reach of the authorities. In many of the stories relating to the sufferings of these men there was unhappily a considerable basis of truth, and they only became misleading when they were passed on from mouth to mouth as if they were representative of what is now going on.

Further stories relate to the arrival in England of wounded men still wearing their blood-stained, mud-soaked clothes, and presenting no evidence of ever having had any attention whatever paid to their wounds. We have traced some of these stories to their source, and have found that they relate to Belgian troops, who were hurried straight on board, either at Antwerp or Ostend, on the fall of the former place, there being no alternative between shipping them away forthwith or allowing them to fall into the hands of the Germans.

Other rumours are of a different order. They are based on comments made by the medical officers of hospitals at home on the condition of the patients arriving from the front for treatment at the institutions to which these officers are attached. These comments are to the effect that the patients arrive either when practically convalescent or with wounds gravely infected. These comments are absolutely accurate so far as they go, but the inference sometimes drawn from them we believe to be ill-founded.

The facts are held to suggest that the medical arrangements at the front are inadequate, and that in particular a much larger number of skilled surgeons is required. Careful consideration of the information in our possession has convinced us that neither of these suggestions is at the present time well founded. The general arrangements for the care of the troops at the front are very complete and very carefully thought out, and every development of modern medical and surgical knowledge is brought into play. The direction of the medical affairs of the army is fortunately in the hands of men who are of great administrative experience and follow Lord Kitchener's example in scorning red tape. A prolonged inquiry into what is being done by them has satisfied us that they have spared no effort to guard the troops against undue sickness, to secure the comfort of the sick and wounded so far as this is humanly possible, and to provide everything that can help them towards a rapid recovery.

As regards the supply of men of special surgical ability, this seems now to be adequate so far as the needs of the British troops are concerned. The number of medical men of admitted surgical skill now at work in France in one or other capacity is indeed remarkable, and the only misfortune is that at the present moment the whole of the talent that they represent could not at once be brought to bear in the corner of Northern France where the British force is now engaged. This, however, has been a passing phase. The transfer of "a certain fraction of our troops from its former line facing north, on the east of Paris, to its present position facing east, in the north-west corner of France," described by the eye-witness at general head quarters has, of course, included the Army Medical Service and its auxiliaries. Already the arrangements for the local treatment of the more seriously wounded, and the transport to England in hospital ships of those deemed fit to travel, are of a satisfactory kind. They in nowise tend to retard the recovery of the wounded men. The suggestion which it appears has been made that the early transfer of cases to England is a cause of death among the wounded cannot be based on real knowledge of the fashion in which the wounded are being brought over. The ships in which they are being transported are real hospitals, and, so far as their environment therein is concerned, there is no reason why the wounded men should not, if the conditions demanded it, begin and complete their treatment satisfactorily on board these ships.

The opportunities afforded by this war for surgical work of the highest kind are very small. The wounds are of a novel character, inflicted by

weapons which have not been used before in any war in which Great Britain has been engaged. They are received in a soil long subject to intensive cultivation, and this likewise is new to the history of modern warfare. The result is that they are infected from the very beginning in quite a peculiar bacteriological fashion, which will be found described in some notes from a special correspondent elsewhere in this issue. At the beginning the mistake was made in regard to their treatment—mainly, however, by French surgeons—of applying twentieth century technique and experience to lesions which, if they have any analogues at all, are of an eighteenth century character. They differ essentially from injuries to be seen in this country, and consequently the practices common in great civilian hospitals have had to be abandoned in favour of the methods employed by Lister in early days. The opportunity for the more detailed and delicate methods of modern surgery does not arrive until a later stage, when shortened and contracted limbs have to be extended, stumps remodelled so as better to bear an artificial limb, nerves sutured, and fragments of missiles sought for and removed the extraction of which, for example from the skull, would in the first instance have been impolitic.

The foregoing statements apply exclusively to the British wounded and to the British arrangements. So far as the French are concerned, we believe that more surgeons are required.

In conclusion, we venture to advise all those who are interested in the subject to be exceedingly chary of accepting as well-founded any rumours that they may hear of a kind unfavourable to the medical men at work in any part of France.

GERMAN EXPERIENCE OF BULLET WOUNDS.

In the Journal for October 24th we published a paper by Surgeon-General W. F. Stevenson, whose dispassionate discussion of the use of "dum-dum" bullets should do much to enable the facts to be seen in their true light. He insisted that civil surgeons, inexperienced in military surgery, were apt, whatever their nationality, to accuse their enemies of using "dum-dum" bullets solely on the ground that the wound of exit was large and ragged. An equally charitable and impartial view of such bullet wounds is taken by Professor P. Kraske, who has published his experiences in the *Feldaerztliche Beilage* of the *Muenchener medizinische Wochenschrift* for September 1st. He was attached to one of the German armies in France, and saw about 600 wounded from the battles of August 9th and 10th. Most of the wounds were due to rifle bullets, and in respect of shape, size, and degree there was no difference between the wounds of the Germans and French. Most of the wounds had been inflicted at a range of 400 to 600 metres, and there was, therefore, seldom any sign of the so-called "explosive" effects of the bullets. There was neither time nor opportunity for the use of the *x* rays, and exact localization of internal injuries was therefore not always feasible. As a rule, wounds of the bones of the lower limbs were quite simple, and the same could be said of wounds of the trunk. Of about 30 cases of wounds of the chest, the majority were unaccompanied by haemoptysis, and yet the lungs had obviously been wounded, for there were haematothorax, pneumothorax, or subcutaneous emphysema, which in some cases extended to the scrotum and thighs.

In several cases of abdominal injury the liver was wounded, and undoubtedly in some of these there was neither severe haemorrhage nor concomitant injury to the intestines. In one case, in which a bullet wound was inflicted at a range of only a few yards, the whole of the abdominal wall was lacerated to an extraordinary degree. The wounds of entry and exit were about 25 cm. apart, and the parietal peritoneum was torn over a wide area, yet the bullet had not penetrated the peritoneal cavity and the intestines had escaped injury. In another case a bullet fired at close range had entered the abdomen and passed out by the lumbar region, leaving a wound as large as a plate, through which a coil of small intestine protruded. Laparotomies were often performed for bullet wounds of the abdomen. Though, in Professor Kraske's opinion, the operation was in most cases necessary, it was often unavoidably delayed, and when performed twenty to twenty-four hours after the infliction of the wound, peritonitis had often already set in, and the prognosis was rendered unfavourable. In three cases, however (in two of which there were multiple perforations of the small intestine), the general condition was so satisfactory on the third day after the operation that the prognosis was good. Wounds of the intestine were often multiple and smooth, and it was possible to close them with a simple suture.

The "explosive" effects of rifle bullets were, he says, greatest in wounds of the head. These naturally were often fatal, but cases were also observed in which, though the bullet had gone right through the brain, the general condition was satisfactory, and there were scarcely any nerve symptoms. In one case a bullet had passed through the calvaria to the right of the middle line, traversing the right cerebral lobe, dividing the optic nerve, and escaping in front of the ear. Yet the patient's general condition was satisfactory and there were no cerebral symptoms. The absence of an explosive effect in this case was attributed to low velocity. In only two out of twenty cases of bullet wounds of the head was the right side hit, and this greater vulnerability of the left side of the head was doubtless due to the soldiers' habit of lying in the firing line with the head turned to the right. The position of the left hand and arm in the act of firing probably also explained the frequency with which they were wounded as compared with the right hand and arm. Among many strange lesions was one of the tongue, a bullet having passed through it from one side to the other without injuring any bone.

Wounds inflicted at close quarters were relatively rare, but were also, as a rule, more serious. In such cases, even when only the soft tissues had been traversed, extensive lacerations and large openings were observed at the wound of exit. Wounds inflicted by weapons other than the rifle and revolver were rare, and Professor Kraske conjectures that the French shrapnel burst at too great a height to be very effective. He notes that the penetrating effect of shrapnel bullets is often so slight that in some cases they were found just under the skin. From four-fifths to five-sixths of all wounds affected the limbs, and in three cases the knee-joint had been shot without the bones being demonstrably injured. On the whole, Professor Kraske considered the treatment of the wounded more satisfactory than he had anticipated it would be. First-aid dressings were so efficient that, contrary to expectation, pain, inflammation, and fever did not usually supervene.

THE POSITION OF BELGIAN MEDICAL MEN AND PHARMACISTS.

A MEETING was held on Wednesday afternoon, November 4th, at the offices of the British Medical Association, to consider the position of the Belgian medical men and pharmacists, whose professional position has been involved in the utter ruin which has fallen upon their country and has destroyed the whole machinery of the medical profession and its adjuncts. The meeting was convened by the editors of the *Lancet* and the BRITISH MEDICAL JOURNAL, in response to representations made by a provisional Belgian committee, whose representative, Professor C. Jacobs, is now in London. There were present at the meeting: Sir Thomas Barlow, Bart., Sir Rickman Godlee, Bart., Sir Frederic Eve, Sir William Bennett, Dr. Frederick Taylor, Dr. Meredith Townsend, Dr. H. A. Des Voeux, Dr. George Ogilvie; Dr. Alfred Cox, Medical Secretary, and Mr. Guy Elliston, Financial Secretary, of the British Medical Association; Dr. S. Squire Sprigge, Dr. Dawson Williams; Mr. E. T. Neathercoat, Vice-President, and Mr. W. J. Woolcock, Secretary, of the Pharmaceutical Society; Mr. F. Pilkington Sergeant, Mr. A. J. Chater, and Mr. A. Hagon. Sir Rickman Godlee took the chair, and after a brief explanation of the position by Professor Jacobs, the following committee was appointed, with power to add to their number, to make an early report on the procedure to be adopted: Sir Thomas Barlow, President of the Royal College of Physicians of London; Sir Watson Cheyne, President, and Sir Frederic Eve, Vice-President, of the Royal College of Surgeons of England; Dr. Meredith Townsend, Master of the Apothecaries' Company; Sir Rickman Godlee; Dr. Frederick Taylor, President of the Royal Society of Medicine; Mr. T. Jenner Verrall, Chairman of Representative Meetings of the British Medical Association; Dr. Des Voeux; Mr. E. T. Neathercoat, Vice-President, and Mr. Woolcock, Secretary, of the Pharmaceutical Society. Dr. Sprigge was appointed Secretary and Dr. H. A. Des Voeux Treasurer. The instructions of the meeting to the committee were (1) to communicate with the Belgian Minister and the authorities of the Belgian Relief Fund; (2) to apply to America and other countries if desirable for assistance in the raising of any fund; and (3) to report generally.

THE HUXLEY LECTURE.

THE Huxley lecture at Charing Cross Hospital was delivered by Sir Ronald Ross on November 2nd. Before proceeding to the main subject of his address, which discussed recent advances in science and their bearing on medicine and surgery, with special reference to malaria and the transmission of diseases, he paid a well conceived tribute to Huxley, who, Sir Ronald Ross said, was not only the bulldog of Darwin, and the interpreter of Darwin's profundities to the world, but also a patient and passionate investigator and a patient and dispassionate thinker regarding phenomena. But, the lecturer continued, Huxley was still more: he was a philosopher possessing all the very first qualities required for true philosophy. The clarity of his style was itself a guarantee of the genuineness and completeness of his thought. Secondly, his mind was fiercely critical in its search for truth, and he accepted nothing as fact which he himself had not endeavoured to probe to the depths. Thirdly, no one has ever doubted that his aim was, not to astonish or to defeat or to persuade, so much as to reach the actual truth of every matter with which he dealt. He would have been delighted, had he lived, to recognize the bearing of recent advances in science on the medicine of the tropics. Sir Ronald Ross devoted the main part of his lecture to tracing the history of the modern application of parasitology to etiology and pathology, dealing in particular with the growth of knowledge with regard to filaria, piroplasma, and the malarial organisms. He sketched his own researches, the full history of which had, he said, been given in his Nobel lecture.[1] It was only after several years' work that he recognized that the malarial infection was carried by a certain genus of mosquitos only, not by *Culex* or *Stegomyia*, but by the anophelines. He made the observation that the spores of the analogous malarial parasites of birds which he had already recognized in *Culex* entered the insect's salivary or poison glands. This led to the disclosure of the full truth, namely, that the parasites were not only taken from man by the mosquitos, as Manson had supposed, and not only put into man by the mosquitos, as King supposed, but that both hypotheses were true, the insects carrying the parasites directly from man to man. Summarizing the results obtained, he said that from the time of the Romans it was known that the malarial fevers were connected with marshes and stagnant water in warm countries. Later, when it was seen that the disease was not confined to the proximity of marshes, the theorists conceived that there was a telluric poison which caused malaria and was especially abundant in damp places. All this was a very general proposition; and in order to prevent the disease, it was necessary to undertake very extensive drainage. The new knowledge obtained rendered it possible to particularize the exact route of infection. It was now known that the poison was not spread uniformly in the air of warm countries, but was always contained in the minute bodies of certain insects, and more than that, in the still more minute salivary glands of these creatures. The discovery of the full life-cycle of the parasites made it possible not only to predicate the route of infection, but to determine exactly which species of mosquitos were concerned, and to study the habits of the inculpated species. The genera *Culex* and *Stegomyia*, which it was found did not carry the malarial parasite, breed most commonly in artificial collections of water around houses, the anophelines breed principally in natural collections of water such as marshes, puddles, streamlets, and the edges of lakes, ponds and rivers. These observations showed the way to other inquiries which cleared up the epidemiology of yellow fever, sleeping sickness, tick fever, plague, and might possibly throw light on that of dengue, Mediterranean fever, and measles.

MENTAL AND NERVOUS SHOCK AMONG THE WOUNDED.

WE hope the public will give Lord Knutsford the £10,000 for which he is asking. Among the men who are coming home are some, wounded or unwounded, who are suffering from severe mental or nervous shock. In addition to exposure and the severe strain and tension of the fighting line, the depressing effect of the horrible sights and sounds of modern battlefields have to be reckoned with. Officers returned wounded say, for example, that the rending clang of a bursting shell produces a special kind of auditory impression which in time becomes very oppressive and almost physically painful. It is not surprising that there are a good many men suffering from mental and nervous shock, and it is true that such cases are not suitable for general hospitals. They require rest and quiet under special medical care. It is proposed to get a large quiet house in London and a convalescent home in the country. The scheme has received the sanction of the War Office, and the following is a list, arranged alphabetically, of the names of physicians who are willing to help and form a committee of management: Dr. Stanley Bousfield, Dr. Milne Bramwell, Dr. Douglas Bryan, Dr. F. W. A. Bryden, Dr. A. G. Buchanan, Dr. J. Campbell McClure, Dr. James Collier, Dr. Maurice Craig, Dr. David Forsyth, Dr. Bernard Hart, Dr. T. B. Hyslop, Dr. E. T. Jensen, Dr. Ernest Jones, Dr. Constance Long, Professor

[1] *Journal of the Royal Army Medical Corps*, 1905.

W. McDougal, Dr. Crichton Miller, Dr. T. W. Mitchell, Dr. Heatly Spencer, Dr. Purves Stewart, Dr. Lloyd Tuckey, Dr. Aldren Turner, Dr. Hugh Wingfield, and Dr. Maurice Wright.

COMPENSATION FOR EYE INJURIES.

Workmen's compensation in injuries of the eye was the subject of a discussion opened by Dr. William Robertson of Sunderland at the Ophthalmological Congress at Oxford last July. As soon as the Act came into force he was appointed by a mutual insurance company to examine every case of injury as soon after the accident as possible. He found that most of the men were honest in their claims; many exaggerated their disability, some unconsciously, others consciously, and received compensation for longer periods than was necessary; but the number who deliberately made fraudulent claims did not amount to more than 1 per cent. of those hurt. The most difficult problem which presents itself is the occurrence of traumatic neuroses and of malingering after eye injuries. The ophthalmic surgeon may himself have a clear conception of the relation which exists between the actual injury and the nervous symptoms complained of by the workman, but if he be not very careful he may fail to convince the court. The increasing length of time the applicants are off work and the number who complain of traumatic neurosis is to be attributed in large measure to the payment of compensation weekly instead of a lump sum. The immediate results of an accident, apart from the local lesion, are shock or acute hysteria. The late results which concern us more closely are neurasthenia and chronic hysteria. A very large proportion of the eye cases which come before us present the symptoms of chronic neurasthenia. Although these men are not actually malingerers, it is notorious that in many cases no actual physical injury has been sustained, and that rapid recovery usually follows the receipt of a lump sum in compensation. The condition has a psychic basis and is due to fright and to the mental attitude towards the subject of compensation. The ocular neurasthenic complains of dazzling, lacrymation, and light phenomena, such as fluttering fiery balls, and muscae volitantes, or he says that objects disappear and that his eyes get rapidly fatigued. The difference between these claimants who make much out of little is in marked contrast to an ordinary patient who is anxious to get well. The hysteric often shows contraction of the fields and inversion of colour fields. In making a report upon such a workman it is well to consider the subject under three heads: The applicant's statement, the account of the condition found on examination, and the opinion formed upon the case. The applicant's statement should contain a clear but brief account of the accident, of what the patient did immediately afterwards, and when he first sought medical aid. The results of the examination should as far as possible be set forth in non-technical language. A sharp look-out should be kept for causes of inability to work other than those claimed. The opinion should include a statement as to the connexion between the alleged accident and the actual condition of the eye. An opinion must be given as to whether as a result of the accident the workman is wholly, partially, or not at all disabled from work, and an estimate made of the probable duration of any disability. Dr. Robertson considered the problem of the one-eyed. Even when the remaining eye is normal the central vision of one eye is somewhat less than that of both together, and one-sixth of the visual field and stereoscopic vision is lost. The various tests for binocular vision were described and critically discussed and the diaphragm test was recommended. It is necessary to consider each individual case upon its merits with especial reference to the man's occupation; thus loss of visual field would be serious in the case of a cabdriver but would not prevent a watchmaker from earning full wages.

BELGIAN REFUGEES' DISPENSARY.

A dispensary has been opened at 265, Strand, W.C., under the auspices of the War Refugees' Committee, for the medical treatment of sick Belgian refugees. In the earlier days of the exodus assistance was given at the Aldwych Rink by the 4th London Voluntary Aid Detachment of the British Red Cross Society, under the commandant, Miss Davenport, with such volunteered medical aid as the occasion required. But with the enormous influx of refugees, many of whom only speak Flemish, it was found imperative to organize the medical relief, to secure separate quarters, and to enlist the co-operation of Belgian doctors, many of whom have found asylum in this country. Accordingly, on October 20th a meeting of doctors who had already been giving their services was held, by the invitation of Dr. J. H. Philpot, at 61, Chester Square, S.W., at which the following were present: Dr. H. A. Des Vœux, Dr. Kielemoes (Melle), Dr. D. F. Maunsell, Dr. Clément Philippe (Brussels), Dr. Victor Philippe (Brussels), Dr. J. H. Philpot, Dr. Austin Philpot, and Miss Davenport. It was resolved that those present should constitute themselves a provisional committee with Dr. J. H. Philpot as chairman and Miss Davenport as secretary, which, with the authorization of the War Refugees' Committee, should undertake the management of the Refugees' Dispensary, and arrangements were made for a continuous service of consultations daily from 10 a.m. to 1 p.m. and 2 p.m. to 6 p.m., and on Sundays from 10 to 11 a.m. The War Refugees' Committee has accepted these arrangements, and the dispensary, though in rather cramped quarters, is now in full working order, with an efficient staff of nurses belonging to the above-named detachment of the Red Cross. The general expenses of the institution are borne by the War Refugees' Committee, but liberal donations have been made by friends of the movement in order that medicines and dressings may be supplied free. Many Belgian doctors now in London, some of whom are well-known specialists, have inscribed their names at the dispensary and offered their assistance for consultation in special cases. Persons desiring to offer hospitality to Belgian doctors can, we are informed, obtain information by addressing the Secretary of the Dispensary.

INTERNATIONAL CONGRESS TRANSACTIONS IN THE LIBRARY OF THE ASSOCIATION.

It was announced in our issue of September 26th that the Library of the British Medical Association had then received certain additional parts towards completing its set of the *Transactions* of the Seventeenth International Congress of Medicine. The Librarian is pleased to acknowledge gifts from Dr. F. E. Batten of Section XI (parts i and ii), Neuropathology, and from Dr. H. C. Bastian Section III (part ii), General Pathology and Pathological Anatomy. Twelve volumes have thus far been received—namely, those dealing with Sections III (part ii), VI, VII, VIIa (part ii), XI, XIII, XXIII, and the General Volume. The Librarian will be grateful for any of the remaining volumes.

At the celebration of the twenty-fifth anniversary of the foundation of Johns Hopkins Hospital, held in October at Baltimore, a portrait of Sir William Osler by Mr. Sargent was presented to the institution.

The new *Army List* issued this week presents a considerable contrast to the last which was issued in August and contained information only of conditions as they existed before the war. Not only is the new volume more bulky, but the arrangement is in many parts different, and the information to be extracted not always very illuminating. It has been "corrected generally to about the beginning of October." It contains skeleton staffs for the divisions and brigades of the 1st and 2nd and 3rd new armies, but there is no definite indication of the areas to which the units are allotted.

THE WAR.

MEDICAL ARRANGEMENTS OF THE BRITISH EXPEDITIONARY FORCE.

[*From a Special Correspondent in Northern France.*]

WOUND CHARACTERISTICS.

I DO not often see English papers, but when I do it sometimes seems to me that even now the British public does not realize that what is going on in France and Belgium at the present time is a war and not a game played according to definite rules, with every move foreseen. They seem to forget sometimes that at least a million men on each side are trying to kill one another with singularly efficient weapons; that in the course of the struggle the survivors are constantly moving from place to place; and that meantime they have to be fed, kept fully supplied with ammunition, and the wounded and dead removed out of the way as rapidly as possible.

At any rate, it is quite certain to my mind that the majority of the public and many members of the medical profession have but a very slight idea of the nature of the wounds that are being received in this war by the combatants on both sides, and of the circumstances in which medical men engaged at the front have to deal with the cases placed in their charge. Some of the wounds—indeed, a considerable proportion—are relatively slight, but many others—possibly a majority—are of almost incredible severity. To me what seems remarkable is not that deaths take place, nor that tetanus and emphysematous or gas gangrene occur, but that any considerable portion of men so wounded ever reach home at all. Some of the lesions, especially those of the trunk and lower limbs, are so extensive and grave as to lead one to wonder how the patients were ever got out of the fighting line alive, and then sadly to conclude, though often quite erroneously, that at any rate they will never get any further than the base or other fairly distant hospital at which they come under final treatment. They are of such a kind that, if seen at home in civil life, they would create a buzz of excitement among the whole staff of the institution to which they were admitted. Furthermore, not only are the wounds of the utmost gravity on account of the extent and the nature of the lesions produced, but they are infected from the very beginning, that is to say, the wound and the infection are caused simultaneously.

It should be added that the infection is of so peculiar a character that two bacteriologists of very great experience who are now working in Northern France have informed me that the conditions are totally novel to them. In infected wounds as seen in civil life in England and elsewhere, organisms of the staphylococci and streptococci families are almost exclusively present. In the wounds seen in France the very reverse is the case. Ordinary pus organisms seem to be, initially at any rate, prevented from gaining any foothold by the extraordinary quantity of anaërobic organisms, such as the tetanus bacillus, the *Bacillus aërogenes capsulatus*, and the bacillus of malignant oedema. It is only after a considerable time, and sometimes not at all, that ordinary pus begins to form. The reason of this bacteriological peculiarity of the wounds is not that they have failed to receive early treatment, but the nature of the country in which the men are fighting. The soil of France, as also that of Belgium, is cultivated to a degree unknown in Great Britain. It has been thoroughly and steadily manured for an untold number of years, and consequently teems with tetanus and other anaërobic organisms which inhabit the intestines of the higher animals. In trenches dug out of this soil the men stand for hours and get their clothing and hands caked with mud. It is not surprising, therefore, that when hit by a missile the latter carries in with it millions of anaërobes. This is one of the circumstances which it would seem is not appreciated at home, the result being that the grave infections from which so large a proportion of all the wounded suffer are quite wrongly written down as the result of lack of early treatment.

TRAIN TRANSPORT.

Equally inadequate appears to be the conception of the circumstances in which these cases have to be handled. Of late they have arrived in Paris in ones and twos, but at an earlier date in Paris, and at the present time in the seaport from which I am writing, they are arriving by dozens each day. When I say dozens, I am thinking of individual hospitals; if the aggregate experience of all the hospitals were in question, the daily number would have to be multiplied many times over. Having said this I add, since I do not wish to figure as an alarmist, that the wounded now reaching the town from which I write represent the greater proportion of the total collected during or at the end of each day's war operations at the front, and that among them there are many patients not of British nationality. All these patients are being conveyed to the base in circumstances very much more favourable to their recovery than at an earlier stage of the war. The time occupied on the journey is much shorter, and the conveyances used, instead of being mere trucks, are in the nature of travelling hospitals. Each is provided with a staff of not less than three surgeons, four women nurses, a number of sick-bay orderlies, and all the requirements for changing dressings, and even, if necessary, for the performance of operations, by running the train into a siding for the time being. The feeding of the patients during their transit is also adequate, each train being provided with one or more kitchens.

It is regrettable, of course, that seriously wounded men should have to be moved by train at all, but moving them by train is infinitely preferable to carrying them long distances over badly laid roads in fast moving automobile ambulances on journeys of many hours. Practically, however, the men seem to stand these journeys remarkably well, and to suffer much less than might be expected. Probably the reason is that when moved they are suffering more or less from the nerve exhaustion consequent on their previous labours and the initial shock of their wounds. At all events, it can be said that those who are being wounded in such numbers at the present time are a great deal better off than their predecessors earlier in the campaign.

The work on these trains, I should add, is exceedingly hard. From the moment they begin to load up with wounded at the rail head to the moment when they have at length handed over all the wounded to the base hospital the train staff is ceaselessly at work, the opportunities for meals or a little sleep being rare and irregular. For the most part, too, their time during the intervals between journeys is well occupied by attending to such matters as train cleansing, the provision of fresh linen, the handing over of accoutrements, and reprovisioning. Still, matters have improved to some extent for the staff as well as greatly for the wounded. Some of the train staffs were habitually on duty earlier in the war for as many as

three nights and days in succession—that is to say, the journeys with loads of wounded lasted that time, and the journeys up to the front again were seldom much shorter. The provision of reasonably comfortable accommodation for the responsible and subordinate staff is one of the points that the builders of hospital trains should take into consideration more fully than they appear hitherto to have done. Mere multiplication of the number of officers, nurses, and men employed on train duty does not meet the needs of the situation.

Sea Transport.

The town from which I am writing has, I am told, completely changed in appearance in the last fortnight or so. Earlier in the war it was a military base of some importance, but soon after the British troops got actually to work it subsided more or less into its normal condition. Now that the British troops are fighting no longer in the centre of Northern France, but on the Belgian frontier and in Flanders, it has become the principal hospital base. Consequently there are so many khaki-clad individuals of one kind and another to be seen around the quays that one might almost imagine that these rather than the black-coated passers-by were the normal inhabitants of the town. The transformation must have been very rapid, for four large army hospitals, as well as one Indian hospital and more than one hospital working under the aegis of the British Red Cross Society, have been in operation in the area for at least a week; yet despite this there is little to suggest that they have only recently set up their tents.

The word "tent" is used metaphorically, for as a matter of fact all these hospitals are established in large many-roomed buildings. One of the army hospitals, for instance, has for its home a well known casino. To those of us who have visited it in more peaceful times and played therein *petits chevaux* the change of appearance is remarkable. One of the advantages of the utilization of this building is the fact that all its rooms are excellently lighted and perfectly ventilated. Owing to the very large number of wounded that are reaching this base the pressure on these hospitals is at present very great; but this is not likely to last long, for there are at least ten other large hospitals ready to move into proximity with this base so soon as military considerations permit this to be done. Meantime those already established are able to do their work efficiently, despite the pressure to which they are subjected, thanks to the fact that this base is an important port to and from which and England hospital ships ply daily.

The general plan seems to be for the hospital ships to take home only patients who have already been under treatment in one or other of the base hospitals, but when the wounds of the men brought down from the front are comparatively slight they appear to be sent on board forthwith. The system, in fact, seems to be for the principal medical officer at this base to be warned a few hours in advance that a train is on the way and for him to be ready with his staff to meet it and decide in consultation with the train medical officers which cases shall be sent home and which transferred to the shore hospitals. He has, of course, with him a statement showing exactly how many beds are instantly available, or can be got ready in each institution in the town. The fact that patients can be sent home not only enables the hospitals at this base to do their work efficiently, but is of immense advantage to the men themselves. Subconsciously the thought of every wounded man appears to be a desire for home, and it is a perfectly conscious thought on the part of those who are wounded in such fashion that they are well able to think out the situation for themselves. This is not because they are dissatisfied with their treatment, but because a desire for home is a kind of natural instinct to every human creature in distress, and especially to a man who has been separated from his friends for many weeks.

There might be a good deal to be said against their transfer in this fashion if the vessels in which they were taken were mere tugs or cross-channel boats, but this is not the case. On the contrary, the boats used are nearly all of them very large vessels withdrawn for the purpose from the transatlantic passenger trade. To fit them for their present purpose bulkheads have been removed, so that instead of their internal accommodation being split up into more or less small cabins the space between decks has been transformed into large wards. They are well lighted and ventilated, and provided with lifts, operation theatres, and all other necessaries. I am informed that, thanks to their size, no Channel weather hitherto experienced has been able to disturb their stability, and that the average passage is about ten hours. So far as the interest of the patients is concerned, the passage might last ten weeks, for these ships are hospitals in the fullest sense of the term. Apart from the nature of their arrangement and equipment, each of them is staffed with a very large number of surgeons, trained women nurses, and orderlies, and there is no reason whatever why the treatment of patients, however greatly wounded, should not be conducted on one of them from first to last.

Personnel.

There are some well-known faces to be seen at this port just now, two of them being bacteriologists of world-wide fame, namely, Sir William Leishman and Sir Almroth Wright. The former has been abroad for some weeks, and the latter arrived, I understand, a few days ago. Apart from visiting the hospitals themselves they have daily reported to them direct by the officers concerned any cases in which treatment coming within the field of bacteriology might be beneficial, or the bacteriological study of which might possibly prove of assistance. Both seem to find their present occupation exceedingly interesting, and though research work, as that term is usually understood, does not, I fancy, come within their direct duties, conversations with them left upon my mind the impression that some valuable additions to existing knowledge on bacteriological subjects are not unlikely to result from their own work and from that of several less well known bacteriologists who are on the professional staff of the Expeditionary Force. Other faces to be seen are those of two equally well known men who commenced their duties abroad about the same time as Sir Almroth Wright. These are Sir John Rose Bradford and Sir Wilmot Herringham. Their work, I understand, is to act as consulting physicians to the various hospitals, and to exercise general supervision over the medical as distinct from the surgical part of the work. Whether they will both remain here I do not know. As, however, this port is, and seems likely to remain, the principal hospital base for some time to come, one of them, I should think, is likely to remain within its area, the other visiting by motor car or otherwise any other base at which there are patients as to whose treatment the advice of a pure physician is esteemed likely to be useful. All four officers will no doubt, too, act as advisers to the Principal Medical Officer of the Expeditionary Force in regard to any special medical questions that may arise from time to time.

I have also seen two well-known London surgeons who are acting as consulting surgeons to the forces. These are Mr. Makins of St. Thomas's, and Mr. Burghard of King's, both of whom hold rank as full colonels on the Army Medical Staff. The third consulting surgeon, whom

I did not see as he is working further north, is Sir Anthony Bowlby of St. Bartholomew's. The two former have each had assigned to them one half of the military area of Boulogne and act as consultants to the hospitals therein. They also at times, I understand, perform operations themselves. With one of them who had only recently arrived I had an opportunity of conversing, and he expressed regret that the conditions prevailing in France were not better understood by his colleagues at home. Were this the case comments on the condition of cases arriving in London such as he had heard before his departure, both among medical men and the general public, would not be made. I heard also that four or five other surgeons selected from the staffs of London hospitals were daily expected. Why they are coming is not very clear to me, for there is already a profusion of British surgical talent in France.

The army hospitals themselves have far larger professional staffs than would be the case if official regulations were observed, and, thanks to the system of specialization introduced in the Royal Army Medical Corps some ten years ago, the staff of each of them includes at least one man who is a thoroughly skilled and experienced operating surgeon. Furthermore, of the many men who have been enlisted as temporary lieutenants, a large proportion are by no means youngsters, and those selected for service abroad seem usually to be men of at least considerable surgical experience. A good many of them are Fellows of the Royal College of Surgeons of England.

The way, indeed, in which medical men of excellent attainments have streamed abroad to occupy quite inconspicuous positions in the hospitals and the way in which I have seen them doing their work makes me proud to be able to rank myself as one of their colleagues. I am speaking now not only of the army hospitals and the semi-civilian workers therein, but also of the voluntary hospitals. All of these that I have hitherto seen are possessed of staffs which any well-advised, well-managed hospital in Great Britain of equivalent size would gladly accept as a whole in substitution for their present staffs if necessity arose.

I should add that at the present time many of these voluntary hospitals, as well as a good many army hospitals, are established at places where their staffs find comparatively little to do; this is because the tide of war has ebbed away from them and the stream of patients has ceased, but as military considerations make it possible most of them are being moved up north. The hospital line has, in fact, already been advanced to some extent, and when the change has been completed every need in the way of clinical and operative surgical ability will be very fully met so far as the British troops are concerned. The result, I suppose, will be that a majority of the wounded will be kept under treatment in France for a longer time than is the case at present, but for reasons already indicated in a previous note, I am by no means clear that this will be any distinct advantage to them.

I have said nothing in this note about nursing, though in previous letters I think I have made it clear that the British Red Cross Society seems to have at its command a perfectly inexhaustible supply of thoroughly trained women as well as St. John Ambulance orderlies. They are so numerous, in fact, that some of them have been employed, for the first time, I believe, in British warfare, at hospitals within a few miles of the firing line.

NOTES ON 150 CASES OF WOUNDED FRENCH, BELGIANS, AND GERMANS.

By ALBERT WILSON, M.D.,
London.

I SPENT October at Dieppe visiting various hospitals, and was given the charge of one large hotel under French military control (Hospital 37), containing about 100 beds. As a result of my experience I would enunciate the principle that the main object of military surgery is not to make things worse. I cannot make interesting statistics of my 157 cases, but a few general observations may be useful.

Dressings.

The French surgeons rely chiefly on strong tincture of iodine and hydrogen peroxide. The former is applied at once, and very freely into the wound, however deep. It may seem drastic, but such is not the case, considering the exposure to septic conditions from clothes, and tetanus from the soil, not to mention the lowering of vitality from exposure. Nevertheless, it is apt to send the temperature up, even to 103° F., and usually causes malaise, often sickness, and in some cases a petechial rash. Hydrogen peroxide is employed freely for washing and syringing afterwards, on the theory that it combats the tetanus bacillus, which is anaërobic.

Unfortunately, this amount of preliminary treatment is insufficient, and the wounds become very septic and sloughy, owing partly to the contusions and lacerations, which lower the vitality of the tissues.

I was very limited for dressing materials, but I made a mixture of 1 part of iodoform with 3 of salicylic acid powder for dusting from a pepper castor. The result was most satisfactory. Thus in one case a shell had carried away the patient's haversack, and inflicted a wound 4½ in. wide, 11½ in. long, and 1½ in. deep—it was a vast gaping slough. In three days it was clean, and by strapping, in three weeks it was 1½ in. wide and superficial. It was very painful, but an injection of eucaine removed all sensation during dressing. Potassium permanganate was a favorite dressing.

On the other hand, aseptic surgery is a distinct failure. It must be antiseptic. Weak carbolic (1 in 40) or weak mercurial solutions are the best. In bad cases cyanide gauze is preferable to aseptic gauze. I have seen failures under aseptic surgery, and a limb sacrificed which by careful antiseptic cleansing would probably have been saved.

Wounds.

Bullet wounds (*Balle*) present endless variety. The entry is sometimes round and small, but may be oval, if the bullet struck somewhat obliquely. The exit varies also, from a slit to a hole much larger than that of entry. It is often difficult to decide which is entry and which is exit. I usually asked the patient to put himself in the same position as when struck. The tracks vary much. The most wonderful case was one shown by Major Gouillard. The bullet entered the back on the left side behind the heart and came out between the fourth and fifth rib, inside the mammary line. It must have passed round the chest; but the direct route was through the heart.

Many men were struck behind or in the side between the ribs. In some cases the bullet came out without entering the ribs. In two of my cases they remained inside. In one case in which it caused pain it lay at the base of the right lung. Most of these cases spit blood for about a day and then have bronchopneumonia, but eventually do well.

The following case was very severe. A bullet, thought to be explosive or dum-dum, entered the upper third of the forearm (in the attitude of firing), inflicting a large wound 5 in. long, 3 in. wide, splintering the ulna. The military authorities say that such wounds are caused by ordinary bullets fired at a distance of about 40 yards. The exit was about 2 in. square. It looked like a large crucial incision, and admitted three fingers. There was a large hernia of muscle from the outer wound, a smaller hernia from the inner wound. The wounds were very offensive. In two or three days they were clean, and six days later I removed the fragments of bone, the longest measuring 3 in. I slightly shaved one protrusion of muscle, which I consider was a mistake, as in a fortnight all muscle got into place, and was covered by granulations. There was a gap of 3 in. between the ends of the ulna. A week later I examined under chloroform, and found that granulations covered most of the previously bare bone. It was trimmed up with forceps, and after three weeks was doing well.

In another case the bullet entered above the pubes, 3 in. to the right of the middle line. The man was in the trenches two nights and one day after being wounded, and had only two apples to subsist on. He said he passed blood after the injury. The wound, which was very septic, was enlarged. I found the horizontal ramus of the left pubis perforated and smashed, and removed the spicules, but could not trace the bullet in the thigh. A skiagram was taken of the pelvis, but showed nothing. I then had the thigh radiographed, and found the bullet on a level with

the great trochanter pointing outwards, as if fixed in the inner aspect of the femur. The wound was still more or less septic, but the patient was doing well. The bladder was uninjured. The wisest course to follow in this case will be to leave the bullet till it approaches the skin. Searching for bullets which cause no irritation is a fundamental error. It is often difficult, even with a skiagram, to locate the missile exactly, especially if a fragment.

In another case a bullet struck the tibia 2½ in. above the malleolus, causing a groove along the bone. On the fibula side there were two superficial wounds, as if from a fragment of shell, but this could not have been the case, as there was no artillery firing. The tibia, which was broken, was set in plaster. Five weeks later a skiagram when taken showed an oblique fracture from below upwards and backwards at the junction of the lower and middle thirds. How did the fracture occur? The bullet wounds were half-way between the fracture and the end of the bone. The man walked two metres after he was struck, and then his "ankle gave way." The method of bullets is strange.

In another case a ball entered the middle of the right buttock. The wound healed, but pain continued in the right groin. As there was no wound of exit, a skiagram was taken; it showed the bullet in the pelvis, pointing toward the lower lumbar vertebra. How did it get there?

In yet another case a ball entered 4 in. to the right of the twelfth dorsal vertebra, and came out 1½ in. above the right nipple. This man was very ill with broncho-pneumonia and haematemesis. The temperature went up to 102.9 F.

Shell Fragments and Shrapnel.

Wounds produced by shrapnel and by fragments of shell, being rough and jagged, cause much irritation and pain. They must be carefully located and removed, and are often difficult to find. The wounds they produce are always very lacerated, even when superficial. They do well, however, as a rule, but must be rubbed up with iodine. At times, however, they are troublesome. I had two artillerymen, each struck in the back by the same shell, with wounds about 4 in. across. One was superficial, the other had a pocket running 7 in. under the lumbar fascia into the pelvis. This man had a temperature varying from 101° to 104° F.

One Belgian from Dixmude was wounded in the left foot. The shrapnel entered at the root of the third and fourth toe, tore up the whole sole to the instep, and curved back again nearly to the great toe. There was a great protrusion of tendon and muscle. The wound suggested a Syme amputation, but having seen these hernia recede I dressed it and it did well, although putrid at first.

Air Concussion.

The following is a case of injury to the internal ear from the explosion of a "105" shell. The man was slightly wounded in the knee with shrapnel, and had synovitis. There was a wall between the soldier and the explosion. The left membrana tympani was ruptured; there was bleeding from the ear, and blood came into the throat. This occurred on October 8th. I saw him three days later; during the whole of the interval he had been in the train. He could not hear a watch, even applied to the left half of the skull. Conversation 4 or 5 ft. off was only heard if very loud. A watch placed on the middle line of the skull was heard on the right side.

After the accident he had giddiness, with a sense of rotation to the right. This passed off, but he had nystagmus looking laterally, most when to the right side; not at all when looking up or down. Romberg's sign was not present. On October 26th all symptoms except deafness had subsided; he could catch words of loud conversation 6 or 8 ft. off. Probably there was haemorrhage in the labyrinth.

Air concussion acts often like a heavy solid blow, causing pain and bruising to soft parts. It was common to find tenderness of the lumbar region, or of a shoulder, or intense headache. Pain was an important factor; the soldiers call it rheumatism. Other effects of explosion without wound occurred from flinging the man 10 or 15 ft. in the air. One man fell on his shoulder and had a large haematoma under the deltoid.

The nerve-racking effects of explosion are worthy of notice. In one case a Belgian officer had pain in his left leg, and what might be called "neurasthenia." After some days' rest, though he walked erect, he could only step 6 or 8 in. at a time and one step every three seconds. Another man was so exhausted that his life was in danger; the pulse was 42, on the next day 48, and then 52. I had to get his mate to shout at him. Sensation was almost gone in the legs, but he could after three seconds feel a hard pinch in the arm. The knee-jerks were normal, and the pupils reacted normally. These cases form a nerve group by themselves, diagnosed and named accurately "*faiblesse*." They get well with rest.

Stage fright occurred in a youth of 17, a "*volontier*," who had slain two Germans in trenches and taken about forty prisoners (probably willing ones). He almost cried with fear, but after two days in bed insisted on returning to the front.

Occasionally men are dumb, but they understand all that is said to them. I saw one such case. They recover after a few days' rest. Of one case, a deaf-mute, the following particulars were given to me by his physician, an alienist.

A native of Paris, aged 23, a sergeant. His mother was of neurotic family. As a boy he was either sad or "bizarre" but always refined and intelligent. When the war began he was excited, ambitious, and courageous. During a battle at Compiegne, after an explosion of a shell (*obus*), he suddenly stopped speaking, and ceased fighting as if stunned. In the fracas his companions carried him to a barn, where he lay for a day. A wounded soldier being placed beside him gave him some bread, which he devoured voraciously. After this he clung to his companion, and was therefore removed with him to Dieppe. There was complete mutism and cerebral deafness. Words had no significance, but if a noise was made he turned in that direction. He was an electrician, and showed much interest in lamps and wiring, yet he had no appreciation of a bunch of keys. He appeared to know his mother, but there was no communication between them. He followed the soldier about like a dog. He was sent home after a month's rest quite unchanged.

Tetanus.

I had one case of tetanus following a superficial shrapnel wound. There was stiffness of the jaws, pain in the scaleni and the muscles at the back of the neck, stiffness and pain in the lumbar region, rigidity of the calves, and the toes were in extension. Dr. Gilbert Hare administered 20 c.cm. of tetanus antitoxin on October 16th, 17th, 23rd, and 29th. Every dose did good, and on October 23rd his jaw opened freely, the cramps were less frequent, but pain and rigidity in the neck were severe. Any effort to eat solids fixed the jaws.

I saw a Frenchman with tetanus, which developed three weeks after a superficial wound. He died in forty-eight hours, in spite of antitoxin. He had a rise of temperature during the last twenty hours. A German with putrid compound fracture of the thigh died after repeated injections of large quantities of antitoxin. I saw 5 cases which had been cured by antitoxin. Each had been treated with 20 c.cm. at once. Three cases had a second dose on the eighth day. Two cases had three injections, the second on the third day, and the final injection, of 10 c.cm. only, on the tenth day. There was some rise of temperature at the beginning in these cases. One case began three or four days after the wound, the other cases sixteen to twenty-two days after. They presented no symptoms some three to five weeks after the attacks began. It is of interest to note the small dosage, as some authorities advise very large doses at short intervals.

It might have been expected that some of the large gaping wounds would be specially exposed to tetanus, but this is not the case. I think it is an unfortunate mistake to give antitetanus serum prophylactically until the serum is as abundant as the water in the Channel. On the other hand, at the first warning—stiffness, rigidity, pain, either in jaw, neck, back, or limbs, it should be given whether in doubt or not.

I do not think psychologists will get many cases, although shock plays a great part. Such cases as I had improved rapidly with rest and good cheer and watching their brave companions. Lowered vitality plays a great part; rest and stimulants seem required.

I must add a word about wounded German prisoners, of whom I saw about eighty. They are very badly wounded by the French artillery—more seriously than the French.

They were very starved and exhausted, and had a high mortality. There were several compound fractures, some requiring amputation. Consequently the mortality was high. But the French attend to them as carefully as to their own, and I had it from several of them that they were more than satisfied with their treatment.

THE HOME HOSPITALS AND THE WAR.

THE WOUNDED IN AND AROUND EDINBURGH.

A FIFTH trainload of wounded arrived in Edinburgh on October 24th, the majority of the soldiers being from the Ypres district; they were transferred by motor cars and ambulances to the Craigleith Military Hospital. They numbered 100; 20 cases were seriously wounded, and 10 were "medical" cases due to exposure in the trenches. Accommodation for 50 wounded soldiers has been provided by Mr. and Mrs. T. A. Nelson, who have transformed part of their house, St. Leonards, into a home hospital. Thirty-four of the beds are at present occupied by soldiers who have received treatment at Craigleith, and are now convalescent. The staff consists of a resident doctor—Dr. Balfour Gourlay—a matron, six nurses, and six orderlies. Colonel R. G. Wardlaw Ramsay, of Whitehill, has also placed Whitehill House, Hawthornden, Midlothian, at the disposal of the Red Cross Society for the accommodation of wounded soldiers.

PRINCESS LOUISE HOSPITAL, ROSENEATH.

H.R.H. Princess Louise, Duchess of Argyll, is having the hospital at the Ferry, Roseneath, renovated and prepared for the reception of soldiers who have suffered in the war. This is merely the continuation of a good work which the Princess has been carrying on for many years. During the Boer war, and since, many a "war-broken soldier" has found a haven of rest and the best of treatment in the comfortable quarters provided at Roseneath. Her Royal Highness has not only secured skilled medical attendance (Sir William Macewen, the distinguished surgeon, is at the head of the staff), but she has given her close personal attention to the comfort and well-being of the patients. No doubt many an old soldier bears in his heart a grateful memory of his residence at Roseneath, and the personal kindness of the gracious lady who paid such frequent visits to cheer the sufferers and see to their comfort. The hospital is situated at the mouth of the Gare Loch, amid beautiful scenery, and is a charming place, even in winter.

SCOTTISH WOMEN'S HOSPITAL FOR FOREIGN SERVICE.

The Committee of the Scottish Women's Hospital for Foreign Service announces that its first hospital unit is now made up, and will be ready to start for Serbia, where the need is great, in about a fortnight. A number of motor ambulances, an ambulance barge, and convertible cars have been offered to the hospital; *x*-ray apparatus is being appealed for.

DUBLIN.

Early last week a hospital ship arrived at Queenstown from the north of France with over 700 wounded officers and men on board. More than half were rapidly distributed among the hospitals in the south of Ireland—Cork, Fermoy, Waterford, and Limerick. On October 27th, 254 wounded officers and men arrived by two ambulance trains in Dublin, and were immediately distributed among the Dublin hospitals: the more severely wounded and the stretcher cases were taken to Dr. Steevens's Hospital as being the nearest to the railway terminus. A large proportion of the wounds were in the hands and feet; many of them, either due to shrapnel or rifle bullets, showing an explosive effect from contact with the bones, with severe destructive effects. The majority of those who were severely injured had received an injection of antitetanic serum before they left France; the wounds had been inflicted from one week to ten days before their arrival in Ireland. Two cases, however, died of tetanus in Cork within forty-eight hours of being landed from the hospital ship. According to the latest reports, all the cases in Dublin are doing well, and it is expected that within the next few days it will be possible to remove several of the more slightly wounded to the convalescent homes which have been already prepared for this purpose in the neighbourhood.

2ND LONDON GENERAL HOSPITAL.

Since the outbreak of war, upwards of 2,000 men have passed through the 2nd London Territorial General Hospital at Chelsea, and its sections established at St. Thomas's and the Great Northern Hospitals. At the present moment the number of beds occupied is 520 at Chelsea, 200 for men and 23 for officers at St. Thomas's Hospital, and 65 at the Great Northern Hospital, making a total of 803 beds. The 2nd London Territorial Hospital, therefore, considerably exceeds the minimum establishment contemplated by the War Office. As the men recover they are drafted to convalescent homes, or, in the majority of cases, to their own homes. In the first days of the war the War Office had an excellent plan of a central register of convalescent homes, and the commandant of a hospital on application could usually have allotted to a patient a home near his place of origin. If a patient needed special treatment during convalescence, he was allotted to a special institution. Now, however, that procedure has been altered, and commandants receive a list of convalescent homes and are left to make their own arrangements for sending convalescents away.

Early last week a convoy of very seriously wounded men came to the hospital; several, after being wounded, had been lying out in the open, without food, without water, and without dressings, for four days. Some had been wounded prisoners in the hands of the Germans and had been retaken by our own troops. In some cases those who had been in the hands of the Germans said they were very well treated, especially when under the care of the German medical department. On the other hand, some soldiers said they had been very badly treated, and that the first thing the ordinary German soldier did when he got a prisoner was to eat all the food the prisoner had with him. The German soldier always asked first for English bread—perhaps an indication of indifferent bread in the German army. In several instances, also, the Germans took away the British soldiers' greatcoats, whether for disguise or for additional warmth did not appear.

Two men who came in with shrapnel wounds had been lying in the mud for nearly four days unsuccoured. One had the upper part of his left chest crushed in, the left pleural cavity was filled with blood clot and pus. The wound was very septic, and the man was deeply jaundiced, emaciated, and delirious, with high fever. Nevertheless he is now recovering. The one proceeding that seemed to give him relief was tipping him up and emptying a large quantity of discharge from his chest. The second man had a very bad compound fracture of the arm, which was septic. The arm was amputated, and he began to improve, but, two or three days later, he suddenly collapsed and died. Another man, to whom Lieutenant-Colonel Callender, the officer commanding the hospital, spoke in the train before he was taken out, did not appear to be ill. He said he had a wound in the abdomen, but he was not in pain, and was puzzled because he only had one wound, and yet his "guts" were coming out. When admitted to the ward he was found to have a bullet wound in the upper part of the abdomen. A large mushroom-shaped portion of omentum was protruding. Although in a septic condition, the man had no pain and no fever, and when the omentum had been cleaned by boracic fomentations for a few days it was removed and the wound closed. The man is now doing well.

Another patient, wounded in the loin, had been lying out for three or four days untended. When he reached the hospital he had acute septic peritonitis and the abdomen was full of gases of decomposition and pus. He was operated upon, but after five days collapsed and died. Only one case of tetanus had been observed; the only symptom was trismus, which came on fourteen days after the injury. He appeared to be recovering when he developed pneumonia, which caused death. Another man, with a very large wound of the thigh, developed gangrene of the limb, complicated by diabetes. He died very rapidly.

In several instances compound fractures of the femur and humerus had been shown by the *x* rays to be comminuted to the last degree, but under treatment good union had been obtained, the limbs being now in use in several cases. From the *x*-ray picture these fractures would have been thought hopeless, and the limb utterly

shattered; in more than one case it seemed that amputation would be inevitable, but postponement had resulted in the limb being saved.

A sad case at present in the hospital was that of a man shot through the head. The sight of both eyes was destroyed. In other cases of wounds of the head the brain was exposed, and the wound was septic. One patient in this state died of cerebral meningitis; another somewhat similarly wounded is recovering.

It was, remarked Colonel Callender, reassuring to note that very few cases of sickness were received, either from the expeditionary or the home forces. Only one case of enteric fever had been received from the front and one from the home forces. Cases of dysentery had been received both from home and the front, but it had always been in men who had acquired it previously in India or somewhere in the tropics. There had been no diseases due to climate, except rheumatism, caused apparently by working in wet trenches.

There have been one or two cases of mental derangement in officers. One had headache, insomnia, and delusions of persecution; another had almost complete loss of memory; neither had any bodily injury. It was curious, going round the wards at night, to notice that quite a number of men talked in their sleep—always about the war. They apparently thought themselves again in the trenches and being attacked. As regards mental conditions generally, there was a complete absence of depression, and a complaint of any kind was seldom heard. The men were extraordinarily cheery; this national characteristic came out prominently. A Scotsman with nine bullet wounds spent most of the day amusing his comrades in the ward by playing very well indeed upon a penny whistle!

Colonel Callender added that the general administration of the hospital had gone smoothly, though the work was hard. Much labour was involved in the filling in of documents in respect of each patient. Six documents were necessary for every wounded officer.

1st Southern General Hospital, Birmingham.

The 1st Southern General Hospital, established in the University Buildings, Edgbaston, Birmingham, has accommodation for 520 patients, and has accomplished a large amount of work since the war commenced. About 1,400 patients have been treated; considerably more than half have been from the Expeditionary Force, 200 have been Belgian wounded soldiers, and the remainder soldiers from the Territorial Force. The work has been chiefly surgical, and in addition to small operations in the wards, about 250 operations have been performed. The wounds have healed remarkably well, and the rapid improvement after a few days in the hospital has been really wonderful. Two cases of tetanus have occurred; both are recovering. There have been six deaths—a very small number, considering that many very serious cases were received. The *x*-ray department has been very busy localizing bullets and pieces of shrapnel, and examining fractures. Over 450 *x*-ray examinations have been made. The General Hospital, Birmingham, has kindly lent its portable *x*-ray apparatus, which is most efficient. The work on the medical side has been very light in comparison with that on the surgical.

Everything in the hospital is running smoothly. Visitors are not permitted except in special circumstances, but the relatives and friends of patients are allowed to visit them on Wednesday and Sunday from 2 to 4, and at other times if the patients are very ill. Often after a fresh batch of patients has arrived there are some visitors who come from a distance, and these are permitted to see the wounded at other times than on the visiting days. It is found that this arrangement works very well. The discipline of the patients and the men of the R.A.M.C.(T.) is excellent.

An increased amount of work falls on the administrative officers of the hospital, as it is part of their duty to send out the patients as soon as they are fit to move to the smaller civil hospitals or to convalescent homes. While the patients are in these smaller hospitals and homes they are still controlled by the central hospital, where all their movements have to be recorded, and arrangements made for their return to their dépôts, etc.

THE BRITISH RED CROSS SOCIETY.

A Period of Severe Pressure.

Sir Frederick Treves informs us that for several days past the pressure upon the British Red Cross organization has been exceedingly severe; more so than at any previous period since the war began. In eight days nearly 10,000 wounded soldiers were removed from trains to hospitals. Sir Frederick said a number of surgeons had been sent to Boulogne in the last ten days, but during that time three batches of orderlies, each 50 strong, had been sent to the same port. The R.A.M.C., in Sir Frederick's opinion, had coped with the great rush in an admirable way; the work could not have been better done. The service was exceedingly well equipped in every particular.

Help for the Allies.

The British Red Cross Society is still rendering considerable help to the French. A large party of doctors and dressers has been sent to Rennes, and another to Calais to supplement the work amongst the French wounded. The Society has also been the means of sending a party of surgeons to Dunkirk to help the Belgians. There are, however, a great many private persons assisting with the treatment of Belgian wounded. Sympathy with the Belgians is so strongly felt in this country that many private expeditions to help them have been equipped. The call for aid from the British Red Cross Society, therefore, has not been very urgent. The plan of keeping a staff of surgeons always in readiness at head quarters for an urgent call has enabled help to be given in response to all demands with a rapidity which has caused some surprise.

Conveyance of the Wounded.

The first British Red Cross hospital train will be running this week; it will convey nearly 500 wounded in a single journey. Motor ambulances are being placed in the field as rapidly as possible; the need is now for liberal funds to meet the heavy running expenses.

FURTHER CASUALTIES IN THE MEDICAL SERVICE.

Army.

Killed.

Since the list of casualties published in our issue of October 31st the names of eight officers of the Royal Army Medical Corps, and one medical man serving as motor cyclist dispatch rider appear among the killed, and one other officer of the Royal Army Medical Corps has died.

Captain Michael Joseph Lochrin, R.A.M.C., took the Licence of the Dublin Colleges in 1904, entered the R.A.M.C. as lieutenant on July 30th, 1906, and became captain on January 30th, 1910. He was recently stationed at Aldershot.

Captain Rupert Henry Nolan, R.A.M.C., was educated at University College, London, took the M.R.C.S. and L.R.C.P.Lond. in 1908, and after serving as assistant medical officer to the London County Council Asylum at Banstead, got his first commission as lieutenant on January 30th, 1909, becoming captain on July 30th, 1912. He had recently gone through a course at the R.A.M. College.

Captain Richard Dominic O'Connor, R.A.M.C., was killed in action on October 25th in the battle of the coast. He was born in 1884, the third son of the late Mr. F. W. O'Connor, F.R.C.S.I., of Limerick. He was educated at Clongowes Wood College and at St. Bartholomew's Hospital. He took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1907, and entered the R.A.M.C. as lieutenant on January 28th, 1907. He became captain on July 28th, 1910. He was recently stationed at Multan.

Lieutenant George Henry Chisnall, R.A.M.C., attached to the 1st Battalion Cameron Highlanders, died of shell fire wounds at Poperinghe, Belgium, on October 24th, aged 28. He was the son of Mr. C. N. Chisnall, of Frating Abbey, Essex, was educated at London Hospital, and qualified in 1908. He took the degrees of M.B. and B.S.Lond. in 1910, and was also F.R.C.S.Eng. A member

of the teaching staff of his school has sent the following tribute to his memory:

Perhaps in nothing is the waste of war more apparent than in the loss of those who, after long years of patient study, have slowly perfected themselves in the art of healing only to be blindly crushed at the very outset of their career.

The thoughts of many at the London Hospital must have yielded some such reflection on hearing of Chisnall's death. Not only was Chisnall, as his academic distinctions prove, a student of outstanding ability—he combined with a very thoughtful temperament an originality of outlook, an industry, and a tenacity of purpose which persuaded his many friends that he would some day take high position in his profession. The essay on "Fractures of the Upper Part of the Humerus and their Treatment," with which he won the Jonathan Hutchinson Prize at his College, was regarded as an earnest of a steady outflow of original work in the future. Personally he was noted for an imperturbable serenity of mind and a geniality of manner which made him beloved by all who knew him.

Having held almost all the resident appointments in the gift of the London Hospital, he volunteered for service in the Royal Army Medical Corps at the beginning of the war. There only remains to us a memory, and a hope that after all Death may not be the gaunt spectre we imagine. To the Greeks it will be remembered θάνατος was a thoughtful youth of not unkindly aspect; right in so much, perhaps they were also right in this.

Lieutenant Reginald Edward Porter, R.A.M.C., was educated at London Hospital. He took the diplomas of M.R.C.S. and L.R.C.P., and the degrees of M.B. and B.S.Lond. in 1911. After serving as house-surgeon of the Royal Free Hospital, he entered the R.A.M.C. on July 26th, 1912, one place above Lieutenant Shields. He was recently stationed at Limerick.

Lieutenant David Wylie Rintoul, R.A.M.C., was killed in action on October 21st. He was 25 years old, the elder son of Mr. D. Rintoul, of Clifton. He was educated at Dundee and St. Andrews, and took the degrees of M.B. and Ch.B. at the University of St. Andrews in 1912. On June 1st, 1913, he was appointed lieutenant in the 3rd South Midland Field Ambulance (Territorial), stationed at Bristol; and got his commission as lieutenant in the R.A.M.C. on January 30th, 1914, having only recently finished his course of training and been confirmed in the army when the war broke out.

Lieutenant Henry John Sladen Shields, R.A.M.C., was killed in action on October 26th. He was the son of the Rev. A. J. Shields, of Thornford Rectory, Sherborne, Dorset, and was educated at Loretto, Jesus College, Cambridge, where he was stroke of the university boat, and the Middlesex Hospital. He took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1912, the M.B. and B.S.Camb. in 1914, and entered the army on July 26th, 1912. He was recently stationed at Pirbright Camp. When the British Expeditionary Force left England he was attached to the Royal Irish Guards; and on September 10th was reported missing in the retreat from Mons, but rejoined a few days later.

Dr. Sidney Nelson Crowther was killed in action on October 18th, while acting as a motor cyclist dispatch rider. He took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1903. He had filled the posts of Prosector at the Royal College of Surgeons, senior house-physician at Westminster Hospital, and assistant medical officer at Brookwood Asylum, before he was appointed senior medical officer of the Surrey County Asylum at Netherne, Merstham, the post he held when he enlisted for service in the war. He was 39 years old.

Death by Accident.

Lieutenant Douglas Wardleworth, R.A.M.C., was accidently drowned at Havre on October 24th. It was a fine morning and he went to bathe. He was seen to dive, but never rose again, and though two of his colleagues went to his assistance, the body was not found until later about a hundred yards from the spot where he had disappeared. Dr. Wardleworth had not been feeling well for some days, and a *post-mortem* examination showed that death was due to heart failure. He was educated at Owens College, Manchester, took the M.B. and Ch.B.Vict. in 1905, and after serving as house-surgeon to the Royal Hospital, Salford, and house-physician to the Royal Infirmary, Manchester, went into practice at Sheringham, Norfolk. He had been gazetted temporary lieutenant in the R.A.M.C. so recently as October.

Wounded.

Hayman, Lieutenant J. R., R.A.M.C. (Reserve).

Prisoner of War.

Field, Captain S., R.A.M.C. (reported missing on September 26th).

NOTES.

PREVENTION OF TYPHOID IN HOME CAMPS.

WE have received the following letter from Dr. Christopher Childs, D.P.H., who worked with Dr. Victor Vaughan, the only surviving member of the U.S.A. Army Commission, in preparing its report upon the typhoid outbreaks among the U.S.A. volunteer camps during the Spanish-American war:

Prevention of Typhoid in our Home Camps.

Sir,—Attention has frequently been called in your JOURNAL and elsewhere to this matter, and yet it seems desirable to press home and repeat several facts in connexion with it.

In all military expeditions, where the soldiers have been encamped in one place for more than two or three months at a time, typhoid fever has invariably broken out and generally spread with epidemic violence.

Examination of the annual army medical reports from the time of the Crimean war shows that this has been the case with our own troops in whatever quarter of the globe our army has taken the field and occupied fixed camps for any length of time. Similar evidence is forthcoming from the records of wars carried on by other nations.

Apparently the impression is general that our typhoid epidemics in the South African war were more severe and extensive than usual. Such is not the case. The epidemics during some of our Egyptian expeditions were far more intense. The Germans, when besieging Metz during the Franco-German war, suffered more severely. So also did the U.S.A. Volunteers in their selected encampments in their own country during the Spanish-American war. You gave an account of the conclusions reached by the able Commissioners, who were appointed to investigate the cause and course of these epidemics, in the BRITISH MEDICAL JOURNAL of September 19th, 1914, p. 510, and a fuller account was published in the BRITISH MEDICAL JOURNAL of July 13th, 1905, p. 137. The statement which concerns us chiefly at present is this—that, out of some 100,000 troops under their observation, about 20 per cent. were infected with typhoid fever during five months, and about 1.5 per cent. died.

At present we are informed that there are 600,000 Territorials, recruits, and other troops encamped or billeted in different parts of the United Kingdom. Fortunately, there are various factors which would prevent such immense losses among them by sickness and death as occurred in the U.S.A. camps. In the first place, the typhoid morbidity and mortality in this country are far less than they were in the U.S.A. at that time. Consequently the number of typhoid first-cases introduced from our general population into the camps must be far fewer. Secondly, our camp sanitation is and will be far more perfect, and the seasonal influence more favourable. Thirdly, a large proportion of these troops will have received the protection of antityphoid inoculation.

But there are also other preventive measures which are plainly indicated by the evidence contained in the report of the U.S.A. Commission. The facts so carefully collected and correlated by them compelled them to conclude that water and the other generally reputed vehicles of typhoid infection were not important factors in the spread of the epidemics, but that the infection was chiefly conveyed from man to man and tent to tent. They made an exhaustive examination of many thousand cases of diarrhœa, "simple continued fever," etc., and were convinced that many of these were in fact cases of incubating or ambulatory typhoid. Such cases are, from various circumstances, constantly overlooked, but are probably the source of much of the infection which experience shows is apt to spread through military camps, unless special and systematic measures are taken for their detection. This is, no doubt, the most important lesson to be learnt from the evidence of the Commission.

Preventive inoculation may reduce the individual susceptibility of the troops to a minimum, but for the prevention of camp infection in our own country (where there

ought to be no difficulty in insuring a supply of pure water, milk, etc.), the most important measure is the detection and separation of these first cases of typhoid.

To carry out and record such observations amongst troops engaged in actual warfare may be very difficult, but it is obvious that the difficulty would be vastly decreased in the case of camps in our own country, where cases of a suspicious character might be separated, put under special observation, and tested bacteriologically with the aid, if necessary, of local bacteriological laboratories. In this way much of the typhoid infection might be cut off at its source.

It might be expected, on *a priori* grounds, that typhoid fever would be directly infectious in military encampments. The age of the soldier corresponds nearly with the age of typhoid susceptibility. A man suffering from the disease in the incubating or ambulatory stage will bring myriads of the disease germs into the tent day after day, infecting the tent itself, the bedding, the soil within and around the tent, and the companions with whom he is frequently in close contact. All these considerations call for the organization of systematic detection, disinfection, and separation of these first cases.

If these preventive measures, together with others mentioned above, are carried out efficiently and systematically, it may assuredly be hoped that with the help of antityphoid inoculation the typhoid invasions which otherwise threaten our home camps may be reduced to a practical minimum.

At some future time it will be of high interest and importance to compare the progress and development of typhoid invasion of our home camps (if it occurs) with that of the U.S.A. Volunteers. Our camp affords a unique opportunity for making systematic etiological investigations, such as has never occurred before, and will not, we may hope, occur again. To the epidemiologist who is keenly interested in the natural history—the etiology—of typhoid epidemics to neglect such a chance will seem simply criminal.

No doubt a commission will be appointed to make a special investigation of the progress, arrest, or development of typhoid in the encampments, and executive as well as medical officers are aware of the need of detecting first cases as early as possible. But it would be well that the rank and file and also the general public should be made acquainted with this source of infection which hitherto has not been generally recognized, in order that they may render intelligent help in carrying out the measures for the prevention of infection.—Yours faithfully,

CHRISTOPHER CHILDS, M.D., D.P.H.

October 27th, 1914.

Wreck of the Hospital Ship "Rohilla."

The hospital ship *Rohilla*, Captain Neilson, was wrecked off Whitby on Friday, October 30th, with considerable loss of life. The last survivors were taken off on Sunday morning. Fortunately there were no patients on board at the time, but she carried a large medical staff. The following is a corrected list of the medical officers who were on board:

The Fleet Surgeon, E. C. Lomas, D.S.O., R.N., in medical charge.
Surgeon S. L. Maclean, R.N. Reserve.
Surgeons, R.N.V.R.: T. C. L. Jones, H. L. Murray, A. E. W. Hird, L. S. Ashcroft.
Temporary Surgeon, R.N.: T. H. Cresswell.
Civilian Dental Surgeon: F. W. Paul.
Nursing Sisters: Miss M. B. Bennett, Miss M. B. Bennington, Miss M. B. Paterson, Miss M. L. Hocking.

All have been saved.

There was a large number of R.N. Sick Berth Staff and R.N. Auxiliary Sick Berth Staff on board, and a considerable number have been drowned, but the total is not yet known.

Mr. Littler Jones, who is surgeon to the Liverpool Royal Infirmary, in giving evidence at the inquest, said that he had joined the ship early in August. Captain Neilson had commanded all the time and discipline had been good. The ship struck at about 4 a.m. on October 30th; the weather was very heavy. The ship's starboard lifeboat was launched successfully, but the line it took parted; the crew of the boat was landed. The Whitby lifeboat arrived shortly after daybreak. The captain of the *Rohilla* ordered the women to go first, then the doctors, sick attendants, and crew and officers, the captain himself being the last to be rescued. Mr. Jones thanked the Whitby inhabitants, high and low, rich and poor, for all they had done for the rescued. Evidence was given by the second coxswain of the Whitby lifeboat that with a motor lifeboat at Whitby no lives would have been lost.

"French Flag Nursing Corps."

A committee formed in this country through the instrumentality of Sir Thomas Barclay, formerly president of the British Chamber of Commerce in Paris, has received a communication from the French Minister for War asking for 300 fully-trained British nurses to take service in the French military hospitals in the regions of Rouen, Le Mans, Rennes, and Nantes. The committee has been authorized to select the nurses and to undertake the necessary organization of "the French Flag Nursing Corps." The French Ministry of War (Service de Santé Section) has undertaken all financial responsibility for the nurses' salaries, travelling expenses, etc., the preliminary financial arrangements being in the hands of the French Consulate in London. Suitable provision has also been made for the supervision and comfort of the nurses.

One detachment of nurses has already been sent to Rouen, and are at work in the military hospitals in that city, and further detachments are being sent out weekly as required. Applications from fully-qualified nurses, particularly from those who can speak French, may be sent to the President of the Committee, Lady Barclay, 60, Nevern Square, London, S.W., or to the Treasurer, Mrs. Bedford Fenwick, 431, Oxford Street, W. The medical advisers of the committee are Drs. R. Murray Leslie and J. Dundas Grant.

The St. John Ambulance Department.

Appeal to Girls.

A special committee of ladies, acting with the European War Fund formed by the Ambulance Department of the Order of St. John of Jerusalem in England, has issued an appeal for funds. In order to extend its work among the wounded in the war, it appeals to the girls of England to give their personal services, and to help in collecting the money required by means of a shilling subscription. It stated that already, under the auspices of the Order of St. John of Jerusalem in England, 150 hospitals and convalescent homes have been established and staffed, and that over 5,500 orderlies have been dispatched to the expeditionary forces, or to the ships and naval and military hospitals, in addition to doctors and nurses. Large quantities of medical stores and supplies have been sent out to the sick and wounded; a number of motor ambulances are being dispatched to France, and a dépôt for the convenience of troops has been established at Southampton, where they can obtain food and medical assistance day and night. The offices of the fund are at Marconi House, Strand, London, W.C.

Convalescents.

The Swiss authorities have issued a statement to the effect that the Federal Council has recently had under consideration the question of whether wounded soldiers belonging to any of the belligerent armies who desire to complete their convalescence at a Swiss health resort are liable to arrest and internment. The Council has decided that, provided such wounded persons cross the Swiss frontier in plain clothes, it is no part of the duty of the local authorities to make inquiries as to their status. On the contrary, the Council desires to be of service to all the belligerent countries by offering every possible facility to those who desire to visit Switzerland for the purpose of renewing their health.

Field Ambulance (Reserve).

3rd Welsh Field Ambulance (Reserve).

Captain E. Brice, R.A.M.C.T., officer commanding the 3rd Welsh Field Ambulance (Reserve), asks us to state that it is in need of medical officers. Communications should be addressed to him at the Drill Hall, Swansea.

The Legion of Honour.

The *London Gazette* for November 3rd announces that the President of the French Republic has, with the approval of His Majesty the King, bestowed the decoration of the Legion of Honour on a number of British officers for gallantry during operations between August 21st and 30th. The list includes the following officers of the Royal Army Medical Corps—one of them, Captain

H. S. Ranken, was killed before the honour could be announced. *Croix d'Officier:* Major S. L. Cummins. *Croix de Chevalier:* Captain S. E. Lewis, Captain J. T. McEntire, Captain H. S. Ranken.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

ULSTER MEDICAL SOCIETY.

THE opening meeting of the winter session was held in the Medical Institute, Belfast, on October 29th. The outgoing president, Mr. A. B. Mitchell, F.R.C.S.I., took the chair, and introduced his successor, Dr. J. S. Morrow, Belfast, who delivered his inaugural address. After referring to the deaths of Dr. Henry O'Neill, Dr. John Gorman, and Dr. James C. Ferguson, and to the Fellows and Members who were at the front or had offered themselves and were in training, Dr. Morrow went on to deal with the main subject of his address, which was disease in its medico-legal relations to accident. He divided the cases first from a legal point of view, according to the Act under which they came, and then from a medical point of view; and, drawing on his long and extensive experience as medical referee to one of the largest shipbuilding firms in the world and to other firms, he gave a most interesting and instructive review of the subject, illustrated by many cases which had come under his own observation.

Sir John Byers proposed in a happy vein a vote of thanks to Mr. Mitchell for his able conduct in the chair last year and his kind hospitality, and to Dr. Morrow for his fresh and welcome address, which combined both the scientific, the clinical, the legal, and the common sense aspects. This was seconded by Professor Sinclair, and passed by acclamation.

SCARLATINA IN BELFAST.

There has again been a rise in the scarlatina rate in Belfast. The disease has been epidemic in Belfast since 1909, and each winter has seen an exacerbation; already this year 1,800 cases have been notified, and 277 new cases have occurred within the last four weeks. The Health Committee is spending £60,000 a year, or 10d. in the £. The Purdysburn Fever Hospital is well equipped, well officered, well nursed; the committee appointed temporarily two medical officers last year to investigate the disease. It is argued that isolation and fever hospitals seem to spread the disease; but, of course, the epidemic might have been still more severe if these means of prevention had not existed. Diphtheria is also increasing. Typhoid fever, formerly rampant in Belfast, is now by comparison nearly extinct. Can nothing be done for the other zymotic diseases?

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

MANCHESTER AND DISTRICT.

THE MIDWIVES SUPERVISING COMMITTEE.

FROM the report of the Manchester Midwives Supervising Committee for 1913 it appears that there were in that year 178 midwives practicing in Manchester, of whom about 80 per cent. were certified. During the year 507 inspection visits were paid to midwives by the executive medical officer, about 80 of the visits being in connexion with cases of puerperal fever or other infectious diseases which had occurred. In addition to this, the mode of practice of 51 of the midwives was investigated in the homes of their patients. In 75 instances the midwives were suspended from practice in connexion with puerperal fever cases, though generally the suspension was only for a few hours until personal disinfection had been carried out. In 22 other instances midwives were suspended owing to various conditions in order to prevent infection of patients. There can be little doubt that the efficient inspection of the midwives has succeeded in obtaining a most satisfactory midwives' service in Manchester.

The records show that midwives advised that a medical practitioner should be sent for in accordance with the Midwives Act, in 2,596 cases. Of these, 77 were for miscarriages or unusual features of pregnancy, 237 for abnormal symptoms during the lying-in period, and 1,301 for difficulties at confinements. Of the last-named class, 404 were for tedious labour and 385 for rupture of perineum. In 981 cases medical aid had to be summoned for the infants, and of these 402 were cases of inflammation of the eyes or eyelids. Though medical aid was thus called in in so many cases, only 519 claims for fees were sent in to the Supervising Committee by the medical attendants. These claims were considered by the Medical Subcommittee, and payment made in 439 cases, amounting to £240. Of the 80 cases rejected as not fulfilling the conditions on which the committee pays medical fees, in 57 the income of the family was above the scale; in 11 the patients themselves paid the fees, while in 6 they could not be traced owing to late application for the fee being made. In the year 1912 the sum paid to medical men summoned by midwives was £535, and the decrease was due to the fact that from April 1st a large number of the payments were modified in respect of deposit contributors under the National Insurance Act. In consequence, however, of the alterations made by Section 14 (4) of the Insurance Act, 1913, with regard to medical fees, the Supervising Committee decided to revert to its former arrangements, and in future fees varying from 2s. 6d. to £1 1s., according to the nature of the case, will be paid to medical men summoned by midwives in respect of patients where the family income does not exceed 23s. a week for man and wife. Where there are already children in the family the income limit will be raised 2s. for each child, so that, for example, the fee will be paid by the committee where the total income of a man and wife with seven children does not exceed 37s. a week. The lowest fee of 2s. 6d. is for a simple visit to the newborn child, while the maximum fee of a guinea has to cover any operative measures necessary at labour or cases of secondary *post-partum* haemorrhage or puerperal fever.

During the year 124 cases of puerperal fever were notified, of which 24 occurred after miscarriages; the total number of fatal cases was 21. In 45 cases the onset of fever occurred within the first four days, in 52 from the fourth to the eighth day, in 11 from the eighth to the tenth day, and in 16 on or after the tenth day. In 51 cases, of which 5 died, midwives alone were present at the confinement; in 18, of which 5 died, both doctor and midwife, were present; and in 55, of which 11 died, doctors alone were present at the confinements. The total births registered for the year were 19,052, and midwives attended at 12,251, or rather over 64 per cent. From this it is evident that there is a higher percentage of puerperal fever among the confinements attended by doctors alone than among the midwives' cases with a much higher death-rate. This is partly accounted for by the fact that the doctors' cases are more frequently treated during the whole course of the illness in homes which are often far from sanitary, while the midwives' cases are more generally sent to Monsall Hospital, where the most efficient sanitary conditions are obtainable. On comparing the figures for 1911 before the Insurance Act came into operation, it appears that in spite of the maternity benefit now payable, there is still a tendency to an increase in the percentage of confinements attended by midwives as compared with those attended by doctors.

Considerable attention has been paid to the question of stillbirths. The total number of stillbirths of which there is any record was 695; this includes 401 in the practice of doctors and 294 in the practice of midwives. The causes are, of course, often obscure, but apart from accident or abnormality or definite illness of the mother, the report states that it has seemed reasonable to credit 5 cases to specific disease, 19 to drink in a marked degree in one or both parents, and 16 to drug taking to procure abortion. There is only too much ground for believing that the last-named cause will account for a much higher number of stillbirths than stated, as the trade in the so-called "female remedies" in the Manchester district is enormous, and in many cases inquiry is difficult and only likely to meet with refusal to confess or absolute denial.

The report concludes with an account of the work of

the two special nurses appointed by the Supervising Committee, one for septic work and the other for non-septic work: in addition, there are two ophthalmic nurses. The work of all the nurses has been much appreciated by both medical practitioners and midwives.

Correspondence.

ANTISEPSIS AND ASEPSIS IN WAR.

Sir,—Professor Tuffier is well known in this country, where the excellence of his work and the soundness of his judgement are justly recognized. It must, therefore, be a source of much satisfaction to Lister's most faithful followers to read in your last number that M. Tuffier, in his report of his inspection of the medical arrangements of the French army, read before the Académie on October 13th, stated, as the first of his general conclusions, "that antisepsis was incontestably superior to asepsis."

Some of us fear that, in the present war, the modern enthusiasm—I had almost said craze—for what is called aseptic, as opposed to antiseptic, treatment of wounds will to a large extent nullify the effects of Lister's teaching. We know that this would have been his own opinion. Aseptic gauze and sterilized water are broken reeds to trust to as compared with a trustworthy antiseptic dressing and carbolic acid, by preference pure, for the first purification of a wound which is possibly infected with the organisms of tetanus or spreading gangrene.

This is written in the hope that it will be read by some of those who may be called to the front, where battles are being waged upon highly cultivated land reeking with these organisms, some of the most resistant to strong antiseptics. I would remind them that in Lister's early compound fracture cases the wounds were treated rather freely with undiluted carbolic acid without any evil result following. They should also bear in mind that mixtures of carbolic acid or corrosive sublimate with blood or serum are very much less potent than solutions of the same strength in water. It is therefore most important to make the wound as dry as possible before starting the process of disinfection. If iodine is employed a saturated watery solution is the best to use; the addition of alcohol, as in the tincture, much diminishes the effect.

Some day, no doubt, the virtues of antisepsis will be rediscovered or reannounced. There are signs, such as Professor Tuffier's strong pronouncement, that the time is not far distant, if it has not already arrived.

I should like to add an urgent appeal in favour of an immediate prophylactic dose of antitetanic serum in all suspicious cases, however slight the wound. If this be combined with vigorous antiseptic purification, it may be confidently anticipated that many lives will be saved.—I am, etc.,

London, W., Nov. 1st. RICKMAN J. GODLEE.

CARE OF THE WOUNDED.

Sir,—May I suggest that our Association is worthy of something better than the anonymous statement on page 769 of your last issue? Surely we ought to have a Special Commissioner present with the forces and reporting fully on the care of the wounded. It is well known that nothing has ever exceeded the devotion and efficiency of the R.A.M.C. personnel, of which the severe losses they have suffered is sufficient proof, but that has nothing to do with the question whether this exceedingly wealthy nation has made the fullest possible provision for the treatment of the wounded after the first dressing on the field. I consider that it has not.

Your correspondent gives a description painfully like those of "Eye Witness," whereas the condition in which the wounded have arrived up to now, shows quite clearly in the opinion of many of us, that in consequence of the enormous numbers of wounded suddenly brought in to the field and base hospitals in France it has been impossible for the surgical and nursing staff to cleanse the patients, to attend to their comforts, and, above all, to sufficiently frequently change the dressings as should have been done, particularly in view of the special dangers to septic infection in this campaign.

As regards the base hospitals, of course the Royal Army Medical Corps has been subjected to great difficulty and confusion caused by strategically necessary changes of bases, but considering that Calais, Boulogne, and Havre are only a few hours from London, a much larger medical and nursing staff could have secured far better conditions than those which at present exist.

I observe that your correspondent refers to motor ambulances. In my opinion it is also not creditable to the nation that private subscriptions should have been set up in order to provide such absolutely essential means of transport of our wounded. Indeed, it is stated that an offer to the War Office of such motor ambulances was originally refused. But, however this may be, it is quite clear that in the first weeks the transport was chiefly by trains, which took days to reach the coast, and here again, in consequence of undermanning in both the medical and nursing staff, a great deal of unnecessary suffering and probably loss of life has occurred.

Unless we have a full and frank record of the work in this campaign military medicine will lose invaluable experience, but what is much more serious our country will lose invaluable lives.—I am, etc.,

London, W., Nov. 4th. VICTOR HORSLEY.

P.S.—As though the conditions surrounding wounds in the present campaign were not sufficiently complicated, there has now been shown to me a memorandum purporting to be issued by the War Office and prepared by Sir Rickman J. Godlee, Bart., in which the terrible proposal is made to swab out recent wounds with pure liquid carbolic acid!

RED CROSS WORK IN FRANCE.

Sir,—Having spent some time at Dieppe at a base hospital, I think I can give some useful information about doctors and nurses. Nurses, however capable, seem unable to get work. One reason which I have received personally is that the British Red Cross take untrained though influential ladies. This has created a very sore feeling, and naturally so. When I left Dieppe some of the upper ten were busy sifting these rumours, either to discover or to cover. Considering the vast sums the British Red Cross receives, the matter should not rest where it is. With its worthy past every one wishes well to the British Red Cross, and it would be a disaster if it became the machine of a faction, or one route to a tinsel glory.

The Croix Rouge Française is poor but very earnest, and doing excellent work with very little money. I visited their head quarters at Dieppe at the Casino. They had some very bad cases, which came in about September 19th—compound fractures of the thigh, etc. Their surgeons are good. This organization will place either surgeons or nurses, but those who apply must not expect "Légions d'Honneur," but only good honest hard work. The London address is 53, Redcliffe Gardens, W.

I joined the French military service, applying to Major Gouillard, who was in control, and I was appointed to a hotel of 80 beds. Everything worked splendidly. In these hospitals a number of French ladies give their services free and freely. I had also two English nurses. I would recommend this entrée as the best. The French rather feel that some of the English want to boss it over there, and there is friction in places. Extreme courtesy is a very essential lubricant in France. They are the most delightful people to work with.

There is at present so much confusion and small rivalry between the various organizations, that all work which cannot be attached to and placed under the direction of the Royal Army Medical Corps should be attached to the French medical military service (head quarters now at Rouen). There is also a good deal of disorganization in the transport of the wounded. I had men from Arras and district who had been five days in the train. Some of the cases were on stretchers. Last week one of my men was wounded at Dixmude in the arm, and not dressed for twenty hours—and then at Calais. From Calais he went to Cherbourg, eighteen hours by sea; and from Cherbourg to Dieppe by rail twenty-two hours. The long journeys are due partly to other trains bringing up troops; but as serious and simple cases are mixed it would be well to have more union amongst the surgeons at the front, who would then send milder cases to Dieppe, Havre, Cherbourg, and England. What, then, about serious cases? I consider

that we should send out twenty or thirty well recognized operators, who should have well-equipped motor vans, and would be able to deal with grave cases at a near but safe distance behind the firing line. There are many cases lost in the first few hours for want of surgical skill and judgement of the best quality. I was told of many cases where main arteries wanted ligaturing, and so on.—I am, etc.,

London, W., Nov. 3rd. ALBERT WILSON, M.D.

ENTERIC AND CHOLERA INOCULATIONS WITH MIXED VACCINES.

SIR,—Sir W. Leishman, Professor Dreyer, Dr. Ainley Walker, and others have emphasized in your columns the importance of antityphoid inoculations. While completely agreeing with these authorities, I would suggest that a mixed typhoid + paratyphoid A + paratyphoid B vaccine should be used instead of simple typhoid vaccine, the reason being that paratyphoid A and B are by no means rare in those parts of the Continent where operations of war are taking place.

The objection raised against the use of this mixed vaccine is that it will probably give a much less amount of immunization for true typhoid than does simple typhoid vaccine, and that paratyphoid A and B, being diseases of much less importance than true typhoid, it would be a mistake to run such a risk. This belief is, I venture to say, incorrect. Experiments I have made in mixed vaccines in the lower animals in 1902, and in man since 1905, have, I think I may venture to say, demonstrated that animals inoculated with three different species of bacteria produce agglutinins and immune bodies for all of them, and that the amount of agglutinins and immune bodies for each germ is practically the same as in control animals inoculated with one species only.[1] I may add that the mixed typhoid + paratyphoid A + paratyphoid B vaccine has been used in man in Ceylon continuously since 1905 with very good results, and that such combined vaccination has been recently introduced into the Japanese Marine Service by Kabeshima[2] with great success.

Details of the preparation of a mixed typhoid + paratyphoid A + paratyphoid B vaccine may be found in an article of mine published in this JOURNAL (December, 1913). It is prepared on a large scale by the Serum Institute of Berne (Switzerland).

If cholera, too, as is by no means improbable, should make its appearance, I would strongly advise the use of the mixed "cholera + typhoid + paratyphoid A + paratyphoid B vaccine," which I have used fairly extensively in Ceylon with satisfactory results. This vaccine consists of a carbolized emulsion of typhoid, paratyphoid A, and paratyphoid B bacilli and cholera vibrios. It is prepared as follows: Agar cultures twenty-four hours old are used; the growth of the typhoid agar cultures is washed off with 0.75 per cent. salt solution containing 0.5 per cent. carbolic acid, is stored at room temperature eighteen to twenty-four hours, and then tested for sterility and standardized in such a way that 1 c.cm. of this carbolized typhoid vaccine will contain approximately 2,000 million of typhoid bacilli. The same procedure is carried out with paratyphoid A and paratyphoid B, but these two vaccines are standardized to contain 1,000 million germs per cubic centimetre. The same technique is used to prepare the cholera vaccine, but this vaccine is standardized in such a way as to contain 4,000 million per cubic centimetre. After having prepared, standardized, and tested for sterility these four different vaccines, they are mixed together in equal parts. The mixed vaccine will therefore contain per cubic centimetre:

Typhoid	500,000
Paratyphoid A	250,000
Paratyphoid B	250,000
Cholera	1,000,000

This mixed vaccine is, therefore, merely a carbolized emulsion of the various germs, no heating being used, as the presence of 0.5 per cent. of carbolic acid is sufficient to kill the bacteria. Ten minims, or about 0.6 c.cm., is given subcutaneously in the arm the first time, and double the dose the second time, a week later. It is of advantage, whenever possible, to give a third inoculation (same dose as the second) two weeks after the first. The reaction is not very severe and the inoculated persons are generally fit for work twenty-four to thirty-six hours after inoculation.

The use of this and other mixed vaccines has been found of advantage in Ceylon, as it is in this way possible to give a certain degree of contemporaneous immunity for several different maladies. Moreover, in my experience, very few people will submit themselves to the discomfort of repeated injections—which would extend over a period of several weeks—in order to be inoculated against three or four different diseases.—I am, etc.,

Colombo, Ceylon, Sept. 30th. ALDO CASTELLANI.

[1] In rabbits no good results are obtained by using more than three species of bacteria, but in man satisfactory results may be obtained by inoculating four and even five species.

IODINE IN SKIN WOUNDS.

SIR,—The war has brought the subject of wound treatment into prominence. While opinion has not yet crystallized on the question of the best form of treatment for the wounds of warfare there is evident in certain quarters a tendency to advocate in military surgery the "iodine treatment" of wounds, which (a revival of an old method) is at present fashionable in civil practice. On the value of the iodine method in military surgery I offer no opinion. Against its routine use in civil practice I am in protest, both in operation and accident cases.

Operation Cases.

At the Brighton meeting of the Association I read a paper on the Surgery of Childhood,[1] in which occurs this passage:

> The practice of not preparing the part for operation until the patient is under anaesthetics on the table receives full support from the results of operations in a children's out-patient clinic where preliminary preparation is impracticable. Further, the experience of operating through skin merely washed with soap and water, followed by methylated spirit, in young children, tends to the attempt to simplify the process of preparation in adults.

Such simple preparation I have often used in adults as well as children. During the past year in my clinic in the Western Infirmary, Glasgow, we have tested it systematically. Cases of the same nature (hernia, hydrocele, gastro-enterostomy, etc.), that is, "clean" cases, have been arranged in pairs for operation without preliminary preparation. Each pair has been washed with soap and water and dried with sterilized gauze, after which one case has been washed with spirit and the other painted with iodine before and after operation. Over a large number of cases the results have been uniform. No case of sepsis has occurred. The use of iodine in clean operation cases would appear to involve needless expenditure of time and money.

Accident Cases.

There can be no question that a large number of simple accident cases painted and dressed with iodine heal perfectly. So do a large number of accident cases treated with dry sterilized dressings, with or without spirit. Accurate comparative tests of the iodine and spirit methods are not possible, but at least the application of iodine in these cases appears harmless.

In lacerated and soiled accident wounds, however, routine treatment by the iodine method cannot be regarded as harmless. In such cases the rapidly drying iodine paint locks up, to incubate in the damaged tissues under a crust of iodine and blood clot, germs which would otherwise escape with the oozing blood into the dry sterilized dressing to lie there inert till the dressing is changed. Further, from what one sees of the ultimate stages of many cases it is difficult to avoid the conclusion that the minds responsible for the primary treatment have been so imbued with the idea that iodine is a germicide and will "disinfect" a dirty wound as to have lost sight of the fact that many accident wounds are not suited to any form of primary dry dressing, iodine or other. To substitute, as a *primary* measure in such cases, iodine paint for a careful search for embedded earth, shreds of cloth, etc., the cutting away of tags of damaged tissues, and the removal of impurities by the use of the douche, limb bath, or wet dressings is to court sepsis.

Iodine may have its uses in surgery. Time will show.

[1] BRITISH MEDICAL JOURNAL, September 27th, 1913.

The present routine and somewhat indiscriminate use of it appears to be opposed to the principles of modern aseptic surgery.—I am, etc.,

Glasgow, Nov. 3rd. JAS. H. NICOLL, M.B.

FEVER AND WAR.

SIR,—It is generally recognized that in time of war the risk of decimation of the fighting strength by the human enemy alone is often incomparably less than is the risk of disablement by invisible bacterial hosts. This applies to bacterial infection of wounds as well as to epidemic disease. Thanks, however, to the efficiency of our own Army Medical Department, there are good grounds for hoping that in the present crisis the experience of previous campaigns as regards infections of all kinds amongst the British units may be reversed. In this connexion it is only necessary to mention the splendid efforts which have been made under the guidance of Sir William Leishman, Sir Almroth Wright, and others to lessen the incidence of medical and surgical infection by vaccination. Recent statements by the Director-General of the Army Medical Department as to the satisfactory nature of the health of our troops in this respect after three months of war, and of preparation for war, abundantly justify the hope that these efforts will not have been in vain. Prevention, the greatest of all the auxiliaries of medicine, promises, indeed, amply to repay the genius of organization which has given it birth. Nevertheless, even in the British units there are inevitably some, and there will certainly be more, who have slipped through the mesh of prevention, and have become infected cases, either in the medical or the surgical sense. And to those of our Allies whose preventive efforts have been for one reason or another unavoidably discounted the bacterial peril may at any moment present greater terrors than the Teutonic onslaught.

The cardinal feature of systemic bacterial invasion from septic wounds or from epidemic disease is fever. Continued fever in adult man spells systemic infection, and to this rule there are few, if any, exceptions. For all practical purposes it is indeed a sure and certain sign that the time for prevention has gone by. Full understanding, therefore, of the true meaning of continued fever is the master key to problems presented by established infection, under whatsoever guise it appears. In the case of the epidemic scourges of the camp, such as enteric, plague, typhus, and the like, the significance of continued fever, especially when severe, is in no danger of being missed. In these, the gravity of known septicaemia is fully recognized, and this also applies to serious cases of surgical sepsis. On the other hand, the significance of lesser degrees of fever, such, for example, as may obtain in early stages of surgical sepsis, is frequently misunderstood. Too often the fever in such cases is variously ascribed to reflex irritation, absorption of hypothetical toxins, pus formation, or other shibboleths of the past. The result is that frequently no attempts are made to determine the true cause of the fever by examining the bacteriological content of the blood. And even in cases of high continued fever this examination is by no means always carried out as a routine procedure. It used to be taught that bacteriaemia is a relatively rare condition, and that septicaemia, or the multiplication in the blood stream of organisms that have gained access thereto, is a condition of fatal import. We now know that this teaching was unsound. Septicaemic cases frequently recover—a fact to which the returns of typhoid and pneumonia recoveries are faithful witnesses. And pathogenic bacteriaemia is extremely common. The point, however, on which I wish to insist is that prolonged clinical and experimental research has convinced me that continued fever in the adult is generally, if not always, due to bacteriaemia, by which I mean the presence of living organisms in the blood. And every case of pathogenic bacteriaemia thus defined is potentially one of septicaemia. The dividing line between a feverish cold in the head and irretrievable disaster is always perilously thin. And this is as true of continued fever, however slight, associated with septic wounds caused by weapons of war and by dirt as it is of epidemic disease, however trifling.

The moral, therefore, is that every case of continued fever, whether occurring in medical or surgical practice, should be at the earliest practicable moment submitted to a searching bacteriological investigation, especially of the the blood. This is necessary both for purposes of diagnosis and of treatment, and especially of vaccine treatment. To wait for the advent of a swinging temperature, profuse sweating, and other signs of grave intoxication is to wait too long. In mild or severe cases of surgical fever it is not sufficient to examine by cultural methods the discharge from wounds, and to prepare vaccines from the varied flora grown, in the hope of hitting off the organisms that have entered the blood stream and are causing the fever. Nor, if fever persists, however slight in degree, is it sufficient to devote attention to the cleansing and disinfection of surface areas of sepsis. In all such cases early cultural examination of the blood should be attempted, and in many of them the results of carrying out a routine procedure of this nature will come as a revelation.

Unfortunately, however, the high bactericidal power of the blood often leads to disappointing cultural results in cases in which bacteriaemia has not yet led to the establishment of a blood-fast race. In these cases examination of the urine for evidence of its infection from the blood stream often unmasks the fever-producing organism, and in so doing provides the instrument for its destruction. In enteric fever, plague, undulant fever, and other diseases we have long recognized haemic infections of the urine with the respective organisms concerned. And, as I have recently shown, this list may be indefinitely extended to numerous morbid conditions, accompanied by fever from slight to severe. Incidentally these haemic infections of the urine in all grades of fever go far towards justifying the dogmatic statement that the essence of continued fever in the adult is the circulation in the blood of living pathogenic organisms.

Hence to bacteriological examination of the blood in continued fever should be added bacteriological examination of the urine, and experience has taught me that time so spent is well spent.

To many no doubt this appeal for routine bacteriological examination of the blood and urine in all cases of continued fever, whether mild or severe, whether occurring in medical practice or surgical, is quite superfluous. A great deal of invaluable work of the kind is admittedly being carried out in many places. On the other hand, there is unquestionably room for wide extension, if one may judge from the number of cases of continued fever in which one is asked to find the cause. On the threshhold of a war that may be greatly prolonged, it is at least our duty to see that every hospital and nursing home that is being used for military or naval purposes shall be generously equipped in laboratory installation and expert personnel. If our large metropolitan and provincial hospitals now serving the forces are already well dowered in this respect, there should be the less excuse for not meeting the legitimate demand of less favoured houses. For this purpose the fortuitous aid of neighbouring laboratories of research, where other work is being carried on, is insufficient; if hospital funds are inadequate to maintain independent, and if possible resident, bacteriological assistants, funds should be obtained by appeal. For it is only by intimate personal contact of pathologists with hospital staffs and their patients that the best results can be obtained.—I am, etc.,

London, W., Oct. 28th. EDWARD C. HORT.

SLEEPING SICKNESS.

SIR,—Your leading article, prompted by a statement from the medical men of the Livingstonia Mission, with which it appeared in a recent number of the BRITISH MEDICAL JOURNAL, is most opportune.

One is loath to send a communication to you which contains no new contribution to knowledge. However, the circumstances under which your leading article and the statement of the medical men who have practised their profession for so long in Central Africa are published, impel me to put on record once again the entire agreement of my experience of sleeping sickness with all that your editorial and the Livingstonia Mission maintain. The facts recorded there, and the deductions resulting from those facts, accord completely with the views at which those working in the Liverpool School have arrived as a result of their studies on trypanosomiasis. These

views have been amplified, completed, and confirmed abundantly by other workers.

That the measures which accurate knowledge of the disease dictates have not been enforced can only be ascribed to that slowly-acting spirit of British administration which demands most complete proof of the necessity of any measure before it is enforced, and never secures the enforcement of any measure until the demand for its enforcement assumes the proportions of a popular outcry. It is for the purpose of adding my voice to an outcry which may possibly secure reasonable action, that entire accordance with the views maintained in the editorial and in the statement of the medical men at the Livingstonia Mission is here recorded.—I am, etc.,

J. L. TODD.

Department of Parasitology, McGill University, Montreal, Oct. 22nd.

Universities and Colleges.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE CALENDAR FOR 1914.

"OUR world has passed away, in wantonness o'erthrown," says Kipling, but the current *Calendar* was in print before the peace, which but three months since seemed secure, had been violated. Hence it includes no record of the emergency arrangements for the examination of candidates. In the chronological register of Fellows we are glad to find that Mr. Barwell and Mr. Bryant still head the list. There are now 1,641 Fellows of the College. Only one, Mr. Arthur Barker, F.R.C.S.I., of University College Hospital, was elected *ad eundem*: 4 were made Fellows by election, 27 were elected as Members of twenty years' standing: 1, Miss Eleanor Davies-Colley, is a Fellow by examination under the Medical Act of 1876, which allows women to receive the diploma, but without conferring on them the privilege of the franchise, whilst 1,608 are Fellows by examination. The total number of Fellows has increased by 52, the total number of Members (17,161) by 35, the ratio being rather unusual. Of the suppressed diploma of Licentiates in Midwifery there remain 268 members of the profession who hold it, 19 less, we regret to say, than last year.

The licentiates in dental surgery number 2,635, which is 76 more than in July, 1913. There are 848 diplomates in public health, an increase of 62, whilst there are 17 diplomates in tropical medicine and hygiene, 4 more than last year, but only 8 are Fellows or Members of the College of Surgeons. This diploma is granted conjointly with the College of Physicians.

Mr. Victor Plarr, the librarian, reports that during 1913–14, July to June inclusive, the library was opened on 273 days, and the number of readers who signed their names was 8,804, the average being 32 daily. The gross income of the college, exclusive of the income from trust funds, amounts to £26,833, an increase of £819, whilst the expenditure in respect of revenue for the past year is £21,425, a decrease of £836 since July, 1913. Probably for the first time the year's expenditure on books has reached the figure of £1,000.

UNIVERSITY OF EDINBURGH.

AT the half-yearly meeting on October 30th of the General Council of the University of Edinburgh, under the presidency of Principal Sir William Turner, there was not much distinctively medical business transacted. It was intimated, however, that among the changes in the university staff were the appointments of Dr. John Thomson as lecturer on diseases of children, of Dr. F. D. Boyd as a senior lecturer on clinical medicine, and of Mr. James M. Graham as lecturer in surgical pathology. It was stated that the war had markedly affected both the teaching power of the university and its complement of students, for twelve members of the staff (lecturers and assistants) were serving with His Majesty's Forces, and the number of matriculated students for the academic year 1914–15 was fully 700 less than at the corresponding date last year. It might reasonably be assumed that the great majority of them were serving with the naval or military forces of the Crown. A roll of honour was being prepared. Already five members of the council had laid down their lives in the cause of their country. These were all medicals, to wit, Drs. John Crocket, H. J. Hopps, J. L. Huggan, A. E. Turnbull, and J. H. D. Watson.

On October 24th Lord Kitchener was unanimously elected Lord Rector of Edinburgh University for the period of three years. But for the war there would have been the customary contest, the Unionists and Liberals having both selected their candidates although neither of them was in the medical profession. On the outbreak of hostilities, however, the political candidates were, with their own acquiescence, withdrawn, and Lord Kitchener's election was not opposed. A telegram was received from Lord Kitchener stating that he was very grateful, and felt much honoured by his unanimous election. He assured the university that even in the press of work at the War Office he would not be unmindful of its interests.

UNIVERSITY OF ST. ANDREWS.

AT its meeting on October 24th University Court intimated its opinion that it was the duty of every able-bodied man student to join the Officers' Training Corps.

A letter was read from Professor Musgrove offering as a gift to the university his anatomical museum for use in the anatomy department at the Bute Medical Buildings, St. Andrews. The Court accepted Professor Musgrove's valuable collection with very hearty thanks, and expressed the opinion that it would be of very great service to the teaching of anatomy of St. Andrews.

UNIVERSITY OF GLASGOW.

THE following candidates have been approved at the examinations indicated:

FIRST M.B. (B., Botany; Z., Zoology; P., Physics; C., Chemistry).—T. A. J. Aitchison (P.), J. S. Aitken (B., P.), J. L. Anderson (B., P.), T. Anderson (B., P.), J. Barlow (B., P.), B. Barrowman (B., P.), R. Bethune (B., P.), A. S. Bisset (B., Z., C.), A. Black (B., P.), D. MacC. Blair (B., P.), S. B. Borthwick (B., P., C.), D. C. Bowie (B., Z., P.), R. R. S. Bowker (B., P.), E. T. Boyle (Z., C.), A. D. Brown (B., P., C.), M. J. Cahalane (B., P.), J. P. Chisholm (B., Z., C.), M. B. Clark (C.), H. A. Cochrane (B., P., C.), A. C. Connell (B., P.), J. S. Cook (B.), G. M. Cooper (B., P.), J. L. Cowan (B., P.), E. M. E. Cumming (Z., C.), A. M. Davidson (B., P.), D. R. F. Davidson (B., P., C.), J. Donald (B., P.), J. C. Dow (B.), A. B. S. Drysdale (B., P.), W. W. Ferguson (B., P.), A. B. Ferrie, M.A. (B., P.), D. Finlayson (B., P., C.), R. A. Forsyth (B., P.), A. D. Fraser (B., P.), G. K. Fulton (P.), M. F. Gibson (B., P.), W. Gibson (B., P.), J. S. M'L. Gray (B., P.), W. Guy (P., C.), J. A. Hamilton (C.), W. Harrison (B., P.), J. G. Harrower (P., P.), A. Henderson (B., P.), J. Hewitt (B., P.), T. J. Honeyman (P.), J. Hood (B., P.), T. O. Howie (B., P.), T. Hutchison (B., P.), M. Hyman (B., P.), J. Irving (B., P.), R. P. Jack (B., P.), J. Johnston (B., P.), W. Jope (B., Z., P.), G. M'C. Kennedy (B., P.), A. A. Kirkland (B., P.), W. M. Knox (B., C.), J. C. Laurie (B., P.), R. G. Letters (B., P.), B. Levine (B., P.), A. C. Lindsay (B., P.), D. M. Lindsay (B., P.), J. Lipschitz (B., Z., P.), A. J. Macartney (Z.), S. G. M'Clelland (Z., P., C.), D. MacColl (Z., C.), A. B. Macdonald (Z.), W. D. Macfarlane (B., P.), W. M. MacFarlane (B., P.), S. W. M'Ghee (P.), R. T. M'Gibbon (B., Z., P., C.), J. A. C. MacGregor (B., P.), W. S. M'Intyre (C.), A. Mackay (B., Z.), J. W. Mackay, M.A. (C.), P. A. Mackay (B., P.), R. Macl. M'Kean (C.), A. A. M'Langhland (C.), A. H. M'Leau (B., P.), A. Maclean (B., Z., C.), D. Maclean (P., C.), N. A. MacLean (B., P.), W. S. L. M'Leish (C.), W. M'Linden (B., P.), W. B. M'Queen (B., P.), A. W. M'Rorie (B., P.), J. Matheson (P.), J. M. Melvin (P.), J. G. Miller (B., P., C.), J. H. Miller (P.), K. S. Miller (Z., P., C.), M. S. Molema (B., P.), N. M'E. Montgomery (P.), W. Moore (B., Z., P., C.), J. W. Morton (B., P.), W. Napier (B., P.), G. Nelson (B., P.), B. F. Niblock (B., P.), J. Nicol (B., P.), J. Nicolson, M.A. (B., Z., P.), I. L. Oluwole (B., P.), J. Paterson (B., P.), N. B. Peacock (P.), J. W. Pedeu (B., P.), B. T. Pelham (Z.), R. J. Peters (B., P.), A. G. Petrie (Z., C.), J. Pollock (B., P.), J. B. Potter (B., Z., P., C.), R. U. Qureshi (B., C.), D. Reid (B., P.), A. Riddell (C.), J. M. Ritchie (B., P.), A. Robertson (B., P.), G. M. Robertson (B.), H. A. Ross (B., P.), R. P. Smith (B., P.), P. Speed (B., Z., P., C.), T. Stark (B., P., C.), H. W. J. Steen (P.), J. Stevenson (Z., C.), R. M. Stevenson (C.), A. S. B. Stewart (B., P.), J. Stewart (B., Z., P., C.), A. S. Strachan, M.A., B.Sc. (Z.), J. T. Taylor (C.), E. J. T. Thompson (B., C.), J. Todd (P.), J. L. Turpie (B., P.), M. F. Turpie (B., P., C.), A. S. van Coller (Z., C.), J. C. Vaughan (B., P.), A. R. Waddell (P.), H. D. Wallace (B., P.), J. A. Walls (P.), H. Wands (B., P., C.), D. M. Watson (B., P., C.), J. C. Watt (B., P.), R. K. Watt (B., P.), J. T. Wilson (B., P.), J. W. Wilson (B.), G. M. Wishart (B., P.), J. S. Young (Z., C.), Helen F. Allinson (P.), Ellen D. Anderson (B., P.), Helen C. Cameron (B., P.), Mary T. L. Clark (B., P.), Margharita M. L. Conner (B., P.), Charlotte A. Douglas (B., P.), Grace A. Fleming (B., P.), Jane E. Hanson (B., P., C.), Janet W. Hepburn (B., P.), Helen Hogg (B., P.), Margaret Logan (B., P.), Elizabeth C. Loudon (B., P.), Mary J. Macdonald (B., P.), Alice M'Elwee (B., P.), Alice M'Glashan (B., P.), Evelyn C. M'D. M'Gregor (B., P.), Maud E. D. Mackinnon (B., P.), Mabel M. Maclean (B., P.), Margaret G. M'Vey (B., P., C.), Muriel M. M'Walter (B., P.), Florence F. M. Milne (B., Z., C.), Georgina Murdoch (B., P.), Kathleen Nicol (Z., C.), Elizabeth P. Y. Paterson (B., P., C.), Vida J. Perry (P.), Louise E. Pigeon (B., P.), Margaret I. Prangnell (B., Z., C.), Agnes P. Routledge (P.), Marjory N. Scanlan (B., Z., P.), Jane E. Shortt (B., P.), Margaret M. C. Steedman (B., P., C.), Dorothea H. Suttie (Z., P., C.), Lydia I. H. Torrance (Z.).

SECOND AND THIRD M.B.I (A., Anatomy; P., Physiology; M., Materia Medica and Therapeutics).—W. Adams (A., P.), R. Aitken (A., P.), G. W. Allan (A., P.), J. Ashforth (A., P.), A. B. Austin (A.), J. W. W. Baillie (A., P.), W. Baird (M.), J. E. Bannen (M.), M. N. Bhattacharjie (M.), T. Blackwood (M.), J. Bradford (A., P.), A. G. Brand (A.), J. P. Broom (M.), A. C. Brown (M.), H. D. Brown (M.), J. A. Buchanan (M.), S. E. A. Buckley (M.), R. S. Caldwell (A., P.), D. Cameron (M.), W. J. S. Cameron (A., P.), J. MacD. Clark (P., M.), D. Clyde (M.), A. F. Cook (M.), A. S. Cook (M.), W. G. Cook (M.), H. L. Coulthard (A., P.), J. S. Craig (A., P.), J. Crerar (M.), H. A. Cruickshank (A., P.), R. Cunningham (M.), G. del Pino (A., P., M.), M. Devers (A., P.), A. Dick (A., P.), S. N. Dykes (M.), W. Edgar (A.), J. P. Fleming (A., P.), T. Forrest (A., P.), W. W. Forsyth (A., P.), L. L. Fotheringham (M.), R. J. L. Fraser (A., P.), J. B. D. Galbraith (A., P.), L. M. Gemmell (A.), A. B. Gibson (A., P.), W. H. Gibson (M.), J. G. Gilmour (M.), W. H. Gordon, M.A. (A., P.), G. O. Grant (A., P.), T. Gray (M.), W. R. D. Hamilton (A., P.), D. Heard (M.), S. J. Henderson (M.), J. Sinclair (M.), Jane Stalker (P.), Alison D. Wilson (P.), Marion B. D. Wilson (P.),

† Old or New Ordinances.

NATIONAL UNIVERSITY OF IRELAND.

The Senate met on October 29th.

The late Sir Christopher Nixon.

The following resolution was adopted unanimously:

The Senate hereby records its deep regret at the death of the Right Hon. Sir Christopher Nixon, Bart., M.D., LL.D., who as Vice-Chancellor of the University and as its representative upon the General Medical Council and other public bodies has rendered invaluable and unfailing service to the advancement of the University since its inception; and the Senate desires to offer to Lady Nixon and the other members of her family its most sincere sympathy with them in their bereavement.

Appointments.

Sir Arthur Chance, F.R.C.S.I., has been appointed to be a member of the Senate, and Dr. Joseph F. O'Carroll a representative of the Senate on the governing body of University College, Dublin.

The following were appointed to the offices indicated:

Soaghan, P. MacEnri (John P. Henry), M.D., M.A., B.Ch., D.P.H., Professorship of Ophthalmology and Otology, University College, Galway; Miss Adeline English, M.B., Lectureship in Mental Disease, University College, Galway; Professor Brereton, Lectureship in Operative Surgery, University College, Galway; Joseph F. O'Carroll, M.D., F.R.C.P.I., Professorship in Medicine, University College, Dublin.

A Travelling Studentship Examination in Medicine (Physiology) has been awarded to Michael T. MacMahon, M.Sc., M.B., B.Ch., B.A.O., of University College, Dublin, and the Dr. Henry Hutchinson Stewart Medical Scholarship has been awarded to Patrick T. Murphy, of University College, Cork.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A comitia was held on Thursday, October 29th, Sir Thomas Barlow, Bart., K.C.V.O., the President, being in the chair.

Admission of Members.

The following gentlemen, having passed the required examination, were admitted Members of the College:

Philip Heinrich Barr, M.B.Camb., L.R.C.P.; Vraspillai Gabriel, L.R.C.P.; Alfred Howell, M.D.Lond., L.R.C.P.; Ernest Rivaz Hunt, M.D.Camb., L.R.C.P.; Hugh Basil Greaves Newham, L.R.C.P.; James Herbert Rhodes, M.B.Lond., L.R.C.P.

Licences Granted.

Licences to practise physic were granted to sixty-seven gentlemen who had passed the requisite examinations.

Jenks Scholar.

It was reported that Mr. J. D. M. Cardell had been appointed the 22nd Jenks Scholar.

Harvey.

The gift by Sir R. Douglas Powell of a photograph of the painting by Yeames of Harvey at the battle of Edgehill, was accepted with the thanks of the College.

Venereal Diseases.

It was resolved that the President of the College should become, *ex officio*, a member of an Advisory Board to the National Council for Combating Venereal Diseases.

Sale of Narcotics.

A further report was received from the Censors Board concerning restrictions in the sale of opium and other narcotics. The Board recommended that Clause 4 of their original report, which clause was referred back to the Board at the Quarterly July College, should read as follows:

> 4. That with regard to prescriptions which, when fully made up, contain 1 per cent. (1 grain in 110 minims, which is approximately 4.5 grains to the fluid ounce) or more of the alkaloids in question, and in the case of every preparation intended for subcutaneous use, the doctor should state in his prescription the number of doses to be supplied. The prescription should not be dispensed more than once unless at each renewal it is fully signed and dated by a qualified medical practitioner.

The report was adopted.

Colonial, Indian, and Foreign Universities.

The Committee of Management reported that the Committee had had under consideration the existing regulation as to the admission to the final examination of students of Colonial, Indian, and foreign universities recognized by the Board. It was considered that the present requirement was a hardship. A recommendation of the Committee that Clause IV should be altered to read as follows was adopted:

> IV. Members of Colonial, Indian, or foreign universities who shall have passed such an examination or examinations at their universities for the Degree of Doctor or Bachelor of Medicine or Surgery as shall comprise the subjects of the first and second examinations of the Examining Board in England, and who shall have completed the curriculum of medical study required by the regulations of the Board, will, two years after having passed such examinations, be eligible for admission to the third or final examination of the Board; any candidates so admitted to examination will be required to pay a fee of twenty guineas; and any such candidates who shall have passed the third or final examination shall, on the further payment of not less than twenty guineas, and subject to the by-laws of each college, be entitled to receive the Licence of the Royal College of Physicians of London and the Diploma of Member of the Royal College of Surgeons of England.

Prince of Wales's Fund.

On the recommendation of the Finance Committee the College resolved to contribute 200 guineas to the Prince of Wales's Fund for relief of distress caused by the war.

Committee of Management.

Dr. J. A. Ormerod was re-elected a member of the Committee of Management.

After some further formal business the President dissolved the Comitia.

CONJOINT BOARD IN SCOTLAND.

The following have passed in the examinations indicated:

First Examination.—Mahmond A. K. Mofreh, W. B. Lawson, A. B. MacDougall, E. E. Bronstorph, and Hassan A. Madwar, and two passed in Physics and three in Biology.

Second Examination.—J. B. Minford, N. J. Laubscher, H. Morley, R. Woodside, F. Jones, J. L. West, P. Vertannes, W. U. D. Longford, C. Pullao, G. M. S. Lindsay, and three passed in Anatomy, and five in Physiology.

Third Examination.—E. P. Dewar, G. T. Makhijani, Y. N. Kadam, C. E. Meryon, J. R. B. Robb, W. G. Bowie, M. A. White, A. E. Elliott, and three passed in Materia Medica.

Final Examination.—A. B. Hawkins, F. W. Heyworth, N. H. Brewster, W. H. O'Grady, J. R. Fleming, G. C. S. Perera, W. C. Fraser, A. E. James, L. O. Woinman, A. A. Murison, J. Martin, G. L. Pierce, W. S. O'Loughlin, Khusru R. Mehta, and four passed in Medicine, ten in Surgery, twelve in Midwifery, and eleven in Medical Jurisprudence.

SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have passed in the examinations indicated:

SURGERY.—*†J. A. A. Boldy, *†M. M. Burt, *†P. H. Burton, *W. Brown *C. H. Fischel, *†J. Stephenson.

MEDICINE.—†W. Brown, *H. H. Fairfax, †C. H. Fischel, *N. W. Rawlings, *†G. Robinson, *†J. Stephenson, *†W. C. S. Wood, †A. K. S. Wyborn.

FORENSIC MEDICINE.—W. Andrew, C. E. Clark, A. J. Fradersdorff, N. Hoffmeister, G. Robinson, J. Stephenson, W. C. S. Wood.

MIDWIFERY.—A. U. L. Bennett, M. M. Burt, C. S. Dodson, J. Stephenson, W. C. S. Wood.

* Section I. † Section II.

The diploma of the Society has been granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery: P. H. Burton and J. Stephenson.

The Services.

PAY AND ALLOWANCES.

WE have received inquiries and representations with regard to the pay of medical officers of the R.A.M.C.(T.), and, as far as we have been able to ascertain, the following are the facts:

It would appear that during an ordinary camp training a captain in the R.A.M.C.(T.) was entitled to:

	s.	d.	
Regimental pay	15	6	a day.
Mess allowance	4	0	,,
Field allowance	3	6	,,
Half lodging allowance	1	1½	,,
Total	£1	4	1½

Less income tax deducted from his regimental pay and half lodging allowance.

Under present conditions a captain in the R.A.M.C.(T.) is entitled to:

	s.	d.	
Regimental pay	15	6	a day.
Rations, or in lieu thereof a sum of ...	2	0	,,
Field allowance, if not provided with lodging and attendance	3	6	,,
Total	£1	1	0

Less income tax, but *plus* 3d. which can be paid for the use of a hut or shelter for him.

The regulation with regard to field allowances (Section 15, paragraph 472) states that field allowances are "granted to officers and warrant officers in aid of the expenses caused by their being placed under canvas, or, when during mobilization, manœuvres, or military training, they are accommodated in war shelters, temporary hutments, or quarters equipped according to the scales for officers' tents in standing camps, laid down in the Equipment Regulations, Part I. The allowance is not issuable in respect of active service to staff officers in receipt of consolidated rates of pay, nor to officers paid at the same consolidated rates and under the same conditions."

The volunteer surgeon recently enlisted receives in the new army £1 4s. 6d. per diem *plus* rations and shelter and a gratuity at the end of the war.

INDIAN MEDICAL SERVICE.

A GOOD service pension of £100 per annum has been conferred upon Surgeon-General T. Grainger, C.B.; Surgeon-General G. F. A. Harris, C.S.I., V.H.S.

Medico-Legal.

KEATS *v.* BRACEY-WRIGHT AND ANOTHER.

Before Mr. Justice Bray and a Special Jury.

THE re-trial of this libel action—the jury having disagreed at the previous hearing in March last—began on October 13th, 1914, and lasted five days. The action was brought by Dr. W. C. J. Keats, medical superintendent of the Camberwell Infirmary, against Mrs. C. A. R. Bracey-Wright (also known as the Countess de Lormet) and Mr. W. H. C. Bracey-Wright, her son, to recover damages for alleged libel. The defendants pleaded that the statements complained of were true in substance and in fact, and that the opinions expressed were fair comments on matters of public interest. They also pleaded that the occasion of publication was privileged.

Mr. McCall, K.C., and Mr. A. Neilson, instructed by Messrs. Le Brasseur and Oakley for the London and Counties Medical Protection Society, Limited, appeared for the plaintiff, and Mr. Cecil Walsh, K.C., and Mr. Simey for the defendants.

The alleged libels complained of by the plaintiff were published in an election address issued by the defendants during their candidature for election to the Camberwell Board of Guardians and in a leaflet circulated by them. The allegations made against the plaintiff were that as medical superintendent of the infirmary he had been concerned in the flogging of child patients with what was described as a five-tailed lash, and that a practice of flogging convalescent children prevailed at the infirmary. The jury returned a verdict for Dr. Keats with £300 damages.

CONVICTION OF UNQUALIFIED PRACTITIONER.

ON October 28th, at the Sheffield City Police Court, Robert Reginald Stanley Renton was at the instance of the Medical Defence Union charged under Section 40 of the Medical Act, 1858, with falsely pretending that he was a physician and surgeon. According to the report in the *Sheffield Daily Telegraph*, an inquest was held on August 31st with regard to the death of a woman with whom the defendant had been living; it appeared that he had prescribed for the woman, but that there was no suspicion about the medicine ordered. In giving evidence the defendant had stated that he was an unregistered dentist. The police found on the door of the house where he resided a plate describing him as "R. Renton, B.A., M.B., L.M., physician and surgeon." Another plate on the premises bore the words "R. Renton, the Dental Surgery Branch." Further inquiries showed that the defendant had practised dentistry at Liverpool under the name of R. S. Renton, and appeared to have attended several persons in the character of medical adviser. After the inquest he joined the army, and was now a sergeant in the Bedfordshire Infantry. The defendant, who expressed his regret at what had happened, denied that he had absconded when the inquest was over, and stated that, having previously been in the army, he rejoined. The Bench imposed a fine of £20, or two months' imprisonment.

Obituary.

GEORGE RYDING MARSH, M.D.,

LATE CHAIRMAN, BRIGHTON DIVISION, BRITISH MEDICAL ASSOCIATION.

DR. GEORGE RYDING MARSH died on October 24th, at Hove, in his 57th year. He was the son of the late Dr. J. C. Lory Marsh, a well-known medical practitioner of Nottingham, and one of the founders of the Royal Sanitary Institute. An accident in boyhood resulted in tuberculous disease of the spine, and though he recovered from this illness, the history of his subsequent life was that of a successful struggle against physical weakness and indifferent health. He received his medical education at Guy's Hospital, and in spite of delicacy had a highly successful course, taking prizes in his first, second, and third years. He graduated M.B.Lond. with honours in 1881, and M.D. in 1887. On leaving Guy's he became house-surgeon to the Royal Surrey County Hospital, and subsequently to the Royal Alexandra Hospital for Children at Brighton. On resigning the latter appointment, he started in practice at Hove, where he achieved considerable reputation as a surgeon, and gained the confidence and affection of a large circle of patients. He was for twenty-three years honorary surgeon to the Brighton and Hove Dispensary, and on the opening of the Carr-Burton Hospital became a member of the visiting staff, and devoted himself with much skill and industry to the extension of the work of that institution.

He was one of the most useful and hard-working members of the Brighton Division of the British Medical Association; in 1904, the year following its formation, he became honorary secretary, an office which he held until, in 1911, he became vice-chairman, and, in 1912, chairman of the Division. The year 1912–1913 was unusually trying, for it was the chairman's duty to preside at the many important, and sometimes stormy, meetings preceding the passing into law of the Insurance Act. Besides this, the preparation for the annual meeting which was held in Brighton in 1913 threw a large amount of work and responsibility upon the shoulders of a man who was already in failing health.

It was characteristic of Ryding Marsh that, when in the early part of 1913 he became aware of symptoms pointing to a recrudescence of his old complaint, he came to the deliberate conclusion that treatment would not be likely to effect a permanent cure, and therefore decided to go on quietly with his work so long as his health enabled him to do so. To this decision he firmly adhered, visiting his patients until increasing weakness prevented him getting into his car, and even then continuing to receive patients at his house.

The last year of his life was passed resting patiently and cheerfully in bed, bearing the burden of pain and failure of strength without complaint, and never failing to take a keen interest in his profession and in the welfare of his former patients.

ALEXANDER HAY HILL McMURTRY, M.D., M.CH., R.U.I., L.M.GLASG.,

BELFAST.

IT was with great regret that the announcement of the death of Dr. McMurtry was received in Belfast; he had been in failing health for a year or so, and had been confined to bed for a few weeks with cardiac trouble before the end came on the morning of October 18th.

Dr. McMurtry was 71 years old; he was born in Ballymoro, and, after an excellent schooling, entered the old

Queen's College in 1860, where he won the entrance classical scholarship; during his medical course he gained numerous prizes, and held the Malcolm Exhibition in the old Royal Hospital; in 1864 he took the degree of M.D. with second class honours, and shortly afterwards commenced private practice in Belfast, where he worked uninterruptedly.

Dr. McMurtry had a large practice; he was much beloved and respected by his patients, and trusted as few medical men are; he was cultured in the true sense of the word, well read, and a good linguist. He was an ardent teetotaler, and contributed both to the medical societies and lay press many articles, all characterized by sound common sense and scientific knowledge; the first anti-alcohol manifesto from the medical profession in the United Kingdom was issued at his suggestion almost fifty years ago, although the initiative was taken by Mr. Robert Rae, of the National Temperance League, London. Dr. McMurtry was for his whole professional life a logical, strenuous, and consistent opponent of the use of alcohol as a beverage; this steadfastness of purpose and fixity of character and resolution would alone constitute a claim to a high place in our estimation. The profession and the public want such men; some may regret that he did not strike higher in his efforts, that his ambition was not equal to his powers. Few men, however, have died so respected and so beloved.

He leaves a widow, six daughters, and one son, with whom much sympathy is felt.

J. HERBERT SIMPSON, M.D.,

CONSULTING MEDICAL OFFICER, RUGBY HOSPITAL.

On October 22nd there passed away, at Rugby, Dr. James Herbert Simpson, who was for thirty-five years one of the leading general practitioners in the Midlands. He was born in Yorkshire sixty-four years ago, and educated at St. Bartholomew's and Aberdeen University, where he graduated M.B., B.C. in 1876. In that year he settled in Rugby as partner to the late Dr. S. B. Bucknill, a name honourably associated with Rugby for many generations. Dr. Simpson graduated M.D.Aberd. in 1878 and took the diplomas of M.R.C.S. and L.S.A. in 1876.

He was a man who earned for himself, by his own personal merits and conscientious devotion to his profession, the love, respect, and esteem of a large number of people, both rich and poor, in Rugby and the immediate neighbourhood, where he built up a large practice. He was a type of the best class of general practitioner, extremely methodical in all his transactions, punctual in his work, sound in business, and thoroughly upright. He was one of the early pioneers of the St. John Ambulance Association, and his work in connexion with that society and the London and North-Western Railway (to which he was surgeon) will long be remembered.

He was also a zealous Freemason, was Past Master of the Lodge of Rectitude, No. 502, Past Grand Warden of Warwickshire, and a generous contributor to the Royal Masonic Benevolent Institution.

Four years ago his health gave way and he was reluctantly compelled to give up practice.

He is survived by one daughter and two sons, one of whom is a master at Rugby School and the other at Tonbridge School.

Dr. Herbert E. Rayner, who died after a short illness at Brighton, retired nearly two years ago from active professional work after a breakdown in health. He had so far recovered, however, that a few days before his death he had offered himself to the War Office for medical service at the front. Dr. Rayner, who was in his 50th year, was a student of the London Hospital, and took the diplomas of L.R.C.P. and M.R.C.S. in 1885 and of F.R.C.S. in 1891. He was house-physician and clinical assistant in the out-patient department of the London Hospital and afterwards surgical registrar and anaesthetist at the Hospital for Sick Children, Great Ormond Street, and clinical assistant at the Royal Ophthalmic Hospital at Moorfields. Dr. Rayner had a large practice at Camberley and took an active part in the public life of that district. For three consecutive years (1899–1902) he was chairman of the Frimley Urban District Council, and during that time was chairman of the Sanitary Committee. On the completion of his period of office he retired from the Council. He re entered it in 1905, and once more became its chairman in 1911, an office he continued to hold till he gave up practice in 1913. He was at one time medical officer and public vaccinator for the Frimley district. Dr. Rayner was one of the best all-round sportsmen in the district; he was the founder of the Camberley Hospital Football Cup Competition, and donor of the handsome "Rayner" Challenge Cup, one of the best football trophies in England. The Committee of the Cottage Hospital recognized his generosity by naming after him a bed at the institution. Dr. Rayner was also a vice-president of the Camberley and Yorktown Football Club, and the now defunct Camberley St. George's Football Club. He had himself, in his younger days, been a strenuous player, and before he took up his residence at Camberley was one of the founders of a West of England football club which has since developed into one of the leading professional clubs. He was an enthusiastic cricketer, a keen motorist, and fond of yachting. As a medical man Dr. Rayner was much beloved by his patients, and his cheerful manner always did much to brighten the sick room. He leaves a widow and family, for whom the greatest sympathy is felt in their bereavement. At the funeral, which was largely attended although it took place in a heavy downpour of rain, the district council and other local public institutions were represented.

We regret to have to record the death of Dr. Wallis, which occurred at Leiston, Suffolk, on October 27th. Edward Darby Wallis was born at Bodmin, Cornwall, in 1847, and after passing through University College took the diploma of M.R.C.S. In 1872 he went to Suffolk, where he spent the whole of his professional life. He held several public appointments, including that of medical officer of health to the Leiston Urban District Council, and was honorary surgeon to the Aldenham and Thorpe Convalescent Home. He leaves a widow and seven children, one of whom is a lieutenant in the R.A.M.C., and is now serving at the front. The funeral took place at Leiston, when there was a large and representative gathering to testify to the high esteem long enjoyed by Dr. Wallis.

Medical News.

Dr. J. G. Gordon-Munn, M.D., F.R.S.E., of Heigham Hall, Norwich, and Weybourne Court, Norfolk, has been selected as the new Lord Mayor of Norwich for the coming year. Dr. Gordon-Munn is the first medical Lord Mayor of Norwich, though Sir Peter Eade, M.D., F.R.C.P., filled the office of Mayor in 1893.

Dr. W. J. Howarth, Medical Officer of Health for the City of London, will read a paper at the meeting of the Society of Medical Officers of Health on November 13th on the marking of meat. Dr. Howarth will discuss directions in which the administrative measures with regard to the examination of meat can be improved.

The new University of Frankfort has been formally opened, notwithstanding the war. Among the appointments to the medical faculty are the following: Excellenz Paul Ehrlich to the chair of experimental therapeutics; Karl Herxheimer to that of dermato-syphilography; Ludwig Edinger to that of neurology; and Ludwig Rehn to that of clinical surgery. The total number of professors in the faculty is fifteen.

It is announced that the award of the Nobel prizes for medicine, literature, chemistry, and physics will be postponed till next year. When will the Peace Prize be awarded? It is proposed in future to make the formal distribution of the prizes every year in June instead of December 10th, the anniversary of M. Nobel's death, when the awards will merely be announced.

We have received from Mr. H. K. Lewis, of 136, Gower Street, London, a "List of Medical Journals" conveniently grouped under subjects and giving the subscription rates. It was compiled and printed before the European crisis became acute, and journals issued in enemy countries cannot at present be supplied. Though the list includes nearly 300 names, only the leading publications are included.

The work of the Dundee Medical Service, set up to take the work of practitioners on military service, during

the eight weeks to the end of the quarter, was as follows: Cases attended at home, 1,539; confinements, 60; attendances at the central consulting-rooms (daily average), 113. The number of medical hours at the consulting-rooms was 614, and the number of hours' work estimated for the visits, 1,026, giving a total of 1,640 hours. The amount distributed in payment, excluding confinements, was £408. The expenses to date amount to £54 4s. 7d. (telephones, £19 4s. 9d.; wages, etc., £24 15s.; stationery, etc., £11 4s. 10d.). About 40 per cent. of the profession are now on military service. Those who remain are each making over ten extra visits daily.

A CERTAIN number of Belgian professors and a growing number of students from Louvain, Liége, Ghent, and Brussels are now in Cambridge, and although it has proved impossible for the Louvain University to transfer its corporate and official existence to Cambridge, unofficial courses have been instituted, combining, as far as possible, systematic instruction on the lines of the Belgian Universities with the individual requirements of refugee students. In view of the appeal issued by the Belgian Government for volunteers, it has been decided, in consultation with the Belgian Government, that only such students as are physically unfit for military service or have been rejected for other reasons by the Belgian authorities, and are in possession of a certificate to that effect, can be accepted by the hospitality and academic committees.

AT the autumn meeting of the Midland and Northern Division of the Medico-Psychological Association held at Wye House, Buxton, by invitation of Dr. Graeme Dickson, on October 22nd, Dr. R. C. Stewart opened a discussion on Restraint in Mental Disease. He considered briefly mechanical restraint, the use of single rooms, the question of locked doors in asylums, and the treatment by sedatives. He was of opinion that everything that took away the feeling of restraint tended to benefit the patient. During the discussion it was generally agreed that the difficulty of finding a suitable means of restraint arose in chronic cases. The use of verandahs and sleeping out of doors for noisy patients were considered beneficial. The various forms of sedatives in use were mentioned, and special reference was made to the use of bromides.

THE Professional Classes War Relief Council has been formed to give assistance to men and women of the professional classes who have been severely embarrassed by the war. The chief forms of assistance which it has been decided to give are connected with training for productive work, education of children, and maternity aid. The council has already a maternity nursing home at 13, Prince's Gate, a beautiful house kindly lent for the purpose by Mr. J. Pierpont Morgan. The home has a voluntary medical staff of many well-known medical men and women, and a voluntary nursing staff of certificated nurses. It is hoped that in time similar homes may be established in the provinces. The council also proposes to give help by way of supplying free maternity nurses, arranging for free medical attendance, and providing maternity necessaries. The committee under which the scheme is working has Mrs. Scharlieb, M.D., as chairman, and among the members are Sir Francis Champneys and Dr. Samuel West, Treasurer of the Royal Medical Benevolent Fund.

THE Government Committee for the Relief of Distress has issued a circular to local representative committees suggesting that women members of the committee should be detailed to interview expectant and nursing mothers, and that no discrimination should be made between married and unmarried. If assistance is found to be necessary, care should be taken that the women are supplied with proper nourishment and to make certain that the women themselves benefit by it. It is suggested that local representative committees should utilize the machinery of existing organizations for the provision of meals, defraying the actual cost of meals so supplied. Where medical assistance is required the case should for this purpose be referred to the local sanitary authority which is empowered to supply such assistance. All maternity cases should be recommended to attend maternity centres when such have been established. The Central Committee on Women's Employment is arranging, as an experiment, for the training of a number of women as household helps, and a grant in aid of this scheme has been made from the Queen's Fund. It is suggested that local representative committees should consider the advisability of organizing such a scheme in their districts. The secretary of the Government Committee is Mr. A. V. Symonds, Local Government Board, Whitehall, S.W. The Subcommittee for London has issued a model scheme for administering relief adopted by subcommittees in the metropolitan area.

Letters, Notes, and Answers.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Aitiology, Westrand, London.* The telegraphic address of the BRITISH MEDICAL JOURNAL is *Articulate, Westrand, London.*

TELEPHONE (National):—
2631, Gerrard, EDITOR, BRITISH MEDICAL JOURNAL.
2630, Gerrard, BRITISH MEDICAL ASSOCIATION.
2634, Gerrard, MEDICAL SECRETARY.

☞ *Queries, answers, and communications relating to subjects to which special departments of the* BRITISH MEDICAL JOURNAL *are devoted will be found under their respective headings.*

QUERIES.

J. (Manchester) asks for suggestions for the treatment of syringomyelia, with great pain in arms and feet and progressive inability in walking.

M.B. asks for information as to non-operative treatment of a case of enlarged non-malignant prostate in a man, aged 60. Can *x* rays or high-frequency currents, he asks, be trusted, and are they advisable? Is such treatment painful and prolonged?

M.B. would like information on treatment (medicinal and dietetic) of a case of periodic attacks of perihepatitis in a professional man, aged 37, who is an abstainer, has never been abroad, and has never had syphilis. The usual remedies only give temporary relief. There is pain over the region of the liver, worse at night; he has heavy breath during attacks, and is losing flesh; he suffers also from dilated stomach.

ANSWERS.

BREAD FOR DIABETICS.

M.—Brusson Jenne diabetic bread must not be regarded as a remedy for diabetes, or as possessed of any therapeutic properties that would be likely to make its use effect a reduction in the quantity of sugar. Its advantage is that each roll contains a known quantity of starch equal to about 500 grains, so that if a patient is being allowed a diet containing a definite quantity of carbohydrate food as is the modern method of dieting, these rolls are convenient; they are well made and are palatable. For example, a patient may be allowed 1,500 grains of carbohydrate daily, which may be obtained by allowing him—

1 Brusson Jenne roll ...	...	500 grains
1 pint of milk ...	...	400 ,,
¾ lb. of potatoes ...	...	400 ,,

In addition he may get a little carbohydrate from green vegetables, or perhaps from such fruit as a baked apple, which would make it up to about 1,500 grains. The minor fluctuations that occur in the amount of sugar excreted by a diabetic often depend upon other conditions—apart from diet. The Brusson Jeune rolls now being made in England are practically identical with those formerly made in France, but they can only be recommended if their use is strictly limited as above described to the amount of carbohydrate which it is desired to allow in any given case.

LETTERS, NOTES, ETC.

THE PRACTITIONER AND THE NEW "PHARMACOPOEIA."

DR. WM. V. FURLONG (Dublin) writes: Dr. McWalter has quite rightly drawn attention to the interference with the present strengths of some of the most important tinctures in the present *Pharmacopoeia*, and no doubt any such interference will be very serious, both to the prescriber and his patients. If there were any object to be gained by this alteration one would quite understand it, but the same thing happened in the *Pharmacopoeia* of 1898, where the strengths were altered from the former edition, and few pharmacists would refer to the date of their prescriptions to modify the tinctures. Accordingly it will be uncertain whether the patient gets the dose intended or not, and in this state of uncertainty many may prefer to order definite quantities of the drug itself, in tablet form, fearing to trust the uncertainty of changing *Pharmacopoeias*.

THE BORDERLAND OF DISEASE.

BY

GUTHRIE RANKIN, M.D., F.R.C.P.,

PHYSICIAN TO THE DREADNOUGHT AND ROYAL WATERLOO HOSPITALS.

THE cure of disease, as it presents itself to us in hospital practice, is, for the most part, concerned either with acute infective or inflammatory processes, or with established organic changes which may admit of compensatory improvement or arrest of progression, but often connote either a hopeless prognosis or a lame and partial recovery. The ordinary hospital patient, in fact, only seeks admission when driven to it by one of two sets of circumstances—an illness of acute onset which alarms him from the outset, or a chronic disturbance of health, which patching-up processes at home, often over a considerable length of time, have failed to relieve. It thus comes about that in the daily routine of ward work we see very few patients, other than those suffering from acute disorders, who are not victims of the end-products of disease. They become inmates of a hospital, in many instances, when the most hopeful opportunities for arresting or curing the malady from which they suffer are past and gone. Unwillingness to give up their work or their domestic duties; dislike of discipline and hospital routine; and a careless indifference to symptoms which, though inconvenient and long-lasting, do not entirely incapacitate them, make the large bulk of our working-class population continue to depend upon a bottle of medicine or a box of pills until sheer inability to get about compels them at last to seek shelter and rest in a hospital or infirmary. Among the leisured and wealthy classes who, by paying the requisite fee, can command professional service at any time, and in that large section of the population whose members are able nowadays, under the conditions of the recent Insurance Act, to summon the aid of the panel doctor on any excuse, however trivial, if it interferes with the comfort and convenience of everyday life, ample opportunity is offered for the investigation of disturbed health processes in their early manifestations. In a vast proportion of patients belonging to these classes, however, the minor ailments are, in such large measure, either unimportant or imaginary that they fail to arrest attention, and are apt to be dealt with perfunctorily and without any clear-sighted intuition as to their bearing upon hereditary predisposition or prospective possibility. This casual attention to minor ailments is explained and to some extent condoned by the experience of every panel or club doctor that capitation payments on insurance principles mean the creation of a desire on the part of the contributors to get something back for their money, and consequently an endless appeal, not so much for advice and guidance as for a tangible return for their outlays in the form of medicine, pills, liniments, and what-not. The easiest plan of alleviation, and that which gives least trouble and at the same time satisfies the patient, is an empiric prescription or a bottle from a stock mixture, accompanied by the confident assurance that the disability is a passing one and of no importance.

It is true that our knowledge of functional disturbance is still primitive, and that its more thorough investigation is seriously handicapped by the large number of subjective ailments which apparently have no appreciable organic or functional change to account for them, but if the class of patient who comes only to secure his "pound of flesh" be eliminated, is it not possible that too little heed is given in many instances to mental and emotional irregularities which, if discovered, would be illuminating and explanatory? Is it not nowadays more necessary than ever before that the functional and neurotic departures from health should be dealt with systematically, and that closer scrutiny and more detailed investigation, either in the hospital or in the patient's home, should be given to all obscure and rebellious ailments which do not yield, within reasonable time, to simple methods of treatment? It is obvious that there must be a cause for every discomfort that drives an ordinary and honest person to consult a doctor or to consent to a course of treatment. Something in that individual's state of health has become disarranged so that the normal balance, upon which perfect comfort as regards health depends, is disturbed. It matters not whether we are able to locate the origin of the trouble or not; it exists, and it is the first duty of the medical practitioner to endeavour to restore such economic stability as will enable the client who consults him to go back to the affairs of everyday life freed from any signs or symptoms that remind him he is mortal, and reasonably assured that, with proper precautions, recurrence may be avoided. Just as in questions of public health it is becoming more fully recognized that preventive measures are more valuable and economical than curative processes, so must it ultimately emerge in the case of the individual that he will come to concern himself far more with keeping than, as he now does, with getting well. This trend of events is already foreshadowed in the promulgation of a science of eugenics, which, however much it may at the moment suffer from the impracticability that in many directions is the price of over-enthusiasm, is yet a movement calculated to frustrate the invasion of many diseases by providing the individual with a soil on which morbific germs will find it difficult to thrive, or even to exist. The durability of the human mechanism must have a limit, but there is no reason why the average length of life should not be materially increased if the contributory circumstances of disease were better understood and combated. The exceptional men and women who live to reach a century or more of existence prove that the capacity of the human body for carrying on its functions over such a length of years is a determinable fact. It requires only a sufficiently wise insight into questions of incidence, and a more rigidly scientific control of all the circumstances inimical to perfect health which advancing civilization, increasing luxury, and restless ambition bring in their train, to make a century of life the rule rather than the exception of human existence.

Probably one of the first directions in which a drastic change is necessary before such a desirable amelioration in the conditions and duration of the individual life can be achieved is a revised system of tuition for medical students. As educational methods are at present arranged, the only practical knowledge of disease which the undergraduate meets with and the only clinical evidence which is brought before him of ill-health is the material chosen from the wards of his hospital, or from its *post-mortem* rooms and pathological museums, to illustrate the ravages of which disease is capable when it has become a firmly established condition in the life, or a demonstrable cause of the death, of the patient chosen for illustration. Structural changes in any organ which admit of physical signs to verify the text-book description, or some unusual variety of disease which has a sensational interest because of its rarity are eagerly seized upon by most clinical teachers as the texts from which their educational sermons are preached. But necessary and valuable though all such instruction is, it only illustrates, after all, the damage which disease inflicts—a damage which, in many instances, is beyond repair, and at best is typical of an end-process that has scarred the patient and left him a less perfect machine than it found him. Of the conditions which preceded his illness, the circumstances upon which probably the first departure from normal health depended, the proclivities to disease to which his inheritance and upbringing exposed him, and the intimate habits of his life which brought him within the danger zone, the student learns little or nothing. In the acute infections, which form a very small item in his hospital experience, he may see a case through all its stages and witness either a fatal issue or a complete recovery. In the event of recovery, what does he know, or what is he taught, of the future risks that such a patient ought to be warned against? If death ensues he may have demonstrated to him in the *post-mortem* room the havoc wrought by this particular disease, and this is knowledge which is all-essential for his future guidance; but if the illness ends in recovery his opportunities for additional experience cease with the discharge of the patient from hospital. He has watched the man through an acute illness, and has seen him sent home with the satisfactory assurance, duly recorded for statistical purposes on his history sheet, that he is "cured" or "improved," but his information ends there, whereas for future usefulness it is just where it ought to begin. Is the patient who is discharged after pneumonia as "cured" really as good as he was before, or has

his illness paved the way for a succession of after-effects which render him no longer a first-class life? Is it quite certain that the case of enteric fever, who was labelled "cured" when he left the hospital, does not subsequently develop evidences of imperfect metabolism, or of biliary disturbances to which he was formerly a stranger, or that he does not remain an unconscious carrier of his ailment to those with whom he is associated in domestic or civil life? What guarantee is there that the child "cured" of chorea will not have a recurrent attack within six months, or slowly develop an insidious mitral disorder that will ultimately unfit her for active work and usefulness? Many similar illustrations might be quoted, but these are sufficiently graphic to fortify my contention that the education at present offered in our hospitals is faulty and in want of serious revision. Attendance in the out-patient room where minor ailments are the rule is, I am fully aware, a compulsory part of the curriculum, but every doctor need only appeal to his personal recollections to realize how little attention is given to the disorders which mostly present themselves there for treatment. Who of us ever bothered over the examples of indigestion, chronic rheumatism, simple cold, mild tonsillitis, constipation, diarrhoea, or the hundred and one other trivialities which constitute the bulk of the practice in the out-patient room or dispensary? They were all too commonplace and insignificant to be worth either time or attention. What drew the student crowd was a major operation by a chief who had a way all his own of carrying it out; or, on the medical side, some extremely rare case which it had required all the clinical ingenuity of a distinguished professor to diagnose and all his dialectic skill to demonstrate.

But if these imperfections of tuition during the undergraduate career of future members of our profession constitute a flaw which prevents the raw material being worked up to something more near its possibility of perfection before it is stamped with a seal of competency and launched forth to cure the ills and prevent the woes of humanity, what is to be said for the few who aspire to occupy positions in the higher ranks of professional service? So far as the young surgeon is concerned, the present system of advancement may have something to commend it because his hospital affords him the necessary opportunities for the practice of his handicraft and the acquisition of manipulative dexterity. But what about the young physician? The present process by which he aspires in time to become a consultant is one which binds him hard and fast to the practice of his hospital, and to it alone. In the course of many years he plods through the various steps of progression from house-physician to a place on the medical staff. His upbringing has been such as to debar him from any familiarity with the minor ailments of the average work-aday life or the management of the sick in their own homes, and has therefore afforded him no opportunity for intimate acquaintance with the preliminaries of disease or with the difficulties of its guidance and control outside of a hospital. He has, in short, acquired no knowledge of general practice, and yet it is from that source of revenue he hopes to draw his income. The old-fashioned apprenticeship system had its faults, but something like it will require to be re-established if the public is to retain the confidence it ought to have in those from whom it seeks a confirmatory—and presumably an experienced—opinion.

For any man who desires to be an accomplished exponent of the art of medicine it is from these minor ailments that he ought to learn his business. They belong to what I have ventured to describe as the borderland of disease, and it is in this area of petty foes that success is to be sought if a general invasion or a territorial conquest is to be avoided.

A homely, everyday illustration presents itself in the case of the infant whose fretfulness, sleeplessness, and general malnutrition prompt its mother early to seek medical advice. If the sign-posts are intelligently read, a skilful adjustment of the child's diet may preserve it from rickets with all its subsequent penalties and deformities; or from convulsions with their dreaded sequelae; or from marasmus with its fatal possibilities.

To all who have reached the goal-posts of experience and are able to estimate retrospectively the value of clinical observation, it must be a matter of genuine regret that we have so often failed to estimate at its true value the "writing on the wall" which has frequently been, in the light of subsequent developments, the earliest evidence that the Angel of Death had entered upon his campaign of relentless activity and instituted his earliest insidious attacks upon the ramparts of health. At the moment we did not appreciate the full significance of the small disabilities which seemed to be mere ripples on the surface of the placid stream of unbroken and reliable health, but as the months and years have passed on evidence has accumulated and compelled us to recognize that we have confused the "post" with the "propter" or alternatively the "propter" with the "post," and have failed to grasp the true inner significance of these early phenomena, whose real meaning cannot be mistaken when illuminated by the fuller evidence of pathological tissue change. The following examples, taken at random from my own borderland experience, will recall to others many similar clinical memories.

A lady of 48 years of age, who had enjoyed a life of unbroken health, came to see me many years ago complaining of recurring attacks of tightness in her chest and oppression of breathing, especially after exertion. She was the mother of three children and, in addition to her domestic duties, had always taken an active and leading part in the social life of her day. She was energetic, restless, and distinctively neurasthenic. She had no evidence of organic disease, but her pulse was always one of moderately plus tension, and though her heart was normal in size and its valves perfectly competent, there was a distinctive accentuation of the second aortic sound. When she reached the menopause she suffered much from flushings and other evidences of vasomotor instability, her neurasthenic tendencies became more pronounced, and the attacks of chest oppression were more frequent and somewhat more severe. They never caused her serious alarm, and the firm opinion of the many physicians she consulted was that her recurring discomfort was pseudo-anginal in type, dependent upon an unstable nervous system temporarily aggravated by her climacteric and free from any serious risk to life. One afternoon while walking leisurely in the park she suddenly experienced a more than usually severe attack similar to many she had previously gone through. She went home by hansom, and before reaching her house was comparatively comfortable, though not completely free from pain. She ate some luncheon and then retired to her room to rest, having in the meantime telephoned to ask me to look in upon her during the afternoon. When I arrived I found her lying on her bed partially undressed, but complaining of nothing worse than a continuing slight sensation of tightness in her chest, which made her glad to have her corsets undone for greater freedom in breathing. Her pulse was full, regular, and numbered 64. On auscultation, the only physical fact of consequence was the accentuated second aortic sound, which seemed no different from what it had been on many previous occasions when her chest had been examined. As I was leaving her room, she suddenly exclaimed, "The pain is coming again," and by the time I reached her bedside she was cyanosed, and within two or three minutes she was dead. Permission was given for a partial *post-mortem* examination, when it was found that she had a congenital narrowing of the right coronary artery, with early sclerotic changes in the aortic arch as well as in both coronary arteries and in the wall of the left ventricle. The circumstances of her health-history justified the confident opinions that had been given during life, and no known methods of investigation could have discovered the congenital fault from which she suffered, but the subjective manifestations meant, in her case, no mere functional disturbance, but a veritable organic lesion undeclared by physical signs. Though the borderland could not be explored by present methods of investigation so as to reveal the true meaning of her symptoms, the lesson of such an experience must surely be a warning against over-confidence in the generally accepted unimportance of what is described as false angina.

Another class of patient whose broken health declares itself through the circulatory system, and who often comes to us for help when his symptoms are still confined to the borderland country, is a familiar visitor to all our

consulting-rooms. He is usually a man of gouty habit of body, who has reached his fifth decade along the roadway of a strenuous, ambitious life, who has "burned the candle at both ends" for many years in a daily round of ceaseless endeavour to reach the top of his tree both professionally and socially. He has worked hard day in and day out, and has found his relaxation in active devotion to sports and convivialities. He has paid large tribute to Mammon, and has also worshipped at the shrines of Venus and Bacchus. He has been what is called a successful man of the world, and has eventually reached that stage in his life-journey when he must reckon with waning energies and declining powers of recuperation. His health record has been one of such unbroken success that he has had no personal experience of the "ills to which flesh is heir" and has probably never consulted a doctor. But inexorable Fate at length finds him out and ominous headaches, palpitations, shortness of breath on exertion, and an unaccountable sense of weariedness and inertia drive him to seek advice. The following is a typical example of this oft-repeated record:

A vigorous, enterprising, gouty type of man who had lived every hour of his life without having been ill, save once in his 30th year when he suffered from pneumonia, began to find when he was 56 years of age that he occasionally rose with a slight headache, which disappeared after breakfast; that he sometimes waked about 3 o'clock in the morning with an unpleasant sense of abdominal distension and accompanying palpitation; that the usual exercise to which he was accustomed produced unwonted fatigue, and that sudden effort gave rise to slight dyspnœa and a passing unpleasant sensation of vertigo; that he was compelled to get up once or twice every night to pass water, and that he was developing an impatience of temper to which in his earlier years he had been a complete stranger. None of these ominous warnings gave him the least alarm, and he brushed aside the repeated suggestions offered by his wife that he should see a doctor. He attributed all his discomforts to his liver—the usual *bête noire* of every variety of physical malaise—and endeavoured to correct them by a blue pill followed by a morning saline draught sufficient to set up a temporary diarrhœa. In passing it may be asked, Why does humanity pin its faith so implicitly to aperient medication? No matter what the disability may be, nine people out of ten endeavour to correct it by a dose taken at their own hand, and in most instances apportion the value of their self-chosen remedy to the violence with which it acts. The gentleman whose case I am now relating rapidly became a slave to his favourite pill, and lulled any suspicions he may have had about his health into a sense of security by periodically providing for a drastic clearing out of his bowel, without any attempt to modify his ordinary habits of life. For a time his plan of self-medication seemed to answer, but ultimately, when he was 58 years of age, he began to realize that his pill was losing its charm, and that his troubles were gradually becoming more pronounced and a source of increasing annoyance. Very much against his own inclination he was then persuaded to seek advice, and here is a short account of his condition when he presented himself for investigation: "A stout, florid man, of 58 years of age, prematurely grey, and to appearance older than his years; obviously hampered in his breathing by even slight exertion, with morning cough, hawking, headache, and nausea; troubled with frequency of micturition, especially at night; and disturbed by increasing imperfections in his digestion and a constant sense of languor and weariedness, for which he could in no way account. On examination his liver was found to be enlarged and tender; his heart was hypertrophied, sufficiently to displace a thrusting apex-beat outside the nipple line, and on auscultation revealed a short systolic murmur in the aortic region with a loudly accentuated second sound, and an occasional dropped beat; his arteries were thickened and tortuous, and the sphygmomanometer recorded a tension of 180 mm. of mercury; his urine was pale in colour, with a density of 1026, and contained a faint haze of albumin, together with sugar to the extent of 1.75 per cent.; his knee-jerks, though present, were feeble, and a fine tremor could be detected in his muscles when they were put on the strain." Some weeks after this examination the patient began to suffer from mild attacks of cardiac asthma, accompanied subsequently by a passing sense of constriction in his chest. Ultimately, after a long day of unwise exertion, followed by a public dinner at which he made a speech, he retired to bed completely tired out, woke from his sleep about 2 in the morning with a severe headache and feeling of sickness, which terminated in an apoplectic seizure. From this he partially recovered, but it proved the prelude to another of greater severity some weeks later, to which he succumbed. Here was a clear history of at least two years, during which invaluable borderland symptoms were allowed to pass unheeded and the golden opportunity for staving off terminal disaster irrevocably lost.

In the pulmonary system cases occur constantly in which misinterpretation of, or neglect to search for, the explanation of early and often unobtrusive signs allows the enemy to gain full possession, whereas he might have been kept at bay or defeated if he had been resolutely opposed while he was still merely a borderland foe. Here is a graphic case that came under my own investigation only a few months ago. A man of 43 years of age who occupied an important position in one of our great public services, had been troubled with a slight but persistent cough for six months. He saw a doctor from time to time and complained of the annoyance which this cough caused him. Knowing that he smoked a great deal and was dyspeptic, the doctor regarded the cough as unimportant and assured him it was entirely due to tobacco and an inactive liver. Despite this assurance, however, the cough continued with increasing persistence, and the sufferer became alarmed when he found that he was unable to sleep at night on account of it, was gradually losing flesh, and beyond all was so tired out from his day's duty that, as he expressed it, he felt every evening that he was completely "played out." This was the story with which he came to me and it was one which at once aroused suspicions. On examination there was no evidence of disease in his heart, nervous system, or abdominal viscera. His tongue was coated and his pharynx granular, both conditions doubtless due in great measure to his tobacco. When his lungs were examined, there were very few physical signs, but the left chest, when seen in profile, expanded less freely than the right; on gentle percussion the note on that side was correspondingly flat, and the respiratory murmur was wavy and bronchial in quality, especially over the second and third interspaces close to the sternal border. Behind there was impairment of the breath sounds over the supraspinous fossa, and after coughing there came a suspicion of one or two small moist râles. Throughout the lower lobe an occasional creaky râle could be heard, but there was free air entry from apex to base, and no suspicion of dullness anywhere. The right lung was without physical signs except in front, where, from the clavicle to the level of the third rib, the breathing was harsh, with the expiratory part of the murmur ominously prolonged. These physical signs, though indeterminate, were, in the light of the accompanying symptoms, disturbing, and the patient was advised to have a skiagram of his chest taken, and also to have his sputum examined bacteriologically. The skiagram showed a mottled shadowing in both upper lobes, much more marked on the left side than on the right, with a deeper density of shadow, and with long streaks radiating downwards throughout the whole upper lobe of the lung. The sputum was found to contain tubercle bacilli in large numbers, and at a second examination, four days after the first, the suspicious sounds in the supraspinous fossa had become so pronounced as to leave no doubt as to their true nature. The patient at once gave up his work and went into a sanatorium, where he is now undergoing the usual course of treatment. This is a case which illustrates how much misled we may be if, in early cases of phthisis, we trust to the evidence of subjective symptoms or of physical signs alone. X-ray examination helps the diagnosis in many obscure cases, and ought never to be omitted when the circumstances are suspicious. In this instance the evidence of the sputum was all that was necessary to clinch the diagnosis, but there are lots of cases in which, if the stage be sufficiently early, there may be no sputum, or where such as there is contains no tuberculous organisms. And it is in such circumstances that treatment offers the best chances of success, so that again we have, from an example of this kind, evidence of the superlative value of

borderland manifestations. But another lesson is to be derived from this case: the borderland symptoms were referred to a doctor, who was consulted again and again, but who jumped at conclusions that because of the patient's habits he had contracted a cough which he said was "a reflex from his liver." He omitted to auscultate his chest, to ask to see the sputum, or to inquire into the progress of events so far as they concerned the general nutrition of the sick man. More mistakes, as we all know, are made from lack of painstaking than from want of knowledge, and this case is a regrettable example of mischief that might have been curtailed by being earlier discovered had this scrap of common knowledge been borne in mind.

(To be continued.)

OUR PRESENT KNOWLEDGE OF THE THYROID GLAND;

*WITH A PRELIMINARY REPORT ON A CASE OF THYROID GRAFTING.**

By MARCUS MAMOURIAN, F.R.C.S.E.,

ASSISTANT SURGEON, THE DISTRICT INFIRMARY AND CHILDREN'S HOSPITAL, ASHTON-UNDER-LYNE.

THE work that has been done on the thyroid gland within recent years has acquired enormous dimensions, but, remarkably enough, the clinical, operative, and pathological observations and physiological investigations constitute a perfectly congruous study of wide practical applicability and interest which concerns almost every branch of medical science.

In a comprehensive survey of this subject it is of advantage to refer, first of all, to a few developmental points.

1. *Development.*

The thyroid gland is said to have a double origin. The main portion arises from the base of the tongue and grows downwards into the neck, where it bifurcates. This pharyngeal bud or projection is, to begin with, a tube—which suggests the probability of the secretion being poured into the mouth in antenatal life—and is known as the thyroglossal duct. Out of the bifurcated end are formed the isthmus and the larger portions of the lobes, the lesser segments of which were thought to originate from the fourth branchial arches, but this view of an "epiblastic contribution" is not now generally accepted. In course of time the hyoid bone is developed across the duct, which thus becomes divided into a lingual and a thyroid section and ultimately obliterated, the meatus of the lingual portion remaining as the familiar foramen caecum, and the thyroid part occasionally surviving as the so-called pyramidal lobe. In some instances a mass or masses of thyroid substance fail to coalesce with the main gland, and are known as "accessory thyroids." Our study of the development of the thyroid not only throws light upon the anatomical peculiarities already indicated, but it also explains certain pathological conditions which are met with in the neck, such as the vascular tumour which grows at the base of the tongue (lingual thyroid) and the cysts in the middle line of the neck, both being thyroglossal in origin, and which are liable to be mistaken for the cystic enlargements of the hyoid bursae and dermoids, but the latter are rarely situated mesially, as they are attached, as a rule, to the great cornu of the hyoid, the styloid, or the mastoid processes.

2. *Anatomy.*

The important fact to bear in mind is that the gland is tied down to the trachea by cervical fascia (the surgical capsule); hence the liability of the windpipe to compressional changes and the diagnostic importance of the act of swallowing. With the exception of giant goitres, which, owing to their size, impede tracheal movements, fixation here, as in the breast, is indicative of malignancy, and more definitely so if there be aphonia. The inferior thyroid arteries are of primary surgical importance owing to their intimate relationship with the recurrent laryngeal nerves, which are liable to be torn or included in the ligatures for these vessels.

Physiology.

The physiology of the thyroid gland is a chapter of absorbing interest. It presents for consideration functions of the most intricate order by means of an internal secretion, which has eluded the efforts of many investigators to analyse or identify it definitely. We are all familiar with the microscopical appearances of a section of the gland—the sphereid vesicles lined with columnar epithelium and filled with colloid material. A noteworthy feature is that, with the exception of the colloid substance, the gland shows no other sign of secretory activity, and no secretion or its active ingredients have been isolated or their presence proved in the veins or the efferent lymphatics of the gland. For all that, there can be no doubt of the great rôle that the thyroid plays in animal economy, and Dreschel's opinion to the effect "that it secretes a complex material which subserves more than one essential function" is doubtless correct and conforms to the present conception of glandular secretions in general, which are looked upon as influencing metabolism by acting as excitants or stimuli (hormones) to some or as agents of control or inhibition to other organs. It is now conclusively proved that the thyroid has a profound influence on the metabolism of growth, specially with regard to calcium and nervous tissues; that it affects sexual functions, as evidenced by its increased activity during menstruation, pregnancy, and lactation and the retrogressive changes observed in the genitalia in experimental thyroid inefficiency; that it is concerned in the glycogenic work of the liver by its inhibitory action upon the pancreas, the pancreatic hormone being the principal stimulus to the sugar-producing cells of the liver; further, it influences the circulation by virtue of its vaso-dilator property, and the fact that the gland receives part of its blood supply from two cerebral vessels (the vertebrals) points to the probability of its having a bearing on intracranial blood pressure. There is also what Gley terms its neurochemical relationship with the other ductless glands, the parathyroids, the pituitary, the suprarenals, the ovaries, and the thymus, which is pretty constantly in a condition of hyperplasia in cases of Graves's disease.

Such substances as have been chemically obtained have not shown the potency of the gland extract, and of which may be mentioned Bubnow's thyro-protein, which acts in the manner of an enzyme; Fraenkel's thyre-antitoxin—a significant term suggestive of the view, now held by many workers, that the thyroid secretion possesses the property of neutralizing toxins, and that in Graves's disease this defensive element is absent or impaired; Rees and Bauman's thyro-iodine, which also contains a trace of phosphorus. In Hutchinson's opinion the iodine and phosphorus containing substance is the active one.

3. *Pharmacology and Therapeutics of the Gland Extract.*

Allusion has already been made to the vaso-dilator effect of the gland's secretion. Accordingly, the extract lowers the blood pressure. It produces tachycardia, diuresis, and its prolonged administration brings on glycosuria. It causes a mononuclear leucocytosis (a condition present in Graves's disease, and which becomes reduced after the ligation of the vessels or hemisection of the gland). No true exophthalmos has ever been produced.

Thyroid medication may be said to occupy the foremost place in organotherapy. The brilliant results obtained by the exhibition of this drug in myxoedema are well known. In some rare instances, however, it fails to act, and then the question of other measures arises. In this connexion the following notes on a case of congenital myxoedema may be of interest: "E. H., 4 years of age, a typical cretin (Fig. 1), was brought to the Ashton Infirmary early in 1907. For about three years he was treated with thyroid extract without intermission. He came under my care in January, 1910, and I continued the treatment for over six months, prescribing 20 grains of the dry extract per day. Neither his physical nor mental condition underwent any appreciable change. I then decided to try grafting. I had a sheep killed in hospital while the patient was being anaesthetized. I removed the thyroid, placed it in hot saline, and after incising it in several places planted it into the child's omentum, which I scarified with a needle.

* Delivered to the Twenty Club, March, 1914.

Now this case has made wonderful headway, as shown in the photograph (Fig. 2) recently taken (four years after operation). The boy has entirely lost his repulsive countenance, and looks pleasant and intelligent. He can now read and write, tell the time, and recognize coinage. I have had excellent reports of him from his teacher. He has grown to the extent of 10 inches in four years. Since the operation he has very occasionally had a 5-grain tablet owing to a stutter which he develops at times, and which, according to the observation of the boy's mother, completely disappears when a small dose of the extract is given. Thyroid grafting has been carried out by many surgeons, notably by Bircher, Horsley, Payer, the Mayos, and others, the favourite sites being the subcutaneous tissue, the spleen, and recently Kocher has advocated the medullary cavity of the tibia. No one, however, so far as I know, has hitherto utilized the omentum, which by virtue of its vascularity strikes me as eminently suited for all kinds of grafts, be they thyroid or ovarian.

Fig. 1.

In parenchymatous goitres, especially those associated with myxoedema, there is no better treatment than thyroid extract. No case should be submitted to operation without a trial of this remedy in preference to iodine and iodides, which bring about local adhesions and render the work of the surgeon more difficult. Thyroid extract is a potent remedy in cases of nocturnal incontinence in children, in obesity; but in the latter condition its use is not free from risk, as, in addition to its depressing effects upon the circulation, it may cause wastage of albuminous substances. It has been recommended in the treatment of rheumatoid arthritis, spasmodic torticollis, and adenoids. It has been used successfully in recurrent mammary cancer. Could it be, one is tempted to ask, by inducing over-production of pancreatic enzymes which Beard regards as the only scientific cure of malignant disease? I am convinced that in many cases of cancer large doses of thyroid have an inhibitery influence upon the growth. The extract has a field of usefulness in cardio-renal conditions with high arterial tension, especially when the nitrite group of drugs has proved of no avail. It has been used in dermatology in conditions characterized by keratosis and in post-operative tetany (but the parathyroid extract is to be preferred). It is one of the most useful drugs in gynaecological conditions, notably menstrual derangements, and as a preventive of an early menopause. Its employment in Graves's disease has proved worse than useless.

Fig. 3.

4. *Pathology and Treatment.*

Myxoedema.—Reference has already been made to this condition, which results from congenital absence, atrophy or parenchymatous degeneration of the gland. Three types are recognized—(*a*) the infantile, with its interesting geographical distribution, (*b*) the adult (Gull's disease), and (*c*) the post-operative. There is no difficulty, as a rule, in recognizing a typical cretin with the stunted body, bloated face, flat nose, puffy eyelids, the scanty hair, and the striking mental sluggishness. In Gull's disease the changes are more or less similar, but the localized distribution of the oedema, as in the hands, the neck, etc., might be mistaken for diffuse lipomatosis. It may be pointed out that the tumefaction of the subcutaneous tissue is not a true oedema but a hyperplasia of connective tissue rich in mucin and therefore embryonic in type.

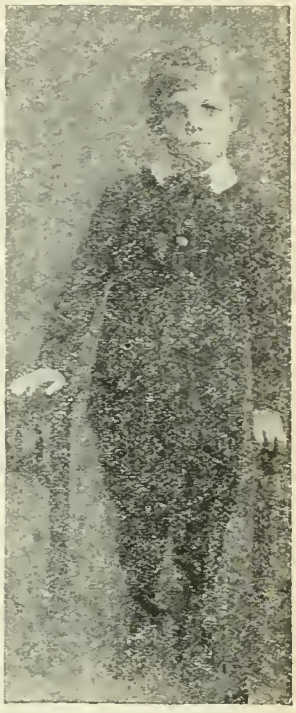

Fig. 2.

Thyroiditis.—The thyroid is seldom attacked by inflammatory conditions, but may become secondarily infected in the course of certain fevers, specially in pneumonia and typhoid.

Malignant Disease (rarely met with).—The gland may be the seat of either carcinoma or sarcoma. Sometimes the metastases of definite thyroid gland cancers consist of normal thyroid tissue by way of atavism (De Quervain). The metastatic growths show a selective preference for the osseous system.

Goitre.—This term is applied generally to enlarged thyroids, but enlargement may be brought about by a variety of structural changes; thus we have the parenchymatous (cystic or colloid), the fibrous adenomatous, and the vascular—terms which are descriptions in themselves. There is no correlation between the dimensions that the gland may attain and the constitutional effects produced. Thus, we may have goitre and myxoedema, goitre and Graves's disease, and Graves's disease or myxoedema without goitre. Puzzling as these differences may appear, they are easily understood by the aid of the microscope, and the work of Wilson and McArty of the Mayo clinic has helped in explaining these seeming anomalies of thyroid pathology. As a rule each lobe is visibly hypertrophied. Sometimes the isthmus is the prominent part. One is liable to be misled however, by retrotracheal, retroclavicular and retrosternal enlargements; the latter have been mistaken for mediastinal tumours. Osler and Packard have reported a case of a cystic accessory thyroid filling the entire right pleura. Pressure effects are not always dependent upon size. The firm fibrous goitre may reduce the tracheal lumen to a mere chink. In cases of intractable asthma or paroxysmal dyspnoea it is worth while to bear this in mind.

The sudden development of a thyroid tumour points to haemorrhage in the gland substance. A parenchymatous

goitre may acquire enormous dimensions which may produce marked congestion of the veins of the face, chest and upper extremities, and which may lead to actual thrombosis. If a goitre is producing respiratory embarrassment, the sooner operation is undertaken the better.

Graves's Disease.—The cardinal signs of exophthalmos, tachycardia, and tremor make the diagnosis of this condition easy. The ocular signs are well known. The etiology of the disease is obscure. The main issues are (*a*) that it is a neurosis, (*b*) that it is the result of perverted secretion or hypersecretion, (*c*) that it is due to sepsis. Pathologists have described haemorrhages in the fourth ventricle. If these haemorrhages were a constant feature we may be justified in assuming that the glycosuria of Graves resulted from a medullary lesion analagous to Claude Bernard's puncture of the fourth ventricle. Amongst the noteworthy features of this condition we have the cutaneous manifestations, which may take the form of pruritus, leucoderma, or of a pigmentation akin to that of Addison's disease; the unsusceptibility of these patients to cold, the occurrence of oedema, both simple and angioneurotic, and of intractable vomiting and diarrhoea. Singularly enough, in the glycosuria of Graves, as in diabetes, the patellar reflexes are lost.

The relation of hyperthyroid states to tuberculosis has been studied by Professor G. R. Murray, who holds the view that there is some sort of antagonism between the two conditions, as these patients rarely die from tuberculosis, and even if a focus be present it remains quiescent as long as the hyperthyroidism continues. The case which he mentioned in his presidential address at Brighton was operated on by me. There can be no doubt that, after the removal of the major portion of the gland, the patient, who had had the disease for over twelve years, succumbed to acute phthisis.

The treatment of Graves's disease still remains on an unsatisfactory basis. The bulk of the cases are still being treated with bromides and iodides. Kocher thinks well of phosphorus, and the Mayos and Thurstan Holland of *x* rays. The late A. Gibson claimed to have cured most of his cases by suprarenal gland extract, but the experience of others is very disappointing. Moebius's serum has not been a success. Pychlau recently reported a case which was cured by the administration of the milk of a thyroidectomized woman. Sir Thomas Fraser used to speak of marriage as having a curative influence on adolescent female exophthalmics. Good results have been obtained by antiseptic medication of the bowel and the elimination of all sources of sepsis. The excision or short-circuiting of the colon is not a measure likely to meet with general acceptance.

Surgery can claim the most brilliant and the most lasting results, but in this connexion we must bear in mind that institutional life, *x*-ray exposures, and tonic medication contribute to no small extent to the recovery of these patients. Crile's anoci-association method has a useful field in this condition in which "psychic strain" is a pronounced characteristic. Kocher favours the plan of ligating the vessels at successive sittings. Most surgeons prefer the removal of one lobe with the isthmus. One or both vessels of the remaining lobe may be ligatured later if the improvement after hemithyroidectomy is not satisfactory. Halsted has recommended the excision of practically the whole gland, leaving merely a strip on each side to maintain the blood supply to the parathyroids.

I have noticed that exophthalmic subjects, thin or even emaciated as they are as a rule, put on fat to an extraordinary extent after operation (Fig. 3). I have never seen complete recession of the eyes after operation or other treatment. Drs. Bythell and Barclay of Manchester assure me that they have obtained complete disappearance of exophthalmos by *x*-ray treatment alone.

THE *Journal of the American Medical Association* lately called attention to a two year graduate course offered by the University of Minnesota for the training of doctors who desire to specialize in ophthalmology. This course is analogous to the graduate courses offered by several medical schools for the training of health officers. It is thought probable that similar courses will be established for the training of those who wish to limit their practice to other special provinces of medicine.

NICOLLE AND BLAIZOT'S VACCINE IN THE TREATMENT OF GONORRHOEA.

BY

R. DONALDSON, M.A., M.B., CH.B., F.R.C.S.E., D.P.H.,

PATHOLOGIST, ROYAL BERKS HOSPITAL, READING.

THIS vaccine, which goes by the name of "Dmegon," was prepared by MM. Ch. Nicolle and L. Blaizot, of the Pasteur Institute, Tunis, and placed on the market as a stable, non-toxic vaccine for use in all cases of gonorrhoea. In October, 1913,[1] they maintained its superiority over the vaccines in ordinary use.

The drawbacks to the use of the latter, and of gonococcal vaccines in particular, where results have been far from uniform or encouraging, had led them to seek a means of overcoming these defects. In their opinion the two chief obstacles to the success of vaccine-therapy are the present crude methods of sterilizing the living cultures, and the more or less constant toxicity of all vaccines, but more especially of gonococcal vaccines. Even Besredka's method of sensitizing has failed, according to them, to abolish this toxicity.

They stated that, as the result of a year and a half's work, they had succeeded in entirely suppressing the toxicity of gonococcal vaccines, and claimed by their new method of sterilizing to have prepared a vaccine in which the organismal elements are conserved practically in the same condition as obtains in the living culture—in other words, that their vaccine was non-toxic and stable. How this was attained was not at first divulged; the authors merely stated that the toxicity had been abolished by growing the organisms on a special medium, while stability had been achieved by the use of a special solution as lethal vehicle.

Their personal statistics up to that time covered some 200 cases, including 24 cases of ophthalmia, 3 of rheumatism, 25 of orchitis, and 127 cases of acute and chronic urethritis. They stated that ophthalmia was cured after a few injections, sometimes after one, an injection being given each day; that in acute orchitis the pain disappeared in a few hours, or at most within a day or two after the first injection, fever declined, and the patient was able almost at once to resume his daily occupation; and that gonorrhoeal rheumatism rapidly cleared up under two to eight injections. The most striking case was one where a woman, bed-ridden for eight months, was able to come for the eighth injection. In acute urethritis the symptoms, they stated, cleared up with equal rapidity. The discharge ceased later, but in many cases it had disappeared after the third injection. They recommended that the injections, which were repeated every two days, should be continued till seven or eight had been given. Simultaneous local treatment had a favourable effect. None of the acute cases under prompt treatment developed any extra-urethral complications. Old-standing gleets (a year and a half) had been cured by this vaccine, the injections being given every three or four days.

Truly these are wonderful results and all obtained without provoking any untoward or disagreeable reaction! Beyond these facts, however, nothing was known about this vaccine till in November, 1913, Nicolle and Blaizot[2] revealed their secret.

Vaccines prepared in the usual way are damaged by the coagulating effect of heat, and are unstable because they undergo later a process of autolysis. To obviate these disadvantages the authors make use of a fluoride solution since fluorides have been shown by other workers not to possess the property of coagulating albumin.

Method of Preparation.

The organisms are suspended in a 0.7 per cent. solution of sodium fluoride in which they die after a variable time depending on the temperature and species. For instance, gonococci die after forty-eight hours' exposure in an ice-chest to the action of the fluoride. The authors claim that the organisms remain practically unaltered and, since the solution retards autolysis, long preserve their morphological and staining characters. The fluoride is also said to aid in diminishing the toxicity. The latter, however, is mainly brought about by growing the gonococci on special culture media which at first consisted of: Broth 100, urea 0.4, glucose 2, phosphate of ammonia 0.5, agar 1.5.

To this in tubes of 5 c.cm. each are added 0.5 c.cm. rabbit serum. The gonococcus is first grown on this and, by sub-

culture on successive media less and less rich in serum, it is trained to grow on the above medium minus the serum.

A twenty-four hours' growth is then scraped off, suspended in the fluoride solution and repeatedly washed and centrifuged in order to obtain well isolated organisms.

Since gonococcal vaccines, as ordinarily prepared, yield very inconstant and disappointing results, the authors sought for and claim to have found another organism frequently found along with the gonococcus. To this organism they give the name "Synococcus." The latter closely resembles the gonococcus, but grows easily on serum-free media, produces an orange pigment, and is Gram-positive. It provokes no reaction, but possesses the same curative effect as the gonococcus. They suggest that it is related in some way to the gonococcus, and that ordinary gonococcal vaccines owe their lack of success to a failure to recognize the important part played by this new organism.

Their vaccine, then, consists of one part of gonococcus to 9 parts of the synococcus, and, since it is given in doses of 0.5 c.cm. containing 250 million of cocci, it follows that only 25 million consist of gonococci proper, while the other 225 million are "synococci."

In the directions for the employment of the vaccine it is recommended that the 0.50 should be diluted with 1.50 c.cm. physiological saline, supplied in a separate ampoule, and the 2 c.cm. injected deeply into the muscles. This is preferable to subcutaneous injection owing to the slightly caustic action of the fluoride. In the instructions, however, no reaction is said to follow either method, while intravenous injection is decried, as it is likely to determine a febrile reaction. The above summarizes the main facts known about the vaccine, together with the claims advanced by the authors. The next question that arises is, How far have these claims been justified? In order to answer it I have collected as many published references as I could find, and to these I add a very brief account of 4 cases which have been treated with this vaccine in the out-patient department of the Royal Berkshire Hospital, Reading.

I omit reference to the few cases chosen from among the 200 mentioned by Nicolle and Blaizot in their communication, as well as those published by their colleague, Remlinger[3] of Tunis.

Bar and Lequex[4] give their experience with the vaccine whose nature at that time was unknown to them. Their series includes:

A case of purulent ophthalmia in a child 4 days old cured by one injection of 2½ drops.

Four cases of salpingitis in non-puerperal women:

1. Cured in fifteen days by four doses of 10 drops each.
2. Cured in seventeen days by three injections; both of these cases were of moderate severity.
3. Cured after seven injections, although previously she could not be examined owing to pain.
4. Double salpingitis; right tube cleared up after three injections. Operation, performed later, showed that the left tube was still affected, and gonococci were demonstrated in it.

The same authors state that slight anuria of a few hours' duration was occasionally observed, and once they noticed an urticarial rash. Some of the patients complained of a fairly acute pain at the site of injection, which might last some four or five hours, and even recur after some days.

Masson[5] reported a case of salpingitis cured by the injection of antimeningococcal serum. Sauvage[6] tried this new vaccine on a little girl, the subject of acute vulvo-vaginitis, who four days after infection developed peritonitis; 1.0 c.cm. of the vaccine was given on the third day after the onset of peritoneal symptoms, and the same dose was repeated on each of the two subsequent days without any effect. Laparotomy was performed, and gonococci were subsequently shown to be present in the tube.

Troisfontaines[7] mentions 5 cases. In 3, men with acute epididymitis occurring in the course of chronic gonorrhoea, the most striking effect of the vaccine administered subcutaneously was the disappearance of the pain and swelling either immediately or after two injections. The vaccine did not influence the discharge, and gonococci were found at the end of the so-called cure as at the beginning. Two cases of gonorrhoeal arthritis in women were cured by three injections.

Broussegoutte[8] employed the intravenous method of administering the vaccine, without any untoward results, in 3 cases:

1. Cystitis and prostatitis cured after injections of the vaccine combined with rigorous local treatment.
2. Urethritis cured in the same way.
3. Case of acute orchitis, which rapidly lost all pain after receiving the vaccine, but an abundant discharge returned, which contained numerous gonococci. In this case only two injections were given.

C. and H. Fromaget[9] record a case of purulent ophthalmia treated with this vaccine for four days. After the second injection there was a recrudescence of the trouble, and recourse was then had to silver nitrate in addition to the vaccine. Cure was effected at the end of eight days after three injections had been given. Leuret[10] reports 3 cases:

1. Gonorrhoea, contracted about two months before, which had not cleared up under the usual classic remedies, was cured after three injections, with complete disappearance of the discharge.
2. Gonorrhoeal arthritis of four months' duration, cured after four injections. The first injection was followed by slight febrile reaction and headache, thought to be influenzal in character.
3. Gonorrhoea and arthritis of nearly three months' standing, almost cured in nine days after four injections.

Mauriac[11] mentions 4 cases: 2 had urethritis, 1 suppurating arthritis of the knee, and 1 epididymitis. The arthritis rapidly cleared up, and after 3 injections the patient was able to walk. Mauriac has noted pain the day following the injection, and sometimes a slight general reaction with temperature. He goes on to say that the effect of the vaccine on the discharge appears to be nil, though the gonococcus appears to be more sensitive to the action of antiseptics. Fieux[12] has treated two patients suffering from an acute exacerbation during the course of a chronic affection (salpingitis) with good results. He records one failure, a case of ophthalmia neonatorum treated on the fourth day.

Dr. Wansey Bayly,[13] in a recent article in this Journal, states that in his limited experience some cases benefited, but he was not much impressed with its merits.

The following are brief notes of the cases at the Royal Berkshire Hospital:

1. Female, infected two months before, received eight injections, one every two days, into the muscles. Result: Severe local pain after each inoculation, together with headache and malaise; vaginal discharge considerably diminished, but still present.
2. Female; vaginal discharge of three to four months' duration, untreated; now received nine injections, as in Case 1, and was instructed to wash external genitals with weak antiseptic. Result: Discharge rapidly diminished and apparently disappeared; following the ninth injection, however, her temperature rose, a pustular eruption appeared on the body and subcutaneous nodules on the shins. On recovery she was examined again, and a copious discharge, containing gonococci, was found.
3. Male, infected eleven months before, treated in the classical way till only a "morning drop" remained. Treatment: Four injections, one every third day: after a week's rest seven further injections were given with the same spacing, sometimes intramuscularly, sometimes subcutaneously. Result: Headache and dizziness after the first four injections, coming on towards evening and lasting a few hours. The discharge remained uninfluenced and gonococci were still plentiful.
4. Male, infected twenty-two months before, treated in usual way, together with stock vaccines; slight morning discharge, however, remained obstinate. Hospital treatment: Four injections of the Nicolle and Blaizot vaccine on alternate days, followed by a week's rest. Another five injections were then given with same spacing. Result: Slight headache on one occasion, but at the end of the treatment the discharge had actually increased and gonococci were still present.

From a consideration of these cases it must be admitted that the vaccine has not completely fulfilled the claims of the authors and their colleagues.

It is true that the number of published observations made by independent workers is comparatively small. I do not, of course, include the cases referred to but not published in detail by Nicolle and Blaizot, nor do I include Remlinger's. These, we are told, were successful cases. The others which I have summarized number 29, and of these only 15 are reported as definite cures. Several of the patients showed signs of undoubted general disturbance such as is common after the use of ordinary vaccines. Judging from these reports the vaccine does not always cure and is not always atoxic. Of course it may be urged by the supporters of the vaccine that in some of these cases a sufficient number of doses was not given. In the 4 cases reported here for the first time the average number of doses said to be necessary for a cure was exceeded and in one case the only result was an increase in the discharge. Moreover, each dose costs

5 francs. The majority of the cases, however, according to the reports, seem to have benefited, and probably the most striking effect of the vaccine has been the rapid manner in which it appears to have relieved pain in cases of arthritis and orchitis. Whether it will always act in this way in the hands of other workers remains still to be seen. Several cases of a similar nature have cleared up as rapidly after the injection of antimeningococcal serum.

Another feature is the ease and rapidity with which ophthalmia cleared up, but a sufficient number of cases have not yet been recorded. If it proves to be a constant character of the vaccine, we have a very potent weapon with which to combat a disease which, as a nation, we are endeavouring to control.

An interesting question is how far the cases of urethritis as reported cured are actually infection-free or whether the disease has merely been rendered latent. This is a point not brought out in the cases recorded.

As regards the fluoride vehicle, I doubt if it can have much effect in reducing toxicity. Lately I have been preparing vaccines in this way, and have found that the focal and general reactions respectively have been as marked as those produced by the injection of autogenous vaccines prepared by one of the older methods. In any case there is one objection to the use of fluoride solutions where rapidity of preparation is an essential. Gonococci, according to the authors, are only killed after forty-eight hours' exposure to the solution in an ice chest, and the length of time necessary to sterilize a given organism depends on the temperature and the species, but it depends also on the concentration of organisms in the vaccine. I find that the greater the number of organisms present per cubic centimetre the longer is the exposure necessary to effect complete sterilization. For instance, a vaccine containing 1,600 million of staphylococci per cubic centimetre still gave a growth after six days' exposure at room temperature. In such cases, therefore, we must adopt one of the older methods for the sterilization of the preliminary doses at any rate. As regards the constituents of the vaccine, the toxicity of one of them, the gonococcus, is said to be reduced in the manner described. But this organism represents only one-tenth of the total number of organisms present, since there are only 25 million present in each dose.

Moreover, while the synococcus provokes no reaction on inoculation, according to Nicolle and Blaizot, it nevertheless possesses the same curative action as the gonococci themselves. If this be so it seems at first sight unnecessary to go through the elaborate process of reducing the toxicity of the gonococci proper when present in such small number or even to include them at all.

What exactly the "synococcus" is, and what relation, if any, it bears to the gonococcus proper, is not clear, but the suggestion is that in gonorrhoea we are dealing not with a single strain but with a group of organisms all more or less related to one another—not at all an unlikely thing. On the other hand, the synococcus may be related in no way to the gonococcus proper except in so far as their symbiosis may modify the course of the disease. In other words, one must take account not merely of the main causal organism but also of other organisms in symbiosis which may considerably modify its effect and character. It would be interesting to know if the authors have used the gonococcus alone after modifying its toxicity in the method they advocate and in the same doses, and if the same effect could not be got in this way, leaving out altogether the synococcus.

These are some of the questions that arise in connexion with this preparation. Meanwhile, one must remain sceptical until a sufficient number of cases can be investigated and a little more of scientific value is known about the vaccine. This ought to be a matter of a short time only since there are no contraindications to its use, and the administration can easily be carried out by the general practitioner, no special bacteriological knowledge being necessary for its proper control. As for the route by which it is administered, it would appear from the cases recorded that it may be given either under the skin, into the muscles, or directly into a vein. Contrary to what the authors say, subcutaneous inoculation may be painless, intramuscular injections may be followed by severe pain, while no ill effects seem to attend intravenous inoculation.

BLOOD PLATELETS IN THE TREATMENT OF DISEASE.

BY LYN DIMOND, M.B.VICT.,
LATE PATHOLOGIST AND BACTERIOLOGIST, ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

(*Preliminary Note.*)

THE employment of blood platelets together with the plasma in which they are suspended has given such very satisfactory results in the treatment of a large variety of morbid conditions that I think it well to publish this short preliminary note upon the methods of preparation, the technique, and results of administration.

I have employed blood platelets therapeutically in three definite ways. In the first the blood platelets are isolated from a person in perfect health, the absence of specific disease being determined by means of the Wassermann test, and of tuberculosis by means of von Pirquet's cuti-reaction; the platelets so obtained are used parenterally in varying amounts according to indication, in order to reinforce the powers of the body against the different local and general diseases due to bacteria.

In addition to satisfactory clinical results following the administration of blood platelets, determinations of the opsonic and phagocytic index, quantitative agglutinin tests, as well as complement deviation reactions, indicate that after each of such injections there is a very marked rise of the antibody content of the blood.

The different immunity reactions applied to the platelets and their containing plasma, more especially when applied thereto after recovery from microbic disease or after preliminary vaccine injection, indicate that they contain a very large part of the different antibodies produced in response to bacterial invasion of the organism. In addition to germ-caused diseases, the exhibition of blood platelets has been found satisfactory in cases of deep-seated haemorrhage, such as haemoptysis, haematemesis, and renal haemorrhage.

A second way in which I have employed blood platelets therapeutically in the treatment of bacterial disease has been as follows:

The specific organism is isolated from a patient and with a vaccine made therefrom a healthy friend receives several injections until the various opsonic or agglutinin reactions indicate that this person's serum has a high antibacterial content to this particular organism. The blood platelets and their plasma are then obtained and used in the treatment of the original case. The employment of stock instead of autogenous vaccines has also given good results and effects a considerable saving of time. I have also used platelets isolated from patients who have passed through an attack of bacterial disease, such as those due to staphylococci, streptococci, and pneumococci. In such cases I have made the opsonic index my guide and have only used the platelets isolated from patients whose opsonic index is high.

A third method, used in cases in which the toxaemia is not extreme, such as chronic ulcers, furunculosis, acne, and tuberculosis, has been to sensitize vaccines obtained by isolating the organism from the patient's lesions by means of the platelets and their plasma. In addition to good clinical results obtained therewith, the completeness of the sensitization can be gathered from the very slight local reaction which follows their employment.

The usual technique I have used for the preparation of such sensitized vaccines has been to make an emulsion of the organism in as small a quantity of saline solution as possible, usually 5 c.cm. This emulsion I have generally exposed to a temperature of 60° C. for half an hour in order to kill the organisms; in certain cases that has been effected by adding 1 per cent. phenol after sensitization is complete.

The emulsion is added to the platelets, and their plasma under sterile paraffin, and exposed to a temperature of

37° C. for ten hours. The organisms are then separated and washed free of all plasma and suspended in as small a quantity of normal saline as possible. They are then preserved in amber-coloured ampoules upon ice in a refrigerator, being diluted immediately before use. I have usually standardized the vaccine immediately after resuspension in normal saline.

If the indications are to use platelets alone, they are obtained by allowing them to sediment by gravity after separation of the red and white corpuscles by centrifugalization. The white deposits of platelets which form at the bottom of each tube are then shaken up with 1 or 2 c.cm. of the plasma left in the tube after removal of the rest by means of a sterile pipette. I have generally used for a single injection the platelets isolated from 30 to 40 c.cm. of blood, and in cases of deep-seated haemorrhage where such an injection of platelets has been administered the resulting cessation of bleeding which rapidly follows has often been remarkable.

The methods of preparation unfortunately require time, labour, and the conveniences of a fairly well equipped laboratory, but the results have been so satisfactory that they more than repay one for the labour entailed.

Technique.

The plasma, with its platelets, is isolated in the following manner, with, of course, all due precautions to ensure the perfect sterility of all the apparatus, tubes, and media employed:

Sterile small test tubes 8 cm. long and 1 cm. in diameter are sterilized by pouring into them 1 to 2 c.cm. of sterile liquid paraffin, the liquid paraffin being employed in order to line the inside of the tubes, so as to prevent the platelets from adhering to the surface of the glass wall of the tube.

After a Record syringe has been sterilized by means of hot liquid paraffin, 4 c.cm. of the paraffin are retained in the syringe and all air excluded; 8 c.cm. of normal saline, containing 1 per cent. pure sodium citrate, is sucked up into the syringe, care still being taken to exclude air, as to the surface of the air bubbles the platelets tend to adhere.

When the paraffin and saline citrate solutions have reached the temperature of the body, this temperature is maintained in an incubator. The maintenance of the body temperature is advisable, as, in addition to facilitating isolation of the platelets by causing them to retain the rapid movements of their processes, which to a certain extent oppose the centrifugal forces that throw down the red and white corpuscles when centrifugalized, the moving apparently living platelets seem to give better results than after their movements have been slowed by exposure to the temperature of the air.

After a vein of the forearm or at the bend of the elbow has been made prominent by means of a tourniquet around the arm above the elbow, the needle of the syringe is plunged into the vein and 8 c.cm. of blood slowly withdrawn into the saline citrate solution. After withdrawal of the needle from the vein the syringe is slowly rotated in order thoroughly to mix the blood and saline citrate solution. The first few drops of blood are rejected, as some clotting may have taken place in the needle which would tend to destroy the whole specimen. The intermixture of the blood with the saline citrate solution of a higher surface tension seems to cause the red blood corpuscles to render up their platelets to the plasma.

The blood and saline citrate solution is then slowly syringed into the small sterilized tubes, so that it lies under the 1 to 2 c.cm. of liquid paraffin which they contain and which is at body temperature, as the tubes are kept in an incubator at 37° C. until required. In this way the platelets are not allowed to come into contact with the glass, to which the majority of platelets would otherwise adhere and consequently be lost.

These small tubes are then placed in the boats of a centrifuge, surrounded by liquid paraffin at 37° C., and with the hand centrifuge I employ rapidly centrifugalized for five minutes. The living platelets with their flagella beating the plasma to a certain extent oppose the centrifugal force, and at the end of the time stated are found floating in the cloudy supernatant fluid.

Where large quantities of platelets have to be isolated I generally employ an electric centrifuge rotated at about the same speed for the same time.

As a rule the platelets are found quite free from red or white cells; if any remain they can be separated after decantation either by centrifugalization or by sedimentation by gravity.

When the cloudy plasma has been decanted by means of a paraffin lined pipette into other similar tubes under paraffin, it is examined by the trypan red-paroleine method which I have described elsewhere for the presence of platelets and their number. The platelets and their plasma are administered by a Record syringe which has been sterilized by hot liquid paraffin, the liquid paraffin fulfilling two services—namely, sterilizing the syringe and needle and lining the piston and glass of the syringe so that the blood platelets are thereby prevented from adhering thereto.

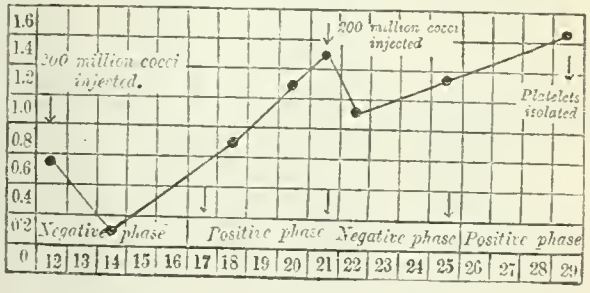
The platelets and their plasma are drawn up from under the liquid paraffin by means of a sterile filler attached to the syringe the inside of which has previously been sterilized by hot liquid paraffin.

The needle, previously sterilized by hot paraffin, is fixed to the syringe and the contents are administered hypodermically at a convenient site, the skin at the point of puncture being previously sterilized by painting with tincture of iodine.

Though good results are obtained from small doses of platelets and their plasma, such as from 1 to 5 c.cm., I have in particular cases, according to the indications, by means of 20 c.cm. Record syringes, administered as much as 30 to 40 c.cm. directly into the connective tissues under the skin between the shoulder blades. During an experience of many hundreds of injections, varying from 1 c.cm. to 40 c.cm., I have never yet seen any untoward result apart from a slight reddening of the skin for a few centimetres around the puncture which clears up in from twenty-four to thirty-six hours. The patients have never complained of any pain as an immediate or after result of the injections, and in the majority of cases the hyperaemia of the skin is simply accompanied by a slight sensation of itching.

When vaccines are administered either with the platelets or after sensitization by means of the platelets and their plasma, more definite local signs are the result, but never so marked or so intense as when the vaccine alone is injected.

Where preliminary vaccine treatment of a donor by means of a stock vaccine or an autogenous vaccine prepared from the causal organism obtained from the patient is undertaken, I have almost invariably followed the course of the immunity reaction by means of the opsonic index, agglutinin reactions, etc., and have abstracted the blood when the index is at its highest point.



Advantage has also been taken of the cumulative action of vaccines when their dose is properly spaced. Two doses are given successively so as to raise the patient's index by successive steps to a higher level of immunity. Such accumulative action following two properly spaced doses of *Staphylococcus pyogenes aureus* can be noted in the accompanying diagram, the doses in each case being 200 million cocci at an interval of ten days.

After the administration of tuberculin the platelets are obtained during the positive phase, between the fourth and seventh day after, and in the case of staphylococci between the sixth and tenth day after.

Having been fortunate enough to be able to treat with platelets a large number of acute and chronic pulmonary conditions, as well as numerous cases of the secondary infection in phthisis, I have found that for the organisms noted below the most suitable time for isolation of the platelets is, as a rule, as follows:

Diplococcus pneumoniae,	platelets withdrawn	5th	day	after	injection.
Micrococcus catarrhalis	,,	,,	3rd	,,	,,
Friedländer's bacillus	,,	,,	8th	,,	,,
Bacillus influenzae	,,	,,	2nd	,,	,,
Streptococcus pyogenes	,,	,,	3rd	,,	,,
Bacillus septus	,,	,,	6th	,,	,,
Bacillus pertussis	,,	,,	3rd	,,	,,

Regular estimations of the opsonic index in certain of these cases have shown that when the platelets are withdrawn after the above interval following the vaccine injection the best immunizing response is obtained.

I hope shortly to deal with the clinical history of my cases.

THE late Mr. Oliver H. Fowler, in practice for many years at Cirencester, left estate value £29,031.

ON account of the war the Executive Committee for the Organization of the Second Eugenics Congress has decided that it will be impossible to hold it as arranged in New York in September, 1915.

INSECTS AND WAR:

IX.—*TICKS.*

BY A. E. SHIPLEY, Sc.D., F.R.S.,
MASTER OF CHRIST'S COLLEGE, CAMBRIDGE.

A waterleche or a tyke hath neuer ynow, tyl it brestyth.
Jacob's Well, 1440.

TICKS are mites "writ large," and until about the beginning of this century they were regarded with what one might call mild disgust and regret. Now, however, that they have been proved to play a part, and a very important part, in the dissemination of disease, we have come to regard them, as Calverley said we should regard the decalogue, "with feelings of reverence mingled with awe."

The body of a tick is covered with a tough, smooth or crinkled skin, capable of any amount of extension. Until they have fed they are flattened in shape, but after a meal of blood they very soon lose the outlines of a Don Quixote and attain those of a Sancho Panza. In the adult the legs are eight in number and have six segments ending in two claws and sometimes in suckers. Some have eyes and some have no eyes. The most formidable part of their armour is, however, the mouth parts, consisting of the cutting and tearing chelicerae, the tactile pedipalps, and the piercing probe which they stick into our bodies. This consists of a median hypostome, an outgrowth of the ventral part of the mouth, with recurved teeth. On each side are a pair of four-jointed palpi and a pair of slender two-jointed cutting chelicerae encased in a finely-toothed membranous sheath. This sheath is an outgrowth of the upper part of the mouth, and when the chelicerae have cut a way into the flesh, and the rostrum is inserted, the sheath with the rostrum forms a tube up which the blood is sucked by the sucking pharynx. It is the teeth on the hypostome, and not the chelicerae, which anchor the ticks to their prey.

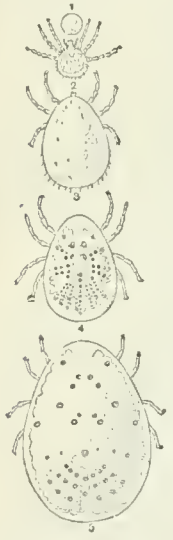


Fig. 1.—Evolution of *Argas persicus*. 1, the egg; 2, the six-legged larva; 3, the same gorged; 4, an unfed nymph; 5, nymph gorged.

Ticks, as they affect the soldier, may be divided into two families. The *Argasidae*, which are usually associated with human dwellings, fowl-houses, dovecotes, and so on, and are more commonly parasitic on fowls than on cattle or human beings. The members of this group hide away in crevices and corners during the day, and come out at night and feed, for "their deeds are evil."

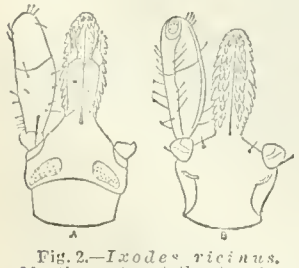

Fig. 2.—*Ixodes ricinus*. Mouth parts of the female, A, seen from the dorsal, B, from the ventral surface. The median, dotted, portion of the left hand figure is the sheath; the toothed portion the rostrum. The lateral process is the pedipalpus. × 35. (After Nuttall and Warburton.)

Argas persicus, known to travellers as the "teigne de miana," is of an oval form, of brownish-red colour. The male measures 4 to 5 mm. in length by 3 mm. in breadth; the female 7 to 10 mm. in length by 5 to 6 mm. in breadth. This creature frequents the northern parts of Persia, and occurs in many other warm countries. In South Africa it is known as the *Tampan* and *Wandlius*, where it is mainly a fowl parasite. In Persia it is very much dreaded, though probably the effects of its bite are due to the unsuitable treatment the punctured skin receives and the consequent invasion of the tissues by septic bacteria. In South Africa it is frequently fatal to fowls, especially to chickens, but the death is there believed to be due to the loss of blood.

We have not yet explained that ticks pass through several stages as they advance from the egg to the adult. The larval stage of *A. persicus* will remain on its host for five days. It then leaves, and moults in retirement. After the moulting it visits its host by night and remains

Fig. 3.—*Argas reflexus*, female. On the left the dorsal view of a specimen laying eggs; on the right a ventral view of the same.

on it for about an hour. This second stage, known as the nymph stage, moults twice, and the female in each stage becomes much distended with blood—"gorged," as the saying is. With each moult it becomes larger, but otherwise does not alter much in appearance. The adult female also, like the nymph, visits the host from time to time, and between these visits deposits eggs in great quantities in sheltered crevices, some 50 to 100 being deposited at once. *Argas reflexus*, the "marginated tick," is yellow and white—the Papal colours. It is common near dovecotes and pigeon-houses, and often attacks people sleeping in their neighbourhood. Its bite

Fig. 4.—*Ornithodorus moubata*, an unfed female. To the left a ventral, to the right a dorsal view, showing the crimped skin.

causes much irritation, and sometimes leads to vesicles and ulcers. At one time it was common in Canterbury Cathedral, and so worried the worshippers that it took all the eloquence of the "Very Reverend the Dean" to overcome its repellent powers.

Another species, *Argas chinche*, is extremely troublesome to the natives of the temperate parts of Columbia.

Ornithodorus moubata (= *O. savigneyei*), sometimes known as the "tampan," occurs pretty often in South Africa, and was a cause of considerable trouble to our troops during the South African war. It lives normally in the shade of vegetation, but frequently invades the native huts. It is catholic in its taste and attacks most mammals, and it has a decided preference for men. In Uganda the natives frequently die from its bites—dying of so-called "tick fever." I myself once assisted in identifying two ticks in the nymph stage taken in Cambridge from the ear of an American visitor to this country who had been camping out in Arizona shortly before his arrival. This tick turned out to be a species of *Ornithodorus megnini*, which, as a rule, attacks the horse, the ass, and the ox about the ears. But it frequently attacks man, and is well known in the United States, infesting the ears of children. An allied species, *O. turicata*, proves fatal to fowls in the Southern States and in Mexico, and is very harmful to human beings. The chief harm that these ticks do is to transmit protozoal diseases to man and other animals.

Fig. 5.—*Ornithodorus moubata*. Female, gorged, seen in profile.

A very few ticks are said to be pathogenetic, but by far the greater part lay fertilized eggs, and lay them in

considerablo numbers, aud the eggs are agglutinated together in solid little masses, by the sticky secretion of a cephalic gland, which opens below the rostrum. The eggs are small and elliptical, and are laid to the number of many thousands. The young tick, which is usually born with but three pairs of legs, hatches out in a few days if the weather be warm, or a few weeks should it prove cold. A certain amount of moisture must be present, or the eggs are apt to dry up. These masses of eggs are laid on the ground under herbs or grass, or on leaves. The issuing six-legged embryos larvae, like the young of other animals, are very agile, climbing on to leaves and herbage, and waiting with their front legs eagerly stretched out for the passage of the host upon which they desire to settle. Of course, not one in a thousand succeeds, and it is terrible to think of the amount of unsatisfied desire which must be going on in the tick world! The rest perish miserably. Those that do succeed attach themselves to the skin of the host, and thrust their rostrum and sucking tube into the hole already prepared by the cutting chelicerae. They suck the blood, and when gorged fall to the earth, or in some cases remain on the host in a state of inertia or apparent syncope. Soon, however, the gorged larva moults, and gives rise to the first nymph—an eight-legged creature. This one affixes itself anew upon a host, either upon the same or another one, again gorges itself, and in all points resembles the adult, except from the fact that the sexual orifice has not yet appeared. After some days the first nymph moults, and this again remains either on the host or it falls to the ground. In some cases there are two nymph forms. But as a rule the first nymph gives rise by a second moult to the adult form, which again for the third time regains a host. The adults are now ripe for pairing, and the male having enlarged the orifice of the oviduct by inserting its rostrum, deposits therein a spermatophore or capsule full of spermatozoa. The female is often successively fertilized by several males.

Fig. 6.—*Ixodes ricinus*. The male is inserting its rostrum in the female genital duct before depositing its spermatophore. × 6. (From Brumpt.)

In many cases the male dies after fertilization. The female swells enormously when gorged, sometimes becoming as large as a filbert, or even a small walnut. These ticks are seldom parasites of one particular host, but attack many mammals indifferently. They have many natural enemies, amongst the most important of which are certain hemipterous insects whose female attacks the nymph of the *Ixodes*, and lays within the body of the tick a number of eggs which develop inside the nymph until they reach the adult stage, when they make their escape through an orifice generally at the hind end, leaving behind them the dead body of their host. Three species of such hemipterous insects are known, parasitic on ticks, of these *Ixodiphagus caucurtei* is ubiquitous. It attacks all kinds of ticks, but especially *Dermacentor venustus*.

Fig. 7.—*Ixodiphagus caucurtei* laying eggs in the nymph of *Ixodes ricinus*. × 20

Ixodes ricinus, of a brownish colour in the male, is very common in England and, indeed, almost everywhere. The female is yellow and flattened, somewhat resembling a grain of rice. It is the well-known dog tick, but it attacks oxen, especially goats, deer, horses, and man. It also attacks the grouse, and is particularly common in some parts of Great Britain. It is impossible to rid certain areas of these troublesome guests. In some cases they produce tumours and introduce bacteria, and in cattle it introduces an organism known as *Babesia bovis*, which is the cause of haematuria in oxen. *Dermacentor venustus* transmits Rocky Mountain fever, which is common in certain parts of the States. The fever is accompanied with pains in the joints and muscles and an eruption on the surface of the skin, appearing first on the wrists and forehead, and invading in time all parts of the body, followed by a scaling of the skin during a period of convalescence. In Montana the mortality caused by this disease is very high, varying in different years from 33 to 75 per cent. In Idaho it only attains a mortality of 4 per cent.

Ornithodorus moubata inoculates man with a spirochaete (*Spirochaeta duttoni*) which is the agent of the African tick fever or relapsing fever. One of the curiosities about the organisms transmitted by ticks is that they live through the whole cycle of the tick's life. If they are taken in by the larva they are only transmissible by the following larval stage. If they are taken in by the nymph they are only transmissible when again the nymph stage is met with, and the same is true of the adult. Think what such a protozoon must have seen! The fertilization of the egg by the spermatozoon, the fusion of the nuclei, the breaking up of the egg into segments, the gradual building up of the tissues of the larva, the sudden inrush of the host's blood when the larva is safely fixed, the moulting, the changes in the nymph, the development of the generative organs, the formation of the eggs! What a textbook of embryology and anatomy it could write if only it had descriptive powers! If I may paraphrase Kipling:

Think where 'e's been,
Think what 'e's seen,
Think of his future,
And Gawd save the Queen!

C

EPIDEMIC POLIOMYELITIS.

BY

ARTHUR A. PIM, F.R.C.S.E.,

BEAMINSTER, DORSET.

In August and September of this year there was in this town and the surrounding country an outbreak of poliomyelitis, and an account of the types of the disease observed may be of interest and possibly some service to readers of the British Medical Journal.

During the hot weather in August a number of children, whose ages ranged between 1½ and 16 years, were taken suddenly ill. The symptoms in all cases were nearly the same: the temperature was high, sometimes reaching 104°, the tongue was furred, the breath offensive, and there was in all cases obstinate constipation, which was frequently only relieved by enemata. The majority of the children complained of pains in the back and limbs, and in all cases in which pain appeared early paralysis of some muscles or groups of muscles followed in from one to seven days. In one child the paralysis affected all the muscles of the trunk and limbs, and respiration was entirely diaphragmatic.

There were, however, a number of other cases in which early pain was entirely absent, but the other symptoms were present which later, generally at the end of seven to ten days, sometimes after a day or two of apparently complete recovery, developed acute sciatica; in no case was the sciatica accompanied or followed by paralysis of any muscle. There were also a certain number of other children who exhibited the early symptoms — of rise of temperature, furred tongue, and constipation — who recovered completely without any after-effects.

In only one case did I note the preparalytic twitchings regarded by Colliver of Los Angeles as pathognomonic of the disease. A period of incubation has, I believe, never yet been determined for poliomyelitis, but it is suggestive that two children who developed the disease after leaving the town did so on the eighth day after departure.

The cases were widely scattered, and although in two instances more than one child was attacked in one house, the development of the disease was practically simultaneous. The distribution of poliomyelitis by flies and dust has been suggested, but a very striking fact was that in the poorest and dirtiest street of the town no case appeared. In one case the evidence in favour of infection having been conveyed by an earth closet used by a child, who developed the disease, was considerable.

Dr. MacClaren, one of the medical officers for the county, has drawn my attention to the probability of the

infection having been conveyed by four parents, who worked together in the same shop, to a child of each living in entirely separate parts of the town. The fact that this shop was a butcher's might suggest a field for investigation.

The treatment adopted was evacuation of the bowels followed by large doses of salol, and spraying the mouth, nose, and throat, not only of the patient, but of all contacts, with solutions of hydrargyri peroxidi or potassium permanganate.

EIGHTY-SECOND ANNUAL MEETING
OF THE
British Medical Association.

Held in Aberdeen on July 29th, 30th, and 31st.

PROCEEDINGS OF SECTIONS.

SECTION OF SURGERY.

J. SCOTT RIDDELL, M.V.O., M.B., C.M., President.

THE TREATMENT OF CERTAIN CASES OF APPENDIX ABSCESS.

By C. MAX PAGE, M.S., F.R.C.S.

IF one reviews the voluminous current literature on the treatment of acute appendicitis it is noteworthy that the opinion of the majority of observers on the surgical treatment in the early days of an attack is practically the same, whereas the rules laid down for the treatment of localized acute appendicitis (including abscess) are very varied, not only in relation to the proper time for operation, but as to its technique.

Statistical reports support the common conviction that surgical interference at any time in the first forty-eight hours of an acute attack is the right line to adopt. The same view is taken if, at a late stage of the disease, a case presents signs of definitely spreading or general peritonitis, but until every practitioner and patient is convinced of the soundness of immediate operation, cases continue to come under the care of a surgeon for the first time after the third day of the disease; and it is in relation to the treatment of some types of this class of case that I wish to make certain criticisms of the commonly adopted treatment.

At St. Thomas's Hospital, from the reports of which institution I propose to draw most of my figures, it has in recent years been customary to operate on cases of localized appendicitis at any stage of the disease, when the presence of an inflammatory mass and the level of the temperature suggest the possibility of suppuration; it will be admitted that it is impossible to say definitely from clinical and blood examination whether a case of acute localized appendicitis of from five to six days' standing will resolve or lead to abscess formation, or even whether there is pus present in the centre of an inflammatory mass or not. The appendix is removed if this is possible without too great disturbance of the surrounding structures, and if pus is found the cavity is drained. If the inflammatory mass had involved the anterior parietal peritoneum the results are good and complications seldom ensue. If however the general peritoneal cavity was not shut off, and the same line of treatment be carried out, a spreading peritonitis from the disturbed area is liable to ensue. The end result in such instances may occasionally be death from peritonitis, more often it entails a prolonged convalescence with the possibility of residual abscess formation.

The likelihood of such a complication arising from operations involving the transperitoneal opening up of an infective focus is well recognized, and in order to avoid it different procedures are advocated. The two commonest are:

1. That practised at St. Thomas's Hospital and advised by Murphy and others—namely, after opening the abdomen, to carefully pack off the surrounding peritoneal cavity with gauze plugs, deal with the infective focus and sponge out the abscess. The plugs are then removed and the abdominal wall sewn up except where a drain is left down to the infected area.

2. To lay the abdominal wall freely open, and, after opening the cavity, pack it completely with gauze and leave the abdominal wound open.[1]

There are other methods in less common use, Sonnenburg,[2] in his classical monograph, and several other German surgeons advocate draining such cases via the pericolic cellular tissues in the loin, the peritoneum being stripped away from the anterior and lateral walls, a drainage tube is brought out along the line of approach. Maylard[3] swabs out the abscess cavity with pure carbolic acid, sprinkles it with iodoform and closes the abdominal wound, leaving an aperture for a small draining tube.

As already stated, the first of the above methods is the one that has been used in general for the cases for which I propose to quote figures. Criticism of the other methods I shall not attempt here, though I shall quote figures showing the results of some of them.

I maintain that if the resistance of a patient is such that he is able to definitely localize a peritoneal infection, that patient should not subsequently suffer from spreading or general peritonitis. If he does, it is in nine cases out of ten due to mechanical causes, which should be avoidable.

The figures I am able to put forward show that a good number of appendix abscess cases do suffer from spread of the infection after operation.

The following table shows the mortality at St. Thomas's Hospital from appendix abscess for the years 1909 to 1913.[4]

Appendix Abscess, 1909–13, St. Thomas's Hospital.

	Cases.	Deaths.
1909	66	6
1910	91	4
1911	71	6
1912	81	2
1913	50	7
Total	359	25 = 6.9 per cent.

That this death-rate is not above the average is shown by the following figures taken from various sources.

Source.	Cases.	Deaths.	Mortality.
Burgess, BRITISH MEDICAL JOURNAL, 1912, p. 415	107*	2	1.86%

* Appendix removed. † Appendix not removed.

An analysis of the cause of death in the cases quoted from *St. Thomas's Hospital Reports* is given. The following table gives the total results:

Cause of Death in Twenty-five Fatal Cases of Appendix Abscess, St. Thomas's Hospital, 1909–13.

General peritonitis	17
Intestinal obstruction	4
Portal pyaemia	3
Erysipelas...	1

In the reports of 1911–13 particulars are given of the method of operation in the fatal cases, to the effect that of the 12 cases dying from general peritonitis in those years the abscess was opened across the peritoneum in 10.

This proves, as far as figures can, that the technique I have described for the treatment of abscesses not adherent to the anterior abdominal wall is unsatisfactory. To emphasize this I may quote the figures given in the 1912

report, which show that these cases treated in this way, when not fatal, have a higher incidence of complications and a long convalescence.

In 12 cases out of a total for the year of 81, the abscess, though well localized, was not adherent to the anterior abdominal wall. Ten of these 12 cases suffered from residual abscess formation; the other 2, as already stated, died.

The inference to be drawn from these figures, I think, is that operation has been undertaken at a stage while the contents were extremely virulent and dangerous to the peritoneum of the patient not already involved in the inflammation. Some investigations made by A. G. Gardner confirm this.

In the course of a research into the inflammatory peritoneal exudates he found that aggressins—that is, substances found in the course of bacterial multiplication in the body and which inhibit the action of the phagocytes—are present in the pus of recently formed appendix abscesses. He makes the following statement: "My experiments strongly suggest that it is a dangerous proceeding to break through the wall of an abscess containing aggressive pus, and thereby to put its cavity into communication with uninfected peritoneum. For such a proceeding does not merely open a channel of bacterial infection, which the healthy peritoneum might be expected to resist, but it also admits the escape of a fluid which is capable of paralyzing the defences of the cells with which it comes in contact."

From clinical experience it is well recognized that the contents of an appendix abscess are extremely virulent from about the fifth to the tenth day.[5]

To remove the risk of operation at this stage one of two courses is open: (1) To wait till between the tenth and fourteenth day before operating, so that it will seldom be necessary to evacuate an abscess across the general peritoneal cavity, and in any event the pus will be sterile or relatively non-virulent; (2) to operate in such a fashion that the pus in the abscess cannot possibly come in contact with uninfected peritoneum.

The former line can be adopted in a certain number of cases, but I do not think it is satisfactory as a routine method; it does not deal with the pain and the disadvantage of leaving a septic focus undrained for a considerable period. It also involves the slight risk of spontaneous rupture of the abscess into the general peritoneal cavity.

With regard to a safe operative method, in a series of cases I have carried out, with excellent results, a conservative and, I believe, old-fashioned operation. If on opening the abdomen the abscess is found not to be shut off from the general peritoneal cavity, no attempt is made to open the cavity or do anything further; a cigarette drain of medium size is put down to the outer side of the inflammatory mass and the wound sutured.

Abdominal hot-air baths or, if they are not available, hot fomentations are then applied to the abdomen.

Spontaneous discharge of the abscess occasionally occurs along the tube; in a surprising number of cases, however, the inflammatory swelling subsides without any pus appearing.

If the temperature keeps up and the pain persists after the second or third day, the tube is removed and a finger inserted along its track under gas, and in this way the abscess can usually be broken into. At this stage adhesions around the line of the drainage tube remove the risk of infecting the peritoneum.

The following abstracts from the notes of my cases will give a clearer idea of the results of this method of treatment. The abstracts are taken from a series of 112 cases of appendix abscess treated by myself, Mr. B. C. Maybury, or Mr. Rouquette, and extend over the years 1909–14. The operations were carried out on behalf of various members of the St. Thomas's Hospital staff, and I am indebted to them for permission to make use of the material.

Operation.	Number.	Deaths.
Type A.—Cases of localized abscess opened across the open general peritoneal cavity	25	3
Type B.—Similar cases treated by conservative operation (described above)	19	0

Statistical Abstract of 23 Non-fatal Cases Treated by Operation Type A, and 12 Cases by Operation Type B.

	Opened Transperitoneally.	Conservative Operation.
Average day of operation after onset of attack	8.8	8.2*
Number of days in hospital after operation	48	15.05
Signs of extension of peritonitis present in	14	0
Secondary abscess formation (operation)	10	0
Secondary local peritoneal swelling (spontaneously subsiding)	2	0
Average time temperature remained above 99° F.	17.7 days	5.1 days
Faecal fistula formation (temporary in all cases)	6	0
Sinus (present on leaving hospital)	4	0

* One case, the history of which was indefinite and extended over four weeks, has not been included.

The 3 fatal cases occurring after treatment of Type A all died from general peritonitis, according to *post-mortem* examination. All were females, aged respectively 16, 27, and 50. The respective intervals between the onset of the attack and operation were twelve, four, and ten days. Death ensued in thirteen, three and four days after operation.

One cannot dogmatize on a small series of figures such as these, but the short convalescent period and absence of complications in the cases in which the conservative type of operation was adopted is very striking.

SOME PRACTICAL CONSIDERATIONS IN THE DIAGNOSIS AND TREATMENT OF ABSCESS OF THE CEREBELLUM.

By Sir William Milligan, M.D.,

Consulting Surgeon, Manchester Ear Hospital; Aurist and Laryngologist, Royal Infirmary, Manchester; Lecturer upon Diseases of the Ear, the Victoria University of Manchester.

(*Abstract.*)

The decades from 10 to 20 and from 20 to 30 provide the largest number of cases of abscess of the cerebellum.

Males are affected twice as frequently as females, and abscess upon the left side is twice as frequent as abscess upon the right side.

The great majority of chronic cases are secondary to labyrinthine suppuration, the aqueductus vestibuli being the actual route of infection in nearly 30 per cent.

Of clinical indications of cerebellar disease, nystagmus is one of the most important. In labyrinthine suppuration it is first directed towards the affected side and subsequently towards the sound side. It remains towards the sound side throughout the course of the disease and decreases *pari passu* with the destruction of the labyrinth.

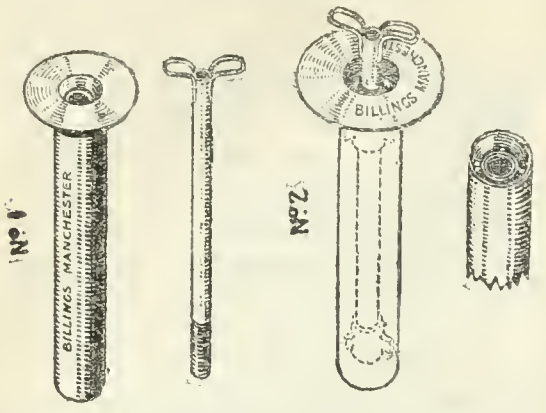
Cerebellar nystagmus is directed first towards the sound side and subsequently towards the affected side. It increases with the progress of suppuration within the cerebellum.

To test the function of the labyrinth the caloric test is the most convenient and can be applied with the patient sitting up or lying in bed. To fix the position of the eyes a goniometer is useful.

Speaking generally, exploration for cerebellar abscess should be made through the posterior antral wall in the space between the internal auditory meatus and the sigmoid sinus groove.

Counter-drainage behind the "groove" is a valuable measure and much facilitates after-treatment. Prior to operation the withdrawal of a small quantity of cerebrospinal fluid is advisable to lessen existing intracranial tension and to prevent sudden respiratory or cardiac failure.

For the drainage of chronic abscesses the author uses a special form of drainage tube (see Fig. 1), a tube within



a tube, so constructed that the inner tube may be removed without disturbing the position of the outer tube.

Operative Results Obtained during the Past Ten Years.
Number of cases operated upon—27.

Males ...	17	Right side ...	7	Cured	17
Females ...	10	Left side... ...	20	Died	10

DISCUSSION.

Mr. W. G. Spencer (London) asked if in acute cases with cerebral tension and meningitis it would not be better to remove more bone behind the lateral sinus, and so do away with the necessity for the tube. The objection to this procedure was the risk of formation of hernia, but the important advantage would be the saving of the patient's life in the meantime.

Sir William Milligan, in reply, said that although many of the acute cases were the result of direct infection from lateral sinus thrombosis, it was better to open all cases through the antral wall in front of the sinus. It was true that the opening could not be so big as through the posterior route behind the sinus. Before operating intracranial tension could be relieved by lumbar puncture; thereafter, in both classes of cases, the abscess was best reached through the antral wall, because cerebellar abscess was almost invariably found below that point. In reply to another question, he pointed out that nystagmus could be produced in any one; it was a normal physiological function. If the tympanic membrane were intact nystagmus could be produced in thirty to forty seconds; if the membrane were gone and the labyrinth normal, the sign was produced very much quicker—in about ten seconds.

ON THE TREATMENT OF VESICAL PAPILLOMATA BY THE HIGH-FREQUENCY CURRENT.

By Andrew Fullerton, M.Ch., F.R.C.S.Irel.,
Honorary Surgeon in Charge of Out-patients to the Royal Victoria Hospital and the Belfast Hospital for Sick Children.

The method of treatment by the high-frequency current has not as yet had a very general acceptance by British surgeons. The method was suggested by Edwin Beer in 1912, and up to the present the total number of cases reported does not amount to much over 200, the large majority having been under the care of American surgeons. E. S. Judd[1] says:

The employment of the high-frequency current is one of the most useful adjuncts in the treatment of these tumours. We have used this method of treatment in 17 cases. This number includes 11 cases of recurrence after previous operations done in our clinic and elsewhere. The patient longest under observation since treatment by the high-frequency current was seen after fifteen months. In this case there is no evidence of recurrence. Five patients have been examined one year after treatment, and in none was there any sign of recurrence. . . . We have found the villous growths on small pedicles the most favourable type for treatment by the high-frequency current.

Dr. Lewis Wine, in a more recent communication, published in the *Clinics of John B. Murphy* of April, 1914, states:

In 31 cases treated by the high-frequency current through the cystoscope I have had only one recurrence, and that was in a patient who refused to follow directions. He did not report for treatment regularly; he was a high liver, and indulged in a considerable amount of alcohol. In this case the recurrence was not malignant, and fulguration has entirely cleared up the condition.

Last year, in the Urological Section of the International Congress of Medicine, held in London, a portable outfit was demonstrated to the members by Loewenstein of Berlin, and it is with this apparatus that I have treated the cases I am about to mention. Two electrodes are supplied with this coil—one a broad, flat electrode, protected by webbing, for application to the suprapubic region, and the other a modified ureteral catheter containing a central wire which terminates at the business end of the catheter in an acorn-shaped platinum point. The patient is prepared as for cystoscopy, and the large electrode, well moistened with saline, is pressed firmly on the lower part of his abdomen. The cystoscope, with the modified ureteral catheter in position, is introduced into the bladder, the latter having previously been filled with fluid in the ordinary way. The intravesical electrode is now manipulated through the cystoscope like a ureteral catheter so that it buries itself in the papilloma about to be treated, and the current is turned on. Immediately a stream of sparks issues from the platinum point and cauterization is begun. As this proceeds the tendrils of the papilloma are seen to crumple up, and after a few seconds coagulated portions of the tumour adhere to the platinum point. It may be necessary to remove the electrode in order to clear away the adherent coagula before continuing the operation. After a few minutes, the superficial part of the tumour becomes converted into a white more or less homogeneous mass obscuring the central or deep part of the growth. For several days the patient passes coagulated remains of his tumour, and it is well to wait until these have cleared away from the urine before attempting a further application. The exact limits of the destructive process will then be visible.

In my own cases I have allowed an interval of a fortnight to elapse between one treatment and the next. Whatever remains of the papilloma after separation of sloughs is now treated in the same way until all trace of the growth is gone. Probably three or four or even more applications may be necessary. The area of the bladder from which the growth has been removed is finally lightly treated with the spark in order to prevent recurrence. I have noticed that the patients complain of rather acute pain when the electrode approaches the bladder wall, but that the tendrils of the papilloma may be destroyed with little discomfort. In the intervals between the applications the patient suffers no pain, but free haemorrhage may take place. No anaesthetic is administered, and the patient may be allowed to get about during the course of his treatment. I have to report two cases successfully dealt with by this method.

H. P., a male aged 54, was sent to me at the Royal Victoria Hospital by Dr. Patton of Belfast. The patient had had no trouble with his urine until seven weeks previously, when he noticed blood in it. He had to make water every two hours during the day, but was not disturbed at night. The patient was cystoscoped on June 16th, 1913. At the base of the bladder, a little to the left, there was a small papilloma, subsessile, with seaweed-like tendrils, and about the size of the last joint of my little finger. I did not see the patient again until January 12th, 1914, when I discovered a second papilloma behind the one just mentioned and about the same size. I may have missed this at my previous examination seven months before. The current was applied in the way I have just described to both papillomata. On January 27th the posterior papilloma was replaced by a blood-stained area, and the anterior one was reduced in size. The current was again applied, and the remains of this growth were destroyed. On February 11th there was no trace of the posterior papilloma, and the site of the anterior was occupied by a white area like a patch of snow. As a precautionary measure the spark was lightly applied to and around this area.

The patient was lost sight of until June 29th, 1914, when he attended at my request for examination. His urine was quite clear, and he could retain for seven or eight hours. After the most careful examination with the cystoscope, I was unable to discover any trace of papillomatous growth in any part of his bladder. Thus, after five months this patient remains free from recurrence, although he really had only two applications of the current.

When I saw this patient in January, 1914, he was anaemic, wasted, weak, and ill, and was suffering from bronchitis, so that a severe operation was out of the question. His appearance at the last visit was greatly improved, and he was at work every day.

The second case was that of a married lady, aged 62, referred to me by Dr. Darling of Lurgan. For about a year she had been having intermittent painless haematuria, the attacks coming on at intervals of three weeks. Occasionally a few clots were passed. The attacks of bleeding were of very short duration, lasting for part of a day, or a day, at a time. She had no other symptoms whatever. I first saw her on April 8th, 1914. The urine was then quite clear, and her general condition was excellent. On cystoscopic examination I found, well to the right of the right ureteric orifice, a soft pink papillated mass, about the size of a small marble. This was subsessile, and was composed of minute finger-shaped processes. Extending from the main growth as far as the ureteric orifice there was a fringe of fine villi, like sprouting blades of grass. To the left of the left ureteric orifice, and well out from it, was a small papilloma, about the size of a large pea. On the posterior wall there was another commencing papilloma. The bleeding had evidently come from the largest growth, which showed an area of ecchymosis at one part.

With the current the main portion of the right-sided papilloma was destroyed, and, moving the electrode along towards the ureteric orifice, the villous fringe was cauterized. On May 7th examination showed a seared area leading downwards and inwards towards the right ureteric orifice. This area was lined on either side by a little hedge of villi which had escaped destruction on the former occasion. The small papilloma on the left and the villi just referred to were dealt with at this visit. After this sitting the patient had a little bleeding, and mentioned the fact that she had for a few days passed small pieces of a whitish soft material.

On May 19th the cystoscope showed at the areas last touched patches of redness with greyish-black centres. The third application was now made, and the remains of the largest papilloma, that on the right side, were destroyed. On June 2nd the site of the right-sided papilloma was represented by a whitish raised area with some black dots in it. This area was further treated. The site of the small left papilloma was now seen to be filling in by indrawing of the mucous membrane, which was red and swollen around it. The patient bled rather severely for ten days after this visit.

On June 23rd all traces of papillomatous growth were gone and there only remained a white slough on the right side. A light application of the spark was made around this area as a precaution against any trace of growth having been left behind. A recent examination shows a normal bladder. In this patient four applications were apparently sufficient to destroy the papillomata. She complained of a good deal of pain when the electrode touched the bladder wall. In the intervals between her visits she was quite free from pain. She came up from the country for each application and returned by the next available train, all the time carrying on her usual duties. If this case had been operated on by suprapubic cystotomy it would have been impossible to have seen the small outlying villi near the right ureter. These could only have been seen while floating in water under good light, as villi of the small intestine are frequently examined. Hence the likelihood of recurrence after an open operation.

I would suggest that a fair trial should be given to the high-frequency current; for it should be of great service in the treatment of small papillomata easily reached through the cystoscope, and for the destruction of recurrences in the early stage. All patients who have had operations for vesical growths should be examined every few months for several years, when treatment by this method may be sufficient to stamp out the disease.

As to the mode of action of the current, I believe that it acts simply as a cautery, and that there is no specific electrical action produced. The method is easy of application, accurate in picking out the smallest visible villi, practically without risk to the patient's life, and convenient in that he can attend to his ordinary duties during the treatment. One great advantage of this method, to my mind, is that the villous processes are destroyed, and are therefore unable to graft themselves on to fresh places on the bladder wall.

OPERATIVE TREATMENT OF ABDOMINAL ANEURYSM.

By W. I. DE COURCY WHEELER, F.R.C.S.I.,
Visiting Surgeon, Mercer's Hospital, Dublin.

(*Synopsis.*)

MR. DE C. WHEELER in an extemporary communication drew attention to the subject of abdominal aneurysm, and to some points in connexion with the operative treatment of cases in which this condition existed. Among symptoms of the condition, that of pain was, in his experience, the most pronounced, and two factors, he believed, played the main part in its causation; the first of these was stretching of the post-parietal peritoneum, and the second, the heaving and tugging on the peritoneum which took place at each pulsation of the aneurysm.

In regard to operative measures, he was opposed to electrolysis, which seemed to him to introduce both a risk of sepsis and an increased probability of the occurrence of embolism. The measure he preferred was the utilization of Colt's apparatus. In using this it was important to make sure that the end of the trocar was lying free in the lumen of the aneurysm; this would be shown to be the case by there being free return of blood through the cannula. Unless this precaution were taken there was a danger that the introduction of the wire would prove ineffectual, because instead of being passed into the lumen where it could do its work, it had been pushed into a part of the sac already filled with laminated clots. It was also well to place the patient in the Mayo Robson gall-bladder position, for this brought the aneurysm well foward, and thus facilitated the operation.

Mr. Wheeler also stated that he had used the measures indicated with success in three cases, which he intended to describe in detail at a later date. Before operation was undertaken they were given a course of salvarsan and mercury, and immediately prior to operation injections of horse serum were made. In one of the patients the sac eventually ruptured, but the point at which it ruptured was remote from the place at which the wire had been introduced, and the whole occurrence was secondary to an attack of intestinal obstruction. Of the other two cases, one was alive and well when last seen four years after the operation, and the other, when seen nine months after his operation, was not only alive and well, but had been passed as sound for service in the Naval Reserve, and subsequently took up active employment as a chauffeur.

Mr. Wheeler acknowledged the assistance and information he had obtained through the courtesy of Mr. D'Arcy Power and Dr. Colt.

DEMONSTRATION.

NOTES ON SOME APPLIANCES.

By ERNEST W. HEY GROVES, M.S., F.R.C.S.,
Surgeon to the Bristol General Hospital.

MR. HEY GROVES demonstrated a series of appliances, and in connexion with them made the following among other observations:

A Fixation Apparatus for Fractures.—I have on several occasions drawn attention to the excellent results which can be obtained in fractures of the leg by the use of two transfixing pins, above and below the site of injury, clamped together by extension rods which lie on each side of the limb.

I have always pointed out that it is essential for the success of this double transfixion appliance that the two transfixing pins should be passed through the limb in an exactly parallel direction. Hitherto I have been content with using a bar of metal pierced by many parallel holes as a guide, through which the pins are passed. But Messrs. Down Bros. have now suggested and made for me a device which obviates the necessity for a separate instrument. It consists in making at each end of the outside extension bar a socket $\frac{3}{4}$ in. long which exactly fits the pin. Both extension bars are fitted with a fine and a coarse adjustment in length, so as to vary between 9 and 15 in. In applying the apparatus the limb is strongly extended and held in correct anatomical position; the extension bar with the sockets is adjusted as to length so that the sockets lie over the points that the limb is to be perforated; it is firmly held against the outer surface of the leg, and the two pins are then driven right through the bones after passing through the sockets. Each pin has a bradawl point and a detachable handle, which makes it serve as its own drill.

When both pins are in position, the inner extension bar is adjusted and the whole frame is complete. The screw adjustment with which each extension bar is provided enables a very great force to be applied in the

length of the limb, and this force can be used gradually day by day until all overlapping has been reduced.

The simplicity of the application of this apparatus as well as its great efficiency makes it of great service in cases of open or of comminuted fracture of the leg bones, and particularly in those involving the ankle-joint. In the latter case the os calcis takes the transfixion of the lower pin.

It is only necessary for the apparatus to remain in position for about three to four weeks, during which time the patient is up on crutches. It permits the free application of massage and of movements.

Tapped Plates with Converging Screws.—That a simple plate fixed to the outside of a bone by a series of "wood" screws is an absolutely inefficient fixation appliance has been demonstrated both by experiment and by clinical experience. Therefore whenever possible the fractures of long bones which necessitate operative treatment must be transfixed by bolts which hold the plate to the whole thickness of the bone by a broad head or flange. But there are some cases, notably that of the humerus, where it is not desirable to bare the bone on three surfaces in the way demanded by the bolted plate method. For such conditions I have shown that a curved or quadrant plate bearing "metal" screws tapped in its own substance is very efficient. I am showing you now some very simple narrow plates which require the minimum exposure of the bone, but which embody the same principle. They are curved to fit the surface of cylinders ½ in. to 1 in. in diameter, and they have series of holes near their edges which are tapped to take ⅛ in. screws.

The plate is temporarily clamped on to the bone, and holes are bored with a simple drill which just clears the metal ($\frac{7}{64}$ in.) Then metal screws, with self-tapping points, are put into the plate, the thread of which holds them in position and so obviates the necessity of a special screwdriver. They are driven into the bone, in which they cut their own thread. When the screws are all in position they form two converging series lying in two different radii of the bone cylinder. This not only greatly increases the strength of the fixation, but as the screws are fixed in the plate and enter the bone at a converging angle, they cannot become loose nor drop out of place, as happens so commonly with the simple plates and screws.

Modification of the Bolted Plates.—When I showed this method last spring, several surgeons in speaking to me about it objected to the way in which the heads of the bolts and the nuts formed outstanding projections. We have now overcome this objection; when the bolts are screwed home there is no projecting head at either end. The nuts, instead of being adjusted by a spanner, are round, and are cut like screw heads; they are tightened by a tubular screwdriver, which fits over the projecting end of the bolt. This end is cut off when the nut has been finally adjusted.

A New Circular Saw for Bone Work.—The most important subject in the conservative reconstruction of bones is undoubtedly that of the bone graft. Both for the cutting of a graft and for the shaping of the socket in which this is to lie a powerful motor-driven saw is often necessary. Those in common use are open to the objection that they cannot be used upon a bone which lies at the bottom of a deep wound. This is because the small saw blade is at right angles to the shaft which propels it, and the latter, by its contact with the soft parts, prevents the saw working except upon a projecting bone. The saw which I am showing you works by means of a bevelled cog, parallel with the handle or cable, and it therefore can work at the very bottom of a wound of any depth without interference with the soft parts.

Possibly these small details of technique may be thought by some too trivial to be worthy of attention, but I am convinced that all who have worked much at the conservative surgery of bones will agree that it is upon such little points of technique that the possibilities of accurate cutting, fitting, and fixing the bones depend for success.

The Fowler Position.—After dwelling on the advantage of the Fowler position after operation and the reasons of its utility, Mr. Hey Groves showed a model of an apparatus for securing this position, which will be found figured in *A Textbook for Nurses*, by himself and Dr. Fortescue-Brickdale. There was, he pointed out, many specially constructed beds by which the same sitting position could be secured, but the apparatus shown had the advantage of being capable of being fitted on to the frame of any ordinary bedstead. It consisted, he said, of two parts: one a frame which elevated the trunk, and the other over which the legs were bent, so that the patient could not slip down in the bed. There were no rigid bars across the middle of the back to cause discomfort when the patient was lying flat. The body and leg portions of the apparatus were clamped on to the bed frame 8 inches apart, so that when in use this space accommodated the patient's buttocks. The whole apparatus lay between the bed-frame and the mattress, and could be adjusted in position at a moment's notice when required. He had used this bed-frame for the last seven years both at the General Hospital, the Cossham Hospital, and at a private nursing home, and it had been of such invaluable service that he ventured now to bring it to the notice of the profession in the hope that others might find it useful.

(The bed-frames are made for Mr. Hey Groves by Messrs. Hodges, of 104, St. Thomas Street, Bristol, and the price is 27s. 6d. In ordering it is necessary to state the exact outside width of the bedstead and the thickness of the side bars of the bed-frame.)

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

TREATMENT OF TETANUS.

Pure Carbolic Acid.

THE reading of Dr. Alfred MacConkey's paper on tetanus[1] recalls to my mind two cases treated by myself and one under the care of Dr. Fotheringham, which was treated by him in a similar manner at my suggestion. They were cases, it is true, which were late in developing, and which, unfortunately, had not been recognized until their condition was desperate, and, while we used antitetanic serum, we felt that the disease was too far advanced for the serum to have much effect. In addition, I injected into the site of infection pure carbolic acid 2 parts, in glycerine 1 part, in an endeavour to bring about a coagulation necrosis at the site and try to prevent the absorption of fresh toxin.

The patients also received intramuscular injections of 1 drachm of pure carbolic with 1 drachm of glycerine every four hours, first in one pectoral region and then in the other, and in the groins or thighs. One patient took 9 drachms of pure carbolic acid in this way before showing any signs of carboluria. As soon as the carboluria disappeared the treatment was resumed.

Of course one is aware of the fact that the carbolic acid would have no effect on the toxin and a doubtful effect on the tetanus bacillus, but it does induce an enormous leucocytosis, as is clearly shown in Fotheringham's case.[2]

All three of these cases recovered, and I mention the fact hoping that some poor fellow, whose symptoms have not been recognized sufficiently early for antitoxin to be of much use, may have an extra chance.

Toronto. F. N. G. STARR.

Intracerebral Injections of Antitoxic Serum.

TETANUS has played such havoc among the wounded that I feel that I ought to draw attention to the very remarkable success which followed intracerebral injections in a case under my care some few years ago.

The patient, an officer in the Royal Horse Artillery, was thrown from a dogcart and fell upon his knees on the road. He sustained a lacerated wound over the tubercle of the tibia and the ligamentum patellae of the left knee. The wound was at once washed out with hyd. perchloride lotion and an antiseptic dressing applied by an officer of the Royal Army Medical Corps.

On the ninth day a little stiffness of the jaw muscles appeared. On the tenth day I saw him for the first time in consultation. There was then definite rigidity of the jaws. Under anaesthesia the wound was freely excised and rubbed with pure carbolic acid, 30 c.cm. of antitoxin administered hypodermically and 20 grains of potassium bromide and chloral hydrate ordered to be given by the rectum every four hours.

[1] BRITISH MEDICAL JOURNAL, October 10th, 1914.
[2] *Canadian Medical Association Journal*, October, 1914.

On the following day the injections of antitoxin (30 c.cm.) were repeated morning and evening.

On the next day, the twelfth after the accident and the fourth since first appearance of symptoms, his condition was in every way much worse. There was episthotonos, firm rigidity of jaws, and a tendency to convulsions. The subcutaneous injections of antitoxin were repeated in large doses, but no tendency to improvement was noted. At 2 p.m. on this day Mr. Swinford Edwards, of London, saw him in consultation with me. On entering the patient's room a very severe general convulsion came on, involving respiratory muscles. He became intensely cyanosed and unconscious. The attack lasted about five minutes. It was obvious that a few more attacks of this kind would be fatal, and the case appeared to be quite hopeless. Mr. Swinford Edwards suggested that as a last resource we should try the effect of intracerebral injection of the serum, and agreed to perform the injection at once. The patient was anaesthetized with chloroform, the head shaved, and the scalp sterilized. A point was selected midway between the right external angular process and the centre of the middle line from bregma to occiput. A small flap half an inch in diameter was turned down and the bone penetrated with a bradawl. Through the aperture the needle of the syringe was inserted for a depth of 2 in. from the skull, so that the point was well in the centrum ovale; 20 c.cm. of serum were injected very slowly, a few drops every half-minute, so that half an hour was taken up by the actual injection. The effect was marvellous; during the rest of the day he had no more convulsions and was much more comfortable.

The improvement lasted during the whole of the following day, but as he then began to go back a little—slight convulsions reappearing—I repeated the dose, injecting the serum through the same puncture with the same precautions.

He complained of severe headache for the next two days, but a steady improvement was maintained until complete convalescence. He was subsequently able to resume his military duties.

Daily subcutaneous injections of antitoxin were continued for a few days after the intracerebral injection and of bromide and chloral by the rectum, but I am quite certain that he owed his recovery to the intracerebral injections, and I am sure Mr. Swinford Edwards would endorse this.

At the same time I think it probable that the large amount of serum given subcutaneously helped the intracerebral injection to produce the extraordinary effect. I think this method should certainly be tried whenever possible, and should be accompanied by intravenous injections of serum.

Ipswich. HERBERT H. BROWN, M.D., F.R.C.S.

BISMUTH SUBGALLATE GAUZE IN THE TREATMENT OF WOUNDS.

MAY I bring to the notice of the profession, many of whom are now engaged in the treatment of our wounded men, the great value of bismuth subgallate gauze in the treatment of suppurating and infected wounds? In an article published in the *Lancet*, June 28th, 1913, I wrote:

> It serves all the purposes for which iodoform gauze used to be advocated. It is definitely inimical to sapraemic infection, and quickly abolishes the fetor of foully septic wounds. I use it for packing suppurating cavities and sinuses, and dressing granulating sores, and certainly find that it checks and shortens suppuration.

Further experience of it has only served to confirm my previous opinion, and I can confidently assert that any surgeon who tries it will not be disappointed. Its bright primrose colour serves to distinguish it at once, an advantage that gauze prepared with the colourless salts of bismuth does not possess. It is further non-volatile and (unlike iodoform gauze, for instance), is therefore sterilizable.

Messrs. Burroughs, Wellcome and Co. have placed it on the market at my suggestion. But it is easily and quickly prepared by immersing and kneading ordinary gauze, previously just moistened with water, in an emulsion of the salt in a mixture of 1 part of glycerine with 2 parts of spirit. By using moistened gauze an even diffusion of the emulsion is rapidly attained. Lengths of one yard or four yards are most convenient for use. The only data required are (1) the weight of the dry gauze, dividing which by 10 gives the amount of the salt required for 10 per cent. gauze, and (2) for economy in materials, the exact quantity of glycerine and spirit which the gauze will take up. This is arrived at by an experimental test with water, the length of gauze being first saturated and then squeezed dry, the amount of fluid being collected and measured. After drying and sterilization it is ready for use.

I may also add that as it appears to me to be ideal in meeting the requirements of a reliable and permanent first field dressing, I have asked Messrs. Burroughs, Wellcome and Co. to prepare such a packet, and anyone who may be interested in it should communicate with them.

E. A. R. NEWMAN.
Calcutta. Lieutenant-Colonel I.M.S.

DERMATITIS VENENATA.

THE apparent infectiousness of the dermatitis venenata due to rungus described by Dr. Hornsey (BRITISH MEDICAL JOURNAL, April 4th, 1914, p. 759), can be explained by the transmission of a minute quantity of the original poison, and I should like to narrate the following experience in support of that view.

In October, 1912, I saw a man with a dry erythema followed by coarse desquamation of the opposing surfaces of the right forefinger and thumb and the corresponding interdigital space. Two days previously he had been weeding in his garden and described the prevalent weed; when shown an illustration of knot-grass (*Polygonum aviculare*) he recognized it. Knowing the acridity of the plant, I told him it was the cause, and prescribed ung. glyc. plumbi subacet. ʒij and suggested that he might prove the correctness of my opinion by next year testing his susceptibility, which might possibly be increased. His susceptibility to the poison was proved before the return of the plant. Five months later he returned with a small cut on the forearm, surrounded by a zone of erythema the size of a five shilling piece. When asked what he had applied to the wound, he said he had used the ointment which he had been given for the "eczema" on his hand, and when told that some of the poison must have been carried from the surface of the ointment he suggested that a rash on his chest and back had been caused in the same way. He had undressed after using the ointment without washing his hands, and it was customary with him to give his chest and back a scratching after taking off his vest. Both the chest and back showed broad lines of erythema where the fingers had been drawn across.

When one thinks of the small quantity of poison that could be carried from the two days' old, frequently washed localized erythema to the ointment and of the further dilution which would occur in the reinoculation from the ointment to the skin, the apparent contagiousness of a dermatitis due to such a powerful poison as described by Dr. Hornsey can be understood.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

DORSET AND WEST HANTS BRANCH.

THE autumn meeting of the Branch was held at the Mont Dore Hotel, Bournemouth, on October 21st, the President, Mr. H. H. DU BOULAY, being in the chair.

Uterine Haemorrhage.—Dr. ELEANOR C. BOND, in opening a discussion on this subject, referred to it first in its physiological aspect and briefly reviewed some of the theories of the production and control of menstruation. Pathological conditions which brought about excessive and irregular uterine haemorrhage were considered under the heads of functional irregularities, fibrositis, and simple and malignant tumours. The PRESIDENT emphasized the importance of early diagnosis in malignant disease of the uterus, and commented on the tendency to put off the evil day of operation too long. Dr. MAHOMED raised the question as to whether the menstrual flow could be correctly called haemorrhage seeing that several important constituents of the blood, such as fibrin and fibrinogen, were absent from it. Having

regard to the natural process of arrest of haemorrhage from the uterus by the contraction of its muscular coat, he also raised the question as to why fibroids caused haemorrhage seeing that they contained so much muscular tissue. Dr. SABERTON, speaking of the value of intensive *x*-ray treatment in the therapeutics of fibroids, cited two cases in which they had been remarkably successful.

CASE I.—A patient, aged 41, with a fibroid reaching to within half an inch of the umbilicus and suffering from excessive menstruation, daily haemorrhage and a discharge. After three months' treatment her doctor reported great diminution in the mass of the uterus with cessation of the haemorrhage and discharge. Treatment was stopped and three months later the patient reported herself as feeling quite well. There had been no recurrence of the haemorrhage and the menses had ceased.

CASE II.—A patient with a large fibroid and severe haemorrhage, which had reduced her to the last stages of anaemia and exhaustion, operation being consequently out of the question. Application of the rays was made twice weekly, and two months later the patient was much stronger and the haemorrhage considerably less. Improvement continued without further treatment, and the patient is now, nine months later, in good health.

Dr. Saberton thought that the beneficial effect of the rays was due to their action on the ovaries and on the embryonic cells of the fibroid. He did not advocate *x*-ray treatment in every case. The drawbacks were the length of time—usually six to seven months—occupied in the treatment and the possible production of peritoneal adhesions causing difficulty later, should operation eventually become necessary. Dr. LYS took exception to Dr. Boud's statement that ergot was of little use in the treatment of uterine haemorrhage. He thought that in nine cases out of ten it would control the haemorrhage, and that it might be taken for years without any ill effect. Mr. SIMMONS cited a case in which, after supravaginal hysterectomy for fibroids, the haemorrhage still continuing, *x* rays caused a cessation of the haemorrhage. He thought that as the exact action of the rays was not fully understood, it was wise to hesitate before recommending them. Was it certain that the action of the rays was limited to the tissues requiring treatment, and that it did not go further, and act deleteriously on healthy tissues? He thought that the latter was the case, and that the adhesions formed complicated subsequent operative interference. Mr. RAMSAY laid stress on the importance, in treating uterine haemorrhage, of never being content until the cause was known. He instanced the case of a girl of 17 with a history of repeated uterine haemorrhages since puberty. Examination under an anaesthetic revealed an ovarian tumour whose existence had not been suspected. He agreed with Mr. Simmons that *x*-ray treatment could only be recommended in the treatment of fibroids if further experience proved its value. At present he doubted its utility; in some cases it produced sterility owing to its action on the ovaries, and also symptoms resulting from insufficiency, or absence, of the ovarian secretion. A drawback to *x*-ray treatment was that the patient still retained the fibroids, and consequently ran the risk of future haemorrhage or symptoms resulting from degeneration. Dr. MIDELTON, speaking of the etiology of endometritis and other pathological conditions of the uterus, expressed the opinion that they might often be due to germs from some previous infection lingering in the system, and instanced scarlet fever as a possible factor. He praised thyroid extract in the treatment of uterine conditions when associated with chilblains and other signs of thyroid insufficiency. Adrenalin was, he said, valuable in the treatment of fibroids when combined with ergot. Dr. BOND, in replying, said she was doubtful as to the advisability of *x* rays in the treatment of fibroids, but would recommend them in cases of haemorrhage that were unsuitable for or refused operation. Ergot, she maintained, was of very little value, while surgery offered a certain cure.

Abdominal Cases.—Mr. NORMAN FLOWER (Yeovil) read notes of two cases of interest.

CASE I. *Chronic Pancreatitis simulating Gall Stones.*—Mrs. R., aged 40, gave a history of recurring attacks of abdominal pain during several years, with jaundice and tenderness over the gall bladder. At the operation no stones were found, but the pancreas was found to be uniformly enlarged and hard. Cholecystenterostomy was done, with a favourable result, fourteen days later the patient being up, with only a trace of jaundice remaining. Before operation the urine yielded a decided indican reaction, and sugar was present to the extent of 3.4 parts per 1,000. Cammidge "C" reaction, which unfortunately was not done before the operation, was afterwards found to be negative. In view of the long history and the general enlargement of the pancreas, a diagnosis of interstitial pancreatitis seemed more probable than that of a neoplasm.

Commenting on the case, Mr. Flower pointed out that a single negative Cammidge reaction did not exclude chronic pancreatitis, as the reaction was only given when active degenerative changes in the gland were actually going on. Cirrhosis due to past inflammation did not therefore cause a reaction, which was only given in about 25 per cent. of cases of cancer of the pancreas. A short reference to the alternative procedures of cholecyst-gastrostomy, cholecyst-jejunostomy, and cholecyst-colostomy was made. The first proceeding did not cause the discomfort that might be expected, and had been carried out several times in patients whose ages varied from 6 to 60 years with satisfactory results. The second operation had as a drawback the tendency to the production of a kink in the jejunum at the level of the stoma. The third was the easiest proceeding, but the risk of infection of the bile passages by the *Bacillus coli* introduced a grave element of danger.

CASE II. *Reflex Gastric Symptoms from an Appendix Lesion.*—Mrs. S., aged 55, with a long-standing history of mucous colitis and chronic constipation, had suffered for five months from loss of appetite, epigastric pain, and abdominal tenderness. Examination revealed a small lump in the epigastrium, not invariably present, and often gradually disappearing under the surgeon's hand. *X*-ray examination showed that the stomach emptied itself with great rapidity, that the pylorus was abnormally relaxed, and that there was no delay in the passage through the colon. Gastric analysis demonstrated only 0.109 per cent. active HCl. On the probability of an early growth of the stomach being present operation was undertaken, but the only lesion found was an appendix containing three concretions. This was removed, and progress had been satisfactory; the epigastric tumour had never since been detected.

Mr. Flower referred to Mr. Sherren's recent article in the *British Journal of Surgery*, and remarked that the case seemed to fall into Mr. Sherren's second group—namely, those in which the symptoms were the result of ileal obstruction rather than of irregular action of the pyloric segment of the stomach. In these the conditions found were a flabby stomach with a widely relaxed pylorus, a large duodenum, and a low gastric acidity. It also possessed to an exceptional degree the irritability which in his first group Mr. Sherren associated with excess of acid, the evidence of this being the epigastric tumour, the result of muscular contraction of the stomach, and in this point lay the interest of the case.

Reports of Societies.

MEDICAL SOCIETY OF LONDON.

Operative Treatment of Tumours of Caecum and Colon.

AT a meeting of this society on October 26th, the President, Sir J. BLAND-SUTTON, being in the chair, a discussion was held on the operative treatment of tumours of the caecum and colon, especially in relation to immediate resection, colostomy combined with secondary resection, and short-circuiting.

Mr. H. J. WARING, who opened the discussion, dealt with malignant disease of the caecum. This, he said, was usually a columnar-celled carcinoma of the exuberant type, and less commonly an annular scirrhous growth tending to produce at a comparatively early stage intestinal obstruction. A small proportion of the neoplasms of the caecum were sarcomata. When compared with carcinomata in other parts of the body carcinoma of the caecum and other portions of the colon were less malignant. This was especially so when the neoplasm was of the adeno-carcinomatous type, and extended into the lumen of the bowel as a cauliflower-like protuberance. With regard to frequency, he had found that among 107 cases of malignant disease of the large intestine (excluding the rectum), 17 were examples of carcinoma of the caecum. He detailed the forms of treatment which he would adopt for different types and stages of the disease.

Mr. JAMES SHERREN divided his remarks into treatment of the tumours of the pelvic colon and those of the descending, including the iliac colon. The pelvic colon

was the most common site in the large intestine for the development of carcinoma, the descending colon the rarest. Thus, among 376 cases of carcinoma of the colon, 211 were of the pelvic colon, 20 of the descending colon; 40 per cent. were operated upon for acute obstruction. In cases with urgent obstruction free drainage of the intestine was indicated, but primary resection should never be carried out. Unless compelled by disaster to the caecum, he considered preliminary caecostomy an unwise procedure. He did not favour operations in which the growth was exteriorized and removed at the original operation, and the closure of limbs left to a later stage. After excision of the growth in dealing with large intestine completely covered by peritoneum, end-to-end anastomosis by suture had proved perfectly satisfactory. It was wise, however, to leave a tube in for a few days. In every case in which the peritoneal covering of the gut was incomplete, lateral anastomosis was to be adopted. When the carcinoma affected the lowest part of the pelvic colon, anastomosis by invagination was the most satisfactory. His practice in the treatment of carcinoma of the pelvic and descending colon might be summed up shortly thus: In all cases of acute obstruction colostomy should be carried out, left iliac if the growth be in the pelvic colon, transverse if in the descending. In resection the lymphatic area draining the affected gut should be removed. Continuity should be established by end-to-end suture if the gut had a complete peritoneal covering, by lateral anastomosis if incomplete, sufficient room being obtained by mobilization.

Mr. E. M. Corner spoke especially of growths of the transverse colon. Clinically they exhibited, he said, these characteristics: absence of symptoms which warned the patient, the unannounced onset of acute intestinal obstruction, and the presence of a small annular growth. The intestinal obstruction should be relieved first. Having done this, the anastomosis might be made near the site of the excised carcinoma where possible, by oblique or circular enterorrhaphy. If too little transverse colon remained to allow of an end-to-end anastomosis being done the best procedure was to close the ends of the bowel, cut off the caput coli with the appendix, and anastomose by implanting the caecum into the upper rectum or sigmoid.

Mr. H. W. Carson continued the discussion. He referred to the importance when excising the gut of removing the most distal glands, for these might contain carcinomatous cells, whilst those nearer the bowel were apparently free from growth. The method of relieving the obstruction which he preferred was excision of the growth with the formation of an artificial anus, if the growth was free from adhesions. If there was difficulty in delivering the growth through the wound, he preferred a colostomy in the neighbourhood of the growth rather than at a distance.

After Mr. G. E. Gask, Mr. Swinford Edwards, Dr. Herbert French, and the President had spoken, Mr. Corner, Mr. Sherren, and Mr. Waring replied.

Reviews.

THE LABYRINTH OF THE EAR.

At a time when the problems of the labyrinth of the ear occupy the centre of interest in the otological world a book on *The Labyrinth*,[1] described as "an aid to the study of inflammations of the internal ear," comes most opportunely. Dr. Alfred Braun, of New York, and Dr. Isidore Friesner, also of New York, in producing their work have kept in mind the importance of having a groundwork upon which to base any further study or investigation of this fascinating subject, and also that such a groundwork must consist of those basic truths regarding labyrinthine disease which have thus far been established beyond doubt. They have divided the book in which they present these truths into six chapters; the first three deal respectively with the anatomy, the physiology, and the methods of examination of the internal ear, and more than half of the volume wisely has been given up to this part of the subject; the remainder describe the pathology, the symptoms of labyrinthitis and its treatment.

Despite the amount that has been written and said within recent years about labyrinthine inflammations, our present knowledge of the subject is still in the developmental stage; and our experience of the operative treatment of labyrinthitis is undoubtedly in the experimental stage. The last chapter of this work, in which the treatment is discussed, sets out some sound general principles, which in view of the remarkable increase in the number of cases of labyrinthectomy and labyrinthotomy brought forward within recent years are not untimely. The opening sentence of this chapter reminds us that "a large number of cases of labyrinthine disease recover without treatment." Whilst fully recognizing that labyrinthitis is an extremely serious condition, the following paragraph may none the less be cited:

> It is of the utmost importance to positively establish our diagnosis before operating on a case of labyrinthine disease. For to place a normal labyrinth into open communication with an infected middle-ear cavity invites certain infection of the labyrinthine contents. In a diseased labyrinth, on the other hand, inflammatory adhesions have, in most cases, shut off the infected labyrinth cavity from the intracranial lymph spaces before operation.

Those who wish to study the complex problems of the labyrinth in the light of recent research will find this book a useful compendium, and to those who wish to pursue the matter further the bibliography appended to the book will be very helpful. In the bibliography the authors wisely have made no attempt to mention every work written on the subject, but have referred only to the publications used in the preparation of their book. In the same way, on those topics regarding which there is still considerable difference of opinion, they have made no attempt to state all the opinions, since this would only tend to confuse the reader. Attention has been confined to the hypotheses which seemed to be most plausible.

The work is illustrated with fifty figures in the text and thirty-four half tones on thirty-two plates. The illustrations for the most part are original and made by one of the authors. The typography throughout is good and appears to be remarkably free from errors.

VOLCANIC ACTION AND DISEASE.

Dr. Johnston-Lavis shortly before his death published in book form the essay on the *Effects of Volcanic Action in the Production of Diseases*,[2] which was awarded the triennial Parkin prize of the Royal College of Physicians of Edinburgh. The work epitomizes the present state of knowledge, to which Dr. Johnston-Lavis himself made several contributions. In the first two chapters the main physical and chemical facts are discussed, while in the third and following chapter the effects upon man and other animals are considered. Where death is the result of being overwhelmed by lava streams it is in almost all cases, Dr. Johnston-Lavis thinks, due to stupidity or carelessness; but when, as in the Soufrière eruption, there is a discharge of highly heated solid stones and dust by a blast of hot gases the case is different. In the Soufrière eruption the hot blast travelled at the rate of thirty miles an hour, and killed all it reached. The author mentions the famous case of the elder Pliny, and rightly questions whether the true cause of death may not have been apoplexy or heart failure accelerated by heat, dust, and excitement. The actual words of the younger Pliny—who says of his uncle's end, "Ut ego colligo: crassioro caligine spiritu obstructo clausoque stomacho, qui illi natura invalidus et angustus et frequenter aestuans erat"—support this opinion.

Several writers are quoted as to the supposed causal relation between outbreaks of epidemic disease and the occurrence of volcanic eruptions, the most interesting citation being a description of epidemic pneumonia in the neighbourhood of Vesuvius following the eruption of 1754, contained in a letter of Dr. Jean Vivinzio addressed to Padre de la Torre. It is justly pointed out by the author that the connexion in many cases may have been accidental, and that in none can the influence have been other than indirect.

[1] *The Labyrinth: An Aid to the Study of Inflammations of the Internal Ear.* By A. Braun, M.D., and I. Friesner, M.D. London: Rebman, Limited. 1913. (Sup. roy. 8vo, pp. 250; 50 figures, 32 plates. 17s. 6d. net.)

[2] *On the Effects of Volcanic Action in the Production of Epidemic Diseases in the Animal and in the Vegetable Creation, and in the Production of Hurricanes and Abnormal Atmospherical Vicissitudes.* By H. J. Johnston-Lavis, M.D., D.Ch., M.R.C.S.Eng., L.S.A.Lond., F.G.S. London: John Bale, Sons, and Danielsson, Ltd. 1914. (Cr. 8vo, pp. 67. 3s. net.)

With respect to the influence of volcanoes upon plant life, the author remarks that although direct injury to vegetation by the fall of dust and lapilli may be done, the complete destruction of worms, snails, insects, and parasitic fungi must be set against such losses.

The supposed significance of volcanic eruptions from the epidemiological point of view was part and parcel of a system of thought which attributed so many harmful effects to a corruption of the air, and with the passing of that system the subject has lost some of its importance. But the actual phenomena are so striking, and the calamities due directly and indirectly to volcanic eruptions so overwhelming that the subject must always be of interest, and Dr. Johnston-Lavis's book deserves to find a wide circle of readers.

NOTES ON BOOKS.

THE little work on *Tropical Hygiene for Anglo-Indians and Indians*[3] by Sir PARDEY LUKIS and Major BLACKHAM has quickly reached a second edition, and deservedly so. The work has been carefully revised and in many instances largely rewritten. Times change so quickly now that this is necessary. The book contains twelve chapters, as follows: (1) The communicable diseases of the tropics. (2) Malaria, yellow fever, kala-azar and sand-fly fever. (3) Air and ventilation in hot countries. (4) Water and water supplies in the tropics. (5) Food in the tropics. (6) Clothing in the tropics. (7) Houses and their surroundings in the tropics. (8) The disposal of refuse in the tropics. (9) Insects and disease in the tropics. (10) Disinfectants and disinfection in the tropics. (11) The disposal of the dead in hot countries. (12) The climate of the tropics. A glance at the above shows that everything of importance for the civilian in India is included, and a careful study of the pages of the work should do much to prevent many of the maladies so common there. Clearly written and clearly printed, the contents should be easily assimilated. The book can be heartily recommended.

ROYAL MEDICAL BENEVOLENT FUND.

AT the last meeting of the committee thirty-seven cases were considered and grants amounting to £303 voted to thirty-two of the applicants. The following is a summary of the cases relieved:

Daughter, aged 42, of M.R.C.S.Eng. who practised at Shrewsbury. Training for rescue work. Mother died recently and the little income she had was only for life. Applicant required a little help until able to commence work. Voted £5.

Widow, aged 42, of L.R.C.P. and S.Irel. who practised in Ireland and Australia. Usually earns her own living as a teacher of languages, was in Berlin at a post when the war broke out and had to return to England without her belongings or money. She proposed to go to Madrid, where she could obtain work. Previous grant £10. Voted £5 as gift and £7 as a loan.

Widow, aged 66, of M.R.C.S.Eng. who practised at Notting Hill. Has five daughters, one a trained nurse who has had to give up her post to nurse her mother, who is suffering from malignant disease in the breast. Try to make a little by letting room. Relieved fourteen times, £176. Voted £5.

M.R.C.S., aged 81, who practised at West Kensington. Has the old age pension and a pension from another charity. Is blind. Has four children, the eldest of whom is practically blind and the others unable to help. Relieved twice, £14. Case referred for further inquiry and the sum of £5 placed at the disposal of the visitor.

Widow, aged 63, of M.B.Glasg. who practised at Carnarvon. Unable to work and only income £16 from investments and 5s. per week temporarily from brother. Three children married and unable to help. Relieved twice, £12. Voted £12 in twelve instalments.

Widow, aged 46, of L.S.A.Eng. who practised at Leyton. Left with five daughters, ages 9 to 16 years. Very delicate and only able to do very light work. Hopes to take in paying guests and wishes to remove to a more suitable house. Voted £10 towards removal expenses.

Widow, aged 39, of L.R.C.S. and P.Ire. who practised in Monmouthshire and New South Wales. Acts as working housekeeper at about £15 per year, and her youngest child is allowed to live with her. Eldest child, aged 12 years, adopted by grandparents. Wants assistance towards the education of daughter, aged 11 years. £10 voted through the Guild who were also going to assist.

Widow, aged 67, of M.B., B.S.Lond. who practised at Islington. Only very limited means. Eldest son used to help, but owing to the falling off of his business unable to continue. Endeavouring to obtain an Epsom College pension. Voted £12 in twelve instalments.

Daughter, aged 48, of M.D.Glasg. who practised at Glasgow. Endeavours to make a living by letting rooms at a seaside resort, but owing to short season in consequence of the war is unable to meet her expenses. Voted £10.

Daughter, aged 35, of M.R.C.S. who practised at Streatham. Very delicate, and only a few pounds per annum from an investment. Supplements this by painting, but no market for pictures at present. Voted £5.

Widow, aged 58, of L.R.C.P.Dubl. who practised in London. Endeavours to make a living by taking boarders and nursing mental cases, but in consequence of recent illness has not been able to attend to this thoroughly. Voted £10.

Daughter, aged 56, of M.R.C.S.Eng. who through ill health was unable to practise. She is suffering from carcinoma of the breast and too ill to work. Only income £16 10s. per annum. Voted £12 in twelve instalments.

Widow, aged 60, of M.D.Glasg. who practised at Burnham and was an annuitant of the Fund. She is a confirmed invalid and unable to help herself. Only small income provided by friends. Voted £12 in twelve instalments.

Widow, aged 35, of M.R.C.S.Eng. who practised at Bexhill-on-Sea. One child 4 months old. Left totally unprovided for. Voted £3 and the case referred for report.

Widow, aged 35, of M.R.C.S.Eng. who practised at Monmouth and was killed at the front. Widow left with two children, 3½ and 1 year. Voted £25.

Widow, aged 58, of M.R.C.S.I. who practised at Newnham-on-Severn and died two years ago, leaving widow and family penniless. Two daughters, one of whom is a nurse at the front, and one son at the front. Only income 15s. per week allowed by children. Relieved once, £10. Voted £10 in two instalments.

Widow, aged 42, of M.B.Edin. who practised at Sheffield. Health very bad and unable to obtain suitable employment. One son being educated by grandparents. Promise of light work when a little stronger. Relieved once, £10. Voted £10.

Widow, aged 49, of M.R.C.S. who practised at Bexhill. Tries to earn a living by taking boarders, but it requires six to make it pay and only has three at present. Two daughters ages 19 and 10½, eldest a clerk, who is only able to contribute £12 per annum. Relieved twice, £20. Voted £10.

Daughter, aged 60, of M.R.C.S.Eng. who practised at Hackney. Applicant is blind. Only income an annuity from another society and £12 from friends. Relieved four times, £34. Voted £12 in twelve instalments.

Daughter, aged 61, of M.D.Lond. who practised in London. Is quite blind. Only income a pension of £20 from the Blind Society. Relieved twice, £18. Voted £12 in twelve instalments.

Widow, aged 65, of L.R.C.P.Edin. who practised at Port Carlisle. Suffers from cardiac asthma, and recently operated on for carcinoma of the breast. Left without any means, and of the five children only youngest daughter able to help with 10s., for which she has her board. Relieved once, £12. Voted £12 in twelve instalments and referred to the Guild.

Widow, aged 59, of M.D.Dubl. who practised at Acton. Endeavours to earn living by taking boarders, but has not been successful lately. Son who usually pays rent for her unable to continue owing to war. Relieved once, £10. Voted £5.

Widow, aged 55, of M.R.C.S. who practised at Kensington. Successfully earned a living of late by taking boarders, but the four she recently had have all joined the army, so she is now without. Relieved once, £10. Voted £10 in two instalments and referred to the Guild.

Widow, aged 63, of M.R.C.S.Eng. who practised at Newtown, N. Wales. Very poor health and heart trouble. Eldest son abroad has in the past paid her rent, but is now unable to do so on account of ill health. Six children, the youngest unable to work on account of ill health, and the others unable to help. Relieved six times, £55. Voted £13.

Daughter, aged 52, of L.R.C.P.Lond. who practised at Birmingham. Endeavours to make a living by letting rooms, but, owing to short season, has not made much this year. Eyesight very bad. Relieved three times, £32. Voted £12 in twelve instalments.

Daughter, aged 55 years, of M.R.C.S.Eng. who practised in London. Suffers from chronic glaucoma and general bad health. Only income £24 per year. Relieved six times, £55. Voted £12 in twelve instalments.

Widow, aged 52, of L.R.C.S.Edin. who practised on the West Coast of Africa. Endeavours to earn a living by letting rooms and nursing. One invalid daughter at home and two sons abroad unable to assist. Relieved three times, £35. Voted £12 in twelve instalments.

Daughter, aged 63, of M.R.C.S.Eng. who practised at Keynsham. All money lost by the foreclosure of mortgagees. Tries to earn a little by painting, but has found it difficult recently in obtaining clients. Relieved once, £12. Voted £18 in twelve instalments.

Widow, aged 55, of M.R.C.S.Eng. who practised at Donhead and who had been a recipient of help from the Fund. Unable to work; has one daughter unable to assist. Since husband's death a sister has assisted her, but cannot now continue. Voted £2, and referred to the Guild for report.

Contributions may be sent to the Honorary Treasurer, Dr. Samuel West, 11, Chandos Street, Cavendish Square, London, W.

THE INDIAN MEDICAL SERVICE.

THE NEWLY PUBLISHED DISPATCHES.

Five years ago, in 1909, the Indian Government published the correspondence which had taken place between it and Lord Morley, then Secretary of State for India, on the constitution and recruitment of the Indian Medical Service. The most important papers were a dispatch from the Government of India, dated August 20th, 1908, and the reply, dated December 11th, 1908, from the Secretary of State, in which Lord Morley strongly urged upon the Indian Government the promotion of the growth of an independent medical profession in India by throwing open to private practitioners a number of the civil appointments then (and now) held by members of the Indian Medical Service, and raised strong objections to any increase in the numerical strength of that service. This correspondence created considerable interest at the time, and gave rise to a good deal of discussion in the British Medical Journal, the *Lancet*, and the *Indian Medical Gazette*.

The Government of India consulted all the provincial governments on the subject. It was generally understood that these governments had unanimously objected to the proposals, and, after Lord Morley's connexion with India ceased, the matter appeared to have been tacitly dropped. Further correspondence on these proposals, between the Home and Indian Governments, has taken place during the last four years, and this correspondence has now been published in the *Gazette of India* for August 1st, 1914, where it fills twenty-one folio pages.

Lord Morley's Dispatches.

Lord Morley's first dispatch called attention to previous communications, in 1899-1900, from Lord George Hamilton, then Secretary of State for India, in which he remarked upon the increase in numbers of the Indian Medical Service between 1884 and 1899. We have not the exact figures of the strength of the service in these two years, but undoubtedly a considerable increase in number did then take place. What appears to have been altogether overlooked, however, is the reason for that increase. In January, 1882, the strength of the whole service, for all three Presidencies — Bengal, Madras, and Bombay—was 688. In 1882 a large number of regiments of the Indian army were disbanded. Recruiting for the service was cut down to the lowest possible limit; for some years only five admissions were made at each half-yearly examination, and by January, 1886, the numbers had sunk to 603, the lowest touched for almost a century past. During the next ten years new regiments were raised in the place of those disbanded in 1882, and by the end of the century the strength of the Indian Medical Service had considerably increased. In January, 1914, the numbers were 770. But even this number, large as it may seem, is considerably less than the strength sanctioned half a century earlier. After the suppression of the Mutiny the amalgamation of the Indian Medical Service with the medical department of the British army was for long under consideration, and for four and a half years no new admissions to the Indian Medical Service took place. When the proposed amalgamation was finally negatived the future constitution of the Indian Medical Service was discussed in a military letter from the Secretary of State, dated November 7th, 1864, and in the seventeenth and eighteenth paragraphs of that letter the number of 861 was sanctioned as the strength of the Indian Medical Service. That number was never actually attained; but in July, 1861, the actual strength of the service was 819. Over fifty years have passed since 1861. Upper Burma and British Baluchistan have been annexed, and the number of appointments under the Foreign department on the Indian frontier and in Persia has been considerably increased, while one new branch of the medical service—the bacteriological department—is entirely a creation of the last fifteen years. Yet the strength of the Indian Medical Service has diminished from 819 to 770, and is now some 6 per cent. less than it was fifty-three years ago.

Dispatch from the Government of India, 1910.

The most important item in the correspondence now published is a dispatch from the Government of India (Home Department, Sany.-Medl., No. 21, of November 17th, 1910) and recently presented to Parliament as a White Paper (Cd. 7547). It is of great length, and the briefest summary must occupy a considerable space. The first two parargaphs refer to Lord George Hamilton's dispatches of fifteen years ago, and the increase in the numbers of the Indian Medical Service which had then recently taken place. In the third it is stated that the primary question then raised was the advisability of substituting unofficial for official medical men; that the Secretary of State advocated the encouragement of European medical men to settle in India: and that the replacement of European civil surgeons by Indian practitioners was only a secondary consideration. The fourth paragraph is one of the most important in the whole paper. The Government of India states that when its dispatch of August 20th, 1908, was written it had not yet consulted local governments; that it had gravely underestimated the objections to the transfer of appointments from the Indian Medical Service to other hands; and that it now felt bound to recede from the position then taken up.

> "In 1908 we pointed out that about one-third of the civil appointments now held by the Indian Medical Service do not form any part of the war reserve, and that consequently there would be no objection, from a military point of view, to their transfer to medical men not belonging to that service. Starting from that premise, we concluded that, subject to certain specified conditions, a considerable number of the appointments not included in the war reserve might gradually be transferred to medical men not belonging to the Indian Medical Service. We had not at that time had the advantage of the opinions of local governments, and we regret to find that we gravely underestimated the objections, on other grounds than those connected with the requirements of the Indian army in time of war, to the transfer of appointments which we contemplated. We have now given the whole question our most careful consideration in the light of the opinions of local governments. We recognize most fully the importance of encouraging the growth of a private medical profession and the impossibility of the Indian Medical Service being expanded so as to meet all the medical needs of India. But we feel bound to recede from the position which we previously took up, because, on further consideration of the question, we are convinced that the mere transfer of a certain number of Government appointments from the Indian Medical Service to private practitioners would do practically nothing to encourage the growth of an independent profession; that most of the civil appointments now held by the Indian Medical Service could not suitably be given to men not in regular Government service, with whom their private practice would be the first consideration, and that the retention of a considerable number of superior medical appointments for the Indian Medical Service is essential, not only in the interests of administrative efficiency, but also for the purpose of making the service itself attractive to able medical men. In short, while we adhere to the views previously expressed—that it is impracticable to provide from the Indian Medical Service for the growing needs, beyond the ordinary administrative duties, of the country in respect of medical relief—we hold strongly that the appointments now held by officers of the Indian Medical Service are required strictly for ordinary administrative duties, which cannot suitably be performed by men otherwise recruited."

Paragraph 5 states that outside large towns there is no demand for medical men qualified on the European system.

Paragraph 6 is also of much importance; it gives the means which the Government of India thinks most suitable for adoption in order to assist the development of an independent medical profession. These are:

(*a*) Provision of more medical schools.

(*b*) Throwing open posts of house-physician and house-surgeon in large general hospitals to men not in Government service.

(*c*) Encouragement, under due supervision, of private medical schools.
(*d*) Demonstration of advantages of Western medical science.
(*e*) Association of private practitioners with the staff of Government hospitals as honorary physicians and surgeons.
(*f*) Checking the abuse of hospitals by patients able to pay.

It is interesting to see that this last complaint, so commonly made in England, is also put forward in India. Every civil surgeon knows that such abuse of hospitals by well-to-do patients is more common in India than in England, though doubtless with more excuse.

Paragraph 7 speaks of the necessity for registration of duly qualified practitioners, and for the publication of a medical register; while paragraph 8 states that medical certificates from registered medical men may in future be accepted without countersignature.

Paragraph 10 quotes some opinions of local governments on the whole subject; and paragraph 11 asserts the agreement of the supreme Government with these opinions.

Paragraph 12 emphasizes the importance of not doing anything to lower the attractiveness of the Indian Medical Service, and paragraph 13 notes the falling off in the number and quality of the candidates for that service. It is acknowledged that Lord Morley's dispatches of 1907–8 have given rise to widespread uneasiness, and this point is emphasized by quotations from the three medical journals above mentioned.

The next three paragraphs speak of the difficulties of the policy proposed by Lord Morley, of the lack of qualified Indians, and of the impracticability of recruiting European medical men in India, and state that the promotion of civil assistant surgeons is the only practicable method of carrying out this policy.

Paragraph 17 insists on the necessity of providing European medical attendance for the European servants of Government.

Paragraphs 18 and 19 recount the civil appointments held by members of the Indian Medical Service, including special appointments, and paragraph 20 recalls that the late Decentralization Commission, which sat and took evidence some five years ago, reported that the establishment of a separate civil medical service was inadvisable. Paragraph 21 states that the civil appointments held by the Indian Medical Service cannot be reduced in number.

The Conclusions of the Government of India.

Paragraph 22 recapitulates the whole subject, and is of such importance that we quote its summary in full.

"We sum up our conclusions as follows:

"1. An independent medical profession trained on Western lines is steadily growing up in India, but it has yet to overcome its universal rival in the form of the *kaviraj*, *hakim*, *vaid*, *ojha*, and the like, who are trained according to indigenous methods, and whom the mass of the population still trust.

"2. Government can do much to encourage an independent medical profession in the various ways enumerated in this dispatch.

"3. The giving up of a few appointments to private medical practitioners will have no appreciable effect on the development of an independent medical profession, and might, on the contrary, tend to hinder a healthy development.

"4. The present policy of reduction, which was inaugurated without previous reference to the local governments, has already given rise to considerable uneasiness in professional circles, and, if carried further, is likely to cause a decided deterioration in the Indian Medical Service.

"5. The bulk of the civil surgeoncies must be manned by officers of the Indian Medical Service, exceptions being made in favour of civil assistant surgeons.

"6. The Government medical colleges and schools must, in the main, be manned by officers of the Indian Medical Service, but a few professorial posts can be made available to locally recruited men.

"7. European medical men cannot be expected to establish themselves in this country, except in cities and large towns and in special areas where there is a large European population, and it is, generally speaking, undesirable to recruit from among them.

"8. When European medical men are required, they should usually be recruited in the Indian Medical Service. Indians and Europeans recruited locally in special cases should be employed on special terms."

Paragraphs 23 and 24 complain of the difficulty of carrying out Lord Morley's order that no increase in the civil cadre of the Indian Medical Service should be permitted, and recommend the withdrawal of that order. Paragraph 25 states the impossibility of recruiting men locally to fill bacteriological appointments. Paragraphs 26 to 28 again summarize the previous arguments, and refer to the extravagance of the claims put forward by some Indian medical men in memorials submitted last year to the Public Service Commission.

DISPATCH OF SECRETARY OF STATE, 1912.

The dispatch summarized above was answered by one from the present Secretary of State for India, Lord Crewe, dated November 22nd, 1912, which agrees that the constitution of the Indian Medical Service must remain unchanged, and withdraws the order that no increase in the number of civil appointments may be made; it also suggests that military assistant surgeons should no longer be promoted to civil surgeoncies.

DISPATCH OF THE GOVERNMENT OF INDIA, 1914.

In a short dispatch (Home Department, No. 2 Medl. of March 5th, 1914) the Indian Government repeats the advantages, to India and to the army, of the appointment of a certain number of selected military assistant surgeons as civil surgeons; and in the third and concluding paragraph states, in the following words, that some increase in the strength of the Indian Medical Service is inevitable.

> "3. There are several proposals pending before us for an increase of the civil cadre of the Indian Medical Service, which we shall hereafter submit separately for Your Lordship's orders. In all these cases we hope that we will be able to show that, looking to the work to be done, the services of Indian Medical Service officers are indispensable. In view of the growing medical needs of the country which necessitate the employment of a larger staff of medical officers, some expansion of the Indian Medical Service is inevitable, and such expansion should not, in our opinion, be regarded from a different standpoint from the enlargement of any other cadre in response to the development of the work to be performed."

LETTER OF GOVERNMENT OF INDIA TO PROVINCIAL GOVERNMENTS.

The last paper is a letter, dated May 23rd, 1913, from the Government of India to the provincial governments on the subject of medical registration and the suppression of bogus degrees and diplomas.

MOTOR AMBULANCE DEVELOPMENTS.

BY H. MASSAC BUIST.

THE NEED FOR STANDARDIZATION.

A STUDY of the miscellaneous efforts that are being made with the common and wholly laudable aim of further relieving suffering by the provision of adequate supplies of motor ambulances for our forces at the front, suggests the urgency for cohesion and centralization. Too many appeals are being made. To judge from not a few examples of what has materialized, it must regretfully be concluded that in a vast number of cases ambulances of a kind, certainly not the most suitable, have been produced. Far from the trouble of overhang—to which attention was drawn in these columns many weeks ago—being overcome, later examples seem to point to the fact that in many cases stocks of short wheelbase chassis have been "worked off" and fitted with ambulance bodies, two-

thirds of which project beyond the back axle. Were all the efforts centralized and supervised by one authority, there would be no opportunity for any mistakes of this sort to occur—far less to be repeated—because anybody who was trying to "work off" chassis of unsuitable length would be checkmated before his plans had materialized.

In the meanwhile the British Red Cross Society, which is dealing with this matter in a really businesslike fashion, has not been content with mere theorizing as to what is or is not a suitable type of motor ambulance. It has made very careful study of how the first machines sent out answer under the actual conditions of field service in France and Belgium. As the result of this study, which has produced much knowledge concerning the possibilities of the motor ambulance, the Society has modified the specification of its requirements, with results that are portrayed in practical form in *Cooper's Vehicle Journal*. That organ has been requested by the Society and by the Engineering Department of the Royal Automobile Club that examines its chassis and complete ambulances before they are sent abroad, to print drawings of the types of body now approved. These embody the Red Cross Society's modified standard specifications, the drawings being supplied, together with all particulars, by the journal in question at 104, Long Acre, London, to motorists who offer their cars for ambulance work. Before giving orders to local coachmakers, therefore, particular care should be taken that these specifications are faithfully adhered to, because all the modifications embodied in them are the result of experience on active service in France. The designs, moreover, are suitable to various forms of chassis and sizes of motor ambulances, some being for two, others for four stretcher bodies.

Supported in Place of Suspended Stretchers.

The chief point of departure in the modified design is that the stretchers are supported and are no longer suspended. Methods of spring support or suspension have been discarded. The lower stretchers rest on the floorboard of the vehicle, and the upper on ledges, shelf fashion. The central pillars supporting the two inner ledges are carried quite down to the floor of the well of the car.

Experience at the front has confirmed what was written in these columns in anticipation at the outbreak of war concerning the disadvantages of overhang. This has been found to cause very appreciable trouble in early vehicles. Hence it is the more to be regretted that later ones sent by some organizations to the front have this fault in very pronounced degree.

In the new designs the Royal Automobile Club's engineers have stipulated that four-stretcher bodies may be fitted only to chassis affording a minimum length of 6 ft. 3 in. from the steering wheel to the centre of the back axle. Thus, in the modified design now approved by the British Red Cross Society, the overhang, that is to say the projection of the ambulance behind the back axle, in no case exceeds 2 ft. 9 in. Even that is too much for the ideal. Unfortunately, we have in large measure to improvise our motor ambulance service for this war; therefore we have to make the best use possible of the chassis available.

Ambulance Bodies Last Only Two Months.

The necessity for good suspension and reduction of vibration will, perhaps, be better realized in this country when it is stated that the work which the ambulances have to do at the front is so rough that it is not expected that the wearing life of the coachwork will be much longer than a couple of months. This does not mean that each motor ambulance is utterly done with in that period. On the contrary, after slight readjustment, the chassis are good for very much more service. But the coachwork springs and warps, therefore new motor ambulance bodies are needed very frequently. Medical men can do good work by bringing some of these facts to the notice of those they encounter who are interesting themselves in this splendid effort to save valuable lives and reduce suffering to a minimum. Each chassis sent to the front should be capable of being fitted with a succession of new bodies as each is rendered unsuitable by the racket of active service conditions.

Types of Chassis Needed.

It should also be widely understood that there are nothing like a sufficient number of motor ambulances for the immediate needs of the campaign. The information as to the rapidity with which these vehicles wear out will make it abundantly plain that redoubled efforts must be made to increase the number of motor ambulances. In some districts omnibus chassis have to be employed for carrying the worst cases. Considering the rough nature of the country often to be traversed, it will be appreciated that vehicles so hardly sprung are scarcely ideal for the purpose.

In the beginning certain well-meaning folk seemed to have the idea that any old chassis they could spare was good enough; whereas the truth is that it is no use sending out a chassis other than one in thoroughly sound condition, of modern design and thoroughly standardized type, so that there may be no difficulty about spare parts for any minor feature of it that may develop a defect.

As far as chassis are concerned, the ideal method would be to employ as small a variety of types as possible, each convoy being made up of a common type of chassis so that the travelling workshop that ought to be provided with every convoy would only have to carry sets of parts for one sort of chassis. In this respect the problem is exactly the same that obtains in regard to other portions of the mechanical transport services, including those of the ammunition and commissariat columns and the motor equipment of the Royal Flying Corps. Undoubtedly, in future warfare, we shall have a standardized type of chassis for ambulance work only. That type will be reproduced in every example employed by a given army in a campaign. This will enormously simplify the problem of stores and spares. The campaign has already illustrated in quite other branches of motoring than ambulances that by far the greatest wastage of motor vehicles is sustained merely through multiplicity of types. Often chassis are to be found abandoned on the roads in the most extraordinary numbers for need of some little part that has failed, which weighs only a few pounds, which often costs only a few shillings, but a spare example of which does not happen to be available, therefore a vehicle costing anything up to £750 is perforce cast on one side. These are among the valuable lessons of the war we are learning by which to profit not only as the campaign progresses, but also, and in more absolute fashion, in our equipment for future campaigns. Of course, should the campaign be much prolonged, such a misfortune might itself provide the margin of time in which to produce a complete equipment of motor ambulances designed throughout in the light of actual experience in the field. In the meantime the manner in which the war is spreading is such as to leave no leisure for designing and building motor ambulance chassis as chassis; therefore the most intelligent compromises possible must be made by putting the most suitable sorts of ambulance bodies on the likeliest varieties of touring-car chassis.

During the three weeks ending November 5th ten cases of plague and nine deaths from the disease occurred at Mauritius.

The past and present members of the scientific staff of the Rockefeller Institute for Medical Research, New York, gave a dinner to Dr. Simon Flexner on October 16th in celebration of the tenth anniversary of the opening of the laboratories under his direction. Dr. S. J. Meltzer presided, and a short address engrossed on parchment and signed by the members of the staff, was presented to Dr. Flexner. Among the speakers were Dr. W. H. Welch, Dr. Hideyo Noguchi, Dr. Jacques Loeb, and Dr. Flexner.

A free public issue is now being made by the British Fire Prevention Committee of the necessary "Fire Warnings" for emergency hospitals, convalescent homes and refugee hostels. They are small red posters measuring 8 in. by 20 in., embodying useful reminders and hints as to matches, smoking, illuminants, open fires, stoves, the use of spirit, celluloid, etc. Copies are supplied upon written application to the Registrar of the Committee, 8, Waterloo Place, Pall Mall, S.W., stating the number of beds or number of refugees which the applicant has to deal with. Summarized translations in the Flemish and French languages, on posters of a somewhat smaller size, will also be provided on request.

British Medical Journal.

SATURDAY, NOVEMBER 14TH, 1914.

THE INDIAN MEDICAL SERVICE.

The correspondence which has passed between the Government of India and the Secretary of State for India at home during the last four years has at length been published in the *Indian Gazette*, and has been presented to Parliament in a White Paper. From the summary which we give in another column it will be seen that the policy embodied in the letter which Lord Morley, when Secretary of State for India, addressed to the Government of India in 1908 has been definitively abandoned. The conclusions at which the Government of India has arrived in paragraph 22 of its dispatch of November 17th, 1910, are set out in full elsewhere. They were accepted by the Secretary of State on November 22nd, 1912, and are those to which an unbiassed and dispassionate survey of the whole subject necessarily lead; they will, we believe, be acceptable to the Indian Medical Service and to the medical profession as a whole. They appear to grant all that has been urged for the I.M.S. as regards its services to India and its claims upon the Indian Government.

The pity of it is that these papers were not published long ago. A year after the publication of the correspondence of 1908 the Indian Government had discovered that a mistake had been made, and two years later the Secretary of State endorsed its conclusions. The new papers are dated four and two years ago respectively. Yet, as far as was known to the public and to the medical profession, until the very recent publication of this later correspondence the suggestions of 1908 still held the field. Four years have passed since the admission was made that the former suggestions had "given rise to widespread uneasiness," and had caused a serious difficulty in recruiting for the I.M.S. During these four years this difficulty in recruiting has gone from bad to worse, as shown by the results of recent examinations. Truly "the evil that men do lives after them."

It is not likely that the publication of this correspondence can make much difference at present in the way of stimulating recruiting for the I.M.S., and we understand that it is not proposed to hold the examination which in the ordinary course would have taken place in January. While England is engaged in a life and death struggle on the Continent, the demand for young, newly qualified men for service with the armies at the seat of war is very great. This demand is one which appeals with greatest force to the class of men who might otherwise enter the I.M.S., the class who are specially needed in and suited to that service. While the war lasts no great improvement in recruiting for the I.M.S. can be expected; but when it is over a large number of the young men who have received temporary commissions in the R.A.M.C. will return to civil life, as that corps, with its present establishment or with any probable increase therein, will not be able to find room permanently for more than a fraction of the recent accessions to its strength. Sixty years ago, in the Crimean war, the Army Medical Department recruited temporarily large numbers of young doctors, the majority of whom left the army on the conclusion of the war. Many of them entered the I.M.S. during the next few years. History sometimes repeats itself, and when peace is re-established in Europe the I.M.S. will again, we hope, under the assurances now given and with the liberal terms which the service offers, find no difficulty in filling its ranks with men well up to the standard of their predecessors.

SAFEGUARDING THE HEALTH OF TROOPS AT HOME.

The Local Government Board in Scotland has issued a circular letter to clerks of counties, district committees, and towns, and to medical officers of health, calling attention to the duties which it falls to the last-named officers to perform in order to fulfil the requirements expressed in the circular issued by order of the Army Council on October 10th to general officers commanding in chief. The Army Council's letter was printed in the Journal of October 24th, page 730, and the circular letter of the Local Government Board in Scotland is a very practical exposition of the assistance which medical officers of health can give in many directions to the military authorities.

The circular letter now issued by the Board is in extension of a previous letter circulated on September 10th. The new letter, which is dated November 10th, states that the duties of a medical officer of health of a district or burgh in which troops are quartered should include in the first place inquiring for, and bringing to the notice of the local authority, any conditions in which sanitary services can be rendered by them to the military population—for example, by extending water mains, opening or extending sewers, providing latrines or baths, providing hospital accommodation for cases of infectious disease, disinfecting clothing and blankets, destruction of refuse, and making special arrangements for scavenging. Reports on these matters, it is stated, should be dealt with as urgent, and special meetings of the local authority should be called to consider them if necessary. Medical officers of health should also inspect billets systematically, as well as camps or other places solely in military occupation, as regards the water supply, methods of disposal or removal of all solid and liquid refuse, general cleanliness, and for the prevention of exposure to infection. They should take action by making recommendations to the military authorities, or by reports to the local authority, or otherwise, with a view to the removal of any dangerous or objectionable conditions, and should give information to the medical officer with the troops as to the local cases of infectious disease as soon as they come to knowledge, and as to any localities, premises, bathing places, etc., which on health grounds should not be frequented by the soldiers. In some districts troops will need to be cautioned against the consumption of sewage-polluted shellfish. It is also the duty of medical officers of health to ascertain what hospital provision is available for cases of infectious disease among troops in the district, and to assist in making arrangements for such provision, existing civil resources being made available to the greatest practicable extent for infectious cases among troops, care being taken not to diminish the accommodation for the civil population unduly. The circular points out that the assistance desired by the War Office in respect of the establishment of billets is of great importance, and that when a medical officer of health

of any local authority learns, by an official intimation or otherwise, that billeting is likely in his district, he should at once communicate with the chief constable or superintendent of police, and obtain from him any further information of impending billeting which he may possess.

A medical officer of health is instructed, should he find it necessary to make formal written recommendations, to address them to the Deputy Director of Medical Services, Scottish Command, Edinburgh, but it is indicated that such written communications should usually be restricted to matters of importance in which the medical officer of health, after local inquiry and conference, finds it necessary to put his advice on record. He is further requested to furnish copies of all such formal written recommendations to the Local Government Board.

With regard to expenses, the Board says that it does not consider it necessary or even desirable that all items of expenditure directly or indirectly resulting from sanitary services rendered to troops should be separately computed and made the subject of charges to military authorities. It recognizes, however, that cases must arise in which charges have to be made and that delay may occur in settling the nature and amount of the charge; but necessary sanitary work should not be postponed on this account, and the Board is prepared to advise local authorities in cases of difficulty which may arise under this head.

POSITION OF BELGIAN MEDICAL MEN AND PHARMACISTS.

A MEETING of the Committee appointed on November 4th, as reported in the JOURNAL of last week, to consider the position of Belgian medical men and pharmacists whose professional positions have been involved in the ruin that has fallen upon their country and has destroyed the whole machinery of the medical profession and its adjuncts, was held at the office of the British Medical Association on the following evening. Sir Rickman Godlee was in the chair, and the other members present were Sir Thomas Barlow, President of the Royal College of Physicians; Sir Watson Cheyne, President, and Sir Frederic Eve, Vice-President, of the Royal College of Surgeons of England; Dr. Meredith Townsend, Master of the Apothecaries' Society; Dr. Frederick Taylor, President of the Royal Society of Medicine; Mr. E. T. Neatbercoat, Vice-President of the Pharmaceutical Society; Dr. Des Voeux, Treasurer, and Dr. Squire Sprigge, Secretary of the Committee. The information before the Committee was to the effect that in a large number of instances, if not in all, the enemy had appropriated the doctors' instruments and the pharmacists' drugs. A general desire was expressed to do anything possible to enable the medical profession in Belgium to resume its duties. The subject was discussed in a very sympathetic spirit, but it was felt that in the present military position, and in view of the fact that almost the whole of Belgium was at the moment in the occupation of the German forces, it was very difficult to ensure that assistance in money or kind should be utilized for the purpose in view, and for the assistance of the doctors it was desired to aid. The decisions of a meeting of the Committee summoned for last Thursday evening will be noted in our next issue. Dr. Des Voeux, Treasurer of the Committee, has received a letter from a meeting of Belgian medical men in London which took place recently, expressing their thanks for the sympathetic reception they have had from their English colleagues. The Committee of the London School of Tropical Medicine has decided to offer the hospitality of the school to Belgian medical graduates who may find themselves stranded in this country. The authorities will therefore be glad to hear from any Belgian doctor who would like to reside in the hostel attached to the school and partake of such cheer as they are able to offer. In addition, such graduates would be afforded an opportunity of attending the classes in the school. Application should be made to the Secretary, Mr. P. Michelli, C.M.G. The Belgian Government has appointed an official committee to watch over the interests of Belgian refugees in the United Kingdom. It will work in close co-operation with the Departmental Committee recently appointed to the same end, but its functions will be mainly consultative. It will render aid to the various organizations in this country for the assistance of Belgians, but will not collect subscriptions or receive gifts. The president of the committee is M. Berryer, Belgian Minister of the Interior, and the Honorary Secretary is M. Davignon, Winchester House, St. James's Square. Mr. Millard Shaler, who recently went to Brussels on behalf of the Commission for Relief in Belgium, reported that people were pouring back into Antwerp, and that between that city and Malines the destruction of habitations in every town and hamlet was practically universal. Distress is also said to be very great in the Ardennes, and it is stated that in Liége, where the annual budget is 14 million francs, the war contribution and requisitions amounted to 50 million francs, and that the industrial population is entirely out of work, and cannot earn its food. It is evident that such conditions among the population must react very injuriously upon the economic position of the medical and pharmaceutical professions in Belgium even were it not that in many instances their houses and shops have been destroyed.

THE PREVENTION OF VENEREAL DISEASES.

THE movement against venereal diseases, like all other social efforts, has necessarily been to some extent damped owing to the war. It is none the less true that the need for action has been enhanced and not diminished by war conditions, and this not only by reason of the aggregation at the present time of soldiers in camps of varying size, where temptations are often exceedingly obvious, but also on account of the fact that a great war has invariably brought in its train a pronounced increase of these forms of disease. The organization of effort in this direction falls naturally under two categories—military and civil. As far as the former is concerned, there is good reason to believe that the military authorities are getting the matter well in hand, and there can be no doubt that, if they should find any difficulty in meeting the demand, they could obtain the willing service of medical volunteers in the various districts. But the organization, as far as the army is concerned, may be left with entire confidence to the army authorities. In this matter, however, the military and civil problems are closely interwoven, and on the civil side there is room for a carefully organized effort both by the civil authorities and by voluntary organization. For this reason we welcome the formation of the National Council for Combating Venereal Diseases, at a meeting held last Wednesday at the house of the Royal Society of Medicine; the Council, which comprises both medical and non-medical members, is in touch with the Committee of the Liverpool Medical Institution, appointed in May of this year, which is already doing active work of a similar nature in that part of England. Dr. McKenna, of this Committee, has produced a useful brochure on the dangers of venereal disease, suitable for distribution to soldiers; while the inaugural address at Liverpool by Dr. Charles Macalister will repay study, being a clear and plain exposition of the facts and how to deal with them. The military authorities will welcome any civil movement which helps to lighten their task; it is only

necessary that co-operation towards a common goal should have no savour of interference. The success of the whole enterprise must largely depend on the wisdom and tact of the organizers and workers. We can only express our satisfaction that the inaugural meeting of the National Council has not been postponed to the end of the war, since there is a wide field of utility for it here and now.

THE BREAD OF OUR TROOPS.

IN the *Times* for November 3rd a letter appeared, criticizing the bread supplied to our soldiers, and stating that the flour of which it is made "consists of a great excess of starch good for heat producing only, and protein of a peculiarly indigestible kind." The writer asserted that the "army buyers are ignorant of the fact that by getting a slightly more expensive flour they would obtain six or seven more good loaves per sack, so that even their apparent economy is a false one." He wrote of the bread as "admittedly nasty and scientifically unwholesome," and alleged that "the stuff is barely fit for making coarse biscuits, and in normal times is used solely for pig food." This letter, if based on real facts, might be justifiable, but from inquiries made and from personal inspection we are able to state that although it is impossible to assert that bread of an inferior quality may not have been supplied somewhere or at some time, yet it is on the whole of excellent quality. The letter was promptly answered by an officer writing from Lulworth Camp, who says: "Here we have the ordinary ration bread in our mess, and better bread I have never eaten." An officer writing to us from Essex, speaking of the bread, says: "I always eat it, and find it quite good; there is not the slightest discontent in our division about the quality of the flour you may rest assured about our rations, for when the men themselves do not complain there is not much wrong." A lieutenant quartermaster R.A.M.C.(T.), who in peace times was known to us as a very intelligent pharmaceutical chemist, writes: "My experience of this branch of the service is that the Army Service Corps officers are excellent judges of the quality of the supplies purchased. I am sending you herewith a sample of the bread, and you will see it is of excellent quality. Although the statements in the letter to the *Times* may be true with regard to some particular unit in some particular district it will not apply to the army at large." Let us take the writer's statements separately. He complains that seconds flour makes a bread that is indigestible, and consists of a great excess of starch. Dr. R. Hutchison states that "Seconds flour yields a bread which is richer in protein than the product of most blends"; consequently, so far from containing an excess of starch it contains less. Dr. Hutchison also states: "A very white loaf means a loaf in which the starch is at a maximum and protein at a minimum," and that is certainly not desirable. Moreover, the comparatively recent investigations which have shown the importance of the so-called vitamines, which apparently inhere in rice to the husk of the grain, should make us careful not to dogmatize as to the superiority of flour from which a certain amount of the not unimportant envelope of the grain has been scrupulously excluded. With regard to the writer's contention that white flour would be more economical because it makes a larger number of loaves, it is quite true that the volume of bread that can be made from white flour is larger, but the actual quantity of food is not thereby increased. There can be no justification for speaking of the bread made of seconds flour as admittedly nasty and scientifically unwholesome, or only fit for feeding pigs. In so writing the author of the letter shows some ignorance; writing as a supposed expert his letter is calculated to stir up discontent where none exists, and to embarrass the work of a department which we are convinced is as a rule performing its duties under considerable difficulties with great zeal, ability, and discretion.

RADIATION DOSAGE.

SIR ALFRED PEARCE GOULD, who is the new President of the Roentgen Society, delivered an interesting address from the chair of that body at the inaugural meeting of the session on November 3rd. The trend of his remarks was to deprecate a tendency among radiologists to carry over into the sphere of *x*-ray therapeutics the ideas and even the terms which belonged quite properly to *x*-ray physics. He instanced the term "milligram hour" as one which was coming into use in treatment; although some similar expression might quite accurately be used in radiography, when dealing with living cells such an expression became gravely misleading. It was not at all the same thing for a living cell to be exposed to 1 mg. of radium for 100 hours as it was for that same cell to be exposed to 100 mg. of radium for one hour. The living cell introduced considerations which threw to the winds the mathematical formulae current and effective in physics. It did matter very much from the point of view of ultimate effect whether a tube of radium was left in a growth for forty-eight hours continuously, or the same tube of radium was introduced for a series of shorter periods totalling forty-eight hours. It was necessary, therefore, to be very cautious in speaking of the "dose" of *x* rays or radium. Personally he did not believe that it was the intensity of *x* rays or of the gamma radiations of radium which governed the therapeutic effects. Intensity of ray action was undoubtedly of great assistance on the photographic side of *x*-ray work, but in *x*-ray therapeutics there was some controlling factor other than intensity. No fewer than 605 unsuccessful preparations had to be made before it was discovered what dose of arsenic would link on to the protoplasm of the spirochaete so as to render it inert, and the effective dose, when it was forthcoming in the form of salvarsan, was shown to depend, not upon any question of amount, but upon the particular form in which the preparation was presented to the spirochaete. It was possible, he thought, to institute an analogy between Ehrlich's discovery and radiation dosage. Sir Alfred instanced a patient he had recently treated for a cauliflower epithelioma of the tongue. Operation was contraindicated, and a tube of radium was placed under the base of the growth for twenty-four hours, with the result that, seventeen days later, the whole growth had disappeared as completely as though it had been shaved away. That same tube of radium had been put into many epitheliomas of the tongue, for the same time, and by the same hand, but in no case with so speedy and complete a result. He could not help thinking that in the particular cells there was something which exactly fitted into or corresponded with the rays, linking on to them as hand linked with hand, and bringing about the destruction of the malignant tissue.

RED TAPE FOR WOUNDS.

WE have red tape in abundance in our Government departments, and it has been freely used to strangle civilian enthusiasm even in the form of offers of help for the wounded. But we do not think that a story told by M. Clemenceau could be matched by any circumlocution office now existing in this country. It must be remembered that M. Clemenceau, besides being a statesman of the first rank who not many years ago held the office of President du Conseil, equivalent to Prime Minister, of France, is a doctor of medicine who has been in actual practice. His criticism of some of the arrangements for the care of the French wounded brought down upon his head the thunderbolts of the censorship. His paper *L'Homme Libre*, was suppressed, but like Achilles he defied the lightning of the official Jupiter and at once reappeared with a new paper appropriately called *L'Homme Enchaîné*. But M. Clemenceau rattles his chains vigorously, and still asks awkward

questions as to the provision for the wounded in Paris. In the issue of November 6th he tells the story to which we have referred. A non-commissioned officer was wounded by a shell in the neck. He managed to extract the splinter of metal, and as all the officers of his company were killed or wounded, he insisted on remaining in the fighting line in command of his men. Some days later a severe attack of furunculosis, evidently a sequel of his wound, compelled him to go to hospital. In time he rejoined his dépôt, where he was informed that his injury could not be counted as a wound received in action. This meant the loss of fifty francs of pay for not having applied for treatment as soon as he had received his wound. But, as if to add insult to injury, the authorities in their wisdom further decided that as the furunculosis did not come under the head of an injury received in the service, the unfortunate *sous-off.* must pay the cost of his maintenance and treatment in the hospital. Surely the force of red tape could no further go than to make a man pay for the privilege of being wounded on the battlefield in defence of his country!

We have to announce with sincere regret, which will be shared by a large circle of friends and former pupils, the death, on November 8th, of Mr. C. B. Lockwood, Consulting Surgeon to St. Bartholomew's Hospital. It was due to septicaemia contracted at an operation for septic peritonitis.

New regulations have been issued by the War Office with regard to the equipment of Field Ambulances. In future the transport will consist of seven motor ambulances and three horse-drawn. This information will be of interest to those who are now engaged in organizing field ambulances, and we would advise them to apply to the Secretary of the War Office for a copy of the new document in which all details with regard to the personnel and equipment of field ambulances are fully set forth.

The seventh annual general meeting of the Army and Navy Male Nurses' Co-operation was held at 89, Harley Street, on November 4th, when Lord Howe, who represented Queen Alexandra, took the chair. The annual report, presented by Sir Dyce Duckworth, stated that during the past year the Co-operation had employed 90 nurses and had nursed 312 patients; the confidential reports from the friends and relatives of the patients had in every case been excellent. The war, however, had made a considerable difference to the Co-operation; the majority of its members were reservists, and a large number were already at the front, and consequently for some time to come there would be many less at the service of the public. This must mean loss of income, and for the first time in its existence the Co-operation found itself forced to appeal for funds to enable it to carry on its work. The committee had been advised to fill the gaps left by those members who were on active service with civilians, but there was a strong feeling against employing men for whose training the Co-operation had not been responsible. The Co-operation was doing good work for the State in providing employment for discharged soldiers and sailors, and it was doing good work for the public in supplying it with fully trained and competent male nurses. The committee was fully resolved not to close the Co-operation if it could possibly be avoided, and looked with confidence to the generosity of the public to enable it to carry on this excellent work. Mr. Sankey, who presented the financial report, said that the Co-operation had never been intended as a charity, but as a society for giving work to the trained nurses of either service. A proportion of the fees received by its members was always made over to the society, whose position improved so rapidly that during the last three years it had been nearly self-supporting. The accounts to June last showed a fall of £35 in the annual income, and since then the receipts had fallen to about half the usual amount. The annual expenditure of the Co-operation amounted roughly to about £850, of which £450 were covered by the commissions received from the nurses, and a sum of between £300 and £400 was needed to make up the deficit for the current year.

THE WAR.

THE MANAGEMENT OF THE BRITISH WOUNDED IN FRANCE.

Sir Richard Havelock Charles, G.C.V.O., Sergeant-Surgeon to the King, has furnished us, at our request, with the following brief note on observations made during a recent visit to Northern France:

Sir Trevredyn Wynne and I were sent to France by the Indian Soldiers' Fund Committee of the St. John Ambulance in order to find out with a seeing eye and a hearing ear the condition of affairs relative to the state of the wounded and the ambulance transport at the front.

We were provided with the necessary papers, by the use of which we were enabled to visit wheresoever we desired without let or hindrance. We covered in our tour upwards of 1,100 miles. We saw the men of the British forces marched to the trenches, we were at the trenches, we saw the wounded removed from these and brought to the field ambulance. We noted the manner in which they were received at the field ambulance and their treatment there. We noted the great rapidity with which they were removed from the field ambulance to the clearing hospital. We saw a clearing hospital situated in a girls' school, a building of upwards of four stories. A clearing hospital, it may be stated, is supposed to receive 200 cases, but there were nearer 800 than 700 cases in it at the time of our visit, and 1,500 had passed through it the day before. We saw the wounded laid out in rows with injuries of all degrees of severity; we talked to the men, and from none of them did we have a complaint, or hear a moan, or a groan. We saw the officer in command of that clearing hospital, who had been up all night, still going, and meeting the emergencies and the strain of work with a cheerful eye, a smiling face, and a sympathetic Irish brogue. His personality was an asset throughout these wards filled with injured soldiers. In a very large room adapted for dressing the wounded we spent some considerable time, we saw the routine, and noted the arrangements by which exhausted men could receive sustenance as well as attention to their injuries. I have no hesitation in saying that there was less delay there than there is to be met with in London at any time during peace at the extern department of any large hospital. We met here Sir Anthony Bowlby and Sir William Leishman hard at work and with plenty to do. We saw the transport of the wounded from the clearing hospital to the ambulance train; we inspected the ambulance trains. We saw the arrival of the invalids at the general hospitals, transferred thither by the motor ambulances. We noted the overwhelming work going on in these hospitals. We saw in these hospitals devoted men and women doing their best to meet, and succeeding in doing so, such a condition of affairs as has never occurred in any previous war.

At present tetanus seems to have stopped, and gangrene is in comparative abeyance. For the surgeon of common sense the principles of antiseptic surgery seemed to be demanded by the conditions at the front. Pure aseptic surgery would be an absolute danger. I would like here to state the feelings of admiration and regard which I hold for the British soldier. I would say it is an honour to be a British soldier, and it is an honour to have charge of them. It is possible in such an immense field of operations to cavil at and find fault with supposed shortcomings. With a desire truthfully to comfort the fathers, mothers, sisters and sweethearts of the brave men who are at the front, having read grumbles in the press, having heard complaints from people who have never been there, I wish now to place on record the things which I have seen with my own eyes and which I had heard with my ears. I am neither ignorant of the vicissitudes of travel nor of the difficulties that may arise in camp life. Experience has taught me to appreciate those who work well, and my past life has frequently put me in conditions where energy, promptitude, and assidnity were essential. "Not ignorant of evil," I desire now to add my meed—my small meed—of praise to the work of the army doctor.

Another object in our tour was to determine some plan by which "comforts" could be with certainty brought to the man in the fighting ranks. We have made our report to the Indian Soldiers' Fund Committee of the St. John Ambulance Association, which committee has adopted our recommendations, and there is every prospect, as far as the Indian soldier is concerned, that the little presents and comforts which his friends in England send to him will by this means promptly arrive at the destination.

MEDICAL ARRANGEMENTS OF THE BRITISH EXPEDITIONARY FORCE.

[From a Special Correspondent in Northern France.]

I HAVE now been at the principal British hospital base in France for about ten days, and almost feel as if I could have described it more easily, if less accurately, within a couple of hours of my first arrival at its station. But in this I am not peculiar; some people, indeed, seem so happily constituted that they are able to draw impressive pictures of what is going on within its area without ever having visited it even for two minutes. I did, as a matter of fact, supply you with a description of this base in its medical aspects about four days after my arrival, and, looking up the record of what I then said, it would seem that, kaleidoscopic as appear the changes from day to day, the general picture remains unaltered. In fact, to bring it up to date, all that is required is merely to retouch the higher lights. The suggestion of that picture was that, although the hospital trains were bringing down the wounded in very large numbers, the needs of the situation were fully met by the arrangements at this base. They were, in fact, met even more fully than I knew to be the case at the time I wrote. In other words, there are more hospitals than those I then described, and more men of distinguished surgical ability engaged in the conduct of the work connected with them than those to whom my last letter made reference. Sooner or later I hope to be able to send you a complete list; at present this is impossible.

As for the number of the wounded and the character of their lesions, these may be described as practically unaltered, despite the fact that to others who have been out for a long time, as well as to myself, the proportion of very extensive injuries—leaving out of count, of course, those producing immediate or very rapid death—seems smaller than it was among the wounded reaching Paris from the battlefields south of the Aisne. But this is a point on which it is very easy to be mistaken, so I merely record the impression, and for the sake of our soldiers hope that eventually proof of its accuracy may be forthcoming. There is one statement, however, that can be made with rather more assurance. "Gas gangrene" and tetanus both still occur, but the number of cases in which they make their dreaded appearance is less considerable than in Paris a few weeks ago. Whether this statement is true of the wounded among the French and Belgian troops, as well as of our own wounded, I am unable to say, since I have not recently had an opportunity of visiting any French military hospital. Indeed, so far as I am aware, there are none in this particular area.

The prevalence of gas gangrene among the wounded in this war has been explained on so many different theories that it is almost futile to attempt to account for its apparent relative disappearance. The fact that the fighting line is more mobile than it was when the British troops were approximately in its centre on the Aisne valley, and that in effect the base hospital line is much closer up than before, has been adduced in this connexion. It is also to be borne in mind, however, that during the past three weeks or so there has been comparatively little rain; the weather, indeed, is remarkably fine for the time of year, and the trenches and their surroundings are drier. They are drier also, as a whole, for a further reason—namely, that many of them are dug in sandy soil; consequently, the men are less plastered with mud than the earlier wounded. This favourable factor in the general environment of the men may obviously cease to operate at any moment, and it will be interesting to note the effect of any definite change in the meteorological and other environmental conditions.

As for tetanus, consideration of its relative prevalence is influenced by the fact that even at the beginning there was great irregularity in its incidence. I learnt, for instance, when in Paris, from a distinguished French surgeon working in one of the larger civilian hospitals, that he had recently had placed under his treatment at practically the same time men from two different convoys, and that among the patients belonging to the one he had had only a single case of tetanus from beginning to end of their treatment, while among those belonging to the other over a dozen cases had occurred within a few days of their arrival. It would be easy, however, to attach undue weight to this irregularity, and taking as a basis the combined experience of the many hospitals established since this port became a hospital base between two and three weeks ago, it seems to me indubitable that the tetanus ratio has diminished from what it was when I was in Paris. According to the calendar this is really only a short time ago, but mentally it seems months. For most people out here the days are so full that what happened last week seems like ancient history.

Before ending this note I should like to add that the *moral* of the men continues to be admirable, and their physical condition, apart from their wounds, is usually remarkable. Frequently on removing the dressing from the wound of a man who has just arrived from the front, one is astonished to find how grave and extensive are his lesions. I use the plural, for it may almost be said that multiple wounds are the rule rather than the exception. Except when the thorax or abdomen has been penetrated, there is commonly nothing in the patient's face to suggest a seriously injured man. They recall to my mind the peasants with whom I used to be familiar many years ago in the near East. These were always fighting among themselves with blunderbuss-like guns and daggers, but recovered from the severe surgical injuries caused with astonishing ease. Surgically, in short, these pugnacious, vendetta-loving peasants and mountaineers exhibited the most remarkable vitality. They were not impressed by the gravity of their wounds, seemed to suffer relatively little pain, maintained their spirits, and frequently recovered from apparently irremediable injury. Medically, it was far otherwise. Very slight illnesses destroyed their *moral*, and they often succumbed to quite trifling maladies. Here the analogy ceases, for our soldiers, though they belong to a much higher type of man and show the same courage and resistance when seriously wounded, do not, as far as I have been able to observe, lose heart even when attacked by medical disorders. Their capacity for resistance is another matter, and at present I am not prepared to express any opinion on the point. For so far the amount of disease has been singularly small.

SEPTIC INFECTIONS OF WOUNDS.

From what has been said to me by some recent arrivals and from other sources of information, I conclude that there is on your side of the water a very deep-seated belief to the effect that the marked septicity of many of the wounds seen in England is due to the lesions not having received proper attention over here, and that in its turn the latter circumstance is due to the lack of an adequate number of skilled surgeons.

I made some remarks bearing more or less directly on this point in a previous letter, but, in view of the absolute erroneousness of both conceptions and of the unfairness to all concerned of their being allowed to secure continued currency, I must be forgiven if I repeat myself in endeavouring to bring out the true facts. Briefly stated they are as follows: The septicity of the lesions has been directly due to the environment of the men at the moment they receive their wounds; no means exist by which it could be prevented, nor any practical way in which it could be brought to an end with rapidity, and the general arrangements for dealing with all wounds, whether septic or otherwise, include a very ample supply of skilled surgeons and plenty of subordinate trained workers. I propose to adduce the proofs of these statements and further deal with them in separate notes.

The septicity in question is initially, at any rate, of a special character; it is due to the action of spore-bearing anaërobic bacteria, which are at present in enormous numbers, and for some days as a rule entirely prevent the growth of ordinary pyogenetic micro-organisms. The first

two of these statements are facts demonstrable by any competent bacteriologist, and demonstrated on a great number of occasions. The third is to some extent an assumption, but I have been assured of its accuracy by two workers whose authority and judgement few practical men would question. These spore-bearing anaërobes are present in the wounds because the soil of north-western France and of southern Belgium has been subjected to intensive cultivation—which includes the free and constant use of animal manures—for at least twenty years, and with this soil the clothes and persons of our troops in the advanced line have been habitually contaminated. This was inevitable, for they were fighting in trenches by day, digging them or repairing them by night, and sleeping in them or near them, and on the bare ground, during their brief intervals of rest. Nor were their officers in materially better case, for, as a private soldier mentioned to me incidentally only to-day, and with a kind of pride and satisfaction, they are sharing the labours and hardships of their men to the full. Neither one class of soldier nor the other could possibly prevent his clothing becoming impregnated with earth even if it were dry; indeed, about the only complaint that one ever hears from a man fresh from the firing line is that he could rarely get a good wash. Teeming, therefore, as was the soil with anaërobes and contaminated with the former as are the men's clothes, it is inevitable that every wound caused by a relatively slow travelling missile should be instantly, and for the time being, irremediably infected. I say "irremediably," because even from the point of view of a bacteriologist there are few ways in which a spore-bearing micro-organism can be killed with certainty and real rapidity, and none of them could be utilized when such bacteria are lying amid living tissues. Still more absolutely true is this statement if those tissues are not pure surface tissues, but the bundles of deep-lying muscles, the sheaths of nerves and arteries, periosteum and the internal structure of cancellous and long bones. In fact, the majority of the shell wounds caused in the present war cannot usually be ridded even of their initial supply of germs, nor growth of the latter arrested by the surgeon, for several days, if ever. Small as may be the external wound its internal surface is extensive and irregular. Not seldom is it difficult even to get out of its interstices a relatively enormous foreign body such as a shrapnel bullet, a fragment of shell casing, or a scrap of the sheathing of a rifle bullet. At any rate, I have several times seen a French surgeon of indisputable skill abandon the attempt as being better not further pursued, even in cases in which the foreign body had been located on the *x*-ray screen. Obviously, therefore, it must be more difficult still to make certain of the removal of morsels of clothing, which cast no shadow; or to get out organisms so minute as to be capable of hiding in hundreds behind a single thread of nerve tissue or muscle fibre, and possessed of such vitality as to resist a 5 per cent. carbolic solution or any other bactericide in use. In fact, as a surgical acquaintance put it one day, the only way to cleanse thoroughly many of the shell wounds to be seen would be to dissect out the whole of the subdermal tissues, and leave 6 or 7 in. or more of a limb represented by nothing but the skin.

Possibly the nature and inevitableness of this septicity will be still better realized if I illustrate it by recital of a case. I take the very first septic case that I happened to see this morning, and do so because its history was readily obtainable. Frequently it is far otherwise. This patient had been struck by a large fragment of shell. He was at the moment out of range of all but heavy gun fire, so there was no difficulty in reaching him. Consequently he was removed to a field ambulance for treatment almost as soon as his first-aid dressing had been applied. At the field ambulance he received attention from one of the medical officers in charge, and was then sent to the connected clearing hospital, reaching it within a few hours of the receipt of his wound. There not only was his wound re-examined, but in order to facilitate its thorough cleansing, so far as this was surgically possible, the process was conducted while the patient was under a general anaesthetic. At this clearing hospital the patient was detained for two nights, the wound being dressed anew meanwhile, and after an eight-hour journey he reached the base hospital, at which I saw him on the evening of the third day after that on which he had been wounded. Unlike many shell wounds, the lesion was perfectly simple, that is to say, there was no bone broken and a relatively small, though jagged, external wound did not conceal a huge irregular cavity. The shell had done its best, so to speak, to undo its own evil deeds—that is to say, though it had caused a very large flesh wound it had opened it up freely from end to end. Here there was a lesion which, from its nature and the skilled and constant attention that it had received right from the beginning, might reasonably have been expected to be found in a favourable condition. Yet this was not the case. Though the patient was cheery, he was febrile, and the peculiar smell caused by the presence of the anaërobes that I have described was readily perceptible. Furthermore, though there was nothing that most surgeons would describe as gangrene present, there were many patches of tissue which were black, and when these were portions of muscle it was observed that the necrotic process extended far below the general wound surface. Comment on this case is superfluous, for obviously it supports very fully what has been said in the earlier part of this note. To myself, who have seen any number of such cases and know the abilities of the men through whose hands they pass, it seems wholly incorrect to ascribe their occurrence to lack of proper provision for their treatment.

THE INDIAN SOLDIERS' FUND.

The Indian force has arrived in Europe fully equipped with all the necessaries of war, and complete arrangements have been made for field ambulances, base hospitals, and the like. The Indian Soldiers' Fund, which was instituted under the auspices of the Order of St. John of Jerusalem, is intended to supplement the Government provision just as the British Red Cross is furnishing from voluntary sources hospitals, ambulances, nurses, and comforts to British troops in Europe. The head quarters of the Fund are at 1, Carlton House Terrace, S.W., but gifts of clothes or comforts may be sent direct to the Warehouse Subcommittee, 29, Somerset Street, W. The chairman of the committee in this country is Sir John Hewett, G.C.S.I., and the vice-chairman Colonel Sir Trevredyn Wynne, K.C.S.I.

The Fund has, in response to a recent appeal, already received £75,000. The appeal was endorsed by Lord Roberts, who, in a letter dated October 9th, said that it had two objects: "The first is to provide for our Indian soldiers, who may be wounded or fall sick in this war, a hospital in a warm climate, in which they will be able to regain health and strength, so as to return either to the front completely cured, or to their own country happy and in good spirits. The second is to provide comforts for the Indian soldiers while in the field, and to replace the warm clothing with which they will start fully supplied, but in regard to which losses must inevitably occur."

Surgeon-General Sir Havelock Charles, who is a member of the committee, and Colonel Sir Trevredyn Wynne recently visited France as commissioners for the Fund, in order to make arrangements to ensure that the gifts shall reach the units. It has been arranged to appoint agents at the port and at the rail-head, and that motor lorries bearing the name of the Fund shall run from the rail-head to the divisional head quarters, and thence to the regiments, where the gifts will be handed over to the officer in command, by whom they will be distributed. The lorries will not run under the protection of the Red Cross, but will take the chances of war.

In an interesting report of their tour of inspection, during which they covered some eleven hundred miles and visited every part of the field of operations from the extreme front to the base, the Commissioners state that the wounded are receiving every possible care and attention, but that there is a large field for voluntary aid in ambulance work supplementing the regular ambulance arrangements, but working under the direction of the regular army medical services. It appears that the British Red Cross, while supplying ambulance cars ready for work, takes no initiative in their use. Cars are kept in a dépôt until such time as the local regular medical officer sends a requisition to the society. The required number of cars are then handed over to the medical officers and remain in

their charge as long as they are wanted, being maintained and supplied with petrol and oil by the military authorities. Sir J. Willcocks, the general officer commanding the Indian forces, warmly approved of the proposals of the Indian Soldiers' Fund, and gave every facility for organizing the work of carrying the stores from the port to the rail-head, and there distributing them, as described, by motor lorries. Part of the personnel will be two motor cyclists, who will be employed to let regiments know where the supply lorries are and ascertain what is wanted. The offer of General Sir Alfred Gaselee, formerly in command of the northern army, India, to go to France to make the preliminary arrangements, has been accepted, and it is expected that any difficulties in detail of organization will easily be overcome.

The medical service of the Indian Expeditionary Force has of course its own personnel and equipment. Clearing hospitals and a stationary hospital, which may be a section of a general hospital, putting up some 200 beds will necessarily be established in the rear of the force in the country in which it is engaged, but the question of where the main base hospital should be established is one which is receiving anxious consideration. At the present time a general hospital for 500 beds has been established in two hotels at Forest Gate and Balmer Lawn near Brockenhurst in the New Forest. A hut hospital for 500 beds is being established in Brockenhurst Park which has been placed at the disposal of the authorities through the kindness of Mrs. Morant, and another 500 beds will be provided on ground adjoining the Forest Gate Hotel. The surgical work at the hospitals will be carried out by officers of the Indian Medical Service, who, as civil surgeons in India, have held important hospital appointments. Sir Havelock Charles has inspected and approved of the site in Brockenhurst Park, and has reported that the huts, including drainage, repairs, lighting, and heating, will be supplied free by the War Office, and will probably be ready within six weeks. The staff will consist of—

Ten medical officers—namely, a senior surgeon, a senior physician, and eight others, and an assistant surgeon. Dressers: It is believed that Indian senior students from Edinburgh would give their services in this capacity. Thirty orderlies furnished by the St. John Ambulance Association; 28 nurses, consisting of a matron, 2 assistants, and 25 ordinary nurses, most to speak Hindustani; 2 dispensers, 2 storekeepers, 4 clerks; and, from India, 8 cooks, 6 bhishtis, 20 sweepers, 5 havildars; total, about 113.

The duties of nurses will be confined to the general supervision of the cleanliness of the wards, orderliness of beds, and the distribution of food and medicines to the exclusion of dressing cases and any menial work.

The estimated cost to the Fund of the hospital, including the establishment, for a year is £50,000. Pending the establishment of the hut hospitals at Brockenhurst camp it is proposed to lend the staff of the Committee's hospital to the War Office at the hospitals at Balmer Lawn and Forest Gate, where such help is likely to be needed immediately.

It is not, however, considered expedient that the policy of bringing wounded or sick Indians to this country to convalesce should be a permanent arrangement. On this head medical opinion is at one with that expressed by Lord Roberts in the letter quoted above. The Indian is not accustomed to our cloudy winter, and eventually it will probably be found wisest to establish general hospitals in France, and a base hospital in Egypt. The Prince of Wales Museum, Bombay, will, it is stated, be temporarily used as a base hospital for Indian troops returning to India from the front, and, with the Viceroy's permission, will be named the Lady Hardinge Base Hospital. The whole expense of its establishment and upkeep will be borne by the Bombay branch of the Imperial Relief Fund, and the women's branch of the same fund. The officer in charge will be Lieutenant-Colonel J. G. Hojel, M.B.Dublin, Bombay Medical Service, Surgeon-in-charge of the Gokuldas Tejpal Hospital, Bombay.

THE WAY HOME OF THE WOUNDED MAN.

[By One who has Travelled It.]

A man may be wounded in the firing line—that is, in the trenches—or on the open road. In the latter case he will probably be directed to the nearest ambulance, but in the former should first pass through the hands of his regimental medical officer. In either case he will be sent on by the field ambulance to the clearing hospital, from there to the ambulance train, and so to the base hospital. The stages of medical treatment are as follows (in full):

1. First field dressing (applied in the trenches).
2. Regimental aid post (regimental medical officer).
3. Field ambulance (advanced dressing station).
4. Clearing hospital.
5. Ambulance train.
6. Base hospital.
7. Ambulance ship.
8. Ambulance train.
9. General hospital (London or provinces).

It is the purpose of these notes to consider briefly some of these stages with reference to the time occupied in transit and the facilities for medical treatment, and, finally, to adduce some arguments in favour of attempts at curtailing their number.

The First Field Dressing.

This is carried by every soldier attached to his tunic. It is composed of two small packets in a canvas cover. In each packet is a pad of antiseptic gauze and a bandage. The bandage is sewn to the gauze to facilitate application, and full instructions are given on the outside. The German field dressing is very similar, but the French contains aseptic and not antiseptic gauze. This dressing the man applies himself, or has applied by some one near by. It is often applied very well, and in that case is left undisturbed, at least until the clearing hospital is reached. It is too small for any but the least severe wounds of entry and exit, as it only measures 4 by 3 in. The gauze can be opened out into a much larger and more useful pad, but the soldier does not do this.

After being wounded the man may, if he is able, leave the firing line at once, but this may prove impossible from the nature of the wound or of the military situation. On the whole more leave at once than would be expected, and occasionally are wounded again in so doing. If unable to leave, they are fetched by the regimental stretcher bearers or by the bearers of the field ambulance. The activities of the two overlap, and stages two and three are run together in two ways—namely, by the stretcher bearers of the field ambulance being sent up past the regimental post to the firing line (or even in front of it) and by the wounded coming straight to the ambulance without passing through the hands of the regimental officer.

The Regimental Aid Post.

The site of this is selected by the regimental M.O. and is in theory placed in a position offering some cover and as near the firing line as is reasonably safe. It is supposed to be near a road so that the ambulance may send wagons to fetch the wounded under cover of night. As a matter of fact no position anywhere near the firing line is at all safe owing to the intensity of the shell fire—it is not now a matter of avoiding only rifle fire—and night offers little cover since the battle is not infrequently as fierce after dark as in the day. It is, however, usually possible to select a site on or near a road and also to obtain some such cover as is afforded by a roof which is efficacious against rifle fire and also against any but very low bursting shrapnel. It may be noted that any building so placed that it is likely to harbour members of the fighting forces is very apt to be shelled. But the writer during three months in the field has neither seen nor heard anything to suggest that the Red Cross is deliberately fired on, nor has he met with any evidence that the wounded are badly treated by our enemies. If, as is sometimes the case, the regimental M.O. is required to be in the trenches, his usefulness is very much curtailed. At the aid post splints and tourniquets can be affixed to such as need them, and as well as the supply of suitable material allows. Morphine can be given to those in need of it, for example, abdominal wounds, which seem to cause more pain and mental distress than any others. The first field dressing can be replaced by one more adequate, and the wounded man made more or less comfortable. The regimental M.O. carries his medical equipment on a two-wheeled cart. It is obvious that this cannot always follow the firing line during the fighting; in such cases the facilities at the aid post are much reduced.

The regimental M.O. can direct such cases as are able to walk to the nearest ambulance, can order them to be forthwith carried there by his stretcher bearers (he starts the

campaign with eight stretchers and sixteen bearers), or can send a message to the field ambulance asking them to send up bearers or wagons.

The Field Ambulance.

On the receipt of such a message or on getting information from any source as to the location of wounded men, the field ambulance may send for them. For choice horsed wagons should be sent, as stretcher carrying is very hard work and extremely slow. Moreover, fewer people can be dealt with in this way. An ambulance has eighteen stretchers with its advanced post (we are here dealing only with the advanced post of the ambulance) and six bearers to each, thus enabling eighteen cases to be carried a considerable distance, but only at the rate of about a mile an hour. Its wagons can carry forty over the same distance in a shorter time, and can often carry more than forty, inasmuch as many cases unable to walk are able to sit up in a wagon. A single wagon holds four cases on stretchers but thirteen sitting up (one on the box). It cannot, however, be used if cross country work is required owing to the ditches and raised roads.

The journey to the ambulance is usually a short one—not more than a mile—and, however it be accomplished, should not prove very fatiguing for the wounded. At the ambulance the wounded man can usually get some hot drink, operations of urgency can be performed, and more morphine given if required. Amputations are the only operations undertaken in practice, and these only when there is no other way of dealing with a limb.

The ambulance—to put it bluntly—repacks the man for further transport, and takes his name, etc., for the official returns. It also acts as a collecting station for the wounded from the various regiments in its area. From a purely medical point of view, it does little for the patient that might not have already been done, and it interposes a delay and a change from wagon to wagon or otherwise which cannot be said to be in the best interests of the patient.

Sometimes it is practicable to bring motor ambulances up to the ambulance, but more often it is not. In the latter case the journey to the clearing hospital is continued on foot or in horsed wagons, according to the severity of the wound. Occasionally the change from horse to motor ambulance may be made *en route*, presumably with the idea of sparing the horses and releasing the horsed wagons for further use. Against the bringing of motor ambulances right up to the field ambulance or even to the regimental aid post, it is urged that they require head lights at night, and also that if they break down they are more difficult to move out of the way, and may obstruct the passage of troops. These reasons are not quite convincing.

The Clearing Hospital.

This unit can provide attention for the worst cases, but as a rule can give no attention to the light or moderately severe wounds. It is an administrative rather than a medical unit, and is concerned in the collection of wounded from three field ambulances and their forwarding to railhead. The latter is usually in the same town, but not always. It sends on only such numbers as can be forthwith put on an ambulance train. The writer gathered that it had no means of rationing the wounded, and during his stay in one such hospital certainly provided most, but not all, of his own food, as did some eight other officers present with him. Some of these had been at the hospital for three days. It is fair to state that this was at a time of great pressure on the accommodation available, and thus in somewhat exceptional circumstances. This difficulty in rationing the wounded is felt all down the stages to the ambulance train, and the provisioning for meeting it does not seem to be systematized. Too much reliance seems to be placed on the official supposition that the wounded man brings with him any unconsumed portion of his day's ration. He very seldom does anything of the sort. In the same way, he seldom brings the reserve ration which he is supposed to carry.

The wounded man will seldom if ever reach the clearing hospital earlier than twelve hours after being hit, and may occupy as much as thirty-six hours in getting there. In some cases it will be longer than that. He may expect to spend at least one night there.

The Ambulance Train.

The ambulance train comes up to rail-head, and is met by motor wagons containing the wounded. It may be mentioned that all control of the railways rests with the French, even in areas which can only be concerned with our troops. This is undoubtedly necessary for the adequate working of a large system, but may in effect lead to delay to our ambulance trains, which can neither be foreseen or avoided. In any case the wounded man will probably not leave the ambulance train until the morning of the day following that on which he entered it, or for an equivalent period. It requires some considerable time to load and unload a train with wounded.

An ambulance train has a staff of three medical officers, and also sisters and R.A.M.C. personnel. The writer has travelled in two such trains and has seen others. In one of these stretchers were placed three deep—that is, one above the other—and this seemed to preclude any really adequate attention to any of the three. Nor was there, in fact, sufficient space between them (this, of course, is governed by the width of the rolling stock available for conversion into ambulance carriages). In a train on this side of the Channel beds were arranged in place of slings for stretchers, and these were convenient, but presumably entailed moving the patients from the stretchers.

The Base Hospital.

The base hospital, or rather the moment for adequate medical treatment, would hardly be reached until sixty hours after being wounded. If the patient is transferred direct to the hospital ship from the train the time taken is, perhaps, a little longer. The writer reached the ambulance at about midday on September 29th, and the base hospital about midday on the 31st. This is only forty-eight hours, but others met by him had occupied much longer on the same journey. At the same time, the experience of one journey cannot be taken as entitling him to make broad generalizations in regard to the time occupied, and these here stated are submitted only with reserve.

It has been suggested in the writer's hearing that possibly the medical men are in some way to blame for the infrequent dressings which some cases seem to have had. He would therefore state that even amongst those most aggrieved at the delays of the journey he has heard nothing but praise for the medical men concerned and sympathy in the difficulties they had to overcome.

Conclusions.

With the further stages of the journey the writer is not now concerned except to state that slight wounds might possibly not be dressed again before London was reached, but that in this case it would probably be due to the tendency of the slightly wounded to wander into any place except that in which they could be asked if their wounds had been recently dressed again. This was especially the case on board ship.

The following conclusions seem to the writer to emerge—namely:

1. That at none of the stages dealt with is the organization sufficiently elastic to cope with an unexpectedly large number of wounded without injustice to some. He himself was sent from the field ambulance in a wagon that did not belong to that ambulance, was housed outside the clearing hospital in a building occupied hastily in the emergency, could not lie down in the ambulance train owing to four cases being in a carriage (ordinary first class), slept on the floor on his own valise at the base hospital, had another in his cabin on the boat, and finally slept in a room intended for one only at a nursing home with two others. No complaint is made—on the contrary, one is only too pleased to have any place at all in which one can exist comfortably—but the pertinent fact does emerge that where not even adequate housing is provided it is likely that medical treatment will prove difficult or impossible.

2. The time occupied, and in particular the frequent changes from one conveyance to another, are inimical to the wounded. On the journey the writer travelled in one horsed wagon, four motor cars, two trains, and an Atlantic liner. In the same time he came under the care of seven different medical officers attached to seven different administrative units. This obviously gives great

opportunity for the overlooking of essential facts in the proper care of individual cases.

Is there any remedy, or is this the best that can be devised? Obviously only those at the head of affairs are really in a position to decide such a question, but it is nevertheless one which has frequently been discussed by the writer with those concerned in its practical working. Hence it is, perhaps, permissible to make a suggestion.

It seems to the writer that the objections urged against the bringing of motor wagons right up to the regimental aid post are not insuperable. A horsed wagon can and does go so far, and from the patients' point of view it matters little which sort he is upset out of, if it comes to that, or in which he experiences the jolting inseparable from well-worn roads. That motors can pass all these roads is certain from the fact that staff cars and supply lorries do so, and also armoured motor cars and motor cycles. Nor is the writer convinced that it is necessary for a motor car to carry head lights when near the firing line. Every other vehicle gets out of the difficulty by going very slowly, and, if need be, by having a guide to walk in front.

Once on a motor car there is no very apparent reason why the wounded man should not be conveyed straight to the base. The motor has also the advantage that it can take any road it wishes, and could go straight to a base even if the latter were not actually an important railway centre. This would perhaps render available various large buildings in the neighbourhood of towns at present too full of hospitals and yet with insufficient beds for the wounded. Thus the now necessary restriction of base hospitals to railway termini would be avoided.

Many cases are brought to this country only by the time that they are fit to return. These might be dealt with on the other side of the Channel, for a regimental aid post if fortified with some of the field ambulance personnel, that is to say, with perhaps an extra medical officer, should be able to classify very many such cases while actually loading them into motor wagons. They could then be sent to base dépôts which need partake very little of the nature of a hospital and very much of that of a convalescent home.

Finally it might be necessary in any such scheme to provide with each fleet of, say, fifty motors, one of larger size which would carry some medical equipment and could be used as a "surgery" if need arose.

If motor cars are more liable to be injured by rifle fire than horsed wagons (and a horse is very easily wounded), it should be possible to provide light armouring over the vital parts. Most motor cars have a bonnet, which is in effect light armour.

These suggestions are admittedly made from a partial knowledge of the difficulties to which they might give rise if adopted, but the writer can speak with experience of the difficulties and dangers which they are designed to overcome, and is convinced that these latter still require some more comprehensive effort to meet them. It is true that matters have much improved since the earlier days of the war and since the battle of the Aisne, but much remains to be done. The multiplication of stages—at each of which the wounded man's name, religion, etc., are duly entered on another official form—in the way home of the wounded seems to be the greatest difficulty of all, and the one most calling for attention.

THE HOSPITALS FOR SICK AND WOUNDED IN PARIS.

[From our Correspondent in Paris.]

General Conditions.

The wounded soldiers received into the hospitals are, almost without exception, in excellent physical condition. The number of medical cases encountered in the military hospitals is very small compared with the number of wounded, and the epidemics so disastrous to many other campaigns have not hitherto occurred in the present conflict. One seldom sees a case either of typhoid fever or dysentery, and it was recently stated by an authority here that the proportion of such cases seemed to be even smaller than in times of peace.

For the past month or so in Paris the number of wounded has been steadily diminishing, the French authorities adopting, as far as possible, a territorial distribution. In consequence of the movement of the British troops towards the coast the greater part of the British Red Cross staff, formerly stationed about Paris, has moved to Rouen, Boulogne, Calais, and other towns about that district. The British hospitals in Paris still have many patients, the greater part being those who were wounded at the battles of the Aisne and Marne. As soon as they are convalescent they are sent from Paris either to the base or directly home to England. Most of the convalescents are evacuated by means of ambulance trains, but a more pleasant method has recently been introduced, that of floating them down the Seine in specially equipped yachts and barges. Closer to the actual fighting one would imagine that the hospital accommodation was severely taxed, but at Rouen a few days ago I ascertained that there was equipment for three large temporary hospitals not yet in use, but which could be ready in a few days should occasion arise.

Tetanus.

The incidence of tetanus, so remarkable in the earlier part of this war, seems to have somewhat diminished. The greatest number of cases of this disease which I have observed here came from the districts north-east of Paris, about the valleys of the Marne and the Aisne. Whether the diminution is due to the transfer of the armies to another district, or to the improvement of the early treatment of wounds, it is too early to discuss. A very elaborate but concise form for recording statistics of tetanus has been prepared and circulated to all the military hospitals by Dr. Bazy.

It is believed that the death-rate in the present outbreak of tetanus will be markedly lower than is usually recorded in textbooks. If this prove to be the case the reduction will certainly not be due to any single mode of treatment, as each hospital seems to have its own particular method. For the most part the use of the antiserum has been dispensed with after the appearance of the disease, strong sedatives of various kinds being then most in favour. Lately, however, there has been an increase in the use of intraspinal injections of serum, occasionally combined with magnesium sulphate, after the appearance of symptoms.

In discussing "gaseous gangrene," Dr. Delorme asserts that large incisions and amputations are too often resorted to. "Experience has proved," he says, "that nothing is so toxic to the bacillus of gaseous gangrene as hydrogen peroxide." His method of treatment is as follows: Above the swollen, discoloured, and emphysematous part of the limb affected, a circular row of injections of hydrogen peroxide is made into the subcutaneous cellular tissue, at intervals of about half an inch. A second circle of injections is then made an inch or so higher up the limb, the points of the second injections being opposite the intervals of those of the first injections. By this means he hopes to form a barrier against the further invasion of the bacilli. If necessary, these injections can be repeated the following day, or even on the same day, either above or below the original injections, according to whether or not the gangrene has advanced or receded. Should the tension of the limb become so great that gangrene by compression of the vessels is feared, it is necessary then to incise the aponeurotic envelopes, and the incisions should be followed by irrigation with hydrogen peroxide. The prophylaxis of gaseous gangrene may be summed up in the rapid transport of the wounded from the field of battle, the early extraction of foreign bodies, and adequate disinfection, especially with hydrogen peroxide.

Typhoid and Cholera Vaccines.

Up to the present the prophylactic injections of typhoid vaccine seem to have been a great success. At the Pasteur Institute large quantities of cholera vaccine are now being prepared, most of which, I believe, is being sent to Servia. During the recent campaign in the Balkans this vaccine was used by the Servians with great success.

FRENCH WOUNDED FROM SOME EARLY ACTIONS.

Experiences of a British Doctor in a French Town.

The first batch of 250 wounded from the French forces on the frontier arrived at 2 a.m. and the local doctors, who had organized themselves into a committee, were there to receive them with an adequate staff of volunteer bearers. The first step was to throw open each compartment or luggage van, requesting those able to walk to come forth, thus leaving room to get at the more gravely wounded. The latter were mostly in the luggage vans and cattle trucks, some lying on straw on the floor, others on suspended stretchers on which they were conveyed to the waiting-rooms. The proportion of grave to slight wounds in this convoy, which came from one of the earlier actions near the frontier, varied from 10 to 15 per per cent., but this did not show the real proportion on the battlefield, because the gravest cases of all do not get beyond the nearest hospital; further the convoy comprised cases of illness as well as wounds. There were plenty of willing helpers to assist in transferring the bad cases to the motors and conveyances awaiting them outside the station. In order to secure an equable distribution among the various hospital centres (for there were ten of them), numbered cards had been prepared—for instance, "Municipal 1 to 50"—so that no one centre could be overcrowded. The less gravely wounded were dispatched on foot in charge of a guide.

The distribution took about an hour, whereupon we set to work to attend to the poor fellows, some of whom had been in the train three or four days without any surgical attention after the first dressing and with very little food, solid or liquid, beyond an odd cup of chocolate or beef-tea provided by benevolent townsfolk at intermediate stations. Arrangements have been improved since, and the wounded are no longer exposed to these unnecessary vicissitudes. It had been arranged that the principal civil hospital in the town should receive the graver cases, so that it was 10.30 that morning before the 46 patients had been dressed and put to bed.

By far the majority of the wounds in this convoy were inflicted by fragments of shell and shrapnel, not 10 per cent. being bullet wounds. The shrapnel ball is the shape and size of a small marble, and, like the shell, carries in bits of clothing with it. The proportion of bullet and shell wounds, however, varied in each batch, though in every instance the effects of artillery fire predominated. The aperture of exit of some of the bullet wounds was so extensively lacerated as to suggest the dum-dum bogey, but in all probability the damage was wrought by splintering of the bone, or by the bullet impinging on the bone and wobbling. The parts affected by the shrapnel and shell wounds were principally the buttocks, backs of thighs and calves. We had two chest wounds—the bullet going right through—and they both did well, though one developed pyohaemothorax, which had to be drained through a splintered scapula.

It should be borne in mind that when men are wounded and fall in a hotly contested field of operations, perpetually swept by shot and shell, it may not be possible to pick them up for many hours or even days. I have heard of cases in which three, four, or even five days have elapsed before they could receive assistance. As it is, the mortality among the bearers is very high; in one instance, of half a dozen who sallied forth to fetch in the wounded, only three returned. This is sure to be the case when firing takes place at such long ranges as to render it impossible to distinguish between combatants and non-combatants.

Then, too, life in the trenches is insanitary in the extreme, and soldiers in the fighting line may be unable to wash or change linen for days or weeks. What with the forced marches, exposure, and the total absence of facilities for self-cleansing, the wounded are often in a lamentably dirty condition, their plight being aggravated by a long, tedious journey by rail. It is therefore not surprising that practically every wound was septic on arrival; indeed, some were in an advanced stage of putrefaction. In two cases in the first convoy the huge contused lacerated wounds were infested by worms—sturdy, ivory-white, nimble parasites, firm to the touch and capable of jumping a foot or so; in fact, like magnified cheese mites, which, indeed, they closely resembled.

The nursing was done by volunteers, male and female, who might or might not have gone through a summary course of instruction in their duties, so that to begin with there was a certain confusion due to lack of experience and method. After a few days, the unsuitable aids having been eliminated, things settled down into a routine and worked smoothly enough, the surgeons attending to the severer cases and the nurses dressing the minor injuries.

The following is an example of a fairly common history. A man was wounded on a Sunday morning (bullet in right buttock) and was at once taken to a house not far away and dressed (pocket dressing). There he remained until 11 at night when he was placed on a cart and after several changes was taken to a temporary hospital, a couple of miles to the rear, where he passed that and the following night. At 7 a.m. on Tuesday he was placed in a train which went six miles and then waited in a siding for ten hours "out of sight, out of mind." Then by easy—very easy— stages it proceeded on its journey leaving some of the graver cases en route; it arrived at its destination on Thursday morning. The bullet had splintered the ilium, passing through it into the pelvic cavity, where it could be seen in the radiogram lying behind the caecum quite out of reach except from the front; as the foreign body gave rise to no abdominal symptoms it was left alone and after a good deal of suppuration the track leading to the aperture of entry gradually healed.

It is not surprising in the circumstances that the numerous cases of compound comminuted fractures of the long bones gave us a great deal of trouble, owing to extensive cellulitis, profuse suppuration with blue, horribly offensive pus, leading in two instances to secondary haemorrhage, necessitating amputation, which proved fatal from shock and exhaustion.

As all the wounds were septic on arrival the first step was to cleanse them thoroughly with dilute mercury perchloride, potassium permanganate, or iodine solutions; to remove necrosed tissues and foreign bodies (fragments of clothing, splinters of bone, bits of shell, etc.), to insert sutures when required, and to apply a plain dressing of sterile gauze.

Abdominal Wounds.

Dr. Duvernay showed me an interesting case.

A soldier, 25 years of age, was wounded on September 8th, at 8 a.m. His company was making a bayonet charge, and when about 500 yards from the enemy's trenches he was struck by a fragment of shell in the belly. He fell to the ground, and, on getting up, a bullet hit him in the left axilla. He fell on his knees, and crawled into a ditch, where he waited till fighting ceased at nightfall, when he dragged himself, a few feet at a time, towards the French lines, which he reached at midnight.

The abdominal wound, half way between the anterior iliac spine and the umbilicus, inflicted by a bit of shell, ran downwards and backwards, the aperture of exit being in the upper gluteal region. It was painted with tincture of iodine and left undisturbed; it healed without any reaction or complication.

The other wound was caused by a bullet which entered the left axilla, passed through the upper part of the thorax, coming out four fingerbreadths from the manubrium sterni, fracturing the first rib and sternum on its way; it then penetrated the neck, and came out on the other side after a superficial course. Here again no serious mischief was done, and he suffered no inconvenience beyond a little pain on moving the neck and some discomfort on swallowing.

The patient was evidently born under a lucky star, but it is worthy of remark, as bearing on the absence of injury to the pelvic viscera, that for three days he had had nothing to eat except a few berries, so that his intestines were empty, especially as he had had an evacuation that same morning. The case shows, moreover, the advantage of abstaining from any exploration and unnecessary manipulation in penetrating wounds of the abdomen.

An infantry soldier was shot in the back, the bullet entering at the junction of the upper third with the lower two-thirds of the sacrum, on a line running to the posterior superior spine of the ilium. When the man came under Dr. Whitling's observation he was very ill, with a high temperature. On examination under chloroform a large track was discovered passing through the muscles to a hole in the body of the ilium, which was badly splintered. It was evident that the missile had passed through it into the interior of the pelvis. There was a good deal of necrosis, with pus having a faecal odour. Dr. Whitling cleared away several large fragments of necrosed bone from the sacrum and from the body of the ilium, and introduced a drainage tube.

The man did very well for a week, when suddenly his

temperature rose to 104° F., and he had a good deal of pain in the gluteal region with slight tenderness in front, in the region of the caecum. There was, however, no dullness nor muscular rigidity in that region though the dressings had a faecal odour throughout. A second operation was undertaken under chloroform, still from behind, because the abdominal symptoms did not seem marked enough to justify intervention from the front. Necrosed bone was cleared away, and a good deal more from the sacrum, which proved to be more extensively injured than had been anticipated. Following up the track of the missile a hole, 1¼ in. in diameter, was gouged right through the ilium. This gave issue to much foul pus with a faecal odour. Even then no missile could be detected with finger or probe. Later on a radiogram showed that the missile, a fragment of shell, was lying nearly 2 in. below the opening in the ilium. A large drainage tube, ¾ in. in diameter, was introduced through the hole in the bone, and the patient began to improve at once.

This patient was seen by Inspector-General Professor Delorme, who expressed his satisfaction that no attempt had been made to remove the missile, which was apparently becoming encapsuled. It was plain that the posterior surface of the colon or caecum had been opened extraperitoneally, as shown by the escape of faecal matter through the wound. The patient made an excellent recovery without any further rise of temperature.

Bullet behind the Larynx.

In another case a man was admitted with a very stiff neck and great difficulty in swallowing. Later a huge swelling formed on the right side beneath the jaw. This was opened and the symptoms cleared up. He was able to go home, although the sinus had not ceased discharging. The missile remains *in situ*. A radiogram showed that it lay in a plane posterior to the larynx, apparently in front of the spine.

Pyohaemothorax.

A young soldier received a bullet in the right scapular region traversing the chest, wounding the liver and coming out low down on the left thorax.

He had a formidable haemothorax with surgical emphysema on the left side, but was doing well, when a bulging swelling formed over the site of entry, now thoroughly healed up, and his temperature rose to 103°. Dr. Whitling found that this swelling was a pyohaemothorax communicating with a cavity in the lung, as shown by the fact that by pressure it could be squeezed back into the latter. On opening the swelling, pus and air escaped, and the sound passed some 8 in. along a track leading into the lung substance, which, on the patient being sick, gave issue to a considerable quantity of pus and blood. A drainage tube was passed into the cavity through the splintered scapula, and the man made a perfect recovery without another bad symptom.

Fractures.

Dr. H. Forestier, surgeon to one of the auxiliary hospitals, showed me a patient whose left thigh had been fractured just below the trochanter by a bullet.

The wound had become septic from the aperture of exit on the outer side of the limb and a large abscess formed. The suppuration was so copious that it was necessary to renew the dressing daily, a very painful process, and to the detriment of consolidation of the comminuted bone. In these circumstances it occurred to Dr. Forestier to establish siphonage of the wound by means of a long rubber tube which went to the bottom of the wound cavity. In this way it ceased to be necessary to take the limb out of the gutter splint for the purpose of dressing, and consolidation made more progress in a week than it had previously done in twenty-two days, in fact on the thirty-fifth day the limb could safely be rotated and abducted.

Dr. Forestier also showed me the radiogram of a much comminuted fracture of the humerus below the surgical neck caused by a bullet at 20 metres distance. There was a small free splinter of bone in the centre, but both wounds were small and escaped infection, so that repair took place much more promptly than was anticipated. A month after receipt of the injury the man was able to rotate and abduct the limb one half of the normal scope.

Tetanus.

Dr. Forestier has had 5 cases of tetanus in his service out of 74 wounded (32 seriously). Of these 5 cases 2 occurred in the subjects of grave wounds, and 3 in wounds of medium severity. The disease supervened, in one on the fifth and in the others on the sixth and seventh days from the receipt of injury. Two of them had been injected with antitetanic serum on arrival—that is, three days after infliction of the wound. The first case was that of a man wounded by a fragment of shell in the thigh, with formation of diffuse abscess. The first symptoms of tetanus came on twenty-four hours after admission, and he died thirty-six hours later. The second, who had a trivial wound of the leg by shell, only presented trismus for five days; he progressively improved, a limited contracture of the wounded leg (equinus) was still present on the thirtieth day of the disease. The treatment adopted comprised Bottini's method (injections of solutions of carbolic acid), intraspinal injections of magnesium sulphate, intravenous injections of sodium persulphate, and the administration of large doses of chloral, chloroform, and morphine, but, except in the case mentioned above, proved unavailing.

Antityphoid Vaccination.

Dr. Goddard, who has just vaccinated several hundred men against typhoid, mentioned to me some interesting details concerning the reaction at various ages. Of 200 men between 20 and 25 years of age, one only complained of feeling unwell on the following morning. He had a temperature of 38.5° C., but his indisposition only lasted twenty-four hours. It was quite otherwise with reservists between 25 and 35 years of age, of whom fully 60 per cent. felt ill, and had temperatures running as high as 39.5° C. So marked was the reaction, local and general, in the latter that he thought it inadvisable to vaccinate any of the territorial soldiers aged from 35 upwards.

"Traumatic Hysteria."

A good example of "traumatic hysteria" occurred in an officer, a highly nervous subject, who, while retreating with his men through a wood, was thrown down by an explosion seven or eight yards away. He only sustained a few bruises of the right leg, but he says that some blood escaped from his ears and that he was deaf for a quarter of an hour. He had to be supported by a couple of his men because he felt so giddy. On reaching the nearest village he collapsed and was put to bed. When he came to he had a good deal of pain in the back of the neck and gradually developed paralysis of both lower limbs, most marked on the left, with loss of sensation to heat and cold and touch on the left side. There was fugitive amnesia and a difficulty in moving the tongue. He also noted diminution of visual acuity, especially in the left eye. These symptoms cleared up in the course of six weeks and he has now returned to the front.

Another instance belonging to the same category was that of a soldier who received a blow on the left temporal region from a bit of shell on August 26th. This left him unconscious for twenty-four hours, and when he reached an ambulance at Nancy he complained of marked giddiness, and was found to be nearly blind.

He was transferred to an auxiliary hospital on October 1st. On admission he presented, 8 cm. above the top of the ear and 4 cm. behind the median line of the tragus, a depressed scar prolonged by a furrow upwards (fissure of bone) which could be felt to pulsate. In exactly the same situation on the other side was a pink, star-shaped, non-tender scar. There was some paresis of the right upper limb, but nothing to note in respect of the bladder or rectum. The patellar reflexes were normal. Ophthalmoscopic examination showed the fundus of the eye to be normal on both sides, with hypermetropia 3 D. on the left and 2 D. on the right side. The pupillary reactions and corneal sensibility were normal, and ocular movements intact. There was no diplopia and no hemianopsia. Vision: right, ½; left, ⅓. In the absence of any ocular lesions these signs and symptoms seem to point to hystero-traumatism.

THE HOME HOSPITALS AND THE WAR.

3RD NORTHERN GENERAL HOSPITAL (T.F.).

SHEFFIELD.

THE general hospitals in Great Britain were primarily organized for the Territorial Forces of the country, but while they have dealt with the sick and injured coming from the various Territorial camps, this has been a comparatively small and unimportant part of the work they have been and are doing. Thus, of the 1,543 men admitted to this hospital since the outbreak of hostilities, only 419 have come from Territorial camps, while the remaining 1,124 have arrived from overseas. They included 348 Belgian wounded. Whatever may be the ultimate verdict arrived at on Lord Haldane's scheme for a Territorial army, there is already abundant evidence to show that his Territorial hospitals have been a huge success. At the

present time the twenty-three general hospitals are providing accommodation for 11,500 men and 460 officers. When it is added that all these beds are being used, and that there is a constant cry from head quarters for additional accommodation, one shudders to contemplate what we should have done without them.

Under the supervision of its commandant—Lieutenant-Colonel Connell—the 3rd Northern General Hospital works with a precision and an efficiency that would be difficult to surpass. Linked up with it are a large number of beds in civilian hospitals and convalescent homes in the neighbourhood of Sheffield, which have been generously placed at the disposal of the War Office.

The overseas wounded come in convoys of from 120 each upwards, the largest having been one of 240 wounded Belgian soldiers from Antwerp. They are conveyed from the railway stations to the hospital in motor omnibuses and ambulance carriages—the former for those who can sit up, the latter for cot cases. The number of cot cases has risen steadily with the advent of each convoy, and our last batch included 61 of such out of a total of 150. This change in the severity of the cases has brought about an increased demand for ambulance carriages, which is being met by the voluntary contributions of a generous public.

The proportion of shrapnel to rifle bullet wounds has been high, averaging quite ten to one, but it has varied considerably, and among the last two convoys the relative preponderance of shrapnel wounds has been decidedly lower. Most rifle bullets go clean through, and leave little to be desired from a surgical point of view. Slight suppuration at the points of entrance and escape takes place in perhaps 20 per cent. Truly the modern army bullet may be fairly described as a "kindly foe."

Several cases of perforation of the lungs from rifle fire have been treated, and it is amazing how little the patients suffer—a cough for a few days, with expectoration of a little blood, and then steady and rapid convalescence.

1 and 2, Shrapnel casing; 3, shrapnel lead bullet; 4, German rifle bullet; 5, English rifle bullet, deformed by striking bone.

We have had several very interesting abdominal cases following rifle wounds. In one the bullet entered the chest on the right side between the ninth and tenth ribs on the anterior axillary line, and escaped just below the twelfth rib on the left side, about 3 in. from the spinous processes. The patient was conveyed, without a rest, from the fighting line on the Belgian frontier to Sheffield, and arrived after a journey of seventy-two hours. The abdomen was greatly distended, rigid, and tender, and he had vomited many times during the journey. Although his condition gave rise to much anxiety, his pulse and facial expression did not support the view that he had general peritonitis. Owing to this defect in the picture, and also because of the great abdominal distension and the extensive manipulation which an exploratory operation would have involved, it was decided to treat him on expectant lines. A large abdominal fomentation sprinkled with belladonna liniment and a series of turpentine enemata caused the expulsion of much flatus and a gratifying improvement, which is being maintained. The gaseous distension was probably a result of damage to the great abdominal sympathetic plexus.

When rifle bullets strike compact bony tissue the result is apt to be vastly different, and the worst wounds we have had have resulted in this way. Two such wounds of the forearm are in hospital at the present time. In each case the bullet entered the flexor aspect of the forearm and produced an extensive comminuted fracture of the radius. The outlet wound on the dorsum measured 6 in. by 3 in.

There have been a number of cases of injury to important arteries, among which may be mentioned one of aneurysmal varix of the femoral vessels, and two of traumatic aneurysm of the axillary and brachial arteries respectively.

Three cases of compound fracture of the skull, with more or less protrusion of the brain, including one in which a shrapnel bullet has lodged in the centre of the brain, are under treatment and are doing surprisingly well. All have been dealt with by enlarging the openings in the skull, removing depressed and splintered fragments of bone and providing suitable drainage.

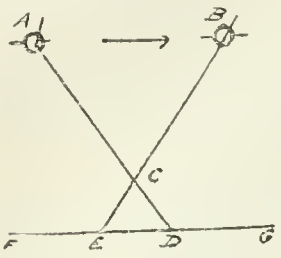
Quite a number of cases of injury to the trunk nerves of the arm and leg have been admitted. Two of these show evidence of complete severance, and will be dealt with by secondary nerve suture when the wounds have healed. In others temporary paralysis, followed by severe and persistent neuralgia, indicate merely contusions of the nerve trunks.

The most gratifying feature has been the small number of deaths. Down to November 7th they numbered five—two from tetanus and one each from pneumonia, peritonitis and gas gangrene. The tetanus fatalities were both hyperacute cases, with a short incubation period. One of these is recorded in the appended notes. The second developed spasm of deglutition, for which gastrostomy was done. We have had a third case of tetanus, which is now convalescent. He was treated by frequently repeated injections of large doses of antitetanic serum, but owes his recovery probably to the fact that the attack was a mild one with an incubation period of thirteen days. The fatal case of gas gangrene followed an extensive wound of the shoulder from a lyddite shell. The volume of gas emitted from the infected area was prodigious.

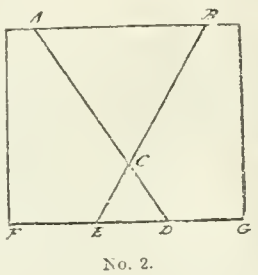
The surgical staff owe much to Major Rupert Hallam for the excellent work he has done in localizing bullets and pieces of shell, and so rendering their removal in most cases a comparatively easy task. To him we are indebted for the following notes:

The nature of the injuries has of necessity involved a large amount of *x*-ray work. The custom I have adopted in dealing with this has been as follows: Each case is first examined with the fluorescent screen. If a bullet or a fragment of shell is seen, a skiagram is taken and sent to the medical officer in charge of the case. Should it be deemed advisable to remove the foreign body, stereoscopic *x*-ray plates are made, or the foreign body is localized; that is, its depth is calculated from a certain landmark on the skin. It will be remembered that the ordinary *x*-ray negative gives no idea of the contour of the limb. The stereoscopic method is most useful when the bullet is near a definite bony structure. When lying in a thick muscular area or in one of the cavities of the body, exact measurements are often a necessary addition, for the guidance of the surgeon. The methods of localizing I use are a slight modification of Sir Mackenzie Davidson's or by means of Dr. Furstenau's calipers. The former ingenious method is the oldest and the basis of many of the newer ones. It is accurate, and with a little practice easily accomplished. It may be briefly described as follows: A skiagram of, for example, a leg is taken from a certain definite position. The *x*-ray tube is then moved parallel to the plate for a certain distance (usually 6 cm.) and the exposure repeated, on the same plate. The plate when developed shows two shadows of the bones, etc., and of the bullet. The plate is then placed in a suitable frame and fine threads are carried from the double shadows to marks representing the positions of the tubes in the two exposures. These threads cross. The height from the

plate where they cross is measured, and gives the position of the bullet relative to the surface of the leg which was lying on the plate. In the diagram No. 1, A represents the *x*-ray tube in the first position, casting a shadow of C (the



No. 1.



No. 2.

bullet) on the *x*-ray plate F–G at D; B is the second position of the tube, casting a shadow of C at a point E. Diagram 2 represents the frame. F–G is the finished plate with the double shadows E and D. A thread is carried from D to A, and another from E to B. They cross, and give the position of C (the bullet).

The Royal Infirmary has placed 100 and the Royal Hospital 40 beds at the disposal of the Military Hospital. Most of the serious operations are performed at these institutions, and the infirmary has up till now received nearly 300 patients.

We are indebted for the notes of the following cases to Captain Mouat, R.A.M.C.(T.F.):

Injury of Cervical Nerves.

L. R. (Loyal North Lancashire) on September 14th sustained a bullet wound in the right side of the root of the neck. He lay in a trench from 10 a.m. till 9 p.m., when a field dressing was applied. The following morning he was taken to Angers Hospital. He was admitted to the 3rd Northern General Hospital ten days after injury. He had complete paralysis of the right shoulder and scapular muscles—that is, the muscles supplied by the fifth and sixth cervical nerves. In addition to this the patient presented a large area of cutaneous anaesthesia, both protopathic and epicritic, over the lower part of the right side of the neck and the upper aspect of the shoulder, due apparently to division of the descending cutaneous branches of the third and fourth cervical nerves. The reaction of degeneration was presented by the affected muscles.

A, Wound of entry; B, wound of exit; C, area of protopathic and epicritic anaesthesia.

J. W. (4th Royal Fusiliers) was wounded on October 20th, near Lille. A shrapnel bullet entered the left side of the neck, fractured two cervical transverse processes, and was deflected downwards in front of the spine to the mediastinum, where it lodged. The patient was admitted to the 3rd Northern General Hospital a week after injury and presented apparently complete paralysis of the left shoulder muscles. The deltoid, supraspinatus, infraspinatus, biceps, and brachialis anticus were completely paralysed and gave the reaction of degeneration. There was an area of cutaneous anaesthesia over the point of the left shoulder and the outer aspect of the upper portion of the arm. The descending cutaneous branches of the third and fourth cervical are intact.

A, Wound of entry; B, situation of bullet; C, area of cutaneous sensory loss.

Injury of Brachial Plexus.

T. B. (Northumberland Fusiliers) was wounded on October 19th, near Lille. Contusion, with resulting physiological division of the upper cord of the brachial plexus, resulted. He presented a lacerating wound of entrance on the back of the right shoulder. A radiogram showed the presence of a large piece of shrapnel lying deep to the coracoid process. Movement at shoulder-joint was much limited in every direction; there was no loss of cutaneous sensation. The paralysis of shoulder-muscles, at first apparently complete, is being gradually recovered from.

Wound of Motor Area.

J. B. (2nd Belgian convoy) was admitted on October 28th. He presented a shrapnel bullet wound of the right parietal bone over the motor area. On admission the patient was conscious, but apathetic and drowsy, and there was complete flaccid paralysis of the left arm and leg. On October 29th he was trephined and pieces of depressed bone were removed. Efforts to locate the bullet with the telephone probe were unsuccessful. The wound was closed with drainage.

Traumatic Aneurysm, Left Brachial Artery.

C. (1st Cheshire Regiment) was wounded on October 20th at La Bassée. The bullet entered the postero-internal aspect of the left upper arm about 2½ in. above the elbow, and emerged about the middle of the anterior aspect of the upper arm, 4 in. above the elbow-joint. The patient complained of tingling in the hand and forearm, worse at night. The wound, on admission, was aseptic and practically healed. There was a pulsatile swelling over the line of the brachial artery, below the wound. The increased resistance and pigmentation of the superficial tissues appeared to be due partly to extravasated blood and partly to a true aneurysmal dilatation of the brachial artery, as the pulsation diminished when pressure was applied to the artery above the site of injury. There was a systolic thrill on palpation and a bruit increased with systole was audible on auscultation. A typical aneurysmal pulse was shown by the sphygmograph.

An operation was performed on November 5th, and a false aneurysm of the brachial artery was found. The brachial artery was torn and the extravasated blood had acquired a false sac from surrounding tissues. The brachial artery was ligatured above and below the damaged area.

Aneurysmal Varix.

W. W. (Northumberland Fusiliers) was wounded with pieces of shrapnel on October 19th near La Bassée. He sustained wounds of both thighs and the right shoulder. He was wounded at 11 a.m., and lay in the trench till 7 p.m. He was unconscious for about an hour. He stated that when he recovered he found himself lying in a pool of blood. Since recovering from the shock he has been conscious of a curious tingling thrill at the site of the wound at the upper end of the left thigh. A continuous thrill, increasing with systole, can be felt through the dressings covering the wound. A small wound is present over the upper end of the anterior aspect of the left thigh immediately over the femoral vessels. A startlingly loud bruit is heard over and distal to the site of the wound, the noise of which resembles the throbbing of the engines of a steamboat.

For the following notes we are indebted to Captain Cobb, R.A.M.C.(T.F.):

Amputation of Arm: Tetanus: Death.

This man received a severe shell wound of his left arm in the fighting on the Aisne. Two days later his arm was amputated at a base hospital in France. When admitted on the seventh day, the stump was very septic, and large sloughs were present in the wound. These were cut away, the whole area was swabbed with hydrogen peroxide, and a prophylactic dose of antitetanic serum administered. The next day he complained of twitchings in his shoulder, and later in the day he developed well-marked trismus. He very rapidly became worse; the spasms became generalized, and could only be checked by the administration of chloroform. He died on the third day of the disease, and ten days after receiving his wound.

Compound Fracture of Femur.

We have three cases of compound fracture of the femur, all in Belgians, and all sustained in the fighting around Dixmude. In each case the fracture is just above the knee, and the wounds are unfortunately septic. They are all put up with a long Liston splint and extension.

Nerve Injuries.

Among the nerve injuries are two cases of section of the musculo-spiral nerve by means of rifle bullets, and one case of section of the spinal accessory nerve by a rifle bullet.

Another man was shot through the neck; a piece of shrapnel was discovered in the chest. He has very severe pain, which radiates along the arm, and is probably due to inflammation around the roots of the brachial plexus.

Compound Fracture of Skull.

Among several cases of compound fracture of the skull one is very severe. He is a young Belgian, who received a shrapnel wound on the right side of his head. On admission there was a large hernia cerebri, which was septic, and the tissues of the scalp were infiltrated with pus, and there was left-sided hemiplegia. The eyelids on both sides were swollen and red, especially on the right side. He was quite conscious. Under anaesthesia loose pieces of bone and septic pieces of brain matter were gently removed, drainage being thereby facilitated. His general condition has improved.

EDINBURGH.

On November 3rd another large party of wounded arrived in Edinburgh from Southampton; they numbered 150, and 110 were sent to Craigleith and 40 to the Deaconess Hospital. This is the first occasion on which this, the well-known Church of Scotland Hospital in the Pleasance, has been used to accommodate wounded men from the expeditionary force. Again, on November 5th, a train load of 136 men came into Edinburgh; about 30 were taken to the Royal Infirmary, and the others were

distributed between Craigleith Hospital and Dalmeny House, the Earl of Rosebery's residence on the south bank of the Firth of Forth. There are also 63 wounded Belgian soldiers at Craigleith Military Hospital.

At a meeting of the managers of the Edinburgh Royal Infirmary, held on November 2nd, it was reported that the wounded soldiers and sailors were being taken on the same footing as ordinary patients; the War Office and the Admiralty were not charged anything for the institution's care of them.

DUBLIN.

Last week the converted steamship *Oxfordshire* brought a second contingent of wounded soldiers to Ireland. About a fortnight ago she arrived in Queenstown with over 700 wounded officers and men. This time she brought 45 wounded officers and 595 men to Dublin. Between 60 and 70 of these were stretcher cases. Within a few hours of the arrival of the boat at the North Wall all the wounded were disembarked and on their way to their several destinations; about half the number were sent by ambulance trains to Cork, the Curragh, and Belfast. The remainder were distributed among the Dublin hospitals. Nearly, if not all, were wounded in the trenches in the neighbourhood of Ypres, and had received treatment either at Bethune or Boulogne, or both places. Among them were twelve German soldiers. The majority of the wounds were in the legs and arms, cases of shrapnel and shell wounds preponderating over those caused by rifle fire. Already a considerable number of those who were brought to Dublin a fortnight ago have recovered sufficiently to be sent either to their own homes or to a convalescent home. All the wounded who arrived last week spoke in the highest manner of the kindly and attentive manner in which they had been treated from the moment they were rescued from the battlefield through the various stages of the journey. They were unanimous in their expression of gratitude for the splendid work done by the R.A.M.C. and the officers of the Red Cross Society.

JOINT WORKING OF THE BRITISH RED CROSS SOCIETY AND THE ORDER OF ST. JOHN.

It is satisfactory to know that in the course of the last week or so an amicable arrangement between the British Red Cross Society and the Order of St. John of Jerusalem has been reached, and that the two Societies are now conducting their business in co-operation. Previously the selection of surgeons for the war and for home hospitals was carried on partly by Sir Frederick Treves on behalf of the British Red Cross Society, and partly by Mr. Edmund Owen from the offices of the Order of St. John. In the same way sisters, nurses, and orderlies were engaged partly by the Order of St. John and partly by the Red Cross Society. Thus there was a considerable waste of energy. Now, however, through the good offices of the Hon. Arthur Stanley on behalf of the Red Cross Society and Sir Claude Macdonald on behalf of the Order of St. John, it has been arranged that the work of the two Societies shall henceforth be carried on in these respects by a joint committee. In furtherance of this object Mr. Owen has left St. John's Gate, and is now working in Pall Mall with Sir Frederick Treves in the selection of surgeons and dressers, and the Red Cross Society has given over to the charge of the Order of St. John the selection of all sisters and nurses for home and abroad. The selection of nurses is in the hands of Miss Swift, who was formerly matron of Guy's Hospital, and of certain able and well known nurses who are working with her. Under this arrangement it is impossible for any amateur nurse to be foisted on our wounded soldiers, for Miss Swift and her colleagues insist that every nurse appointed shall have served her three years in a recognized hospital, and have acquired a nursing certificate. The selection of orderlies is left entirely in the charge of the Order of St. John, and nearly 7,000 of these men have been chosen by Sir James Andrew Clark and his colleague, Mr. Darvil-Smith, for service in the various military hospitals and on the Continent. This complete fusion of the two Societies into one body is regarded by each as a very happy occurrence, and it will go far to assure the public that the best is being done for the wounded soldiers without waste of money or energy. There is apparently a lull at the moment in the demand for doctors, nurses, and orderlies, but arrangements have been made by which an almost unlimited number of reserves may be drawn upon.

THE BRITISH RED CROSS SOCIETY.

The Situation well in Hand.

Sir Frederick Treves states that with the dispatch in the last ten days of 21 doctors and 31 dressers every call has now been met, and no more assistance of any kind is needed for British, French, or Belgian troops at Boulogne, Calais, or Dunkirk. Nor has the British Red Cross Society received requests for help from hospitals in other parts of France where wounded soldiers are under treatment. Steps are being taken to stop the rush of unauthorized persons to the front, whether as ambulance or hospital parties. Sir Frederick Treves believed that all the requirements of the wounded are met, and that they have never been better looked after.

Another Hospital Ship.

Thanks to the generosity of Mr. Fielden, the British Red Cross Society has acquired the steam yacht *Paulina* for the purposes of a hospital ship. By royal permission the vessel will be renamed the *Queen Alexandra*. It is being fitted to provide 21 beds for soldiers and three cabins for officers, and will be used for the transport of personnel and medical stores and to bring back wounded in the intervals when the transports and larger hospital ships are not running. The vessel will also be able to convey wounded from one English port to another, and is well adapted for such work.

The Nursing Question.

In reply to the letter from Dr. Albert Wilson, published in the last issue of the British Medical Journal, p. 813, Sir Frederick Treves reiterated his assurance that no nurse has been engaged by the British Red Cross Society since the commencement of the war who is not a fully trained hospital nurse with a certificate of three years.

Co-operation with the St. John Ambulance Association.

As noted in another column, a Joint War Committee of the British Red Cross Society and the St. John Ambulance Association has now been formed in order to prevent any overlapping in the work of the two societies. The joint committee, of which Mr. A. P. Stockings is the honorary secretary, has issued a statement that surgeons and nurses should refrain from lending their aid to private schemes for sending aid to the wounded. The War Office strongly urges this for its own reasons, and Mr. Stockings informs us that although various private parties have been able to do valuable work others have got into difficulties, principally of a financial character. Appeals for aid have then been received by the British Red Cross Society, which, although always ready to help where possible, takes the view that it should have a measure of control over the spending of the grants. It is considered to be in every way better that those wishing to help should work through the Red Cross Society and not as free lances. Only in that way can there be any assurance of fully qualified attendance upon the wounded. Private expeditions have included unqualified persons, and as all members wear the Red Cross badge, misapprehension is likely to occur.

Mr. Stockings mentioned that the Joint Committee has under consideration a proposal to establish a hospital with 2,000 beds in London for sick and wounded soldiers. Pressure upon accommodation, both in military and voluntary institutions, is now severe in all parts of the country. It is hoped that the Government may lend a building suitable for the purpose.

An Anglo-French Committee.

There has been established at the offices of the British Red Cross Society an Anglo-French Committee, whose purpose will be to co-ordinate offers of help for wounded soldiers of the allied armies made by people in this country. Near the fighting line the military authorities will not allow any more hospitals to be established, but much useful aid could be rendered by

hospitals placed in other parts of France. The Anglo-French Committee will act as an intermediary between the French authorities and private persons here who wish to help the French or the Belgians, and it is intended to arrange that all hospitals so established shall be available, in case of emergency, to receive British wounded.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

SOME casualties in the Medical Department of the Royal Navy must have taken place in the sea fight off the coast of Chili, in which the *Good Hope* and the *Monmouth* appear to have been lost, but no official list has yet been published.

ARMY.

Killed.

Since the list of casualties published in our last issue two officers of the Royal Army Medical Corps have been reported as killed. Captain R. C. G. M. Kinkead, who was serving with the 10th Hussars, and Lieutenant Angus Macnab, one of the medical officers of the London Scottish. We intend to publish an obituary notice of Lieutenant Macnab in an early issue, and print below short accounts of the services of Captain Kinkead, and Captain Pockley of the Australian Expeditionary Force.

Captain Richard Crofton George Moore Kinkead was the only surviving son of Professor Kinkead of Galway. Captain Kinkead was born in Galway in 1883, and educated at Erasmus Smith's Grammar School there, and at Portora Royal School, Enniskillen. He received his medical education at Queen's College, Galway, and graduated M.B., B.Ch., B.A.O., in the Royal University of Ireland in 1908. After serving for a year as house-surgeon to the Coventry and Warwickshire Hospital, he entered the R.A.M.C. in 1909. He became captain on January 31st, 1913, and was recently stationed at Bloemfontein. At the end of August he was recalled and attached to the 10th Hussars, with which regiment he went to the front on October 6th. While a student he joined the South of Ireland Imperial Yeomanry, and served four trainings with that corps. He rowed in winning crews for the Royal Galway Club, was a good rifle shot, and a fine horseman. His death is a loss to the service, and deep sympathy is felt with his bereaved father and mother. This has already found expression in the resolution adopted by the County Galway Medical Committee, and in a letter from Dr. Frederick W. Kidd, President of the Irish Medical Association. Captain Kinkead, in a letter written as late as October 26th, spoke of the high spirit and courage of the officers and men with whom he was serving. "The other day," he said, "a farm, where I had been sleeping in a barn, was shelled and set on fire. My corporal, thinking I was still asleep, went into the blazing fire to fetch me out, and was not satisfied until he had searched the whole place. Now, this corporal was one of the 10th Hussars, and had only known me since I came to the regiment—just over two months." Speaking of himself, he said he was fit and well, except for pains in the back and legs, from overstrain of the muscles due to lifting men out of the trenches. This it was necessary to do, as the trenches were very small, and one or two wounded filled up the hole. "If," he added, "we had only had a million and a half of an army of our present standard the Germans would be on the Rhine by now, and the war nearly over."

It is with sincere regret that we record the death of Captain Brian Colden Antill Pockley, aged 24, who was killed whilst serving as medical officer with the Australian Expeditionary Force in its attack on German New Guinea. When the first encounter took place he was called upon to attend a wounded sailor. Finding it necessary to send him to the rear Captain Pockley took off his own coat with the red cross badge and wrapped it round the wounded man. He then went on attending to other wounded. He was in his shirt sleeves and was shot by a German captain, who excused himself on the ground that Captain Pockley was not wearing a badge. Captain Pockley graduated M.B., Ch.M. this year from the Sydney University. As a boy he attended the North Sydney Church of England Grammar School, and both at school and at the university he was most deservedly popular. He was highly esteemed for his fine personal qualities, brilliant scholarship, and all-round athletic prowess. His early death will be most deeply regretted by a wide circle of personal friends. His father, Dr. F. Antill Pockley, of Macquarie, Sydney, was for many years on the Council of the New South Wales Branch of the British Medical Association, and at one time its President. In 1911 he was president of the Australasian Congress, held that year in Sydney.

Macnab, Lieutenant Angus, R.A.M.C.(T.).

Died on Service.

Second-Class Assistant Surgeon Frederick Joseph Bernard, of the Indian Subnedical Department, is reported to have died on service at the front in France. He was born on February 22nd, 1880, entered the department on March 13th, 1902, and attained his late rank on March 31st, 1907. He was on the Madras Establishment and was recently stationed at Malapuram.

Wounded.

Gibson, Captain H. G., R.A.M.C.
Grant, Lieutenant G. R., R.A.M.C.
Littlejohn, Lieutenant C. W. B., R.A.M.C.
O'Driscoll, Lieutenant J. A., R.A.M.C. (Special Reserve).
Osburn, Captain A. C., R.A.M.C.
Thatcher, Lieutenant F. G., R.A.M.C.

Prisoners of War.

Captain B. Johnson, R.A.M.C., reported missing on October 24th, is a prisoner.

Captain W. G. Egan, R.A.M.C., taken prisoner at Landrecies on August 28th, is a prisoner at Crefold, near Düsseldorf.

Missing.

Fraser, Captain A. E. G., R.A.M.C. (previously reported as Captain A. D. Fraser.

Pollard, Captain A. M., R.A.M.C.

NOTES.

REWARDS FOR DISTINGUISHED SERVICE.

Distinguished Conduct Medal.

THE King has approved of the grant of the medal for distinguished conduct in the field to Lance-Corporal J. Jonas, No. 5 Field Ambulance, Royal Army Medical Corps, for bravery on September 14th at Pont Arcy in carrying in under a heavy fire Sergeant Stansfield, 49th Battery, Royal Field Artillery, who was dangerously wounded.

Medaille Militaire.

An Army Order issued on November 7th states that the President of the French Republic has, with the approval of His Majesty the King, bestowed the French military medal for conspicuous services on the following warrant officers, non-commissioned officers and men of the Royal Army Medical Corps, serving with the British Expeditionary Force, in recognition of their gallantry during the operations between the 21st and 30th August.

Sergeant-Major G. W. Carnell.
Quartermaster-Sergeant R. Craig Blair.
Private H. Faun.
Private A. Goodfellow.
Sergeant-Major A. T. Hasler.
Private H. G. Jupp.
Sergeant-Major E. R. Loft.
Sergeant H. M. Prince.
Private A. V. Sworn.

AMBULANCE HELP FOR THE FRENCH.

The British Ambulance Committee has been formed to place at the disposal of the French Red Cross Society such assistance in obtaining motor ambulances as it may be possible for the friends of France in this country to render. The Duke of Portland is the president of the committee, and the British Ambassador in France and the French Ambassador in England are among the members. Mr. G. Cecil-Baker and Mr. B. Peyman are the honorary secretaries, with offices at Queen Anne's Mansions, Westminster. It is hoped to assemble a fleet of fifty cars, divided into units of five, each unit being staffed by a surgeon and two dressers. The ambulances will be placed under the control of the French Red Cross Society. In an appeal to the public issued this week the committee states that it has the support of the Queen, Queen Alexandra, the Prince

of Wales, President Poincaré, and others. The British Red Cross Society has expressed its sympathy. The heavy demands which the size of the French army and its greatly extended front make upon the medical organization are emphasized in the appeal. Since nearly the whole of the active male population of France is under military orders, there is hardly any one left to whom the French authorities can appeal for voluntary assistance, and the local supply of motor cars is exhausted. Subscriptions are invited towards the first £50,000 necessary for the work. Cars may be lent for a minimum period of three months, and be supplied either with or without drivers and mechanics. The minimum cost of conversion is about £50 and the maintenance cost about £10 a week.

We mentioned recently that the Council of the Surrey Branch of the British Medical Association had made an appeal to the profession in the county to subscribe for a motor ambulance. Mr. Cecil P. Lankester, Honorary Secretary of the Branch, 1, Rectory Place, Guildford, says that he has now received £260, but that the fund should amount to £300. It is hoped that the remaining £40 will shortly be provided.

Red Cross Hospital near Boulogne.

The Red Cross hospital which Sir Henry and Lady Norman have organized is being established at Vimereux, a few miles north of Boulogne. Mr. H. M. W. Gray, surgeon to the Aberdeen Royal Infirmary, and Dr. A. H. Lister, physician to the same institution, are senior physician and senior surgeon respectively in charge of the hospital, which will provide about 100 beds.

Hospital at Southall.

A temporary hospital has been established in the recreation institute at the works of Messrs. Otto Monsted, Southall, near Ealing. The building was only erected in 1911. The greater part of the equipment has been provided by public subscription and gifts from residents in Ealing. Surgeon-General Greany, I.M.S.(ret.), will be in charge, and Sir Alexander Ogston, Surgeon-in-Ordinary to the King in Scotland, and Sir Robert Burnet, physician to the King's household, will act as consulting surgeon and physician respectively. The visiting medical officers are Drs. Caley and Lyle, of Ealing, and the emergency surgeons, Drs. Vercoe and Galloway, of Southall. The Ealing Voluntary Aid Detachment has for some months been engaged in the work of preparation, and the medical officers of that detachment who are in charge of wards are Dr. Margaret Dobson, Dr. Ethel Bowlby, Dr. Davidson (Hanwell), Dr. Fenton, jun. (Ealing), Dr. Hill (Chiswick), and Dr. Wallace (Acton). Dr. E. A. Chill is responsible for the general organization. Dr. Felten, a Belgian medical practitioner, who speaks Flemish, has offered his services in case the hospital is called upon to deal with wounded Belgians. Two trained nurses will be in charge of each of the wards, and the members of the detachment will give assistance according to their training.

The Medical Staff of the German Army.

The German medical staff has already suffered very severely in the present war. Up to the middle of October 135 medical officers were reported killed, wounded, or missing, 74 of these having been killed. Among them is Friedrich König, professor of surgery in the University of Marburg, and son of the late Professor Franz König of Berlin; he was killed in action at the eastern seat of war. In the entire Franco-German war of 1870–71 only 11 German surgeons died on the battlefield or from wounds there received. The German medical staff has not escaped the meteoric shower of iron crosses rained by the Kaiser on his armies. According to the *Berliner med. Wochenschrift* of October 19th, that decoration had then been bestowed on 120 medical officers.

Among those who intend to take part in the discussion on Surgical Experiences of the Present War, to be opened at the meeting of the Medical Society of London on Monday next, at 8.30 p.m., by Sir Watson Cheyne, are Sir Frederic Eve, Mr. Arthur Edmunds, Mr. R. P. Rowlands, Mr. D'Arcy Power, Mr. Charters Symonds, Dr. Embleton, and Dr. Ironside Bruce. It is probable that the discussion will be adjourned.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

Aberdeen.

The University and the War.

The opening of the winter session finds two of the chairs in the Medical Faculty of the university occupied by new professors. The vacancy in the Chair of Chemistry caused by the retirement of Professor F. R. Japp, LL.D., F.R.S., after twenty-four years of good work and service has been filled by the appointment of Mr. Frederick Soddy, M.A., F.R.S., formerly Lecturer in Physical Chemistry, including Radio-activity, in the University of Glasgow. It is unnecessary to do more than to refer to the distinguished work that has been accomplished by Professor Soddy. His researches into the phenomena of radio-activity at first carried out in collaboration with Sir William Ramsay and latterly in Glasgow are well known.

Professor Theodore Shennan, M.D., F.R.C.S.Edin., who has been appointed by the Crown to succeed the late Professor George Dean in the Chair of Pathology, is a distinguished graduate of the University of Edinburgh. For a number of years he held the important post of Pathologist to the Royal Infirmary, Edinburgh, and he was also university lecturer in morbid anatomy, and an extramural lecturer in systematic and practical pathology and bacteriology.

The influence of the war is apparent in the number of students who have matriculated for the current session at the university. In October, 1913, 1,024 students of all Faculties entered the university, but this year the number has dropped to 785, of whom 458 are male students. This represents, as regards male students, a reduction of 35 per cent. on last year's numbers. The number of medical students is 214, as against 271 last year, being a decrease of 28 per cent. About 530 members of the university, graduates and students, hold commissions or have enlisted in His Majesty's Forces. Of the students, over 200 are serving in the ranks, and about 40 hold commissions. Of the teaching and research staff, 5 are absent on service. Three professors and six lecturers and assistants, while continuing on duty at the university, are also attached to the 1st Scottish General Hospital.

The election of Rector of the University, in succession to Mr. Andrew Carnegie, took place on Saturday, November 7th, when the Right Hon. Winston L. S. Churchill, M.P., First Lord of the Admiralty, was unanimously elected to the office.

The Hospitals and the War.

The mobilization of the 1st Scottish General Hospital was ordered on August 5th, and was completed within the allotted eight days. The usual number of beds, namely, 520, were provided, and this number has since been increased by 80. In addition the Royal Infirmary have lately provided 50 additional beds for cot cases, while also holding a number of beds at the disposal of the Admiralty. At the beginning of the war a certain number of sick and injured men were received at the infirmary from the fleet in the North Sea, and a proportion of sick from the troops were also received at the 1st Scottish General Hospital. The first batch of overseas wounded arrived at the latter hospital on September 26th, and so far a total of 1,250 wounded men, including 350 Belgians, have been admitted. Half of the patients arrived within one week, and patients already in hospital were transferred to cottage hospitals and Voluntary Aid Detachment formations throughout the Highland divisional area to make room for new cases. This scattering of semi-convalescent soldiers into small hospital formations under Voluntary Aid Detachment nurses has many drawbacks. The morals of the soldier are controlled by the existence of disciplinary powers laid down in King's Regulations. Given the temptations of Scotland's common hospitality, namely, wine and women, military means must be afforded all such Voluntary Aid Detachment hospitals for the protection of the sick and wounded soldier. The Administrator here suggests that authority should be given the Red Cross District Commissioners to obtain from the nearest military dépôt a guard of one or more soldiers for each such hospital formation. This would

help to avoid indiscretions, and would relieve the medical attendant and the voluntary nurses from much anxiety. It is hoped to give some details of the work carried out at the 1st Scottish General Hospital in the course of further communications.

Correspondence.

THE TREATMENT OF GUNSHOT WOUNDS IN THE PRESENT CAMPAIGN.

SIR,—As misconception appears to exist as to the general principles guiding the treatment followed by the medical service, it may be of interest to your readers to be given a short précis.

On the reception of a wound the first field dressing, consisting of a pad of gauze, etc., is applied by a surgeon, a comrade, or the patient himself.

On arrival at the field ambulance this dressing is changed, and the patient is removed to the clearing hospital, where the wound is cleansed, if necessary, and painted freely with a solution of iodine in spirit. Where needful this dressing is repeated during the journey in the ambulance train to the base.

A prophylactic injection of antitetanic serum has been given at the clearing hospital (or in many instances earlier at the field ambulance) during the last month.

At the base hospitals the cases are treated according to their requirements. Bullet wounds of a normal character are covered with a dry dressing of bicyanide gauze, no further antiseptic precaution being necessary. A better example of the success of this treatment cannot be given than in the case of wounds of the chest with haemothorax, in no case of which which has come to our knowledge has suppuration occurred.

Large and septic wounds are dressed with moist antiseptic compresses, the medium varying in different cases, carbolic acid, mercury perchloride, creolin, or lysol being the commoner forms of lotion employed. Beyond this, the wounds are irrigated with hydrogen peroxide, or iodine water (tr. iodi ʒj to Oj). In many cases baths are employed for wounds of the arm, forearm, or leg.

Many of the larger wounds are cleansed under an anaesthetic, and obviously hopelessly damaged tissue removed. In others the wounds are enlarged to drain thoroughly the large cavities usually produced by the fragments of high-velocity shells.

The necessity for the latter forms of treatment is naturally more common when delay in the transport of the patients has been unavoidable.—I am, etc.,

G. H. MAKINS,
Colonel, A.M.S., Consulting Surgeon.

THE WORK OF THE R.A.M.C.

SIR,—I have just returned from France, where I have, with the permission of the Director-General, Sir Alfred Keogh, and by the courtesy of Sir Arthur Sloggett, who is in command out there, seen the hospitals provided for our wounded at Boulogne, and for the Belgian wounded at Calais. I have had every opportunity of carefully studying all the arrangements made for the proper treatment and transportation of our wounded soldiers. I took with me two members of the London Hospital surgical staff, who were directed to stay out and help, if help were needed.

For the peace of mind of the public, and especially of those who have relatives wounded, I do ask to be believed when I say that the arrangements, as far as my hospital experience permits me to judge, are amazingly perfect. The two surgeons were convinced that their services were not required, and they returned to England.

At the hospitals at Boulogne there are not only some of the leading English consultant surgeons to supervise the work and give advice and help when necessary, but, in addition to surgeons belonging to the Army Medical Corps of great skill and experience, there are many Fellows of the College of Surgeons working in the wards. If more are needed they can be obtained in a day.

I cannot, of course, speak as to the treatment of the wounded at the front, but I am well sure that if this part of the work were not being well done there would very soon be severe criticism from the surgeons at the base hospitals.

I have seen the trains arriving from the front full of wounded unloaded. I have seen the wounded taken thence to the hospitals. I have seen them put into the hospital ships for England. I have seen the ships arrive and the wounded taken out of them and put into the hospital trains for all parts of England. Pain, misery, and discomfort there must be, but I wish I had language which would not seem exaggerated to describe the present smoothness and perfection of the whole organization.

A critic determined to find faults will always find them, doubtless, and if such criticisms are sent to the proper quarters I know they would receive every consideration.

But, apart altogether from the organization to which I have already referred, the impression left on me is just this—that the whole spirit of the work our there, both of surgeons and nurses, is not the military, "Go there," "Come here," "Do this," but that everywhere there prevails a tone of sympathy, kindness, and gentleness which makes one's heart beat a little faster to see, and one comes away proud of the men and women who are doing this work with such untiring devotion and forgetfulness of self.—I am, etc.,

KNUTSFORD,
November 9th. Chairman, London Hospital.

ANTISEPSIS AND ASEPSIS IN WAR.

SIR,—May I comment upon the two letters bearing upon this subject in your issue of November 7th? With the letter by Sir Rickman J. Godlee I am in entire agreement, and I think his suggestion for the thorough disinfection of dirt-soiled wounds by swabbing them with pure liquefied carbolic acid at the earliest possible moment after infliction a most timely and valuable one, and I fully concur that it would, if conscientiously carried out, be the means of saving many lives, and probably entirely preventing tetanus and hospital gangrene.

The letter, or rather postscript, of Sir Victor Horsley referring to "the terrible proposal . . . to swab out recent wounds with pure liquid carbolic acid" is, in my opinion, most unfortunate. Sir Victor is rightly considered one of our leading operators, and if I had to have my Gasserian ganglion removed or a tumour excised from my brain I should desire none better to operate upon me. But in this particular instance I venture to assert that Sir Rickman is right and Sir Victor wrong. Sir Victor is accustomed to operating under aseptic conditions, where a clean wound is made under ideal circumstances, but he has probably had far less experience of operating under such conditions as must obtain in war, or even in the common accidents of civil life.

In war particularly it may be laid down as a safe rule that some septic infection is inevitable in every wound, and the only wise course is to nip this in the bud by a thorough and vigorous antisepsis of the wound.

If this is wrong then antisepsis is wrong, and Lister was a false prophet. I venture to think and hope that the majority of surgeons in this country will still adhere to Lister's teaching.

But, I would ask, is the swabbing of a wound with pure phenol a "terrible" matter at all? Has Sir Victor Horsley ever tried it upon himself, or in his practice? Presumably not. I may tell him from personal experience, and from over twenty years' practice, that it is by no means terrible, even if *not* performed under an anaesthetic, whereas under an anaesthetic the patient feels nothing of it at all. I have never had any case of carbolic acid poisoning, or even carboluria from its use, and I have treated every case of compound fracture and most badly soiled recent wounds by it since the method was first brought to my notice by reading Sir Watson Cheyne's advocacy of it many years ago—in his work on wounds and ulcers. Most of these cases, including some bad compound fractures of the skull, with loss of brain substance, have healed without the slightest pyrexia or septic development.

I would add, in conclusion, that besides swabbing with pure carbolic I subsequently wash out with sterile water or weak carbolic, and also cleanse the skin all round the wound, and keep the wound dressed antiseptically.—I am, etc.,

Bowdon, Nov. 7th. P. R. COOPER.

SIR,—It makes extraordinary reading, in your issue of November 7th, to find two of my old teachers taking up such an antagonistic attitude over the subject of treating the wounded. I refer to Sir Victor Horsley's criticism of Sir Rickman Godlee with regard to swabbing the wounds with strong carbolic acid.

The great art of treating wounds is to keep them free from germs, and whilst strong carbolic helps one to arrive at such a freedom by the destruction of the germs (to say nothing of the tissue cells), an equally marked freedom can be obtained by removing all the products of destruction that can act in any way as a breeding ground for these germs.

The destruction by chemicals of healthy cells that are so necessary for repair, imposes an increased burden on the patient in that these healthy cells have to be built up again, whereas the removal of the germ nidus frees the wound of germs and allows the healthy cells an opportunity of doing their work in a satisfactory manner.

Our great desire then should be to obtain asepsis in the easiest way, which in my opinion can be done by spraying petrol on the wounds. Petrol cleans the wound not only of the gross dirt, but also of the half destroyed cells which with the liberated fat form the great breeding bed for the germs, an advantage it possesses over any aqueous solution of a disinfectant, and this combined with its readiness to evaporate helps to render the wound dry—a condition suitable for healing by first intention. Petrol is readily obtainable, non-poisonous, and can be applied by any one before the ordinary field dressing is put on.

The presence of anaërobic organisms which is so marked a feature of the wounds at the front only goes to emphasize the great importance of surface tension in their treatment, and herein lies the value of petrol which tends to modify it in such a way as to interfere with the life-history of these organisms.—I am, etc.,

Swansea, Nov. 7th. G. ARBOUR STEPHENS.

SIR,—It really begins to look as if the conditions now obtaining as regards the surgery of the war were going to bring antisepsis—as opposed to asepsis—into its own again.

As a pupil of Sir Joseph Lister in the eighties, it was antiseptics that I learnt, and the work which has since fallen to my lot in such diverse corners of the empire as Fiji, Cyprus, East Africa, and also on board Indian emigration ships, has convinced me that it could only have been dealt with satisfactorily by such methods. Aseptics, away from the full equipment and surroundings so essential to their reliability, prove a broken reed indeed.

I have found pure carbolic safe to use in certain conditions, as for instance in cases of infective gangrene of subcutaneous tissue due to *Staphylococcus pyogenes aureus* —the introduction of crystals of the glacial acid will often have an almost magical effect, without any hint of carbolism. It seems to be much a question of extent of exposed surface, but no matter of what extent, I have never found that sponging or swabbing with carbolic acid in rectified spirit, 1 in 12 or 15, had other than good results. This solution will also arrest oozing and haemorrhage from multiple small points, and in an emergency, when a lot of small instruments require quickly sterilising, a little of it poured over them in a tin or basin and then a match applied will do the trick effectively.—I am, etc.,

STUART OLIVER,
Surgeon Superintendent Indian Emigration Service.

November 9th.

SIR,—The three letters in your last issue by Sir Rickman Godlee, Bart., Sir Victor Horsley, and Mr. Nicoll respectively show widely divergent views as to the treatment of wounds received in warfare.

In the August number of *Surgery, Gynaecology and Obstetrics*, p. 199, there is a most interesting paper by an American surgeon, Behan, on the treatment of gravely infected wounds seen by him in the last Balkan campaign. Many of the wounded arrived at the base hospital in an indescribably filthy condition, some having only received the first field dressing, and that some days previously. Behan's conclusion was that the best dressing for badly infected wounds was a wet compress of 60 per cent. spirit. Mr. Nicoll shows that pure spirit is as good a preparation for the skin as iodine, and it is known that a 70 per cent. spirit represents the optimum per cent. for the sterilization of organisms in catgut.

During the past two months at the 1st Western General Hospital T.F. (Liverpool) I have had the opportunity of applying this spirit method in treating infected wounds from the front. These cases reach us on an average from four days to a week after being in the firing line, and, therefore, can hardly be so serious as those unable to be transported. Nevertheless, some of the wounds are gravely infected, and present sloughing surfaces 3 in. to 4 in. in diameter. I refer to the badly lacerated shell wounds.

Scissors and forceps are used to remove obvious dirt and pieces of clothing, and the wound is well washed out with a mixture of two parts of methylated spirit and one of water. A compress of gauze wet with the same mixture is then applied, and splinting and drainage used when necessary. No protective is employed. If the wound is sloughy, the compress is changed three or four times daily, but if covered with healthy granulations the dressing is allowed to dry, and is only renewed once daily. The skin does not become sodden and white as with an ordinary watery compress, and the spirit does not interfere with the delicate epithelial margin. It is the most successful dressing I have tried for wounds of this nature. —I am, etc.,

ROBERT E. KELLY, M.D., B.Sc., F.R.C.S.,
Liverpool, Nov. 10th. Captain, R.A.M.C. (T.F.).

SIR,—It was Lord Lister's fate to be misunderstood, misrepresented, and misquoted by his unscientific and uninformed contemporaries for many years while he was yet alive.

It is melancholy to see our JOURNAL once more made by Sir Rickman J. Godlee the vehicle of similar perversions of Lister's scientific principles of surgery. He actually says in your issue of the 7th, "I would remind them" (meaning ourselves, the surgeons of the present day) "that in Lister's early compound fracture cases the wounds were treated rather freely with undiluted carbolic acid without any evil result following."

Fortunately, Lister has left his real opinions on record.[1] He did at first experimentally apply undiluted acid to some cases of compound fracture, but he abandoned that practice immediately he discovered that he could get better results with a 5 per cent. solution in water; and, moreover, what analogy is there between the limited puncture or laceration of the skin in a compound fracture with the severely contused wound caused by a shell or high-velocity projectile? Lister himself laid it down that "undiluted carbolic acid is a powerful caustic," and that the tissues must not be "irritated"; while in respect of his treatment of compound fractures he especially says that the watery carbolic solution is "obviously superior to the strong acid, since it does not produce the slightest sloughing from caustic action"; besides, it may be used on "tissues which are the seat of extravasation with a freedom that could not be used with the acid of full strength."

All this is clear enough, and no one could have imagined that because Lister had experimented on one surgical condition that the method he himself so soon abandoned should now be put forward as Listerian by the late President of the Royal College of Surgeons of England for the treatment of other and even worse conditions.

To prevent once and for all any repetition of these dangerous misrepresentations of Lister's work, I will conclude with one more quotation from the Address in Surgery at the Plymouth meeting in 1871. After dealing in detail with the object of an antiseptic—namely, to disinfect but not to injure—Lister says: "At one time I used the undiluted acid; and in doing this I could not avoid producing not merely irritation, but a certain amount of *sloughing*."

And now, when our wonderful troops are exposed to anaërobic infection and to sloughy wounds, we have Sir Rickman J. Godlee advising that their sufferings and dangers should be aggravated by producing more sloughs and more nidus for the anaërobes.—I am, etc.,

London, W., Nov. 11th. VICTOR HORSLEY.

A MEDICAL WAR INSURANCE FUND.

SIR,—I notice the sad case of the young surgeon killed in the war, leaving a widow and two young children in great temporary distress.[2] Why should dependants of

[1] BRITISH MEDICAL JOURNAL, 1868.
[2] BRITISH MEDICAL JOURNAL, October 31st, p. 776.

brave men be left to endure poverty and privation and be dependent on charity? Why cannot we have a war insurance fund run, say, by the Medical Sickness and Accident Society, to which every British medical man, whether he goes on active service or not, might pay a premium whilst the war lasts, and so insure a certain sum against death by accident, wounds, or disease, or pension if crippled for life. Perhaps those who go to the front might pay a higher premium, or, better still, let their stay-at-home colleagues pay the extra for them.

Let me mention another idea. Judging by the number of the wounded, the surgeons at the front must have a strenuous time of it, and if the work keeps on at the same rate they must be liable to a breakdown from nervous strain and other causes.

Why not, therefore, organize a relief supply of men who, though unable to leave their practices for the duration of the war, could yet spare a month or two to act as locums without fee for the regular men, their own practices being looked after by their colleagues? I should be pleased myself to act as a "war locum."—I am, etc.,

Yarmouth, I.W., Nov. 5th. JOHN THOMARSON, M.D.

NUTRITION AND MEAT EXTRACTS.

SIR,—Answering Professor W. H. Thompson's second letter (BRITISH MEDICAL JOURNAL, October 24th), I have only to remark that neither the stimulating effect of meat extract nor the purely scientific object of Professor Thompson's research was ever called in question by me, either in *Nutrition* or elsewhere, the only point at issue being whether retention of water offered an explanation of the observed increase in weight of dogs when meat extract was added to their diet. Having shown how Professor Thompson's own words justified that suggestion, I do not consider it necessary to ask you to grant space for further discussion of that subject.

I quite willingly recognize that the startling assertion, found on advertisement hoardings and in the public press not long since, to the effect that body weight might be raised to an extent equal to from ten to twenty times that of the meat extract consumed—a doctrine which, unfortunately, arose as a consequence of Professor Thompson's report—cannot have been sanctioned by him, and its abandonment is a further justification of my attitude.—I am, etc.,

London, N., Oct. 31st. CHARLES E. SOHN.

Obituary.

HUGH RICHARD KER, F.R.C.S.EDIN., M.R.C.S.ENG., L.R.C.P.EDIN.

MANY members of the Council of the British Medical Association and a large circle of professional friends must regret to see the death of Mr. Hugh Richard Ker, who was for many years a member of the Council of the Association, a leading member of the Birmingham and Midland Counties Branch, and afterwards of the Metropolitan Counties Branch.

Mr. Ker was the son of the late Vicar of Tipton, Staffordshire, who died only a few years ago, having lived to a very advanced age.

Educated at Guy's Hospital, after an apprenticeship in the Staffordshire Black Country, Mr. Ker settled in practice at Cradley, Worcestershire, where he soon became extremely successful, having a large connexion, not only amongst the various ironworks and collieries, but among the residents around. After some years Mr. Ker took a partner and went to live at Halesowen, a few miles away, still keeping up his old connexion; in 1890 circumstances led to his removing to London, where he practised up to his recent illness and death. While in Birmingham he was for seven or eight years one of the representatives of the local Branch on the Central Council of the Association; he was one of the most assiduous in his attendance at the quarterly meetings and was frequently selected for work on important committees. He was also President of the Midland Medical Society. After removal to London he held the offices of President of the Metropolitan Counties Branch, President of the South-West London Medical Society, and represented the Metropolitan Counties Branch on the Council of the Association, retiring from the latter position in 1910. His industry, ability, and genial nature secured him success in all that he undertook and gained him troops of friends. At one time Mr. Ker undertook a certain amount of operative surgery, for which he possessed much skill and a good deal of enthusiasm, but recognizing the incompatibility of combining serious operative work with a large general practice, he gave it up some years before he retired from the Birmingham district. He will be long remembered as a loyal and worthy colleague by those who had the pleasure of working with him, and by his death the Association has lost a staunch supporter and friend.

Professor SAUNDBY writes: I see with much regret the death of my old friend and colleague, Mr. Hugh Richard Ker. I know that he has been in ill health for some months, and I was asked to see him last summer, when his condition was very unsatisfactory, and left his friends little hope of his recovery. Mr. Ker was my colleague in the representation of the Birmingham and Midland Counties Branch from 1885 to 1890, and when I joined him as a newcomer he behaved to me in the kindest and most loyal manner. We used to sit together, sharing information and helping each other in the work that came before us, so that I always felt that I owed very largely any success I met with in the work of the Council to the instruction and assistance Mr. Ker gave me during those years. Mr. Ker was an enthusiastic fisherman and his chief holidays were spent in the pursuit of this favourite sport. His patients were devoted to him, and I am sure that his death will be regretted by a very large number of people inside and outside the medical profession.

H. J. JOHNSTON-LAVIS, M.D.,

SOMETIME PROFESSEUR AGRÉGÉ, ROYAL UNIVERSITY OF NAPLES.

WE regret to have to record the death of Dr. Johnston-Lavis, of Beaulieu-sur-Mer, and Vittel, which occurred on September 10th, near Bourges, in the department of Cher, as the result of a motor accident. Henry James Lavis, who in later life added his mother's name to his original patronymic, was descended from a Huguenot family settled in Devonshire. He was born in 1856, and after receiving his early education at a private school in England and at Marseilles, entered University College, London, as a medical student in the early seventies. He afterwards migrated to St. Mary's, and pursued his studies at Marseilles and Lyons. He became M.R.C.S.Eng. and L.S.A. in 1878, and took the degree of Bachelor of Science at Paris in 1879. After holding some appointments in this country he settled as a consulting physician in Naples in 1880. He took the degree of M.D. there in 1884, and was medical adviser to Sir William Armstrong's works at Pozzuoli from 1892 to 1897. During that period he practised during the summer season at Harrogate. He left Naples in 1895 and, having taken the degree of M.D. at Lyons, practised in the winter at Beaulieu on the Riviera, where at different times he had the late Lord Salisbury and Mr. Gladstone among his patients. He was consulting physician and founder of the Queen Victoria Memorial Hospital at Nice. In 1909 he established a summer practice at Vittel in the Vosges, where he was one of the physicians to the Etablissement des Bains.

He was the author of numerous contributions to medical literature, including a paper on physiological disequilibrium or chronic toxaemias and their treatment, which appeared in the *American Journal of Physiological Therapeutics* in 1911; reports of cases illustrating chronic toxaemia and the effect of the Vittel treatment in such conditions, and an analysis of a series of cases of hypertension and hypotension treated at Vittel, all published in the BRITISH MEDICAL JOURNAL in 1910, 1912, and 1913; and a case of gonococcic empyema, published in the *Proceedings of the Royal Society of Medicine* in 1912.

Lavis was a distinguished geologist. At University College he came under the influence of Professor John Morris, and he was elected a Fellow of the Geological Society when only 19, and before he was 21 he had written several papers on geological subjects. At Naples he became interested in vulcanology and was associated with Professor Palmieri, of whom it used to be said that he

kept his finger on the pulse of Vesuvius. Lavis kept a diary with photographic records of the action of Vesuvius, and prepared a geological map illustrating the past history of the volcano with petrological studies of its ejected materials. These studies, says a writer in *Nature*, led to one of his most important memoirs, undertaken in conjunction with Professor J. W. Gregory, in which the non-organic nature of the one-time famous *Eozoön canadense* was finally demonstrated. Lavis also did much useful work on vulcanology and seismology of the whole South Italian region. He was for some years *agrégé* Professor of Vulcanology in the University of Naples, and was offered the post of director of the Vesuvian Observatory. Only a few months ago he was awarded the triennial Perkin Prize of £100 in the gift of the Royal College of Physicians of Edinburgh, as recorded in the British Medical Journal of June 6th, 1914. The subject proposed for the thesis was "On the effects of volcanic action in the production of epidemic diseases in the animal and in the vegetable creation and in the production of hurricanes and abnormal atmospherical vicissitudes." His graduation thesis at Lyons dealt with the part played by edible molluscs in the diffusion of gastro-intestinal disorders. He was also the author of a *Monograph of the Ischian Earthquakes* and of a *Great Geological Map of Vesuvius*. He was a man of remarkable intellectual versatility and untiring industry; he was the author of more than 160 papers on volcanoes, earthquakes, mineral waters, and medical subjects. He was for many years a regular attendant at the meetings of the British Association for the Advancement of Science, and had made expeditions to Iceland and a number of other places for the purpose of scientific exploration.

Personally, Lavis was a man of great charm of manner and of an obliging disposition. His conversation was made particularly interesting, not only by the largeness and variety of his knowledge and experience, but by the lucidity of his thought and the clearness of his expression. He married a French lady, and leaves a family.

SIR JOHN READE, K.C.B.,

ARMY MEDICAL STAFF (RETD.).

Surgeon-Major-General Sir John By Cole Reade, K.C.B., Army Medical Staff (retired), died at 25, Coleherne Road, Earl's Court, on November 5th, aged 82. He was the son of George Hume Reade, staff surgeon, and colonel of the 3rd Regiment, Canadian Militia, and was born at Perth, Upper Canada, on July 7th, 1832. He was educated at Edinburgh University, took the L.R.C.S.Ed. in 1854, and entered the army as assistant surgeon on March 24th, 1854. He became surgeon in 1866, surgeon-major in 1873, surgeon-major-general in 1888, and retired on April 1st, 1893. His last five years' service were spent as professional assistant to the Director-General, A.M.S., at the War Office. He had a long list of war service and of honours. He served in the Crimea in 1854-55, and was present at the battle of Alma, the sortie of October 26th, the battle of Inkerman, the assaults on the Redan on June 18th and September 8th, and the siege of Sebastopol, where he was wounded. He received the medal with three clasps and the Turkish medal. In the Indian Mutiny in 1857–58 he took part in the actions of Cawnpore, the siege and capture of Lucknow, the attack on Fort Rooya, the action of Aligany, the battle of Nawabganj, the passage of the Gumti river, the occupation of Sultanpur, the affairs of Bonki and Sitka Ghat, and the Oudh campaign, receiving the Mutiny medal with the clasp for Lucknow. Lastly, he served in the second Afghan war of 1878–80, was present at the relief of Kandahar, was mentioned in dispatches, and received the medal. He was made C.B. on May 29th, 1886, K.C.B. in 1903, and was granted a distinguished service reward in 1892. He was appointed honorary surgeon to the late Queen in 1895, and retained that honour under King Edward and King George. He received also the Diamond Jubilee medal in 1897, and the Coronation medals in 1902 and 1911. He was a Knight of Grace of the Order of St. John of Jerusalem.

Temporary-Surgeon Albert Evelyn Fairfax Kynaston, R.N., of H.M.S. *Devonshire*, died on October 13th of enteric fever at Dunskaith Hospital. He was the second son of the late Mr. Albert Edward Kynaston, of Falkingham, Lincolnshire. He had only recently qualified and joined the navy for the war, in fact his appointment to the navy in the *London Gazette* was published in the *Times* of October 28th, two weeks after his death.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

The following degrees have been conferred:

M.D.—A. Abrahams, A. Feiling.
M.B.—C. G. H. Campbell, R. A. Ramsay.
B.C.—C. G. H. Campbell, G. L. Keyner, F. G. Lescher.

The Raymond Horton-Smith Prize has been awarded to P. H. Bahr. Subject: Research in Sprue.

UNIVERSITY OF LONDON.

MEETING OF THE SENATE.

A meeting of the Senate was held on October 21st.

Acting Vice-Chancellor.

Sir Alfred Pearce Gould was appointed to act for the Vice-Chancellor during Sir Wilmot Herringham's absence as Consulting Physician to H.M. Forces at the seat of war.

Medical Students and the War.

It was resolved:

That the regulations in medicine for internal and for external students be amended as follows:

By the addition of the following footnotes to the Red Book (1914-15), Sections (3) and (10) on p. 191, with a cross reference to the last paragraph on p. 190; and to the Blue Book, September, 1914, Sections (3) and (10) on p. 230, with a cross reference to the paragraph headed "Certificates" on p. 229:

Footnote 1.—During the continuance of the war students who have not passed the second examination for medical degrees in anatomy and physiology, but who have completed one year's study after passing the first examination for medical degrees, will be allowed to count not more than six months' service as clinical clerk or not more than six months' service as surgical dresser in a recognized hospital as if they had so passed the examination in question.

Footnote 2.—Clinical service during the continuance of the war, for any period of not more than twelve months in a medical unit of the Regular or Territorial Forces, or in a hospital or detachment of the Red Cross Society or in any hospital recognized by the military or naval authorities for war purposes, will be accepted by the University as equivalent to the medical and surgical practice in a recognized hospital for an equal period; and, further, any portion or the whole of the time so spent will be accepted as equivalent to time spent either as a clinical clerk or as a dresser, at the choice of the candidate.

Clinical service during the continuance of the war, as set forth above, will be similarly accepted for a period not exceeding six months from students who have not passed the second examination for medical degrees in anatomy and physiology, but who have completed one year of study after passing the first examination for medical degrees, as if they had so passed the examination in question.

(10) That the following addition be made to the regulations for the M.D. (Branch I) and M.S. (Branch I) for internal and external students respectively (Red Book, 1914-15, pp. 201, footnote ‖, and 209, footnote §; Blue Book, September, 1914, pp. 238, footnote 1, and 245, footnote 2):

A temporary commission held during the continuance of the war either in the Royal Army Medical Corps or the Royal Navy Medical Service will be considered as equivalent to an approved appointment for the purpose of this regulation.

(11) That in the case of foreign students of allied nationality the principal be authorized to deal with the question of the fees payable by such students for examination under Statute 116.

Regulations for the M.D. and M.S. Examinations.

Amendments were made in the regulations for the M.D. and M.S. examinations to come into force in 1917. Copies of the amended regulations may be obtained on application to the University.

Chelsea Physic Garden.

Dr. E. G. Graham Little was reappointed a member of the Committee of the Chelsea Physic Garden.

Faculty of Medicine.

Sir Alfred Pearce Gould has been appointed Dean of the Faculty of Medicine for 1914-6.

Physiological Laboratory Committee.

Sir David Ferrier, F.R.S., has been elected chairman for 1914-5.

Lectures.

A course of five lectures on the biology of the acid-fast bacilli was given at the Royal College of Surgeons of England by Mr. F. W. Twort, Superintendent of the Brown Sanatory Institution, on November 9th, 10th, 11th, 12th, and 13th.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE annual general meeting of the Fellows and Members will take place at the College on Thursday next at 3 p.m. Mr. Sidney C. Lawrence, Honorary Secretary, 22, Latymer Road, Lower Edmonton, N., informs us that the following resolution will be moved by Sir Victor Horsley and seconded by Mr. George Jones:

That this thirtieth annual meeting of Fellows and Members again affirms the desirability of admitting Members to direct representation on the Council of the College, which as now constituted only represents those Members who also hold the Fellowship; and that it does so in order that the constitution of the Council of the Royal College of Surgeons of England shall be in keeping with modern ideas of true representation.

[A note on the Annual Report of the College to be presented to the meeting is published in the SUPPLEMENT, p. 236.]

Medical News.

SIR HENRY GREENWAY HOWSE, late President of the Royal College of Surgeons, left estate of the gross value of £30,367, of which £21,183 is net personalty.

AT a meeting of the Section of Dermatology of the Royal Society of Medicine on October 15th, the President, Dr. J. J. Pringle, announced that it would meet as usual during the forthcoming session. A number of interesting cases were then demonstrated.

THE Local Government Board has revised its memorandum of September 25th on the care of Belgian refugees. Local committees can obtain copies on application to the county or county borough council or the urban district council as the case may be.

THE meeting of the Pathological Section of the Royal Society of Medicine which was to have been held on November 17th has been postponed until Tuesday, December 1st, when Professor S. G. Shattock and Dr. Dudgeon will read a paper in the course of which they will discuss the subject of cytocides.

AT a general meeting of the Medico-Psychological Association of Great Britain and Ireland to be held at the rooms of the Medical Society of London under the presidency of Dr. D. G. Thomson on Tuesday, November 24th, at 3.30 p.m., the chief business will be to consider the holding of meetings, etc., during the war.

ACCORDING to the New York *Medical Record*, Dr. Louis Livingston Seaman, whose name is well known as the author of a book on the Russo-Japanese war, has resigned his commission as First Lieutenant, Medical Reserve Corps, U.S.A., in order to be free to tell what he saw of the horrors of war as carried on by the Germans in Belgium, President Wilson having forbidden officers of the army and navy to comment on the situation.

MEMBERS of the medical profession who are not Fellows are invited to attend and take part in the discussion on enteric fever in war and the means for its prevention, which will be opened by Sir William Osler before the Society of Tropical Medicine and Hygiene on Friday next, at 8.30 p.m., at the house of the Medical Society of London. A précis of Sir William Osler's paper can be obtained on application to the secretaries at the above address.

IN the list of mayors elected on November 9th are the following members of the medical profession: Dr. S. R. Alexander, Faversham (re-elected); Dr. J. P. Atkinson, M.D., Saffron Walden (re-elected); Dr. R. Jones Evans, Pwllheli (re-elected); Dr. W. G. Gordon-Munn Norwich (Lord Mayor); and Alderman Dr. Hale Puckle, Bishop's Castle (re-elected). Drs. Alexander and Atkinson have now been re-elected to the office of mayor four times in succession, while Drs. Hale Puckle and R. Jones Evans are re-elected for a second period.

THE Local Government Board in England has issued a circular to sanitary authorities pointing out the importance of having in immediate readiness adequate arrangements for dealing with any cases of small-pox which may appear. Under present conditions the introduction of the disease is not unlikely, and the prevention of the spread of the disease, if it should appear, will depend almost entirely on the efficiency of the arrangements made previously for dealing with and following up early cases. The circular is accompanied by memorandums on the steps to be taken on the notification of a case of small-pox, and in places where small-pox is prevalent. Copies of the circular letter and memorandums have also been sent to medical officers of health, county councils, and boards of guardians.

Letters, Notes, and Answers.

☞ *Queries, answers, and communications relating to subjects to which special departments of the* BRITISH MEDICAL JOURNAL *are devoted will be found under their respective headings.*

QUERIES.

A BELGIAN doctor at present staying in the country will be glad to receive hospitality in London where he desires to study. He is accompanied by his wife, their two children, aged 6½ and 4 years, and a nurse. Communications should be addressed to Dr. Alfred Cox, 429, Strand, London, W.C.

R. S. asks whether the mushroom known locally in the north of England as "blue-stalks," and said to be much appreciated as an article of diet in some town districts, is wholesome, and whether it requires any special preparation, whether it must be freshly gathered and whether it requires to be cooked in any particular manner. The stalk bulb has a violet-blue staining.

HEREDITARY HYPERIDROSIS.

A. C. asks for advice or references on the following case: A married man, whose disease (hyperidrosis?) is as indicated below, wishes to know: (1) If, were he to have a child, it would probably be afflicted, as he has been, since infancy; (2) is there any treatment which, if applied early and thoroughly to a similarly affected child, would make its life much more comfortable than his has been? The patient's father suffered from it, and likewise the following relations of the father—namely, two of his four sisters, his mother and his maternal grandfather. A remote connexion of the family also had it in a slighter degree, and in this case, too, it was hereditary. The case is, briefly, that the patient has never been able to move about for more than ten minutes without the feet becoming hot and inflamed, so that further walking is painful and difficult and causes subsequent tenderness. But tenderness is often present even without previous walking, this being remarkably the case during the first hour or so after rising in the morning. The sweating has been greatly diminished by *x* rays, and the keratosis on the pressure areas of the soles of the feet has been reduced from time to time by various treatments.

ANSWERS.

SIR JAMES BARR (Liverpool) writes as follows in reply to questions in the JOURNAL of November 7th:

Thyroid extract, 5 or 10 grains daily, and decalcifying agents such as phosphoric acid are fairly effective in the treatment of enlarged prostate. I tried *x* rays in a case without any beneficial effect.

Regarding the case of perihepatitis "M.B." should see whether there is any marked deficiency of hydrochloric acid in the stomach, and whether the *Bacillus coli* has become an inhabitant of that organ. This not infrequently happens, and if it be the case with his patient, the treatment is fairly obvious.

Q.—*Mentally Defective Children*, by Alfred Binet and Th. Simon, M.D., being an authorized translation by Dr. Drummond, of Edinburgh (Crown 8vo, cloth, price 2s. 6d. net. London: Edward Arnold), contains in an appendix the Binet-Simon tests in their latest form given in full, with the diagrams and illustrations necessary for certain of the tests. Another convenient explanatory pamphlet is published by Henry H. Goddard, Ph.D., Psychologist to the Training School, Vineland, N.J., U.S.A. It contains sixteen pages, price 15 cents (8d.), and can be obtained from the above address. A larger work by the same author has recently appeared. Binet published his tests in *L'Année Psychologique* (1905). The most generally useful work on the subject is *Mental Deficiency (Amentia)*, by A. F. Tredgold, 2nd edition (London, 1914, Baillière, Tindall, and Cox, price 12s. 6d.).

LETTERS, NOTES, ETC.

A CORRECTION.

THE opener of a discussion at the Ophthalmological Congress at Oxford last July on compensation for eye injuries, a short account of which was given in last week's JOURNAL (p. 803), was Dr. William Robinson of Sunderland, not Dr. Robertson, as printed.

Remarks
ON
THE TREATMENT OF WOUNDS IN WAR.

Made in opening a Discussion at the Medical Society of London on November 16th, 1914,

By SIR W. WATSON CHEYNE, Bart., C.B., F.R.S., Etc.,
President of the Royal College of Surgeons of England.

Mr. President and Gentlemen,—I propose to-night to limit my share in the discussion on surgical experiences in the present war to the treatment of injuries sustained from missiles. The treatment of these injuries naturally falls under two headings:

1. The treatment of the wound itself; and
2. The treatment of the various injuries which may be done to the structures or organs through which the missile passes.

It seems to me that at this stage of the war the most urgent and profitable heading to discuss is the first—namely, the treatment of the wound as a wound, apart from the other injuries which may be present. As regards the latter, we can as yet only speak of individual cases, which, however interesting to the surgeon himself, are not sufficiently numerous or advanced to enable us to make any fresh generalizations apart from those which have already been made in connexion with other wars.

Character of Wounds in this War.

Naval wounds are, practically entirely, caused by fragments of shell or portions of the ship itself broken up by the shells, and these produce large, ragged, lacerated wounds which cannot scab over, and where bones are injured they are very much broken up. We have not had from our ships a single instance of a bullet wound, but we had some bullet and also some shrapnel wounds among the marines from Antwerp. A considerable number of the wounds have also been complicated with burns, while in many cases there have been burns without any wound, as the result of the explosion of the enemy's shells or of our own.

In the case of the army, a large proportion of the wounds are due to the sharp-pointed, narrow bullets, many of which pass through the tissues and leave only small apertures of entrance and exit, which scab over and seldom require any treatment for the wound itself. Occasionally, however, for various reasons, the wound of exit may be large, in which case sepsis may occur there. The round shrapnel bullets make larger orifices of entrance and exit than the rifle bullets, and do not so often scab over, while if they fracture bones the injuries are much more severe. The wounds with portions of shell resemble those met with in naval warfare.

The Prevalence of Sepsis.

Now the first thing which strikes every one who is actively engaged at the present time in the treatment of the wounded, whether on land or sea, is the great prevalence of sepsis. Giving my own experience of naval cases, *all the wounds which I have as yet come across have been septic*, some of them very badly so. I hear also that those who are working at the army hospitals are having a large amount of sepsis in shell and shrapnel wounds, and in addition, at any rate while our army was towards the centre of the line, were having a good many cases of tetanus and acute spreading gangrene. So far, we have not had tetanus in the naval wounded, and that is, of course, natural, for, seeing that the tetanus bacillus reaches wounds from the soil, it is only those wounded on land who would get their wounds contaminated with this organism. And, probably for the same reason, I have not met with a case of acute spreading gangrene.

It is a very serious matter that all the larger wounds which arrive at the base are septic. It is true that in some the sepsis is not so severe as to threaten the life of the patient, but it is no light thing for a wound to become septic. Once get sepsis into a wound, especially a compound fracture or a wound of a joint, and you have no certainty as to what the result may be. The patient may lose his life from one or other of the septic diseases, or his limb may have to be removed in order to save his life. His convalescence will be prolonged and may be interrupted by the occurrence of fresh abscesses, while he will suffer much pain. He may be left with serious deformities from the difficulty of replacing parts or of keeping them in proper position on account of the septic wound; and as the result of the extension of the inflammation and suppuration to the various parts in the neighbourhood, structures become matted together and great disability may ensue.

Its Causes.

It is now exactly fifty years ago since Lister formed the opinion that the cause of septic wound troubles was the entrance of bacteria into the wounds, and since he first put that idea to the test in a case of compound fracture. And in that case he saw for the first time in his experience a compound fracture following the course of a simple fracture and not undergoing suppuration. His earliest communication on the subject of the treatment of wounds dealt with compound fractures, most of them severe cases and much soiled, and he was able to record a number of aseptic results and to observe various phenomena, such as the organization of blood clot, which only occur in an aseptic wound. During the rest of his active life he had to treat many compound fractures and other serious injuries, and with some exceptions, to which I shall presently refer, he obtained aseptic results.

You may well ask, then, why are we not having the same experience to-day in this war? Why are all the large wounds which reach us from the front in a septic condition? For this there are several reasons. One very important point which affects this question of septicity in these wounds is the length of time which may elapse after the injury before the patient comes under treatment. The conditions in the army and the navy are very different from those in civilian practice. In the latter the patient can generally be attended to within a very short time after the infliction of the injury, and can be transported quickly to his own home or to a public or private hospital, where the immediate and subsequent treatment can be at once carried out under the most favourable circumstances and without any further movement of the patient.

In the Army.

In the case of the army the wounded must lie where they fall and cannot be attended to perhaps for many hours. Formerly, where there was not such a terrific hail of missiles over the field of battle, and where, perhaps, a greater feeling of humanity existed, and where also the distances between the combatants were not so great, the Army Medical Corps went out with ambulance wagons and were engaged during the progress of the battle in ministering to the wounded and in picking them up and removing them to a region of comparative safety at a short distance away. The ambulance wagons and dépôts for first aid were respected as far as possible by the combatants, and though the members of the Army Medical Corps exposed themselves to great dangers, still it was possible in many cases to commence the treatment of the wounded comparatively soon after the infliction of the wound; and further, battles were over usually in a few hours. At the present time the condition of matters is quite different. In many instances it would be madness to attempt to pick up the wounded while the engagement is going on, not only on account of the tornado of missiles, but also because the combatants are often too far apart for the Red Cross badge on the arms of the men, or even on the wagon, to be recognizable even if it were respected. Besides, the presence of the wagons and men wandering about the field might give important information as to the position of the combatants. The result is that the wounded often cannot be attended to for a long time, sometimes, indeed, we hear of forty-eight hours or longer having elapsed before they are collected, and in the meantime the wounds are becoming more and more infected. It is true that where a medical officer is present in the trenches he may be able to do a little, but only very little, in the way of treatment.

Again, when the wounded have been collected, they must nowadays be removed for a considerable distance, sometimes a good many miles, to the field or temporary hospital, and naturally with enormous numbers of wounded this transport cannot be carried out in a particularly

expeditious or comfortable manner. Even at this field hospital the patient is not at rest: he can only remain there while those parts of the treatment that are most essential are carried out, and then he is sent on to the base. At the field hospital, however, the treatment of the wound itself can be carried out, at any rate in the more serious cases, but in many cases it is not till the patient reaches the base that full attention can be paid to the injuries caused by the missiles.

In the Navy.

In the case of the navy the conditions are also very unfavourable. In the old days the wounded were carried down from the deck to the surgeon's quarters as soon as they fell, or very soon afterwards; nowadays the surgeons and non-combatants on a battleship are all kept below, and only those actively engaged in the fight are on deck, and consequently the wounded must lie where they fall till the battle is over, or, at any rate, till a lull in the fighting occurs. From the battleship the wounded are transhipped as soon as possible to the carrier or hospital ship, from which again they are transferred to the hospital at the base, but the treatment of the wounds can be commenced as soon as they get on board the carrier or hospital ship. So far the wounded have been sent back to the base in a destroyer or other quick war vessel, but this is very unfortunate for them, as a doctor is not as a rule carried on board a destroyer, and little or nothing can be done for them during the transit—at any rate, in the way of remedying sepsis. It seems to me that wherever possible a hospital ship should be in the neighbourhood of the action, and the badly wounded should be taken on board it as soon as possible; or, if this is not advisable, doctors, orderlies, and dressing materials should be transferred to the destroyer so that the treatment of the wounds may be commenced at once. The position of the hospital ship and the transference of the wounded is, of course, a matter dependent on the military necessities of the case; but the commander should always have present in his mind the supreme importance of the immediate treatment of the wounds, and the inadvisability of allowing several hours to elapse before they can be attended to. The point is not the speed with which the wounded can be got ashore; it is the earliest time that treatment can be commenced, and this, of course, can be begun at once on board ship if the necessary means are at hand, however slowly the vessel proceeds to the base. The naval wounded have therefore an advantage over the army in that the wound is not so much soiled, and can, as a rule, be attended to sooner; they have the disadvantage that the wounds as a whole are more severe.

Now, as I shall presently point out, the chances of rendering a wound aseptic are comparatively small after twenty-four hours, and practically *nil* after forty-eight hours; indeed, after that time I should not make any attempt to disinfect the wound. If, therefore, the case does not come under treatment within twenty-four hours, I do not think that we can blame any surgeon or any system of treatment for the septicity of the wound.

Disinfection of Wounds.

But, in spite of the above disadvantages, a large number of cases do come under suitable conditions for treatment within the period of time that I have laid down, and that being the case, a considerable proportion of these patients should reach the base with aseptic wounds. This leads us to the question of the disinfection of the wound—a branch of the treatment of wounds which, I fear, is but little taught in the schools. Lister's experience and practice in this matter are forgotten, if, indeed, they are now known.

This omission really arises from the want of precision and the carelessness which is creeping into the treatment of wounds at the present time. I do not make this as a universal charge by any means. There are many surgeons who take the very greatest care, whose operations it is a pleasure to watch, and whose results are excellent. But there are others who do not seem to have got a proper grip of the matter, and whose results leave much to be desired. They follow the fashion in having a well-finished operating theatre, and in dressing themselves up in the most approved and elaborate fashion, and in having instruments and dressings sterilized, but they end there. They forget the ubiquity of bacteria, and that their instruments, gloves, etc., may lose their sterility during the course of the operation; they deride antiseptics. If suppuration occurs in the wound afterwards, they ascribe it to all sorts of causes, such as the silk, catgut, migration of bacteria, gout, influenza, etc.—to anything rather than the real cause—namely, their own faulty manipulations. And their example is naturally followed by those whom they teach.

In one of my books I placed at the beginning as a motto the following sentence: "Suppuration in a wound made by a surgeon through unbroken skin is due to some error on the part of the surgeon." This gave great offence, but it is absolutely true, and unless a man takes that view and, when things go wrong, searches his own procedures to see where the error was, I quite despair of his ever being a trustworthy aseptic surgeon.

The Risks of "Asepsis."

To exemplify the carelessness which is not uncommon in the treatment of wounds, I could entertain you for the rest of this meeting in telling you the quaint things which are done by those engaged in operations, and the constant opportunities which are afforded for the entrance of bacteria during an operation, and the crude ideas which are abroad as to "asepsis" and "sterilization."

I saw an operation the other day; everything had been sterilized, a dry sterilized towel was spread out on a table, the boiled instruments were turned out on this towel, and were then arranged by a nurse, who did not wear a mask. Something excited her attention, two other nurses came up, also unmasked, and the three became agitated, all bending over the instruments and talking at the same time; people were coming and going, and at least twenty minutes elapsed between the time that the instruments were turned out and the commencement of the operation. Were they still aseptic? and yet the surgeon comes in completely booted and spurred, innocently picks up a knife, and goes on with the operation. Is it any wonder that that surgeon has a good deal to say about catgut, silk, and so-called stitch abscesses?

I am always very suspicious of so-called sterilized towels and swabs, especially in work in private. They are often placed in a sort of potato steamer for a few minutes, an apparatus which would take hours to cook a potato, and therefore if I do not know the nurses, I always order the towels to be boiled in a pan for half an hour, and not touched before I arrive. Well, in one case nurses were sent out from a large aseptic hospital who were said to be fully trained and most excellent. They received my instructions about the towels, and on my arrival I found a very small, poky room with very few dishes in it (not the palatial apartments in which some of my more fortunate *confrères* are accustomed to operate). I looked about for my towels, but could see no trace of them. I therefore called the nurse and asked her for them. She lifted the lid of the commode, and there were my aseptic towels, reposing at the bottom of the nightstool—another source of *coli* infection of wounds which is worth remembering.

A fresh instrument is wanted during an operation, or an instrument falls on the floor. It is popped into some boiling water and presented to the surgeon "sterilized" within a minute! and so on.

A surgeon is doing an intestinal anastomosis, clips away mucous membrane, rinses his scissors in some salt solution, leaving the tags of mucous membrane and portions of faeces in the basin, and when his hands become sticky, rinses them in the basin repeatedly during the course of the operation. When an abscess containing *Bacillus coli* forms, he is much interested and refers to the remarkable habit that *coli* bacilli have of wandering through the coats of the intestine in cases of intestinal anastomosis, separation of adhesions, etc. This pernicious habit of the *Bacillus coli* seems to be particularly common in operations in the pelvis. It never seems to occur to the surgeon that he has introduced the sepsis during his operation, and that migration of bacteria, if it occurs at all, only takes place through the inflamed wall of the intestine.

I think the man who annoys me most is the boiled water man!

Some surgeons seem to take a particular pride in emphasizing their contempt for antiseptics and the extreme simplicity of their methods. A surgeon comes to an operation and finds a dish containing some fluid. He asks what that is, and the nurse, who has been carefully trained in real aseptic work, says, in fear and trembling: "That is carbolic lotion for your instruments." It is most

instructive to see the look of contempt on the surgeon's face as he says: "Carbolic lotion! Who on earth uses antiseptics nowadays? I thought that no one out of an asylum ever thought of them. Take it away and bring me a bowl of boiled water." He does not disinfect his hands, but trusts to the protection of boiled gloves, which, however, are soiled at the very beginning by being put on with unsterilized hands. He thinks that he is no end of a great man, and the unfortunate thing is that the nurses and students think so too and follow his fatal example. I wonder whether, if such a man had a son at the front at the present time, he would feel happy in the thought that the only thing that the surgeon had at hand for the treatment of wounds in war was a basin of boiled water! The futility and littleness of it all makes me sick.

The result of this slackness is that a good many men are being sent out from the schools every year who are not impressed with the bacteriological problem involved in the treatment of wounds, or who have come to believe that no such problem is involved, while they have become thoroughly impregnated with the idea that the use of antiseptics is an abomination, and that no surgeon who has any self-respect left, or who is not in his dotage, would ever think of using them. When they are confronted with soiled wounds, such as occur on the field of battle, they do not know what to do or how to proceed, beyond painting the skin with iodine and covering the wound with a piece of gauze. The consequence is that the bacteria get a firm hold on the tissues before any means which might have been efficient in the first instance can be adopted. Hence the results which Lister obtained with compound fractures at the very beginning of his work fifty years ago, and which he continued to obtain subsequently, are not being met with in the present war.

The answer, then, to the question, Why do practically all wounds in the present war become septic? is threefold: (1) Because there is often long and unavoidable delay in collecting the wounded and commencing treatment; (2) because the wounds may be very large and complicated and almost impossible to disinfect thoroughly; and (3) because in a good many cases no attempt is made to disinfect these wounds, or, if it is made, it is utterly inefficient.

Treatment of Wounds in the Present War.

How, then, should the large open wounds which occur in warfare be treated? The treatment of these wounds may be considered under two headings, according to the time at which they come under the notice of the surgeon—namely, (1) those which can be treated during the first twenty-four hours after their infliction; and (2) those which are only met with at a later period, when sepsis and suppuration are already established.

1. *Treatment of Wounds which come under the Surgeon's Care within the first Twenty-four Hours after their Infliction.*

Let us consider the condition of such a wound from a bacteriological point of view, and here I shall only speak of the larger wounds sometimes caused by bullets and wounds caused by fragments of shell or by shrapnel bullets. Wounds due to the modern small bullets, when they pass directly from one side of the body to the other without injuring bone or becoming deflected, are very small and sometimes difficult to find, and usually scab over and close without any further attention than a piece of dry dressing, unless some important internal structure has been injured.

With regard to the larger wounds, they must, of course, be widely infected with bacteria at the time of their infliction—at any rate, to a considerable depth; and not only is the wound infected at the moment of injury by the bacteria carried in from the skin and clothing by the fragment of shell, but it very rapidly becomes much more seriously infected by dirt from the clothing or from surrounding objects, and, in the case of land warfare, by the soil of the place in which the wound is inflicted.

These large wounds are consequently infected with all kinds of bacteria, not only with naked, easily killed organisms, but also with highly resistant spores, the latter being most common and most dangerous in wounds soiled with earth. These organisms are not only living free in the cavity of the wound and thus apt to be washed away by the blood, but they are also adherent to the tissues which form the sides of the wound, if, indeed, they have not been actually driven into them. These bacteria, finding themselves in a highly nutritious soil and at a suitable temperature and with plenty of moisture, at once begin to sprout and multiply with great rapidity. I do not know how long it would take a spore to sprout in the first instance, but I do not suppose it would be any great length of time; but once they have sprouted they multiply rapidly. Many organisms divide and double their numbers within twenty minutes. At that rate it does not take long for a wound to be filled with myriads of organisms. Suppose we take it that each organism divides in half an hour, that would mean that each organism gives origin to over 15 million at the end of twelve hours. Further, not only do these organisms multiply in the fluids which are free in the wound, but, being in contact with weakened or dead tissues, the pathogenic varieties soon penetrate the tissues and establish themselves there. Within the first twenty-four hours, therefore, we may take it that the state of matters is that the fluids in the wound are already teeming with actively growing bacteria, and that they have also penetrated into any pieces of dead tissue on the surface of the wound, and, to a slight extent, into the living tissues forming the wall of the wound. Once they have penetrated into the tissues, they establish themselves there, and are extremely difficult to dislodge.

Now it is evident that the only efficient way of dealing with such a state of matters is to destroy these organisms which have entered the wound as soon as circumstances permit, and before they have had time to grow and establish themselves firmly in the tissues, bearing in mind the fact that every hour that passes they quadruple their numbers at the very least. This will not be done by painting a little iodine over the skin around, or even by pushing it in among the blood, and covering the wound with a piece of aseptic gauze; very much more careful and vigorous treatment is required than that. And it should be in the mind of every man who deals with these wounds that the ultimate results depend to a large extent on the prevention of sepsis, these results concerning not only the life of the patient, but also the rapidity and smoothness of his convalescence and his later condition.

As to the period of time during which it is advisable to attempt disinfection of the wound my own opinion is that it is only during the first twenty-four hours that it is at all likely that bacteria can be eradicated; and, indeed, after twelve hours the result is not at all certain. During the first twelve hours, however, the great majority of wounds, unless they are large and irregular or complicated with extensive comminution of bone, can be quite readily and immediately rendered aseptic, and if proper precautions are taken afterwards, will remain aseptic, and thus the whole troubles resulting from the primary soiling of the wound will be avoided. Even up to twenty-four hours the infection can be rooted out in a considerable percentage of the cases. In the circumstances under consideration, where wounds are soiled with earth and where, therefore, there is considerable danger of tetanus and gangrene, I think that the period during which an attempt at disinfection should be made might be prolonged up to forty-eight hours. After that time the disinfection will certainly fail, and the attempt will do more harm than good by injuring the tissues which are opposing the invasion of the bacteria and thus enabling the infection to spread more easily and rapidly.

Hence I would lay it down as an axiom of practice in the class of wounds under consideration, *that if the treatment can be carried out within the first twenty-four hours (and, in the case of wounds soiled with earth, forty-eight hours) an attempt should be made to kill the organisms which have entered the wound.* These organisms can only be got rid of by means of chemical antiseptics; I fear that, try how you may, you cannot avoid their use.

Choice of a Disinfectant.

Two points must be taken into consideration in making this attempt. The first point is, that we have not only to kill actively growing bacteria, but also the spores of bacilli, seeing that some of the latter class of organisms are highly pathogenic. For example, the tetanus bacilli and various other bacteria which cause pathogenic processes such as some forms of gangrene, are spore-bearing, and are thus extremely resistant to all destructive agents. Hence the agents we use must be sufficiently potent to kill spores

under whatever circumstances they are found, whether dry or in albuminous or oily materials. And the second point is, that these spores must be killed quickly, because one cannot keep such potent agents for any length of time in contact with the tissues, otherwise they may destroy them, and furthermore, these agents, if absorbed into the system, are all more or less poisonous.

There are three potent antiseptics in common use at the present time, namely, carbolic acid, bichloride or biniodide of mercury, and iodine. Of these we may exclude the mercurial salts, because although they kill microbes quite readily and in very considerable dilutions if these organisms are free or in a slightly albuminous fluid, they are of no use when the organisms are present in albuminous or oily substances. In the case of the former, mercury combines immediately with the albumin, forming a compound which possesses very little antiseptic power; and as regards the latter, these salts do not dissolve in oil, and therefore organisms lying in oily material are not reached by the antiseptic. We are therefore left with the two substances, carbolic acid and iodine, and we must now consider these substances and determine which of them is best and most suitable and in what strengths they should be used.

(a) Carbolic Acid.

A saturated watery solution of carbolic acid (1 in 20) will kill naked, actively growing bacteria in a few seconds, but will not kill spores with certainty under from twelve to fifteen hours, and this time will be still further prolonged if these spores are present in albuminous or oily material, because a certain amount of the antiseptic power of the carbolic acid is lost in combining with these substances.

It is evident, therefore, that washing out the cavity of the wound with 1 in 20 carbolic lotion will not disinfect it if it contains the spores of pathogenic bacilli. On the other hand, liquefied carbolic acid will kill spores in a very few minutes—as soon, in fact, as it can soak into them. And therefore, if carbolic acid is to be employed in wounds soiled with material such as earth containing pathogenic spores, it must be used in the form of liquefied carbolic acid.

Carbolic acid precipitates and combines with albumin, but the compound is still strongly antiseptic. It also dissolves readily and in large amount in oil, still retaining its antiseptic property, though not so strong as in watery solution (1 in 10 oily solution is about equal antiseptically to 1 in 20 watery solution). Hence the presence of oil does not protect the bacteria. This is the chief reason why I prefer carbolic acid for the disinfection of the skin rather than any other antiseptic, because it dissolves in the natural oil on the skin, and so can extend its antiseptic action down the hair follicles and the orifices of the sebaceous glands. Further, carbolic acid is an anaesthetic, and its application causes very slight pain, which subsides almost immediately.

(b) Iodine.

The antiseptic power of iodine is practically the same as that of carbolic acid, so that the 2 per cent. iodine solution in common use is of about the same value as 1 in 50 carbolic lotion. What the effect of a 5 per cent. solution of iodine, or of still stronger iodine, would be on the tissues I do not know, but I fancy it would be intensely irritating, to say the least. Even with the 2 per cent. solution the skin must be dry before it is applied, otherwise it is very apt to be blistered, and the antiseptic properties of the iodine solution are said to be diminished. How it could be used in the field with the impossibility of drying the skin and keeping it dry I do not know, and I am told that there have been several cases of iodine burns of the skin where this antiseptic had been employed.

Further, iodine causes great pain, which lasts for a considerable time, as is well known in connexion with the iodine treatment of hydrocele. When I was a student the treatment of hydrocele was the injection of a strong solution of iodine, and the agonies which the patient suffered afterwards, and the pain and the inflammation which lasted for some days, were in very marked contrast to the painlessness and absence of inflammation which follow the injection of carbolic acid.

Hence, though I may be thought not to be up to date, I still prefer carbolic acid to iodine, not only for the disinfection of the skin, but also, and more especially in the circumstances with which we are dealing—namely, as a means of destroying the bacteria which have already entered wounds before they come under the care of the surgeon. I am not, however, prepared to say that a sufficiently strong preparation of iodine might not possibly effect the same purpose, but in a few cases which I have seen in which iodine has been applied to the wound it had not prevented the sepsis. Personally, if I had a wound I should insist on the use of carbolic acid in preference to iodine, both from the point of view of efficiency and of comfort.

Other antiseptics have been suggested, but none of them are sufficiently potent for the cases under consideration. Of these, hydrogen peroxide seems to be a favourite abroad, but its antiseptic power is comparatively weak, and it would be useless against spores.

Method of Disinfection.

Before deciding the details of the procedure to be adopted in disinfecting a wound, let me recall Lister's first work and our subsequent experience. Lister's first attempt at aseptic work was by the use of a crude solution of carbolic acid, called German creosote, so impure that at first he thought that carbolic acid was insoluble in water. For a time his experiments were made only on compound fractures, of which a large number, some of them very serious, occurred in Glasgow where he was located at that time. His original plan at first was to introduce a piece of lint, soaked in this crude carbolic acid, into the wounds and thoroughly rub it into the recesses and then to put in some more carbolic acid and stir it up with the blood so as to form a sort of paste which filled up the wound. Every day he painted a little carbolic acid over this coagulum, and, in order to diminish the evaporation of the acid, he covered the clot with a piece of block tin. Ordinary towels were then applied around to catch the discharge which soaked through; no other dressing was employed.

What was the result? All the cases followed an aseptic course so long as he continued the application of the carbolic acid; there was no temperature, no inflammation, no sloughs separating, no poisoning—in fact none of the dreadful things which students are led to believe will result from the application of carbolic acid. No doubt in some cases where the carbolic acid was in contact for some time with the skin a small superficial slough formed, which, however, was of no consequence. After a time, when he peeled off the superficial layer of the clot, he found a healed, or almost healed, wound beneath. And, as showing the absence of any injurious effects, it was in cases so treated that he first observed and demonstrated how blood clot, if aseptic, acts as a mould for the penetration of cells and for the formation of new tissue—what is now known as healing by blood clot.

In some of his cases he discontinued the application of the carbolic acid after the deeper part of the wound had healed and when there was only a superficial sore, and as he had not devised any antiseptic dressing then, he employed the ordinary dressings which he had previously been in the habit of using. Two or three of these cases showed septic troubles after the carbolic acid was left off; and, indeed, phagedaena occurred at this late stage, thus affording additional proof of the protective effect of his new treatment. I would recommend those who hold up their hands in horror at the idea of applying liquid carbolic acid to infected wounds, to read and digest Lister's early papers.

As he developed his system and found that carbolic acid was soluble and active in oil and water, he modified his plans, and later his method was to wash out compound fractures thoroughly with 1 in 20 carbolic acid lotion, taking measures to see that all recesses of the wound were subjected to its action. With this second plan the majority of compound fractures also remained aseptic, but a certain proportion did not do so, these results differing, therefore, from those which he obtained in the early days with the crude carbolic acid; these failures chiefly occurred in wounds which were badly soiled. We now know the reason of this—namely, that the dirt may be so ground into the tissues that the carbolic solution does not penetrate it thoroughly; and, further, that the 1 in 20 solution does not kill pathogenic spores in a short time. This led us to remove all visibly soiled portions of soft tissues or bones, and to apply liquid carbolic acid to these surfaces, using the 1 in 20 lotion for the rest of the wound,

and this diminished the number of failures, and this is the plan I adopt in civilian practice.

I believe that this plan would be quite satisfactory in the majority of wounds in war, but where they are very badly soiled with earth, as is so often the case at present, we should, I feel sure, revert to Lister's original plan in so far as to paint the whole surface of the wound with liquid carbolic acid, with the exception, perhaps, of narrow tracks in the deeper parts. Certainly this ought to be done in all cases of compound fracture.

In carrying out the disinfection of the interior of the wound, not only must it be done methodically and thoroughly, and all the recesses of the wound carefully attended to, but one must not forget that it is most important to disinfect the surrounding skin most carefully. It is useless to disinfect the interior of the wound and to leave bacteria on the skin, free to multiply there and spread in and infect the wound again. I also think that it is best to *begin* with the disinfection of the skin.

Again, one great difficulty in obtaining proper disinfection of a wound is the constant flow of blood from the wound, which dilutes and washes away the antiseptic, and steps must be taken as far as possible to arrest or control the hæmorrhage in the first instance; this is a very important point. It may also be necessary to open up the wound, not only in order to arrest the bleeding, but also to reach all the recesses of the wound for the purpose of disinfection. Further, the process is painful, and therefore I should advise that in all cases an anæsthetic should be administered.

Procedure.

The procedure would be as follows: The patient having been put under an anæsthetic, the first thing is to control the bleeding. In the case of an extremity a tourniquet is applied, but where the wound is situated in the trunk, any visible bleeding points should be clamped and the wound temporarily stuffed with gauze or large sponges.

The next step is to cleanse and disinfect the skin thoroughly. In the first place scrub it thoroughly with 1 in 20 carbolic lotion and ether soap, then shave it, and finally wash it thoroughly again with the carbolic lotion, leaving a cloth saturated with the lotion over the whole area, so as to continue the disinfecting action and protect the skin while the interior of the wound is being attended to.

The interior of the wound must now be disinfected, and if it is necessary to gain access to the deeper parts in order to enable one to see what one is doing, which is very important, the wound must be enlarged by incisions made in suitable directions. The blood must be thoroughly swabbed out, the wound made as dry as possible, and the skin or fat or other structures which are visibly soiled with earth or dirt should be cut away; the wound being then held wide open by retractors, a piece of sponge dipped in the liquefied carbolic acid is carefully and thoroughly applied to the whole surface of the wound and to all the recesses, care being taken, by holding a swab in the other hand on the edge of the wound, to prevent the acid running over the skin. It is well to sponge out the wound after the first application, and then to apply the acid a second and even a third time if there is bad soiling. If, at the bottom of the wound, there is a long narrow track leading into the tissues, it may not be necessary to disinfect it along its whole length, because the probability is that the bullet or fragment of shell does not carry the organisms in to a very great depth. If it is a large wound which has to be soaked with the undiluted carbolic acid, it may be well, after about five minutes, to wash it out first with 1 in 20 carbolic lotion and then copiously with saline solution, so as to get rid of the excess of carbolic acid, and thus reduce the chance of absorption.

Having completed the disinfection of the wound, the tourniquet is relaxed, the vessels tied, and a good sized drainage tube inserted down to the bottom of the wound, or even through a counter opening if there is any doubt as to the thoroughness of the disinfection. Any incisions made by the surgeon may be closed by stitches, but no attempt should be made to stitch up the original wound, unless possibly where flaps of skin have been turned to one side, in which case they may be brought roughly into position by two or three stitches. After the disinfection of the wound is complete, it is well to give the skin around an additional wash with the carbolic lotion, in case it may have again become soiled from the wound.

In the case of a wound on the trunk or neck, where no tourniquet is available, and where therefore the bleeding cannot be thoroughly checked, the disinfection is much more difficult and uncertain, because blood is constantly washing away and diluting the antiseptic. Hence, the first thing to be done under these circumstances is to open up the wound and try to check the bleeding by clamping any bleeding points; these, however, must not be tied at this stage. The wound should then be firmly packed with gauze, so as to check the capillary oozing. Having done this, the skin around is cleansed and disinfected in the manner already described, and attention is then turned to the wound itself. The plug is then taken out and a smaller one substituted, so as to leave the skin and subcutaneous tissue exposed to view. The surfaces so exposed are then dealt with in the manner already described, badly soiled skin and fat being clipped away, and the surface thoroughly soaked with the antiseptic. Further portions of the plug are then removed, so that the whole surface of the wound may be disinfected bit by bit; in addition it is well to irrigate it thoroughly with 1 in 20 carbolic lotion, and then with salt solution. Finally, the vessels are tied, and in doing so it is well, in the first instance, to take off the forceps one by one, daub the vessel with carbolic acid, catch it again with clean forceps, and then tie it; the *rationale* of this procedure is that the piece of tissue caught by the forceps has not been disinfected, and if it were tied at once, a septic point and ligature would result.

Dressings.

In both cases, after the disinfection is complete, an antiseptic dressing (not merely an aseptic one) should be applied. The reason for using a dressing containing an antiseptic is that, in the first place, aseptic dressings are seldom available on the field of battle; and, in the second place, it may not be possible to change the dressing for some time, and if a non-antiseptic dressing is used the discharge passes through it, and bacteria rapidly develop in it and reach the wound. On the other hand, a dressing containing an antiseptic which is soluble in the serum may give enough of the antiseptic to the serum to render it an unsuitable medium for the development of organisms, and thus, if the dressing cannot be changed early, an aseptic result may still be obtained. I believe that wool impregnated with salicylic acid is the best for this purpose, but it is well to put a piece of cyanide gauze (which is itself only feebly antiseptic) over the wound, so as to keep the salicylic acid from the skin.

It takes a long time to describe this matter, but it is perfectly simple, and I have adopted this method of dealing with compound fractures and other open wounds for years with a very large measure of success, and I should be very much ashamed if any considerable number of cases which came under my care within twelve hours after the accidents did not follow an aseptic course.

If iodine is preferred, I cannot say what strength should be used, but it certainly ought to be much stronger than the ordinary 2 per cent. solution, which is the favourite at present. The procedure would be the same as I have already described.

If iodine is used instead of carbolic acid for the disinfection of the skin, it should not be applied directly over the dirty skin, and therefore here also the skin must be thoroughly washed and shaved and dried, first with a dry cloth, and then with acetone. The trouble is that the skin will soon be wet again with the blood and serum when the wound is taken in hand, and not only is the disinfection imperfect, but the skin painted with iodine, if again wetted, is liable to be much irritated. I have not the slightest hesitation in saying that the disinfection will be much more thoroughly and satisfactorily done with carbolic acid with less loss of time and also with less irritation of the skin.

Possibilities of Early Treatment.

The proper disinfection of a wound cannot be carried out in a hurry, and unfortunately in the army it will not be till the patient has arrived at the first field hospital, and in the navy till the patient reaches the surgeon's quarters on the battleship, or the hospital ship itself, that it can be taken in hand thoroughly.

Whether anything can be done in the field or trenches which might help to delay or circumscribe the sepsis, is a problem well worth considering. The first dressings

with which the soldiers are provided are of no use except to prevent the entrance of further dirt, and the surgeon cannot be expected to carry with him the necessary arrangements for disinfecting the wound, though he might carry some antiseptics which might be introduced into the wound. Thus we have been trying at Chatham to make soluble bougies or suppositories, each containing 1½ grains of carbolic acid, which might be pushed into a wound before the emergency dressing is applied, or the surgeon might be provided with strong iodine solution, and pieces of gauze soaked in this solution might be pushed into the wound and left there. No thorough disinfection can, however, be carried out till the patient has reached some place (field hospital or sick bay) where he can rest for some time, and where the methodical disinfection of the wound can be undertaken. As soon, however, as the patient has arrived at such a place, the wound should be disinfected thoroughly, whether anything has been done previously or not. Even at the field hospital or sick bay it may not be possible to keep the patients long enough for all the wounds to be thoroughly disinfected, but, at any rate, all compound fractures and wounds of joints which do not require amputation, and all wounds badly soiled with earth, should be dealt with as far as possible.

Antitetanic Serum and Antisepsis Vaccine.

At the present moment great stress is being laid on the particular kinds of organisms which may have entered the wounds, but very little is said about disinfecting the wounds. Instructions are being given as regards the army that immediately the patient comes under treatment he should have a subcutaneous injection of antitetanic serum and another of polyvalent antisepsis vaccine. Now I cannot speak with any authority as to the prophylactic value of antitetanic serum when injected into the subcutaneous tissue, but although *subcutaneous* injections of this serum are of no value in the treatment of tetanus once it has developed, those who have worked at the subject state that subcutaneous injection of the serum is of value if used immediately on the occurrence of infection. As regards antisepsis vaccine as a prophylactic, I am very sceptical indeed. It may possibly modify the severity of the impending sepsis, but I feel sure it cannot be depended on to prevent it. At the same time, we must not disregard any possible safeguard, and for the present I think it is well—in military surgery at any rate—to inject these substances in the manner which has been advised. I should not think that it is necessary in naval surgery to inject antitetanic serum.

I do hope, however, that those who have to treat these wounds will not take it into their heads that, after making these injections, they have done all, or, indeed, anything of any real importance, for the safety of the patient. I am very much afraid that some men will be satisfied with these injections, and will take no further local steps to render the wound aseptic, and will look on these injections as a way of avoiding the use of the much-hated chemical antiseptics. By all means use these injections, but never lose sight of the fact that the only trustworthy way of avoiding the septic diseases which otherwise inevitably follow these wounds is to kill the organisms before they have taken root in the body. Remember also that we have not to do with only one species of organisms; we have to do with a great many, and even if the methods suggested were as effectual as we could hope, it leaves many other organisms untouched.

2. *Treatment of Wounds if more than Twenty-four or Forty-eight Hours have elapsed since the Infliction of the Wound.*

It may happen that patients cannot be treated within the period above mentioned, and the question then arises whether any attempt should be made to disinfect the wound in the manner above described. By this time the organisms will, for the most part, have got a firm hold on the tissues and any attempt to get rid of them by antiseptics will fail, and if the attempt fails at this stage it may cause a great deal of harm by injuring the actively granulating tissues. It may possibly be well still to clip away any visibly soiled tissues and touch the raw surfaces with liquid carbolic acid, but I think that any attempt at general disinfection of the wound would be a very injudicious and harmful procedure, and still more so if suppuration has begun. Indeed, I would go further and say that not only should strong antiseptics be avoided, but also even weaker ones. I usually find that surgeons at once get busy syringing out these early septic wounds with various antiseptic lotions, and not only on the first occasion but every time the dressing is changed, and I consider this to be very bad practice indeed.

Misuse of Antiseptics.

In fact, my views on the relation of antiseptics to wounds are exactly the opposite to those in vogue at the present time. It may be that I am not up to date, but I fancy that I have, perhaps, been trained to take the treatment of wounds more seriously than most people, and to think and work a great deal at it. My own view is that if a wound is aseptic, while I do not willingly put antiseptics into it, their entrance will not interfere with healing at all, so long as no bacteria have been let in by the surgeon. But on the other hand, if bacteria are already established in a wound, I think it is the worst treatment possible to meddle with it more than one can help, and more especially to syringe it out with antiseptics, and to poke gauze and other things into it. The general practice at present is just the reverse, namely, to avoid antiseptics when the matter is of no consequence, and when their use outside the wound may help to prevent the reinfection of instruments and materials used; and on the other hand, to use them when the wounds are septic, when they cannot kill the bacteria and when the only effect they can have is to damage the natural defences of the tissues. The only antiseptic which I would use in septic wounds, and that only in foul-smelling ones, is hydrogen peroxide, which, although a feeble antiseptic, certainly seems to overcome the fetor and does not irritate the tissues to any marked degree. If it is deemed advisable to wash out a septic wound, use normal saline solution as a rule, though very weak antiseptic lotions may do no noticeable harm once granulation is fully established.

I believe that the chief reason for the present prejudice against antiseptics was the free use of these lotions formerly by surgeons who deluged their wounds with antiseptics, but took no care as regards disinfection of hands, skin, instruments, etc., and infected their wounds thereby, at the same time damaging the resisting power of the tissues by their antiseptics. The result was that the wounds did badly, but not, as they thought, as the direct effect of the antiseptic, but from the introduction of bacteria into the weakened wounds. They thought they were practising Listerism, and therefore gave it a bad name, but they were not following the master's teaching. I remember in the old days of the carbolic spray remarking to Lister more than once that while practically all our wounds healed aseptically, yet if a wound did go wrong with us, it went wrong worse than in the hands of septic surgeons. The reason was that the irritation of the spray diminished the local resisting power, and so enabled the organisms introduced to grow more readily; if no organisms were introduced, this temporary diminution of local resisting power did not matter. It is curious how difficult it is to make people understand that carbolic acid or other antiseptic *is not used as an application to a wound, but as an application to the bacteria outside the wound.* The healthy tissues are sterile, as I was the first to demonstrate many years ago, and they need no antiseptic application to them; the enemy—the bacteria—come from without, and should be killed outside the wound.

Drainage.

As the wounds have come to us at the base hospital they are not only septic, but they are often imperfectly drained. It is therefore necessary in most cases of large wounds, and especially where bones or joints are injured, to interfere with them by operative measures on their arrival at the hospital, but this should be done, as far as possible, once and for all. The patient having been put under an anæsthetic, the skin should be cleansed and disinfected in the manner previously described, and if there is any earth or gross dirt still visible about the wound the tissues involved should be cut or clipped away and the raw surface daubed with liquid carbolic acid. Apart from this, which is only occasionally necessary, the important point is to provide the freest possible escape for discharge, and in order to obtain this it is often necessary to enlarge the original

openings and to make counter openings. Further, any foreign bodies which are readily accessible, such as clothing or fragments of shell retained in the wound, should be removed, but at this stage it is not advisable to open up fresh wounds in the deeper tissues in order to hunt for bullets or pieces of shell, for this is only to expose fresh tissues to infection unnecessarily before the body generally has developed its full resisting power.

As to the actual drainage of the wounds, that must be carried out by the use of as large drainage tubes as can be conveniently introduced, with holes of suitable size cut in their sides; where there are counter openings, it is well to pass the tube through from one opening to the other. A most extraordinary practice has grown up of late—namely, instead of using open tubes, to introduce masses of gauze into the wound, under the idea that they will drain away the pus. Even those who use tubes generally slit them open at one side and fill them with gauze. Now, the object of drainage and dependent openings in these cases is to let the pus run away as soon as possible so that the products of bacteria shall not lie in the part and cause local irritation or be absorbed. To push gauze into a sinus is effectually to prevent the pus escaping freely; and the pus, soaking into the gauze and lying there, undergoes still further changes as the result of the bacteric growth, and thus the plug becomes a highly poisonous and irritating substance. Whoever heard of stuffing a drainpipe with gauze so as to let water run away, far less thicker material like pus?

I cannot conceive how this method of draining wounds ever arose. I fancy it was some aseptic surgeon who found that when he put a drainage tube into a wound the wound always suppurated, and the bright idea occurred to him that by using gauze instead he would keep bacteria out. However it arose, I regard it as one of the most foolish and mischievous things that has ever been introduced in connexion with the treatment of wounds, and especially of suppurating ones.

I may illustrate this by an anecdote. Some years ago I built a house in the country and we had some difficulty in getting a proper water supply. At length I found a spring on the top of a hill in the neighbourhood where the earth had been somewhat hollowed out and which was used by a crofter not only for household purposes but also to water the animals. I got leave from the landlord to make a proper well there and to get the overflow for my own use. This I did, making a nice clean well for the crofter, with an overflow to water the animals, and this left ample water for my house. The crofters are very conservative people, though they always vote for the Radical candidate, and this particular old lady had a great affection for the old well and resented very much the new one. To relieve her feelings she put all sorts of things—rotten fish, etc.—into the well. We did not notice this at first, but thought the water was extra good and tasty, but presently the flow of water through our pipe began to fail and ultimately stopped altogether. On examining the well the spring was all right, and therefore there was nothing for it but to dig up the pipe. About a hundred yards from the well I found a piece of dirty linen, evidently a piece of the old lady's chemise, which was very rotten, and completely prevented the flow of the water. Now this is exactly what you do when you fill a drainage tube with gauze—you prevent the free exit of the pus, and the gauze becomes very rotten and poisonous.

I do not think that one can go too far in preventing the accumulation of septic material in a wound. Two of the very best cases which I have so far had have been cases of fracture of the pelvis with extensive tearing of the rectum. For a few days they were treated by drainage. A large tube through the anus, constant irrigation, etc., without any improvement, but as soon as I performed colotomy and cut off the access of faeces, their improvement was immediate and most remarkable, and one of them has already healed and will soon be in a condition to have his colotomy opening closed.

Dressings.

As regards dressings in these cases, of course aseptic dressings are not only useless but injurious. The septic discharge soaks into them and decomposes there, and the dressing simply becomes a septic poultice which poisons the wound. Antiseptic dressings are rather better, and in small wounds do well enough, the dressings I use being cyanide gauze next the wound, with salicylic wool outside. But in large wounds the pus does not take up enough antiseptic to stop the decomposition entirely, and I am not at all satisfied with large masses of dressings over a wound. To pile dressings on septic wounds, whether these dressings do or do not contain antiseptic substances, is only to revert to the old methods of two or three centuries ago, which have been long since and quite rightly discarded.

I believe that in these bad septic cases the less dressing you apply the better, and my experience is that as regards dressings it is best only to lay a few layers of antiseptic gauze over the wound to prevent it being soiled by the clothing or blankets, and to apply boracic fomentations and change them frequently.

Irrigation.

Wherever it is possible, however, especially in the case of large wounds and those involving bones or joints, constant irrigation with normal saline solution is by far the best method of treatment where circumstances allow of the employment of this plan. The irrigation is at first continued day and night, but after some time, as the discharge gets less and the wound begins to heal, boracic fomentations may be substituted during the night, but the irrigation should be continued during the day till healing is nearly complete. Where gangrenous processes set in, a water bath, frequently changed, with a little iodine or potassium permanganate in the water, is the best treatment.

Removal of Missiles.

There is just one other point to which I shall refer to-night—namely, the question of the removal of the missile which has done the damage. Of course, if it is present in the main wound, or is doing harm by pressure or otherwise, it should be removed at once; but not uncommonly fragments of shell or bullets pass into the tissues for a considerable distance from the main wound, and, if left alone, may become encapsuled and not do any harm, and the wound of entrance will heal quite well. Such fragments can be removed by a separate incision later on if necessary. I think that there is too great a tendency to hunt for small fragments of shell or bullets at the present time. It is interesting that when they traverse the tissues for some distance, they seem to shed the septic material which they have carried in with them. I have one case where a piece of shell passed through the rectum and is embedded deeply in the other thigh and is not causing any irritation. It is well, however, to have a stereoscopic skiagram taken in all these cases as soon as the condition of the patient allows; this will help the surgeon to determine later on whether he should remove the fragment or not.

Conclusion.

Gentlemen, I am afraid I have taken up far too much of your time to-night, but the question I have been referring to is one of tremendous importance, and I entreat you to give it your most earnest consideration. If you have followed what I have said, it is clear that I only advocate the use of antiseptics at the very commencement of the treatment, but at that time, in order to serve the purpose, they must be sufficiently powerful. I am much opposed to their use in suppurating wounds. Some object to the use of these strong antiseptics on the ground that they may cause a slough. This, however, is a mistake; used as I mention, they may kill a microscopic layer but no visible slough, but even if they did, if you have destroyed the bacteria, a slough is of no consequence; it will be absorbed like any other piece of aseptic dead tissue. Even if there were a slough, what does that matter as compared with the life of the patient? It is very trying for those of us who are parents to feel that any day we may hear of the death of our boys in battle. If they die on the field of battle, they at least die nobly in fighting for their country and for the safety of those they have left behind. Surely it makes it still harder for us to know that if they escape death on the field of battle they may still, as a result of imperfect disinfection of the wounds, die from sepsis or be maimed for life. I beg of you to consider this matter calmly and logically and without prejudice, and see that every possible means is taken to avoid this great calamity.

An Address
ON
THE PRINCIPLES OF WOUND TREATMENT AS ESTABLISHED BY LISTER AND THE SUBSEQUENT MODIFICATIONS IN TREATMENT.

DELIVERED TO THE STUDENTS' MEDICAL SOCIETY, ABERDEEN.

BY FRANCIS M. CAIRD,

REGIUS PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY OF EDINBURGH.

AT the present time, when horrid war is rampant, it seems singularly appropriate to consider the principles of wound treatment established by Lister, and to review the various changes in the methods and materials which have gradually been evolved in the application of these principles.

It will be well, then, to glance briefly at the pre-Listerian conditions. If we go back to the year 1864, about which time Lister was already engaged in his wondrous researches, we find that in Paris—then the scientific and political European centre—the deaths among 1,144 amputations were 622, and that, speaking roughly, a mortality from 45 to 50 per cent. was by no means uncommon in hospital practice after amputation. The old hospitals had become foul and tainted, surgeons no longer attained the success of their predecessors, and questions of hospitalism were in the air. Ten years after this date the most inexperienced and junior student could not fail to recognize that a new order of things had arisen, for in the same old hospital he could pass from wards where the peculiar musty odour, the painful wounds, the frequent dressing, and the rife pyaemia gave place to a purer atmosphere, painless wounds, infrequent dressings, and a minimum mortality. He thus realized that empiricism had yielded to science, treacherous chance to sweet certainty, and that surgery had been freed from its most dreaded associations.

Lister framed his principles on the scientific basis that wound fevers and suppuration were due to the access of micro-organisms which came from without, entered the damaged tissues, multiplied therein, and by their multiplication gave rise to fermentation with all its disastrous train of consequences.

He had finally solved the question of the prime difference between a simple fracture so free from danger and a compound fracture so fraught with danger. He held that we should be able to destroy all the organisms which had gained access to a wound or compound fracture, thus rendering the wound innocuous and restoring the compound fracture to the condition of a simple one; and, further, that the surgeon should also be able to prevent the access of all germs when operating, so that his wounds would run a course as safe and uneventful as that of a simple fracture. In other words, he strove to establish a curative as well as a prophylactic attack against sepsis and putrefaction.

The methods he was already following in 1869 permitted him to state that: "The universal adoption of the antiseptic system, whether in the form it has now received or whether in some other or more perfect shape can only be a question of time."

The problem which Lister faced in attaining an ideal wound treatment involved a consideration of the sources of wound infection. Hence he directed attention to the purification of all the wound surroundings. He feared contact and implantation infection. He gained his object by a definite procedure. First, the surgeon's hands, nails, and flexures had to be carefully disinfected; so also the instruments, sponges, and whatever might be brought in contact with the field of operation. He devised the great boon of antiseptic catgut ligature.

Secondly, similar methods were employed to purify the wound and its environment.

Thirdly, he endeavoured to obviate the danger of atmospheric contagion.

Fourthly, he sought to prevent the subsequent access of germs to the wound by suitable antiseptic dressings.

I need not at present detail the long and persevering quest which he followed in gaining the desired end. It will suffice to say that he was satisfied to find in carbolic acid (pure phenol) a reliable antiseptic which was most potent to destroy organisms and yet inflicted the minimum of injury on the tissues of the body. The volatile character of phenol, the ease with which it combined with oily and other substances, its local anaesthetic action and powers of penetration, rendered it most acceptable and convenient. It practically remained his most favoured antiseptic.

Lister insisted that only pure forms of phenol should be used. He drew attention to the disadvantages of inferior preparations. He employed a watery solution of 1 part in 20 for the initial purification of all surfaces, and this having been accomplished, then changed to a weaker solution of 1 part in 40 of water during the subsequent manipulations.

We may now study the curative antiseptic method he carried out, as in the case of a compound fracture.

The surgeon's hands, instruments, etc., being thoroughly cleansed with 1 in 20 carbolic lotion, the surrounding skin of the wound was in like manner prepared. The wound was then thoroughly soaked with the same lotion, and the parts were manipulated freely so as to cause the lotion to penetrate into the interstices of the wound. The lotion might also be carried with a syringe into the deeper parts, extreme care being taken that there was no forcible injection of the fluid. Clots, foreign bodies, and completely detached pieces of bone were removed. Haemorrhage was arrested. Drainage tubes were introduced, and, if necessary, counter openings were made, so that there could be no question of tension. The thorough purification of the wound entailed a copious serous flow, due to the action of the antiseptic. Hence a large and sufficient dressing was essential, which required renewal whenever discharge appeared. In the case of compound dislocations a lotion of one part phenol in five of spirit was used. The knife and bone forceps were frequently employed to pare off and remove portions of cartilage and bony surfaces into which gross dirt had become ingrained.

Let us now turn to his prophylactic antiseptic methods as carried out in operations on unbroken skin. The procedure was identical with that we have seen in the case of compound fracture, save in one important respect. We find him in 1874 teaching that as the tissues were germ-free, there should be no contact of the antiseptic with the wound. It should not be douched with an antiseptic. The antiseptic is hurtful to the tissues, and where it is not required should be excluded. He endeavoured to reduce the contact of the antiseptic with the wound to a minimum, and hence he operated under the carbolic spray as a means to purify the atmosphere. He held strongly that all wounds made by the surgeon should be drained for at least twenty-four hours until the serous discharge occasioned by the minimal stimulus of the antiseptic had subsided. The wound was carefully closed, a large firm dressing obliterated all spaces, and over the lips of the wound a strip of protective shielded the wound from the dressing. As Lister then expressed it, "An antiseptic to exclude putrefaction, with a protective to exclude the antiseptic, will, by their joint action, keep the wound free from abnormal stimulus."

With the universal acceptance of Lister's principles modifications of his procedures arose. He himself was constantly engaged in experiments and the introduction of improvements. He regarded the spray as the least essential part of his antiseptic precautions. He attempted purely aseptic methods and used carbolated cotton-wool as a dressing. He never quitted the search for milder antiseptic agents and was always open and ready to acknowledge and honour the work of others, accepting everything that seemed to him right and good.

The spread of antiseptic surgery was at first relatively slow. While many were zealous in attempting to carry out the methods, they often failed to grasp the principles on which Lister founded his system, but he gradually received overwhelming support, more especially from his German colleagues, who were quick to grasp the scientific conceptions which wrought such a stupendous change in the surgical outlook.

The fundamental writings of Pasteur were followed by

the investigations of Lister, Ogston, Koch, and others, and thus led to the foundation of the science of bacteriology. Further research and experiments favoured discovery of new antiseptic agents. The study of infective diseases and experimental pathology acquired a new stimulus, and certain changes in wound treatment ensued as a clearer appreciation of Lister's principles obtained.

Thus carbolic acid was replaced by corrosive sublimate; gauze and mackintosh dressing by dry dressings of medicated cotton-wool, etc.; the period of drainage was shortened by the use of horse-hair, catgut or absorbable bone tubes, and finally was almost entirely abandoned, the wounds being completely closed.

It became recognized that the risk of atmospheric wound contagion was exaggerated, and the spray was dispensed with as unnecessary. The trend of surgical thought might be well exemplified by a visit to Neuber's clinic in Kiel about the year 1886.

Here we observed that separate operation rooms for septic and aseptic cases had been substituted for the old many-seated theatre. They were specially constructed with rounded corners, and contained a minimum of furniture. One hour prior to use the rooms were entirely flushed out with water, so that the surgeon entered a dust-free, moist atmosphere. The patient, suitably prepared, was enveloped in a sterile sheet before being brought into the room. The surgeon's hands, instruments, and field of operation were purified by carbolic acid lotion 1 in 20, but after this primary purification sterile normal salt solution was alone used. The instruments had long handles, and every care was taken to avoid as far as possible contact with the surgeon's fingers. Spaces were obliterated by deep catgut sutures, and the wound was closed without drainage. A copious layer of boiled gauze, with corrosive wool firmly applied over all, completed the dressing.

The value of boiling and moist heat for sterilization became now generally recognized, and about this date Schimmelbusch perfected his valuable steaming apparatus, which is now in universal use. Renewed attention was directed to implantation infection caused by faulty purification of the hands, and the difficulty of ensuring an absolutely germ-free integument led to most elaborate and painstaking procedures to gain this end. Much ingenuity was displayed in devising various forms of protective varnish, different antiseptic agents and soaps were tried, and eventually the introduction of sterile rubber gloves seems to have solved this important problem.

As an example of the advance which had taken place, I may note the procedure followed under von Mikulicz in Breslau about 1904. While Mikulicz had formerly condemned the spray, concluding that danger from aërial germs might practically be ignored, in his later years he was ready to admit that Lister was right after all, and that the atmosphere was a loophole of offence which should not be neglected. Hence he insisted that all outer garments and shoes should be removed or covered by sterile overalls on entering the operation room. A limited number of spectators was admitted, and no one with a catarrh or cough dared enter. Silence was maintained; the head, nose, and mouth were veiled. After careful purification of the hands, gloves were employed and frequently changed. From the first incision onwards antiseptic agents were practically discarded and only normal sterile salt solution came in contact with the wound.

We have thus seen that in so far as septic prophylaxis is concerned an antiseptic method has given way to an aseptic. Antiseptics remain still essential for the cleansing of the skin; boiled water and sterile dressings accomplish all else. Provided we exclude all causes of putrefaction from the tissues, "all they need is to be left alone." Lister's ideal has been realized; the surgeon is master of the wounds he has himself inflicted.

One must, however, note that the pendulum of fashion may have swung a little too far in the direction of aseptic surgery. This has led some surgeons who have forgotten the value of the older methods to abandon the succeeding prolonged laborious washing and scrubbing of the integument, and to substitute therefor the use of tincture of iodine as the most convenient and serviceable antiseptic for this purpose. They may have good reasons for adopting such a plan; it does not, however, seem to be the best agent for the purification of wounds.

We may now revert to the treatment of compound fracture and recently inflicted wounds. While the prophylaxis of sepsis has thus developed, it is noteworthy that the curative measures remain practically the same as established by Lister. I have seen no other method realize such excellent results in cases of compound fracture, unclean and lacerated wounds. Not only in the course of long years have such cases been saved from all the ordinary wound complications, but the entire absence of tetanus has been a marvellous feature. I would reiterate the importance of using a pure phenol for the preparation of the lotions already alluded to. I would emphasize the care which a thorough and prolonged cleansing of the wound and its surroundings requires. I would lay stress upon the necessity for free drainage, enlarging the wound if need be, and use must be made of a copious absorbent *antiseptic* dressing, and we must see that it is changed as required.

While it is true that many perforating bullet wounds run a perfect course, receiving no more than a superficial paint of tincture of iodine as a prophylactic, in no circumstances dare we treat lacerated wounds and compound fractures by such simple measures. It is only by a return to the curative methods of antiseptic surgery that we can hope to banish tetanus. I cannot recollect to have encountered tetanus in a wound which was not already septic, nor can I recollect to have encountered one single fatal case of tetanus which developed in a wound which had been thoroughly soaked and treated with carbolic lotion.

It is true that in times of war immediate purification of such cases must present difficulties, and with every hour that elapses the dangers increase; but we know that success has followed even twenty-four and more hours after the receipt of the injury, and so a thorough purification can be effected at a base hospital. I am tempted to recall the following instance:

On September 27th, 1910, H. M., aged 15, was working in the fields when she fell in front of a reaping machine and sustained a severe injury of the right foot. The wound was dressed temporarily, and she was sent from the extreme north of Scotland to Edinburgh Royal Infirmary, where she arrived on September 29th. Next day, under an anaesthetic, the splint and dressings were removed, and a large gaping wound was exposed, which extended from the tibial to the fibular side of the dorsal aspect of the foot. Every structure had been divided. The tendons had retracted. The blades of the reaping machine had worked like a section cutter, laying open the astragalo-scaphoid articulation, almost entirely taking off the head of the astragalus and a quarter of an inch behind that, making a fresh cut almost down to the os calcis. The whole foot and wound were soaked in carbolic lotion 1 in 20, portions of leaves, grass, and earth were cleared away from between the various cuts, and the severed head of the astragalus was removed. An elastic bandage was now applied from the ham downwards, which caused the tendons to protrude in the wound. They were then readily identified, and the divided ends were sutured with fine silk. The nerves were treated in like fashion. A drainage tube was inserted at the inner side, the wound was carefully closed with silkworm gut and horsehair sutures. A deep dressing wrung out of carbolic lotion was applied, and the foot, swathed in corrosive wool, was secured to a splint in the position of extreme dorsiflexion. Subsequent progress was normal. She was dressed on the fourth, seventh, and seventeenth days, when the wound was found to be healed, and the stitches were removed. On the twenty-second day the foot was put up in plaster of Paris, which was taken off on November 10th. She left for home with return of sensation and function. She now writes that the one foot is as good as the other, and that she can walk, dance, and run with perfect freedom.

One word of warning. Under no circumstances should an impermeable layer cover a moist carbolic dressing for any length of time. The dangers of carbolic acid poisoning and gangrene have been absurdly exaggerated and are due to the use of inferior and imperfectly dissolved solutions employed as moist dressings beneath an impermeable covering. As dressing material carbolic acid in the crystalline form, the double cyanide gauze or powder and corrosive wool are sufficiently portable and convenient.

Experimental pathology has also added to our armamentarium in the fight against wound infection by the discovery of vaccines and serotherapy. Lister made frequent allusion to the antiseptic agency of living tissues in combating micro-organisms. Mikulicz attempted to call forth the prophylactic leucocytosis by subcutaneous injection of nucleic acid twelve hours prior to abdominal operations

There is good reason to believe that the prophylactic use of antitetanic serum will do much more to ward off the attack of this most terribly fatal malady in wounds infected with soil, mud and stable litter, than it can possibly accomplish as a curative agent once the disease becomes evident.

It is more difficult to assess the value of vaccines and serums in other grave surgical wound affections, but there can be no doubt that the timely application of the rigorous measures laid down by Lister, carried out conscientiously and thoroughly with a due appreciation of the object in view and the principles involved, will do more to save life than haphazard, half-hearted and ineffectual aseptic measures.

THE BORDERLAND OF DISEASE.

BY

GUTHRIE RANKIN, M.D., F.R.C.P.,

PHYSICIAN TO THE DREADNOUGHT AND ROYAL WATERLOO HOSPITALS.

(Continued from page 824.)

II.

PASSING on from the circulatory and pulmonary systems, which were referred to in the notes of last week, we find similar evidence elsewhere of the importance attaching to early and often obscure indications of disturbed health, and nowhere more frequently than in the gastro-intestinal system, where borderland cases are met with continually. There is, perhaps, no such land of surprises anywhere in the territory of disease as the abdomen, and none in which functional manifestations are so often the forerunners of established organic mischief. Dyspeptic troubles are among the most frequent infirmities of humanity. Many people suffer throughout the greater part of a lifetime from miseries that excite little sympathy because they carry with them apparently no danger, but in a multitude of cases they entail an amount of physical distress and mental depression that robs existence of all its happiness, envelops its achievements and successes in a gloom of personal discomfort, and makes it a burden almost more than can be borne. And yet how much might be done to mitigate this burden of wretchedness by a little more careful consideration of questions of etiology and treatment when the subjective symptoms are still "a voice crying in the wilderness"! Many a gastric or duodenal ulcer might be escaped if more active measures were adopted to correct the early indications of a disturbed digestion; calculi in the gall bladder or urinary tract might be prevented if the preliminary warnings were interpreted in the full light of their possibilities: rheumatoid changes in the joints, degenerative processes in the mucous membrane of the intestines, a whole series of vasomotor disturbances, and a final intractable neurasthenia might be guarded against by proper attention to the hygiene of the mouth, a suitable dietetic regimen, and a wise adaptation of energy output to the vital reserves of the individual. Finally, many of the tragedies connected with what we nowadays recognize as an "acute abdomen" might be of rarer occasion if the prodromal warnings were more thoroughly understood and more carefully dealt with. The following epitomized cases are both illustrative and instructive.

A man of 45 years of age, occupied in scientific research, and living a very strenuous life, came to see me in 1910 complaining of indigestion of many years' standing, which was rapidly ruining his peace both of mind and body, and was becoming worse in spite of all he had done for its alleviation. In outline his symptoms were heartburn, epigastric pain coming on three or four hours after food and at once relieved by sodium bicarbonate or a meal, obstinate constipation, flatulent distension, sleeplessness, irritability, restlessness, and loss of weight. On examination he was of a sallow complexion and spare habit of body. He had increased reflexes and all the other stigmata of a pronounced neurasthenia, a coated tongue, and a mouthful of gold-capped teeth with pus exuding from below the crowns of several of them, marked tenderness and rectus muscle resistance to the right of the epigastrium, a stomach dilated almost to the level of the umbilicus, a gurgling and tender colon, and a loose right kidney which, though smooth, gave to the examining hand the impression of being enlarged. His heart and lungs were normal and there was no evidence of organic disease in his nervous system. The urine contained indican but was free from albumin or sugar. On one or two occasions he had induced active sickness in the hope of giving himself relief, but he had never experienced spontaneous vomiting, nor had he suffered either from haematemesis or melaena. His habits of life were moderate, but uncertain and badly regulated in regard both to food, work and exercise. His condition had been variously diagnosed as dyspepsia, dilated stomach, colitis, and eventually as duodenal ulcer, and he had been advised recently that nothing short of an abdominal operation was likely to do him any good. On inquiry it transpired that he worked very hard, often well into the early hours of the morning; that his life was not only strenuous but full of worrying anxieties and unrelieved by any periods of adequate rest; that he kept himself going by copious libations of tea, and that his daily diet consisted very largely of sweets and carbohydrates. Under the influence of a diet plan from which sweets, tea, and uncooked vegetables were entirely excluded, and carbohydrates rigidly cut down to small amounts; of a course of massage especially directed to the abdomen, and a period of three weeks' complete rest from work, followed by a lazy holiday; and of a drug combination after meals of valerian, carbolic acid, strychnine and codeine, together with 1 grain of calomel twice a week and half an ounce of liquid paraffin every night at bedtime, he achieved a marked improvement, regained his proper habit of sleep, put on weight, and got back again some of the cheerful equanimity which had been characteristic of him in the earlier years of his life. Over a period of fully two years he required to be kept under occasional observation, and derived help from one kind of tonic or another, according to the varying indications of his condition, but for upwards of eighteen months now he has been entirely free from discomfort, and, having arrived at a proper realization of his limitations, has been able so to regulate his daily habits as to keep the balance even and get through, with comfort and success, a large amount of the scientific work to which his life is devoted. It may be of interest to mention that of all the tonic combinations ordered for this patient, that which suited him best, and to which from time to time he still has recourse, was a mixture of papain, reduced iron, salol, nux vomica, and rhubarb, taken in the form of a capsule after meals. The evidence in this case is convincing that the years of functional disturbance threatened to culminate in peptic ulceration, and that all the risk of serious organic disease and probable surgical interference might probably have been avoided if in the earlier days of his ill health the borderland symptoms, which distinctively pointed the way to the rocks ahead, had directed the dietetic, medicinal, and hygienic treatment along lines of greater care and more persistent attention to detail. He was regarded as a sound man who was overworked and in consequence dyspeptic, and one who required no greater attention than an occasional holiday, together with a few doses of an ordinary sodium bicarbonate and gentian mixture. It is impossible to say how many cases of duodenal or gastric ulcer might be prevented if the initial borderland manifestations were taken more seriously to heart. My personal experience leads me to think their number would be very considerable, and that, under the influence of suitable and early medical methods, a largely diminished number of cases would drift to the operating table of the surgeon.

Probably there are no more painful episodes in the whole category of disease than those associated with the passage of a stone. The most frequent situations of calculi are the urinary and biliary tracts, and in both much may be done, by a timely recognition of the prodromal symptoms indicative of a tendency to their occurrence, to prevent their formation, or to limit their harmful effects once they have become an established fact. The following cases are well-marked examples of this type of disorder.

A lady of 68 years of age, stout in build, inactive in habits, and of gouty antecedents, had enjoyed good health until about 48 years of age, when she entered upon the menopause. From the time her menstrual function began to be irregular she suffered from disturbance of digestion, and became subject to occasional attacks

of sickness, which on several occasions were followed by a mild form of jaundice. The bowels had been irregular during her whole life, but they now became obstinately constipated, and required powerful aperients to keep them in order. Her health otherwise was fairly good, but the repeated biliary attacks gave rise to a considerable degree of mental depression, which often made life miserable both for her and her family. For about fourteen or fifteen years her health continued unsatisfactory, but she never became so acutely ill as to necessitate continuous medical care. Suddenly one night, shortly after getting to bed, she was waked by agonizing pain in the region of the gall bladder, soon followed by active sickness, and not relieved until she had half a grain of morphine injected subcutaneously. The attack was followed by very definite jaundice accompanied by a bile-laden urine and clay-coloured sticky stools, and was typical of gall colic, most probably due to the passage of a calculus. It was succeeded by many of similar character, some more severe than others. She saw an eminent surgeon, who said there was no doubt her gall bladder contained stones and held out to her no prospect of relief except by having them removed. He further warned her that the risks of malignant developments were not small. She had an unreasonable dread of an operation, and made up her mind to make the best of things so long as the acuteness of the pain, when it came on, could be relieved by morphine. She was put upon a careful dietary, was induced to do a little more in the way of open-air exercise, and was given occasional doses of blue pill, leptandrin, and rhubarb, with periodical short courses of ammonium chloride, taraxacum, sodium salicylate, and gentian. In addition, she was asked to take one ounce of pure olive oil every night on going to bed. Under this plan of treatment her attacks became less frequent and less severe, until eventually, for the four or five last years of her life, she was completely and permanently free from discomfort. She ultimately died of apoplexy. A case such as this strongly suggests that in the earlier years of her discomfort the condition was in all probability one of inspissated bile, and that more active methods of treatment and of dietetic restriction would have gone far to prevent the actual formation of stones. The early attacks were regarded too lightly, and ascribed to mere biliousness which, in its turn, was believed to be due to climacteric disturbance. No attempt was made to modify her food and her habits of life to the requirements of her condition, and so she slowly drifted into years of broken health, much of which might have been avoided if the early danger signals had been heeded. There is yet another practical point emerging from this case that is worth emphasizing, and that is the value of olive oil in the treatment of gall colic. I am fully aware that it is brushed aside by surgeons and others as a mere faith cure, and I am unable to offer any explanation of the method by which it accomplishes its purpose, but I do know from repeated experiences that in a considerable number of cases the complete relief from acute attacks of pain, together with the accompanying improvement in physical well-being and mental comfort, has been quite remarkable. I do not for one moment suggest that the removal of gall stones by operative methods is not the clearly indicated method of treatment in most instances, but there occur cases, like the one I have just related, when operation is refused, or is undesirable for one reason or another, and in such the value of olive oil should never be forgotten. Its administration can do no harm, and will sometimes yield such brilliant results as to convert a life of misery and gloom into one of contentment and comfort.

Let me now briefly relate a very interesting and instructive case of urinary calculus. A gentleman of 66 years of age had been under occasional observation for several years. In early manhood he had lived freely as regards both food and drink, but for the last eighteen or twenty years of his life he had become, as a result of religious awakening, a practical teetotaler, who devoted the whole of his time to good works among the poor and practised for himself habits of almost ascetic simplicity. He was an active man, of spare habit of body, and cheerful in disposition, who had never suffered from serious illness. His complexion was pale, and from time to time his digestion gave him passing discomfort. He had no evidence of organic disease, and the minor ailments of which he periodically complained seemed fully explained by the busy and self-forgetful life he led. His heart was perfectly normal, but he presented signs of a moderate arterio-sclerosis. The one fact about him that arrested attention was a slight and intermittent albuminuria. The urine was often without fault, and when albumin was found it never amounted to more than a faint cloud, which seemed to synchronize with a greater than usual degree of anaemia. He had no frequency of micturition, suffered no pain in the lumbar region or down the course of either ureter, and the urine had never been discoloured. Suddenly, about a year ago, while living quietly in the country, he was alarmed to find that the water he passed one forenoon was bright red. He still had no pain, but the doctor who saw him in the course of the day found that the redness was due to blood, and that there was slight tenderness on deep pressure over the right kidney, with a noticeable retraction of the corresponding testicle. Under the influence of rest and care the urine soon became normal, and remained so for several weeks. Again, this time apparently as the result of some slight and unusual exertion, blood declared itself, and was associated with a definite subjective sensation of discomfort in the right kidney region. He came to town as soon as he was well enough to travel and was at once *x* rayed, when one large and a second smaller calculus were clearly revealed in the body of the right kidney. When they came to be removed, the large stone was found so closely adherent to the kidney tissue in which it had grown that it offered some difficulty in extraction. The history of the case subsequent to operation was uneventful except for one or two curious hysterical attacks that seemed to be accounted for by the mental disturbance of a passing worry, but were accompanied, on each occurrence, by a very marked temporary diminution in the amount of urine excreted. Before he left the nursing home his urine was practically normal, the operation wound had healed throughout its whole length, and his general condition, except for a certain amount of anaemia and feebleness, was as good as could be expected. The first two occasions on which he drove out he was comfortable and happy, but after his third drive he complained of pain in the right lumbar region, and on returning home passed a small quantity of blood. He was at once put to bed and carefully looked after, but he rapidly developed almost complete suppression of urine, and died very shortly from uraemic coma. Throughout all the years this gentleman came to see me his symptoms never once aroused the faintest suspicion of the existence of a calculus, but in the light of subsequent developments it was clear that the mild albuminuria was all the time a danger signal which was misunderstood. The borderland country had not been explored with sufficient care, and though the albuminuria seemed adequately explained by the anaemia and arterio-sclerosis which undoubtedly existed, an initial recourse to examination by means of the Roentgen rays would have declared the presence of the true cause of the albumin, and would have justified the removal of the calculus at a time when it must have been smaller, and when it might have been less tenaciously anchored to the tissues in which it was embedded. Another feature of this unfortunate case that, in the light of subsequent events, raises a question of borderland importance was the occurrence of nerve-storms, accompanied by a passing diminution of urinary activity which I have related. Was their true meaning not a forecast of the ultimate irremediable cessation of kidney activity, and might the fatal issue not have been escaped by keeping this man completely in bed for a much longer period of time in order to allow the balance of his nervous mechanism to become more stable before it was exposed to the demands of extra strain? No one can tell, but the case conveyed to my mind two lessons I cannot forget: First, that in every patient past middle life who manifests a persistent albuminuria, however slight, an *x*-ray examination should never be omitted; and, secondly, that obscure nervous manifestations occurring during convalescence from a kidney operation call for prolonged rest in bed, and justify a guarded prognosis as regards the ultimate stability of renal function.

The most familiar example I can give of the combination of rheumatoid, colonic, and neurasthenic troubles which

constantly come within the purview of every physician is that met with in women at the time of the menopause. And, in passing, I cannot refrain from expressing a conviction that in the history of man there comes—a little later in his life than in that of the woman—a re-adaptation of tissues and secretions to the necessities of a more advanced stage of existence, which produces a very similar passing disturbance of his functional health. Between 57 and 63 he goes through a climacteric experience that is often wholly misunderstood, and consequently unsuitably treated. In both sexes the climax of life is a true borderland beyond which lies one of two alternatives, either broken health with multiplying and increasing infirmities, or a new lease of life on a plane of lessened activities, modified ambitions, and a chastened philosophy. We need only look at the mortality of the fifth decade of life, and appeal to our own experience of the frequency of breakdown in health that occurs about that period to be convinced that in both sexes Nature then admonishes all of us to take stock of our health and strike a balance so that the future may be wisely ordained with a view to the proper adjustment, under new conditions, of expenditure to income.

A concrete example will provide a picture of the ordinary climacteric instability which characterizes this uncertain time in the life of every woman and, making due allowance for sexual differences, of some men. A lady of 52 years of age, who was the mother of four children and had enjoyed hitherto more than average good health, came complaining of recent discomfort from headaches, impaired digestion, broken sleep at night, a constant sense of weariedness, irritable bowels, flying muscular pains, and an unpleasant experience of mental depression, irritability of temper, and failure of memory. She was a stout, florid, gouty type of woman, who looked as if there could not be much amiss with her health, and who proved, on examination, to have no evidence of serious disease. The prominent features of her condition were irregularity of menstruation for about fifteen months; flushings, polyuria, vertigo, sweatings, dermographia, palpitations, and other minor evidences of vasomotor instability; occipital headaches, marked increase of the knee-jerks with accompanying absence of the plantar reflexes, muscular tremors, impairment of memory, recurring attacks of acute mental depression, restlessness by day and often by night, introspective miseries, and a general unrest of her nervous system; abdominal distension with griping pains, diarrhoea, alternating with intractable constipation, stools that were at one time scybalous, at another liquid, often abnormally pale in colour, and from time to time accompanied by quantities of membranous mucus, and digestive discomforts that compelled her to seek relief by avoiding one article after another in her daily dietary until she was in a perfect maze of confusion as to what she should and what she should not eat; pains which she described as rheumatic and which she referred to the tendinous insertions of her muscles and to the terminal joints of her hands and feet, those of her fingers, especially on the right hand, being obviously the seat of early Heberden thickening; and periodic attacks of aphonia, accompanied by shortness of breath on exertion, and a choking sensation in her throat, for which no satisfactory explanation could be found on physical examination. This bewildering riot of symptoms is peculiarly significant of fundamental changes upsetting the balance of health, and is illustrative, more than any other example that could be quoted, of the disturbance of equipoise which accompanies the passage of most of us through the climacteric borderland. The problem which presents itself for solution in all such cases constitutes an invitation for a reply to the obvious question, What maintains the equipoise of health? No completely satisfying answer can, in the present state of physiological achievement, be given to this interrogatory. But, though our knowledge of the internal secretions is still a mere glimmering in the early dawn of pioneer discovery, enough is known to justify the hypothesis that in ways which are still obscure some break in their normal interrelationships may prove the keynote to a solution of climacteric and many other clinical puzzles which, though without organic explanation, are inimical to comfort and may even mark the threshold of permanently broken health.

When we come to consider the question of "acute abdomen" we are faced with a subject of vast extent and importance. I have interposed it in the currency of this sketch because there are so many examples of the condition which subsequent reflection makes plain to us might have been escaped or prevented if only the initial warnings had conveyed a sufficient sense of the possible dangers they betokened. I need not enter into a discussion of the various conditions upon which the acute abdomen depends. I must content myself with the choice of one cause of this emergency, and the selection recommends itself to me for two reasons: First, because it illustrates graphically in this sphere of disease the value of borderland evidence; and secondly, because the abdominal flare-up is directly and entirely due to medical—as distinguished from surgical—disturbance of the organism.

I do not know whether the accidental circumstances of my particular practice are accountable for the fact that nowadays I see a very much larger number of cases of glycosuria than formerly, or whether this particular form of metabolic disturbance is increasing in prevalence among the people of this country. I rather suspect the latter to be the true explanation, because I am particularly struck with the increasing numbers of such cases that pass through my hands not only in my consulting-room but also in the wards of both the hospitals to which I am attached. If this apparent increase is statistically real, one wonders why it is so, and whether it is yet another of the penalties exacted by an advancing civilization. We are not built so that we can live beyond a certain limited span of years, and all the satisfaction we gain by what we are pleased to call the conquest of one disease after another is relentlessly counterbalanced by increased incidence, and consequent mortality, in some other directions. It seems not unlikely that the greater diversity of food which, within recent years, has become accessible to all grades of society, may with some degree of reasonable likelihood be held responsible for a widespread increase of instability in metabolic integrity. Foreign fruits, chilled meat in ever-growing abundance and variety, preserved foods of every description, all at such prices as to bring them within the reach of a very large section of our population, and in addition the fashionable folly that sets the seal of approval on the provision of all sorts of edible delicacies that are out of season, may account for subtle changes taking place in the human economy, and explain variations in type of disease as well as increased prevalence in some and corresponding diminution in other directions of many disorders. Be this as it may, the point about glycosuria at which I wish, for the purposes of this paper, to arrive, is that one of its less common and therefore less recognized, but still highly important possibilities, is the occurrence as a terminal event of acute abdominal symptoms. My interest in the condition was first excited some years ago by the sudden death of a lady I knew well from what was, at the time, supposed to be some form of acute intestinal obstruction. Her illness was very short and her death came with almost tragic suddenness. No autopsy was allowed, and therefore the provisional diagnosis remains to this day doubtful. It was always significant to me that this lady was known to have had sugar in her urine for many years, and that she belonged to a family of which two members at least had died of true diabetes in early life. The whole story of her last illness and the manner of her death always made me feel that the clinical evidence did not fit in quite conclusively with the theory of an obstructed gut as the explanation. Many years afterwards my memory was carried back to the record of this lady's story by the occurrence of the following case. A lady of 64 years of age came to see me first in 1908 on account of an intolerable and intractable pruritus, which she ascribed to gout. The outcome of an examination into her state of health revealed a definite amount of arterio-sclerosis, with consequent accentuation of the second aortic sound and some increase in arterial tension, together with a urinary secretion of from 90 to 100 ounces daily, containing sugar of varying amount, but averaging between 2 per cent. and 5 per cent. The pruritus was both pudendal and anal, and had been a source of trouble off and on for years. She had no other evidence of organic disease, but gave a record in earlier life of several attacks of abdominal

pain, which seemed not unlikely to have been caused by biliary colic. She was a ruddy, well-nourished woman of active habits and cheery disposition, but one to whom dietetic restrictions were such a serious punishment that complete obedience to a hard-and-fast rule of life was impossible to enforce. Under such guidance as she would submit to, her life was kept fairly comfortable for two years; the amount of sugar did not increase, the quantity of urinary secretion came down to an average of from 60 to 70 ounces per diem, and the pruritus entirely disappeared. Suddenly one night she was waked from sleep with acute pain in the abdomen, followed after two or three hours by active sickness and pyrexia. When I saw her early the following morning she was restless, flushed, and complained of constant pain, which she referred entirely to the epigastric and right hypochondriac regions, and which she declared she recognized as a return of one of the old attacks of years ago. Her pulse was 120, small, thready, and abdominal; her temperature registered 102.5°, and her respirations, though 40, failed to completely satisfy her requirements for air. Her heart presented no new physical signs; her lungs were normal to percussion and auscultation; the abdomen was moderately distended, and over the whole area between the umbilical level and the short ribs there was acute tenderness and increased resistance to touch, but no definite swelling. The bowels had moved freely twice during the previous twenty-four hours, and for twelve hours she had passed no water. Later in the day a specimen was obtained, and was found to contain 28 grains of sugar to the ounce, with a distinct ferric reaction indicative of the presence of diacetic acid. By evening she was becoming somewhat incoherent and drowsy, and though complaining of less abdominal discomfort, was plaintively calling out for open windows that she might have more air to breathe. Respirations, pulse, and temperature were much the same as in the morning. By 10 o'clock she was completely comatose, and so she remained until she died about 5 o'clock the following morning. Obviously there was no question of bowel obstruction in this case, and the explanation of her terminal illness seemed to be an acute pancreatitis, probably of the haemorrhagic type. The symptoms presented by this patient entirely coincided with those related to me by the doctor who attended my lady friend years before, and my suspicions that, in her case, as in this one, though the symptoms bore many resemblances to those that would be produced by an acute obstruction somewhere in the intestinal tract, the more likely cause of the "acute abdomen" from which she died was the preceding glycosuria with a sudden accession of abdominal mischief, probably of pancreatic origin. The point to remember is the possibility of such an occurrence in the course of ordinary glycosuria, because though we are all alive to the risk of coma in such cases, we are not equally familiar with the fact illustrated by these cases, that this comatose state may be ushered in by abdominal symptoms difficult, or even impossible, to distinguish from a like train of events dependent upon entirely different conditions. No opinion should ever be expressed on the etiology of an "acute abdomen" until it has been ascertained whether the urine does or does not contain sugar, because, as we all know, such a condition may have existed for years without attracting the attention of the patient, and without, therefore, having afforded any chance of being discovered.

The subject of borderland illnesses is extensive, but these desultory notes and illustrative cases may stimulate some interest in questions affecting the earliest departures from the high level of perfect health. Perhaps there is almost no such thing as "perfect" health, but it is possible by careful inquiry and patient investigation to make sure that we do not found a firm opinion upon a casual observance of physical signs or a mere negation of subjective symptoms, but that we look a little more sharply after collateral evidence—that, in short, we forage inquisitively in the borderland, where, more often than we believe, we will find evidences of minor imperfections that so often escape discovery. It would be a provident and wise plan if every man went to his doctor for a thorough overhaul once in six months, not because he was driven to him on account of feeling ill, but because he was led to him by the desire to keep well. As custom now dictates it, the doctor is only sought out when there is an evil to remedy, but the day is not far distant when he will be retained in order that the evil may be, as far as possible, averted. It is true that we are more frequently consulted about trivial ailments than on account of acute and serious disorders; nay more, our time is often vexatiously encroached upon by having to listen to a long tale of imaginary woes and a formidable recital of aches and pains for which we can find no physical explanation, but, if my contention is right, all such patients are on the borderland of disease. Their discomforts, whether physical, mental, or emotional, have a foundation in fact somewhere, and clearly point to a fault that disturbs the harmony of perfect physiological activity. The engine is not tuned up to the best work it is capable of, and unless adjusted in time, some part must inevitably become permanently faulty, and constitute the blemish which spells premature consignment to the human scrap-heap. "Prevention is better than cure" is truer to-day than ever before, and we will do much to justify the proverb and to hasten its full realization if we direct our attention more and more to the borderland country and the evidences which are constantly to be found there of the earliest movements on the part of the enemy of mankind.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

TREATMENT OF TETANUS.

I have read with interest the note by Dr. Sheaf, in the British Medical Journal of October 17th, on the treatment of tetanus by chloretone. Tetanus, as every one knows, is of much more frequent occurrence in the tropics than in temperate climates, and during twenty-five years' work in British Guiana I saw a good number of cases. I was fortunate enough to have had a few recoveries even before the days of serum treatment.

Wounds of the foot were responsible for by far the greater number of my cases, a small wound from a splinter of greenheart being the very frequent history. Sometimes the patient denied any knowledge of injury, and no wound could be discovered, but it can be readily understood that natives who go about barefooted will frequently sustain an injury so trivial as to excite no notice. My experience of the disease led me to classify my cases into two groups: (*a*) Those with severe febrile disturbance; (*b*) those with slight or no febrile disturbance. In the former—unfortunately by far the most numerous—the temperature quickly ran up to 103° or 104° and even higher, and these cases almost invariably proved rapidly fatal. In the latter, the febrile disturbance was slight, up to 101°, and subsided very rapidly. In these cases the prognosis was more favourable.

My routine treatment after careful attention to the wound (if any) was to give a very full dose of chloral hydrate and to follow this up with just sufficient of the drug to keep the patient constantly under its influence, and free from spasms. Under this treatment I had quite a fair number of recoveries, including one case of tetanus neonatorum which was severe at the outset.

The most watchful care is required throughout the whole course of the case; nourishment must be given as freely as possible, and some judgement is needed to give just enough of the chloral and not too much, but my experience leads me to think that the more frequent error lies in too small rather than too large dosage.

W. F. Law, M.D., F.R.C.S.I.,
Late Medical Inspector,
Dublin. British Guiana Government Service.

THE TREATMENT OF ENTERIC FEVER.

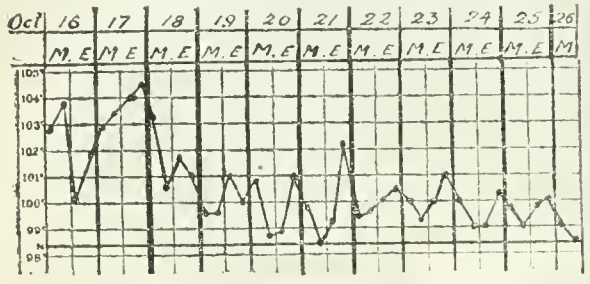
Fortunately previous inoculations will greatly reduce the incidence of enteric fever in this war, but already a certain number of cases have been sent back from France. The disease is of a very severe type, probably owing to the exhaustion of the men.

I should like to recommend the use of an icebag in the treatment. It should be suspended from a cradle over the right side of the abdomen in the region of the lower part of the ileum. It is important that there should be nothing between the icebag and the skin but a piece of

gauze or butter muslin, so that the cold may penetrate as far as possible.

Medicinally, I think there is nothing to equal Sir William Broadbent's prescription of quinine sulphate gr. ij, dilute sulphuric acid ♏ iv, and liquor hydrarg. perchlor. 5½ every four hours (not within half an hour of food). If the diarrhoea is excessive the sulphuric acid can be increased, and if there is constipation magnesium sulphate can be added in sufficient quantity to produce one or two actions of the bowels a day. The use of the sulphuric acid and sulphate also tends to diminish the risk of haemorrhage.

As an illustration of the efficacy of the icebag combined with this medicine, I append the temperature chart of a



case occurring in a slightly wounded soldier who was transferred to my ward on the second day. The temperature, which had been 103.8° the day before, was 104.5° when this treatment was commenced. In twenty-four hours it fell to 101°, and only once afterwards rose to 102°. He had had diarrhoea for four days before admission. There was very marked tenderness in the right iliac region, and the spleen was enlarged and tender. He had never been inoculated. It was a case in which one would have expected deep ulceration and possible haemorrhage, but he has done exceedingly well, and has never caused any anxiety.

WALTER BROADBENT, M.D., M.R.C.P.,
Major R.A.M.C.(T.).

Brighton.

ANAESTHETICS IN EYE WORK.

I SEE that Mr. Harrison Butler has criticized somewhat severely my note on the above subject, which appeared on September 12th.

My contention that chloroform should not be entirely abandoned in eye work is, on the face of it, a moderate one; Mr. Butler's view is extreme, not to say immoderate. He justifies the exclusion of chloroform by saying, first, that a patient is entitled to the "absolute safety" of ether anaesthesia as opposed to the "reasonable degree" of safety of C.E. mixture. Let us examine this argument. We find that the death-rate for C.E. is 1 in 7,000, while for pure ether it is 1 in 10,000. A simple calculation shows that 21,000 cases will have a mortality of 3 in the case of C.E., and 2 in the case of ether. This number of cases represents thirty-five years' work at Moorfields under twelve surgeons. One may safely assume that an ophthalmic surgeon during an operative lifetime of thirty-five years would not do more than half that number of cases, including both hospital and private work. If during these thirty-five years he employed ether he would have one death. If he employed C.E. he would have one and a half deaths, or to put it more accurately, he would stand an even chance of having one death or two deaths. To say that in the former case his patients have absolute safety is, of course, inaccurate.

Further, Mr. Butler says that he does not see the difficulties and inconveniences entailed by ether anaesthesia. Yet, I think, though unseen by him, they exist. I have not had the pleasure of seeing Mr. Butler operate, and so am not aware how he overcomes difficulties which most surgeons find more or less embarrassing. But I cannot but consider the venous congestion, the laboured respiration and consequent movement, the collection of mucus in the air passages, and, not least, the obstruction caused by the Clover or open ether apparatus, to be by no means negligible hindrances to success or even safety. If, indeed, the surgeon be using the actual cautery for conical cornea or corneal ulcer there is with ether a very real danger of explosion.

For these reasons, amongst others, I venture still to think that chloroform and ether is preferable to ether for ophthalmic operations.

I much appreciated Mr. Devereux Marshall's reference to my note, and am glad to know that his naval duties still leave him the time and the inclination to read the BRITISH MEDICAL JOURNAL. I can assure him that those who know him follow with the greatest interest any news we are permitted to have of his ship.

MAURICE H. WHITING, M.B., B.C.Cantab.

London, W.

HAEMATURIA COMPLICATING PREGNANCY.

IN opening the discussion at the Annual Meeting of the British Medical Association at Brighton, in the Section of Gynaecology and Obstetrics, "On the affections of the urinary tract in pregnancy," Sir Halliday Croom stated that haematuria in pregnancy was somewhat rare, as he had only met with one or two cases. Having recently had a case of this disorder, the first in many years' practice, it seems to me worthy of record.

Mrs. D., aged 28, about two and a half months pregnant, consulted me on July 31st, 1913. She stated that she had been passing blood in the urine for four days. She had a similar experience of short duration during her first pregnancy, for which she received no treatment. She had no sickness, pain, or any other complaint. The urine was purple in colour and there was a layer of blood at the bottom of the glass. The specific gravity was 1016 and albumin was present.

She was kept in bed, the diet restricted, and lead and opium, gallic acid, turpentine, saline purgatives, and adrenalin were prescribed in succession without any remedial effect, but there was a temporary diminution of the haematuria after a few doses of Ruspini's styptic, which is said to consist of a strong solution of gallic acid and spirit of roses, with, perhaps, a little zinc sulphate. The pulse and temperature remained normal while under observation.

On August 6th, as there was no improvement, I had a consultation with a medical friend, who was of opinion that the right kidney was enlarged. Ten days afterwards I had a specialist in consultation, who confirmed this opinion, and advised an operation, but the patient declined to go to hospital. In these circumstances I prescribed sol. adrenalin chlorid., ♏ v, with a teaspoonful of Ruspini's styptic, every two hours, and after a few doses the haematuria gradually disappeared. On examining the urine after this, there was a layer of pus at the bottom of the glass cylinder, and under the microscope there were pus corpuscles.

She got out of bed on August 21st, and as there was a slight return of the haemorrhage afterwards she consented to go into the hospital, where she was under observation for three weeks and examined by the cystoscope, but returned home without any operation being performed.

The subsequent history was without deviation from that of a normal pregnancy, and she was delivered, after a rapid labour, of a living child, which was rather smaller than usual. Since then mother and baby have kept well, and the urine, she states, is better than it has ever been.

WILLIAM A. CASKIE, M.A., M.D.

Glasgow.

AT the regular meeting of the University Lodge of Hong Kong No. 3,666, held on September 28th, the Worshipful Master, W. Brother Francis Clark, M.D., P.G.D., referring to the death of the late Brother Sir Kai Ho Kai, C.M.G., M.B., C.M., said he was one of that small band of pioneers who realized, even thirty years ago, that the future of China lay in the hands of those of his countrymen who were prepared to share the knowledge and the science of the West. He was a graduate in medicine of the University of Aberdeen, a barrister-at-law of Lincoln's Inn, and an author of no mean repute. Among his many other achievements, he was a founder of the College of Medicine, which began its career in 1887, and was also one of the prime movers in the establishment of the University of Hong Kong.

Reports of Societies.

ROYAL SOCIETY OF MEDICINE.

Clinical Section.

At a meeting of this section held on November 13th, Mr. Charters J. Symonds, the President, in the chair, the following cases, amongst others, were exhibited:—Mr. Alan H. Todd: *Probable injury of the crucial ligaments* in a man aged 30. The patient had injured his knee while playing football when aged 15. Ever since the joint had felt weak, and sometimes painful and swollen. On several occasions it had becomed locked, but this the patient had been able to reduce by forced extension. Genu varum and a slight limp had developed; there was some limitation of flexion and extension. The joint was slightly larger than that of the other side, apparently due to osteophytes. Dr. W. Essex Wynter and Sir J. Bland-Sutton: (1) *Acholuric jaundice* for which splenectomy had been performed. The man, aged 26, had suffered from jaundice and anaemia all his life. Other members of the family had been affected. For two years it had progressed. The spleen was only slightly enlarged. There was no increased fragility of the red cells. The operation had been followed by marked improvement. (2) *Splenic anaemia* after splenectomy in a boy aged 13. There had been glandular enlargement and some enlargement of the thyroid, whilst the spleen extended 4½ in. below the costal margin. The leucocytes numbered 2,600 per c.mm. After the operation they rose to 8,000. Mr. G. H. Almond: *Myositis ossificans* (juvenile progressive type) in a girl aged 7. Several patches of ossification were present in the muscles, and were especially developed in the left ilio-tibial band, which was completely ossified, and the left hamstrings. The trunk muscles were not affected.

Section of Ophthalmology.

At a meeting on Wednesday, November 4th, Mr. Priestley Smith, President, in the chair, Mr. Hugh Thompson showed a young girl who had *Dilated pupil of Argyll Robertson type*, with well-marked contraction on closure of the lids. The condition was not congenital, as two years previously her pupils were normal and she had only slight myopia. The knee-jerks were normal. He also exhibited a case of *One-sided internal ophthalmoplegia* in a man who was invalided from the navy two years ago on account of supposed aneurysm. He was a stoker, and since he left he had been doing similar work in a brewery. Sir John Broadbent failed to find signs of an aneurysm. Mr. Rockcliffe spoke of two cases with *Mydriasis and irido-cycloplegia*. In one there was a strong family history of retinitis pigmentosa. One patient's end was in an asylum as a general paralytic. Mr. Bishop Harman showed a case of *Congenital entropion*. The mother was normal, but the grandmother was said to have had a double row of lashes. He proposed to split the lid, so as to separate the lashes from the glands, and graft between the two a strip of mucous membrane. If that succeeded he expected the lashes would be prevented from reaching the cornea again. Mr. Mayou referred to three similar cases which he had had. He operated upon them by taking out a narrow band of skin on the outer side of the lid. There had been no recurrence, though one was operated upon five years ago. Mr. Bishop Harman read notes of a case of *High myopia in an infant*. Mr. W. H. Jessop showed a case of *Tumour of the lower lid*, which he regarded as a lymphangioma. Skiagrams showed nothing abnormal about the bones and skilled nasal investigation was negative. Surgeon-Major Elliot mentioned a similar case which he saw in India, and which was found to be due to a form of sporotrichosis. Mr. Leslie Paton had seen a similar case following extensive scarring from lupus, and there was complete blockage of the lymphatics draining the eyelid. He asked a colleague to establish a permanent drain into the lymphatics of the lip. Mr. Harman reminded members of a case shown at the Laryngological Section in which drainage was done into the neck and answered fairly well. Mr. H. L. Easox exhibited an example of *Confluent tubercle of iris*. Tuberculin had not improved it. As perforation was occurring in the ciliary region, the only course was removal of the eye. He had had a case in which perforation occurred in three weeks; in this case it commenced in the fifth week of the history. Mr. Dawnay showed a patient suffering from *Intraocular metastatic carcinoma*. Mr. W. T. Holmes Spicer read a communication entitled *Cysts in the anterior chamber arising from the pars ciliaris retinae*, and illustrated it by a number of slides. The case, which had been under observation seven years, began with a white spot at the edge of the pupil at 3 months of age. At 16 months, when first seen, there were three opaque, finger-shaped masses coming into the anterior chamber from behind the iris. Four years later these had disappeared and a cyst about 4 mm. in diameter was seen floating freely in the anterior chamber. Other cysts appeared later, and finally there were seven, floating like toy balloons in the anterior chamber. In the meantime, the eye had become glaucomatous, a ciliary staphyloma had formed, and the eye was removed. A pathological examination made by Mr. Greeves showed that the cysts were formed of embryonic retinal tissue, containing vitreous. They had their origin in the pars ciliaris retinae, starting from cellular membranes which grew over the iris and also into the vitreous; the cysts grew on the surface of these membranes. There was in many places in the walls of the cysts a resemblance to glioma tissue. The case further proved the non-mesoblastic origin of the vitreous. Mr. Treacher Collins said the case bore out the view of the embryologists that the vitreous humour was derived from neural epiblast, and that it was derived from only one portion of it. Mr. Mayou referred to a case of his own in which there was a pigmented tumour in a microphthalmic eye, consisting of epithelial cells. It occupied only an eighth of the segment of the ciliary body. Mr. W. Lang mentioned a case he saw with Professor Fuchs in which there was a semitranslucent brownish cyst in the anterior chamber. Since then he had had a similar case of his own, but an attempt to deal operatively with it was not successful.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Obstetrics.

At a meeting on October 30th, Dr. M. J. Gibson, President, in the chair, Dr. Gibbon FitzGibbon showed a *Uterus with malignant adenoma* removed from an unmarried woman aged 60. The specimen showed a soft cauliflower growth filling up the cavity of the uterus and growing all over the walls which were very thick, about 1½ in., and at one part showing a line of demarcation which might have been the capsule of an original fibroid. Sections showed typical adenoma with very marked malignant characters in some parts, and invading the wall of the uterus. The cervix was quite free from invasion. A second section was shown of a *Non-malignant adenoma* removed from a woman of 28, which had been extruded from the uterus as a polypus, and showing great similarity in structure but without any malignant characters. Remarks were made by Sir William Smyly, Dr. Rowlette, and the President. Dr. Solomons showed a specimen of *Fibroid uterus* from an unmarried girl aged 27. Fibroid uterus was diagnosed and palliative curettage and styptic treatment were carried out. The haemorrhage, however, recurred and the abdomen was opened in the hope of performing myomectomy, but when the uterus was opened it was found to be studded with myomata, some submucous, others interstitial. Hysterectomy was done. The case was discussed by Dr. Sheill and the President, and Dr. Solomons replied. Dr. McAllister gave a summary of the various conditions of the *Heart and kidneys in pregnancy*. The paper was discussed by Sir William Smyly, Dr. Hastings Tweedy, Dr. Crofton, and the President, and Dr. McAllister replied.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

At a meeting on November 4th, Dr. W. R. Smith, President, in the chair, Dr. C. H. Cattle gave a lantern demonstration illustrating *Irregularity of the heart-beat*. The classification of irregularities now generally adopted follows the lines laid down by Dr. J. Mackenzie and Dr. T. Lewis. Amongst the more common forms of cardiac disorder referred to were the following: (1) Sinus

arrhythmia, or the youthful type of irregularity; (2) delayed conductivity and heart-block; (3) premature contraction of auricle or ventricle; (4) tachycardia with regular or irregular rhythm; (5) auricular flutter and auricular fibrillation; (6) exhausted contractibility and pulsus alternans. The different forms of cardiac irregularity might be differentiated both by means of the polygraph and other clinical methods. Valuable as the graphic method was, its results must always be taken in connexion with a complete survey of all the clinical features of a case. An attempt was made to explain the action of digitalis, and illustrations were shown of its effect in slowing the heart and occasioning coupled beats.

HUNTERIAN SOCIETY.

AT a meeting on November 11th, Dr. GLOVER LYON, President, in the chair, Dr. ALEXANDER MORISON read a paper on *Pernicious anaemia*, which, he said, broadly speaking, was a disease of early middle and middle life. There might be remissions with improved blood condition, but as time went on the patient became increasingly irresponsive to treatment, and the termination was uniformly fatal. Functional disturbances, due to abnormalities in the blood supplied to the various organs, appeared first; organic lesions might occur later. Visceral muscle might undergo degeneration; sclerosis of the central nervous system might occur, and extravasation of blood might take place. Superficial extravasation was never extensive; small visceral extravasations had been detected on microscopic examination after death. Stockman had suggested that these might be considerable, and that the haemosiderin in the tissues might be derived from this source. More probably, however, this had relation to the higher haemoglobin percentage of the anaemic blood and its imperfect constitution. The disease might be due to a blood destruction, or to a disorder of blood production. Whether one believed the disease had a toxic or bacterial origin in the digestive tract or not, the first essential of treatment after rest and fresh air was the rectification of any errors in mouth, stomach, and intestine; organo-therapy and vaccine treatment were disappointing. Iron was of little use; arsenic held out the best hope, whether in inorganic form or as salvarsan. The latter was preferable when the patient was under constant observation, the inorganic form being given afterwards in small doses to maintain the improvement. He had used salvarsan mostly in 0.2 gram doses (= $\frac{1}{3}$ grain arsenic) suspended in oil, given intramuscularly every week, or 0.4 gram every fortnight; benefit was usually, but not always, marked. He had never succeeded in raising the red cells to 5 million. There was no reason to think that arsenic acted in pernicious anaemia by killing micro-organisms or destroying their toxins; had it acted thus, recovery would be more frequent. It must act directly on the blood-producing power of the patient. Dr. A. WHITE ROBERTSON, in the course of a paper entitled the *Master toxin*, said all forms of chronic bacterial or protozoal diseases came to be regarded as not alone due to a specific organism under observation, but as determined in chronicity or failure to resolve by an antecedent toxaemia, which prevented the natural response of the blood elements, in the formation of immunity bodies. It was to the white cells, and not the red, that we must first look for information of a toxic condition of the blood. After long experience he had been able from a simple blood examination to identify, in cases with widely differing symptoms, the master toxin, whose subversive agency had allowed the development of the secondary invasions. Recurrent malaria, especially of the subtertian type, not only masked many subsequent diseases, but actually laid the patient open to them, and the first step in prophylaxis and treatment was the destruction of the predisposing factor. Similarly, it was well recognized that gonorrhoea and syphilis were followed by loss of resistance to other infections. In his opinion measles, whooping-cough, and influenza, no less than exposure, accident and mental shock, acted frequently as neuro-depressants and predisposed to tuberculosis, and the many other bacterial disorders, even after a period of years. After long study of the blood changes in tuberculosis, he had concluded that if the master toxin were recognized, and dealt with, the disease was entirely curable by a direct immunizing process. He believed that infection with mutant forms of the *coli* group of organisms in the intestinal tract played a far-reaching part in the subversion of immunity to all bacterial infection. This was of importance in connexion with intestinal stasis, a condition of insidious onset, but widespread results. Anaemia, in the broadest sense of the term, was always present in the shape of a definite leucopenia affecting the polynuclear, that was to say the phagocytic, cells; this blood picture was constant in all *coli*-typhoid and paratyphoid infections. In cases where vaccine treatment was disappointing—and these were not a few—he believed that a recognizable master toxin was preventing the expected response to the antigen. The master toxin arose from the *coli* group, and *x*-ray examination confirmed the presence of intestinal stasis. He had lately begun to suspect that there might be some connexion between the mutant *coli* group and pernicious anaemia. They might yet come to insist upon *x*-ray examination of the gastro-intestinal tract in this disease. He would like to see such an examination made legally compulsory, before any case of dementia was transferred to an asylum. Dr. LANGDON BROWN believed that certain facts pointed to pernicious anaemia being caused by excessive haemolysis. Free iron was found *post mortem* in the tissues, especially in the duodenum. There was more iron in the blood in other forms than that of haemoglobin, than in any other condition. Deposits of iron occurred in the portal area, and there was excess of urobilin in the urine. Dr. Morison had said that arsenic did not act as a protozoicide in pernicious anaemia, but it was a very efficient protozoicide in malaria, syphilis, and trypanosomiasis. Dr. O. K. WILLIAMSON referred to two cases whose blood pictures were identical, and typical of both complaints. *Post mortem*, the one case turned out to be pernicious anaemia and the other acute lymphatic leukaemia. Dr. RUSSELL WELLS recorded a case of a man who worked with lead, whose blood gave a typical picture of pernicious anaemia. With a change of occupation, and treatment with arsenic, the blood picture became normal in three months. Two years later the case came before him again, under exactly similar circumstances. Again the occupation was changed, and arsenic given; this time the blood picture became normal in nine months, and so far as he knew the man had been well since. Dr. MACKENZIE WALLIS said that analysis of the gastric contents in pernicious anaemia gave results typical of cancer of the stomach, and *post mortem* the mucous membrane was destroyed. He compared pernicious anaemia with bronzed diabetes, and brought evidence to show that, whereas in the latter haemolysis was normal and iron was retained in the body, in pernicious anaemia haemolysis was excessive, iron being both stored up in the tissues and excreted.

HARVEIAN SOCIETY OF LONDON.

AT a meeting of this society, held on October 22nd, Mr. J. JACKSON CLARKE, President, who was in the chair, showed four cases of *Gunshot fractures* incurred in the war. One was a comminuted fracture of the humerus caused by a rifle bullet; the remainder were due to shrapnel. The cases were discussed by Mr. V. Z. COPE, who related a case of severe shrapnel wound in the forearm. Troublesome haemorrhage had occurred some time after the injury. The bleeding points were widely distributed all over the wound. Apparently both the radial and ulnar arteries had been severed, and a free anastomosis had resulted. Dr. LEONARD GUTHRIE showed a case of *Congenital syphilis of the nervous system* in a girl aged 9 years. The knee-jerks were absent, but there was bilateral extensor plantar response. The gait was typical neither of cerebellar nor spinal ataxy. She walked in an awkward shuffling manner, swaying the trunk from side to side, the feet everted, with a tendency to drag them. The pupils reacted neither to light or accommodation. There were pegged teeth and old disseminated choroiditis. The Wassermann reaction of the blood was positive. Her mental capacity was good. Cases of various other diseases were also shown by Sir JOHN BROADBENT, Dr. W. H. WILLCOX, Dr. FREDERICK LANGMEAD, and Dr. G. DE BEC TURTLE.

NORTH OF ENGLAND OBSTETRICAL AND GYNAECOLOGICAL SOCIETY.

At a meeting held in Liverpool on October 16th, Dr. Willett, President, in the chair, Dr. W. K. Walls (Manchester) exhibited a specimen of *Double hydrosalpinx and tubo-ovarian cysts* removed with the body of the uterus from a young lady, married a few months, whose appendix had been removed a few years previously. Dr. Fothergill (Manchester) described a case of *Double uterus with right pyocolpos.* The patient was an unmarried woman, aged 22, with normal menstruation, who complained of pelvic pain of some days' duration, and had a raised pulse and temperature; on examination two masses could be felt which, on account of the symptoms, were taken to be the uterus and a matted appendage. The abdomen was opened and the masses found to be the two halves of a double uterus, with no sign of inflammation, below which, on the right side, a fluctuant swelling could be felt. This swelling was opened from the vagina, and proved to be the occluded right half of the vagina filled with pus. Dr. Gemmell (Liverpool) exhibited a specimen of *Adeno-carcinoma of the uterus*, removed from a patient aged 52, who complained of pain and a slight vaginal discharge. Dr. Briggs (Liverpool) showed: (1) A specimen of a soft *Resilient interstitial uterine fibroid* from a woman aged 30; (2) a *Stony hard fibroid*, which was difficult to diagnose from an ovarian fibroma; (3) a *Uterus from a case of post-climacteric haemorrhage.* Dr. Fletcher Shaw (Manchester) described a case of *Septic miscarriage followed by intestinal obstruction.* An abdominal section revealed a loop of small intestine adherent to a mass of glands in the region of the sacral promontory. The loop was freed, and the patient did very well for two days, when acute peritonitis supervened, for which the abdomen was again opened and drained. The patient made a good recovery. In all probability the glands were enlarged from the septic uterus. Dr. Briggs (Liverpool) read on a note on *The coxalgic pelvis: its lateral tilting.* He described a specimen from the pathological museum which was mounted by the surgeons with the diseased side lowest. From the obstetrician's point of view it should have been mounted with the diseased side highest.

Reviews.

THE CLINICAL ASPECT OF PAIN.

In the preface to his treatise on *Pain*[1] Dr. Behan explains how, impressed by the universality of this symptom and the importance, for diagnostic purposes, of a thorough understanding of its multiform phenomena, he set himself the task of collating the results of a thorough search of the literature of the subject, presenting it in the well-founded hope that it may be of use to those who share his sense of the need of such a book. Of the thirty-five chapters the first three are devoted to preliminary considerations. Then follows a chapter on the perception of pain sensations, two chapters on the classification of pains, and one on their intensity, which includes a description of Dr. Harris's suggested graphic method of recording them. The remainder of the work is devoted to a detailed account of the pains associated with diseases of the principal systems, regions, and organs of the human body. It will be seen that the author's task has been no light one, covering, as it does, the entire field of pathology, so far as this one symptom of primary, if not paramount, importance is concerned. It is a sphere in which, moreover, a considerable amount of original research has of late been carried out by clinicians and physiologists, so that much of the information here brought together is not only lacking in most text-books, but likely to be unknown to many readers. A study of the sensory cutaneous zones related to visceral diseases is, of course, fundamental in the modern view of the pathogeny of pain. Dr. Behan has availed himself freely of Head's results and of those attained by Mackenzie, Kocher, Sherrington, Sherren, and other workers along similar lines; and in the numerous excellent illustrations which embellish the book the areas of impaired or perverted sensibility commonly associated with all sorts of morbid processes and conditions are delineated. Another useful feature is a number of tables in which the points bearing on the differential diagnosis of conditions characterized by pain in a given locality are schematically presented.

In the section dealing with diseases of the central nervous system an interesting account is given of the so-called "thalamic syndrome," for the first account of which we are indebted to Dejerine and Roussy. By these observers it was pointed out that lesions of the thalamus are characterized by diffuse pains involving the same side of the body, notable for their severity, persistence, and intractability to analgesies. In addition to these symptoms, Head and Holmes have called attention to an excessive response to stimuli applied to the side of the body to which the thalamic lesion pertains, and a change of behaviour in emotional states thereby induced. Dr. Behan believes that the study of the thalamic syndrome opens up a way to the better understanding of the entire sensory side of the human organism. The thalamus contains the terminations of all the secondary sensory paths; it is an organ for the grouping and redistribution of sensory impulses, and a centre for the perception of painful and other sensations, and, subject to the control of the sensory cortex, for the efferent and motor responses thereto.

Such problems as this of the psycho-physiological mechanism of pain perception occupy, however, only a subsidiary position in Dr. Behan's treatise. The bulk of it is devoted to the discrimination of purely practical niceties of differential diagnosis, and herein its claim to practical utility is undoubtedly strong. In the estimation of the severity of pain the patient's verbal account of it has often to be discounted; among the various objective signs of suffering particular stress is laid upon reflex vasomotor phenomena—for example, elevation of blood pressure, syncope, and upon dilatation of the pupils. A particularly good section is that devoted to diseases of the hip-joint, in which distinction is made between movement pains and weight-bearing pains, and the leading features of intra-articular abscess are vividly described.

Attention is drawn to such points as the simulation of gastric troubles by aortitis, the intestinal paresis and obstruction due to embolism or thrombosis of the mesenteric vessels, the signs of adrenal haemorrhage, and those indurative changes in the bodies and insertions of muscles of the head and neck which Edinger claims to be the commonest cause of headache. These few random examples may give an idea of the wide range of the book and its high value as an aid to diagnosis.

[1] *Pain: Its Origin, Conduction, Perception, and Diagnostic Significance.* By Richard J. Behan, M.D. New York and London: D. Appleton and Co. 1914. (Roy. 8vo, pp. 942; 191 figures. 25s. net.)

OBSTETRICS.

It is a satisfactory evidence of the success of medical education in India that graduates of Indian universities are devoting themselves to the compilation of textbooks and treatises on medical subjects, including pharmacology, medical jurisprudence, and hygiene. The latest production of this kind which has been sent us is Dr. Kedernath Das's *Handbook of Obstetrics.*[2] Dr. Das has succeeded in compiling a most excellent treatise which is specially adapted to conditions affecting both European and native women in India. The arrangement of the book is systematic and the descriptions terse, clear, and quite up to the scientific and practical standards of the present day. The illustrations are numerous and well selected, and the whole get-up of the work most creditable to the printers and publishers. The handbook will be of signal service to students and practitioners in India, both male and female. The "hints on obstetric surgery" appended to the systematic chapters are most excellent and calculated to impose a restraint on that most pernicious practice—meddlesome midwifery.

[2] *A Handbook of Obstetrics for Students and Junior Practitioners in India.* By Kedernath Das, M.D., Teacher of Midwifery, Campbell Medical School, Calcutta, etc. Calcutta: Butterworth and Co., Ltd. (Roy. 8vo, pp. 612; 376 illustrations. Rs. 10.)

THE ORIGIN AND DEVELOPMENT OF THE RED CROSS.

(Continued from p. 799.)

FRANCE.

IT has been stated in a previous article[1] that some days after the battle of Solferino Henri Dunant had an interview with the Emperor Napoleon III, in which he represented to that potentate the pitiable state of the wounded, many of whom were without medical care, and asked that the services of the Austrian medical officers who had been taken prisoners should be utilized for their relief. The request was granted, and when the work of the surgeons was done they were afterwards allowed to return to Austria. The French Emperor was the first of European rulers to accept the principle of neutralization of the wounded, and those who ministered to them. He wrote Dunant a long holograph letter expressing his approval of the Geneva philanthropist's proposals. Napoleon III also gave active assistance to Dunant in the promotion of his scheme by placing him in communication with the Ministers for Foreign Affairs of various States. The French Minister, Drouyn de Lhuys, assured him that if Switzerland invited the Powers to a congress France would support the proposal. On July 7th, 1867, the Empress Eugénie sent for Dunant, and expressed the wish she felt that the benefits of the Red Cross should be extended to the naval forces. She suggested the equipment of ambulance ships painted white and flying a white ensign with a Red Cross.[2] The subject was discussed at the international conference held in Paris in 1867, and at others held afterwards. As the result a scheme was drawn up, but it was not till the conference held at The Hague in 1899 that the principles of the Geneva Convention were formulated in a convention adapted to naval warfare.

The French Red Cross Society is, like all Gaul according to Caesar, composed of three parts. It is made up of three distinct associations—the Société des Secours aux Blessés Militaires des Armées de Terre et de Mer, the Union des Femmes de France, and the Association des Dames Françaises. The Société de Secours aux Blessés was recognized by the French Government in 1866; the Union des Femmes de France in 1882, and the Association des Dames Françaises in 1883. The decrees by which these bodies were declared to be "establishments of public utility" were cancelled and replaced by a decree promulgated on October 19th, 1892, which covers all three societies and defines their position in relation to the Ministry for War and the Army Medical Service. That decree consists of twenty-three clauses; a detailed account of their provisions was given by Colonel W. G. Macpherson, C.M.G., K.H.P., in an Appendix to the Army Medical Department Report for 1899.[3] An account of the organization of the Red Cross in France, founded on this report, appeared in the BRITISH MEDICAL JOURNAL of April 14th, 1906, p. 873.

It is there stated that each of the three societies composing the Red Cross manages its own internal affairs, but each of them must keep itself constantly in touch with the department whose work it desires to supplement. Each is represented at the Ministry for War by a delegate who must be a member of the central council of the society, and who has as his special colleague an army medical officer appointed by the Ministry of War to represent it on the society's own central council. These two representatives are called *commissaires*, and it is their duty to study every matter connected with its preparations for work in time of war, and to deliver joint opinions on questions affecting its duties in the event of mobilization. In the district of each army corps the society is officially represented by a local delegate accredited to the officer in command and to the principal medical officer. Twice a year (on January 1st and July 1st) this delegate submits to the principal medical officer a statement showing the position of the society locally, both in regard to material and personnel, and on this the principal medical officer of the district bases a half-yearly report on the available voluntary aid resources of the district, which is sent to the Minister for War. There is a consultative body, called the Commission Supérieure, consisting of a president and twelve members, of whom six are representatives of the medical services of the army and navy and six the voluntary aid societies. This body must meet at least once a year under the presidency of the Director of the Army Medical Department, for the discussion of questions connected with voluntary aid in time of war submitted to it either by the societies themselves or by the Ministry for War.

The function of these societies is to make all such preparations and arrangements as may enable them in time of war (1) to establish in the area of operations, in open towns and elsewhere as requested by the Ministry, auxiliary hospitals for sick and wounded soldiers crowded out of the regular army hospitals. (2) To establish similar hospitals on the lines of communication. (3) To forward all gifts for the sick and wounded collected by them wherever directed by the Minister of War. (4) To arrange for rest stations where patients in ambulance trains may receive refreshment and, if necessary, be disembarked for temporary treatment. In addition they can provide hospital ships and co-operate with the army medical department in the task of providing temporary territorial hospitals. None of the societies is allowed to work with the advanced troops or with the *hôpitaux d'évacuation*, establishments placed at the head of the lines of communication. These hospitals, it may be explained, are intended for the temporary reception of patients from the field hospitals, before they are sent down the line in sick convoys. Workers in such of the Red Cross hospitals as are on the lines of communication are subject to military jurisdiction. Wherever they may be during war, an army medical officer is appointed to each of them for general superintendence and maintenance of discipline. The societies provide their own equipment, stores, and so forth, but may be helped by the Ministry of War, if need be, and in any case receive an allowance of 1 fr. a day for each patient they treat. During peace the societies collect funds and train volunteer orderlies and nurses.

The hospital accommodation supplied by the French Red Cross Society is very considerable. In 1899 the Société de Secours aux Blessés had at the disposal of the Ministry for War 260 auxiliary hospitals, with 17,000 beds; the Union des Femmes de France 180, with 12,000 beds; and the Association des Dames Françaises 160, with 6,000 beds—in all 600 auxiliary hospitals, with a total of 35,000 beds. This number has been largely increased since the outbreak of the war by offers of other places which can be used as hospitals, made by private individuals. In addition there are supplementary infirmaries in large number in private houses, schools, and many public buildings. The Union des Femmes de France has organized sixty movable detachments, each composed of a head nurse and six nurses ready to work at the front or in the military hospitals. No auxiliary field hospital can be included in a half-yearly report to the War Office unless it is really ready in every respect as regards complete equipment, funds for its upkeep for a certain time, and a complete staff—professional, administrative, and subordinate. All the societies have many temporary territorial hospitals, one of them being prepared, if need be, to open 20,000 beds in different parts of the country whenever required. In 1899 the Société de Secours aux Blessés had a membership of about 60,000 in 537 district committees, with an annual income of £16,000 to £20,000, and a reserve of nearly £320,000. The Union des Femmes de France had a membership of 35,924, of whom 6,286 were in Paris and 29,638 in the provinces. Its reserve funds, including the value of the stores and other material in its possession, amounted to over £140,000. The membership of the Association des Dames Françaises was about 25,000; it had an annual income of about £4,200, with a reserve of money and material of the total value of nearly £32,000.

The Société de Secours is the oldest of the three recognized bodies composing the French Red Cross Society. They are quite independent, and the only way in which

they can communicate with each other is through their local official delegates and their representatives on the superior commissions. There is considerable friendly rivalry between the several societies, but they are all strictly subject to Government control, which will not allow any hospital, however small, to be used by any of these societies for soldiers until it has been sanctioned by the French Ministry for War. Once this sanction has been given, it becomes an integral part of the French Army Medical Department, under the title of "Ambulance Auxiliaire"—a term which covers all institutions for the reception of sick and wounded soldiers other than those which exist in time of peace as well as war.

(To be continued.)

ALCOHOL AND THE WAR.

A CONFERENCE took place at Caxton Hall, Westminster, on November 12th, under the chairmanship of the ARCHBISHOP OF CANTERBURY, to consider the problem of "alcohol in its relation to the war." It was convened by the Bishop of Croydon, and included a number of leading members of the medical profession, the selected speakers being representative of various interests in religious, political, and social life. It had been decided by those who planned the conference that questions of legislation should not be dealt with in the resolutions which were to be considered, and that attention should be directed to the social aspects of the problem. Emphasis was laid upon two proposals—a pledge of total abstinence for the duration of the war, and a determined effort to supply the wants of soldiers, sailors, and civilians for suitable recreation and refreshment, apart from temptations to drink.

The ARCHBISHOP OF CANTERBURY referred in some detail to the reports of intemperance both among soldiers in training and among their dependants. He felt that the blame attached not so much to those who had fallen into this temptation as to those who had placed temptation in their way or who failed to hold out the helping hand to those who particularly needed help. He believed that the situation could best be met by the wide adoption of a pledge of total abstinence for the period of the war. By this act of self-denial those at home could show their sympathy with those at the front.

The first resolution recognized that, as a result of the war, there had been a grave increase of intemperance, and pledged the members of the conference strongly to support Lord Kitchener's appeal on this matter.

Lord Roberts had signified his intention of being present, and had been invited to propose this resolution, but he wrote a letter explaining that, as he was going to France to see the Indian troops, he could not be present. His place was taken by Sir Clifford Allbutt, who bore testimony to the good behaviour of the troops quartered at Cambridge, but added that at the same time he fully recognized the importance of the matter, and stated that science had made it clear that healthy people were as well or better without alcohol as with it. He contended that the problem of to-day was not so much one affecting individuals as communities. To have a strong community it was necessary to get rid of class distinctions and seek to help one another, and especially the dependants of those who were serving their country in the war. The public-houses had unfortunately been for many the only place for social gathering, and it was most important that counter attractions should be provided.

Cardinal BOURNE, in seconding this resolution, fully corroborated the Archbishop's statement as to the dangers of the day in relation to alcohol, which he attributed to the fact that emotions were excited in the case of those leaving home to go to posts of peril and those who were left behind in distress and anxiety. He advocated further restrictions in the hours of opening public-houses.

Sir THOMAS BARLOW then proposed the second resolution, which recommended the general adoption of the suggestion that people of all classes should join in a pledge of total abstinence during the continuance of the war. Seeing that the resolution proposed a pledge of total abstinence for men in the services and civilians at home, he dealt with a difficulty felt by some as to the possibility of pure water being obtained by the troops, and he said that, having carefully inquired into this subject, he was assured that by the excellent sanitary system initiated by the Army Medical Department there would be no difficulty of this kind. He also commended the system of sterilizing water by the use of chloride of lime advocated by Professor Sims Woodhead. After referring to the subject of sexual disease, nine-tenths of which were believed to be mainly the result of alcoholism, he said that if the young soldier was to be sent across the Channel without any disability alcoholism must be stopped. He had been told that when the German regiments first started out their behaviour was all that could be desired, and it was only when they had been in the wine cellars that the lust, cruelty, and pillaging had taken place. He desired to emphasize the fact that the evil was an insidious one, and must be resolutely met by getting public authorities to do their duty by providing counter attractions and promoting a true sense of brotherhood, and particularly by renouncing the use of alcohol for the sake of others.

The Rev. JOHN CLIFFORD, D.D., seconded the motion in an eloquent speech, pointing out how many of the troops were already total abstainers, including a very large proportion of the Indian troops.

Major LEONARD DARWIN proposed the third resolution, which expressed the opinion that immediate steps should be taken in every locality to secure proper provision of suitable places of recreation and refreshment, both for men and for women, where there would be no temptations to drink, and urged local authorities to carry into effect the Temporary Restrictions Act, 1914. Speaking as an old soldier, he said that it must never be forgotten that the country was fighting the most stupendous war that had ever taken place; there must be no loss of time during training, which would be inevitably caused by drinking bouts, which not only affected the man himself, but his unit. He considered that drink was followed by worse consequences—namely, immorality and disease accompanying it, which might lead to hospitals needed for the wounded being choked by cases of sexual disease. He urged that strong action should be taken to deal with this matter both by legislative and other means, and made an appeal for suitable means of recreation. He hoped that all would rise to the occasion and fight with all their power against every cause of national deterioration.

A fourth resolution determined that "A manifesto should be drawn up embodying the principal resolutions, and that this should be sent to lord mayors and mayors, urging them to take the lead in carrying out the proposals." All the resolutions were carried unanimously.

DR. ALDO CASTELLANI, Director of the Clinic for Tropical Diseases, Colombo, Ceylon, has been appointed by the Italian Government professor of tropical medicine in the University of Naples, and the director of the Royal Clinic for Tropical Diseases in the same city. Dr. Castellani will take up his duties there at the beginning of 1915.

MR. P. MACLEOD YEARSLEY lectured upon the "Classification of the Deaf Child for Educational Purposes" at a meeting of the Child Study Society at the Royal Sanitary Institute, on November 5th. Mr. Yearsley said that deafness was a physical defect which had been terribly neglected until recent years. In his opinion the scheme of classification for educational purposes should include every defect of hearing, and he suggested the following groups: The slightly deaf, the semi-deaf, the very deaf, and the defective deaf. There were difficult cases which did not come under any of these headings, and could be dealt with satisfactorily only by a sympathetic and experienced teacher. In dealing with deaf children the teacher was everything, and his knowledge and patient sympathy could often work a wonderful transformation in a previously irresponsive child. The aural system seemed to be the best means of educating the deaf; if it succeeded in an individual case it should be continued, but if no progress was made the failure should be frankly acknowledged and another system adopted. The deaf child's powers of hearing varied from day to day, and in consequence he required far closer watching and more individual attention than a child whose hearing was unimpaired. Regular attendance at school was far more important in the education of the deaf than in that of normal children, for the loss of two or three days in the week had more disastrous results in the case of the former than the loss of several weeks in the case of the normal child.

British Medical Journal.

SATURDAY, NOVEMBER 21ST, 1914.

THE DUTY OF THE PROFESSION TO THE ARMY.

WE have received a number of inquiries from practitioners who ask for advice and information to assist them in deciding what their duty is to the nation in this crisis of its history. In the following observations we have endeavoured to answer in general terms.

In the first place we have no hesitation in advising that for medical men who have no urgent domestic ties, and are not yet established in practice, especially, that is to say, for young men, the duty is clear. They should put their names on the waiting list kept by the Director-General Army Medical Services, at the War Office, and make up their minds to bide their time until the War Office requires their services, filling in the interval, if possible, by holding resident hospital appointments. The Director-General's list at present contains about 1,000 names of men deemed fit to undertake the arduous work of service in the field. This number, we learn on high authority, is not enough; the list is constantly being depleted, not only by men who are called up by the War Office, but by men who, getting impatient, go to France to help the French. We are aware that the French Red Cross is in need of assistance, but after all the first duty of the British medical man is to the fighting men of his own nation, and we are assured that even if the waiting list was very much larger than it is, the services of all will certainly be required. The same observations apply to nurses.

In the second place, there is the case of medical men settled in practice in this country, who have wives and children or others dependent upon them. Unless their circumstances are such as to enable them to make adequate provision for their families, and to disregard the possible loss of their connexion in practice, we venture to think that they are not at present called upon to volunteer to give their services to the War Office. The recruiting for the new armies, commonly called Kitchener's armies, though it has fallen to a considerable extent during the last month, has already resulted in bringing under military discipline in battalions and brigades a very large number—something like 800,000 recruits. These recruits have been raised in various districts by leading men in those districts whose duty it is to provide the new units with adequate medical service. It is intended, we understand, to maintain the territorial connexion, so that the new battalions will be additional battalions of the regiments associated with the district. It must be some considerable time before these newly raised troops can be converted into a useful fighting force, and in the meanwhile in any town where they are billeted, or in any camp where they are being exercised, they must be under medical supervision, and we apprehend that it would be possible, in many instances, for a medical man to carry on his ordinary civilian practice and yet give the necessary three or four hours a day to the work of attending to the medical ailments and minor accidents of the new recruits, and advising the commanding officer on the measures necessary for safeguarding their health.

In the next place, the policy is to form a reserve Territorial battalion, and some adjustment of the medical service with regard to these battalions will be necessary. It will, we believe, often be found advisable when the first Territorial battalion is passed for imperial service—that is to say, for service outside this country—to retain with the reserve battalion the existing Territorial medical officer, and to fill his place with the first battalion warned for service by a junior officer whose local obligations, if any, are less exacting. In this way some of the more serious disturbances of civilian practice which might be produced by taking away medical men of older standing may be avoided. It is of the utmost importance in the public interest that medical work for the civilian population should be maintained at a high level of efficiency, and the medical profession has shown in many ways that it is ready to make sacrifices to ensure this. There is, we have reason to believe, a real danger of the serious depletion of medical practitioners in some districts, though not at present perhaps in many, and anything that can be done by the War Office by way of facilitating exchanges or otherwise to prevent public inconvenience and to relieve the anxieties of medical men ought to be done, and will, we feel sure, be done. We understand that some public announcement on the subject may shortly be made.

THE BRITISH PHARMACOPOEIA, 1914.

ALTHOUGH the new *Pharmacopoeia* will not be published until the end of the year and will come legally into force on January 1st, 1915, the advance copies which have been accessible to those interested since October 1st have made it possible to become acquainted in the interval with its contents. The series of articles on this subject which have appeared in our columns in recent weeks have summarized the principal features of the work which are of interest from the point of view of the medical profession, and have discussed in some detail the chief alterations and additions; and it is perhaps not inopportune to consider briefly whether the work fulfils all that can fairly be expected of a national and imperial pharmacopoeia. The principal object to be attained, of course, is the securing of uniformity of composition and a proper standard of strength and purity for all medicines in general use; and on the publication of the book it becomes the legal standard for the substances, both simple and compound, described in it, when these are dispensed or sold for medicinal use.

New medicinal substances, due to the development of organic chemistry, to the study of the active constituents of animal glands, and to several other causes, are introduced into practice with such frequency that a pharmacopoeia which is only revised at intervals of between ten and twenty years cannot possibly contain a description even of all those which are in wide use, for more than a short period after its publication. Hence has arisen a need for other books containing descriptions of, and setting up provisional standards for, unofficial medicines, and several well-known books under such names as *Extra Pharmacopoeia*, *Companion to the Pharmacopoeia*, etc., have come into very wide use, and are kept up to date by frequent new editions; one of these, the *British Pharmaceutical Codex*, being issued by the authority of the Pharmaceutical Society, and not by private enterprise, has almost the authority of an official standard. It is clear that the new *British Pharma-*

copoeia does nothing to render such works superfluous. It is evident that the Pharmacopoeia Committee of the General Medical Council has strictly adopted a policy of excluding everything for the inclusion of which strong reasons could not be shown, since, after an interval of sixteen years, only forty-three new substances are thought worthy of inclusion, and even of these several are not really new, but merely replace others of slightly different composition and name which are now dropped.

Without any desire to cavil, serious doubts must be felt as to the wisdom of leaving outside the official book so many medicines which are in common and daily use. Two consequences of so doing are obvious, the one being that a single substance may be made of identical composition by a large number of firms, each of whom gives it a different name. The other consequence of such an exclusive policy is that for a compound preparation—as, for example, bismuth and pepsin mixture—there are dozens of private formulae in use under one and the same name, but differing more or less from each other, and to secure uniformity in the dispensing of a prescription in different parts of the country it is necessary to add the letters "B. P. C.," or an individual maker's name, after the name of the article.

But if the Pharmacopoeia Committee has shown a somewhat excessive conservatism in regard to admitting new articles to the official volume, no such charge can be made in regard to their attitude to changes in composition and strength, some of the alterations being so considerable as to involve serious risk of danger from altered dosage. Some potent preparations are halved in strength, while others are doubled; the most notable case is that of tincture of strophanthus, the strength of which will be actually four times that of the preparation in the present *Pharmacopoeia*. Attention has been drawn to these changes in the articles already published, but we must again emphasize the necessity of prescribers becoming familiar with them, in view of the fact that on and after January 1st the new preparations must be dispensed unless the old are distinctly ordered. The matter is not made simpler from the fact that the changes are not all in one direction, even for preparations of the same class, tincture of aconite, for example, being doubled in strength, while tincture of nux vomica is halved. In the case of tincture of opium, which is increased in strength by one-third, there is a side issue which may or may not have been intended by the Committee; the present tincture contains three-quarters per cent. of morphine, and is therefore in Part II of the Poisons Schedule, and can be sold by a qualified pharmacist to any one, subject to certain conditions as to labelling; but with the strength increased to 1 per cent. of morphine it goes automatically into Part I, and can only be sold to persons known to the seller, with due registration in the poisons book. Whatever inconvenience may be caused by this change, the greater stringency in regard to its sale must, on the whole, be welcomed.

Although some criticisms must be passed on the new *British Pharmacopoeia* in regard to the matters already alluded to, the notes we have published show that in certain other respects it can be praised without reservation. This is the case particularly in regard to the standards of purity laid down for official chemicals; the tests which such bodies are required to pass are perhaps better on a level with current knowledge and practice than has been the case with any previous *Pharmacopoeia*. The standardization of drugs and galenicals, again, has been carried a considerable step further; and although as is well known, the usefulness of a drug is not necessarily limited by or proportional to the amount present of some one definite active principle, still the security of a standard strength in regard to such active principle is more likely to lead to uniform therapeutic effects than would be the case if all the constituents were allowed to vary to the wide extent often met with in natural products.

When judged as an imperial, as distinguished from a national, pharmacopoeia, the new work does not appear to merit any unfavourable criticism. The needs of different parts of the empire appear to have been met in a reasonable manner, but this matter cannot perhaps be altogether accurately judged from the point of view of medicine in the mother country alone, and experience will show whether further modifications and additions may be necessary to make the book truly fulfil its world-wide functions.

OUR BELGIAN COLLEAGUES.

Upon Belgium fell first the ruin which follows the policy of murder, exaction, and destruction deliberately adopted by the German military authorities in the expectation that by these means their enemies may be terrorized into submission. The attempt on the small but gallant Belgian nation failed in its purposes, but it succeeded in spreading desolation throughout the length and breadth of one of the most prosperous and populous parts of Europe. The medical profession in Belgium now appeals to its brethren in other countries to help them, as far as may be possible, now or in the near future, to take up again their duties as the medical advisers and consolers of a population reduced in three months from industrious comfort to penury and misery. The survivors return to their ruined homes, when it may be possible to return at all, to face the winter and the threat of diseases due to exposure, and the epidemics which must be expected to follow the wholesale destruction of all the machinery of civilized life, while their doctors, who have shared in the common ruin and pillage, have not the appliances or drugs for ordinary professional work. The article by Professor Jacobs, published at page 890, puts before us a picture the dark features of which no words that we might add would enhance. The mere catalogue of the provinces and towns pillaged and destroyed—the names of not a few of them call up sad memories in British hearts—is in itself an eloquent appeal. Help is asked as much in the interests of the stricken population as of the medical men and pharmacists who, while sharing their physical sufferings, have the added pain of being deprived of the means of alleviating them.

As announced in previous issues, a provisional committee was formed at an informal meeting in London a fortnight ago, summoned at the instance of the Editors of the *Lancet* and the British Medical Journal after a preliminary interview with Professor Jacobs of Brussels, who had been delegated by a medical committee in Belgium to come to this country. The provisional committee was confronted with a situation presenting very serious practical difficulties. Almost, if not quite, the whole of Belgium has been overrun and pillaged by the Germans, and is still in their hands; a part is the site of the present prolonged battle in and beyond the southern frontier of the country. The committee, therefore, felt that before making any general appeal to the profession in this country or in neutral or

friendly countries, it was essential to get the best information obtainable as to what it was feasible and prudent to do in existing circumstances. The letter published this week at page 890 shows the conclusions that have been reached. Having done this preliminary work, those who have formed the provisional committee hope to give it a national complexion by obtaining the co-operation of colleagues in Scotland and Ireland and throughout the United Kingdom, and eventually to work with the medical committee which has recently been formed in the United States.

The immediate need of the medical men and pharmacists who remain in Belgium is great. Professor Jacobs estimates that 1,000 doctors are absolutely poverty stricken and that 300 pharmcists are unable to earn their living, being deprived of their most necessary drugs, and thus without the means of carrying on their work, while the majority of the remainder of both professions are suffering cruelly through the war. With the cordial approval of the Belgian Minister and the co-operation of the American Ambassador and Mr. L. Hoover, arrangements have been made which it is believed will ensure the delivery of packages of the drugs most commonly used, and of a few necessary instruments to doctors in Belgium, especially those in country districts where many dispense their own medicines.

This particular scheme is intended only as a beginning, and it is hoped that before very long it will prove possible to give further assistance on a larger scale. When the day comes for the nations to adjust the balance and right the wrongs which Belgium has suffered, one of the first duties of the medical profession throughout the world will be to see that the practitioners who have played so distinguished and useful a part in the life of their country are reinstated. We cannot at once rebuild the houses of Belgian doctors, or restock the shelves of Belgian pharmacists, but it is clear that the people require prompt medical treatment, and it is a debt of honour to try to meet the immediate necessities of their doctors and pharmacists. We are well aware that the war has made many calls upon the resources of the medical profession in this country, but we believe that the appeal will meet with a sympathetic response, and that every one will give what he can, so that the Belgian profession may be able to resume its work so far as this is at present possible.

With regard to the Belgian medical men at present in this country—who at the moment number, we believe, about a hundred, and are in many cases accompanied by their families—the Medical Secretary of the British Medical Association has made arrangements (details of which will be found at page 891) with Viscount Gladstone, Honorary Treasurer of the Belgian Relief Fund, to receive the names of medical men wishing to offer hospitality.

NATIONAL COUNCIL FOR COMBATING VENEREAL DISEASES.

THE inaugural meeting of the National Council for Combating Venereal Diseases was held at the house of the Royal Society of Medicine on Wednesday, November 11th. Both the attendance and the tone and character of the speeches must have given much encouragement to the organizers of the council. The quality of the speeches maintained the high level set by Sir Thomas Barlow, and represented the sympathies of medical, social, and clerical members; it also became clear that the movement had the hearty support of members of the Royal Commission. There was a sprinkling also of khaki, showing that those who are occupied with the military side of the question are not uninterested in the civilian movement. The presence also of naval officers indicated the interest felt by that service. It is of sad interest to know that Lord Roberts had hoped to be present. To the public, and perhaps to the medical profession as well, a feature of very special interest was the plea, put forward with great ability and force by three theologians of very different schools of thought—Cardinal Bourne, Dean Inge, and Dr. Scott Lidgett—for a reconsideration of the religious attitude towards this category of ailments. Each in turn refused to tolerate the notion that venereal disease exemplifies divine retribution for sin. We doubt whether such a consensus would have been possible at any previous time, and we welcome the happy boldness which impelled them spontaneously to give what we hope will be the death-blow to that outworn and unchristian philosophy. It is hoped that, in view of the importance of its work, the National Council, whose offices are at Kingsway House, W.C., will receive support, financial and otherwise, both from the medical profession and the general public.

WAR AND VITAL STATISTICS.

No very startling results are yielded by a study of the influence of war upon vital statistics. In some instances a war period has been followed by a marked acceleration of the marriage-rate. In Germany, for example, the marriage-rate during the years immediately following the Franco-Prussian war was considerably higher than during a previous or a subsequent period. To put the fact in another way, for every 1,000 of the unmarried male population of Germany, an annual average of 93 men were married during the years 1872–5, whereas the average was 82 for the years 1876–85, and 83 for the years 1886–95. In France the same thing occurred, though in a less marked degree. From the middle of the last century onwards, the only decade in which the French marriage-rate rose to an annual average of over 8 per 1,000 of population was the decade which opened with the war and the events of the early Seventies. On the other hand, Russia's disastrous war with Japan, and her internal troubles of about ten years ago, synchronized with a depression of the Russian marriage-rate, which, together with the birth-rate, stood at a lower figure for 1901–7 than it had done for twenty years previously; it should be said, however, that the rate of mortality in Russia for the same years was even more markedly reduced. In England and Wales the vital statistics seem to have been remarkably little affected by war. During the years of the Crimean war and the Indian Mutiny, the average number of marriages did not fluctuate by more than 0.5 per 1,000 of population as compared with the previous and subsequent periods, and virtually the same thing was true of the South African war. In Germany, during the years following the successful war of 1870-1, the birth-rate went up by two points per 1,000 of population, but the consistent decline of the birth-rate in England and Wales appears to have been scarcely affected in one direction or the other by the South African war, any more than the fairly consistent increase of the birth-rate during the Fifties and early Sixties of the last century was deflected by the events of 1854-5 in the Crimea, or those of 1857-8 in India. A feature of interest is the variation in the excess of male births following upon war years. It is remarkable that in 1857, the year after the return of our army from the Crimea, the excess of male over female births in England and Wales should have been 17,230, whereas the average for the three previous years was 13,796, and for the three subsequent years, 15,291, the total birth-rate remaining substantially the same. It is also worth noting that in this same year, 1857, there was a parallel drop in the customary

excess of male over female deaths. The figure, which had maintained a steady average of 7,772 from 1852 to 1856, fell to 5,215 in the following year. There were also marked fluctuations in the excess of male over female births during the years of the South African war. The average annual excess from 1897 to 1900 was 15,991, but in 1901, which may be called the first year after the war, the figure rose to 18,081, and in 1902 it was 17,799. The meaning of these figures is not to be explained by statistical inquiry.

EPSOMIANS ON ACTIVE SERVICE.

The medical profession has every reason to be proud of Epsom College, which is its creation. We have often had occasion to recount the academic successes of boys who have received their training at the school. That the education which they receive there fits them for the practice of the arts of peace at least as well as any other public school in England is a fact which need not be insisted on, but it remained for the outbreak of the war to show how thoroughly it cultivates and develops their sense of patriotism, and how ready it makes them to obey the call of their country for service in the fighting line or wherever else they may be most useful with the forces. We learn from the *Epsomian* for October that it is definitely known that over two hundred old pupils of the school are now serving; how many more there may be it is impossible to say. Twenty are officers in the Royal Navy, of whom twelve belong to the medical department. These are P. F. Alderson, Staff Surgeon, H.M.S. *Gloucester;* J. L. Barford, Staff Surgeon, H.M.S. *Hyacinth;* K. D. Bell, Staff Surgeon, H.M.S. *Audacious;* T. E. Blunt, Staff Surgeon, H.M.S. *Rosario;* C. B. Fairbank, Fleet Surgeon, H.M.S. *Hecla;* R. T. Gilmour, Fleet Surgeon, H.M.S. *Glasgow;* W. L. Hawkins, Staff Surgeon, H.M.S. *Cochrane;* H. B. Hill, Staff Surgeon, H.M.S. *Highflyer;* A. O. Hooper, Staff Surgeon, H.M.S. *Natal;* G. Nunn, Staff Surgeon, H.M.S. *Neptune;* J. C. G. Reed, Fleet Surgeon, Special Service, Bermuda Yard; D. D. Turner, Staff Surgeon, H.M.S. *Sappho.* There are three temporary naval surgeons: O. D. Brownfield, E. H. Hugo, G. A. Walker. One is a lieutenant in the Naval Wing of the Royal Flying Corps. Of the army officers the following have been killed in action: Captain T. Scatchard, R.A.M.C.; Lieutenant J. F. O'Connell, R.A.M.C.; Major W. L. Lawrence, 3rd Wales Borderers; Lieutenant H. D. Strong, Royal West Surrey Regiment. Among the wounded are Lieutenant S. A. Gabb, 3rd Worcester Regiment; Second Lieutenant G. M. Gabb, 2nd Royal West Surrey Regiment; and Second Lieutenant G. Y. Gross, Royal West Kent Regiment. Lieutenant B. S. C. Hutchinson, East Yorks Regiment, is missing; Captain A. A. Sutcliff, R.A.M.C., is a prisoner. Major W. L. Lawrence, Captain E. B. Lathbury, and Lieutenant S. A. Gabb have been mentioned in dispatches. Besides these, there is 1 officer on the staff, 2 in the cavalry, 6 in the Royal Field Artillery, 4 in the Royal Garrison Artillery, 2 in the Royal Engineers, 19 in the infantry, 1 in the Royal Marines, and 1 in the Army Service Corps. The following are officers of the Royal Army Medical Corps in addition to those already mentioned: Lieutenant E. G. H. Cowen, Major C. H. Furnivall, Captain A. W. Gater. Lieutenant R. K. Mallam, Major S. M. W. Meadows, Lieutenant W. A. Morris, Captain J. M. B. Rahilly, Lieutenant R. T. Vivian, and Captain H. C. Winckworth. The list of officers in the Indian Medical Service includes the names of Major H. Boulton, Captain A. Cameron, Major R. M. Carter, Captain C. A. Gill, Major G. Hutcheson, Major Y. H. Murray, Lieutenant-Colonel S. E. Prall, and Lieutenant-Colonel S. B. Smith. A number of old Epsomians have also received temporary commissions in the Territorial Force and Royal Army Medical Corps, while many have enlisted in the regular army or have joined the Territorials. Such a list of men who have given their services to their country gives the school which trained them a place among our national institutions. We may all say heartily *Floreat Epsomia.*

THE SOLDIERS' HANDS AND FEET.

Much has been heard of the sufferings of our soldiers from sore feet in the early part of the war, when the bitter experience of the famous retreat showed the truth of Mulvany's regimental doctor's maxim that "a marchin' man is no stronger than his feet." Now that General Winter has come on the field, our gallant defenders by sea and land need all the protection they can get against coldness of the extremities. Chilblains and frostbite may make the most heroic courage unavailing; cold hands may make the finest marksman unsteady in his aim at a critical moment. Vast numbers of women are now knitting mittens, socks, mufflers, and other comforts for our soldiers and sailors, and in general they are working according to regulation patterns. There has been a good deal of the usual official pedantry in this matter, but now the authorities are in a general way glad to get anything that will serve the purpose. The question of protection of the hands and feet against cold would doubtless have been dismissed as a piece of old womanish sentimentalism by the hard-bitten warriors who fought in the Napoleonic wars. To-day the Académie de Médecine does not consider it beneath its dignity to allow it to be discussed. At a meeting held on October 27th Dr. Fernet read a paper in which he said the principle of warm clothing was the same as that of the building of houses, where cold is excluded by walls lined with rubble, and by double doors, windows and blinds. He therefore suggests that to keep the hands and feet warm two pairs of gloves, stockings and drawers should be worn. For the hands the outer glove or mitten should be of knitted wool or of skin lined with fur, the inner being made of ordinary skin or of plain cotton. For the protection of the feet and legs stockings of ordinary cotton should be worn under woollen stockings; this, while greatly increasing the warmth, increases the thickness very slightly, and allows an ordinary boot to be worn. For horsemen the use of snow boots over the ordinary footgear is recommended. All these things, even the gloves or underdrawers, should be sufficiently wide to allow them to be drawn easily on and off, and not to hinder the movements of the hands and feet. There is nothing very original in these recommendations, though they are inspired by common sense. But they must sound almost ironical to men who have hardly any decent garment to wear and whose boots gape. One of the most practical suggestions we have seen is that published by M. Clemenceau in his paper *L'Homme Enchaîné.* It is made by M. Cornu, an artist who served in the war of 1870. It is that vests of sheepskin, without sleeves, should be worn. Other veterans of *l'année terrible* have confirmed his statement that such a garment is as warm as it is simple.

MEDICAL TERMS IN THE NEW ENGLISH DICTIONARY.[1]

An abundance of medical terms is met with in the newly issued part (a section of the penultimate volume) of the *Oxford English Dictionary.* This is not surprising, for the rubrics run from *speech* to *spring*, and include therefore the *spermato-*, the *sphygmo-*, and the *spleno-* group of words. Under the word *sphygmo-*, for instance, are eleven compounds, namely, *sphygmodynamcter, sphygmogram, sphygmograph, sphygmographic, sphygmography,*

[1] *A New English Dictionary on Historical Principles.* Edited by Sir James A. H. Murray. Speech-Spring (Vol. ix). By W. A. Craigie, M.A., LL.D. Oxford: At the Clarendon Press. . . . Humphrey Milford. Double section, price 5s. (1.25 dols.). October 1st, 1914.

sphygmomanometer, sphygmometer, sphygmometric, sphygmophone, sphygmophonic, and *sphygmoscope*. All these are derived from the Greek σφυγμός, the pulse, which in its turn comes from σφύζειν, to beat or throb; and each is illustrated by at least one quotation, the earliest one—for *sphigmometer* (*sic*)—bearing the date 1842. A still larger group contains *spleen*, its compounds, such as *splenstone*, and *spleenwort, splenetic, splenic, splenification, splenitis, splenotyphoid*, etc. It is interesting to find that the earliest illustrative quotation of *splenectomy* carries the date 1859. It will be news to many that the term *spondyle* (a joint of the spine or a vertebra) was in ordinary use in the fifteenth, sixteenth and seventeenth centuries, although it is now obsolete; on the other hand, *spondylitis* and *spondylo-* in such compounds as *spondylodynia, spondylopyosis*, and *spondylotomy*, are only now coming into employment in scientific language. Thus in the *London Gazette*, of 1667, there is a quotation regarding "a great shot . . . entering the spondiles of his back." That Dr. Craigie (under whose care the present part has been prepared) does not easily overlook any medical term is shown by his inclusion of such a word as *spongiopiline* and of so special an expression as *spider-naevus*. *Spigelian*, too, as applied to the middle lobe of the liver, finds a place. *Sphincter*, of course, is clearly defined and abundantly illustrated by quotations from medical works; but, in addition, Dr. Craigie gives a rather quaint instance of its employment in a transferred sense or figuratively—this is in a clause from a book of 1737, in which the author (M. Green) speaks of "avarice, sphincter of the heart," a use which would be somewhat startling nowadays. Further interesting terms are *splay-foot, splint* (with its two meanings, surgical and veterinary), *sporadic* (not always used so exclusively of medical matters), *spotted fever* (meaning either epidemic cerebro-spinal meningitis or typhus, and once signifying any fever characterized by spots on the skin), and *sprain* (substantive and verb). This is emphatically a thoroughly interesting part of the *Dictionary* from the medical standpoint.

THE proposal of the governing body of the Lister Institute to effect an amalgamation with the Committee of the Medical Research Committee established under the paragraph of the Insurance Act providing what is commonly called "the research penny" was not accepted by a meeting of the members on Wednesday last. An amendment proposing to approve the amalgamation upon condition that the representation of the Institute was increased to a fourth of the total number of members of the Research Committee was carried on a show of hands, but when put to the meeting as a substantive resolution was rejected by 39 votes to 32. The chairman, Sir Henry Roscoe, said that as the division showed a majority against the proposal, the governing body must reconsider its plans.

THE first lecture of the series on camp hygiene arranged by the Chadwick Trust was given at Bedford College, London, on November 14th, by Dr. A. T. Nankivell, M.O.H. Poole, who discussed camp sanitation, and showed many interesting lantern slides illustrating camp hygiene, especially in regard to the great camps at present occupied by our new army.

A LIST of periodical publications, official reports, and Blue Books in the Library of the British Medical Association available for issue to members on loan has been printed, and copies can be obtained free on application to the Librarian, at the house of the Association, 429, Strand, W.C. The regulations governing the loan of these publications are stated in the introduction to the list. The Library is open for consultation from 10 a.m. till 5 p.m. (on Saturdays till 2 p.m.).

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

The New Session and the New Taxation.

THE Parliamentary session up to the present has shown a gratifying absence of anything in the nature of party controversy, although in respect of various matters there has been detailed and very healthy criticism on the War Office arrangements and on other matters.

The present sitting will in all probability not be prolonged for many days, being chiefly occupied in financial matters.

Members appear to be taking a very active interest in the medical services, and there seems to be a full and general recognition of the difficulties of transport incidental to the long battle front and the great number of wounded to be dealt with. The relatively small amount of general sickness up to the present is commented upon in appreciative terms; a good deal of interest seems to centre round the question of typhoid and the results of the antityphoid inoculation. We understand that the expert staff of the Medical Research Committee is to be asked to assist in the compilation of the sickness statistics. It is to be hoped that this may be arranged, and that we may obtain thoroughly comprehensive and reliable figures. Expert statisticians in respect of medical matters are often blamed for producing results of a purely negative kind, not doing much more than showing, to their own satisfaction at least, that the records and conclusions of others in various directions are unsound. Let us hope that on this occasion we shall obtain results of a positive kind and a full justification of the wide-mindedness and readiness to make use of expert assistance which General Keogh has displayed in this connexion.

We understand also that the Medical Research Committee is arranging with the War Office to assist in the provision of pathological assistance, where required, to the different military hospitals.

On Monday, November 16th, a short sitting disposed of some very important business. In the course of two and a half hours the House had discussed and sanctioned the Prime Minister's motions to raise £325,000,000 and for an additional 1,000,000 men. At question time it was revealed that Dr. Addison, for the time being, in the absence from the House of Mr. Masterman and Mr. Wedgwood Benn in France, is answering for Insurance.

On Tuesday, November 17th, the Chancellor introduced his financial statement. A loan is to be raised of £350,000,000 to cover the expenditure estimated until July of next year. This sum includes certain loans to our Colonies and to Belgium and Servia, and also repayment of the Treasury bills already issued. The nominal interest is 3½ per cent., but the issue is made at the price of 95 and being redeemable at par in 1925, if desired by the Government, and in any case by 1928, is reckoned to be equivalent to an investment at 4 per cent. The general feeling in the House was that, in view of the rate of interest and the fact that the issue is to be redeemable at par, it would be a very popular investment and would in all probability be rapidly and more than fully applied for. The Chancellor also announced that the Bank of England had arranged to give credit on holders of the War Loan Stock at 1 per cent. under the current bank rate.

In regard to new taxation, the Chancellor urged that at this moment, when personal sacrifice is acceptable to and indeed desired by most members of the community, additional taxation would be taken in a more sympathetic spirit than at any other time, and that we were bound by sound finance, whilst not relieving posterity excessively, to shoulder some of the additional burden of cost here and now.

In brief, the new taxation is on the following lines:

The income tax is doubled as from January 1st next—that is to say, on the last three months of the current financial year. The rate which will fall to be paid on the first nine months of the current financial year will be that which was levied under the Budget passed during the summer. The exemptions remain as at present, except

that the exemptions in respect of children are to be doubled. The tax, therefore, as from January 1st next, on earned incomes will be at 1s. 6d. in the £, and on unearned at 2s. 6d. in the £. Super taxes are doubled in the same way as the ordinary income tax. The double yield in the first whole year after the commencement of the new scale of income tax is estimated at £44,750,000.

The second item of new taxation is the imposition of a charge of 17s. 3d. a barrel on beer, which is equivalent to a ½d. on half a pint. This is accompanied by certain concessions in respect of licence duties, and the total yield of this tax in the first financial year is estimated to be £17,050,000.

The remainder of additional taxation consists of an extra 3d. on the pound of tea which is estimated to yield £950,000 this year and £3,200,000 next.

The total yield, therefore, of the new taxation in the first complete financial year is estimated as follows:

Income tax	£44,750,000
Beer	17,050,000
Tea	3,200,000
	£65,000,000

Various points of criticism of a non-controversial character and many questions were raised. Mr. Austen Chamberlain promised the Chancellor his general co-operation, and the resolutions imposing the increased duties on beer and tea were passed without divisions and the House rose by seven o'clock.

Inoculation and Vaccination.—Mr. Chancellor asked the Under Secretary for War whether recruits who refused to be inoculated will, unless physically disqualified, be given the same chance as those inoculated to proceed to the front and serve their country in the fighting line.—Mr. Tennant said: The instructions to general officers commanding are that special efforts are to be made to secure that no officer or man may, through not being inoculated, possibly risk his chance of seeing active service abroad. Mr. Chancellor asked whether the regulations in regard to vaccination which applied to the army or to the Territorial Forces, were the regulations under which were enrolled recruits who joined for the period of the war only.—Mr. Tennant: The regulations of the Regular Army. Mr. Chancellor asked whether antityphoid inoculation with serum from the Pasteur Institute had been practically universal throughout the French armies; and whether the widespread epidemic of typhoid which has been attributed to germ-laden soil had occurred mainly amongst these well-inoculated troops.—Mr. Tennant: I cannot say definitely that the vaccine used for inoculation in the French army is prepared at the Pasteur Institute, but I believe it to be the case. I have no information as to any widespread epidemic of typhoid in the French army, and cannot be taken as accepting in any way the suggestion contained in the last part of the question. Mr. Chancellor asked the Under Secretary for War if he was aware that, in spite of his statement in the House on September 10th that inoculation was not compulsory, some army doctors was practically enforcing inoculation on unwilling soldiers by threatening not to report them as medically fit, and thus prevent them from serving at the front; whether he had been informed that this action was deterring many desirable men from joining the army; and whether he would issue instructions to army doctors or their superior officers that would protect conscientious objectors from such illegal pressure and persecution.—Mr. Tennant: No information has been received in the sense of the first part of the question, and I am not aware that any men have been deterred from joining the army by the cause stated. The instructions already issued are intended to protect conscientious objectors. Sir Clement Kinloch-Cooke asked the Under Secretary for War whether he was aware that many recruits preferred to be vaccinated by the Government calf lymph issued to the public vaccinators; and whether he would consider the possibility of allowing recruits who were desirous of or were required to be vaccinated to have the services of public vaccinators free of charge, irrespective of the area in which the recruit resided.—Mr. Tennant thought there must be some misunderstanding. The vaccine lymph used in the army was obtained from the Local Government Board's lymph establishment at Hendon, and was believed to be the same as that supplied by the Board to public vaccinators.

St. John Ambulance Brigade.—Mr. Thomas asked whether at the outbreak of the war members of the St. John Ambulance Brigade were asked to volunteer for service and were paid 4s. per day and 10s. per week separation allowance to the wife; that similar invitations had been issued to these men from the Admiralty, the remuneration being 3s. per day and 6s. per week separation allowance; and whether having regard to the fact that these men were drawn from the same class and doing the same work, steps would be taken to make the remuneration equal.—Dr. Macnamara said that members of the St. John Ambulance Brigade employed by the Admiralty were enrolled in the Royal Naval Auxiliary Sick Berth Reserve; such enrolments had been made at various dates since the establishment of this Reserve in 1902. There were different grades in the Reserve, the pay ranging from 3s. to 4s. 6d. per day, according to rating and nature of employment, with increase of pay after six months' service. The separation allowances were in accordance with the navy scale. It was not considered necessary now to alter these conditions of service, which had been accepted by the men on enrolment in the Reserve. In reply to Mr. Bennett-Goldney, the Under Secretary for War (Mr. Tennant) said that members of the St. John Ambulance Brigade who belonged to the Military Home Hospitals Reserve were enlisted into the Royal Army Medical Corps for the "duration of the war" when called up for service. The services of other St. John Ambulance Brigade men belonging to Voluntary Aid Detachments might have been utilized locally by the military authorities in cases of emergency, and for unloading hospital ships, trains, etc. In the latter case the period of employment was temporary and depended entirely on local conditions. He was not aware of any complaints of non-payment for these services.

Chiropodists.—In reply to Sir Clement Kinloch-Cooke, the Under Secretary for War stated that the arrangements for the employment of chiropodists in the Regular Army had been made applicable to the Territorial Force.

Rum Rations.—Mr. Tennant has stated that a considerable quantity of rum has been supplied for the use of the Army. The instructions provided that the rum ration was issued only on the recommendation of the medical authorities, and the unit was asked the number of officers, non-commissioned officers, and men who desired such a ration, and the amount for that number only was issued by the supply branch. The actual issue was under the supervision of officers. Rum was not issued at home except in most exceptional circumstances. None had been issued this year.

Sanatogen.—Mr. Joyce asked the Home Secretary whether his attention had been drawn to a statement made on behalf of the proprietor of sanatogen that the Home Secretary had assented to the business being carried on for the benefit of the proprietor and also to a company being formed for the purpose of acquiring the business from the proprietor; whether the proprietor was an alien enemy; whether any such licence and sanction as alleged had been given, which would have the effect of enabling dealing by a company with such alien enemy; and whether any step was proposed to be taken to prevent the continuance of such a business for the benefit of an alien enemy.—Mr. McKenna said the statement mentioned in the first paragraph of the question is untrue. The proprietor of the firm is an enemy now in Germany, and application was made for permission to convert the business into an English limited company. I have declined to sanction such an arrangement, and effective steps will be taken to prevent any profits being remitted to the proprietor during the war.

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

THE POSITION OF BELGIAN DOCTORS AND PHARMACISTS.

By Professor C. JACOBS,
University of Brussels.

BELGIUM, a blood-stained and ruined country in the horrors of despair, claims the help of her friends to whom her freely consented sacrifice has brought a ray of hope in the dreadful nightmare of the past three and a half months.

I raise my voice with a feeling of intense pity on behalf of thousands of our weeping brethren in their Calvary of suffering, but it is my pride to carry out this duty to my country. The first impulse of the Belgian medical world is to make an appeal to Great Britain, whose kindness has proved itself in such unbounded measure and with such tact and generosity. The German iron fist has closed upon our country; we have to witness the endless series of crimes that are committed in all our provinces, and we have to abide in silence. All the evils of war have been thrust upon us at the same time—a useless and cruel holocaust of human lives, a decimated, despairing, and starving population, ruined homes, and, far worse than all, our children—the only hope of our country—are being mown down by want and disease.

Our doctors have not been spared; they, too, are bearing a heavy share of the general suffering. And now long weeks, nay months, of trial stand before them, during which they know that they will have to bear a terrible burden. They will have to devote themselves untiringly, giving all their care and time, and even their lives, if need be, to the cause of their country; and yet many of them, victims of a barbarian foe, are homeless, deprived of their laboratories, instruments, and their medical stores. What will become of those that still remain of our people, threatened as they are by the grim havoc of war and by contagious disease, its constant follower?

In anticipation of these inevitable consequences it has become my duty, as the spokesman of my Belgian colleagues, to appeal to the medical and pharmaceutical world that an impulse of international fraternity may come to the aid of Belgian doctors and pharmacists. Is it realized what we in Belgium have suffered and are suffering? Duty, and duty only, has bound our doctors and pharmacists to their posts in the devastated localities; some of them are carrying on their profession in the ruined remains of destroyed buildings, whereas others have to improviso at haphazard any kind of shelter for their Samaritan work. Need I describe the manner in which they sustain themselves, and how they manage to nourish their wives and children?

I have witnessed such misery amongst them! Some have had to work as navvies in order to have a few pence in their pockets; others have told me that they had not seen bread for a fortnight, but had lived exclusively on potatoes. Others had a meagre bunch of straw laid on the bare ground as a bedstead; the only pair of boots owned by one of them was falling to pieces in tatters. Men I have seen were dressed in torn garments and their children were in rags. One of my colleagues had to live on wayside herbs for three days and three nights and his wife shared his fate! A professor of a university, bereft of everything, was, when I saw him, in dire want of a bed, and another of equal academic standard was wandering haggard over the countryside, searching in vain for a beloved family. And some of our ranks have been taken as hostages, others have been shot, and their widows and orphans have been left deprived of everything.

This description presents a genuine picture of the distress of the Belgian medical profession, but when these educated people are struck down by want they will never beg for charity; it must be brought to them. It is impossible to calculate how many of them are in this sore distress, and some have been so for days and weeks, but it is easy to see that the distress must be very widespread. Considering now the medical men only, Belgium contained 4,800 doctors; the number of localities that have been destroyed is roughly as follows:

Province of Brabant.—Londerzeel, Merchtem, Capelle-au-bois, Kotselaar, Wildouck, Cortenberg, Gelroode, Nieuwenrode, Wavre, Eppeghem, Beyghem, Ottignies, Mousty, Louvain, Jodoigne, Linsemaux.

Province of Limbourg.—Haelen, Lanacken, Tongres (partly).

Province of Liége.—Liége (partly), Mouland, Bermont, Visé, Micheroux, Batisse, Herve, Hermée, Milmont, Flemalle, Francarchamps, Lincent, Huy, Seilles.

Province of Namur.—Namur (partly), Bierwart, Narille, Tamines, Faliseulle, Andenne, Spontin, Evrehailles, Houx, Yvoir, Dinant, Bovinure, Anhage, Hartiere, Sommière, Walcourt, Mariembourg, Dourbes.

Province of Hainaut.—Charleroi (partly), Montignies, Morlanwelz, Gouy-les-Piéton, Lobbes, Beaumont, Frameries (partly), Merbes, Jemappes, Quaregnon, Marchienne.

Province of Luxembourg.—Rossignol, Etalle, Ethe, Florenville, Virtey, Arlon, Neufchateau, St. Hubert, Anthee.

The deserted province of Antwerp and both the provinces of Flanders have been battlefields since one month, with the great struggle raging round Dixmude, Nieuport, Courtrai, Middelkerke, Ostende. What remains of these places to-day?

Each of those localities has its doctors and pharmacists, and at least 1,000 of the doctors are now absolutely poverty-stricken, and 2,000 to 3,500 doctors are suffering cruelly through this war. We had 1,800 pharmacists all over the country, and at least 300 of them are unable to earn their living, and all of them, with very few exceptions, are deprived of the most necessary trading stock. I daresay that my estimate is below reality.

Consider the immense suffering that our medical brethren have gone through and are still going through. Their pathetic and lamentable distress should unite all in the desire to relieve it. These practitioners have given a lesson to the world of unfaltering energy, but now their breaking courage will have to be kept up. In this emergency I call on the medical profession of England to rally to our help. It will be for us a great debt of honour and of eternal gratitude.

IN AID OF OUR BELGIAN COLLEAGUES.

To the Editor of the BRITISH MEDICAL JOURNAL.

SIR,—The committee whose formation has already been announced in your columns is desirous of starting an immediate attempt to help the Belgian medical practitioners and pharmacists whose plight is so movingly represented by Professor Jacobs, as the delegate from a Belgian committee having similar aims.

The committee has made all preliminary inquiries, and has come to the conclusion that the most practical step which it can take at once is the dispatch to Belgium in portable form of packets of medical and pharmaceutical material. These packets will be made up by Messrs. Burroughs, Wellcome, and Co. in accordance with an approved list, and will be conveyed to Belgium upon advice received from the American Ambassador and Mr. L. Hoover, the Belgian Minister, the manager of Messrs. Harrods, Limited, and Major Gordon, who has already done such good work as a medium for practical assistance between this country and Belgium.

The committee has already received promises of a certain number of subscriptions which justify it in making an experimental consignment, but it appeals to the medical and pharmaceutical professions in this country for funds to enable the Belgian medical practitioners and pharmacists to carry on their work effectually so soon as military and political circumstances permit.

We appeal also for surgical instruments; many of these, though not of the latest patterns, will be extremely valuable. The following are especially required: Scissors, dressing and artery forceps, scalpels, syringes, and midwifery forceps. The instruments should be sent at once to the Master of the Apothecaries' Society, Apothecaries' Hall, Blackfriars, London, E.C., and any small adjustments required in them will be made.

Further, we want money to help the refugee Belgian doctors and pharmacists in this country, most of whom have nothing in this world left to them.

The intention is that the work of the committee shall develop, as the conditions of Belgium permit, and that the work shall be associated with corresponding efforts in Great Britain and Ireland, in the United States and other countries which are neutrals or allies in the war.

Subscriptions should be sent to the honorary treasurer, Dr. H. A. Des Vœux, 14, Buckingham Gate, London, S.W.

and cheques should be crossed Lloyd's Bank, Limited.—We are, Sir, yours faithfully,

RICKMAN J. GODLEE (*Chairman*).
THOMAS BARLOW,
President of the Royal College of Physicians of London.
W. WATSON CHEYNE,
President of the Royal College of Surgeons of England.
MEREDITH TOWNSEND,
Master of the Apothecaries' Society.
W. J. WOOLCOCK,
Secretary and Registrar of the Pharmaceutical Society.
H. A. DES VOEUX (*Honorary Treasurer*).
DAWSON WILLIAMS,
Editor of the BRITISH MEDICAL JOURNAL.
S. SQUIRE SPRIGGE (*Honorary Secretary*).
Editor of the *Lancet*.

November 18th.

MEDICAL HOSPITALITY FOR BELGIAN MEDICAL REFUGEES.

Many communications have been received at the central office of the Association from members of the medical profession who are anxious to provide hospitality for Belgian medical men and their families at present in this country, and these offers have been referred to the War Refugees Committee at Aldwych, of which the President is H.R.H. the Duchess of Vendôme, the Chairman H.R.H. Princess Christian, and the Honorary Treasurer, Viscount Gladstone. As complaints were received that these offers had either not been dealt with or had been dealt with very slowly, the Medical Secretary offered to the War Refugees Committee the use of the office of the Association as a clearing house, collecting through the BRITISH MEDICAL JOURNAL the names of medical men wishing to offer hospitality, inquiring as to the nature and extent of the offers made, and transmitting the particulars to the War Refugees Committee. Lord Gladstone, in expressing his warm appreciation of the offer, welcomed the co-operation of the Association, and explained that the magnitude and novelty of the task imposed on the Committee had at first been overwhelming, and it was only recently that it had been possible to organize the office machinery so as adequately to meet not only the daily flood of fresh work but the arrears. He stated that up to the middle of last week over 50,000 persons had been allocated from the central office to various places throughout the country, and that the daily average of arrivals had gradually dropped from well over 1,000 to between 200 and 350. He freely recognized the appropriateness of the offer of hospitality to medical men by medical men, and said he would be pleased to make use of any offers the Association transmitted to him, in his turn placing before it any case he thought suitable for its services. He was, however, very anxious that it should be made plain that refugees of all classes come very irregularly; for example, the Committee might have a dozen doctors or lawyers on their hands one day and no more for a fortnight. Want of appreciation of this fact had led to disappointment. Medical men, or the wives of medical men, who are prepared to offer hospitality to Belgian medical men and their families, are invited to write to the Medical Secretary stating what hospitality they are prepared to give, and any such offers will be dealt with as promptly as possible. Offers from London would be particularly appreciated. It should be clearly understood that offers to take one or two members of a family are of little use. The refugees themselves greatly prefer to be dealt with as families and not as individuals, and this has been adopted as the general policy of the War Refugees Committee.

AN AMERICAN COMMITTEE.

A committee has been formed in New York under the auspices of *American Medicine* for the collection of a fund for the relief of doctors in Belgium. The committee includes the names of Dr. W. S. Bainbridge, Dr. S. Ely Jelliffe, Dr. W. H. Porter, Dr. Parker Syms, of New York, and Dr. Charles E. de M. Sajous, of Philadelphia. It will work in co-operation with the Belgian Relief Committee.

THE WAR.

SURGICAL EXPERIENCES OF THE PRESENT WAR.

DISCUSSION AT THE MEDICAL SOCIETY OF LONDON.

A DISCUSSION on surgical experiences of the present war was opened on Monday, November 16th, at a meeting of the Medical Society of London. The President, Sir JOHN BLAND-SUTTON, was in the chair, and the hall of the society was crowded.

The subject was introduced by Sir WATSON CHEYNE, who is at present serving as Consulting Surgeon at the Royal Naval Hospital, Chatham, in an extremely interesting address, a full report of which is published at page 865 et seq.

At the conclusion of the address, the CHAIRMAN called on Sir Alfred Keogh, K.C.B., Acting Director-General, Army Medical Service, and Surgeon-General W. M. Russell, Deputy Director-General. Sir ALFRED KEOGH said that the Army Medical Department desired further information as to the value of antitetanic serum and practical advice that would be of use on the battlefield and in the trenches in respect of the treatment of wounds at the very beginning, and also, since very little could be done actually in the trenches, advice was needed as to hospital treatment in its early stages. Surgeon-General RUSSELL endorsed Sir Alfred Keogh's remarks, and hoped that an authoritative pronouncement would be made by those who were so competent to give it.

Sir RICKMAN GODLEE said that he agreed with every word of Sir Watson Cheyne's address from beginning to end. As Sir Watson Cheyne had suggested, he also might now be looked upon as an old fogey, but he believed that soon someone would rediscover the principle upon which Lord Lister worked, and that antiseptic surgery would come back to its own. It had been one of the saddest experiences of this war to learn from those who had been at the front that practically all wounds were septic. The profession wished to know what attempts were made, if any at all were made, to disinfect wounds—not probably in the trenches, but as soon as the patients reached the field hospitals. He had always feared, since the enthusiasm for aseptic surgery had become so pronounced, lest nothing should be done in the way of attempting to purify wounds, only the skin being cleansed—a measure which in itself, as Sir Watson Cheyne had said, was absolutely hopeless. If surgeons had forgotten all that Lister taught, he yet supposed that some of them still read their Bibles. Lord Lister used to say that if he ever wrote a book, which he never did, he would have put as motto on his title-page the verse from the Psalms:

> My wounds stink and are corrupt: because of my foolishness.

Mr. ARTHUR EDMUNDS described wounds he had seen in two of the naval hospitals—Chatham and Plymouth. It was difficult to make any general statement, because the wounds of the men who reached those hospitals were of medium severity. Those of great severity and the more trifling remained on the other side of the Channel. The way in which men supported their wounds might sometimes mislead the surgeon: thus, a man who gave the impression of having little the matter with him was found to have a severe comminuted fracture of the elbow-joint. Although there had been the greatest fortitude in bearing wounds, and surgeons had been able to appreciate the meaning of the *moral* of the navy and army, he had come across one or two interesting neurotic affections. A marine was buried in a trench by the force of an exploding shell. When he came to himself in the field hospital he was found to be deaf and dumb. It was suspected that the dumbness was functional; the ears were examined, and the man was easily persuaded that he could both speak and hear. He returned to duty a few days later. The nature of the wounds had not afforded any great surprises, but it was noteworthy that in some instances of wounds by German rifles there was evidence of the turning of the bullet. In one case a bullet turned sideways, and the whole forearm was ripped up in a manner that suggested an explosive bullet. In another case a bullet reduced the head of the tibia to a mass of small fragments. It had

been necessary to amputate in that case, but the man might have recovered had he not been lost on the field for four days without medical aid. He arrived at the hospital in a deplorable condition, but such a case was exceptional. The men usually arrived in excellent condition, well fed and well looked after, and having borne their injuries very well. It might seem presumptuous for those in England to compliment the transport, but its work had been most impressive, as reflected in the condition of the wounded. He had noticed a difference between wounds received at Plymouth from the front and those that came to Chatham from the fight in Heligoland Bight. In wounds from the land operations, if there was a small wound of exit and entrance, the probability was that the bullet had gone cleanly through, and nothing beyond simple dressing was necessary. But amongst the men wounded at sea there were cases in which a fragment of shell or of the ship had made a small wound of entry, but had ploughed up the tissues. Apparently the shells used by the Germans broke up into small fragments, each rotating and acting like a circular saw, and greatly lacerating the tissue. The conclusion was that penetrating rifle wounds with no obvious laceration had little need of treatment, but in cases from naval engagements laceration should always be suspected and a drainage tube put in, as the wound contained blood and was practically certain to suppurate. He quoted cases in support of Sir Watson Cheyne's advice as to the value of antiseptic methods, and as an example of the freedom of a bullet wound from sepsis in some instances, a case in which the missile traversed the lung, and the bullet was now lying on the diaphragm without producing symptoms. Bullets, on the other hand, were frequently surrounded by a zone of suppuration, and their removal was commonly advisable on this account, even when signs of infection were not obvious. The telephone probe, which enabled a fragment of shell to be distinguished from particles of bone, was often very useful. He had seen excellent results obtained in two operations in a hospital ship; one was an operation for gutter fracture of the skull with hemiplegia and the other an amputation for emphysematous gangrene.

Sir FREDERIC EVE said that as the fighting had taken place largely in trenches, wounds of the upper extremities, especially of the hands, were particularly numerous. Rifle bullet wounds about the root of the neck and shoulder were also frequent. In these concussion paralyses of a transient character were often observed owing to the bullet passing close to the cords of the brachial plexus. In the case of wounds of the neck, remarkable examples of passage of the missile between important structures without doing any great amount of damage were met with. He desired to draw attention to cases of concussion of the central nervous system from the vibratory effects of modern high-velocity projectiles, as these conditions were not observed in civil practice. In one case a shrapnel bullet lodged over the right lamina of the twelfth dorsal vertebra, causing no fracture. The patient had paraplegia with the exception of retention of sensation to light touch over the left lower extremity. Nine weeks after the injury there was very little improvement, but time only would show what amount of repair would take place. It had been shown that in these cases of concussion without fracture or a gross lesion of the cord, extensive degeneration of the grey matter took place, and after two months the cord, in some instances, had become transformed into a custard-like mass. In the following case an extensive lesion of the cerebrum appeared to have been produced in the same manner: A soldier was struck over the left parieto-occipital region by a shrapnel bullet, which caused right hemiplegia and hemianopsia. Five weeks after at an operation a stellate fracture of the skull was found but there appeared to have been no depression and the dura was uninjured. Decided improvement commenced before the operation, and was maintained, but nine weeks after the injury there was still loss of power on the right side, marked loss of sensation, right hemianopsia, and partial aphasia. He showed skiagrams illustrating the explosive effects on the femur of rifle bullets fired at short range. In one case union took place in five weeks with only half an inch shortening. If the wounds were not suppurating it was often unnecessary to remove the missile. To illustrate this point he showed three skiagrams of fractures of the femur in the region of the lesser trochanter in which the projectiles, respectively a piece of shell and two bullets, were left *in situ* without causing any trouble. The fractures all united readily, in two cases with only an inch and a quarter shortening. He strongly recommended the use of Hodgen's splint in gunshot fractures of the femur, as it permitted dressing of wounds without disturbance of the limb, and was more convenient for nursing than a Liston's long splint. With regard to wounds of the chest, he had been impressed with the small amount of discomfort and disturbance caused by a considerable haemothorax, sometimes associated with pneumothorax. For example, an officer received a penetrating wound of the back between the shoulders, the bullet entering on the left side and fracturing the fourth, fifth, and sixth ribs. It penetrated the pleura and wounded the lung. When admitted to hospital on the ninth day auscultation and radiography showed that the upper part of the pleura was filled with air, and blood extended up to the angle of the scapula. This patient walked half a mile after being wounded, and only felt some shortness of breath. During the first day there was some haemoptysis, and on the following three days he brought up a small amount of blood, but that was the only inconvenience he suffered. Sir Frederic Eve had had only one case of tetanus under his care, and it was, perhaps, worthy of note that the man was one of a few who did not receive an injection of antitetanic serum.

Sir WATSON CHEYNE, replying to some of the questions raised, said that Sir Alfred Keogh mentioned a very pertinent matter when he asked if anything could be done in the trenches, where it was very doubtful whether extensive surgical measures could be undertaken. It would, however, be possible for the soldier to carry suppositories of carbolic acid or iodine, which might be packed into the wound before the dressing was applied. It would be worth while to think out the plan very carefully, for something was needed to stop the growth of bacteria until the patient reached the base hospital. Another point was that sepsis was bad, whether much or little; sometimes he had heard attempts to differentiate in that respect.

[The discussion will be resumed on Monday, November 23rd.]

MEDICAL ARRANGEMENTS OF THE BRITISH EXPEDITIONARY FORCE.

[From a Special Correspondent in Northern France.]

SHELL FUMES.

A GOOD deal has been written about the effect on the Germans of the fumes produced by turpinite, the new explosive and rival of melinite and lyddite, but nothing is publicly known as to the extent to which this intensely high explosive is really being used, and much of what is said about its effects is in the nature of mere assumption. Presumably the chemical experts employed at the French arsenal and M. Turpin himself know what gases are formed by its explosion in small quantity and in a closed vessel—though that is not the question which primarily interests them—but the statements made as to the poisonous effect of these in the open air and in action are for the most part based neither on precise chemical knowledge nor on serious pathological considerations. Because A., a soldier still in an attitude suggestive of active life, is found to be stone dead and yet altogether unwounded, or seemingly only very slightly wounded, it is assumed that he has been killed by some instantaneously fatal gaseous poison, generated by the explosion of a shell which other evidence indicates to have fallen in his neighbourhood. If there were well-authenticated incidents of this kind, and still more of cases in which several individuals had been found close to one another in the same trench all dead but all unwounded, and in a life-like attitude, the *prima facie* evidence of the correctness of the assumption would be strong, despite several obvious objections. It is to be remembered, however, that stories of the kind—including others to the effect that the Germans sometimes succeeded in intoxicating aviators by the use of special gas-generating shells—pass from mouth to mouth very readily, and no one makes any real attempt

to test their foundation. It would, indeed, not be easy to do so, and, so far as the effects of the almost equally high explosives used by the Germans are concerned, there are stories which cut both ways in their bearing on the turpinite question. They relate mainly to the shells that our soldiers dub "coal-boxes" and "Black Marias," and for narration I choose one told me yesterday by an old South African acquaintance. In the course of a long account of his experiences between Mons, the Meaux, the Aisne, and Ypres—that is to say, from the beginning of the war up to a few days ago—this soldier, who is a very level-headed man, told me that twice a "coal-box" had fallen within a few yards of his trench, and, in fact, dug a large hole in the ground just outside it. On neither occasion did he suffer any harm, though startled by the extreme loudness of the detonation. On the other hand, a few minutes later he began to feel irresistibly sleepy, and did, in fact, go to sleep, waking up several hours later without headache and feeling perfectly well. He was quite certain that it was not mere fatigue that led to his sleeping. As for their other effects, I am led by various circumstances to conclude that the amount of direct injury these "coal-boxes" may do depends entirely on the nature of the soil on to which they fall. If this be rocky, their own fragments and the masses of stone they scatter in all directions may produce the gravest kind of shell wound. If it be moderately soft, they bury themselves so deep that the walls of the huge hole resulting act as a rampart in which they break. On the other hand, the displaced earth and pebbles fly upwards and outwards in a swift rising cascade, and the effects are sometimes curious. On the back and dorsal surfaces of the limbs of one man who had been standing within reach of one of these cascades I counted as many as thirty wounds of irregular shape. Not one of them was more than about a centimetre deep, and a thumb-mark would have covered the largest of them. In the aggregate, however, they represented a serious breach of surface, and the shock and subsequent inflammatory reaction were considerable.

Conditions in Paris.

Rendered possible by a flying visit, a general survey of the conditions prevailing in Paris indicates that the convalescence of the city, so to speak, continues to make satisfactory progress. About a month ago practically the only foreigners to be seen were stray British soldiers, and the habitually resident population had fallen by a third or more. There are still very few strangers about the streets, but the incoming trains bring back large contingents of ordinary residents each day. Shops other than those which sell absolute necessaries are opening in increasing number every week, and those already at work seem to be well supplied. There are also fewer ambulances, for no British wounded are now arriving, and the ban of the military governor on the admission to Paris hospitals of any large proportion of the French wounded still remains in force. On the other hand, the entire absence of omnibuses, the diminished number of cabs and private automobiles and tradesmen's carts, keeps up the empty appearance of the streets; the fires of most of the larger restaurants have not yet been relighted, the cafés—such as are open—still seem half asleep, the search-lights still career all night across the skies, the edict against the bakeries supplying anything but plain bread still holds good, the trenches and entanglements outside the main gates remain untouched, and the numerous French red cross hospitals, small and great, continue to fly their flags. There are still, therefore, plenty of reminders of the anxious days of September, and of the fact that France is still in the throes of a life and death contest. A good many of the smaller French auxiliary ambulances appear to find some difficulty in keeping up their *moral* owing to lack of work, and the various large institutions which do their work partly or entirely under the control of the Paris branch of the British Red Cross Society are in somewhat like case, though they still have a fair number of old cases on their hands and new ones arrive from time to time. Consequently some of them have allowed members of their staffs to join hospitals working nearer the front, and others have started annexes in places where new cases are more numerous. The Anglo-Franco-Belge Hospital, for instance, has established at Wimereux an offshoot which seems likely to rival the parent body; the Duchess of Westminster Hospital is at work at Le Touquet; the American Hospital has a small movable contingent on the outlook for a site on the northern lines of communication, and a branch well to the south of Paris, near Bourg, has been opened by the Majestic. As for the School of Medicine, this has nominally begun work, but its chief occupation so far has been the holding of final examinations, and practically nothing is in view beyond the classes for junior students. Nearly all those for third and fourth year students have been put off until the beginning of the next summer session, and those not already engaged in the service of the army are being urged to send in their names forthwith. It is easy to understand that there should be some difficulty in securing a sufficiency of French surgeons and dressers. The population of France is, after all, only about the same as that of Great Britain, and the normal proportion of medical men to each 1,000 of inhabitants is somewhat less. Consequently the medical profession in France has a very great task to discharge when it is asked to meet the needs of about ten times as many soldiers as those which Great Britain has thrown into the fighting line. Furthermore, a considerable number of French surgeons have been captured, wounded or killed. The French medical profession is, in fact, figuring excellently in dispatches. Usually they are picked out for mention owing to the courage they have shown in continuing to attend to the wounded, despite being wounded themselves, but in more than one case the mention in dispatches has been won by a surgeon who had rallied the survivors of a regiment which had lost all its other officers.

An Extemporized Hospital.

Lord Roberts fell ill very shortly after his arrival at his destination in France: one of the last official acts of his life was that performed by him as soon as he had set foot on shore. It was one in keeping with his career and the thoughtful kindliness of his disposition. The doors of an extemporized hospital open on to the landing stage, and this building Lord Roberts entered forthwith, had a word to say to many of its inmates, and, after visiting all its wards, expressed to its authorities his pleasure at having been able to see immediately on his arrival, and relatively so near the fighting line, an extemporized hospital which seemed to him thoroughly efficient both from a military and a medical point of view. All those connected with this hospital are therefore to-day regretfully proud of themselves, and its name—No. 13 Stationary Hospital—is not likely to be overlooked by future biographers. It is, however, not only because it was the scene of one of the last acts of Lord Roberts's life that this hospital is worth mentioning. It is also of interest as being a good example of the effects of well directed peace-time training. I have been able to watch its development from an early stage. Just four weeks ago it was a store, and not even a good store—merely a very large single-floored erection built largely of wood. Nor was it a clean store, for it was used for keeping bags of moist and other sugar, and its floors were inches deep in a hard mixture of dirt and exuded saccharine matter. Space was also occupied by large weighing machines, and the grimy plank walls and ceilings were hardly weather-proof. So soon as the need of a hospital in this particular locality was foreseen, the building was assigned to No. 13 Stationary Hospital unit, the officers and men of which started to prepare it for its future work forthwith. It was just one of those tasks which to civilian hospital workers would appear to present insuperable difficulties, but which the special training received by the Royal Army Medical Corps enables it to perform not without great labour but with complete success. The first step was to make the building weather-proof and to clear the floor space of obstructions. This was done with the help of the engineers, the walls being first "stopped," then cleaned with a disinfectant, then lightly coated with cement, then rewashed with disinfectant, and finally given a coat of whitewash. At the same time a sanitary squad chipped away at the floor until the stone slabs of which this is composed were reached, and then polished these up. Rapid progress was made despite the fact that in addition to other difficulties sleeping space had to be found for some 500 men awaiting orders to move up country—and 500 men are apt to create a good deal of litter. In three or four days the

back of the job was broken, and it was then possible to complete in detail the plans that the principal medical officer of the unit, with the approval of the staff medical officer in charge of the whole of this hospital base, had already drafted for dividing up the total available space into all the required sections—wards, operating rooms, dispensary, lavatories, kitchen, sleeping quarters for orderlies, store room, and mortuary. In little over seven days the transformation was almost complete, beds were ready and all other absolute necessaries prepared, and there was no reason why patients should not be admitted if required. In the event, trains of wounded began to arrive two or three days later, and in the fourteen or fifteen days that have since elapsed the record of patients admitted, discharged, and still under treatment at this 200-bed extemporized institution probably exceeds that of most hospitals in England of twice its size during a whole year. As for its merits from a military point of view, Lord Roberts's opinion is decisive, and in respect of its medical efficiency I can claim to be a judge. It is not a "pretty" place from the point of view of the average frequenter of the great permanent medical establishments of Great Britain, or even of those whose conception of war hospitals is mainly founded on the converted great hotels of Paris, but no competent judge could dispute its efficiency. Even in the matter of mere appearances there are points in the scene that it presents which must appeal to any artist eye, while on thoroughly and repeatedly examining the general arrangements it is found that everything required by surgery in this war is duly provided, and that all the machinery—despite the necessity of constant adjustment and expansion to meet each day's varying needs—is working smoothly. In short, it seems to me that a department whose officers can do work of this kind in half a dozen places simultaneously, and not at home but in a foreign enemy-occupied country, and not once but over and over again, has no cause whatever to fear criticism from competent judges.

THE GENEVA CONVENTION.

The Geneva Convention, to which all the powers now at war are adherents, apparently makes very ample provision for the protection of medical officers and all those exclusively engaged in caring for the wounded and sick, but in reality leaves a good deal to be desired. The text of this agreement was published in the JOURNAL of October 17th. It stipulates that the persons of Red Cross workers—including in that term those belonging to the permanent medical establishment of the army concerned—shall be "respected and protected," and ordains that when they fall into the hands of the enemy they shall not be treated as prisoners of war. It also debars from being treated as booty the personal property of Red Cross workers, the material of mobile medical units, and the whole of the property of voluntary units, whether mobile or stationary. On the other hand, the Convention permits of the services of Red Cross workers and all material being commandeered and utilized for the treatment of the sick and wounded as long as may be necessary. Consequently, apart from the danger of being wounded or killed when on duty, every Red Cross worker engaged in the performance of his duties at or near the real front runs the risk of finding himself in a position which may only in theory differ from that of an ordinary prisoner of war. Of this weakness in the Convention the Germans appear to be taking the utmost advantage. Very considerable numbers of officers and orderlies of the medical services both of the British and French armies have at one time and another fallen into the hands of the Germans, and very few indeed have been allowed to return to their own lines. By far the greater proportion still remain in the enemy country, and have before them the prospect of remaining there until the end of the war. The discipline to which they have to submit is moreover severe, if one may gauge the situation from the account given of his experiences by one of the few French medical officers who have managed to return. He said that he had been threatened with a revolver because he demurred at performing an amputation which did not seem to him to be justified. The British and French, on the other hand, are placing a very liberal interpretation on the clauses of the Convention, that is to say, an interpretation highly favourable to the enemy. There are doubtless differences in the practice of the commanders of different British and French army corps and divisions, but the general rule appears to be to cast a blind eye on any spot where German medical officers and their men are known to be engaged in tending their wounded, and to avoid making captures of such groups, if this be possible. During the advance after Soissons several complete units fell into the hands of the French and proved to be very large and elaborately equipped, and organized almost on the lines of a regimental company, despite the fact that the personnel included in one case many women. All the members of one of these units were, I know, sent back to Germany by a devious route. Those of another were treated, and rightly treated, on very different lines. The contents of their vehicles showed that they had been engaged in pillaging on a very large scale; consequently they were placed in prison, and when last I heard anything about the matter they were awaiting trial. Nor is this particular incident the only evidence of German unscrupulousness in connexion with ostensibly Red Cross work that events have brought to light.

It would appear, however, from what passed at a recent meeting of the Medical Society of the Hospitals at Paris that the Germans could not put forward the excuse that their services were, in the terms of the Convention, indispensable in the case of a large number of the French army medical officers now in their hands. Information which has reached the society from various private sources proves, it is claimed, that no pretence whatever of employing these surgeons is being made; they are being treated literally as prisoners of war, despite the fact that their status was rendered evident at the time they were captured by their Red Cross armlets. If the professional services of a captured medical officer are not "indispensable" to the enemy he ought to be sent back by any convenient route, but instead of this these officers are being detained in complete idleness in barracks, guarded camps, and fortresses. The result of the society's consideration of the information before it was a resolution to address a letter to the president of the Cross of Geneva requesting his attention to the matter, and his intervention if he found the statements well founded. Copies of this resolution were directed to be sent also to the French Foreign Office and the Director-General of the Medical Department of the French War Office.

HOME HOSPITALS AND THE WAR.

GLASGOW.

THE 3rd and 4th Scottish Hospitals established in the Glasgow Parish Council's Hospital at Stobhill have been receiving large numbers of wounded during the past three weeks. The accommodation at Stobhill amounts to nearly 1,500 beds in all, and the number of patients is very little short of 1,000. The operative work is still rather hampered by limited operating theatre arrangements, and increased facilities are being rapidly constructed. We have been informed by Lieutenant-Colonel Hay that the number of cases of tetanus has been greater in recent admissions, as also the cases of traumatic aneurysm. The septic condition of these latter has precluded hopefulness in operative treatment, and has frequently necessitated amputation where practicable. The gravity of the various train-loads of cases has varied; some have been all "stretcher" cases, others mostly "walking" cases. The physicians and surgeons of Glasgow are finding the additional demands on their time a rather serious strain on normally busy lives, but they are tackling the work with energy, and derive great interest from phases of surgical work quite new in the experience of most.

Glasgow Royal Infirmary has received two train-loads from the front. The managers were fortunate in having at their disposal several wards of the old infirmary still intact and in good working order suitable for such emergency work. A large proportion of the recent admissions were quite trivial cases. Some were simply bruises and superficial wounds which could have made a good recovery with a short rest in a hospital, say, in Paris. But there can be no doubt that even trivial conditions will benefit greatly from the rest of two or three weeks in convalescent homes and in their own homes.

EDINBURGH AND DISTRICT.

On November 12th H.R.H. Princess Christian made a visit of inspection to the new naval hospital at Queensferry, the building of which was only begun in August. It has, however, been already in occupation for some time, and at the time of the visit there were between forty and fifty patients in it. There are four wards, each capable of accommodating twenty-five patients, and the hospital is equipped and furnished according to the latest improvements in construction and requirements for surgery. The Princess was accompanied by the Marchioness of Linlithgow, and amongst those who received her were Mr. Alfred Mosely, C.M.G., Professor Sir William Macewen of Glasgow, Fleet Surgeon Paget Jones, Dr. Fleming, senior surgeon, and Staff Surgeon Bateman. It will be remembered that this building, called the Queen Mary and Princess Christian Hospital, was provided by a generous and anonymous donor at the beginning of the war. Her Royal Highness also visited Dalmeny Hospital in the same neighbourhood, where she conversed with the patients, some eighty in number, who are now under treatment there. She returned to London on November 13th.

THE BRITISH RED CROSS SOCIETY.

Rapidity of Transport.

Sir Frederick Treves states that, although the number of wounded passing from the base to the various hospitals in France and in this country is still enormous, the task of handling them is rendered considerably less difficult by the shortness of the line of communications during the present phase of military operations. In ordinary circumstances a man wounded in France on Friday is in a hospital bed in England on Sunday. No additional doctors or nurses have been sent to France for some days, and every demand is being met by the large staff already at work.

The Hospital Train and Hospital Ship.

The British Red Cross hospital train in France will be ready for service this week; and the hospital ship, with accommodation for 21 soldiers and 3 officers, is nearly ready.

Fever Hospital for the Troops.

The Joint War Committee of the British Red Cross Society and the Order of St. John of Jerusalem in England has made a grant of £5,000 towards the establishment in a large private house in Addington, Surrey, of a fever hospital for British troops. The War Office has interested itself in this scheme, and will probably make a contribution towards the cost, which is estimated at £20,000 for one year.

Another War Hospital for London.

The proposal mentioned last week for the establishment of a large war hospital in London under the auspices of the Joint War Committee of the two Societies has now assumed more definite shape, although the number of beds to be provided is not likely to be so large as was thought at first. The Government has agreed to lend a large new block of buildings intended for H.M. Stationery Office, and now approaching completion. It is situated in Waterloo Road, near the South-Western Railway terminus, and contains six spacious floors served by eight lifts. The premises were recently inspected by officers of the Royal Engineers and the Army Medical Department and by Sir Frederick Treves and Mr. Edmund Owen, on behalf of the Joint War Committee. There is ample space for upwards of 1,500 beds and for all the accommodation necessary for administrative purposes. The premises are well suited for use as a hospital, and as they are not yet finished, any necessary adaptations can readily be made. At the time of going to press, however, no definite conclusion as to the block being taken over had been arrived at.

BRITISH AND GERMAN SMALL ARM AMMUNITION.

Memorandum Communicated by the War Office Respecting British and German Service Ammunition.

The international law respecting the projectiles that can properly be used in case of war between civilized nations is to be found in the Regulations annexed to The Hague Convention of 1907, respecting the laws and customs of war on land, and in two International Declarations, one signed in St. Petersburg in 1868 on the subject of explosive projectiles, and the other with regard to expanding bullets, signed at The Hague in 1899. The Hague Regulations vaguely prohibit the use of "projectiles calculated to cause unnecessary suffering." The Declarations are more explicit. That signed at The Hague in 1899 is an agreement to abstain from the use of bullets which expand or flatten easily in the human body, "such as bullets with a hard envelope which does not entirely cover the core or is pierced with incisions." The St. Petersburg Declaration is an engagement to renounce the employment of "any projectile of a weight below 400 grams, which is either explosive or charged with fulminating or inflammable substances."

The British service ammunition is known technically as Mark VII, .303 S.A. Ammunition. The length of the bullet is 1.28 in., and its weight is 174 grains. The muzzle velocity is 2,440 ft. per second. The bullet is a pointed one with an envelope of cupro-nickel, which completely covers the core, except of course at the base through which the core is inserted.

The ordinary German service ammunition is very similar. The length of the bullet is 1.105 in., and its weight 154 grains. The muzzle velocity is 2,970 ft. per second. The German bullet is also a pointed one, with a steel envelope coated with cupro-nickel covering the core, except at the base. Both bullets carry out the provisions of The Hague Convention, and it will be observed from the report attached (Appendix I) that Sir Victor Horsley considers the modern pointed nickel-sheathed bullet "probably the most humane projectile yet devised," and that "the long solid point consisting almost entirely of the hard nickel sheath precludes as far as possible any tendency to deformation of shape, while the strength of the sheath prevents the bullet breaking up into fragments except in very exceptional circumstances—that is, after a ricochet, etc." So far, therefore, as their ordinary rifle ammunition is concerned, both Great Britain and Germany have conformed to the principles of international law.

There is, however, clear evidence that Germany has not confined herself solely to the use of this unobjectionable ammunition. Her troops, both in Togoland and in France, have been proved to have used bullets with a soft core and hard, thin envelope, not entirely covering the core, which type of bullet is expanding, and therefore expressly prohibited by The Hague Convention.

Such bullets of no less than three types were found on the bodies of dead native soldiers serving with the German armed forces against British troops in Togoland in August, and on the persons of German European and native armed troops captured by us in that colony. All the British wounded treated in the British hospitals during the operations in Togoland were wounded by soft-nosed bullets of large calibre, and the injuries which these projectiles inflicted, in marked contrast to those treated by the British medical Staff amongst the German wounded, were extremely severe, bones being shattered, and the tissue so extensively damaged that amputation had to be performed. The use of these bullets was the subject of a written protest by the General Officer Commanding the British Troops in Nigeria to the German Acting-Governor of Togoland.

Again, at Gundelu, in France, on September 19th, soft-nosed bullets (that is, those in which the lead core is exposed and protrudes at the nose) were found on the dead bodies of German soldiers of the Landwehr, and on the persons of soldiers of the Landwehr made prisoners of war by the British troops. One of these bullets has reached the War Office. It is undoubtedly expanding, and directly prohibited by The Hague Convention.

There have appeared from time to time in the German press official or semi-official statements to the effect that "dum-dum" bullets had been found on numerous occasions on the bodies of dead British soldiers, and on the persons of British officers and soldiers made prisoners of war. These allegations were made in terms so vague as to be incapable of disproof. It was not even clear what was meant by the term "dum-dum bullet."

Lately, however, specific reference has been made in the German semi-official organ, the *Lokal-Anzeiger*, to certain flat-nosed revolver ammunition found in the possession of the British officers made prisoners of war by the Germans.

This can only refer to the Marks IV and V patterns revolver ammunition, of which specimens are attached.[1] The Germans publish statements alleging that British officers had admitted that they themselves had doubts as to whether the use of this ammunition was in accordance with international law, and the German commentators declare that such bullets can have no other purpose than to cause the most horrible wounds possible. Fortunately, it can be proved conclusively on irrefutable evidence, that these bullets are as humane as any bullet can be, and do not in any way contravene the law of nations. The international law on this subject has already been quoted.

The Marks IV and V patterns have a flat fore-end instead of the usual conical fore-end. The bullet is solid, and of homogeneous material. It is not, therefore, a bullet with a "hard envelope" or "soft core." It cannot, by any stretch of the imagination, be described as "soft-nosed."

Is it, however, a bullet which "expands or flattens easily in the human body"? This question, again, can be readily answered. Since the shape was novel, the most careful experiments were made by the War Office to ascertain whether the bullet, on striking, was subject to more deformation than bullets with the usual conical end. It is well known that the wounding effect of a projectile depends on the possible increase in its diameter by deformation. In the case of the Marks IV and V bullets, such expansion by deformation is notably small, and less than that of the bullet with the conical fore end to which exception has never been nor could be taken. The Government advisers had, therefore, no hesitation in recommending the adoption of the flat-nosed revolver bullet, and the attached report by Sir Victor Horsley (see Appendix II) proves, from an independent source, that the bullet is as humane as the ordinary conical bullet, does not expand or flatten easily in the human body, and is not "calculated to cause unnecessary suffering." In short, it in no sense conflicts with the provisions of The Hague Declaration or Convention.

It is considered improbable that the British officers held as prisoners of war could have made the statements attributed to them. If they did, they must have done so in complete ignorance both of the letter and the spirit of The Hague Convention.

The German official and other statements that British troops are employing projectiles prohibited by The Hague Convention is, therefore, not only untrue, but would appear to have been made for the sole purpose of justifying the previous issue to, and use by, German troops of projectiles which do most undoubtedly contravene The Hague Regulations.

October 7th, 1914.

APPENDIX I.

Memorandum on the .303 (174 grains) Mark VII British Service Rifle Bullet in reference to Explosive Effects.

(By Sir VICTOR HORSLEY, F.R.S., etc.)

Having made, on the introduction into His Majesty's services of the .303 rifle, a long series of researches into the effects produced on living tissues by high velocity projectiles, and having also experimentally investigated the physical causes of those effects, I venture to submit the following observations on the pattern of rifle bullet now employed by His Majesty's Forces:

The modern pointed nickel-sheathed bullet, as used in our service, is probably the most humane projectile yet devised. The two determining provisions of The Hague Conventions, 1899 and 1907, concerning rifle bullets are quite clear firstly, that the structure of the bullet must be such that it should not easily become flattened nor deformed in shape; and therefore, secondly, it should not inflict a wound which, while effecting its necessary object of disabling, caused unnecessary suffering.

In its design and manufacture the British service bullet fulfils these requirements more completely than any other projectile.

The long solid point, consisting almost entirely of the hard nickel sheath, precludes, as far as possible, tendency to deformation of shape, and in like manner the strength of the sheath prevents the bullet breaking up into fragments save under very exceptional circumstances—that is, after a ricochet, etc.

So-called explosive effects are sometimes caused by any projectile under the circumstance of a bullet fired at relatively short range or possessing a residual velocity exceeding 1,500 f.s., and passing through a closed bony cavity (such as the skull or centre of a hollow bone) containing fluid or semifluid and viscous contents—for example, marrow or brain.

Under these circumstances, the velocity being imparted to the particles of fluid, there is set up a hydro-dynamic force of considerable disruptive power, and the comminution of bone thus occasionally produced has been mistakenly attributed to a bullet of an expanding or so-called explosive kind.

It has been suggested that the long narrow point of the British and German bullets leads to the projectile turning over around a transverse axis during its penetration of solid substances, and that this might account in part for the severity of the injuries under certain circumstances.

That this is not the case is, I would submit, proved by my experiments on the effect of firing long cylindrical bullets with very high velocities into moist clay. These researches showed that the disruptive effect was due to the speed of the bullet, and bore no relation to the occasional turning over of the projectile.

There is, therefore, no ground whatever for the statement that the British service rifle bullet is other than a projectile carrying out in the fullest possible manner the provisions of The Hague Convention.

(Signed) VICTOR HORSLEY.

25, Cavendish Square,
September 13th, 1914.

APPENDIX II.

Note on the Flat-nose Revolver Bullet, Mark IV, in reference to the Provisions of The Hague Convention.

(By Sir VICTOR HORSLEY, F.R.S., etc.)

The question whether the flat-nose revolver bullet, Mark IV, at present in occasional use by His Majesty's forces fulfils the provision of The Hague Convention, 1899 and 1907, may be answered at once in the affirmative by the results of direct experimental researches, including my own.

In the first place, as regards possible expansion and deformation, I found that solid cylindrical bullets, such as Mark IV, when stopped by varying substances—for example, clay, wood, flat bone, etc.—exhibit very little deformation. Deformation when present consists in a slight setting up of the fore-end, this seldom increasing the transverse diameter more than about 10 to 15 per cent.

I have also seen the results of independent researches made for His Majesty's War Department of firing such bullets into planks of wood in which the same absence of deformation was also observed.

The revolver bullet Mark IV is therefore in no sense an expanding projectile.

In the second place, inasmuch as my experiments showed that the wounding effects in living tissues depend primarily on the velocity of the projectile, a revolver bullet necessarily produces a relatively small disruptive effect. Further, the same researches established the fact that the influence of the sectional area of the bullet remains the same whatever the shape of the fore-end—that is, whether the bullet is a conically-ended or square-ended cylinder. The wounding effect due to the diameter of the projectile depends on its possible increase by deformation, and inasmuch as that in the case of the revolver bullet Mark IV is notably small there is no question but that the flat-nosed revolver bullet Mark IV is in full accord with the provisions of The Hague Convention.

CASUALTIES IN THE MEDICAL SERVICES.

Royal Navy.

Action in the Pacific.

The Secretary of the Admiralty announced on November 13th that in the absence of further information the loss of H.M.S. *Good Hope* and *Monmouth* must be presumed, and the report from the captain, H.M.S. *Glasgow*, published on November 18th, seems to leave no room for hope. The medical officers of the lost ships were as follows:

Good Hope.

Fleet Surgeon James J. Walsh, M.B., M.Ch., R.U.I., 1885, entered the service in August, 1885, and obtained his present rank in August, 1901. He was appointed to the *Good Hope* in 1913, previous to which he was medical officer to R.N. Dockyard and Sick Quarters, Sheerness.

Surgeon Francis Charles Searle entered the service in November, 1909, and was appointed to the *Good Hope* in July last. He was educated at St. Bartholomew's Hospital, and took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1908, graduating M.B., B.S.Lond. in 1909. He was for a time resident medical officer of the Finsbury General Dispensary, and prosector at the Royal College of Surgeons of England. He was a member of the Rahere Lodge of Freemasons.

Surgeon Fernand Louis J. M. de Vertenil was a Surgeon of the Royal Naval Reserve, and joined the *Good Hope* on August 27th, 1914, having formerly been a surgeon in the Royal Navy. He received his military education in Edinburgh and at King's College, and St. Thomas's Hospital, London. He took the diplomas of M.R.C.S., L.R.C.P.Lond. in 1904, and graduated M.B., Ch.B.Edin. in 1908, and M.D. in the same university in 1909. He belonged to a family well known in the West Indies, and for some time held an appointment in the Trinidad Medical Service. He recently practised at Vancouver, British Columbia, from which place he contributed to our pages articles on the staining of *Treponema pallidum*, on the use of salvarsan in leprosy, and on the site of infection in yaws. He also translated Dr. Maisonneuve's *Experimental Prophylaxis of Syphilis*.

Monmouth.

Staff Surgeon Henry Woods entered the Medical Service, R.N., in November, 1903, and was promoted Staff Surgeon in May, 1912. He received his medical education at University College, Liverpool, and graduated M.B., Ch.B. Vict. in 1903. When the war broke out he was stationed at the Naval Barracks, Devonport, and was appointed to the *Monmouth* on August 1st, 1914. He was the son of Mr. E. Woods, of Preston, and was 35 years of age. He leaves a widow.

Surgeon Albert Joseph Tonkinson joined the Medical Service, R.N., in October, 1913, and was appointed to the *Monmouth* on August 1st, 1914. He was educated at the London Hospital, and graduated M.B., B.S.Lond. in 1911. He was afterwards pathological assistant at the London Hospital, and assistant medical officer, St. John's Hill Infirmary, Wandsworth.

Army.

Since the list of casualties published in our last issue the names of two more officers of the Royal Army Medical Corps appear among the killed, one occurring with the Expeditionary Force and the other in the East African operations. Three officers of the corps have also died of wounds.

Killed.

The tale of the ruthless killing of Captain Angus MacNab, the medical officer of the London Scottish, is told in the letter of a motor cyclist dispatch rider in the *Times* of November 12th. "Their medical officer, MacNab, was actually bayoneted in front of their eyes whilst bending down attending to two wounded men. It was bright moonlight, and he had a white badge and red cross on his arm, and even a blue tunic on, so as to be absolutely unmistakable, and was, of course, without arms of any sort." We may take it this account is a true one, for we have the same details from an independent source. The iniquity of the deed is the worse when it is known that MacNab spoke German fluently, so that without doubt he would have made known to his assailants—if there was any reason left with them—the helplessness of his charges and his own defenceless state.

Angus MacNab was one of the rising opthalmic surgeons of London of the younger generation. He was a New Zealander by birth, and brother of the Hon. Robert MacNab, formerly Minister of Agriculture in that Dominion. He took his arts and science degrees in the University of Otago in 1895–6, thereon migrating to Edinburgh; he graduated in medicine and surgery in that University in 1901. Meantime the South African war had broken out, and he volunteered for service as a civil surgeon, and did excellent work with the Imperial Yeomanry Hospital at Deelfontein, receiving the Queen's medal. Returning to London he studied at King's College and proceeded to the F.R.C.S.Eng. in 1904. He then took up eye work, and after spending some time at Vienna, and for a longer period working with Axenfeld at Freiburg, he started practice in London. His great interest was in the study of the diseases of the cornea, and the results of his researches appeared in a book published in 1906, entitled *Ulceration of the Cornea;* it was a work of distinct originality. Later he did good work in translating Axenfeld's *Bacteriology of the Eye*. As a clinician he was thorough and persistent in his work. He was a regular worker at Moorfields, the Central London, and Charing Cross Hospitals, serving as chief clinical assistant and in other capacities. Recently he had been appointed ophthalmic surgeon to the King Edward VII Hospital at Windsor, and had done special work for the Metropolitan Asylums Board. He leaves a widow and two little children. They are now in New Zealand on account of the health of the younger child. Our sympathies will go out to them.

Killed.

Captain Ernest Muro Glanvill, M.B., received his medical education at the University of Edinburgh, and took the degrees of M.B., Ch.B. in 1901. He had held the offices of assistant house-surgeon at the Devonshire Hospital, Buxton; medical officer to the Casualty Department, East London Hospital for Children, Shadwell; and second assistant medical officer at the Paddington Infirmary. He entered the R.A.M.C. as lieutenant in August, 1903, and was promoted to Captain in February, 1907.

The late Captain Kinkead, R.A.M.C.—We have received from Dr. George E. Nesbitt, Assistant Physician to the Richmond Hospital, Dublin, the following tribute to Captain Kinkead, of whose life and gallant death we gave some account last week (p. 858): To the staff of the Richmond Hospital and the students there eight years ago, George Kinkead was a familiar figure. Coming to us from Galway, he was welcomed for his father's sake, but quickly loved for his own. In the intimate acquaintance with one's fellow-students, which is not the least of the benefits of residence in hospital, he soon endeared himself to all; no one ever had a bad word to say of Kinkead. Keen on his work, popular with his patients, the best of company in the messroom, always ready and obliging when we wanted some one to relieve us of an inconvenient day "on duty," he was bound to make his mark in the career he chose, and for which he was eminently fitted. How little we thought as we parted, our most disagreeable prospect that of a final examination, what the future held in store. Now all we have left is a gracious memory, and a pictured group in which by chance he is the central figure. Though full details are not yet generally known, we may be sure he met his end like a gallant gentleman, responding as ever to the call of duty. To his relatives, who in their sorrow should be proud, we offer deepest sympathy, and such consolation as the knowledge can give that in his life, as in his death, George Kinkead has set before us an ideal we shall strive but cannot hope to compass.

Died of Wounds.

Captain Charles Paget O'Brien-Butler, R.A.M.C., who died on November 1st from wounds received in action, was the elder surviving son of the late Major O'Brien Butler, 60th Rifles. He was born thirty-nine years ago. He obtained the diplomas of L.R.C.P. and S.I. in 1905, and joined the Royal Army Medical Corps in 1907. Though a very good all-round sportsman, he was specially known for his marked ability across country, and won many important races, including the Grand Military Steeplechase, and the Emperor of Austria's cup in the

Pressburg Steeplechase. His ambition was to win the Grand National, but though he rode in the race several times, he never had the good fortune to win it. Five years ago duty took him to India, where he soon became known as one of the best amateurs. During the present war Captain Butler was attached to the 5th Lancers, and we believe was with them when he was fatally wounded. He was a most popular officer, and his loss is deeply regretted by his brother officers and a large circle of friends. Captain O'Brien-Butler was married in 1908, and leaves a widow and one child.

Captain Thomas McCann Phillips, R.A.M.C., received his medical education at Queen's College, Belfast, and took the degrees of M.B., B.Ch., B.A.O., R.U.I. in 1905. After holding the offices of senior house-surgeon and house-surgeon to out-patients at the Royal Victoria Hospital, Belfast, he joined the R.A.M.C. in 1907 as lieutenant; he was promoted Captain in 1911.

Richardson, Lieutenant M., R.A.M.C.

Wounded.

Comyn, Captain K., M.D., R.A.M.C.
Dickson, Captain H. S., R.A.M.C.
Grisewood, Captain A. E., I.M.S.
Irvine, Major F. S., R.A.M.C.
Loughnan, Captain W. F. M., R.A.M.C.
Meaden, Captain A. A., R.A.M.C. (also missing).
Rose, Captain A. M., R.A.M.C. (also missing).
Shore, Lieutenant L. R., R.A.M.C.

Prisoners of War.

Croker, Captain W. P., R.A.M.C.
Dolbey, Captain R. V., R.A.M.C.
Flood, Lieutenant R. A., R.A.M.C.
Holden, Captain C. W., R.A.M.C. (previously reported wounded and missing).
Meaden, Captain A. A., R.A.M.C. (also wounded, previously reported wounded and missing).

Missing.

Butt, Lieutenant J. G., M.B., R.A.M.C.
Mehta, Lieutenant N. M., I.M.S.
Winter, Lieutenant H. G., R.A.M.C.

NOTES.

THE MEDICAL SERVICE OF THE AUSTRALIAN CONTINGENT. THE Australian Expeditionary Force will be a complete unit, and will comprise a full medical department with ambulances and hospitals. The senior officer of the medical service is Surgeon-General W. D. C. Williams, C.B., Director-General of the Medical Service of the Commonwealth military forces, who served in the Soudan and as principal medical officer of the Australian and New Zealand forces in South Africa. Colonel Charles Ryan, principal medical officer Victorian military forces, who served in the Servian and Russo-Turkish wars and through the sieges of Eleona and Eazeroum, and described his experiences in *Under the Red Crescent*, is Assistant Director-General. In addition to regimental medical officers there will be provided for the force one mounted field ambulance, one field ambulance, one clearing hospital of 200 beds, two stationary hospitals of 200 beds each, and two general hospitals of 520 beds each. The hospital equipment is being organized by Colonel Fetherston in Australia, in response to a request from the War Office, and the hospitals will be officered by senior members of the principal hospitals in Australia. The total number of medical officers required is estimated to be about eighty. Mr. Fred D. Bird, surgeon to the Melbourne Hospital, is providing the operating equipment, and the expenses of four nurses for six months. The place or places in which the base hospitals will be established will not be finally settled until the equipment and staff reach this country.

The *Medical Journal of Australia* of October 3rd contains a report of a dinner given at Melbourne on September 19th by the Victorian Branch of the British Medical Association, the Melbourne Medical Association, and the Melbourne Medical Corps to the medical officers attached to the Australian Expeditionary Force. Dr. A. L. Kenny, President of the Branch, was in the chair, and the officers entertained were: Surgeon-General Williams, D.G.M.S., Colonel Ryan, A.D.G.M.S., Lieutenant-Colonel Marshall (N.S.W.), D.A.D.G.M.S., Lieutenant-Colonel Sturdee, Lieutenant-Colonel Sutherland, Major MacKnight Major Hearne, Major F. D. Bird, and Captains Shaw Mathison, Fowler, Black, Honman, Whitford, Hurley, Lind, Quick, Gutteridge, Chambers, Jackson, Nicholas Jolley, Williams, Lewers, and Courtney. In proposing the toast "Our Guests," Dr. Kenny expressed the admiration which all felt for their determination to serve their country and the hope that they would all return unharmed. For the medical man there was no bubble reputation at the cannon's mouth. It was in the long nights and the dreary days with the silent agony or the irrepressible expression of anguish that the surgeon had to do his work coolly and quickly. The cream of the younger members of the profession had joined the forces. Dr. L. J. Balfour, President of the Melbourne Medical Association, and Dr. R. H. Fetherston, Director-General of the A.A.M.C., also spoke. Surgeon General W. D. C. Williams, in reply, said they were going away at the Empire's call and were taking the pick of the profession in the units. There would be over 200 men in the two medical units as well as nearly 3,000 of other ranks, and 100 nursing sisters. The response throughout the Commonwealth had been most gratifying. The Medical Corps was well equipped, so that it could be landed anywhere, and within twenty-four hours or less it could be in active service conditions. The magnitude of the Australian Medical Service would be realized when it was understood what it would supply. Colonel Ryan said he had volunteered because above life and above family ties he placed his duty to his King and country. He knew this would be a fight to a finish, and as to the ultimate result he had no fear. In no army in the world, so far as physique went, could they find a finer body of men than the 6,000 forming part of the Expeditionary Force in camp at Broadmeadows.

MOTOR AMBULANCES.

The members of the medical profession in the county of Essex have subscribed a sum of a little over £420, and have purchased therewith, and presented to the War Office for use of the wounded in France and Belgium, a fully-equipped motor ambulance, providing four stretchers for lying down cases. The subscriptions have been obtained by the various medical officers of health in the county, and a complete list of the donors can be seen at the office of the county medical officer of health. The ambulance will bear a brass plate, on which will be inscribed: "This ambulance was presented to the War Office by the members of the medical profession in Essex, England, November, 1914."

The appeal to the medical practitioners of East Anglia—Norfolk, Suffolk, Cambridge, and the Isle of Ely—issued in October to provide a motor ambulance has met with a generous response. The secretaries, Dr. J. T. C. Nash and Dr. Arthur Greene (4, Theatre Street, Norwich) inform us that the total subscribed to date is £304 5s., and that many donors have promised to increase their contributions if necessary. The subscription list will remain open until the end of this month.

WOMEN ORDERLIES.

During the South African war the women who called themselves nurses without having any claim to the title were the cause of many difficulties. When the present war broke out it was the determination of the British Red Cross Society and the Order of St. John of Jerusalem in England that, so far as they were able to prevent it, there should be no recurrence of the trouble. From the very beginning, however, many women have been applying for work as nurses whose only qualification seemed to be a strenuous desire to "do something" for the wounded soldiers. They are women often of an emotional type, and it is to be feared that already some such people have obtained passports, and have wandered abroad, masquerading as nurses, and in all probability wearing the Red Cross badge. It has been dangerously easy up to the present for any woman to go out as a free lance in this way, but recently the Foreign Office has made some attempt—imperfect though it be—to check such action. In order to find useful work for suitable

women the two Societies have arranged for the establishment of a special class of women to help in hospitals in this country or abroad. They will not be able, by any possibility, to consider themselves as nurses, but it is hoped in this way to provide an outlet for their energies. The women will be selected from the Voluntary Aid Detachments of the two Societies, and they will help in the work of the wards, in the kitchens, and in the store-rooms, their designation being that of "women orderlies." In this way the use of the word "probationer" will be avoided and the untrained woman will have no ground for considering herself a nurse for wounded soldiers. A certain amount of training, however, will be necessary, and it will be required that each applicant should have served for a short time at least in a hospital. Those going abroad must have a working knowledge of French. The women orderlies will be drawn from the two Societies in proportion to the number of women in the Voluntary Aid Detachments, and all applications for work will be submitted to the committee of matrons at St. John's Gate.

The Victoria Cross.

Among the nine officers, non-commissioned officers, and men upon whom the King has bestowed the Victoria Cross for conspicuous bravery whilst serving with the Expeditionary Force is Captain Harry S. Ranken, R.A.M.C. The honour was awarded for his bravery in tending the wounded in the trenches under rifle and shrapnel fire at Hautvesnes on September 19th and on September 20th, and continuing to attend the wounded after his thigh and leg had been shattered. Unfortunately, Captain Ranken has since died of his wounds.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

LIVERPOOL AND DISTRICT.

Physical Standard of Recruits.

It would appear that the latest accession of recruits to His Majesty's Forces in Liverpool is quite satisfactory from the medical standpoint, and comparatively few rejections on that ground have taken place. Earl Derby, who is now quite restored to health, has been most active in encouraging the youth of Liverpool and its environs to come forward for their country.

Annual Medical Service.

The annual medical service was held on St. Luke's day in St. Luke's Church where the Right Reverend Dr. Elliott, Bishop of Gloucester, preached the sermon. The Bishop of Liverpool read the lesson. The attendance of medical men in military uniform and academic costume was very good. The offertory, devoted to the Royal Medical Benevolent Fund, showed an appreciable increase. This was largely due to the Committee in whose hands the arrangements were, having solicited in their notice of the service donations from those medical men who would be unable to be present.

Committee on Venereal Disease.

The special committee formed by the Liverpool Medical Institution about a year ago, to organize an educational campaign against venereal diseases, has issued two pamphlets setting forth the dangers of these diseases. One of these draws the attention of the soldier in plain and forcible language to the risks he runs in exposing himself to infection, and appeals to his common sense and moral courage to avoid them. It is understood that many thousands of these have been circulated among the recruits now undergoing military training. A course of lectures by medical women to members of their own sex has been instituted, and Mrs. Scharlieb, M.D., M.S., recently delivered an inaugural address on the subject at the Medical Institution. A similar course of lectures to men has been held in abeyance owing to the war.

The Medical Institution.

The Medical Institution opened its session on October 8th with an address by the President, Dr. E. W. Hope, on the progress of public health. The number of meetings has been curtailed, as so many medical men, owing to mobilization and extra work entailed upon those engaged in private practice, would not be able to attend. At the first pathological meeting on November 12th a series of interesting *x*-ray photographs taken from wounded soldiers was exhibited. The majority of the wounds were caused by shell fragments and shrapnel bullets, rifle wounds being quite exceptional. Another interesting exhibit was the tongue and a section of the hoof displaying the lesions of foot and mouth disease—stomatitis epizootica.

MANCHESTER AND DISTRICT.

The Midwives Act in Lancashire.

From a report just issued by Dr. Sergeant, M.O.H. for the county of Lancashire, it appears that with a population of 1,748,000, the midwives' register contains the names of 929 midwives; of these 769 are actually practising, while 160 have temporarily ceased to practise, but may begin again at any time. During the year ending September 30th, 1914, there were 2,542 records of cases in which medical aid had been advised by midwives under the rules of the Central Midwives Board. Of these, 759 were for "obstructed labour, uterine inertia, or requiring instrumental assistance," while 352 were cases of ruptured perineum. Comparing the total cases in which medical aid was sent for with the total of similar cases in the city of Manchester, as recorded in the British Medical Journal of November 7th, it would appear that the county midwives are much more sparing in sending for medical aid than the Manchester midwives. Manchester has a population of about 731,000 as compared with the county population of 1,748,000, but in Manchester the midwives summoned medical aid in 2,596 cases, while the county midwives only advised it in 2,542 cases. The proportion of midwives coming under the head of "bona fide," who are on the county register simply because they were already in practice in July, 1901, is extremely high—namely, 536 out of a total of 929, while in Manchester 80 per cent. of the midwives are properly certificated. In the absence of other causes, then, it would appear as if certified midwives, who may be assumed to know their work best and to recognize danger when it exists, are far more ready to summon medical aid than the older class called "bona fide."

During the quarter ending September 30th certified midwives notified 12 cases of puerperal fever, of whom 5 died, while 17 cases, of whom 4 died, were attended and notified by medical practitioners. Arising out of the cases of puerperal fever charges were preferred against several of the midwives of negligence or failure to comply with the requirements. In the same quarter, 93 cases of ophthalmia neonatorum were reported and all those in the practice of midwives were carefully investigated, and here again a number of midwives were charged with neglecting to comply with the rules, the chief offences being the omission to advise medical assistance.

Owing to the high infant mortality in Lancashire, especially in some of the smaller boroughs, an inspector of the Local Government Board has been sent to visit several districts to inquire into the causes not only of infant mortality but of stillbirths, abortions, and miscarriages. A circular containing a number of questions to be answered was sent to 637 of the midwives in actual practice and replies were received from 491. Of these 402 who had attended 16,250 births, 147 abortions and 506 stillbirths during the year 1913, stated that they had no reason to suspect taking of drugs or use of articles to cause abortion by patients they attended. Sixty-six midwives who reported having attended 4,296 births, 66 abortions, and 184 stillbirths, gave their views with respect to attempts made to procure miscarriage, and their reports have been forwarded to the Local Government Board.

The medical officer of health calls attention to what he considers to be a defect in the method of training midwives adopted by the Central Midwives Board, namely, that the Board allows women to sit for their examination who have received the whole of their training under midwives who are not necessarily trained nurses. Dr. Sergeant suggests that candidates should be compelled to take a course of three or four months' training in a hospital or in some other approved institution, and he advises the Local Supervising Authority to address a communication to this effect to the Central Midwives Board.

WALES.

THE MEDICAL SERVICE OF THE WELSH ARMY CORPS.

CONSIDERABLE progress has recently been made in the organization of the Welsh Army Corps. At the last meeting of the executive committee it was decided that recruits should be sent for training to Rhyl, Llandudno, and Colwyn Bay. The responsible duty of raising and organizing the medical units for the corps has been entrusted to Mr. Lynn Thomas, C.B. The formation has been authorized for the 1st Division of three field ambulances and a sanitary company, in addition to the head quarters staff, and, it is to be presumed, battalion medical officers. Each field ambulance will, in compliance with the new regulations, be provided with seven motor and three horsed ambulances. The St. David's Centre of the St. John Ambulance Brigade has undertaken to provide one of the field ambulances. Altogether Mr. Lynn Thomas will be responsible for raising a personnel of about 1,000.

Correspondence.

OPERATIONS OF EXPEDIENCY ON RECRUITS.

SIR,—I venture, with your kind permission, to draw attention to one way in which our general hospitals could render assistance at the present crisis in the vitally important matter of recruiting.

At the Leicester Royal Infirmary we have recently set aside a ward of twelve beds for the radical cure of hernia, varicose veins, varicocele, hammer toe, and other physical disabilities (removable by operation) responsible under present conditions for the rejection of quite a number of keen and otherwise eligible recruits. Such patients only require, individually, a short stay in hospital, and as they have all expressed their intention to reapply for enlistment on recovery, a considerable addition will be made locally to one or other branch of the service. If this were done in a systematic way in the hospitals throughout the country, I think a considerable result would be achieved.

May I also take this opportunity of respectfully suggesting that some definite instruction should be given from head quarters to medical officers examining recruits not to reject on account of varicocele, except in extreme form, otherwise eligible candidates? The different practice among different medical officers in this matter leads at present to inconsistency and individual disappointment, and prevents a considerable number of healthy and active men from entering the army. It seems a pity to disqualify on the score of varicocele a young man leading the active laborious life of a farm labourer, who, until he applies, is unconscious of any disability.—I am, etc.,

C. J. BOND,
Vice-Chairman and Honorary Consulting Surgeon to the Leicester Royal Infirmary.

Leicester, Nov. 15th.

THE TREATMENT OF WOUNDS IN THE PRESENT WAR.

SIR,—A lady of my acquaintance who keeps rather quarrelsome lapdogs heard that the best treatment for a bite was carbolic acid. Unfortunately she was supplied with the pure liquid carbolic acid, and recently, on receiving a small bite on a finger, she dipped it in the liquid and applied a strip of lint. In about an hour increasing pain followed by fainting drew attention to the nature of the treatment, but, in spite of every attention, the result was gangrene and the loss of half of a very useful finger.

In ophthalmic work the great value of pure liquid carbolic acid carefully applied from the point of a match to septic ulcers of the cornea is universally recognized. In my practice it is in almost daily use, and has superseded the electric cautery. Still, I feel constrained to express the hope that some method for dealing with the infecting micro-organisms may be found which is less expensive to the tissues of the wounded soldier than swabbing with pure liquid carbolic acid.—I am, etc.,

A. RUDOLF GALLOWAY, M.B., C.M., M.A.,
Ophthalmic Surgeon, Major 1st Scottish General Hospital.

Aberdeen, Nov. 14th.

SIR,—In regard to the present controversy concerning the merits or otherwise of using pure carbolic acid for the immediate treatment of a wound which one has every reason to suppose has become infected with pathogenic bacteria, may I relate the following?

When in practice at Bloxham, about ten years ago, I was called to attend a farmer in a neighbouring village, and on arriving there two hours after the summons I found that he had been kicked by one of the farm horses over the front of the knee-joint, and had sustained a severe compound comminuted fracture of the patella; the wound was badly lacerated, and the condition looked most grave, inasmuch as a great deal of the mud and urine-soaked litter from the farm horse's shoe had been carried into the joint. I decided at once to persuade this patient to be taken into the Radcliffe Infirmary, Oxford, twenty miles distant. I proceeded to clean the wound by first removing with forceps all foreign matter that could be so dealt with, then douched thoroughly with water from a kettle which had been placed outside to cool, and finally I spent a long time in thoroughly going over every part of the wound, including the fragments of bone, with pure carbolic acid. The knee was covered with a large dressing of sal-alembroth gauze and wool and a long back splint applied. The patient was removed in an ambulance to Oxford the following afternoon, and was operated upon on the day after his arrival. The result was that he made a perfect recovery. No sign of sepsis occurred; the wound healed by primary union, and a very useful joint was preserved for him. The surgeon who so skilfully dealt with this case, Mr. Whitelocke, I believe, wrote to me to say that for this joint and wound to have remained aseptic was, in his opinion, a most astonishing circumstance.

All through my medical practice, whenever I have received the slightest abrasion of the skin, I have immediately applied pure phenol, with excellent results.—I am, etc.,

GERALD SCHOFIELD.

Chesham Bois, Nov. 15th.

SIR,—It seems to me futile to revive the controversy as to the value of antiseptic or so-called aseptic surgery in connexion with such wounds as are inflicted in the present war. I suppose every surgeon would agree that in lacerated wounds made by bullets and fragments of shells (I am not now writing of wounds made by small calibre bullets) it is essential that organisms gaining access to the tissues must be as speedily as possible destroyed, and it is obvious that the only way to do this in the living tissues is by a chemical antiseptic. As it is likely that at the time they are inflicted they may be infected not only with the ordinary pyogenic organisms, but with such deadly ones as those of tetanus and gas gangrene (probably from earth contamination), we must apply to the wound such an antiseptic as is likely to kill all these organisms, and by choice the one least liable to damage the tissues at the same time. If no antiseptic less destructive of tissue than pure carbolic acid would do this, then it seems to me we should have to use that. But, fortunately, we may have confidence in less destructive agents, but I would venture to suggest that it is not enough just to brush or swab them over the wound, even if this is done on more than one occasion. If the wound is merely swabbed over with a solution of iodine, the serous exudation from the wound may soon wash it away. We all know how the iodine on the skin is washed away by the blood in an operation. I should like to suggest that one very thorough attempt should be made to destroy the organisms in the wound as soon as ever it is possible to do so, which I suppose would be at the time the wounded soldier is removed from the trenches to some temporary ambulance station just beyond the fighting line, and that in this attempt an antiseptic solution should not simply be applied to the wound and the wound then dressed, but that the wound should first be swabbed over with a solution of novocain, and that when this has had time to act all tissues so severely damaged as to be likely to slough (if they could be spared) should be cut away, and then the wound packed with gauze soaked in an antiseptic solution, and that the gauze should be left in the wound for at least ten minutes. I should myself prefer the 1 in 1,000 mercury perchloride in 70 per cent. alcohol which Mr. Leedham-Green has found from bacteriological experiment such a powerful

antiseptic, but no doubt a fairly strong spirit solution of iodine would be a good antiseptic to employ. After the gauze was removed I should swab or irrigate out the wound with saline solution, so that all irritating antiseptic solution was removed. In the case of a wound complicated by fracture, or opening a large joint, or forming a long and tortuous track, it might not be possible to pack the whole wound. Then we should very thoroughly syringe out with the antiseptic solution the part of the wound we could not pack. A gum-elastic catheter is most useful for this purpose. But in some cases it may be necessary to enlarge the wound to thoroughly clean it and apply an antiseptic solution. After the novocain had acted, before the gauze was packed into the wound, the surrounding skin should be cleansed (with ether, and then soap and water, and dried with spirit), and the antiseptic solution on gauze also applied to it while the gauze packing was in the wound. It seems to me that an antiseptic dressing should be used rather than one free from chemical antiseptic. I should myself prefer double cyanide gauze (and, if possible, dry sterilized), for the oozing from the wound may be considerable, and it may not be possible to change the dressing for some time. A considerable thickness of antiseptic dressing would therefore also be indicated.

It may be objected that this procedure would take too long to be carried out at the front, but it would not really take very long if, as would probably happen, several cases had to be dealt with at the same time, for while the novocain was acting in one case, another to whose wound novocain had been previously applied could be cleaned up and his wound packed with gauze, and while his antiseptic was acting another case could be dealt with, so that there would be no waste of time.

The pad of gauze carried by the soldier as a dressing to be applied at the time of injury is, of course, of value, inasmuch as it forms some protection to the wound against the entrance of organisms not already introduced at the time of the infliction of the wound, but water carrying the organisms of tetanus and gas gangrene from the soil, to say nothing of the ordinary pyogenic organisms, can soon penetrate it; and by the time the gauze dressing is applied the wound may be already seriously infected by them—that is, they may have been carried in at the moment the wound was inflicted.

As the length of time the wounded soldier may have to lie in the trench or on the battlefield before the wound can be dealt with by the surgeon is occasionally (perhaps often) considerable, could not he carry a small bottle of antiseptic solution (and also, if possible, one of novocain) and apply it to the wound himself, and then put on the gauze pad? A piece of gauze might be included in the dressing he carries with him, with which he could swab the antiseptic solution over the wound. Even if it did not kill the organisms in the wound, it might at least inhibit their penetration into the tissues. The solution of novocain might be a great boon to him, apart from his attempt to sterilize his wound, and I would venture to suggest that some material such as jaconet or battiste should form part of the immediate dressing, so as to protect the wound from infected fluid which would easily penetrate the gauze alone. The muddy water of the trenches could possibly be excluded from the wound in this way.

And if, on account of the anaërobic character of the more virulent organism, it is an advantage to have the wound uncovered, why, after they have been thoroughly treated with an antiseptic in the way I suggest, should they not be surrounded by a rim of antiseptic dressing to catch the discharge, and have placed over them a light wire frame, like the frame of a mask used for the administration of an anaesthetic? Such a frame could be securely fixed by rubber strapping, and might be just lightly covered with gauze or wool so as to allow access of air to the wound.—I am, etc.,

Clifton, Nov. 16th. CHARLES A. MORTON.

SIR,—Colonel Makins's letter on the way in which wounds are being treated in the present campaign is very comfortable reading for those who have relatives at the front. It shows, at any rate, that Sir Rickman Godlee's dangerous leaflet, if cancelled at once, may not do much harm.

Dr. Cooper's good-natured banter is somewhat beside the mark. My apprenticeship on the subject of wound treatment was served in Mr. Christopher Heath's wards, where I had the opportunity of studying all forms of wound infection from acute septicaemia, fatal in three days, to even hospital gangrene (probably the last cases seen in a London hospital).

Every case, in my opinion, must be treated on its merits and not by any routine; I agree with Dr. Stephens that petrol is the best cleanser we possess, and alcohol perhaps comes next. My practice, especially in hospital work, is as often antiseptic as aseptic, but I must beg Dr. Cooper to realize that, having had thirty years' experience of the properties, chemical and clinical, of pure carbolic acid, I am, at any rate, not an escharotic surgeon.—I am, etc.,

London, W., Nov. 17th. VICTOR HORSLEY.

SIR,—May I be allowed space to beg that no one in his zeal for adopting "new" treatment will add further to the suffering of the wounded by the use of petrol, as advocated by Dr. G. A. Stephens in your issue of November 14th?

It was my lot recently to have to take over charge of a lady in a private nursing home, from whom a pelvic tumour had been removed some three and a half weeks previously. Suppuration had occurred, and the wound cavity had been freely irrigated with petrol until within two or three days of my taking over the case, when, in response to the entreaties of the patient, it was discontinued, and lysol solution substituted. The pain produced by the petrol irrigation was described as agonizing and lasting for twenty-five minutes. The local condition of the patient I can only describe as parlous — a large gaping sloughing central wound communicating with the depths of the pelvis, and suppuration extending in the fascial planes into the flanks, and calling as loudly for free incision as the worst case of extravasation of urine. I shall not readily forget the terror depicted in the poor woman's face lest petrol should again be used.

Huge sloughs shortly came away from three and four inch incisions in the loins and inguinal regions. In short, the petrol appeared to have been as successful in destroying tissue as it was in producing pain. I submit that its use in this way is utterly unjustifiable.—I am, etc,

W. F. BROOK, Major, R.A.M.C.(T.),

November 17th. 3rd Western General Hospital, Cardiff.

SIR,—The comments on my letter on Antisepsis and Asepsis in War, which you were good enough to publish on November 7th, are on the whole gratifying. I wish all your readers could have heard Sir Watson Cheyne's admirable address on the same subject at the Medical Society on November 16th. It is to be hoped that they will read it with the attention which it deserves.

May I be allowed to add a postscript? It is suggested that I implied that Lister continued to use undiluted carbolic acid for the primary disinfection of compound fractures throughout his practice. I did nothing of the sort. Lister ceased to do so in 1868, using first carbolized oil, 1 part to 4, and then a 1 to 20 watery solution, as is perfectly well known.

What I said and now repeat is that in Lister's early compound fracture cases the wounds were treated rather freely with undiluted carbolic acid without any evil result following. It may be added that in some of these the wounds were very severe.

The fact is that undiluted carbolic acid, if used with circumspection, does not produce extensive sloughing. The slough is superficial, and, from the fact of its being impregnated with carbolic acid, is an unsuitable nidus for the growth of micro-organisms.

This limited sloughing is not to be compared in importance with the extensive necrosis caused by the growth of septic organisms. That is the really terrible thing to occur in a wound; it is not a mere temporary process, but extends far and wide, first amongst the damaged and afterwards amongst the healthy tissues. If the spore-bearing organisms of tetanus and spreading gangrene have not been destroyed, the septic sloughs and discharges afford an excellent medium for their development. How is it proposed to deal with them?

I speak from ample experience of the action of undiluted carbolic acid. I have, for example, used it very often for the disinfection of tuberculous wounds when it has been

impossible to remove the whole focus of the disease, and also after scraping away the sloughs of carbuncles; and I have never seen it produce extensive sloughing. Moreover, as it is a local anaesthetic, its application is far from being so dreadful as some would have us believe.

It is melancholy to hear from many who have been at the front that almost all wounds except bullet wounds become septic. Two questions naturally arise: First, have the present attempts at wound disinfection any reasonable chance of success? Secondly, if they are really conducted on sound principles, must we fold our hands and sadly confess that it is hopeless to try to adapt the antiseptic principle to military practice?

I cannot believe that the answer to the second question is in the affirmative.—I am, etc.,

London, Nov. 17th. RICKMAN J. GODLEE.

AMATEUR WAR NURSES.

SIR,—How is it that trained women—highly trained nurses—are unable to get work at present from the British Red Cross Society, and other women (titled it may be) are allowed to play the part of trained nurses at the expense of our brave soldiers' lives and pain?

Now, Territorial nurses are in nearly all cases selected from the best training schools, being subjected on joining to a further medical examination as to fitness; and by the best training schools I mean those hospitals with over 100 beds where a course of lectures is delivered by the matron and the medical and surgical staff, and in which hospital certificates are issued on the completion of training to those worthy enough showing the work accomplished, the conduct manifested, and the proficiency exhibited in actual examination.

At present, with the war scare, women of any age, healthy or otherwise, are encouraged by press puffing to take a course of ambulance lectures, obtain by paltry examination an ambulance "certificate," don a cap and apron (though they have never seen a patient), parade about the streets (nearly always in indoor uniform), and mystify the general public more than ever as to the true meaning of a trained nurse. In some cases they are even permitted to waste their own time and that of some hospital staff by doing a month's so-called training. These sentimental women, so misguided, actually imagine, in most cases, that they are all prepared and fully ready for the front.

Now what must women who have given years of their lives to hospital work think when they see a uniform (theirs alone by right, and I have no doubt would be so if registration of nurses were only an accomplished fact) put to such a scandalous use? And we have the definite fact that many hundreds of trained women are waiting for work!—I am, etc.,

Whitley Bay, Nov. 10th. N. A. EDDLESTONE, M.D.

NUTRITION AND MEAT EXTRACTS.

SIR,—I have no wish to find fault with Mr. Sohn's reply to my letter which appeared in the JOURNAL on October 24th, though it does not accurately represent the points raised by his own writing on the above subject, or meet my criticism of his views.

My object in writing now is to express a hope that Mr. Sohn may see his way to adopt my suggestion and join the rank of experimental investigators in the field of nutrition. It is a large field where much awaits research and where every assistance would be welcomed. It is also, I think, "up to him" to do so, because a knowledge of the chemistry of foods, though highly essential, is not sufficient to justify a claim to be a reliable authority on the subject of nutrition. He would, moreover, be in a position to test his theories experimentally.

It would be a source of gratification to me and a useful outcome of our correspondence if it ended in this result. Thanking you for your courtesy in publishing my letters, I am, etc.,

Dublin, Nov. 14th. W. H. THOMPSON.

MEDICAL AUTOGRAPHS.

SIR,—The Reading Pathological Society has during many years collected in an album the autographs of distinguished medical practitioners, especially of such as have contributed to the progress of medicine, and are therefore "on fame's eternall bead-roll worthie to be fyled."

Such autographs, especially when accompanied by portraits, form a delightful addition to our knowledge of those personalities who form the *decus et desiderium medicinae*, and possess no small biographical and historical value. Medical societies will find in the formation of such an album a means of cementing the friendships of the living and of perpetuating the memory of those who have passed beyond the veil.

Our collection already contains many interesting specimens of professional autographs, but further contributions (whether of British, American, or foreign origin) will be warmly welcomed.—I am, etc.,

Reading, Nov. 7th. JAMIESON B. HURRY.

Universities and Colleges.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN Ordinary Council was held on November 12th, Sir W. Watson Cheyne, President, in the chair.

The late Mr. C. B. Lockwood.

The Secretary reported the death on November 8th, at the age of 58, of Mr. C. B. Lockwood, member of Council, and the following vote of condolence was passed:

That the Council do hereby express their deep regret at the death of their colleague, Mr. Charles Barrett Lockwood, whom they highly esteemed as an accomplished and skilful surgeon, and for whom they entertained the warmest feelings of personal friendship. That the Council also desire to express their appreciation of Mr. Lockwood's services to the College as a member of the Council during the last six years, and their very sincere sympathy with Mrs. Lockwood and her children in their bereavement.

Issue of Diplomas.

Diplomas of Membership were granted to sixty-seven candidates found qualified at the recent examinations.

Mr. William Pearson.

An honorarium and a pension were granted to Mr. William Pearson upon his retirement as Prosector to the College.

The Bradshaw Lecture.

This lecture will be given by Sir Frederic Eve on Tuesday, December 15th, at 5 p.m., the subject being "Pancreatitis."

College Insurance.

The President reported that steps had been taken to insure the College.

Students of Colonial, Indian, and Foreign Universities.

The following resolution was adopted—namely, Clause 4 in the Regulations read as follows:

Members of Colonial, Indian, or foreign universities who shall have passed such an examination or examinations at their universities for the degree of Doctor or Bachelor of Medicine or Surgery as shall comprise the subjects of the First and Second Examinations of the Examining Board in England, and who shall have completed the curriculum of medical study required by the Regulations of the Board, will, two years after having passed such examinations, be eligible for admission to the Third or Final Examination of the Board; any candidates so admitted to examination will be required to pay a fee of twenty guineas; and any such candidates who shall have passed the Third or Final Examination shall, on the further payment of not less than twenty guineas, and subject to the by-laws of each college, be entitled to receive the Licence of the Royal College of Physicians of London and the Diploma of Member of the Royal College of Surgeons of England.

CONJOINT BOARD IN ENGLAND.

THE diplomas of L.R.C.P. and M.R.C.S. have been conferred upon the following candidates who were successful at the final examination in Medicine, Surgery, and Midwifery:

Ahmed Abdel-Al, B. P. Allinson, L. M. Banerji, G. A. Batchelor, W. A. H. N. Bell, W. F. Bensted-Smith, G. A. G. Bonser, W. E. H. Bull, P. H. Burton, S. N. Cohen, G. Cranstoun, H. A. Crouch, J. D. L. Currie, Delphine Gertrude D'Abreu, J. E. Davies, J. L. Davies, J. R. Davies, F. H. Dodd, H. A. Fawcett, H. L. Garson, J. A. Gregory, D. W. Griffith, S. S. B. Harrison, W. C. Hartgill, Mary Isabel Hemingway, A. G. Holman, J. C. Jones, T. R. Kenworthy, G. W. King, L. G. Le Blanc, Helena Rosa Lowenfeld, H. W. Maltby, P. M. Masina, G. W. Maw, P. U. Mawer, J. A. Montgomery, W. H. Nicholls, A. H. Pemberton, A. C. Perry, R. Don Hugo Philip, H. R. Pollock, J. S. Pooley, R. N. Porritt, T. G. Prestwich, N. Purcell, P. H. Rawson, G. S. Robinson, C. W. Roe, W. A. Rogerson, W. H. C. Romanis, P. Sai, Mary Schofield, D. C. Scott, E. W. Scripture, J. H. Sewart, P. de S. Smith, H. N. Stafford, J. F. H. Stallman, R. P. A. Starkie, H. Thomas, J. O. Thomas, W. G. L. Wambeek, J. R. N. Warburton, W. Watkins, T. B. Welch, D. H. D. Wooderson, W. A. Young.

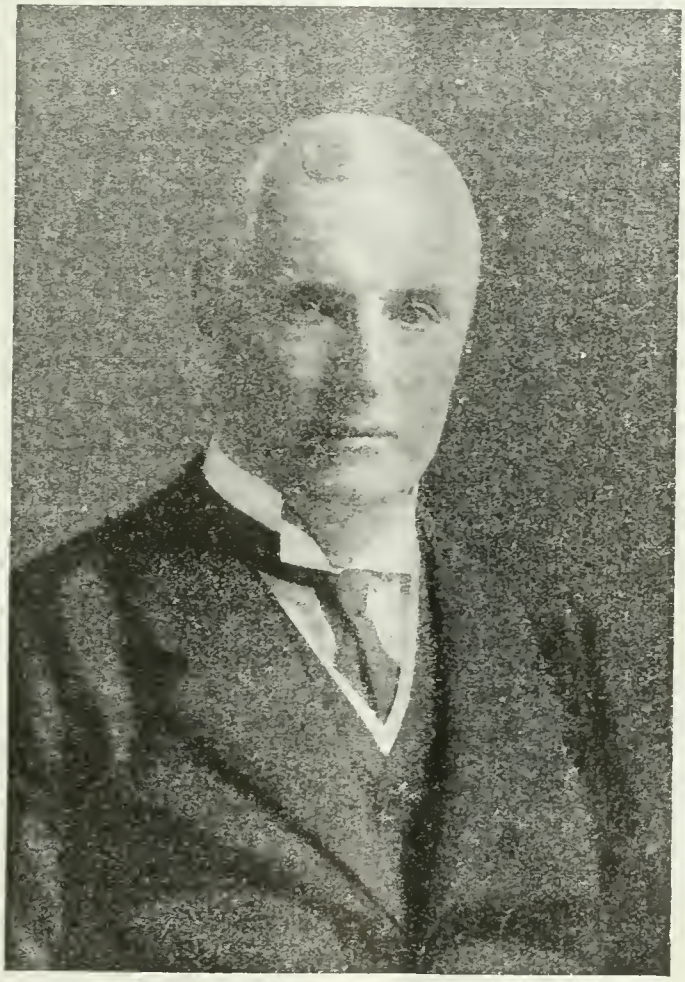
LIEUTENANT ARTHUR KEITH ARMSTRONG, R.A.M.C., who died of wounds on September 15th, left estate valued at £767.

Obituary.

CHARLES BARRETT LOCKWOOD, F.R.C.S.,

CONSULTING SURGEON, ST. BARTHOLOMEW'S HOSPITAL.

The unexpected and early death of a great surgeon must invariably come as a severe blow to those who have worked with him, more especially when the attendant circumstances are of so tragical a nature, as in this case. Here is a surgeon who had spent many years of his life in combating sepsis, who had devoted his talents to the elucidation of the precepts of aseptic surgery, and who had taught on this subject to innumerable sons of St. Bartholomew's and to the whole world; here is such a man finally falling a victim to those very organisms against whose action he had fought so strenuous and so successful a fight. And yet the manner of his death was glorious, typical of the way in which he never spared himself when the life of his patient was at stake. Early in October he was operating on a lady for appendicular peritonitis, a disease on which Lockwood had written so insistently and so thoroughly. The condition of the patient was grave and great speed of execution was demanded, and, in consequence, he pricked his finger when inserting almost the last stitch. He was taken ill the same night and died five weeks later from septicaemia.



Photograph by] CHARLES BARRETT LOCKWOOD. *[Elliott and Fry, Ltd.*

Mr. Lockwood was born at Stockton-on-Tees in 1858, entering St. Bartholomew's when 17 years of age. After taking the diploma of M.R.C.S.Eng. in 1878, he entered the anatomical department, where he soon made a reputation both by his researches on anatomy and by his general teaching capabilities. At this period, though Lockwood was always rather reticent on the subject, it would appear that his life was by no means an easy one. One of his oldest friends writes, "I have seen his career from the struggling demonstrator of anatomy days to the zenith of his fame," and from this, and private information, it was obvious that the fight for supremacy was very strenuous. In this Lockwood was not alone. Sir Henry Butlin, one of his greatest friends, passed through a similar ordeal. Both emerged from the fight with conspicuous success.

When I entered St. Bartholomew's in 1894, Willett, Butlin, and Lockwood were the three surgeons who impressed me most—Willett by reason of his ruggedness, strength of character, and honesty of purpose; Butlin on account of his teaching and wonderful personality; Lockwood through his brilliant wit and striking surgical technique. How little I thought that I should subsequently act as his assistant surgeon for many years and attend him on his deathbed!

In the wards of the hospital he was beloved by his house-surgeons and by his dressers. The patients seemed instinctively to know that they had a great man to deal with. His powers of observation were so keen that no malingerer ever escaped undetected. No point in the history of the case was considered too trivial, and no clinical fact was eliminated except after the most scrupulous scientific and pathological investigation.

During the time that he occupied the post of surgeon to the hospital, 1903–12, three assistant surgeons served under him, each of whom considered that no task was too great if by such undertaking they could assist the man for whom they were so ready to work.

Mr. Lockwood was never a society man. He always expressed himself in few words, concise and dogmatic. He loved nothing better in the evenings, after the day's work was done, than that one of his colleagues or friends should drop in for a chat on surgery or fishing. When visited unexpectedly he was always to be found at work, engaged at his correspondence, writing up his cases—every case that he operated on, whether in hospital or in private, whether serious or trivial, was fully noted. Then, again, he was a great author, his main works on *Aseptic Surgery*, *Hernia and Varicocele*, *Appendicitis*, *Carcinoma of the Breast*, etc., being accepted as standard works throughout the surgical world. During the last few weeks of his life he was fully occupied in working up the surgery of *Movable Kidney*, delighted at being engaged in some new methods of treatment. He was always enthusiastic on his subject, and always dogmatic, totally regardless of opposition, confident in his theories and practice. Of his writings, however, I have always thought that his *Clinical Lectures* were most typical of the man—examples of his marvellous powers of observation and attention to clinical details. He often used to tell me that he rather dreaded giving a clinical lecture. He was more nervous when talking to the students than when carrying out the most serious surgical operation.

There is, however, no character in the world that is perfect, and it cannot be denied that his house-surgeons and dressers occasionally experienced difficult afternoons. He suffered from neuritis, and certain exacerbations of this trouble led to some irritability of temper. At such periods his wit, usually humorous, became caustic. The nursing staff also suffered on these occasions, but he has often said to me, "Yes, I know they hate me, but they always come to me when they want advice and treatment." No one in this world could hate him in reality. Such sentiments were impossible, but he was sometimes feared by those who did not know him and who did not fully appreciate the real greatness of his kind heart. His private patients all adored him, full as they were of admiration for his beautiful and powerful features, his great surgical attainments and scrupulous attention to detail. To those who knew him well he was always most loveable, though such a word barely suffices to express one's real sentiments; he was too great a man and too notable a character—veneration more accurately defines one's feelings.

All possible cynical traits, however, were abolished after his marriage seven years ago, and he had three children,

whom he adored. He remained as keen on his work, as unsparing of himself, and as great a teacher. He was more than ever beloved by those who worked under him. The strain of hospital routine began to have some effect upon him, and he retired from active hospital practice in 1912. He meditated leading a quieter life, took a house at Instow, Devon, and there spent as much time as his private practice allowed.

His five weeks of illness were typical of the man. No one knew better than himself the risks that he ran. Those who attended to him were daily asked such questions as demanded a direct answer, and yet which were most difficult to avoid—How many culture tubes had grown, after what duration? What was the blood count, how much albumin in the urine, pulse-rate, condition of lungs, etc.? Now and again there was a day of great irritability, invariably followed by, and more than compensated for, by days of such sweetness of temperament as melted all hearts. After his last operation he knew that the fight was over. He turned his face to the wall and died bravely. L. B. R.

Mr. Lockwood became a Fellow of the Royal College of Surgeons in 1881. He was appointed surgeon to the Great Northern Central Hospital in 1882. In 1892 he was elected assistant-surgeon to St. Bartholomew's Hospital, became full surgeon in 1903, and on his retirement in 1912 was appointed consulting-surgeon. He was Hunterian Professor of the Royal College of Surgeons of England in 1895, and was elected a member of the Council of the College in 1908. He was a member of the British Medical Association, and was secretary of the Section of Anatomy and Physiology of the Annual Meeting in 1888, when it met in Glasgow, and of the Section of Anatomy and Histology when the Association held its meeting in London in 1895. He was a Fellow of the Royal Society of Medicine, of the Medical Society of London, of the Harveian Society of London, and of the Anatomical Society, and had been President of the three last mentioned. The Council of the Royal College of Surgeons, at its meeting on November 12th, adopted a resolution of condolence with Mrs. Lockwood, which will be found elsewhere in this issue; and Sir John Bland-Sutton, in taking the chair at the meeting of the Medical Society of London on November 16th, paid the following tribute to the memory of one of his predecessors in the chair:

"With profound regret we heard of the death of Mr. C. B. Lockwood last week, and the manner of it. Mr. Lockwood served the Society usefully and well in several capacities—as councillor, then zealously as a secretary, Lettsomian lecturer, and finally as an able and untiring President. In a prophetic way he selected as the subject of his Presidential Address in 1908 *The Strain and Stress of Modern Surgery;* he specially referred to the strain entailed on surgeons by modern operations and the risks of infection to which they are inevitably exposed. It is unusually pathetic that Mr. Lockwood lost his life from a wound incurred in the course of an operation for septic peritonitis, as sepsis and wound infection were subjects he had so persistently studied. The Society has lost a devoted Fellow and many of us a charming, talented and warmhearted friend."

A FORMER COLLEAGUE writes:

For seventeen years—1882 to 1899—Lockwood was attached to the Great Northern Hospital. He joined the staff when the institution was struggling for existence in the Caledonian Road, and he left it when its present state of completion at Holloway had been fully attained. When the move to Holloway was made in 1888, a formidable opposition was raised on the part of the local practitioners of the district, who were alarmed at the establishment of a large out-patient department in their midst; but the movement gradually subsided, owing in large measure to the tact and good temper which Lockwood displayed in dealing with the more turbulent spirits. Not only was opposition stilled, but the local profession was ultimately brought by him into friendly co-operation with the hospital by the establishment of the North London Medical and Chirurgical Society. For many years Lockwood worked quietly in the small hospital museum, which was fitted up as a laboratory for him, at the then unsettled question of surgical cleanliness of the skin, and the validity of the conclusions at which he arrived have been universally recognized. To the thoroughness of his surgical work, communicating itself to all who worked with him, a host of colleagues, resident officers, and nurses can bear witness; his published works speak for themselves. Only those who knew him intimately could appreciate to the full his kindly and sympathetic nature, masked, as it sometimes was in early days, by an assumed brusqueness of manner. His memory will always remain fresh in the hearts of those who have been privileged to enjoy his closer friendship.

Dr. CHRISTOPHER ADDISON, M.P., writes:

Mr. Lockwood is dead, and I am grateful to be allowed, as a former pupil, to say a word in his honour. His memory will live, not so much in the course and incidents of his career as in the minds of those whom he taught, and in the abiding influence of his example. It is rare to find a man whose theory and practice went so clearly and consistently together as did his. He did not take things for granted, for, although he respected tradition and authority, he was not led by them. He investigated facts for himself, and applied his findings in the practice of surgery logically and without misgiving. He was singularly accurate and painstaking in his observations, and very faithful to the truth as he found it, whether it accorded well or ill with his previous experiences and impressions. His work on hernia is perhaps a classical example of careful and precise observation, and of clear statement of the principles of practice to which they led, but it was probably in his work on aseptic surgery that his character and high qualities were best revealed. With patience and with infinite labour he gradually built up a system of skilled and exact art based on principles truly scientific and carefully acquired. For all his scrupulous care in the examination of essential detail, he always had clearly before him that wider view by which he kept things in their place, recognizing their true proportion and knowing what was immaterial and what was not. In his life and later work all who knew him well could recognize the influence of those earlier and original studies of anatomy by which his reputation was first acquired. It cannot be said that Mr. Lockwood endured fools gladly, for his mind had a wide scope and he was impatient of trivialities. But those who were permitted to enjoy the priceless privilege of his friendship knew well how affectionate and generous his nature was. He showed men how to help themselves and stimulated them to do it. He drew out those who made their best endeavours, pointed out the way, and so gave them an education of the best and most enduring kind. It is a joy to render homage to such a master—a bright example of the best in British surgery, and one whose influence on the lives of those he taught is growing always and reaching out to others, bringing thereby to him that ceaseless and unconscious tribute which is the lasting treasure of greatness.

EUSTACE SMITH, M.D., F.R.C.P.,

SENIOR PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL.

THE announcement that Dr. Eustace Smith died on November 14th will cause very widespread and very sincere regret.

He was born in London on October 24th, 1835, the third son of the Rev. John Henry Smith, vicar of Milverton, Warwickshire. One of his brothers was the late Mr. G. Theyre Smith, the dramatic author. Eustace Smith was educated at Leamington College and at University College, London. He was a brilliant student, and after becoming M.R.C.S.Eng. in 1858 he proceeded to the Fellowship in 1860. He graduated M.B.Lond. in the same year, and M.D. in 1865. He became F.R.C.P. in 1874, and served on the council of the college from 1896 to 1898.

Early in his career he was, through the introduction of the late Sir William Jenner, appointed physician to the Duke of Brabant, afterwards Leopold II, King of the Belgians, and travelled with him in the East, visiting India, Ceylon, and China. King Leopold, whose physician he remained until that monarch's death, appointed him a Chevalier of the Order of Leopold.

The body was cremated on November 18th, and the religious ceremony was attended, in addition to members of the family, by Sir H. Bryan Donkin, Drs. Morley

Fletcher, Graham Little, Arnold Chaplin, A. M. Gossage, and R. Warren, members of the visiting staff of the Shadwell Hospital; Dr. Scott Battams, and the matron, Miss Row.

Sir H. BRYAN DONKIN writes:

I send these few words of tribute to the memory of Dr. Eustace Smith with a vivid retrospect of an intimate acquaintance with him during the past forty-three years, beginning when he was assistant physician to the Victoria Park Chest Hospital and I was clinical assistant there, and continued through nearly twenty-five years of singularly pleasant colleagueship on the staff of the East London Hospital for Children until his death. I think that he will be more widely and sensibly missed by all who knew him well—friends, colleagues, and patients alike—than most men of our profession who die in their eightieth year. For he was active to the last, visiting the Hospital for Children with the same regularity as ever, and showing but little abatement of the sprightliness of mind and body, or of the keen interest in his work for which he was so noted.

As a colleague he was genuinely liked and equally respected. Throughout his tenure of the office of senior physician at the Hospital for Children, which was prolonged until the end by the repeated request of those with whom he worked, his tact, good sense, and courtesy contributed very largely to that high degree of harmony which has always, and somewhat exceptionally, marked the relations of the members of the medical staff to one another, and of the staff to the board of management. A former colleague of his at the Victoria Park Hospital says that Eustace Smith commanded respect from all who knew him there, and that, just as at the Children's Hospital, both the medical and nursing staffs regarded him as their unchallenged chief, according to him, by consent, a position that he by no means claimed himself. He adds: "One of Eustace Smith's finest qualities was his steadfast friendship—once a friend always a friend—a man had to do something base to forfeit it."

As a practising physician Eustace Smith was a very successful man, and his success was well deserved. After trying general practice for a short time he was recommended by Sir William Jenner as travelling physician to Leopold II, King of the Belgians, and his tour round the world under such conditions enlarged his knowledge, and doubtless gave him the starting-point he desired. His personal qualities contributed greatly to his popularity and to the confidence with which he inspired both his patients and the many medical men who called him in consultation. But, besides this, he was an excellent example of the clinical physician, one of what may now be called the old school. A keen observer of symptoms and their significance, rather than a deeper searcher-out of their remoter causes, he had great belief in pharmacological treatment, and prescribed medicines with the firm trust that they would produce the desired effect. But he was never given to experimenting with drugs as to the effects of which he had not previously informed himself by study. He was a very good observer, especially of the signs and symptoms of disease of the thoracic organs, and was a first-rate stethoscopist; but from his practical insight and knowledge of human nature generally he was often able to learn more from looking carefully at a patient than a less quick-witted man from a prolonged examination. He often said, on being asked why he gave such and such an opinion, "I don't know; but I have seen such things before, and I feel sure it is so." It may perhaps be said that his practice was based on a thoughtful empiricism rather than on reasoned knowledge.

What is known as the "artistic temperament" was strongly marked in Eustace Smith. His annual holidays were usually spent in sketching in water colours; and his work was recognized as of high order. He had also a fine literary taste; and any works of fiction recommended by him were sure to be more than readable. He was widely read in both English and French prose and poetry, and had a specially intimate knowledge of the Elizabethan dramatists. His own style of writing was very easy and lucid; and, although not marked by any special distinction, was far above the average shown in the medical and surgical writings of the present day. Both from their matter and manner his *Treatise on Diseases of Children* and his *Wasting Diseases of Children* gained him a deserved fame which will surely outlive him.

Dr. ALFRED M. GOSSAGE writes:

Nowhere will the death of Dr. Eustace Smith be more deeply regretted than in the Children's Hospital, Shadwell. He was connected with other institutions, but the children took up more of his time and thoughts, and, I am sure, excited more of his interest. He joined the staff soon after the foundation of the hospital, and for about half a century was the dominant figure in its working. The reputation he achieved outside, and the example he set within its walls, gradually raised it from very small beginnings to an important centre of paediatric study. While his books and other writings have made his name known all over the world, his colleagues and his house-physicians were the only people who really knew how great a clinician he was. When I joined the staff nearly twenty years ago he was already of an age when most men are preparing to retire from hospital practice, and yet only the other day he was still doing his work in the wards. To us his most striking quality was youthfulness. He looked twenty years younger than his real age, his manner was alert, and he worked with all vigour and enthusiasm of youth. He showed the keenest appreciation of all recent medical advance, and readily availed himself of the assistance afforded to diagnosis by laboratory research, though he deplored the tendency displayed by the younger generation to rely too much on the laboratory to the detriment of the training of their eyes, ears, and hands. It was in physical examination that he excelled, and it was remarkable how his senses never failed him, for during all the time I have known him his hearing remained as acute and his fingers as deft as they can ever have been. He was always ready to discuss diagnosis and treatment, and most of his younger colleagues can recall many a pleasant dispute over cases in the wards, or fertile hints on treatment, illustrated by apposite tales from consultant practice, with which the journey back from the hospital was wont to be beguiled. He made an ideal chairman of the medical committee, and his influence had much to do with the fact that the staff always dwelt together in amity, and that the relations with the lay committee were always cordial.

During the past two years my relations with him were still more intimate as we had worked together for the International Medical Congress and the result was a great increase in my admiration and affection. He made an excellent president and much of the success of the section for diseases of children was due to his being in the chair.

In conclusion, I would like to emphasize that in spite of there being nearly thirty years between the ages of himself and his next most senior colleague we deplore in his death not only the loss of a revered leader but of a very dear friend, and I am sure that the affection of his colleagues was shared by everyone else connected with the hospital.

Dr. GRAHAM LITTLE writes:

Dr. Eustace Smith's name is imperishably associated with the East London Hospital for Children, Shadwell, of which he became senior physician as long ago as 1874. As now the oldest remaining member of the active staff of that hospital I should like to put on record some of the personal impressions left by nineteen years of close association with him. Although he had joined the staff long before some of its present members were born, he retained to the very last—and I came home with him from the hospital only twelve days before his death—a vigorous open-mindedness which the youngest of us might envy, and which accorded well with his singularly youthful appearance. He was delighted when, as often happened, patients who had consulted him some twenty or thirty years earlier, sought him out, and, when confronted with him, insisted that he must be his own son. "When I was a child," such a patient would say, "I was taken to see your father," and "sometimes," said my old friend, "I do not trouble to disabuse them by telling them that it was myself they had seen." It was our custom since I joined the staff to hold an annual dinner of past and present members, of which I had the organization. He was, of course, the permanent president of these gatherings, and

has not missed one of them in nineteen years. Awaiting the arrival of guests at one of these functions, I was standing with Sir Bryan Donkin at the head of the stairs leading to the reception-room. We saw a tall and agile figure bounding up from the foot of the long ascent, taking three steps at a time. "That is certainly Smith," said Donkin; "no one else is as young as that"—and he was right.

If Heckford originated the East London Hospital for Children, Eustace Smith made and established its present great reputation. He loved it like a father. Joining the staff only two years after its foundation, for forty-three years he gave unstintingly of his time and thought and care. His management of committee meetings, both medical and lay, was delightful. I feel sure that there are many other members of the present staff who like myself have felt so strong an affection for "our senior physician" that we have remained members longer than we should otherwise have done were it not for the love of that commanding personality. He was ever ready to help his younger colleagues, whether it might be to put practice in the way of the struggling junior, to help a man in the most unobtrusive and delicate manner to the coveted F.R.C.P., or to place at his disposal his marvellous store of experience. His spirit permeated the entire institution, and every one who has ever been associated with "Shadwell" in any capacity whatever, loves it with a very special love.

He had a very happy and humorous readiness of repartee. He used to narrate with glee a little incident which happened in his attendance on King Leopold of Belgium, whose physician he was up to the King's death. During one of his visits to England His Majesty complained of insomnia, which Eustace Smith treated perfectly successfully with a nightly dose of 15 grains of sodium bicarbonate. The King returned to his own country, and it was only after some considerable period of time that he again met his English physician. When he did so, something like the following conversation ensued: "Do you know, Dr. Eustace Smith, that I showed the prescription you gave me for sleeplessness to my court physician, and he tells me that you ordered me *common* bicarbonate of soda." "But, if I remember right, your Majesty benefited by my treatment." "Oh, yes, it cured my insomnia, but bicarbonate of soda is such a very commonplace drug. My physician was quite surprised at your ordering it for me." "Ah, your Majesty, you will forgive me for reminding you that Naaman the Syrian also objected to the Jordan as too commonplace a stream for his use until immersion in it cured his leprosy." Surely a knock-out reply!

Eustace Smith was immensely pleased with the well-deserved compliment paid to him in his selection to preside over the children's section at the last International Congress of Medicine. But there is reason to think that the fatigue, and especially the disturbance of his very regular habits, entailed by the exuberant hospitality of that festival, first impaired his marvellous vitality. It is a curious coincidence that another most beloved octogenarian of a similar abundant activity—Lord Roberts—died on the same day and very nearly at the same hour. It is not too much to say that to a very large circle of friends and patients something like the same void is made by the death of "our senior physician" as is felt by the nation at large to result from the loss of the great soldier.

DEPUTY SURGEON GENERAL E. McKELLAR, I.M.S.

DEPUTY SURGEON-GENERAL EDWARD MCKELLAR, J.P., Bengal Medical Service (retired), died at Brighton on October 27th. He was the son of Mr. Dugald McKellar, surgeon, of Battersea, and was born on May 28th, 1827. He was educated at University College, London, and took the diploma of M.R.C.S. in 1849 and the M.D.St. And. in 1870. Entering the Indian Medical Service as assistant surgeon on July 9th, 1851, he became surgeon on December 20th, 1863, and surgeon major on July 9th, 1871, retiring with a step of honorary rank on March 31st, 1877.

He saw much active service, beginning with the second Burmese war of 1852–3, when he served throughout the war with Her Majesty's 30th Foot; he was present at the capture of Martaban, at the operations before Rangoon on April 12th to 14th. He was in medical charge of Major Cotton's force at the capture of Prome in June, 1852, and subsequent operations in its vicinity. He was mentioned in dispatches in the *London Gazette* of August 20th, 1852, and received the medal with clasp. In the Mutiny he served with the Company's third European regiment in actions near Agra on July 5th and October 10th, 1857, in medical charge of Major Montgomerie's force in engagements with rebels near Aligarh on August 24th, with Colonel Seaton's column in the actions of Gangiri and Patiali, and to the end of the campaign with Murray's Jat Horse (14th Bengal Lancers), serving in Colonel Kelly's brigade in Oudh. He was senior medical officer present in the action with the Nana Sahib's troops near Batwa, on the Nipal frontier. He received the Mutiny medal. Ten years later, in 1868, he served with the 10th Bengal Lancers (Hodson's Horse) in Abyssinia, gaining a third medal.

All of his service, with one brief exception, was spent in military employ, and mostly with the cavalry. After the Burmese war he was posted to the Gwalior contingent, with which he remained till 1857, when it mutinied. In the Mutiny he served with the 14th Bengal Lancers. In 1860 he became civil surgeon of Meerut, and in 1861 went on leave to New Zealand. February 9th, 1862, he was posted to the 10th Bengal Lancers. After the Abyssinian war he went to England on long leave. On December 1st, 1872, he was transferred to the 1st Bengal Cavalry (Skinner's Horse), with which he served till his retirement.

DR. JAMES GREGORY MUMFORD, who died on October 18th, was born at Rochester, New York, in 1863 and educated at Harvard where, he graduated in arts in 1885 and in medicine in 1890. He was appointed assistant surgeon to the Out-patient Department of the Massachusetts General Hospital in 1894, becoming visiting surgeon in 1905. In 1896 he became assistant in surgery in the Harvard Medical School, and instructor in 1903. He was a Fellow of the American College of Surgeons and of many other learned bodies. In 1912 he gave up surgery, becoming physician-in-chief of the Clifton Springs Sanitarium, New York. His literary activity was great. He was the author of *Narrative of Medicine in America* (1903); *Surgical Aspects of Digestive Disorders* (1905); and *Practice of Surgery* (1910, second edition 1914). He wrote the introductory historical article in Keen's *System of Surgery*. He also contributed largely to medical journals. Besides these professional works Dr. Mumford was the author of an entertaining volume entitled *A Doctor's Table Talk* which appeared in 1912. In Dr. Mumford the medical profession has lost not only a very able practitioner, but a graceful writer and a most amiable man.

CHARLES GREY WOTHERSPOON, whose death occurred at Musselburgh, Midlothian, on November 4th, at the comparatively early age of 45, received his education at Malvern and at Exeter College, Oxford, where he graduated B.A. in 1891 and M.A. in 1893, showing at the same time capacities which might have won him distinction in any field. He turned to medicine, and took the degrees of M.B., C.M. at the University of Edinburgh in 1899. Thereafter he held the appointment of house-surgeon in the General Hospital, Sunderland; but on the whole his bent was rather away from the practice of the profession of medicine, as was shown by the fact that he accepted a post in South Africa under Nobel's Explosives Company. For reasons of health this work had to be given up, and Dr. Wotherspoon engaged in practice at Birtle, in Manitoba, Canada; but there also the winter strained his already delicate health, and he returned home to this country more or less of an invalid. Complications ensued, which prevented him from resuming practice, and resulted in his death at the early age above named. He was of a kindly and lovable disposition; his friends were few, but devoted, and they and his relatives (among whom is his brother-in-law, Professor Alexis Thomson, of Edinburgh University) mourn his loss. He is survived by his widow.

DR. WILLIAM FENWICK, who died in Rome on October 25th after a short illness, was born at Perth in 1839 and studied medicine at the University of Glasgow, where he

took the degree of M.D. in 1864. He was admitted a Fellow of the Faculty of Physicians and Surgeons of Glasgow in 1872. Of the forty-four years during which he was engaged in active professional work, thirty-three were spent in a large general practice in the south side of Glasgow. In 1897 he left Scotland and settled in Rome, where, although he gave up practice six years ago, he remained to the end of his life. While a student he worked in the old Glasgow Infirmary as dresser under Lister, for whom he retained unbounded love and admiration. At the Lister dinner in London in 1907 he and the late Dr. Ramsay occupied the places of honour on Lister's right and left, being the only survivors of that time who were present. Dr. Fenwick had greatly endeared himself by his kindliness of disposition and genial manner to the British colony in Rome, and he will be much missed on account of the great interest he showed in all matters affecting its welfare, and of the capacity and common sense he always brought to bear on whatever he took in hand. He was a very old member of the British Medical Association. He leaves a widow.

Colonel Harry Strickland McGill, Army Medical Staff (ret.), died on October 20th. He was the only son of the late Captain William Strickland McGill, of the 79th Cameron Highlanders, and was educated in Dublin, where he took the L.R.C.S.I. in 1880, and the L.R.C.P.I. and the L.M. of the Coombe Hospital in 1881. He entered the army as surgeon on July 29th, 1882; became surgeon-major on July 29th, 1894; lieutenant-colonel on July 29th, 1902; was placed on the selected list from September 17th, 1908: and promoted to colonel on June 8th, 1912. He was placed on half-pay on December 4th, 1913, and retired so recently as July 8th last. During his service he devoted much attention to sanitary matters, taking the D.P.H. at Cambridge in 1887, and the diploma in tropical medicine and hygiene there in 1906. He filled the post of Assistant Professor of Pathology in the Army Medical School, Netley, for some time, and was at one time sanitary officer with army head quarters in India. During his last tour of Indian service, from 1906 to 1911, he commanded the station hospitals at Poona and at Secunderabad successively. His war services comprised Burma, 1887–89, medal with clasp; Chin-Lushai expedition on North-East frontier of India, 1889–90, clasp; Burma, 1890–92, clasp; the Isazai campaign on the North-West frontier of India in 1900; and the China war of 1900, medal.

Public Health
AND
POOR LAW MEDICAL SERVICES.

URGENCY ORDERS.

M.—The giving of a medical order is legally at the discretion of the relieving officer, but where "urgency" is alleged he would be unwise to take the responsibility of refusal at any hour of the day or night. Quite recently a circular was issued by the Local Government Board specially enjoining that there should be no delay in granting medical orders in the first instance, so that a relieving officer's statement that "he has no option in these cases" is in the circumstances practically correct. This has always been a grievance to Poor Law medical officers, as many of the cases for which "urgent" orders are issued are found to be trivial. It is, however, held that it is only by general arrangements of this kind that the occasional serious cases can be safeguarded.

Medico-Legal.

ACTION UNDER THE APOTHECARIES' ACT AGAINST A HERBALIST.

An appeal was heard by the Divisional Court of the King's Bench Division on November 2nd from a judgement given by the Deputy County Court Judge of Worcester on May 13th, 1914, in favour of the society against the defendant for having acted and practised as an apothecary in breach of S. 20 of the Apothecaries' Act, 1815. It appeared that the defendant, Burden, kept a herbalist's shop in the city of Worcester. In August, 1913, he was consulted by a Mrs. Rosina Daniels, who was ill. He attended her, stating she was suffering from an internal abscess, prescribed for and gave her medicine, and remained in attendance upon her up to the date of her death on February 6th, 1914. At an inquest subsequently held upon Mrs. Daniels it was shown by the medical evidence that she died of kidney disease. Upon the facts being brought to the notice of the society proceedings were instituted against Burden in the Worcester County Court, and judgement was given for the society for the statutory penalty of £20 and costs. The defendant appealed against this decision. The court, after hearing counsel on both sides, dismissed the appeal with costs, and refused leave to appeal further.

Medical News.

Dr. W. Collingridge, late Medical Officer of Health City and Port of London, was on November 17th called to the Bar as a member of the Honourable Society of Gray's Inn.

Their Majesties the King and Queen graciously sent a message of sympathy to Dr. and Mrs. Cuthbert, North Queensferry, on the loss of their son, Henry Kenmore Duff Cuthbert, Mid. R.N.R., who died in action on the Chilian coast on H.M.S. *Good Hope* on November 1st.

Since the outbreak of war the Public Health Department of Poplar Borough Council, through the medical officer of health, Dr. F. W. Alexander, has been arranging for the visitation of cases of expectant maternity amongst the wives of soldiers and sailors serving with the colours. In view, however, of the issue by the Local Government Board of suggestions for the administration of the parliamentary grants in aid of provision for maternity and child welfare in respect of the general population the scope of the Poplar scheme is to be somewhat extended, so that local associations taking part may be entitled to share in the Government grants. The Poplar Infant Care Association, the School Care Committees, and the College of St. Katharine, which is now established in the borough, have agreed to co-operate with the borough council in visiting suitable cases both before and after the birth of the infant, continuing until school age is reached. The School Care Committees will forward to the Public Health Department the names of mothers expecting to be confined, a card index will be maintained, and the cases distributed to the voluntary associations according to locality. Midwives practising in the borough will be asked to co-operate by sending the names of suitable cases for visitation. The borough council has asked the Local Government Board to make diarrhoea a notifiable disease during certain months of the year.

In a lecture on the after-care of mental defectives, delivered by Miss Evelyn Fox at a meeting of the Child Study Society held on Thursday, October 29th, at the Royal Sanitary Institute, she said that with the passing of the Mental Deficiency Act the State had for the first time formally recognized the fact that mental defectives were entitled to its protection. The feeling, which seemed to be widespread, that the Act so far had done little or nothing towards improving the status of the mentally defective, was probably due to the fact that under its provisions a large section of those mentally deficient children who had hitherto remained in their own homes were now eligible for admittance into institutions, and that as yet there were not a sufficient number of these establishments to receive them. If the Act worked properly the larger proportion of defective children would in time be placed under restraint. The only way of dealing effectually with the "higher grade" defective was by establishing an efficient system of after-care, by means of which the defective child on leaving school would be well looked after and prevented from losing ground or drifting into bad habits. The value of a systematic system of visiting by persons of skill and knowledge was very great, and should not be confined to the ex-pupils of special schools. The society hoped to see the foundation all over the country of voluntary associations, including every kind of social worker, whose object would be the care of defective children who had not attended special schools. They should possess "observation homes," where difficult borderland cases could be watched in order to discover whether they were capable of profiting by a period of training in some home or institution, or whether they were only fit to pass the rest of their lives under restraint. One such association had just started an "occupation centre," where children who had left school and were unfitted for ordinary work were kept employed for several hours every day; this not only kept them out of the streets, but relieved their families of what was sometimes a very heavy burden. A number of such centres started in connexion with special schools would enable a large proportion of these children to remain in their own homes and prevent the overcrowding of institutions.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Aitiology, Westrand, London.* The telegraphic address of the BRITISH MEDICAL JOURNAL is *Articulate, Westrand, London.*

TELEPHONE (National):—
2631, Gerrard, EDITOR, BRITISH MEDICAL JOURNAL.
2630, Gerrard, BRITISH MEDICAL ASSOCIATION.
2634, Gerrard, MEDICAL SECRETARY.

☞ *Queries, answers, and communications relating to subjects to which special departments of the* BRITISH MEDICAL JOURNAL *are devoted will be found under their respective headings.*

QUERIES.

POST-SCARLATINAL RHINORRHOEA.

T. W. J. asks for suggestions as to the treatment of sore nostrils and persistent rhinorrhoea in patients convalescent from scarlet fever, and any non-operative measures they may have found of value in otorrhoea of the same nature.

PULMONARY TUBERCULOSIS IN IRELAND.

DR. CLIPPINGDALE writes: The late Primate of Ireland, the Right Rev. Dr. Alexander, used to say he remembered consumption being imported from England into Ireland where it was at first known as "The English Cold." Is there any medical corroboration of the Primate's statement? Dr. Alexander was born in 1824.

ADHERENT PLACENTA.

FORWARNED writes: I attended Mrs. G. in her second confinement at the end of July, 1913. Her first confinement occurred in 1908 and was in her opinion normal. She first came under my observation in 1911, and was suffering from dysmenorrhoea and metrorrhagia dating shortly after her confinement. There was a doubtful history of an early miscarriage at the beginning of these uterine troubles. She was curetted in February, 1912, and some improvement in the uterine functions followed. She became pregnant at the end of 1912, and her delivery in 1913 was complicated with total and very adherent placenta. Menstruation recurred in due course and she menstruated normally for several months. She is again pregnant (three months) and feeling quite "fit." I would be glad to obtain some opinion as to the likelihood of an adherent placenta again complicating her coming accouchement.

ANSWERS.

PHARMAKON.—The only way to prepare a solution of novocain which will keep indefinitely is to sterilize it after making. This may be done by boiling for two or three minutes in a vessel the neck of which is plugged with cotton wool, the plug being afterwards left undisturbed, or by filling small vessels with the solution, sealing or otherwise closing them, and immersing for some time in boiling water. If the solution is kept in bulk it must be re-sterilized after each time it is exposed to the air. Novocain hydrochloride undergoes no decomposition when boiled, provided the glass of the vessel does not yield any appreciable alkalinity to water. The dose depends very much on the purpose for which it is wanted; the largest doses recommended are 4 grains in about two or three ounces of physiological salt solution with adrenalin, for infiltration anaesthesia, and up to 8 grains internally.

LETTERS, NOTES, ETC.

3RD HOME COUNTIES FIELD AMBULANCE.

LIEUTENANT-COLONEL G. A. EDSELL, Officer Commanding the 3rd Home Counties Field Ambulance, writes to say that his unit is in want of medical officers both for active service and for a reserve unit to be formed at once. Medical men can join as lieutenants either for the period of the war, when they get £20 to furnish themselves with uniform, or as Territorial officers for four years, when they receive £40 for their uniform, etc. Applications should be addressed to Lieutenant-Colonel Edsell, R.A.M.C.(T.), 3rd Home Counties Field Ambulance, Morn Hill, Winchester.

WILLIAM LANGLEY MEMORIAL FUND.

DR. J. P. FAGAN (P.M.O., Northern Nigeria (ret.), London) writes: A year ago you were good enough to announce in the JOURNAL that my bankers (Sir Chas. R. McGrigor, Bart., and Co.) would receive subscriptions from members of the West African Medical Staff to the above fund. I now beg to state that the sum of £47 5s. 9d. was thus collected and has been transferred, with a list of subscribers, to the Bank of British West Africa, Leadenhall Street, E.C., for the credit of the main fund which is under the control of the Committee at Lagos, Nigeria. I understand that the fund will be disposed of as follows: (1) A brass tablet in the Colonial Church at Lagos in memory of Dr. Langley. (2) A gold medal to be competed for at the Schools of Tropical Medicine. Thanking you for your courtesy in this as in all other matters connected with the West African Medical Staff.

ENLARGED NON-MALIGNANT PROSTATE.

DR. JOHN J. GRACE (London) writes in reply to "M. B." (BRITISH MEDICAL JOURNAL, November 7th, p. 820), who asks for information as to non-operative treatment of case of enlarged non-malignant prostate. The static-wave current, applied with a rectal electrode, is very useful in a large proportion of cases, those, that is, that are due to congestion and hypertrophy. Where there is a fibroma the *x* ray is also required. The treatment is not at all painful, and an average number of sittings required would be twenty.

COMMISSIONS IN THE R.A.M.C.

LIEUTENANT-COLONEL JOSIAH OLDFIELD (R.A.M.C.(T.), Officer Commanding, 3rd Reserve East Anglian Field Ambulance, Drill Hall, Walthamstow) writes: I shall be happy to hear from any medical man who wishes to obtain a commission. There will be vacancies shortly in Field Ambulances earmarked for foreign service, as well as in the Reserve Field Ambulance for Home Service. There will also be vacancies in combatant units for regimental medical officers. For a man who wishes to go abroad, or who wishes to become a regimental medical officer, it is always advisable that he should, as soon as possible, become attached to a field ambulance for training. I shall be happy to give facilities for training to any medical man who is waiting for a commission so long as my unit is posted in London, and shall be glad to help and advise any one in difficulties as to how best to obtain just what he wants.

ALVARENGA PRIZE.

THE next award of the Alvarenga prize by the Philadelphia College of Physicians, amounting to about 250 dollars (£50), will be made on July 14th, 1915. Essays intended for competition may be upon any subject in medicine, but must not have been published. They must be typewritten, and if written in a language other than English should be accompanied by an English translation, and must be received by the Secretary of the College on or before May 1st, 1915. Each essay must be sent without signature, but must be plainly marked with a motto and be accompanied by a sealed envelope having on its outside the motto of the paper, and within the name and address of the author. The successful essay or a copy of it shall remain in possession of the College; other essays will be returned upon application within three months after the award. The Alvarenga prize for 1914 has been awarded to Dr. H. B. Sheffield, of New York, for his essay on the fundamental principles involved in the use of the bone-graft in surgery.

INSECTS AND WAR.

DR. WM. BRAMWELL (Liverpool) writes: In view of the interesting papers by Dr. Shipley at present appearing in the JOURNAL, I may call attention to a passage in Xenophon's *Anabasis* (iv, 8, 20, 21). The following, though not a strict translation, will, I think, give the gist of the meaning: "And swarms of bees were there in abundance, and those of the soldiers who ate of the honeycombs became delirious and vomited, and it went through them downwards. And no one was able to stand upright. But those who had eaten a little were like men violently inebriated, while some who had eaten much were like mad men, but others were like men in the grip of death. And they lay as many as if there had been a defeat, and there was great mental depression. No one, however, died, but on the following day somewhere about the same hour their senses returned to them. And on the third and fourth day they got up again as if from a course of medicine."

CHLOROFORM ANAESTHESIA AND CARDIAC FIBRILLATION.

DR. H. G. JOHNSTON (Jamaica, West Indies) writes: Referring to Professor MacWilliam's address on "Cardiac Fibrillation and its relation to Chloroform Anaesthesia," published in the September 19th issue of the JOURNAL, I would note that about twelve years ago, acting on the theory then believed that sudden respiratory and cardiac failure in dogs when under chloroform was due to an "inhibitory" action of the vagus, I used small doses of atropine hypodermically before beginning the chloroform in operating and experimenting on several dogs, and found that, although the chloroform was given by the ordinary open method with very indefinite and irregular dosage, respiration and cardiac action were in each case perfectly regular and uninterrupted.

I would be glad of any comments those better informed than myself may make on this.

THE WAR AND TYPHOID FEVER.

An Address delivered before the Society of Tropical Medicine and Hygiene, November 20th, 1914.

By SIR WILLIAM OSLER, Bt., M.D., F.R.S.,
Regius Professor of Medicine in the University of Oxford.

I.

From the days of Homer, Apollo, the far darter, has been a much more formidable foe than his colleague Mars. With the two in conjunction unspeakable woes afflict the sons of men. In his great strait David, you remember, chose three days of pestilence as the equivalent of three months' military disaster. To-day the front of Mars is wrinkled, the world is at war, and the problem for the children of Aesculapius is to keep grandfather Apollo from taking a hand in the fray. In this game another member of the family, Hygeia, holds the trump card and gives victory to the nation that can keep a succession of healthy efficient men in the field. The Empire is confronted with a great task, in the successful performance of which the medical profession may play a leading part. For generations the health of the army and navy has engaged the attention of the very ablest men in our ranks. Let me quote a sentence written in 1785 by Gilbert Blane, a pioneer in sanitation, and as true to-day: "The great importance of the subject (that is, prevention) will plead my excuse for again calling to mind that such attentions are not only dictated by humanity, but would be the greatest wisdom in an economical and national light, considering how expensive it is to *replace* men and to support invalids, not to mention that it is upon the health and lives of men that every public exertion essentially depends, and upon which even the character of officers in the day of battle may depend."[1]

Of the camp diseases, typhus, malaria, cholera, dysentery, and typhoid fever, it is a reasonable hope that the armies of the West will escape the first three. Dysentery is pretty sure to cause trouble; but with regard to enteric fever we are on trial as a nation and as a profession, in what way it will be the object of this address to show.

The nineteenth century saw the discovery of the cause of typhoid fever, the recognition of its transmission through polluted water or milk, and the enforcement of sanitary measures, which have caused a steady and gratifying reduction in its prevalence. Those of us brought up upon the writings of Simon, Buchanan, Budd, and Murchison, and convinced of the truth of the water-borne and milk-borne theories, were often confronted with epidemics in schools and barracks and private houses in which it was not possible to trace the infection to either of these sources. Yet experience lent little support to a doctrine of direct contagion. There was some other factor. Even with the purest supply of water and of milk cases would crop up and local outbreaks occurred. Within the past ten or fifteen years we have not only filled gaps in the etiological picture, but we have added so many details to the picture that the canvas is approaching completion. Let me dwell upon four points in our new knowledge.

1. *The Importance of the Individual Case as a Factor in Infection.*

Though the infectiveness was recognized, only within the past decade have clinicians made it an essential feature to completely sterilize the dejecta, urine and faeces, and to avoid all possible contamination about the patient. As in surgery, we have changed the antiseptic to an aseptic battle, and nowadays the physician feels as keen a duty to keep the surroundings of a patient sterile as to treat his symptoms.

This in itself is a great gain, as the possibility of the abolition of the disease is a problem of the sterilization of the individual cases as they occur. I cannot here enter into the question of the methods of conveyance, but it is sufficient to say we have recognized fingers and flies as two of the chief, and the special liability in houses and wards of food contamination.

2. *Recognition of the Protean Character of the Disease.*

Not only are there differences in the germ that causes the clinical picture of typhoid, but the clinical picture itself varies from the textbook standard very much more than was dreamt of by Louis, Budd, Flint, or Murchison. A transient febrile attack, a slight diarrhoea, bronchitis, acute nephritis, an attack of pneumonia, cholecystitis, acute pyelocystitis, may be a manifestation of the infection. In endemic areas mild, indefinite illness in children may be due to the typhoid bacillus. The organism, indeed, may lodge and live in an individual without ever causing symptoms, and then acutely excite an illness without a trace of resemblance to the disease we usually associate with its name. One of the first cases in which this was recogized I saw with Dr. Cushing in Dr. Halsted's wards—a woman, aged 26, who had a clean bill of health except for occasional attacks of abdominal pain and vomiting. It was evident at the time of examination that she had an acute cholecystitis. Dr. Cushing removed fifteen large gall stones; pure cultures of the typhoid bacillus were isolated from the mucous contents of the bladder. Here was a woman who had never had, so far as could be ascertained, typhoid fever, and yet she had probably had for years the organism in her gall bladder, which had ultimately caused the formation of the stones. This case, at the time unique, is no longer so. In the Spanish-American war, and in the South African war, there were an extraordinary number of mild ambulatory cases, which in the former were frequently reported as malaria. In public health work it is all-important to recognize these mild atypical cases. Dr. Chalmers, in the Health Report of the City of Glasgow for 1913, calls attention to the simulation of enteric by mild pneumonia and by intestinal catarrh. Eight cases of enteric appear to have originated from an undetermined case of the latter in a child.

3. *The Discovery of Typhoid Carriers.*

Briefly stated, in from 1 to 3 per cent. of cases of enteric fever the bacilli do not disappear from stools or urine. The patient becomes a chronic carrier and a possible menace to the community. It has been estimated that, in countries in which typhoid fever prevails, the typhoid carriers number from 2 to 3 per 1,000. Infectivity may exist for years, and scores of small epidemics have been traced to carriers. How persistent the infection may be, and how difficult to get rid of, is well illustrated by the case studied for the past five or six years by Davies and Walker Hall of Bristol. The patient had enteric in July, 1905, and eight instances of infection had been traced to her. The special interest in the case is the careful study of the different plans of treatment and the variability of the presence of the organisms in the urine. They were also isolated from her blood five years after the original attack.[2] The relation of the carrier to public health is of vital importance, particularly the question of the detention of notorious carriers who follow dangerous occupations. The New York Board of Health was judged to be within its rights when an action was brought against them for the illegal detention for three years of the celebrated "Typhoid Mary." Carriers should not follow the occupation of cooks, butchers, grocers, as the fingers deposit bacilli on everything they touch unless scrupulous attention is paid to cleanliness after defaecation. The good effect of precautionary measures in the case of chronic carriers is illustrated by the report of Lentz from the Oberstein district.[3] For ten years the disease had been endemic, and then a systematic attempt was made to discover the carriers, of whom six were found in 1894, two in 1897, and one in 1898. They were practically all mothers with large families. It was impossible to enforce vigorous methods of isolation, so that repeated warnings were given, and instructions as to scrupulous cleanliness, particularly after defaecation, never to touch an article of food without a systematic washing of the hands, and having their underlinen carefully sterilized. The fever in the district has practically disappeared.

4. *Immunization.*

Lastly, and the most important point of all, is the discovery of immunization against the disease, for which we

are indebted to the brilliant investigations of Sir Almroth Wright. The net result of the enormous amount of work which has been done since the publication of his first paper—September, 1896—is that, for a time at least, man may be immunized safely and surely. It is only by the statistical method that we are able to judge of the results of the practice. While in a way this is unfortunate, as figures have an extraordinary mobility as manipulated by different individuals, still, as practical men, we have to use them and to form judgements by their help. The new iatro-mathematical school of Karl Pearson and his scholars have made the profession cautious in drawing results from statistics; but in the matter under consideration the figures are, I believe, trustworthy. I will only give a few, the more important.

For many years the death-rate from typhoid fever in the United States has been very high. The disease prevails widely in the country districts. During 1912 it was 16.5 per 100,000 of the population—the lowest for many years. Antityphoid inoculation was voluntary in the U.S. army from 1909 to part of 1911; it was made compulsory in part of 1911 and in 1912 and 1913. Major Russell's last report, dated May 2nd, 1914,[4] gives the following figures:

Typhoid Fever, 1907 to 1913, for the whole Army, Officers and Enlisted Men, American and Native Troops.

Year.	Mean Strength.	Cases.		Deaths.		Percentage of Total Cases.	Occurring Among those who were Vaccinated.	
		No.	Ratio per 1,000 of Mean Strength.	No.	Ratio per 1,000 of Mean Strength.		Cases.	Deaths.
1907	62,523	237	3.79	19	0.30	8.0	—	—
1908	74,692	239	3.20	24	0.31	10.0	—	—
1909	84,077	282	3.35	22	0.26	7.8	1	0
1910	81,434	198	2.43	14	0.17	7.1	7	0
1911	82,802	70	0.85	8	0.10	11.4	11	1
1912	88,478	27	0.31	4	0.044	14.8	8	0
1913	90,646	3	0.03	0	0.0	0.0	1	0

Major Russell states that no harmful effects have been produced. The newspaper reports of death following antityphoid inoculation in the United States have been shown to be erroneous. In the case of Private Pantzer, of the National Guard, Brooklyn, death was shown to be due to malignant endocarditis, and in no way the result of inoculation.[5] The value of these results must be taken in connexion with the fact that in many places the barracks are situated in districts in which typhoid fever prevails. In 1911 and 1912 there was a concentration of many thousands of United States troops on the Mexican border in localities quite as favourable to the spread of enteric as in the Spanish-American war.

Apart from vaccination, there has been in all armies a reduction in the number of cases of typhoid fever; thus, between 1882 and 1909 the incidence in the Prussian army dropped from 6.7 per 1,000 to 0.4, while in the same years in the French army a reduction from 16.6 to 3.4. But the special value of the experience of the American army is the remarkable drop in the case incidence which followed antityphoid inoculation without special change in the sanitary environment of the troops. An interesting comparison is reported[6] of two divisions stationed in nearly the same latitude for about the same length of time each on a good site, with artesian water of unimpeachable purity. In the one at Jacksonville, Florida, in 1892, among 10,759 men there were 1,729 certain cases, probably 2,693 (the question of diagnosis of typho-malaria, etc.), with 248 deaths. At San Antonio, Texas, in 1911, among 12,659 men, all inoculated, there was one case of typhoid fever, and no death. In France the results appear to be equally satisfactory, and there is no country in which measures of protection are more needed, as during the past twenty years among the French troops in France there have been 66,000 cases, with 10,000 deaths.[7] Professor Vincent reported to the International Medical Congress last year that among 30,325 vaccinated men no case occurred, while in the unvaccinated the case-rate was 2.22 per 1,000 in the metropolitan troops and 6.34 in the colonial. Specially good results have been met with in Algiers and Morocco, where the inoculation is compulsory, and the incidence per 1,000 has fallen from 15 to 5. A striking illustration is reported from Avignon by Paget in a recently issued Research Defence Society pamphlet. Out of 2,053 men 1,366 were protected and 687 were not. The non-protected had 155 cases with 21 deaths; the protected had not a case. The Italian experience in Tripoli shows that the incidence of the disease among the unvaccinated was 35.3 per 1,000, while among the vaccinated the incidence for those inoculated once was 1.34 per 1,000, for those inoculated twice 1.65, and for those inoculated three times 0.49. The most careful study of the statistics for the British army are those presented in the report of the Antityphoid Committee, 1912. "The histories, as regards typhoid fever, of 19,314 soldiers, whose average period of service abroad was twenty months, were carefully followed, and every precaution possible was taken to verify the diagnosis bacteriologically. Of this number 10,378 were inoculated and 8,936 not inoculated. The case incidence of typhoid fever among the inoculated was 5.39 per mille, and among the non-inoculated 30.4 per mille.

"There is no reason for supposing that this difference can be attributed to a want of homogeneity between the two groups. The age distribution among inoculated and non-inoculated was approximately the same. They were intermingled and lived under identical conditions."

The profession is greatly indebted to Sir William Leishman and his colleagues, Harrison, Smallman, and Tulloch, for the good work they have done in connexion with this subject.

Symptoms following Inoculation.

As in this country the practice is voluntary, and as in certain quarters opposition has been offered, I have thought it well to collect data of any untoward effects, and I have to thank many correspondents who have replied to my note in the BRITISH MEDICAL JOURNAL of October 10th. In the first place it may be stated that with ordinary care and precautions large bodies of troops may be successfully inoculated with extraordinarily little discomfort or disability. Colonel Hodgetts has kindly given me the figures of the recent inoculations of the Canadian contingent, some 31,000 strong, made under his supervision in the camp at Valcartier in the Province of Quebec. Of the total number only one had a local abscess at the site of injection, and there were no serious sequelae. This may be said to be an exceptionally good record. The inoculations in this country during the past three months have been on a larger scale than ever before attempted, and considering the enormous number—several hundred thousand—the serious sequelae have been very few. We may group the symptoms as follows:

1. A varying proportion no symptoms, other than a little headache or malaise, with slight redness and swelling at the point of inoculation.

2. A large proportion run a normal course of what may be called the inoculation fever, which has many resemblances to the so-called serum sickness. The temperature rises within ten or twelve hours, sometimes with a slight feeling of chilliness, and vomiting may occur. There are headache, fugitive pains in the back and joints, sometimes abdominal tenderness, and for twenty-four or thirty-six hours the patient may feel very badly. In mild forms the temperature rises to 101° or 102°; in the more severe to 103° and 104°, or even higher. Sometimes there is diarrhoea; in other cases, perhaps in the majority, there is constipation. Giddiness and fainting are reported, and one physician within the first ten days had curious nervous symptoms, feelings of apprehension, and a transient state of neurasthenia. He felt inability to control his muscles, and dreaded lest he should be unable to avoid some impulsive act. There was a slight mental disturbance, and he had what he called "dreadful feelings," and had difficulty in forcing himself to do the simplest acts. In the North Midland Division, among nearly 16,000 inoculated, a man, two days after inoculation, had marked mental symptoms suggestive of confusional insanity, which, fortunately, passed away. I saw with Dr. Collier an officer whose case was very fully reported to us by Dr. Joyce of the 4th Royal Berkshire Regiment. He was

inoculated on September 14th and, after the usual slight local and general symptoms, on the 17th the temperature was normal. On the 18th he had giddiness, and on returning to his billet when the door was opened he mistook the parlourmaid for the colonel, and raising his hand to the salute overbalanced and fell unconscious. He had a few days' leave, and some weeks later had several giddy attacks. He got quite well.

Heavy exertion and exposure within twenty-four hours after inoculation may be followed by sharp general symptoms. In connexion with the abdominal pains that may occur, it is interesting to note that Professor Boyd of Winnipeg, now associated with the 3rd North Midland Field Ambulance, reports two cases (admitted on the same day) with appendicitis—one on the third day after inoculation, the other within twenty-four hours. Both had acute perforation. There have been several reports of sharply localized pain in the region of the caecum, with slight diarrhoea. The highest temperature recorded in the notes sent to me (Professor Boyd) was 106.4°, four days after inoculation.

In what may be called the normal course there is oedema and redness at the site of inoculation varying in extent, and several correspondents have noted a curious migration of the erythema downwards towards the elbow, and even reaching to the wrist. Blotchy erythema may occur about the joints, and purpura has been noted.

Cases with Untoward Effects, Local or General.

(*a*) *Locally*, the redness, swelling, tenderness rarely persist for more than a day or two, and may be equally marked at both inoculations, or may be slight at the first and abundant at the second, or vice versa. The local process may go on to suppuration. How rare this is may be judged from the experiences of the Canadian contingent already referred to, in which only one abscess occurred among some 31,000 cases. This is, indeed, a remarkable record, as I doubt if there is any hospital in the kingdom in which during a year's experience abscess does not follow some form of hypodermic injection. I have had no report of severe sepsis following the local abscess. Lance-Corporal Goatley, whose case has been exploited by the "antis," had a septic wound, which proved, on investigation by Surgeon-General Whitehead, to be an abscess following ordinary vaccination for small-pox, and the report states that the bad arm directly followed from his own neglect. And I may state that he was not discharged from the army for ill health due to the vaccination.

(*b*) *General.*—The inoculation fever and its symptoms rarely last more than a couple of days; but in a few cases unpleasant, or even serious, complications may follow.

With the fever there may be pains in the joints, superficial redness, and even effusion. A patient was admitted to the base hospital, Oxford, with effusion in the left knee following antityphoid inoculation three weeks previously. It resembled a gonorrhoeal synovitis, but there was no urethral discharge. I have already referred to the abdominal pains on pressure in the caecum region and the coincidence of appendicitis in two cases. Jaundice has been noticed in a few instances. There were four in the North Midland Division, coming on about a week after inoculation (Boyd). Symptoms suggestive of enteric, and even enteric itself, may follow inoculation.

Dr. Walter Broadbent, of Brighton, sends a report of a case: Second inoculation on October 13th, followed by headache and pains in the limbs on the 14th, then fairly well until the 20th, when he had headache, a temperature of 103.4°; on the 21st the temperature ranged from 101° to 102°° on the 22nd from 98.6° to 102°, then gradually fell to normal. On the 26th the tongue was very furred, there were no spots, but there was a positive Widal reaction on the 24th. The case was not treated as enteric.

Inoculation has been followed by an illness not to be distinguished from typhoid fever.

In a case, the notes of which were sent by Boyd, the second dose, given on October 16th, was followed by sickness and giddiness. On October 19th and 20th he had diarrhoea, for which he saw the regimental medical officer. On October 23rd he was seen by the surgeon of the 1st North Midland Field Ambulance, who found him with a temperature of 101.5°, constipation, rose spots, slight abdominal tenderness, large spleen. After consultation, it was decided that it was a typical typhoid case, and he was sent to the 2nd General Hospital, London.

Occasionally septic fever follows unassociated with the local lesion. A case of this type, under the care of Colonel Hood and Dr. Hobhouse at Brighton, I had the privilege of seeing at the height of his illness. I am indebted to Dr. Hobhouse for the notes.

On October 23rd I saw at Brighton, with Dr. Hobhouse and Dr. Hood, Private Walter Fuller, aged 23, No. 8 Bedfordshires, who had his first inoculation on October 3rd. Slight headache on the 4th, with fugitive pains, but he did not feel badly until the 7th, when there were fever and pains in the joints. On admission to hospital on the 9th the temperature was 102.5°. On the 11th his temperature was 104°, much pain, particularly in the joints, slight swelling and redness of the ankles and the smaller joints of the hands, with great stiffness and inability to use the muscles. On the 17th he began to have pain in the chest, with signs of involvement of the right base. On the 18th the leucocyte count was 15,300 per cubic millimetre, the pains in the chest were worse, he had cough, and the consolidation in the right lower lobe had increased. The Widal reaction was markedly positive. Between the 16th and the 23rd the temperature rose to about 103° each day, there were pain and swelling in the joints, redness over the ankles and knuckles, and much disability. When I saw him on the 23rd he looked very ill, the respirations were 40, pulse 100, the small joints of both hands showed swelling with slight erythema, tenderness on pressure and on movement, redness over the left ankle, moderate effusion in the left knee-joint and right elbow, consolidation of the right lower lobe, and left pleural effusion reaching to the fourth rib in front. The heart sounds were clear; the spleen was not palpable. There was no redness or swelling at the site of inoculation. The patient remained very ill for the following week, although the temperature was lower, rarely going much above 102°. There was a to-and-fro pericardial murmur. The patient then began to improve, and on October 30th the temperature for the first time fell to 99°. Between October 30th and November 5th it fluctuated around 100.5°, and then fell to normal. The smaller joints remained painful, and it was not until November 11th that he began to use his hands and arms. He is now convalescent.

In the same ward I saw, with Dr. Hobhouse, a man with dermatitis in the region of one axilla, which had spread rapidly after inoculation. He had symptoms suggestive of peripheral neuritis, stiffness of the arms, and loss of the knee-jerks. He had had zinc ointment used for a very large area, which Dr. Hobhouse thought might possibly be the cause of the neuritis.

The importance of avoiding exposure for a day or two after inoculation is emphasized by the fact that cases of pneumonia have been reported by several observers. In the North Midland Division series, among nearly 16,000 instances, in two cases lobar pneumonia followed within twenty-four hours (Boyd). Pneumococci were present in the sputum in both cases.

Private G. B. Jones, 12th Sherwood Foresters, reported by Dr. Walter Broadbent, was inoculated October 6th; chill on the 7th, and on the 8th was admitted to the 2nd General Eastern Hospital with pneumonia of the middle and lower lobes on the right side, and the lower lobe on the left, with a temperature of 103°, pulse 120, and much delirium. He had a very severe illness, and died on October 14th.

Reports of death as a result of the inoculation are false. Dr. Selby wrote from Aldershot (October 17th, 1914):

This morning I was trying to persuade my Kitchener army men to be inoculated, when I was confronted by one man who said he went down to Shorncliffe last week-end and that there they had told him that three men had died within twenty-four hours of inoculation.

I wrote to Colonel Wilson, who replied (October 21st, 1914) that there had been no death from this cause and giving particulars of the fatal cases from accident or disease since the formation of the camp.

The Beaujon Hospital nurse, Paris, whose case is so often quoted, died of typhoid fever a month after the last inoculation. She might very possibly have contracted the disease previously. The Neckar Hospital nurse received therapeutic injections of typhoid serum during the course of the disease, not a protective inoculation.

Private Pantzer of the National Guard, Brooklyn, died of malignant endocarditis and the inoculation had nothing to do with his fatal illness.[5]

II.

Perhaps the best chapter in British sanitation is that which deals with typhoid fever. While a decrease in the incidence of the disease has been more or less general throughout civilized countries, nowhere else has the fall been so progressive and striking. Twenty years ago the death-rate per 1,000,000 of inhabitants was above 300; in 1912 it had fallen to 44, the lowest ever recorded; indeed,

up to 1904 the rate had never fallen below 100. Enteric fever may be said to be in its "last ditch," but that it is still putting up a strong fight is indicated by 1,600 deaths in England and Wales in 1912. It prevails less in London than in the Midlands and in the South, and is much more frequent in the North in both urban and rural districts. In certain urban districts the highest case-rate per 100,000 of the population was 34. In many of the large cities in the North, as in Liverpool and Glasgow, in which the disease was very prevalent, the fall has been progressive and rapid. In the former city in 1895 there were 1,300 cases. In 1911 it had fallen below 200. In Glasgow the case-rate per 1,000,000 has fallen from 1,386 in 1891 to 232 in 1913, and the death-rate per 1,000,000 from 218 in 1891 to 36 in 1913. General betterment of sanitation, particularly improved housing, better diagnosis, greater care of the individual cases—to these factors may be attributed a large part of this decrease. But there is another to which the attention of medical officers of health has been strongly directed—namely, the removal of local sources of infection by the isolation of the sick in hospitals,[9] in which in some cities the proportion of cases treated has risen from 30 or 40 per cent. to 80 and 90. It has been well said that enteric fever is the sanitary index of a country; and that to-day our camps are not hotbeds of the disease is a result of more than half a century of intelligent and efficient sanitation. Neither the profession nor the people at large appreciate fully the extraordinary sanitary advantages enjoyed by this country.

In medical practice, if I were asked to state the most striking difference between England and the United States and Canada, I should say the absence of enteric fever in hospital and private work. The tragedy of typhoid fever was ever present, and one felt constantly outraged at the wantonness of the sacrifice. In full measure the tragedy was brought home to the United States during the Spanish-American war. There never has been in history a campaign so fatal to an army not yet in the field. Listen for a moment to the story of what may happen after mobilization in a typhoid-ridden country. Returning to the United States from a visit to England in the autumn of 1898, I found but one subject engaging the attention of the profession—the appalling outbreak of typhoid fever in the volunteer army, distributed in seven camps in different parts of the country. The figures published by Reed, Vaughan, and Shakespeare in their elaborate report, of which a good epitome is given by Dr. Christopher Childs[10] show that in six months, among 107,973 men, there were 20,738 cases of typhoid fever and 1,580 deaths. At Camp Alger, near Washington, with a mean strength of 21,988 men, there were 1,951 cases of typhoid fever. Never have I seen so many cases of fever concentrated together, barrack after barrack filled with the victims of neglected sanitary precautions. The lesson drawn by the authors of the report on this epidemic was that the disease was not water-borne, but that nearly two-thirds of the cases were examples of "connectible attacks"—that is, due to infection within the tent or from adjacent tents. It was the first great epidemic to call attention to the importance of local infection by means of fingers, food, and flies. Two other points were brought out—the frequency with which erroneous diagnosis was made, particularly in the southern camps, where many cases were supposed to be malaria; and the large number of minor attacks indicated by nothing more than transient malaise, slight fever, or a gastro-intestinal attack.

Recommendations.

More than three months have passed, and the reports from the camps indicate that nowhere is typhoid fever prevalent. That isolated cases have occurred should make the medical officers of health and the military surgeons redouble their efforts to prevent the spread. These should be watched with the utmost care, since, as Dr. Childs points out, epidemics in camps are usually preceded by scattered cases or by the unusual prevalence of diarrhoea. *Watch the common ailments*, should be the motto of the camp surgeons. The following measures are indicated:

1. Every recruit should be asked whether he has had typhoid fever, or if during the previous twelve months he has lived in a house with a case of fever. An affirmative answer should mark the man for laboratory study. This may seem an irksome precaution, but in preventive medicine nothing necessary is irksome.

2. A realization of the extremely protean character of typhoid fever, so that mild cases of enteritis, obscure forms of bronchitis and pneumonia, and mild cases of fever should be watched with care.

3. Every typhoid patient should be regarded as a focus of infection, and should be suspect so long as the bacilli are present in the discharges. The cases should not be treated in the general wards with other cases. Measures should be taken in the larger camps and in the garrison towns to segregate the cases.

4. No typhoid patient should receive a clean bill of health until he has been shown by bacteriological examination to be harmless.

5. Ample provision should be made for the careful bacteriological examination of all suspected cases.

III.

Fever in various forms has proved more destructive to armies in the field than powder and shot. It has been well said that bullets and bacilli are as Saul and David, "Saul hath slain his thousands and David his ten thousands." The story of the destructive character of fevers has never been so well demonstrated as in the great Civil War of the United States, during which malaria, dysentery, typhoid fever, and other diarrhoeal diseases were the fatal foes. Woodward's *Report of the Medical History of the War of the Rebellion* is a perfect storehouse of information on camp diseases. It is not easy to pick out the exact percentage of typhoid fever, as a large proportion diagnosed as diarrhoea and many of malaria belong to this disease; but the official figures for the army of the North are sufficiently appalling—79,455 cases and 29,336 deaths! There is the same story in the Franco-Prussian war; among the German troops there were 8,000 deaths from typhoid fever, 60 per cent. of the total mortality! It is said that typhoid fever existed in every army corps at the outbreak of the war, and the campaigns were carried on largely in infected regions. I have already referred to the terrible experience in the Spanish-American war among the volunteer troops in the home camps. The sad memories of the South African war still haunt the memory. That was a war which brought out many new details in campaigning, but the sternest lesson taught is the one we are now considering, as it, too, was a war in which the bacilli counted for more than the men. Of the 22,000 lives lost, the enemy is debited with only 8,000; preventable febrile diseases for 14,000. And among these, as usual, typhoid fever headed the list, 57,684 cases, of whom 19,454 were invalided, and 8,022 died. The *Bacillus typhosus* alone did more damage than the Boers. Here again, as in the Spanish-American war, it was not so much water-borne typhoid as camp infection by fingers, flies, dust, and food.

We are now in the fourth month of the war, and, so far as one can gather from the somewhat meagre reports, the health of the troops at the front has not been damaged to any extent by fever, and, so far, the sad losses have been from bayonets and bullets. On active service the soldier may take typhoid fever with him, or he may find it in the country. A large body of men has a certain percentage of carriers, any one of whom may act as a focus of distribution. The conditions in camp life are peculiarly favourable to case infection; thus it would be impossible for a carrier cook not to contaminate the food of an entire company. Of equal moment is the state of the country in which the troops are working. During the Spanish-American war it was not possible in the United States to locate a camp in a typhoid-free position. In this country it is not possible to pitch a camp in an infected district. In South Africa both conditions prevailed; infection was brought by soldiers, and was abundant in the country. It seems not unlikely that the troops in France and Belgium are reaping the benefit of the past ten years of active campaign against typhoid fever. Details are not at hand as to the prevalence of the disease in the eastern and north-eastern regions of France, but I am told that there has been a great reduction in the incidence of the disease in Belgium, and that the troops have heretofore suffered but little. The Rhenish provinces should reap the benefit of the remarkable antityphoid campaign of the past ten years.

Certainly it is very gratifying, particularly at this season of the year, that comparatively few cases have occurred. Among 2,000 German, English, and Belgian troops who have been, or are at present, in the base hospital at Oxford there have only been five cases of typhoid fever; and this, I believe, to be the experience in other large hospitals throughout the country. It will be a great triumph to go through this war without a devastating experience of typhoid fever. In the fighting line it is not possible always to ask the soldier to carry out sanitary precautions, and in a very infected country, even with the best of intentions, he cannot avoid exposure. Here we may expect to find the protective value of inoculation, and it is very satisfactory that the value of the measure has been so generally recognized by officers and men. An immense proportion of those who go with the Expeditionary Forces will have been protected—for a period at least. While with our present knowledge we cannot but regret that the inoculation has not been made compulsory, let us hope that a sufficient number have taken advantage of the procedure to make impossible a repetition of the enteric catastrophe in South Africa.

In the midst of this great struggle we stand aghast at the carnage—at the sacrifice of so many lives in their prime—

> The many men so beautiful,
> And they all dead did lie.

The bitterness of it comes home every morning as we read in the Roll of Honour the names of the much loved sons of dear friends. Strange that man who so dominates Nature has so departed from Nature as to be the only animal to wage relentless war on his own species. But there are wars and wars, and let our thought to-night be of the other army waging peaceful battles against our true foes. No one has so well contrasted the work of these two armies as the poet laureate of the profession, Oliver Wendell Holmes:

> As Life's unending column pours,
> Two marshalled hosts are seen—
> Two armies on the trampled shores
> That Death flows black between.
>
> One marches to the drum-beat's roll,
> The wide-mouth clarion's bray,
> And bears upon a crimson scroll,
> "Our glory is to slay."
>
> One moves in silence by the stream,
> With sad yet watchful eyes,
> Calm as the patient planet's gleam
> That walks the clouded skies.
>
> Along its front no sabres shine,
> No blood-red pennons wave;
> Its banner bears the single line,
> "Our duty is to save."

We shudder at the needless slaughter of the brave young fellows—allies and foes alike—but think of the slaughter which goes on in our homes, just as cruel as, often more cruel than, that of the battlefield! Tuberculosis alone will kill ten times as many this year in Great Britain than will die abroad for their country. Comparing the death-rate in England to-day with that of fifty years ago we may say that, as a result of the work of the other army, more will be saved from death by enteric fever in 1914 than will be killed this year in the war. Eberth's *Bacillus typhosus* will kill in 1914 in the United States more than will German shrapnel and bullets in France and Russia. Moving in silence, the great army of sanitation, with a general staff and leaders of all lands and languages, claims allegiance only to Humanity. In war it has not often fought winning campaigns, but the new knowledge is full of such promise that even the vanquished may be victors.

A REPORT ON GAS GANGRENE.

BY

SIR ANTHONY A. BOWLBY, F.R.C.S., C.M.G.,
CONSULTING SURGEON WITH THE EXPEDITIONARY FORCE;
AND
SIDNEY ROWLAND, M.R.C.S., L.R.C.P.,
IN CHARGE OF MOBILE FIELD LABORATORY.

(From the Field Laboratory G.H.Q., November 11th, 1914.)

IT seems advisable to briefly record the conclusions at which we have so far arrived on the spreading gangrene which has occurred amongst the wounded of all the armies now in France.

One of us (S. R.) has examined the condition bacteriologically, and this examination was carried out in the Mobile Field Laboratory. In a typical case affecting the hand, a bacillus was found which was isolated for examination. A culture of this, when inoculated into a guinea-pig, caused its death in eighteen hours. *Post mortem* there was found a gangrenous cellulitis from which the inoculated organism was recovered. A second guinea-pig inoculated from this culture was sent to the Lister Institute. It arrived safely and died within a few hours of its arrival, thus affording abundance of fresh material for a more detailed examination than was possible under field conditions. An examination of the culture was meanwhile made in the field laboratory, and the conclusion arrived at was that it was probably the specific organism of malignant oedema. Further examination made at the Lister Institute by Dr. C. J. Martin, F.R.S., and Dr. Arkwright inclined these observers to the view that the organism in question was identical with one that for some time was confused with that of malignant oedema, known as the bacillus of Ghon and Sach. This organism was originally obtained from a case of gangrene in the human subject. There are some ten different organisms that have been isolated from cases of gas gangrene in man, all of which are closely allied, and have the common characteristic of being anaërobic spore bearers. From other cases in the clearing hospitals at the front several more organisms of this group have been isolated, and have been sent to the Lister Institute for confirmatory diagnosis.

A sample of earth from a trench was also examined. The inoculation of a few drops of water, in which this earth had been shaken up, into a guinea-pig, killed the animal in eighteen hours. *Post mortem*, a similar gangrenous cellulitis was found. The animal was also found, like the guinea-pig inoculated from the gangrenous hand culture, to be infected throughout with a spore-bearing anaërobic organism belonging to the same group. It is reasonable to conclude, therefore, that the gangrene found amongst our wounded soldiers is directly due to infection introduced at the time of the wound, and this is especially likely to occur if muddy clothing has been carried in by the projectile or if earth has been carried in by the explosion. We are therefore of the opinion that the gangrene that occurs amongst the wounded is a traumatic infection and dates from the moment of the injury. It is solely due to infection from the soil, and is in no way related to sloughing phagedaena, or so called hospital gangrene.

Clinical Picture of Gas Gangrene.

In the cases we have seen the gangrene has always occurred in connexion with wounds of the extremities. We have not seen it in the head, neck, thorax, or abdomen.

Nature of Projectile.

We have seen it in wounds from rifle, shrapnel, and fragments of shell.

Nature of Wound.

We have seen it in both slight and very serious wounds, but a larger proportion of the serious wounds are affected by it, especially when large bones have been shattered and muscles extensively torn and extruded. We have seen it with and without fractures, and in a relatively large number of fractures of the femur.

Period of Onset.

It is most noticeable that it always shows itself within the first few days, or even hours, following the infliction of the

injury. In two cases we have seen it well marked within thirty-six hours, and in several others already extensive on the third and fourth day.

Several patients have died of it on the third day following that of the injury, and in other patients it has progressed so far that amputation has been performed on the third day.

Onset.

This is characterized by swelling of the injured part, and the gangrene seems especially liable to occur in connexion with that swelling of a limb which is due to extravasation of blood in the subcutaneous tissues and intermuscular planes. It seems to us that interference with the circulation either by extravasation of blood or by tight bandages has a marked influence.

In the early stages the patient complains of severe pain which is perhaps due to tension, the result of the swelling, but in the later stages the affected area becomes completely numbed and insensitive. The edges of the wound are generally ragged and sloughy, and a considerable quantity of blood-stained serum constantly exudes and soaks the dressings. This discharge emits a characteristic and most offensive odour which is so marked as to be almost diagnostic. The skin, if not previously discoloured by extravasated blood, assumes a dark purplish or slate-coloured hue.

In the vicinity of the wound it changes subsequently to a more green colour. The swelling extends coincidently with the change of colour, and a few hours later the skin becomes nearly black, and finally forms a black, leathery slough. Beyond the area of discoloration the limb is swollen with gas and fluid exudation, and an emphysematous crackling can be elicited on pressure with the hand. This may spread to a distance of as much as a foot above and below the actually gangrenous area, and so rapid is the extension of the gangrene that we have seen the whole of the lower extremity completely mortified before the end of the third day after the infliction of the wound.

Condition of Patient.

Temperature is not materially affected in many cases, and high fever is rare. A temperature of 99° to 100° is usual. Respiration is not materially quickened; headache is not complained of. The mind is perfectly clear till near the end. The pulse is not greatly quickened but rapidly loses power, so that several of the patients we have seen have had no perceptible radial pulse. The heart's action is greatly weakened so that its beat is quite difficult to feel.

Vomiting is common and in many cases is frequent; diarrhoea is rare; sweating is not generally present, and before death the skin is cold; the tongue is usually covered with a dirty fur, but the mouth is not exceptionally dry. Death appears to be due to cardiac failure, and we have been struck by the extraordinary clearness of the mind of a patient, almost pulseless, and within an hour or two of his death. In the worst cases the gangrene may spread with such rapidity that the whole limb may be cold, of a purple or black colour, immensely swollen and quite devoid of all sense of touch and power of motion within thirty-six hours of the onset of the gangrene. The smell of such a limb is overpowering, and almost precludes a careful *post-mortem* examination. If incisions are made before or after death gas and sanious fluid bubble up. Pus is confined to the edges of the wound, and is very little in proportion to the sanious discharge.

Practical Conclusions.

The practical conclusions we would draw from these observations are as follows:

1. All tight bandages and especially those applied at the first field dressing should be avoided. Shell wounds are so often followed by so much interstitial haemorrhage that the part swells and the bandage rapidly becomes tighter and interferes with the circulation. Consequently many bandages require to be cut within a few hours of their application.

2. In many cases the tension requires to be relieved by incisions and drainage, and the opportunity should be taken to wash the wounds thoroughly with an antiseptic. Hydrogen peroxide is one of the best. Great care should be taken to remove portions of clothing, as these contain the infective agent. Shattered fragments of bone and pieces of shell or gravel should be taken out.

3. Amputation may often be successfully performed through tissues made emphysematous by gas but not yet gangrenous.

4. The group of anaërobes causing gangrene are spore-bearers, and spores (especially of this group of anaërobes) are especially difficult to kill by any antiseptic solution or even by boiling. Consequently, in order to sterilize instruments and other things that have been infected, other measures are required.

(*a*) Destruction of blankets and clothing soaked by the discharge.

(*b*) Heating in an autoclave at a temperature of 120° Centigrade.

(*c*) Boiling for an hour in a solution of 1 in 20 carbolic acid or lysol (1 in 10).

It should be remembered that the mud on the clothes of wounded soldiers is almost certainly infected, and care should be exercised to see that the area in which operations or dressing of wounds are performed should be kept free from possible contamination from such a source.

5. Where possible, it is advisable to isolate patients under treatment in hospitals, and this is all the more necessary on account of the bad smell which is inseparable from the condition.

The above is a copy of a report sent to the Director of Medical Services on November 9th, and is mainly the result of work done at the clearing hospitals at the front to which patients are taken within a few hours of being wounded. Many of the conclusions and practical recommendations, however, have been conveyed to the hospitals verbally or by official communication and attempts are being made at the Lister Institute to provide an antitoxin.

INJURIES TO THE BOWEL FROM SHELL AND BULLET WOUNDS.*

BY

P. LOCKHART MUMMERY, F.R.C.S.Eng., B.C.Cantab.,

SENIOR SURGEON, ST. MARK'S HOSPITAL, LONDON; HONORARY SURGEON, KING EDWARD VII'S HOSPITAL FOR OFFICERS.

Injuries to the rectum or pelvic colon, which occur in war, whether from bullet or shell wounds, must of necessity be very serious; and as a fact the statistics of previous wars show that injuries of this nature are attended by a higher mortality than injuries to other parts of the alimentary canal. Many of these cases must be fatal owing to concomitant injuries of the large vessels in the pelvis, or to resulting peritonitis. In the Boer war the mortality from wounds of the rectum was 30.7 per cent. of those so wounded, death being due to peritonitis, internal haemorrhage, or septicaemia. We have as yet no means of ascertaining the percentage of mortality from such wounds in the present war; but already there must have been a number of cases of wounds involving the large bowel under treatment in our home hospitals. It is to be hoped that, as the result of increased knowledge and improved technique, we shall be able during the present war to bring the percentage of mortality for wounds of this nature down to a much lower figure than in previous wars.

As these wounds present some unusual difficulties and require special treatment, it does not seem out of place to discuss them at this early stage of the war, if by so doing we can give any assistance to ourselves and other surgeons who may have to deal with such cases during the continuance of the war. In my position as surgeon to King Edward VII's Hospital for Officers I have seen several of these cases during the last three months.

The injuries vary from clean bullet wounds to large septic lacerated wounds due to fragments of shell. There can be no doubt that a high velocity Mauser bullet may pass straight through the abdomen, or across the pelvis, penetrating the large and small bowel, without causing a fatal or even very serious result, always provided that certain conditions are present. Of these conditions the

* Read before the Subsection of Proctology of the Section of Surgery, Royal Society of Medicine, November 11th, 1914.

chief are: the bullet must be travelling at a relatively high velocity, the intestines must be more or less empty of fluid contents, and the proper first-aid treatment must be administered. The Boer war taught us that, in the case of penetrating wounds of the abdomen, the best results were obtained by giving complete rest to the intestines for forty-eight hours after the injury, and that with a view to obtaining these conditions treatment should be confined to giving morphine in full doses, withholding all food, and providing as much rest as is compatible with the circumstances. It was found that such treatment allowed the small wounds in the bowel to seal themselves off, and prevented the risk of faecal leakage.

I should here like to express my unqualified admiration of those heroic members of our profession who, often at the risk of their lives, are so ably administering first aid to the wounded behind the firing line. I have now seen a considerable number of our wounded on their arrival in London, and have been much struck by the efficient treatment which they have in most cases received on the field. The good results which, I believe, are being obtained in the treatment of our wounded soldiers depend, above all, upon the efficiency of the medical treatment at the first dressing station.

The following case, which has recently come under my care, affords a good example of the comparative harmlessness of a clean bullet wound involving the bowel:

The patient was shot through the pelvis, the bullet entering at the external abdominal ring on the left side and passing out through the middle of the right buttock. Fortunately, the patient had urinated only a few minutes before he was struck, and consequently the bladder was not injured. The bullet must, however, have passed through the small intestines in the pelvis, and almost certainly through the upper part of the rectum. It emerged close to the sciatic nerve on the right side. The wound was kept aseptic, and the only inconvenience from which the patient has suffered so far has been severe neuritis in the sciatic nerve, with temporary paralysis of some of the muscles. There have been no bowel symptoms at all.

Wounds involving the large bowel are generally complicated by other injuries—such as fracture of the pelvis, injury to the bladder, or damage to the large nerve trunks. One or more of the nerve trunks may be cut, but more commonly they are only concussed. The symptoms in either case are at first the same—namely, motor and sensory paralysis, which is generally only partial. When the nerve is only concussed, the symptoms begin to pass off in a few days, although it may be some weeks before there is complete recovery. I have seen two cases in which the sciatic nerve was concussed at its point of exit from the pelvis. In both cases there was temporary complete loss of movement, followed by rapid recovery, but also by severe neuritis, which lasted for some time. One officer shot through the pelvis had apparently some injury of the sacral plexus. There was acute hyperaesthesia of the skin in the anal region, with resulting pain and tenesmus on defaecation, and retention of urine. These symptoms, however, passed off in a few days.

The most difficult cases are those associated with fracture of the pelvis and a septic wound.

One officer under my care was shot through the pelvis, the bullet entering at the symphysis and emerging close to the sciatic notch, between it and the acetabulum on the right side. The pelvis was extensively cracked, and the wound had become septic before the patient was admitted to the hospital. When the right leg was moved the sensation was rather like that of moving the parts of a broken basin. The bullet in this case had passed close to the rectum, although without injuring the mucous coat. With the finger in the rectum one could easily distinguish the track of the bullet as a firm elastic ridge passing along the left side of the bowel. Fortunately no faecal fistula developed. The case was treated by free drainage with tubes, and fixation of the patient in a Chappel splint.

Healing in such cases is likely, I am afraid, to be very slow, as considerable portions of bone must separate before healing can occur, and this is a long and tedious process, which cannot well be hastened by surgical means.

The worst cases are those in which a shell wound is complicated by a faecal fistula and fracture of the pelvis. The following case is one of the most serious that I have met with yet:

The officer was wounded at the battle of the Aisne by a shrapnel shell; there was very severe haemorrhage on the battlefield, and three days after he was injured a faecal fistula developed. On admission to the hospital there was a large lacerated wound, on the left side above the hip-joint. This led down to a hole about the size of a two-shilling piece (diameter about 2.8 cm.) through the wing of the left ilium, and all faeces were being discharged through this opening. The patient was profoundly septic, and a secondary haemorrhage occurred soon after his admission. As it was impossible to deal with the wound while it was complicated by a faecal fistula, I decided to open the abdomen, and either to perform a temporary colotomy or if possible to close the wound in the bowel. On opening the abdomen I found that the sigmoid flexure had been injured on its mesenteric border, and that it was adherent to the inside of the ilium. I succeeded in separating it, and after trimming up the edges I closed the wound in the bowel with sutures. The abdomen was closed and the wound drained through the hole in the ilium, another opening being made above the ilium in the loin, through which drainage tubes were introduced into a large lacerated wound in the posterior abdominal muscles, where fragments of the shell had buried themselves. After this it was possible to deal properly with the wound. There was no further trouble from the faecal fistula, the bowels acting in the normal manner. The wound was exceedingly septic, as we had to deal with a compound septic fracture of the ilium complicated by *B. coli* infection. A rather alarming secondary haemorrhage from one of the lumbar arteries was, however, the only complication which occurred, and the patient, I am glad to say, is now making an excellent recovery.

In this case I was able to close the wound in the sigmoid successfully, and so to save the patient the discomfort of colotomy. But this must often be impossible, and I believe that, in most cases, the best way to deal with severe wounds, complicated by a faecal fistula, is to perform a temporary transverse colotomy, at the same time thoroughly opening up the wound and providing free drainage. After the wound in the bowel has healed, the colotomy can always be got rid of by a secondary operation. It is obviously impossible to deal satisfactorily with a serious wound of the pelvis if it is complicated by a faecal fistula, and I feel sure that the best treatment in such cases is a temporary colotomy. This must, of course, be done in such a way as to leave a good spur, so that there is no possibility of faeces passing on into the distal bowel. The old-fashioned colotomy would be quite inadequate to deal with such cases, and the best way of performing colotomy in these cases is by means of a glass rod placed under the bowel. The performance of a colotomy will, I think, be the best routine treatment in all cases in which there is a large or serious wound complicated by a faecal fistula into the rectum or pelvic colon.

In the case of a wound which is quite small and is not complicated by fractured bone, but is complicated by faecal leakage, an attempt may, I think, be justifiably made to get it to heal without resorting to a colotomy, provided that the patient has not developed a serious degree of sepsis. If such an attempt is to be made, the rectum should be drained by means of a tube introduced through the anus. Unfortunately, however, few patients can tolerate the presence of a tube through the anus for long, unless the sphincters have been divided. In the case of large lacerated wounds of the bowel, temporary colotomy is indicated as soon as possible. The closing of the colotomy is not a very easy matter, but, after all, this can be postponed until the patient is in the best possible circumstances as regards hospital accommodation and skill.

Finally, I should like to reiterate the view, which I hold most firmly, that wounds involving the bowel should not be treated by immediate operation, even if proper surgical facilities are available. I believe that very few exceptions should be made to this rule, and that the proper treatment is almost invariably complete rest, absence of food, and the administration of morphine; surgical treatment should be reserved till later for the treatment of secondary complications.

LIEUTENANT H. L. HOPKINS, R.A.M.C., who was killed in action, left estate valued at £169. An obituary notice of this officer appeared in the BRITISH MEDICAL JOURNAL of October 3rd.

AT a meeting of the Académie de Médecine on November 10th, Dr. Langlet, professor in the Medical School of Rheims, of which he is director, was elected a member of that distinguished body. Dr. Langlet, who is Mayor of Rheims, showed the greatest courage and devotion to duty during the German occupation and the bombardment of that city. On November 8th, when M. Viviani, the Prime Minister of France, visited Rheims, he bestowed, in the name of the Government and the French nation, the cross of the Legion of Honour on Dr. Langlet.

LEECHES.

By A. E. SHIPLEY, Sc.D., F.R.S.,
MASTER OF CHRIST'S COLLEGE, CAMBRIDGE.

Hardly anything real in the shop but the leeches and *they're* second-hand.—BOB SAWYER.

As Mr. W. A. Harding has pointed out, eleven species of fresh-water leeches occur in these islands. But one of these, the *Hirudo medicinalis*, seems to be vanishing, and yet it is just the one we should cherish and preserve.

There are people who don't like leeches. This is shown by the agitation amongst the travellers in an omnibus, as depicted in *Punch* by Leech, years and years ago, when an old gentleman had upset a bottle of them in their midst. But the medical leech, which is our theme, is really the friend of man and of the soldier, and is a beneficial and not a harmful animal. There are, of course, other leeches in our rivers and in our seas, but of the latter our knowledge is scanty and it is difficult to increase it at present, at any rate in the Channel or in the North Sea, and in any case they have no human interest except the influence they exercise on our fish-food supply, and this is practically negligible.

Zoologically speaking leeches are undoubtedly degenerate Earthworms (*Oligochaeta*), and some very interesting "Zwischenformen"—in spite of the war we may as well employ a useful expression captured from the enemy—have been found in Russia and Siberia, forms which combine many of the characters of the *Oligochaeta* and the *Hirudinea*. Possibly the degeneracy which leeches are said to exhibit is associated with a semi-parasitic habit of life. But a semi-parasitic habit does not apply to all leeches, in fact it applies but to few genera; there are many others, equally degenerate—if degenerate they be—who have no trace of semi-parasitism.

Fig. 1.—*Hirudo medicinalis*; about life size. 1, Mouth; 2, posterior sucker; 3, sensory papillae on the anterior annulus of each segment. The remaining four annuli which make up each true segment are indicated by the markings on the dorsal surface.

A curious thing about leeches is that all the varying genera have the same number of somites or segments, and though some of these segments or somites are masked and fused, when analysed by the number of segments in the embryo, by the number of the nerve ganglia, and so on, leeches seem always to have thirty-four such segments. These do not correspond with the rings or annulations so visible on the outside, but a certain number of these annulations, varying in each species, "go" to each somite, and so constant are these numbers that it would not be very difficult to represent any given species of leech by a mathematical formula.

The known species readily fall into two sub-orders: (1) The *Rhynchobdellae*, which are marine and fresh-water leeches with colourless blood, with no jaws, and with an extensile proboscis; and (2) the *Arhynchobdellae*, which are all fresh-water or terrestrial, with red blood, and generally with jaws. There is no extensile proboscis, and the anterior sucker has a ventral aspect, and is in no way distinct from the body. There are always in this group seventeen pairs of nephridia. We shall have mostly to do with the latter sub-order.

Hirudo medicinalis, the medicinal leech, is found in stagnant waters throughout Europe and the western parts of Asia. It is rather commoner in the southern parts of Europe than in the north. It used to be common enough in England, where it was bred, but already 100 years ago its numbers were diminishing.

In a treatise on the Medicinal Leech, published by J. R. Johnson in the year 1816, he records "formerly the species was very abundant in our island, but from their present scarcity owing to their being more in request among medical men, and to the rapid improvements which have of late years taken place in agriculture, particularly in the draining and cultivation of waste lands, we are obliged to receive a supply from the Continent, chiefly from Bordeaux and Lisbon." In his time he considered that for every native leech employed at least a hundred foreigners were used.

The same scarcity was very apparent to the poet Wordsworth, whose insatiate curiosity is recorded in the following lines in 1802—Wordsworth was always a curious man:

> My question eagerly did I renew,
> "How is it that you live, and what is it you do?"
> He with a smile did then his words repeat:
> And said that, gathering leeches, far and wide
> He travelled; stirring thus about his feet
> The waters of the pools where they abide.
> "Once I could meet with them on every side;
> But they have dwindled long by slow decay;
> Yet still I persevere, and find them where I may."

In Europe, where the leech was once very abundant, it is now chiefly confined to the south and east, and in Germany it is still found in the island of Borkum and in Thuringia—but just now we need not trouble ourselves very much about their distribution in Germany.

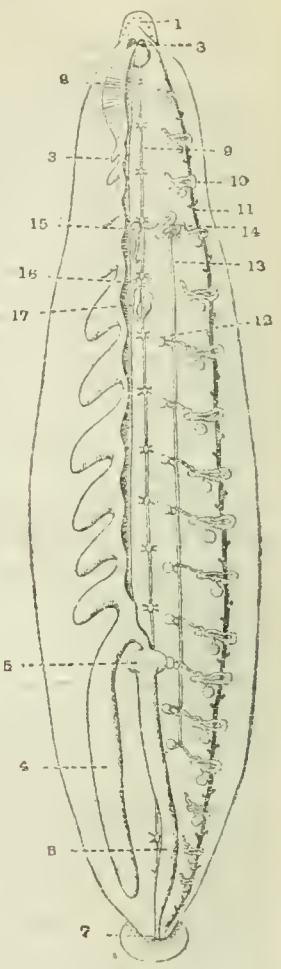

Fig. 2.—View of the internal organs of *Hirudo medicinalis*. On the left side the alimentary canal is shown, but the right half of this organ has been removed to show the excretory and reproductive organs. 1, Head, with eye spots; 2, muscular pharynx; 3, first diverticulum of the crop; 4, eleventh diverticulum of the crop; 5, stomach; 6, rectum; 7, anus; 8, cerebral ganglia; 9, ventral nerve cord; 10, nephridium; 11, lateral blood vessel; 12, testis; 13, vas deferens; 14, prostate; 15, penis; 16, ovary; 17, uterus, a dilatation formed by the conjoined oviducts.

In 1842 leeches were occasionally found in the neighbourhood of Norwich, and there are villagers still living in Heacham in Norfolk who remember the artificial leech-ponds. In the middle of the last century the medicinal leeches "of late years . . . have become scarce." At about the same time it is recorded that they were becoming scarce, though still to be found, in Ireland. Apparently the species is now practically extinct in England, although I know of a naturalist who can still find them in the New Forest, but he won't tell anybody where. If they were getting scarce in the beginning of the nineteenth century they are far scarcer now. *For there is no leech in London.* At least there are only a dozen or two, and they, like those of the firm "Sawyer late Nockem'orf," are second-hand. I have just heard that there is a similar shortage in North America. And yet leeches are wanted by doctors. But Harding tells us that:

Hirudo medicinalis is not the only leech which has been used in phlebotomy. *Hirudo troctina* (Johnson, 1816), occurring in North Africa and in Southern Europe, where it is perhaps an

introduced species, was largely imported at one time for medical uses. . . .

Several other species have been used for blood-letting in different countries. *Limnatis (Poecilobdella granulosa* in India, *Liostoma officinalis* in Mexico, *Hirudo nipponia* in Japan (Whitman), and *Macrobdella decora* in the United States (Verrill), are or have been used in phlebotomy.

Our chief hope seems to lie in India.

Leeches are still used much more than the public are aware. One pharmaceutical chemist in the West End of London tells me he sells between one and two thousand a year, and as they are bought wholesale at about one penny each and sold retail at about sixpence, there is some small profit.

Leeches were well known to the ancients, and it would be easy to quote case after case from the classical medical authorities of their use in fevers and headaches and for many ill-defined swellings. They were frequently used for blood-letting where a cupping-glass was out of the question. With his curious uncritical instinct, Pliny records that the ashes of a leech sprinkled over a hirsute area or formed into a paste with vinegar and applied to the part will remove hair from any region of the body. Leeches were also used by the Greek and Roman physicians in angina accompanied by dyspnoea.

Fig. 3.—Head of a leech, *Hirudo medicinalis*, opened ventrally to show the three teeth and the pharynx *p*, with its muscles; *s*, a nephridium.

Probably the traffic in leeches reached its height in the first half of the nineteenth century. Harding reminds us that in the year 1832 Ebrard records that 57½ million of these annelids were imported into France, and by this time the artificial cultivation of leeches had become a very profitable industry. Although in a small way leeches may have been cultivated in special ponds in Great Britain, the English never undertook the industry on a large scale. In Ireland the natives used to gather the leeches in Lough Mask by sitting on the edge of the pool dangling their legs in the water until the leeches had fastened on them. But the native supply was totally inadequate, and the great majority of leeches used in this country were then imported. In 1842 Brightwell mentions a dealer in Norwich who kept a stock of 5,000 of these annelids in two large tanks. The traffic, as we have seen, was very considerable.

The French merchants recognized five classes as follows:

1. Les filets ou petites Sangsues, qui ont de un à cinq ans;
2. Les petites moyennes, qui ont de cinq à huit ans;
3. Les grosses moyennes, qui ont de huit à douze ans;
4. Les mères Sangsues ou les grosses, qui sont tout à fait adultes;
5. Les Sangsues vaches, dont la taille est enorme.

They also recognized many colour-varieties, of which we need only mention the speckled, or German leech "Sangsues grise medicinalis," with a greenish-yellow ventral surface spotted with black, and the green Hungarian leech with olive-green spotted ventral surface. Both are merely colour-varieties of *Hirudo medicinalis*, which shows great variation in colour, and often forms colour races when bred artificially.

The varying sizes of the five categories mentioned above may be seen by the fact that one thousand of "les filets" weigh from 325 to 500 grams, one thousand of "les petites moyennes" weigh 500 to 700, one thousand of the "grosses moyennes" weigh 700 to 1,300 grams, and one thousand of the "grosses" 1,300 to 2,500 or even to 3,000 grams. Whereas one thousand of "les vaches" weigh up to 10 kilograms, and sometimes even more. To increase their weight the dishonest dealer sometimes gives them a heavy meal just before selling them. They are transported from place to place in casks, half filled with clay and water, or in stone vases full of water. Sometimes they travelled in sacks of strong linen, or even of leather, and these have to be watered from time to time.

One of the modes of moving them was to place them in baskets full of moss or grass soaked in water, but care had to be taken lest they escape. These baskets could not be packed one on another, or the leeches were crushed. In the old days each sack often weighed 20 to 25 kilograms, and travelling thus, suspended in a kind of hammock, *dans une voiture ou fourgon*, from Palota near Pesth, reached Paris in from twelve to fifteen days. They generally travelled via Vienna to Strassburg, where twelve great reservoirs were appropriately placed near the hospital, and here they rested for awhile. Others collected in Syria and Egypt came by ship to Trieste, whence they are sent to Bologna, to Milan, and to Turin, or by water to Marseilles. Marseilles also received directly by sea the leeches from the Levant and Africa, and expedited them to Montpellier, Toulouse, and many other towns in the south.

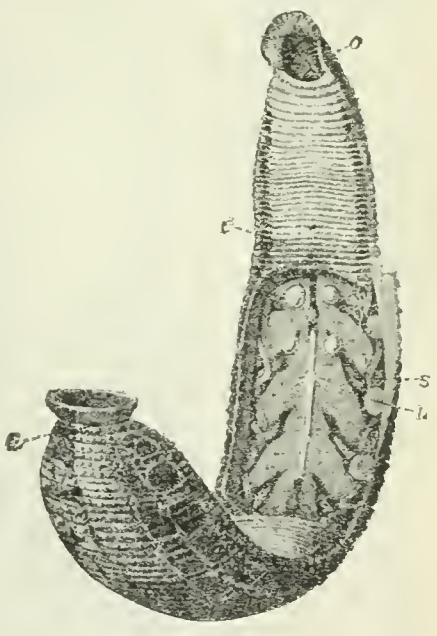

Fig. 4.—*Hirudo medicinalis*. *o*, Anterior sucker covering triradiate mouth; *e* points to an annulus midway between the male and female openings, *s* to a nephridium, *u* to the bladder of the latter; *a*, anus. Four testes and four lateral diverticula of the crop are also shown.

The best time of year for their journey was found to be the spring and autumn. They were more difficult to manage in the summer, and they were all the better for having a rest every now and then, as they used to do at Strassburg. There were days when consignments of from 60,000 to 80,000 used to leave Strassburg for Paris. As in England, however, for the most part the artificial cultivation of leeches has now ceased in France, though half a century ago leech farms were common in Finistère and in the marshes in the neighbourhood of Nantes. There are some years when, if the season was favourable, the peasants carried to market 60,000 a day. Spain and Portugal also furnished them for a long time, but by the middle of last century the Peninsula had become very depleted. But some leeches were still at that period being received from Tuscany and Piedmont. Perhaps the richest fields which still exist are the marshy regions in Hungary. In 1806 a thousand leeches in France fetched 12 to 15 francs, but in 1821 the price had risen to 150 to 200 and even 283 francs. In the latter year they were retailed at 20 to 50 for 4 to 10 sous.

It will be observed that, probably without the knowledge of General Joffre, Field Marshal French, the Grand Duke Nicholas, and even without the knowledge of the German Emperor, the Allies are fighting the Germans on some of the best leech areas in Europe—a point to which we shall return when dealing with the leeches of the Orient. One wonders what the leeches think of it all.

There is no doubt that the medicinal leech is one of the most beautiful of animals. Many of its cousins are uniform and dull in colour—"self-coloured," as the drapers would call them—but the coloration of the medicinal leech could not be improved upon. It is a delicious harmony of browns and greens and blacks and yellows, a beautiful soft symphony of velvety browns and greens and blacks, the markings being repeated on each segment, but not to the extent of a tedious repetition. So beautiful are they that the fastidious ladies who adorned the salons at the height of the leech mania during the beginning of the eighteenth century used to deck their dresses with embroidered leeches, and by repeating the design one after the other constructed a chain of leeches which, as a ribbon, was inserted around the confines of their vesture.

Harding tells us that the dorsal surface of *H. medicinalis* is "usually of a green, richly variegated colour, with orange and black spots, exhibiting an extremely variable pattern, based generally upon three pairs of reddish-brown or yellowish more or less longitudinal stripes, often interrupted by black or sessile spots occurring on the rim of each somite. The ventral surface is more or less green, more or less spotted with black, with a pair of black marginal stripes."

The shape of the medicinal leech, and indeed of other leeches, is difficult to put into figures, as its body is as extensile as the conscience of a politician. The length of *H. medicinalis* in extreme extension ranges from some 100 to 125 mm.; in extreme constriction 30 to 35 mm. The width in the former state would be 8 to 10 mm., and in the latter 15 to 18 mm.

The movements of the medicinal leech are as graceful as its colour is tasteful. When in the water they move like looper-caterpillars (Geometrids), stretching out their anterior sucker, attaching it to some object, and then releasing the posterior sucker they draw the body up towards the mouth. Or, casting loose from all attachment, the leech elongates and at the same time flattens its body until it assumes the shape of a band or short piece of tape, and by a series of the most seductive undulations swims through the water. Kept in an aquarium they are rather apt at times to leave the water and take up a position on the sides of their home an inch or two above the aqueous surface. When outside the water they keep their bodies moist by the excretion of their nephridia and this fluid plays the same part in a leech as the coelomic fluid of an earthworm, which escapes by the earthworm's dorsal pores. There is very little doubt that both these fluids contain some bactericidal toxin which prevents epizootic protozoa and bacteria from settling on their skin, as they do on so many fresh-water crustacea, such as Cyclops, which is a floating aquarium of Ciliata. In fact, leeches, like earth-worms, have a self-respecting, well-groomed external appearance. Like our dear soldiers, they are, so to speak, always clean shaved.

There has been a very widely spread tradition that in their comings and goings in and out of the water, leeches act as weather prophets. The poet Cowper, who throughout his chequered career had always shown but an imperfect sympathy with science, tells us that "leeches in point of the earliest intelligences are worth all the barometers in the world," and Dr. J. Foster mentions that leeches "confined in a glass of water by their motions foretell rain and wind, before which they seem much agitated, particularly before thunder and lightning." Modern opinion, however, prefers the barometer.

The great Chancellor, Lord Erskine, kept a couple of tame leeches, and Sir Samuel Romilly records in one of his decorous letters:

> He told us how that he had got two favourite leeches. He had been blooded by them last autumn when he had been taken dangerously ill at Portsmouth; they had saved his life, and he had brought them with him to town, had ever since kept them in a glass, had himself every day given them fresh water, and had formed a friendship with them. He said he was sure they both knew him, and were grateful to him. He had given them different names, Home and Cline (the names of two celebrated surgeons), their dispositions being quite different. After a good deal of conversation about them, he went himself, brought them out of his library, and placed them in their glass upon the table. It is impossible, however, without the vivacity, the tones, the details, and the gestures of Lord Erskine, to give an adequate idea of this singular scene. He would produce his leeches at consultation under the name of "bottle conjurors," and argue the result of the cause according to the manner in which they swam or crawled.[1]

The medicinal leech lives on the blood of vertebrates or invertebrates, and H. O. Latter records that "cattle, birds, frogs and tadpoles, snails, insects, small soft-bodied crustacea, and worms are all attacked by various species," but the true food of *Hirudo medicinalis* is the blood of vertebrates. The three teeth, which cause the well-known triradiate mark on the skin, are serrated and sharp. The strong sucking pharynx has its wall attached by numerous muscles to the under side of the skin of the leech. By the contraction of these muscles its lumen is enlarged, and by thus creating a vacuum the blood of the host flows in. In the walls of the pharynx and the neighbouring parts are numerous large unicellular glands which secrete an anti-coaguline fluid which prevents the blood of the host clotting, so that even when the leech moves its mouth to another point the triradiate puncture continues to ooze. The same anti-coaguline secretion no doubt prevents the blood coagulating in the enormous crop of the leech in which this meal of blood is stored. Opportunities for a meal presumably occur but seldom, and the leech is the "boa-constrictor" of the invertebrate world. Its interior economy is laid out on the basis of a large and capacious storage and of a very restricted and very slow digestion. The blood sucked into the sucking pharynx passes on to the thin walled crop, which occupies almost all of the space in the animal. This crop is sacculated, having eleven large lateral diverticula on each side. In a fed leech the whole of this crop is swollen with blood, which, as we have said above, is prevented from coagulating by the secretion of numerous unicellular glands in the pharynx and neighbouring parts. The actual area where the digestion takes place is ludicrously small, as shown in 5, Fig. 2. The rectum, which runs from the real seat of assimilation to the opening of the posterior sucker, transmits the undigested food, and there's not much of it.

Fig. 5.—Cocoon of the medicinal leech, and longitudinal and transverse views of the same cut open.

An active leech will draw from one to two drachms of blood, and as much more will flow from the wound when the leech moves, because the blood does not begin to coagulate owing to the secretion of the anti-coagulinate. No scab or clot is formed. The flow of blood can, if necessary, be stimulated by hot fomentations. Sometimes the bleeding is so great that artificial means have to be taken to check it. When leeches are applied to the human integument they are generally first dried in a cloth, and if they will not bite the part required the part should be moistened with sweetened milk or a drop of blood. To remove leeches when replete salt, sugar or snuff sprinkled over the back are used. They may be made to disgorge by placing them in a salt solution of 16 parts salt and 100 of water at 100° F. A full meal is said to last leeches nine months.

Fig. 6.—A *Nephelis* forming its cocoon and withdrawing from it.

Leeches are hermaphrodite, and in some genera the acting male inserts spermatophores or little cases containing spermatozoa anywhere in the skin of the leech that is being fertilized, and the spermatozoa then make their way through the tissues of the body till they arrive at the ovary and there unite with the ova. In the medicinal leech the mating is said to be encouraged by adding fresh water to the vessels in which the leeches are living.

The eggs are laid in capsules or cocoons attached to some water plant or buried in the mud, about twenty-four hours after the leeches have mated. The cocoon is formed as it is in an earthworm, by the secretion of certain glands in the skin forming a secretion which hardens and takes the form of a broad ring, as it were, round the body of the leech. Through this broad ring the body of the leech is with-

drawn and the fertilized eggs are deposited in it, and the two ends close up, but not entirely, for the young leeches eventually make their way into the outer water through one of the remaining pores. Within the cocoon are 6 to 20 ova and these gradually mature and the young hatch out. When they leave the cocoon they are minute, and of the thickness of a pack-thread. More than one cocoon is deposited by each leech, and unless the cocoons are anchored to some submerged object they often rise to the surface of the water and float half submerged, and are apt to be destroyed by water rats, voles, and other enemies of leeches. At times the leeches themselves destroy the cocoons.

Fig. 7.—Cocoons of *Nephelis*, showing the growth of the eggs and the issuing larvae, which, in the lower figure, are leaving the cocoons.

The exact time of the emergence from the cocoon does not seem to be very definitely known, but leeches are long-lived annelids. It is not till their third year that they are of any use for medical purposes, and they are said not to pair until they are six or seven years old. They certainly live twelve or fifteen years. But the fact that they grow up so slowly and live so long shows that it will be difficult to replace the shortage of leeches in Great Britain and Ireland during the present war. This could hardly be done by home culture, for, even if the war lasts three or four years, we have lost the cocoons of the summer of 1914, even if we ever had them.

Leeches have many enemies—water rats, voles, the larvae of the Dytiscus beetle, the larvae of Hydrophylus, the Nepa or water scorpion, the larvae of the dragon-fly, and the adult Dytisens all feed upon them. Many birds also eat leeches, and it is recorded that at one artificial leech farm, where there were 20,000 leeches, they were all eaten up in twenty-four hours by an invasion of ducks. Frogs and newts also devour them, and they are not above eating their own brothers. *Aulostoma* will devour its own species as readily as it will an earthworm.

Fig. 10. A leech farm in the south of France.

Those artificially reared, as is usually the case with animals reared in captivity and probably against their will, are peculiarly liable to disease of various sorts. They not only get disease themselves, but they act as carriers of disease and play the same part to fish which biting insects play to man and other terrestrial animals. They convey to fishes protozoal diseases similar to those that insects convey to man and other warm-blooded vertebrates.

Leech farming used to be a profitable undertaking, but now it has almost fallen into desuetude. Leeches are, however, still cultivated in some parts of the world, and in America. Latter describes a farm, situated at Newton in Long Island, where there is, or was, a leech farm some thirteen acres in extent. The farm consists of oblong ponds of about 1½ acres, each 3 feet deep. The bottom of each pond is covered with clay, and the banks are made of peat. The French writers recommend, as a rule, the use of clay for the banks. The "eggs" (cocoons) are deposited in the peat from June onwards till the weather gets chilly. The adult leeches are fed every six months with fresh blood placed in stout linen bags suspended in the water. A more cruel method of feeding these domesticated leeches is that of driving horses, asses or cattle into the ponds, and this was adopted in the leech farms of France.

Some leeches show a considerable amount of maternal affection. *Glossosiphonia heteroclita*, for instance, carries its eggs about with it, and *Helobdella stagnalis* has its little young larvae attached by their tiny suckers to the mother's back, which they are loath to leave.

Aulostoma gulo, the horse-leech, is, as we have said above, a very ferocious feeder. Exactly why this species is called a *horse*-leech is a matter of speculation; but "horse" used as an adjective seems to imply something large and something rather coarse—for instance, horse-chestnuts, horse-play, horse-sense, and horse-laugh.

Fig. 8.—*Helobdella stagnalis*, with adhering young. Ventral view, magnified. (From Harding.)

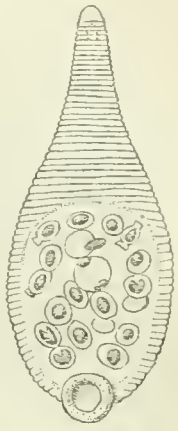

Fig. 9.—*Glossosiphonia heteroclita*, with eggs and emerging embryos. Ventral view. × 4. (From Harding.)

The rapacity of the daughters of the horse-leech is dwelt on in the Bible.[2] I can make no claim to be an authority on exegesis, but I am never quite sure whether these two ladies were not the offspring of the local veterinary surgeon. But *Aulostoma* occurs in Palestine, and its voracity may very well have been known to the Hebrews. I entirely reject the idea that the word indicates some ghost or phantom; that explanation is due to the craven policy of taking refuge in the unknown.

I conclude with a couple of sentences taken from Dr. Phillips's *Materia Medica* on the present use of leeches:

> The special value of leeching is shown in the early stage of local congestion and inflammations, such as arise from injuries, and in orchitis, laryngitis, haemorrhoids, and inflammations of the ear and eye, cerebral congestions, and congestive fixed headache.
>
> Leeches are also of service in a manner less easy to understand in inflammations of deep-seated parts without direct vascular connexion with the surface—for example, in hepatitis, pleuritis, and pericarditis, as well as in pneumonia, peritonitis, and, according to some observers, in meningitis. In all these disorders, however, they are very much less used than formerly—in the larger hospitals, for instance, when at one time they cost many hundred pounds annually, a few dozens in the year would represent the total employed.[3]

M. EMILE COMBES, formerly Prime Minister of France, and still a member of the French Senate, has founded a hospital for the wounded in Pons, of which he is Mayor. M. Combes, who is a doctor of medicine and has had a large experience as a practitioner, is acting as chief physician to the hospital and spends all his time in ministering to the patients.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A RAPID METHOD OF VACCINATING AGAINST SMALL-POX.

THE time-honoured method of carrying out vaccination against small-pox is neither rapid nor economical nor elegant. While such a method may pass unchallenged in ordinary practice, yet at this particular time, when the process has to be applied to thousands and perhaps millions of persons, some technique more economical of time and material is certainly a desideratum.

The method described below is one that has given great satisfaction in its practical application.

Requirements.

A few miniature test tubes, measuring about 4 cm. long by 0.6 cm. diameter. These can be bought, but they are easily made out of glass tubing.

A few simple capillary pipettes, such as are used in the preparation of vaccines or in the estimation of the opsonic index. The capillary portion of these tubes should be of rather large bore.

Rubber teats of 1 c.cm. capacity to fit the barrels of these pipettes.

A glass-cutting knife.

A small lump of plasticine.

The first step is to transfer the lymph from the tubes in which it is ordinarily supplied by the Local Government Board into one of the miniature test tubes. This transference is effected as follows: Five or six of the lymph tubes are held between the finger and thumb of the left hand in a row—palisade fashion. A sharp glass-cutting knife is drawn across these tubes about ½ in. from their ends. A sharp tap with the knife distally administered while the middle portions of the tubes are firmly held will cause their ends to fly off, leaving the tubes open at that end. The tubes are now reversed in the fingers, and their other ends opened in a similar manner. Both ends being thus opened, the contents are expelled into one of the miniature test tubes by blowing them out sharply with the mouth. With a little practice the whole of these operations can be completed in a few seconds. Another set of five or six lymph tubes are emptied into the test tube in the same way, and the operation is repeated until the test tube has been filled; when it is fixed in an upright position on a pedestal of plasticine.

The persons to be vaccinated are placed in a line with their arms bared and their skins suitably prepared. One of the simple capillary pipettes fitted with a teat is sterilized in the flame and then filled with lymph drawn up by suction from the supply in the test tube. The operator then walks along the line of patients and places a drop of lymph from the pipette on one or more places on the arm of each. When ten or twelve persons have been thus treated the pipette is laid aside and scarification through the drops is carried out, the instrument being sterilized between each case by passage through the flame of a spirit lamp. The assistance of one or more colleagues in this part of the work will enable a very high speed to be attained.

The advantages of this method from the economical point of view appear to be very great. It has been found that three doctors working in co-operation were by its means enabled with the greatest ease to vaccinate (with two marks on each arm) nearly one thousand men in about five hours. The same number of operators using the time-honoured method were able with difficulty to get through about one-third of that number in the same period of time. The economy of material was also most marked. The only lymph lost in the process is the small amount which remains adherent to the sides of the test tubes and pipettes; and experiment has shown in point of fact that a saving of some 30 to 40 per cent. of lymph is effected by the use of the method.

W. E. M. ARMSTRONG, M.A., M.D.Dub.,
Bacteriologist to the Central London Ophthalmic Hospital.

SUDDEN DEATH (RUPTURE OF AORTA).

I THINK the suddenness of the occurrence, and the fact that I was in the act of examining the patient, makes the following case of interest. It occurred in my consulting-rooms at a large firm to which I am medical officer.

The patient, a gentleman aged 59, well known to me for the last eighteen years, walked up one flight of stairs to my waiting-room. On answering his knock I found him standing outside with his hat on, having come in on his way to lunch. He complained of some pain between the shoulder blades. The light in the room was poor owing to scaffolding outside, but at first sight there was nothing to indicate that there was anything serious the matter, and he walked into an anteroom as if in his ordinary health.

He took a chair before the window, and leaned forward to place his hat on the sill, and sat back with arms extended on the arms of the chair. I put my finger on his pulse, and asked him if he had had similar pain or indigestion, receiving a negative answer to both questions, when the pulse ceased entirely. It was of fair volume, and I counted eight beats. He was then unconscious, having uttered no sound whatever after answering my questions. I undid his collar and tie preparatory to laying him on the floor, but found it difficult owing to spasm of the neck muscles (there was none of other parts). The spasm passed off immediately and his head fell forward, life being obviously extinct. This was well within five minutes of his knocking at my door.

He was a muscular, healthy looking man of medium stature, thick build, and florid complexion, and weighed about 14½ st. His work was chiefly out of doors, and, as far as I know, he was of very regular habits, and enjoyed the full confidence and esteem of his employers. He had once consulted me for a cold in 1906, and his wife stated he had enjoyed excellent health, and had never complained to her.

I concluded he died from ruptured aneurysm or heart failure, and my diagnosis leaned to the former on account of the thoracic pain and sudden stoppage of the pulse. I had in mind a sudden rupture of the descending thoracic aorta. These opinions I communicated to the coroner on acquainting him of the death. On *post-mortem* examination the pericardium was found distended with blood, the pleural cavities being quite free. The heart weighed 23 oz. In the neighbourhood of the aortic opening the tissues were discoloured with blood pigment. Beyond the muscular hypertrophy there appeared no marked changes in the heart itself.

There was a fusiform dilatation of the ascending part of the aorta, the artery itself being very soft and easily torn, and presenting numerous small atheromatous patches. Above the semilunar valves, in close proximity to the opening of the left coronary artery, was an opening, much the same size as the coronary artery, where the vessel had given way. The liver, spleen, and kidney were soft and friable, but neither they nor the brain presented any other gross changes.

London, S.W. F. D. BENNETT.

A CASE OF COAL-GAS POISONING: RECOVERY.

I WAS called to see a woman, aged 40, at about 1 p.m. on October 13th, and was told by her sister that at 7.30 a.m. she was found on the floor of her bedroom with her head sunk on her breast unconscious, the window being shut, the gas turned on, and the room full of gas.

She was put to bed and restoratives were applied, unfortunately with too much ardour, as they blistered the feet and lower half of the legs. She did not vomit till those about her endeavoured to introduce mustard and water into her stomach, when some of the supper she had taken the night before was returned. They could not, however, rouse her.

I found the patient lying with her face turned to the right and the pupils moderately dilated and fixed. She was breathing stertorously: the limbs were flaccid; the pulse was irregular (90), and the temperature 97.8°. Urine had been passed in bed.

At 6.30 p.m. the temperature was 99.4°, the pulse 120, and the respirations 38. The arms were resistant to flexion, the legs were flaccid, with exaggerated knee-jerks, and the Babinski reflex was well marked on the right, but not well defined on the left side. She was still unconscious.

At 10 p.m. the temperature was 100°, the pulse 100, and the respirations 28. The stertorous breathing had been replaced by natural breathing.

At 10.20 next morning the pulse was 90 and respirations 24. She could be wakened to take fluid nourishment, and I was told at 9.30 p.m. that she had taken it regularly, though drowsy in the intervals.

On October 15th the improvement was marked. The patient was said by her sister to be hysterical and apt to be sleepless. The treatment was simply open windows till consciousness returned, and then hot coffee, milk, and soups.

It is impossible to state how long the unlighted gas had been turned on, as the patient had no recollection of the occurrence. There was nothing of the nature of convulsions.

Corsterphine. ANDREW FLEMING, M.D.Edin.

Reports of Societies.

THE ROYAL SOCIETY.

Thursday, November 12th, 1914.

Sir WILLIAM CROOKES, O.M., President, in the Chair.

The Fixation of Arsenic by the Brain after Intravenous Injections of Salvarsan.

A PAPER on this subject by J. MCINTOSH and P. FILDES, was communicated by Professor W. BULLOCH, F.R.S.; the investigators found that after intravenous injections of salvarsan and neo-salvarsan in man and animals no arsenic could be found in the brain. This phenomenon was not due to lack of affinity between the brain and the drugs, but to an inability on the part of the drugs to penetrate into the substance of the brain. Fixation of arsenic by the brain occurred as readily as by the liver, as shown by experiments *in vitro* and the toxic effects of intrathecal injections. Penetration of neo-salvarsan into the brain could not be obtained even by frequently repeated intravenous injections.

Syngamy in the Trypanosomes.

In a paper by H. M. WOODCOCK and G. LAPAGE, communicated by Professor S. J. HICKSON, F.R.S., it was stated the flagellate *Helkesimastix faecicola* (n.g., n.sp.) occurred in goat dung and sheep dung; it was a "passenger," being carried through the alimentary canal in an encysted state. It had been cultivated in various media, and the entire course of the life cycle in life, from excystation to encystment, observed. The active form was remarkable in possessing only a single flagellum, which corresponded to the trailing flagellum of a *Bodo* or a *Cercomonas (Cercobodo)*. The flagellum was closely applied to the body, but no definite membrane was developed. Syngamy was very general, and the early behaviour of a conjugating pair was remarkable, owing to the very plastic nature of the cytoplasm. Encystment was invariably the direct sequel to syngamy. Intensive culture of this flagellate had resulted in the production of a strain which was no longer able to undergo true syngamy and to form cysts. The existence of this "aconjugating" strain was now dependent on further transferences to fresh medium. This experimental observation had an important bearing on the question of syngamy in the trypanosomes and allied parasitic flagellates. These had in all probability lost the power to conjugate. The conditions of life in their case might be compared to those of the above-mentioned intensive culture of *Helkesimastix*. The authors considered that the loss of syngamy in such forms was due to a surfeit of nutrition, together with the removal of an excess of toxic products from the environment.

The Antagonistic Action of Carbon Dioxide and Adrenalin on the Heart.

In a paper communicated by Professor E. H. STARLING, F.R.S., S. W. PATTERSON stated that carbon dioxide alone depressed all the functions of the isolated heart. Adrenalin, besides dilating the coronary vessels, had a specific action in increasing the rate and strength of ventricular contraction. The effect of carbon dioxide and adrenalin combined was still to allow of more rapid and stronger contraction and rapid relaxation, and also to lengthen the diastolic period. Thus, greater filling of the heart took place, and the heart was in a better condition for putting out a maximal output.

ROYAL SOCIETY OF MEDICINE.

SUBSECTION OF PROCTOLOGY.

AT a meeting on November 11th, Mr. SWINFORD EDWARDS in the chair, Mr. ASLETT BALDWIN showed a woman aged 76½ years, upon whom he had performed an *Abdomino-perineal excision of the rectum*. Mr. IVOR BACK described an obscure case of *Oedema of the sigmoid mesocolon*, in which at operation the sigmoid lay in a groove in the intensely oedematous mesocolon. He invited suggestions as to the pathology of the condition. Mr. SAMPSON HANDLEY showed a case of *Apparently inoperable carcinoma of the rectum which became operable under radium treatment*. The patient had remained free from recurrence up to the present, a period of about a year. A paper was read by Mr. LOCKHART MUMMERY on injury to the bowel from shell and bullet wounds; it is published at p. 914. A discussion followed, in which the PRESIDENT and others joined.

LARYNGOLOGICAL SECTION.

AT a meeting on Friday, November 6th, Mr. HERBERT TILLEY exhibited microscopic specimens from five cases of *Aspergillosis of the antrum* seen by him during the past ten years. All the patients were females, and the chief symptoms were sneezing, marked nasal obstruction, severe pain in the cheek, sometimes causing insomnia; slight purulent nasal discharge, and great oedema and opacity on transillumination. The cases had been readily cured by operation, and there had been no recurrence. Mr. SHATTOCK said that first he believed that the disease was a mucinoid endothelioma such as might be found in the abdominal cavity. Later it seemed probable that it was caused by a mycelium differing from that of thrush, sporothrix, etc. No cultivations of the secretion had been made. Remarks were also made by Mr. DOUGLAS HARMER, Dr. HILL, and Dr. PATERSON. Dr. HILL showed *Skiagrams of frontal sinuses* operated on by Good's method. Dr. WATSON-WILLIAMS thought one could not be too enthusiastic about the results obtained by Good's method, even if a free opening could be made. He referred to the possibility of making a perforation through the partition into the frontal sinus on the opposite side in cases where there was a large frontal cell on both sides. Dr. DUNDAS GRANT considered that the rasp was extremely useful for endonasal treatment of the frontal sinus. Dr. IRWIN MOORE showed a case of *Abnormal overgrowth of nose* (bulbous) in a child aged 2 years. The child was born with the condition simulating rhinophyma. On cutting into it it was found to consist of fine fibrous tissue with no definite capsule, and adherent to the skin and cartilages. Treatment by diathermy was advised. Dr. Irwin Moore also showed a case of *Stricture of the oesophagus* illustrating the benefits of Hill's tube. The patient had worn the tube for eight weeks. During that time he had gained weight, was much more comfortable, and was able to do his daily work. Dr. HILL pointed out that his tube was not so well tolerated in cases suffering from cancer of the cricoid region. Dr. COUPER POTTER exhibited sections from a case of *Perithelioma of the nasopharynx*. Dr. DAN MCKENZIE showed a case of *Abscess of the frontal lobe of the brain* secondary to old-standing frontal sinus suppuration. The abscess had been drained through the frontal cavity and the patient made a good recovery. Sir STCLAIR THOMSON described a case in which the abscess in the brain was on the opposite side to the sinus. He also showed a man of 69 whom he thought to be suffering from *Early intrinsic epithelioma of the larynx*, with free movement of the cord. Dr. ELPHICK exhibited a *Haemostatic guillotine* with which he had found it possible to remove the tonsils with very little loss of blood. Dr. LAMBERT LACK showed a patient whom he had treated for extensive *Papilloma of the trachea*. Dr. GRANT and Dr. HILL said that they had seen similar cases. Mr. HUNTER TOD showed two cases of *Epithelioma of the tonsil* to illustrate the results obtained by diathermy. Dr. HILL and Mr. HARMER expressed the

opinion that diathermy was preferable to the knife in all such cases; with the former method excellent results could be obtained and the dangers of operation had disappeared.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

AT a meeting on November 13th, Dr. HERBERT JONES, President, in the chair, Dr. W. J. HOWARTH introduced a discussion on the *Marking of meat*. He defined the expression as meaning the marking of the carcass either by certificate, label, seal, tag, stamp or brand, or by some other method, the mark indicating that the meat had been examined and approved as fit for human consumption and giving information as to the date and place of inspection. One object of meat inspection was to ascertain its nutritive value, for it should not only be sound but should possess a minimum nutritive value. Only at the place of slaughter, where every organ was available for inspection, could a really reliable decision be arrived at as to the suitability or otherwise of a carcass for human consumption. Owing to the lack of uniformity in methods of meat inspection and the deficient facilities for inspection which were known to exist, a compulsory system of meat marking might not be practicable at the present time though an optional scheme under adequate control might be adopted. The Local Government Board should officially approve a system of meat marking and should decide upon the nature of the mark and the manner of marking, safeguarding the use of the mark only by recognized authorities. The power to use the mark should only be granted where the Board was satisfied that there was adequate and efficient inspection. Dr. VEITCH CLARKE said that if private slaughter-houses were abolished, it would not be difficult to introduce a system of marking. Dr. W. A. BOND considered that compulsory marking was desirable. Dr. GEORGE BUCHAN disapproved of any optional system which might press hardly upon honest butchers. The PRESIDENT was in favour of compulsory marking for the whole country but feared that any optional scheme would be impracticable.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

AT the opening meeting, held on October 20th, Dr. MANKNELL delivered his presidential address, taking as his subject *Vaccination*. After tracing the history of small-pox from the earliest times, he then went on to show by means of statistics how it became apparent that revaccination was necessary. The pathology of small-pox was then discussed in detail, and also its relation to cow-pox and vaccinia. Many statistics were given showing the influence of vaccination upon the severity of the attacks, the modification of the disease, and the alteration of the age incidence. As regards the last, before vaccination small-pox was a disease of infancy. Vaccination had raised the age incidence in two ways: (1) By reducing the number of persons in any given population who were susceptible to small-pox it reduced the chances of epidemics and lengthened the interval between them. (2) By rendering those once vaccinated insusceptible to small-pox for a period of years it raised the age incidence in such to a higher range than among the unvaccinated. The marked influence of vaccination on the fatality of small-pox was also shown by numerous figures, and particular stress was laid on the fact that insufficient vaccination was a great evil, statistics showing that in patients with only one scar the ravage of the disease was far more severe than in those patients with three or four scars. The influence of sanitation on small-pox was discussed.

ASSOCIATION OF REGISTERED MEDICAL WOMEN.

AT a meeting held on November 10th, Dr. JANE WALKER in the chair, Dr. JESSIE CAMPBELL showed: (1) A girl, aged 6, with *Congenital heart disease and congenital dislocation of the hip;* (2) a girl, aged 10, with *Diabetes insipidus;* she had a harsh, dry skin, and a highly-coloured face; she perspired very little, and passed on an average ten pints of urine in twenty-four hours. Dr. E. H. LEPPER showed a woman aged 27, now eight months pregnant, who was the subject of *Spastic paralysis of the right arm and leg, weakness of the right side of the face, and double mitral disease*, with signs of breaking-down cardiac compensation. Three years ago, when nearly at full time with her second child, she suddenly fell down unconscious, and was found to be paralysed on the right side; she remained in hospital a month, and the confinement was normal. She had previously had rheumatic fever four times. Dr. MARY SCHARLIEB read notes and showed specimens as follows: (1) Mrs. K., aged 72, complained of pain in the region of the bladder. An *x*-ray examination appeared to indicate a stone 1½ in. long in the lower part of the ureter. At the operation the mass proved to be a calcified gland outside the ureter, about the size of a pigeon's egg. It consisted of a hard shell enclosing fluid. (2) Miss W., aged 61, who had had *Epithelioma of the vulva*. One patch, the size of a florin, was found on the left labium, and a smaller mass on the right labium; the perineum was occupied by a non-ulcerated mass of growth the size of a walnut. The whole vulva was removed, and large masses of glands were removed from each groin. There was no recurrence for four years, when the patient died from an intercurrent disease. (3) *Uterine cancer:* Miss K., aged 53, suffered from sudden profuse haemorrhage. A small piece of tissue found in the vagina showed cancerous growth; the uterus was scarcely enlarged. Panhysterectomy was performed, and the exterior of the uterus was normal. A large new growth, of the adenoma malignum type, protruded into the cavity from the posterior wall. At the present time, three years later, the patient was in perfect health. Dr. JANE WALKER described a case of *Vincent's angina*, and showed a microscopic slide with well-marked spirilla and non-Gram-staining bacilli. The fauces became greatly swollen, there was difficulty in swallowing, and regurgitation of food through the nose; there was little rise of temperature, but considerable feeling of illness. The patient, an elderly man, recovered in the course of a week. Dr. ALICE BENHAM gave her experiences of *A month spent in Antwerp with the British Field Hospital*. The staff consisted of four women and three men doctors, and fourteen trained nurses; later they were joined by several more nurses and by a surgeon from a London hospital. A large school was converted into a hospital with about 150 beds, and a few days after their arrival 140 wounded were admitted in one day. Many were collapsed, but revived after subcutaneous injection of normal saline and hypodermic injections of pituitary extract. Several required immediate operation—for instance, four abdominal cases, several depressed fractures of the skull, one excision of eye—and all did very well. In a case of bullet wound of the abdomen, the stomach projected through the wound; it was put back, and a good recovery was made. Bullets were left in position if they were causing no harm; the puncture wounds were painted with tinct. iodi, or if septic were treated with H_2O_2. One bullet had passed through the eye and hard palate and out below the chin; the eye was excised, and the patient recovered. Many of the compound fractures were plated, and probably stood early removal better on this account. Several cases required tracheotomy on account of surgical emphysema following bullet wounds; in one case food passed out through the tracheotomy tube, and the patient was fed by means of a stomach tube. There were no cases of tetanus, and only two doubtful cases of typhoid. Septic cases were nursed on the verandah. Fourteen hours after bombardment commenced the patients were removed in seven motor ambulances to Ghent. One died on the way, and one after arrival; the others stood the journey well. A few days later they had to evacuate Ghent, and were brought to England. The members of the medical staff went in turns to the fighting line, where the chief work required was stopping haemorrhage, administering morphine, applying splints, and dressing wounds. During the month about 400 wounded were treated in the hospital—forty English, and the rest Belgians.

Mrs. SCHARLIEB proposed, and Mrs. BERRY seconded, a vote of condolence with Dr. Ethel Vaughan-Sawyer on the death of her husband, Captain Vaughan-Sawyer, who was shot while charging at the head of his regiment.

Reviews.

PHOTOGRAPHY IN COLOURS.

After a careful perusal of the second edition of *Photography in Colours*[1] by Dr. G. Lindsay Johnson, it must be admitted that his contention that the entire work has been carefully revised, and as far as possible brought up to date, and that in fact it may be considered as a new book, is substantiated. A new chapter dealing with the theory of light and colour has been added, which presumably is held to justify the description of the work as a textbook for amateurs and students of physics, whereas the first edition was called a textbook for amateurs. It is probable that students of physics would desire a more extended treatment of the subject, which must of necessity suffer from condensation in such a work as this.

The chapter on the eye compared with a camera is admirably illustrated, most interesting from a physiological point of view, and would go far to convince one that the author's theory of retinal image formation, although contrary to generally accepted views, is correct. The remarkable similarity (commented on) between the coloured granules of the autochrome screen and the coloured oil globules in the retina of certain birds and reptiles is not the least interesting feature of the argument.

The new and important chapter on "uto-color" printing by the bleach-out process will be welcomed by all photographers in colour, who ardently desire an effective method of printing from their colour transparencies. The author's summing up of the results hitherto obtained, however, to the effect that "very effective and faithful copies on paper are reputed to have been obtained in Europe" will be looked upon as only partially encouraging.

It is a pleasure to read the chapters dealing with the various single-plate colour processes, including the new Paget plate, which receives appropriate notice in this edition. All are illustrated and described, and their respective advantages and drawbacks fairly appraised. Full instructions for the practical working of each process are not wanting.

The directions for the after-treatment of a photographic plate, including the remedying of defects—in fact, the details of photographic work in general—leave nothing to be desired, and show that the author is a master of his subject, while the marked superiority of the specimen plates over those illustrated in the first edition show that he, too, has profited by experience in the interim. The all-important question of exposure, accuracy in which is an indispensable element of success in colour photography, receives extended consideration in this edition. A new chapter deals with three-plate colour photography, of which the best known process is the Sanger-Shepherd.

Minor "errata" have crept into the text—for example, on page 12, we think "air cells" should read "hair cells"; on page 189, "35 grams of tannin" should be "3.5 grams"; on page 207 there is confusion, if not error, in the comparison of the respective exposures for the different plates; and on page 124 "put a smear of *green* on the aperture" seems to be an error. But these are minor defects. The book is a useful and well-nigh indispensable guide to the amateur photographer in colours, and we may express the hope that in the next edition, which will assuredly be soon required in connexion with an art which is developing so rapidly, Dr. Lindsay Johnson will see his way to add many new chapters on the applicability of photography in colours to various arts and sciences, including that of medicine.

MOLECULAR PHYSICS.

It is common knowledge that much experimental work has been done in recent years on the subject of electrons, and that it has led to considerable modifications and extensions of the atomic theory; but probably few save those engaged in such work have any clear view of the actual results so far attained. Any one possessing some general knowledge of science and wishing to gain a general acquaintance with this latest extension of the field of knowledge will find Mr. J. A. Crowther's *Molecular Physics*[2] an excellent little book for the purpose. As demonstrator in physics at the Cavendish Laboratory, the author has been closely associated with the work of Sir J. J. Thomson, and has himself taken part in the researches. A chapter is devoted to the important new method for the detection of minute traces of gaseous elements, in which an electric discharge is passed through the extremely rarefied gas in a vacuum tube, and the positive particles are subjected at the same time to a magnetic and an electric field, and then allowed to strike a photographic plate; parabolic lines are traced on the latter by the positive particles, from which all the constituents of the gas can be detected and their molecular weights at once calculated. The method is far more delicate than spectroscopic analysis; one-hundredth of a cubic centimetre of a gas can be examined, and as little as four-millionths of a cubic centimetre of helium has been detected when working with this quantity of argon. But the main results of the work, of course, do not lie in the introduction of new practical methods, but in the explanations of the facts of valency, of thermal and electric conductivity, etc., which the ascertained facts about electrons now supply.

NOTES ON BOOKS.

Few men, perhaps, have better opportunities for studying the psychology of the crowd than the popular lecturer or preacher, the secret of whose success depends very largely upon the skill with which he plays upon the emotions of that complex being, Pope's "many-headed monster of the pit." Mr. E. Tennyson Smith, the well-known temperance advocate, is familiar with audiences in every quarter of the English-speaking world, and not the least interesting part of his recently-published memoirs is the chapter devoted to the description of the different characteristics of British, Colonial, and American crowds, and their methods of signifying approval or dislike. The author of *From Memory's Storehouse*,[3] moreover, possesses a sense of humour, a quality invaluable to all who have to deal with large numbers of men, and his book is full of good stories, many of which are directed against himself. We have neither the space nor the inclination to discuss Mr. Tennyson Smith's opinions, or the means he employs to promulgate them; but his sincerity cannot be questioned, and forms the most pleasing feature of this interesting record of his labours amongst all sorts and conditions of men and in every kind of surroundings.

THE ORIGIN AND DEVELOPMENT OF THE RED CROSS.

(Continued from p. 883.)

Russia.

In the Crimean war the medical service of the Russian Army broke down even more completely than that of the British. A vivid description of the state of the military hospitals and the unfortunate inmates is given by Tolstoi in *Sebastopol*. The Grand Duchess Helena Paulowna of Russia, widow of the Grand Duke Michael, organized a system of aid for the wounded. Accompanied by three hundred Russian-Greek nuns—Sisters of the Exaltation of the Cross—she went to the seat of war. They tended the wounded, not only in the hospitals of Sebastopol and Simpheropol and in the ambulances, but in the immediate neighbourhood of the batteries under the fire of both musketry and artillery. The want of unity of action and practical direction, however, was a serious obstacle to the efficiency of this voluntary service. The women of Russia strove to send comforts to the army, but owing to defective organization much of the material intended for the troops never reached its destination.

A number of bales of lint prepared by their hands were sent from St. Petersburg to the Crimea, but they went astray; and while the want of them was urgently felt by the surgeons, they found their way to be used up at some paper mills. It is said that the terrible scenes which met the eyes of the Czar, during

[2] *Molecular Physics* (*Textbooks of Chemical Research and Engineering*). By J. A. Crowther, M.A. London: J. and A. Churchill. 1914. Cr. 8vo, pp. 175; 29 figures. 3s. 6d. net.)

[3] *From Memory's Storehouse: Incidents of My Life Work.* A record of thirty-five years' personal experiences as a preacher and temperance advocate in a world-wide parish. By E. Tennyson Smith. With sixteen illustrations. Published by S. W. Partridge and Co., Ltd., Old Bailey, London. 1914. (Pp. 256. Price 3s. 6d.)

his visit to the hospitals of the Crimea in the first dreadful winter of the campaign, did much to induce him to conclude peace when Sebastopol fell.[1]

When Henri Dunant was attending the Congress of Statistics at Berlin in 1863 he was invited to dine by the Prussian Minister of the Exterior, Count Enlenburg, Honorary President of the Congress. During the course of the dinner M. de Semenoff, Court Councillor of Russia, told Dunant that the Grand Duchess Helena Paulowna had been the first to realize his aims. After reading his book (*Souvenir de Solférino*) she had sent a number of Sisters of the Exaltation of the Cross to Poland to nurse the sick and wounded, Poles and Russians, without distinction of nationality. The Grand Duchess was represented at the Conference of Geneva by her private librarian and secretary, M. E. Essakoff. The Grand Duke Constantine Nicolaievitch, brother of the Czar Alexander II, sent his aide-de-camp, Captain Kireiew. The Grand Duchess Helena and the Grand Duchess Olga, daughters of the Czar Nicholas I, sent messages to Dunant expressing interest in his work.

Professor Bernard Pares, who some time ago was appointed official representative of the press of the Russian Army, gave an account of the Russian Red Cross in the *Pall Mall Gazette* of October 17th. It is a permanent organization which controls the ambulance work in the actual sphere of operations. It has first-aid stations behind the firing line and field hospitals for further aid and for the seriously wounded and those not fit to be moved. The nurses are called Sisters of Charity, but they are not nuns. They take no religious vow, but give their lives to nursing without any salary beyond food, clothes, and lodging. According to Millicent H. Morrison, in the *Windsor Magazine* for November, there are about five of these sisterhoods in St. Petersburg, seven in Moscow, and others in all Government towns. They are attached to large hospitals in which the sisters are trained for two or three years before they are allowed to wear the Red Cross emblem. A certain proportion get married, and if left widows may take up private nursing; but even the well-to-do, if ill at home, prefer to have a Sister of Charity. In case of war the nuns of such convents as the Martha Maria at Moscow, founded some years ago by the Grand Duchess Serge, sister of the Czarina, and who include among their sisterhood a princess and other aristocratic ladies, offer their services.

Professor Pares says Red Cross work has a strong attraction for public men in Russia. The second in command of the whole organization in the present war is Mr. Homyakov, who as president of the Duma came to England in 1909. He is now organizing the reception of the wounded at Kieff. In Warsaw the hospital work has been organized by Mr. A. Cuchkov, who succeeded Mr. Homyakov as President of the Duma. For the care of wounded Europeans, Russia was before the war divided in two by a line passing roughly through Petrograd, Moscow, and Harkov, the half furthest removed from the fighting line being set aside for the systematic treatment of the patients. It was found that the ultimate care of the wounded was too great a task for the already overburdened departments of the Government. In the Japanese war there had been created a League of County Councils (Zemstva), which had done good service under Prince G. Lvov and Mr. Cuchkov. The Government asked the League to take over the whole care of the wounded in the interior. The Zemstva assigned £600,000 to their own individual work and an equal sum to the League as a whole. Large contributions were made by the public. There was also founded a League of Town Councils, with the chief municipal authorities of Petrograd and Moscow at its head. All these bodies were co-ordinated by a central Red Cross Committee in Moscow, with deputies from the official Red Cross, the League of Nobles, the Zemstva League, the League of Towns, and the merchant organizations. The contributions of the fund to the Moscow Exchange last month amounted to £1,200,000.

The military or official Red Cross has clearing points for the dispatch of the wounded, and besides its own hospital trains fifty are being equipped by the Zemstva League. At Moscow the trains will run into a special hospital station organized by the Town League which here takes up the work. The number of wounded to be provided for is 750,000, a figure which, as Professor Pares says, of itself shows what the war means to the Russian people. Temporary provision of all kinds has been made, and the central committee assigns a destination to each patient in Moscow or in one of the eastern provinces. It inquires of the various organizations what beds they have ready, and the Zemstva and Town Leagues make the further arrangements with the provincial Zemstva and various town councils.

The Russian Government has authorized the Red Cross to import medicines and surgical instruments free of duty during the war.

(To be continued.)

THE CHEMICAL CONSTITUTION OF CERTAIN PROPRIETARY DRUGS.

SEVERAL Panel Committees have found it desirable to issue for the guidance of panel practitioners a list of proprietary medicines and their equivalents, and other Committees no doubt have the matter under consideration. It has been thought, therefore, that it would be convenient to publish a list of some of these drugs with annotations.

The information in the notes may also be of interest to others, including consultants, who are not engaged in practice under the Insurance Act.

The contractions *B.P.* with date is used for the *British Pharmacopoeia*, and *B.P.C.* is used for the *British Pharmaceutical Codex*, 1911.

Acetozone.

This is a name applied to benzoyl-acetyl-peroxide, formerly known as benzozone. It is put forward as a germicide. The trade name Acetozone indicates the product of Messrs. Parke, Davis, and Co.

Acidol.

This is a name given to the hydrochloride of betaine, which is a base found in the sugar beet and many other plants. The principal use of the salt is as a source of hydrochloric acid, which it liberates in the stomach. The trade name Acidol indicates the product of Aktiengesellschaft für Anilin-fabrikation, Berlin.

Acitrin.

This name is applied to the ethyl ester of phenylcinchoninic acid. It is put forward as a goat specific. The trade name Acitrin indicates the product of Farbenfabriken vorm. Fried. Bayer, Elberfeld, Germany.

Acoine.

This is a name applied to the local anaesthetic di-para-anisyl-monophenetyl-guanidine hydrochloride, for which the *B.P.C.* gives the short name guanicaine. The trade name Acoine indicates the product of Chem. Fabrik von Heyden, Radebeul, near Dresden.

Acopyrine.

A name given to the acetylsalicylate of antipyrine. The trade name Acopyrine indicates the product of Chem. Fabrik von Heyden, Radebeul, near Dresden.

Actol.

A name applied to silver lactate, used as an antiseptic and disinfectant. The trade name Actol indicates the product of E. Merck, Darmstadt.

Adalin.

This is a name applied to bromdiethyl-acetylcarbamide. It is put forward as a sedative and hypnotic. The trade name Adalin indicates the product of Farbenfabriken vorm. Fried. Bayer, Elberfeld, Germany.

Afridol Soap.

A soap containing 4 per cent. of afridol, which is a name applied to sodium-hydroxymercuric tolnylate. The soap is said to have a germicidal action. The trade name Afridol Soap indicates the product of Farbenfabriken vorm. Fried. Bayer, Elberfeld, Germany.

Agathin.

A name applied to salicyl-alpha-methyl-phenyl-hydrazone. It was introduced as an antineuralgic and anti-

rheumatic. The trade name Agathin indicates the product of Meister, Lucius, and Brüning, Hoechst a/Main, Germany.

Agurin.

This is a name applied to a mixture or weak combination of theobromine sodium and sodium acetate, which is put forward as a diuretic. The trade name Agurin indicates the product of Farbenfabriken vorm. Fried. Bayer, Elberfeld, Germany.

Airol.

A name applied to bismuth oxyiodogallate. The trade name Airol indicates the product of Hoffmann-La Roche Chemical Works, Basle, Switzerland.

Albargin.

This is a name given to silver gelatose. The trade name Albargin indicates the product of Meister, Lucius, and Brüning, Hoechst a/Main, Germany.

Albulactin.

A name given to milk albumin. The trade name Albulactin indicates the product of J. A. von Wülfing, Berlin.

Alphol.

This is a name given to alphanaphthol salicylate, which is said to have similar properties to those of the ordinary naphthol salicylate, which is the beta-compound. The trade name Alphol indicates the product of E. Merck, Darmstadt.

Alumnol.

This name is applied to aluminium beta-naphthol-sulphonate, of which the *B.P.C.* name is aluminium naphthol-sulphonate. The trade name Alumnol indicates the product of Meister, Lucius, and Brüning, Hoechst a/Main, Germany.

Alypin.

This is a name given to benzoyl-tetramethyl-diamino-ethyl-dimethyl-carbinol hydrochloride, for which the *B.P.C.* gives the name amydricaine hydrochloride. It is put forward as a local anaesthetic. The trade name Alypin indicates the product of Farbenfabriken vorm. Fried. Bayer, Elberfeld, Germany.

Anaesthesine.

A name applied to para-amino-benzoic ethyl-ester, for which the *B.P.C.* name is benzocaine. The trade name Anaesthesine indicates the product of Meister, Lucius, and Brüning, Hoechst a/Main, Germany.

Anthrasol.

This is a name applied to coal tar which has been purified and decolorized. The trade name Anthrasol indicates the product of Knoll and Co., Ludwigshafen-on-Rhine, Germany.

Antileprol.

This is a name applied to purified chaulmoogra oil, consisting of the ethyl-ester of chaulmoogric acid. It is put forward for the treatment of leprosy. The trade name Antileprol indicates the product of Farbenfabriken vorm. Fried. Bayer, Elberfeld, Germany.

Antipyrin.

In the *B.P.*, 1898, the substance phenazone is included and a footnote states that it is commonly known as antipyrin.

"Antipyrin," as a branded article, is made by Messrs. Meister, Lucius, and Brüning, Hoechst a/Main, Germany. Phenazone may be made by any one.

Aponal.

A name given to tertiary amyl carbamate, put forward as a soporific. The trade name Aponal indicates the product of Zimmer and Co., Frankfort.

Argonin.

Described as silver casein. The trade name Argonin indicates the product of Meister, Lucius, and Brüning, Hoechst a/Main.

Argyrol.

A name applied to an organic compound of silver which is stated to contain 30 per cent. of metallic silver; referred to in the *B.P.C.* as silver vitellin. The trade name Argyrol indicates the product of A. C. Barnes Co., Philadelphia.

Aristol.

This is a name given to dithymol-diiodide, the *B.P.C.* name for which is thymol iodide. The trade name Aristol indicates the product of Farbenfabriken vorm. Fried. Bayer, Elberfeld, Germany.

Arrhenal.

This is a name applied to disodium methylarsinate, given in the *B.P.C.* as synonymous with sodium meth-arsenite; another trade name for the same substance is Arsinyl. The trade name Arrhenal indicates the product of Adrian et Cie., Paris.

Arsacetin.

A name given to sodium acetyl para-aminophenyl arsonate. The trade name Arsacetin indicates the product of Meister, Lucius, and Brüning, Hoechst a/Main, Germany.

Arsan.

Described as "arsen-glidine," and intended for use in place of arsenious acid in chronic skin diseases. The trade name Arsan indicates the product of Dr. V. Klopfer, Dresden-Leubnitz, Germany.

Arsycodile.

A name applied to sodium cacodylate. The trade name Arsycodile indicates the product of E. Bloch, Basle, Switzerland.

Arterenol Hydrochloride

A name given to the hydrochloride of dioxyphenyl-ethanolamine. It is put forward as a substitute for preparations of the suprarenal gland. The trade name Arterenol Hydrochloride indicates the product of Meister, Lucius, and Brüning, Hoechst a/Main.

Asaprol.

This is a name applied to calcium betanaphthol-alpha-monosulphonate, which is given in the *B.P.C.* as calcium naphthol sulphonate, synonym calcinaphthol. The trade name Asaprol indicates the product of Fabrik Chem. Produkte, Mülhausen, Alsace.

Aseptol.

Described as a 33 per cent. solution of ortho-oxyphenyl-sulphonic acid, or sozolic acid. The trade name Aseptol indicates the product of E. Merck, Darmstadt.

Aspirin.

Acetyl-salicylic acid appears in the *B.P.*, 1914, under that name, and also in the *B.P.C.* which states that other names by which the substance is known are acetysal, acetosalin, aletodin, saletin, salaretin, xaxa, etc.

Aspirin is made by Farbenfabriken vorm. F. Bayer and Co., Elberfeld, Germany. Acetysal is made by Messrs. Fritz-Petzoldt and Süss, Vienna. Xaxa is made by Messrs. Burroughs, Wellcome and Co., London.

Asurol.

A name given to a compound of sodium amino-oxybutyrate and mercury salicylate. It is stated to contain 40 per cent. of metallic mercury. The trade name Asurol indicates the product of Farbenfabriken vorm. Fried. Bayer, Elberfeld, Germany.

Atophan.

A name given to phenyl-quinolin-carboxylic-acid. It is put forward for the treatment of gout and rheumatism. The trade name Atophan indicates the product of E. Schering, Berlin.

Atoxyl.

This is a name applied to sodium aminophenylarsonate, for which the *B.P.C.* gives the name sodium aminarsonate. Other trade names for this body are Arsamin and Soamin, and it is sometimes termed Sodium Arsanilate. The trade name Atoxyl indicates the product of Vereinigte Chem. Werke, Charlottenburg, Germany. Soamin is made by Messrs. Burroughs, Wellcome and Co., London.

British Medical Journal.

SATURDAY, NOVEMBER 28TH, 1914.

THE EFFECT OF WAR ON MEDICAL PROGRESS.

THE maxim that medical science knows no national boundaries has been rudely shaken by the present war. In all the belligerent countries medical investigators have left their laboratories in response to the call to minister to the wounded. Already several have fallen on the field of honour. We need only mention Captain H. S. Ranken, who was a member of the Sudan Sleeping Sickness Commission and gained the remarkable double distinction of the French decoration of the Legion of Honour and the Victoria Cross, although he died before either was actually bestowed. Many teachers have also been called away from their work. The publication of the results of medical research and observation has necessarily suffered, and though our British journals have been issued regularly, it has been in a shrunken condition. Many of the Continental periodicals ceased to appear for two or three months, and although there are signs of revival, most of the leading French journals are still in a state of suspended animation. The Belgian journals have shared in the temporary extinction of their afflicted country. From Germany naturally we receive none, but we may gather how the war has affected them from the following passage in the *New York Medical Journal* of October 10th: "The few medical journals received from Germany early in September contained a good deal concerning the war, mostly in the form of official notices and comments on the significance of various passages in the laws bearing on mobilization and military service; their size has generally been diminished."

The discontinuance of the exchange of intellectual produce is a most serious obstacle to progress. The practical humanity of the medical practitioner, shown in so many ways, is indeed a relief to the horrors of a conflict in which angry nations use every means of destruction to exterminate each other. But the blast of war that blows in our ears makes the still small voice of science inaudible. All the medical congresses which were to have been held in Germany during the course of next year have been postponed. The fourth Italian Antituberculosis Congress and another on mental disease, both fixed for October, did not meet. The organizing committee of the International Medical Congress, which was to have met at Munich in 1917, has suspended its work of preparation. The *Deutsche medizinische Wochenschrift* observes that probably the feelings of hatred and rancour aroused by the war will not have died out by that time, so that it would be difficult to welcome representatives of the nations now fighting each other with anything like cordiality. That difficulty could, of course, be got over by leaving Germany—which by that time may have learnt that her "culture" is not an indispensable factor in progress—to sulk apart, and arrange for the holding of the congress elsewhere.

Already the Fatherland seems to be preparing for isolation from the medical world. Just as, many years ago, the Kaiser laid his ban on French words in table menus, so now German scientists have, it is announced, embarked on a campaign against all words of English, French, or Russian origin. The ingenuity of Teutonic philologists will be taxed to discover words of native growth; if such cannot be found, the Latin and Greek dictionaries will be ransacked. A committee is to be formed for the purpose of framing a purely German medical nomenclature. The vocabulary will assuredly, like the word "poltic" according to that distinguished Teuton (as we assume him to have been) Count Smorltork, "surprise by himself." It is not at all unlikely that such an attempt will be made, for German "intellectuals" have shown themselves to be like Habakkuk, according to Voltaire, *capables de tout*. Nor need the rest of the world grieve too much if they show their mingled vanity and spite in this way. It will only help to stop the tendency to what has been called Pan-Germanism in medicine, which has within the past few years been visible in America and in this country. On this subject we may quote from a shrewd observer, Dr. H. P. Greeley, who from his own observation wrote in the *Boston Medical and Surgical Journal* of September 10th: "There are certain tendencies in the evolution of medicine as a pure science as it is developed in Germany which are contributing to the increase of charlatanism. These tendencies are worthy of analysis to us who are so rapidly Germanizing our methods, as a warning, so that we may escape like evils. A medical school has two important duties—one to medical science, the other to the public; one encouraging and promoting medical education and scientific progress, the other supplying to the public well-trained practitioners. The latter function is really the greater, for out of every graduating class 90 per cent. are practitioners, and less than 10 per cent. are scientists, and of these probably only one or two are so eminently fitted for scientific work as ever to accomplish much. The conditions in Germany are reversed. There, there are ninety physicians dawdling with science to every ten doing practice. Of this ninety, fully 75 per cent. are wasting their time as far as permanent results are concerned. There are thousands of investigators producing thousands of publications yearly, only a very few of which stand the test of time. The keen competition promotes such a desire for priority that the merest hints of new sidelights and theories are hastened into print, only to die ignominiously because of their shallow soil. The very strength of the teaching of theory and the weakness of clinical teaching in Germany produces a few scientists, a large number of pseudo-scientists, and few good practitioners." Dr. Greeley says that in Germany the scientific side is over-developed while the human side is greatly neglected. German physicians do not know how to treat the individual and recognize only the disease. The comfort of the patient or the recognition of his personality is not considered. Even in the new institutions, splendid as they are in a material sense, it is easy to see from the spirit manifested by the staff that the improved conditions were not for the comfort of the patients. These conditions are, Dr. Greeley believes, the natural result of German medical standards.

Does war offer to medicine any compensation for the harm it does in hindering the advance of science? Ambroise Paré learned by a fortunate accident in his first campaign that the universal belief held at that time (1537) that gunshot wounds "partake of venenosity by reason of the

powder" was unfounded, and that they did not therefore need to be treated with boiling oil. The experience of the present war has already taught surgeons a good deal about the proper application of Listerian principles to treatment of septic wounds. Something may also be learnt as to the efficacy of antityphoid inoculations and as to the prevention of dysentery and other diseases which have in former wars decimated armies. But such advances in knowledge as have been mentioned, valuable as they are in themselves, have comparatively little application to ordinary life. In other directions war brings progress in the healing art almost to a standstill.

GERMAN PROFESSORS AND BRITISH HONOURS.

The animosity against this country so violently expressed in the German lay press is reflected in the medical journals. A surgeon who has lately left Berlin, where he has had ample opportunities of studying the psychology of the German medical profession, states that he is totally incapable of giving a true picture of the Teutonic feelings towards England. From a psychological point of view these feelings were, he says, almost the most interesting feature of his visit to Berlin. The "mass action" of the intense hatred of England almost carried him off his feet, and its suggestive force often made it hard for him to keep cool. A reconciliation, even a compromise, between these two nations seemed to him to be impossible.

In the British Medical Journal of October 31st reference was made to the amazing "declaration by German professors and men of science" issued some time before, and bearing the signatures, among many others, of von Behring, Paul Ehrlich, Czerny, August Bier, Haeckel, and Wilhelm Wundt. One passage in the declaration was to the following effect: "Those of us who have received marks of distinction from English universities, academies, and societies of scholars do renounce, as a matter of national feeling, all such honours and the rights attached to them." This renunciation, which the professors evidently regard at once as an act of noble self-sacrifice and a sort of pontifical anathema against this country, leaves us quite unimpressed. We will leave the appreciation of its character to the professors' own countrymen. Professor Max Verworn, of Bonn, writing in the *Berliner Tageblatt*, describes it as childish and unworthy of German men of science. We agree, but feel compelled to add that it is of a piece with the childish displays of temper which from day to day make "cultured" Germany more ridiculous to people with any sense of humour. Professors Waldeyer, Martin, and Orth have also protested against the foolish conduct of their colleagues. But while the others object to the war being carried into the fields of intellectual activity in which people of all countries should work together for progress, Orth has an eye to business. He points out that after the war there will in time come peace, and the enemy of to-day may be the ally of to-morrow. Therefore, we gather, he thinks it impolitic to continue to sow seeds of lasting hatred. Referring to some suggestion or movement to prevent foreigners learning the advances made in science by Germany by denying young men of other nations admission to her universities, Orth sagely says that such a measure would be made futile by the fact that the reading of German books and journals could not be prevented. Besides, do not the foreign students bring cash to Germany? Orth sees this with a clearness hardly to have been expected from a man belonging to a nation which professes to despise us as a people that only looks for financial gain. Having uttered these wise words of warning to his countrymen the worthy professor thinks it prudent to clear himself of any suspicion of not being a thoroughgoing patriot, for he says that in giving laboratory appointments and facilities Germans must remember that they themselves are their nearest neighbours—that, in the words of the homely proverb, they "maun gie their ain fish-guts to their ain sea maws." With the frankness that makes the German character so attractive he adds that during the seventy-three semesters he has been director of university institutes "never has a foreigner been preferred to a German, never has a post in a laboratory been given to a foreigner until all the demands of Germans were satisfied." Professor Orth, in fact, would not keep German science a *mare clausum*, because that would not be good business. He would admit the foreigner to feed on the crumbs which fall from the rich table of German knowledge, but he would make him pay well for the privilege. In the German manifesto reference is made to our "contemptible envy of Germany's economic success." We envy that success as little as we deny it; but we cannot help wondering why we are called a nation of shopkeepers when the leaders of German culture seek to provide in so barefaced a way against a loss of foreign custom.

And why does another German man of science, the astronomer Wilhelm Foerster, who has denounced the spirit of the manifesto, speak of the policy of this country as one "which in its essential features is still purely selfish"? Is it not notorious that England, of which it has been said, by poetic licence, that it "never did, nor never shall, lie at the proud foot of a conqueror," is more the prey of foreign, especially German, invaders than any other country on the earth? The stress of life has been made more grievous for our struggling poor by the undesirable alien; German clerks and waiters have taken the bread out of the mouths of our own; in schools, universities, museums, and laboratories foreigners have secured positions to which natives might be thought to have the first claim. Well might Professor Mommsen exclaim, when he heard of the appointment of a fellow-countryman to a chair in an English university, "Hef you no hompogs of your own?"

THE WAR AND THE DEMAND FOR LOCUMTENENTS.

In discussing last week the duty of the profession to the army the opinion was expressed that young men without ties ought to put their names upon the waiting list kept by the Director-General of the Army Medical Service at the War Office. The reason given for this opinion was that though the names, at present on the list, of men fit to undertake the arduous work of service in the field numbered about a thousand, that would not be sufficient to meet the calls which will certainly be made before very long. But we also expressed the view that medical men settled in practice in this country, who have wives and children or others dependent upon them, and who are not in a position to make adequate provision for their families or to disregard the possible loss of their connexion in practice, were not at present called upon to volunteer. We have received some inquiries as to the facilities with which locumtenents can be obtained. The position at present seems to be that, while there have been more vacancies for locumtenents than usual since the

commencement of the war, there has been no great difficulty in filling them where the engagement desired has been short. Many such engagements have been accepted by medical men who are waiting until they are actually called up for service. As the number so called up increases, the medical men available to act as locumtenents must be very considerably decreased. We understand that it is more difficult to obtain locumtenents for long engagements, more especially for an indefinite period, such as the duration of the war. Already, we understand, many medical men who have been called up have been unable to arrange for substitutes who would carry on the work during their absence the duration of which is indefinite. As has frequently been stated, the members of the medical profession in most populous districts have taken measures as far as possible to diminish the loss to individual practitioners and the inconvenience to the public, due to the fact that so many members of the profession are employed with troops abroad or at home. There seems reason to hope that in such districts the difficulty may be met, to a large extent at any rate; but it is otherwise in country districts, and practitioners in such districts ought to have the first call upon such locumtenents as may continue to be available. It is a question whether practitioners in these districts are justified in offering their services in a military capacity until the supply from the more populous areas has been exhausted. We do not disguise from ourselves the difficulties of the position, which will become much greater owing to the immense increase in the military forces in the country which is now taking place. In reply to a question by Mr. Hinds, the Under Secretary of State for War stated, on November 23rd, that the new army will be provided with medical arrangements on the same basis as the Expeditionary Force, that there has been no difficulty in securing the services of a sufficient number of fully qualified medical men, and that it was not anticipated that there would be any shortage in the near future. The immediate difficulties, he said, had been met partly by giving temporary commissions in the Royal Army Medical Corps, and partly by employing civil practitioners locally. Mr. Tennant did not give any clear indication of the arrangements which are being made to provide a medical service for the units of the new army, which within a few months at most will be warned for service abroad. The battalions and brigades will require a medical staff, and though the difficulty may be met at the moment by employing civil practitioners, this will not be a permanent solution. This fact emphasizes all the more the need for the increase of the list kept by the Director-General at the War Office.

VITAL STATISTICS OF THE WAR.

AT the meeting of the Advisory Council of Medical Research, under the provisions of the Insurance Act, held on November 17th, the plans put forward by the Medical Research Committee were generally approved. We hope to be able to print the scheme in detail in our next issue, but we are informed that the arrangements will not be complete for securing the final Ministerial sanction until the end of this week. We understand, however, that the Army Council has approved of the Medical Research Committee giving laboratory help to military hospitals where it is required, and that considerable assistance is already being afforded in different places. The Army Council has also approved of the proposal whereby the whole of the work of dealing with the statistical records of the war shall be undertaken by the statistical staff of the Medical Research Committee, and arrangements for getting the work in hand are now being made. We are glad to know that the military authorities have expressed their willingness to do whatever is possible to facilitate the uniform taking and proper collection of records under the advice of the staff which has to deal with it. As this represents a large undertaking on behalf of the Medical Research Committee the work will occupy a considerable period of time, and will involve substantial expenditure; but there is good reason to hope that the result will be to provide us with complete, well arranged, scientific, and thoroughly reliable statistics.

SMALL BODIES AND BIG SOULS.

WE are glad to see, from the answer given to a question in the House of Commons, that the War Office has set aside the absurd standard of height so far as regards an East Lancashire battalion, and has given permission for a "midget" battalion to be raised of men from the height of 5 ft. to 5 ft. 3 in. We believe another 30,000 recruits might have been secured in the last few weeks if the standard of height had been revised, and the present limitation to East Lancashire is difficult to understand. Not a little is to be said in favour of short infantry. Short men occupy less room in transport; they find cover more easily, and offer a smaller mark to bullets and shrapnel; they are better sheltered in trenches, and require to dig less deep trenches to protect themselves. It takes less khaki to clothe them, and less leather to boot them. The army blanket covers them more amply, and they need less food than tall thin men to keep up their body heat and maintain their marching energy; a smaller service transport, therefore, suffices for their needs. Many short men are tough and wiry, and when sturdily built like the north country miner, are strong and capable of the greatest endurance. The managers of factories where skilled work is done know that the small man is often a better workman than the big one, who is apt to be clumsy. The bony levers moved by their muscles are lighter and shorter, the nervous connexions between the sense organ and muscles of the limbs are shorter, and the speed and balance of the movements executed perhaps better. Those who stand the rigors of cold climates are not always big men, and the sailor, like the wind-swept tree on the coast, may be a short man. Warmth and easy conditions of life rather tend to the development of tall men. The cavalry and artilleryman requires to be big and powerful, but as to those who burrow in the trenches, how can it matter whether they are 4 ft. 9 in. or 5 ft. 6 in.? We are not out for a show and a parade, but to win—a war of sieges and attrition. To hang on with tenacity, and use the rifle with skill, to keep warm and healthy in body, and courageous in spirit—these are the qualities, and the short men have them. The brave soul of the little man in the face of the giant is proverbial. The Japanese soldier has earned the highest reputation for endurance, courage, and fighting capacity, and his average height is between 5 ft. and 5 ft. 3 in. There is waiting the call to enlist an army corps of bantam weights—the sturdy, short-limbed men of the north and the short men of the south and of Wales. The difference is in part due to difference of race, but valour and worth must not be valued by the length of a femur.

CERTIFICATES FROM NON-PANEL DOCTORS FOR INSURANCE ACT PURPOSES.

IT will be remembered that in the case of Heard *v.* Pickthorne it was ruled that an approved society was not entitled to refuse to accept the certificate of a non-panel doctor as evidence of incapacity of one of its members, simply because the certificate was not that of a practitioner on the panel. The profession generally assumed that this case had settled the question, and that approved societies were not likely to raise this particular difficulty again. However, within the past few weeks the attention of the Association was drawn by a practitioner not on the panel to a case in which a patient of his had been refused sickness benefit because the medical certificate was not signed by his panel doctor. In this case the patient went to the non-panel doctor because he

did not feel well enough to go so far as the surgery of his panel doctor, and preferred to continue under his care. The Medical Secretary at once brought the case before the approved society in question, and asked if it intended to persist in refusing to pay the member his sickness benefit unless he could produce a certificate from his panel doctor. It was hinted, not obscurely, in the letter to the society that the Association was so determined to uphold the right of all registered practitioners to have their certificates accepted for all legal purposes, that if necessary the Association would be prepared to take the case further. On being reported to the Insurance Act Committee, the Medical Secretary's action was fully endorsed, and that Committee agreed, if it were found to be necessary, to take legal steps to enforce the right which it was thought that the case of Heard *v.* Pickthorne had firmly established. Fortunately, the society in question has seen the error of its ways, and has informed the Association that instructions have been given to the secretaries of all its branches to accept medical certificates from registered practitioners whether they are on the panel or not. This is a very satisfactory ending to the case, but it shows how important it is that practitioners should be on the watch for attempts to discriminate between the certificates of registered medical practitioners and to undermine the right of insured patients to place themselves under the care of any practitioner they like without risk of forfeiting the benefits of the Insurance Act.

MEDICAL INSURANCE AGENCY.

An interim report on the progress of the Medical Insurance Agency for the nine months ending September 30th was presented by the Chairman, Dr. G. E. Haslip, to a meeting of the Committee on November 5th. The Agency had, he stated, not escaped the effects of the war, the receipts for new life and motor-car business especially having been adversely affected, although the commission on life business effected antecedent to the war had very nearly doubled during the period under review. On the other hand, a substantial business in war risks had been negotiated, and had helped to make good any shrinkage in other classes of business. The surplus shown by the auditor's figures would, the Chairman said, justify the distribution to medical charities of the sum of 300 guineas for the current year, and it was resolved accordingly to make contributions to the Royal Medical Benevolent Fund (100 guineas), the Royal Medical Benevolent Fund Guild (50 guineas), Epsom College Benevolent Fund (75 guineas), the Royal Medical Benevolent Fund Society of Ireland (25 guineas), the *Lancet* Editor's Fund (15 guineas), the Royal St. Anne's School (10 guineas), and, provisionally, to the fund for distressed Belgian medical men (25 guineas). The subscription to the Royal St. Anne's School was made with the specific object of assisting daughters of medical men in obtaining election to that school. Altogether the agency since it was instituted has voted a sum of £1,075 to medical charities, and, in addition, it has returned to insurers a sum of over £3,000. The agency is prepared to undertake to arrange policies for insurances of all kinds, and from the experience already gained it is able to advise medical men as to the best form of policies, and as to their satisfactory adjustment to meet the varying needs of individuals. Further particulars can be obtained on application to the Agent and Secretary, Medical Insurance Agency, care of British Medical Association, 429, Strand, London, W.C. The Committee of Management consists of Dr. G. E. Haslip (Chairman), Dr. Alfred Cox, Mr. Guy Elliston, Sir Frederic Hewitt, M.V.O., Dr. H. A. Latimer, Dr. J. A. Macdonald, Dr. D. J. Mackintosh, M.V.O., Mr. H. Betham Robinson, M.S., Dr. S. Squire Sprigge and Dr. Dawson Williams.

THE TEETH OF RECRUITS.

The distribution of prizes to the successful students of the Royal Dental Hospital took place on November 17th. The Dean, in his report, stated that of the senior and junior members seven were serving as lieutenants and captains in the Royal Army Medical Corps, and one as a captain of the East Surrey Regiment. Of the present students, twenty-seven had joined the army in various capacities; some held commissions, some were in the medical service, and others held a not less honourable post of privates in line regiments. Of past students very many were serving with the navy and army. Information was not available regarding all, but it was known that twenty-two were serving in various ways. Those who before the war belonged to Territorial regiments had to throw up their practices and give their whole time to military work. The sacrifice this entailed was not, he thought, fully realized. He felt that whatever claim the wives of officers in the regular army might have on the nation, the wives of officers in the Territorial Force in all justice should receive allowances from the Government whilst their husbands were absent on service. Experience in dealing with the teeth of recruits and of men newly enlisted showed that, for the most part, the condition of the teeth was appalling, and, although dentists certainly did not intend to support the idea that recruits with bad teeth should be refused, yet the teeth of the recruits should have attention. He understood that up to the present the War Office had made no attempt to deal with the problem. If, as was suggested, this army was to take the field in six months, the time was all too short to deal with the matter. When he read accounts of men serving in the trenches filled with water, and knowing as he did from seeing men who had returned from the front the condition of their teeth, he was horrified to think that their miseries should be aggravated by allowing them to go to the front with their mouths full of decayed teeth, exposed nerves, and septic roots. Mr. Arthur Hood, Chairman of the Managing Committee, after presenting the prizes, delivered an address, in the course of which he referred to the part the hospital had played in undertaking the work of looking after the teeth of sailors, soldiers, and recruits sent there by military authorities. Already 917 men had attended, many requiring considerable work done. In addition to help in this work given by old students the school was also indebted to them for having voluntarily undertaken in many instances to provide dentures free of charge.

THE RED CROSS AND TUBERCULOSIS IN GERMANY.

The Red Cross is doing useful work in Germany, quite apart from its activities in connexion with the wounded. It has, for example, made extensive preparations for the treatment of soldiers who may develop pulmonary tuberculosis. At the outbreak of the war Germany had 149 sanatoriums for adults and 32 for children. There were also 108 hospitals, containing 20,000 beds, for weak and scrofulous children. In addition, there were 1,819 dispensaries and 115 forest homes (*Walderholungsanstalten*), and 19 large institutions, with 1,496 beds, for cases of tuberculosis of the bones and joints. Further, there were several institutions for the treatment of lupus. When the war broke out most of the physicians and nurses attached to these hospitals volunteered for active service, and the hospitals being temporarily closed were put at the service of the army medical staff. The risks entailed by this precipitate abandonment of work among the tuberculous were, however, soon realized. Very few indeed of the hospitals were suited for the treatment of the wounded, and their services have been retained by the Government only for cases of tuberculosis among

soldiers. In the remaining hospitals work has again been resumed on the old lines for the benefit of the civil population.

REPLY OF FRENCH UNIVERSITIES TO GERMAN PROFESSORS.

WE have already dealt, in the BRITISH MEDICAL JOURNAL of October 31st, with the proclamation *urbi et orbi*, in which ninety-three of the leading "intellectuals" of Germany sought to throw the blame for the terrible war which is now raging on other countries, particularly England, alleged for some obscure reason to be jealous of Teutonic "culture." Reference was made to the dignified reply to this extraordinary manifestation of what Herbert Spencer would have called the "bias of patriotism" raised to the degree of frenzy made by a number of representative men of learning in Great Britain. We have received a copy of an equally dignified and crushing reply addressed by all the universities of France—with the exception of that of Lille, whose corporate activity is for the time in abeyance—to the universities of neutral countries. The following is the text of the document: "The German universities have protested against the charges brought against their country on account of the war. The French universities will confine themselves to submitting to you the following questions. Who wished for this war? Who, during the short period of respite allowed for deliberation by the Powers of Europe, strove to find bases of conciliation? Who, on the contrary, refused all those successively proposed by England, Russia, France, and Italy? Who, at the very moment when the dispute appeared to be subsiding, declared war as if the favourable opportunity had been waited and watched for? Who violated the neutrality of Belgium after having guaranteed it? Who declared, with regard to this, that neutrality is a word, that 'treaties are scraps of paper,' and that in time of war 'one does what one can'? Who regards as null and void the international conventions by which the signatory Powers agreed not to use in the conduct of war any form of force constituting 'barbarity' or 'perfidy,' and to respect historical monuments, places of worship, buildings dedicated to science, art, and charity, except in cases in which the enemy, first diverting them from their purpose, uses them for military operations? In what conditions was the University of Louvain destroyed? In what circumstances was the Cathedral of Rheims burnt? In what circumstances were incendiary bombs thrown on Nôtre-Dame de Paris? The reply to these questions is to be found in facts alone. Already you may consult documents published by the Chancelleries, the results of inquiries made by neutrals, the testimonies found in German notebooks, the testimonies of the ruins of Belgium and the ruins of France. These are our proofs. Against them it is not enough, as the representatives of German science and art have done, to utter denials based only on an imperative 'word of honour.' Nor is it enough, as the German universities do, to say, 'You know our teaching; it cannot have formed a nation of barbarians.' We know what has been the value of that teaching. But we also know that, breaking with the traditions of the Germany of Leibnitz, Kant and Goethe, German thought has declared itself at one with, tributary and subject to Prussian militarism, and that carried away by this, it claims universal domination. Of this pretension proofs abound. Only the other day a master of the University of Leipzig wrote: 'It is on our shoulders that the future fate of culture in Europe rests.' The French universities, for their part, continue to believe that civilization is the work not of one people alone, but of all peoples; that the intellectual and moral wealth of humanity is created by the natural variety and the necessary independence of all national characters. For their part, like the allied armies, they defend the liberty of the world." A bishop once declared in the House of Lords that he would rather see England free than sober. We think that, after the way in which the results of German thought have during the past few months revealed themselves to a wondering world, civilized nations will consider themselves fortunate in escaping the "culture" that Germany would impose upon them.

ELECTRO-PHYSIOLOGY OF PLANTS.

PROFESSOR J. C. BOSE of Presidency College, Calcutta, recently described to a general meeting of the Royal Society of Medicine experiments designed by him which show "that the phenomena of contractile response in the plant reveal characteristics similar to those of the animal; that even ordinary plants exhibit under excitement a responsive electrical variation of the same sign as in the animal; that excitatory impulses are transmitted through certain conducting tissues of the plant in a manner precisely similar to the nervous impulse in the animal; and that there are rhythmic tissues in the plant which react under various external conditions in a manner just the same as those of the animal." In the telegraph plant (*Desmodium gyrans*) the small lateral leaflets exhibit automatic pulsations, and Professor Bose finds many points of similarity between these pulsations and those of the frog's heart. For example, the pulsation of each is arrested in diastole by the action of lactic acid and in systole by the action of dilute caustic soda. Ether brings the contraction of both to a stop. The pulsations of both increase in amplitude and diminish in frequency on lowering the temperature. The anode depresses and the kathode exalts the contraction of either. The author's ingenious methods of recording plant response were demonstrated. They are described in his book, *Comparative Electro-Physiology*, published in 1907. By electrical methods of investigation he claims to show that "every plant, and each organ of every plant, is sensitive and exhibits the state of excitement by electromotive variation, of galvanometric negativity—that is to say, an electrical change identically the same as that induced in an excited animal tissue." Working with the sensitive plant (*Mimosa*), Professor Bose finds, as with nerve muscle preparation, that a single stimulus, by itself ineffective, becomes effective upon repetition; that cold abolishes, while warmth increases and accelerates the response; that within limits the amount of work performed increases with the cold; that the latent period is prolonged by fatigue, and shortened by warmth and a strong stimulus. He finds, too, that Mimosa has a diurnal variation of excitability. "It has been hitherto supposed that in Mimosa the impulse caused by irritation is merely hydro-mechanical, and quite different from the nervous impulse in the animal." Against this view Professor Bose puts those results obtained by him. He says the impulse can be initiated by the polar action of an electrical current without mechanical disturbance. The velocity of transmission can be varied by physiological means—for example, cold. The impulse can be arrested by electrotonic block or local application of a poison. He concludes that "the plant is not a mere mass of vegetative growth, but that its every fibre is instinct with sensibility." "We find it," he says, "answering to outside stimuli, the responsive twitches increasing with the strength of the blow that impinges on it. We are able to record the throbbings of its pulsating life, and find these wax and wane according to the life conditions of the plant, and cease with the death of the organism. We have seen how the whole plant is made one by connecting threads, so that the tremor of excitation initiated in one place courses through the whole; and how this nervous impulse, as in man, can be accelerated or arrested under the several actions of drugs and poisons."

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

The thirty-second expedition of the school, consisting of Professor Warrington Yorke (Walter Myers Professor of Parasitology) and Dr. B. Blacklock (Director of the Runcorn Research Laboratory), left Liverpool on November 18th for West Africa. They are proceeding to Sierra Leone on a research expedition, and also to report upon a suitable site for the "Sir Alfred Jones" Laboratory of the school in that colony. At a luncheon given in their honour Mr. F. C. Danson, Chairman of the Liverpool School of Tropical Medicine, said that the objects of the expedition were twofold: in the first place to make a study of the biting insects and tropical diseases in the colony of Sierra Leone, and of their distribution; and in the second place, to report fully as to the possibility of successfully establishing a laboratory in that colony. He believed that the school would never do its best work until it could have a centre for its expeditions actually working and really alive on the coast of Africa. He read an extract from a letter from the Under Secretary of State for the Colonies, which stated that "The Secretary of State appreciates the spirit in which the proposals are made, and he will gladly ask the Governor of Sierra Leone to afford all proper facilities. Mr. Harcourt trusts that the result of the enterprise will come up to the anticipations of the school authorities." The Chairman said that it was hoped shortly to open their new school in Pembroke Place, and the transfer of the Runcorn Laboratory to that building would make it a complete unit. In addition they had the infirmary ward fully equipped for patients close to the university. Professor Yorke, in responding, said that he was very glad that the laboratory on the coast was at last likely to take some definite form; it would be of great value to the school by serving as a centre for research which could not be carried on in this country, and also in it students would be trained actually amongst the diseases with which they would have to deal.

We regret to announce the death, on November 20th, of Dr. Burney Yeo, consulting physician to King's College Hospital, and the author of a well-known *Manual of Medical Treatment*.

Dr. Barty King will deliver a lecture in the Robert Barnes Hall of the Royal Society of Medicine, on Tuesday next, at 5 p.m., on some recent personal experiences of Germany in war time, during detention, and their lessons, illustrated by lantern slides from German sources. Visitors are invited.

A month ago we referred to the commercial use which was being made, for the purposes of advertising a remedy, of the name of the late Sir William Smart, K.C.B., one of the naval honorary surgeons to Queen Victoria, who died in 1887. We are asked to state that the subject matter of this advertisement has nothing to do with and is entirely unauthorized by the relatives of the late Sir William Smart. This assurance will, we feel sure, be accepted by the medical profession, and it is to be hoped that the advertisements will cease to appear.

We are gratified to learn that the Education Committee of Stoke-on-Trent county borough, which had contemplated paying a salary of only £250 in respect of an appointment which it proposes to make of a lady school medical inspector, has, on fuller consideration, decided to make the salary £300, the minimum recognized by the Association for work of the kind. It is hardly necessary for us to point out that under present conditions a salary of less than £300 for such an appointment, which requires for its proper discharge special education and experience, would not, it is practically certain, attract well-qualified candidates. We congratulate the committee upon its decision. An advertisement of the post on the revised terms will be found on page 40.

Medical Notes in Parliament.

[From our Lobby Correspondent.]

The sitting of Parliament on November 18th was occupied in a discussion of the general questions arising out of pensions and allowances to soldiers and sailors and their dependants, and in the end the Committee previously arranged for was set up. It consists of Mr. Lloyd George, Mr. McKenna, Mr. Bonar Law, Mr. Austen Chamberlain, Mr. Barnes, and Mr. T. P. O'Connor. It is expected that the Committee will report before the rising of the House, which is generally expected to take place on Thursday or Friday of next week.

On November 19th the time of the House was occupied in discussion of the proposals of the amended Budget. The following two tables are extracted from a White Paper showing the amount of tax to be paid during the remainder of the current financial year and during the first full year of the operation of the new scale of taxation. As explained in our last week's issue, the increased taxation during the current year comes into operation on January 1st, and therefore falls only on the last portion of the current financial year, which ends in April. The effects of the new taxations on the present financial year are shown in Table A and those which will fall on the year commencing April, 1915, are shown in Table B:

Income.	A. Tax Proposed for 1914-15, at Rates Charged under Finance Act, 1914, with Addition of 33⅓ per cent.				B. Tax Proposed for 1915-16, at Double the Rates Charged under Finance Act, 1914.			
	Where Income *Wholly Earned.*		Where Income *Wholly Unearned.*		Where Income *Wholly Earned.*		Where Income *Wholly Unearned.*

3,000	250 0 0	20.0	250 0 0	20.0	375 0 0	30.0	375 0 0	30.0

The table further shows that in the case of an income of £3,001 the income tax and super-tax for 1915 will be £264 0s. 2d., and for 1915–16, £396 0s. 4d. On an income of £4,000 the amounts would be £386 2s. 2d. and £579 3s. 4d. respectively.

At the suggestion of Mr. J. M. Henderson (Aberdeenshire, West), the Attorney-General, on November 24th, undertook, on behalf of the Government, to introduce a clause providing that any person who, in connexion with the present war, is or has been serving as a member of any naval or military force of the Crown, or in any work connected with the British Red Cross Society and the St. John Ambulance Association, or any other body with a similar object, will not be taxed either income tax or super-tax on past averages, but on the incomes that they actually earn this year, 1914–15.

Friday, November 20th, was devoted to the consideration of various emergency bills.

On Monday, November 23rd, the Finance and Consolidated Fund Bills were read a second time, and various other emergency measures were advanced.

War.

Royal Army Medical Corps (Temporary Commissions).

Sir Philip Magnus asked the Financial Secretary to the War Office whether a medical practitioner now serving in the Royal Army Medical Corps with a temporary commission was entitled to a pension for wounds at the same rate and under the same conditions as officers holding permanent commissions; and whether, in the event of his death, his widow and orphans would be entitled to a pension, and, if so, at what rate.—Mr. Baker: Yes, Sir. The rates and conditions are fully set out in the Pay Warrant.

Medical Service of the New Army.

Mr. Hinds asked the Under Secretary of State for War if he would state what arrangements were being made for providing a medical service for the new armies; and, pending the organization of such a service, what provision was made for the treatment of troops in the new battalions or brigades.—Mr. Tennant said that the new armies would be provided with medical arrangements on the same basis as the Expeditionary Force. Large training establishments had been formed at which the subordinate personnel was being instructed in their active service duties. Pending the completion of these arrangements, the new army was receiving medical attendance on exactly the same lines as the regular army in times of peace. Temporarily commissioned officers in the R.A.M.C. and locally employed civil practitioners had been engaged in sufficient numbers to meet all requirements, and nearly a hundred of the R.A.M.C. reserve of officers had been recalled to duty. So far there had been no difficulty in securing the services of a sufficient number of fully qualified medical men, and it was not anticipated that there would be any shortage in the immediate future. All the military hospitals in the country had been very greatly expanded, and several large civil and private hospitals were working in conjunction with them. Up to the present there had been no lack of hospital accommodation.

Army Medical Officers.

Sir Herbert Raphael asked the Under Secretary of State for War whether retired army medical officers holding retired pay appointments of medical officer in charge of troops and military hospitals at dépôts necessitating in peace time an inconsiderable amount of work, and now, since the commencement of the war, requiring all-day service and constant orderly duty day and night owing to the increase of work and expansion of hospital duty, had been refused kit allowance and the same rate of pay granted to retired medical officers who had been recalled to duty; and, if so, whether he would consider the justice and advisability of equalizing the financial position of these two classes of officers.—Mr. Baker replied that these officers, in common with other retired officers who were in the employment of the War Department in peace, were being treated in accordance with the regulations under which they accepted their appointments. If there were any grounds for varying the regulations, they would be considered.—Sir H. Craik asked whether it was not the case that temporary doctors acting in their places were receiving as much as £1 4s. a day, whilst these men were only receiving a salary of £150.—Mr. Baker, in reply, said that if grounds on which the regulations should be altered were submitted, such representations would be considered.

Army Hospital Nursing.

In reply to Mr. Rendall, Mr. Tennant said that the nursing staffs of all the military hospitals had been largely increased since the beginning of the war according to need and without any regard to peace establishment, and were still being increased daily as need arose. Any patient requiring individual attention had a special nurse allotted. The committee of the Nursing Board met every week at the War Office to consider applications of trained nurses, and they were taken on as their services were required. The patients were now receiving all the nursing attention which the nature of their cases demanded.—Mr. Rendall asked whether the same number of patients were assigned to a nurse during war as during peace. Mr. Tennant was unable to say, but promised to make inquiry.

Treatment of Dependants of Men with the Colours.

Sir Henry Craik asked the Secretary to the Board of Education, as Vice-Chairman of the Committee on the Provision of Free Medical Attendance and Drugs, when necessary, to the dependants of men serving with the army, whether any arrangements had been arrived at to make use of the offer of the British Medical Association to provide free medical attendance to such dependants; and what arrangements had been made for the supply of the necessary medicines.—The Parliamentary Secretary to the Board of Education (Dr. Addison) replied as follows: The special committee set up for the purpose have prepared a scheme for utilizing the generous offer of the British Medical Association, and have issued instructions to local representative committees in England and Wales, together with a supply of special medical books for issue to suitable dependants of men serving with the army or the navy. The scheme is now in operation throughout England and Wales, except in a few areas where a local scheme had been adopted. The local arrangements vary, but, as a rule, the books, which are accepted as evidence of bona fides by doctors and chemists working under the scheme, are issued by the local representative committee, assisted by the Soldiers' and Sailors' Families Association. The scheme has also been brought into operation in Scotland, where it is being worked by the Soldiers' and Sailors' Families Association. The Pharmaceutical Society of Great Britain generously offered on behalf of their members to supply the necessary medicines and appliances at cost price. The cost price of medicines and appliances supplied under the scheme is being defrayed from a grant made out of the Prince of Wales's Fund. The work of checking and pricing prescriptions is being undertaken at considerable expense by the Pharmaceutical Society under a system approved and inspected by the committee.

Winter Clothing for Troops.

Mr. Hogge asked what arrangements had been made for the winter clothing of troops at the front; and when these would take effect.—Mr. Tennant replied that Cardigan jackets and warm underclothing had already been supplied, and mufflers and body belts were being sent out as required. Large quantities of fur-lined coats and fur under-jackets were being sent overseas weekly. Warm gloves and warm turned-down hats were also being prepared.—In reply to Sir R. Cooper, who asked whether demands should be made on charity to provide men fighting, both in the army and the navy, with necessary articles, Mr. Tennant said that all the articles which existed in the War Office vocabulary were supplied by money voted by Parliament. Other comforts, such as gloves, were sometimes given by private individuals who sought an outlet for their charity.—In reply to Colonel White, Mr. Tennant said that supplies of gloves had already been sent out to the Expeditionary Force, and gloves of special design for winter use were now being provided. Gloves were also being provided for use at home during the winter months at the public expense.

Socks.

Mr. Hogge asked why the knitting of socks, etc., by private enterprise was stopped and an appeal subsequently made for hundreds of thousands.—Mr. Tennant said the War Office maintained a sufficient supply of socks for the troops at the front, and the knitting of them was not therefore the most useful form the activities of the public could take. It was found, however, that there was so strong a wish on the part of private persons desirous of helping the troops to make and send socks that it became necessary to co-ordinate the efforts, so as to ensure uniformity of supply and proper distribution. The socks sent are extra to, and not in diminution of, the supply considered necessary by the War Office.

Supply of Blankets.

In reply to Sir Clement Kinloch-Cooke, Mr. Tennant said that inquiry was being made as to the alleged

deficiency of blankets in particular cases. There were ample stocks of blankets in commands, and general officers commanding were authorized to issue as required. It had not been found possible at present to provide men with two suits of uniform, but every step possible was being taken to meet the deficiency.

Lined Huts.

In reply to Mr. Haddock, who asked a question as to the lining of huts to prevent draughts, Mr. Tennant said that the first object was to have sleeping huts built for the men to enable them to be under better cover than tents. The question of lining the huts would be taken up later, as it could be done while the men were in occupation.

Death during Training.

Mr. Butcher asked the Under Secretary for War whether it was the intention of the Government to make any provision for the dependants of men who, having enlisted since the commencement of the war, died of some illness contracted during their period of training and before they were sent to the front.—Mr. Baker replied that the question of the rates and conditions of pension for dependants was under consideration, but in the meantime the separation allowance and allotments received during the soldier's lifetime were being continued pending a decision.

Ambulance Cars.

Mr. Hunt asked the Under Secretary for War whether complaints had been received that the War Office refused to accept for ambulance purposes any cars except those of the three makes—Daimler, Wolseley, and Sunbeam; and, if so, what objection there was to accepting first-class cars of French and Belgian make for use in those countries.—Mr. Tennant replied that the purchase of motor ambulances by the War Department had not been confined to those manufactured by the firms named. In addition, the Red Cross had given cars of many different makes. On account of the difficulty of the provision, and more especially of the distribution, of spare parts, the multiplication of the number of types of mechanical transport vehicles was to be deprecated.

Objections to Vaccination.

British Army.—Mr. Brace asked whether a general order was in operation that all recruits for the army at present being recruited must undergo compulsory vaccination or compulsory inoculation; if he was aware that a number of would-be recruits were hesitating to enlist because of their objection to this; and whether he was prepared to take some action, and, if so, what, to remove this difficulty to recruiting.—Mr. Tennant referred Mr. Brace to the written reply given to Mr. Chancellor and published last week (p. 889), and, in reply to a further question by Mr. Brace, Mr. Tennant said that soldiers might go to France or Belgium and fight in the ranks, although they might have conscientious objections to being vaccinated or inoculated.

Colonial Troops.—Mr. Barnes asked whether conscientious objection to vaccination was being respected in the case of soldiers serving among the Canadian, Australian, and other Colonial contingents.—Mr. Tennant said that he had been unable so far to obtain information as to the practice followed in the case of the Australian and New Zealand contingents, but he was given to understand that, in the case of the Canadian contingent, men who objected to vaccination had not been taken.

Inoculation of Recruits.

Mr. Chancellor asked the Under Secretary for War (1) whether the War Office is instructing officers to use influence and persuasion which practically deprives recruits of their legal right to refuse inoculation; and whether soldiers who are physically fit for service at the front are being kept at home solely because, whilst willing to face the enemy's bullets, they decline to risk being poisoned before starting by the inoculation by their own officers of disease into their blood; and (2) whether he is aware that a number of recruits in both the Territorial and the Regular army have been made ill and unfit for service for days and sometimes weeks by vaccination and inoculation; and whether, in view of the importance to the empire of fitting them for service at the earliest possible moment, he will, in the case of unwilling soldiers, instruct officers to cease from exercising influence and persuasion, which in most cases amounts to compulsion, or, in the alternative, will have all recruits informed before enlisting that their legal right to exemption is illusory.—Mr. Tennant: The position in regard to vaccination and inoculation in the case of the Regular and Territorial Forces has been frequently stated. I cannot accept my hon. friend's questions as correctly summarizing the existing regulations and instructions, and the conclusions he draws are, consequently, in the opinion of my advisers and of the Secretary of State, also inexact. I may add that I cannot find that soldiers have been kept at home owing to difficulties about inoculation. The presence of inoculated men amongst the troops is an undoubted source of danger.

In reply to another question by Mr. Chancellor, with specific reference to the 4th Cameron Regiment, Mr. Tennant said that it was made plain to the men that inoculation was not compulsory, but that where the military authorities had a possibility of choice, preference would be given to those who had been inoculated. A full battalion of inoculated men for the 4th Camerons was forthcoming, but to equip this number some equipment had to be given up by the men not selected. The War Office had consistently held that while inoculation was not compulsory it was highly desirable, and where it was possible to get a whole battalion of inoculated men they would be taken in preference.

Treatment of Recruits in Military Hospitals.

Mr. Annan Bryce asked whether treatment in military hospitals was being refused to recruits in the new army raised for service during the war who had been discharged for temporary incapacity due to accidents during training, while in similar cases such treatment was given to recruits in the regular army.—Mr. Tennant said that he was not aware that any distinction was being made. The rule was that a discharged soldier who, on account of illness, was unable to proceed to his home was maintained in hospital. Inquiry would be made into any specific case submitted.

Mental Deficiency Act, 1913.—In reply to Mr. Astor, the Home Secretary has given the following information:

When the Mental Deficiency Act, 1913, came into operation local authorities were invited by circular to submit their proposals for giving effect to the Act to the Board of Control. To assist them in doing so a carefully prepared form was distributed to them with a request that their schemes might be set out in detail thereon and forwarded to the Board of Control by the end of April. The response made by local authorities was very slow, and many of them delayed for weeks, and some for months, the essential preliminary step of appointing a committee to administer the Act as required by law. Up to the present some twenty-three counties and county boroughs have submitted definite schemes which have nearly all received the approval of the Board, and in some seventy other cases correspondence and interviews have taken place which indicate that the preparation of schemes will be proceeded with at an early date. The Board continues to use all its influence towards expediting the action of local authorities, and contemplates the issue of another circular immediately with this object. No local authority has as yet provided a certified institution either alone or in conjunction with other local authorities. Four local authorities have under Section 37 of the Act applied for and obtained the approval of the Board to an equal number of Poor Law institutions suitable for the reception of defectives; provision is thus made for 145 cases. Several other applications for such approval are now under consideration.

Institutions and homes provided by religious and philanthropic associations, and by individuals, have come forward in considerable numbers, and the Board has certified or approved of thirty-one of them, making provision for 2,533 cases. In addition to these there are the nine hospitals and institutions formerly registered under the Idiots Act which have become certified institutions or houses under the Mental Deficiency Act, and continue to provide accommodation for many hundreds of defectives.

Nine local authorities have entered into contracts with one or other of these institutions for the reception of defectives from their area; five of these contracts cover a number exceeding eighty, and in the remaining four the numbers to be received are not specified.

The number of cases which have been notified to the Board as having been dealt with by local authorities under the Mental Deficiency Act by being placed under guardianship or sent to institutions is forty-four. In addition to these, local authorities have assumed financial responsibility for sixteen cases dealt with by orders of the Secretary of State or Criminal Courts.

Many local authorities have appointed officers to execute the Act, and in their areas the work of enumeration and supervision may be said to have made some progress.

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

THE BRITISH COMMITTEE.

As announced last week, the provisional committee formed in London to ascertain what aid it might be possible to give to Belgian medical men and pharmacists in their present dire straits had determined to make the experiment of sending out packets of drugs with a few necessary instruments, and it was stated that arrangements for their conveyance had been made on advice received from the American Ambassador and Mr. L. Hoover, from the Belgian Minister, from the manager of Messrs. Harrods, Ltd., and from Major Gordon. It was also stated that it was hoped to develop the work as the condition of Belgium permitted in association with corresponding efforts throughout Great Britain and Ireland, in the United States, and in other neutral and allied countries.

With the object of extending the committee so as to make it representative of the United Kingdom and Ireland, the President of the General Medical Council and the representatives of the universities and corporations on that body were asked to attend a meeting at the offices of the British Medical Association on November 24th. The response to this invitation was very satisfactory, and included the President of the Council and several of the Crown and Direct Representatives, as well as many of the representatives of the universities and colleges. At this meeting the committee was extended and reconstituted, and the letter printed below was approved for publication in the medical journals and newspapers.

At a meeting of the medical profession in Dublin last week a committee was appointed to collect subscriptions, and in their distribution to work in co-operation with the provisional committee formed in London.

The Scottish representatives at the meeting in London on November 24th undertook to form a similar committee in Scotland.

Members of the British Committee.

The Committee has power to add to its number.

Sir Rickman Godlee, Bart., Chairman.
Sir Donald MacAlister, K.C.B., President of the General Medical Council.
Sir Henry Morris, Bart., Joint Treasurer of the General Medical Council.
Dr. J. A. Macdonald, Chairman of Council, British Medical Association.
Mr. T. Jenner Verrall, Chairman of Representative Meetings, British Medical Association.

England:
Sir Thomas Barlow, Bart., President of the Royal College of Physicians of London.
Sir W. Watson Cheyne, Bart., President of the Royal College of Surgeons of England.
Dr. Meredith Townsend, Master of the Apothecaries' Society, London.
Sir Clifford Allbutt, K.C.B., Regius Professor of Physic in the University of Cambridge.
Dr. Robert Saundby, Professor of Medicine in the University of Birmingham.
Dr. Arthur Thomson, Professor of Anatomy, University of Oxford.
Dr. G. Elliot Smith, Professor of Anatomy in the Victoria University, Manchester.
Dr. Richard Caton, Consulting Physician to the Liverpool Royal Infirmary.
Dr. Frederick Taylor, President of the Royal Society of Medicine.
Dr. F. M. Sandwith, Gresham Professor of Physic.
Dr. Herbert Spencer, Obstetric Physician, University College Hospital.
Sir Frederic Eve, Surgeon to the London Hospital.
Dr. Alfred Cox, Medical Secretary, British Medical Association.
Mr. W. J. Uglow Woolcock, Secretary and Registrar, Pharmaceutical Society.
Dr. Dawson Williams, Editor of the British Medical Journal.

Wales:
Dr. H. A. Latimer.

Scotland:
Sir Thomas Fraser, Professor of Materia Medica and Clinical Medicine in the University of Edinburgh.
Dr. William Russell, Professor of Clinical Medicine in the University of Edinburgh.
Mr. James Hodsdon, President of the Royal College of Surgeons of Edinburgh.
Dr. John Yule Mackay, Principal of University College, Dundee.
Dr. J. C. McVail, Crown Representative, General Medical Council.
Dr. Norman Walker, Treasurer of the Royal College of Physicians, Edinburgh.

Ireland:
Sir Lambert H. Ormsby.
Sir John W. Moore.
Sir W. Whitla (Queen's University, Belfast).
Sir Charles Ball, Professor of Surgery, University of Dublin.

Dr. H. A. Des Voeux, 14, Buckingham Gate, London, S.W. (Honorary Treasurer).
Dr. S. Squire Sprigge, Editor of the *Lancet* (Honorary Secretary), 423, Strand, W.C.

The letter of appeal received for publication is as follows:

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

To the Editor of the British Medical Journal.

Sir,—A provisional committee was formed recently to assist in any way that was found possible Belgian doctors and pharmacists, both those remaining in Belgium and those who are refugees in this country, who are involved in utter distress. A statement received from Professor Jacobs, of Brussels University, acting as the spokesman of a Belgian committee with similar aims, has already been published, and certain measures were taken immediately by the provisional committee, who, in announcing what had been done, recognized that the scope for further effort was enormous, and that the provisional committee ought to be reinforced forthwith by representatives of medicine and pharmacy in England, Ireland, Scotland, and Wales.

As a result a strong committee has been formally constituted. It includes representatives of the medical faculties of the universities, of the great medical and pharmaceutical corporations, of the General Medical Council, and of the British Medical Association, and the activities of that committee will be limited only by the amount of money and material placed at its disposal, and by the exigencies of the political situation.

The committee is aware that great efforts are being made in numerous directions for the assistance of the Belgian refugees and Belgian people generally, but feels that it will be the pleasure and is, indeed, the duty of medical men and pharmacists to help the medical and pharmaceutical professions of Belgium. The movement is one undertaken by doctors and pharmacists on behalf of the Belgian doctors and pharmacists.

The committee has placed before itself a double programme: (1) to distribute what help it can at the present moment; and (2) to collect funds for the assistance of Belgian medical men and pharmacists in the future.

1. As a tentative measure fifty packets of drugs and dressings are under order for dispatch to Belgium. This will test the precautions which are being taken to ensure that the goods dispatched will reach their destination and that they will be used by those only for whom they are intended—that is, the Belgian physicians and surgeons. In the second direction it is hoped to co-operate usefully with the general measures being adopted to succour Belgian doctors and pharmacists in this country.

2. It is clear that no definite steps can be taken as yet for the rehabilitation of the medical and pharmaceutical professions in Belgium. A considerable sum of money will be required to replace ruined laboratories and pharmacies and to re-establish the ordinary course of medical administration, but nothing can be done now. It is intended, however, to communicate with the United States of America and other neutral countries, as well as with the Allied Nations, so that an international movement may be set up to reinstate the two professions.

But the committee feels that the uncertainty which exists with regard to the fulfilment of the second part of the programme should not prevent immediate and strenuous action in the spheres open to its work. The result of an experimental consignment to Belgium of medical stores will be known shortly, and if, as there is

every reason to anticipate, the result is good, such consignments will be made regularly in accordance with the amount of money forthcoming. The committee has evidence that at least 2,000 such packets as have already been arranged for are sorely needed, while each packet costs £5, the price being only kept down to this figure by the willingness of Messrs. Burroughs Wellcome and Co. to forego all profit.

At the same time the committee is aware of grave distress among the refugee medical men and pharmacists, and it feels that the organizations for succouring the great mass of Belgian refugees ought to be especially supported in anything that can be done for the members of the two professions.

It appeals therefore for immediate assistance, and appends a list of the first subscriptions actually received. Numerous promises of help have been made, and the committee is much indebted for the facilities which have been afforded to it by the British Medical Association, at whose house (429, Strand) the meetings have been and will in future be held.—We are, Sir, yours faithfully,

RICKMAN J. GODLEE (*Chairman*).

H. A. DES VOEUX (*Honorary Treasurer*),
14, Buckingham Gate, London, S.W.

S. SQUIRE SPRIGGE (*Honorary Secretary*),
The *Lancet* Office, 423, Strand, W.C.

Dr. Pyle promises further help when necessary, and it is hoped that this example may be followed by other subscribers.

Subscriptions should be sent to the Honorary Treasurer, Dr. H. A. Des Voeux, 14, Buckingham Gate, London, S.W., and crossed "Lloyd's Bank, Limited."

Offers of hospitality to Belgian medical men and their families now in this country should be addressed to Dr. Alfred Cox, Medical Secretary of the British Medical Association, 429, Strand, London, W.C., who is in communication with Viscount Gladstone, Honorary Treasurer of the War Refugees Committee, on this matter.

DURING the fortnight ending November 19th, eight fresh cases of plague with seven deaths from the disease were reported in Mauritius.

THE Chelsea Hospital for Women has received from the executors of the late Mr. Thomas Stephen Whitaker the sum of £2,000 towards the rebuilding of the hospital.

THE WAR.

NOTES AND REFLECTIONS FROM THE FRONT.

By Sir WILLIAM J. COLLINS, K.C.V.O., M.S.Lond., F.R.C.S.Eng.

A BRIEF visit to West Flanders, made the week before last, afforded an opportunity for a *coup d'œil* of the western battlefield at its northern extremity, as well as for some observation of the ambulance and hospital provision for the wounded betwixt Dunkirk and the fighting line.

The *terrain* in this region consists of sandy dunes along the sea front from Dunkirk to Furnes across the Belgian frontier and on to Nieuport. These wind-made hillocks of shifting sand, sparsely covered with scrubby gorse and heather, afford valuable cover, easily capable of improvement with a little spade work. Further inland intensive culture by industrious agriculturalists has converted sand into fruitful soil; sugar-beet fields abound and have recently been harvested, while around the villages the market gardening capacities of the Belgian peasantry are plentifully evident. What were erstwhile prosperous homesteads dot the landscape, and many water-ways intersect the well-ploughed fields. A run of sixteen miles, parallel with and half a mile from the coast, brought us from Dunkirk to Furnes. The latter is now about the only Belgian town yet unravaged by the ruthless invaders. Every few miles along this road the route was barricaded with piles of turf or sandbags, so arranged as to arrest any passing motor and compel its occupants to submit, at the point of the bayonet, their pink "laissez-passers" papers to the careful scrutiny of the sentries. The roads are suffering from the heavy and unwonted traffic they have had to bear and lack of their habitual repair, while here and there a "coal-box" has dug a hole therein, as well as in the adjacent fields. The main roads are highly cambered, and have a central bricked *chaussée*, with muddy, deeply-rutted sideways. Motor ambulances are thereby severely tried, and need cautious driving to avoid peril to their suffering occupants.

Furnes (in Flemish Veurne) in normal times is a quaint and quiet town of some 6,000 inhabitants, with a handsome Grand Place surrounded with gabled sixteenth century houses, overhung by a towering belfry and backed on the north by the Gothic church of St. Nicholas. The gallant King Albert and his brave consort are often seen about the streets, and the latter has paid more than one visit to the little English field hospital established in the convent hard by. This is the nearest hospital to the fighting line. We could hear the guns and at night see them flashing in the distance from its windows. More than once it has been under shell fire. Yet here in two wards are some seventy beds fully occupied by well-tended wounded Belgians, with an occasional German. Here is a good improvised operating theatre, and here excellent conservative surgery is being carried on under many difficulties. Plated fractures of humerus and femur, resection of intestine, suture of intestinal bullet wounds, extraction of shrapnel, balls and bullets, amputations and trephinings had been carried out with excellent results. Here as elsewhere nearly all wounds are septic from the first; suppuration is the rule. One is reminded of Hueter's saying of old time that "suppuration is an epidemic spread over the whole world." Any attempt to isolate the aseptic from the foul is out of the question.

Outside in the courtyard of the chapel are parked up a fleet of Red Cross motor ambulances awaiting the next call to the front. They are mostly converted cars, and they leave something to be desired. The heavy roads need at least 20 h.p. chassis, and many of them are of only 15. They are mostly arranged for two stretcher cases on the left-hand side and three or four sitting cases on the right. This causes a list to the right, intensified on highly

cambered roads, especially when passing commissariat convoys or ammunition trains. On the Continent, of course, the rule of the road is to the right instead of to the left, and in converted cars the projection of the stretcher side of the ambulance to the left of the driver obscures the latter's vision of any vehicle overtaking him on the road.

In Furnes we saw the 12th Regiment of the line of the Belgian army, which has borne the brunt of many a fierce combat, weather-beaten and worn, chilly in the falling hailstorm, yet dogged and determined, and reminding us of Caesar's dictum that of all the Gallic tribes the Belgae are the bravest.

Another run of seven miles brought us to Nieuport, still under shell fire from the German guns at Lombartzyde. It is a mere husk of a town; no inhabitants remain; every house is in ruins and the church tower is shattered. A battery of French guns in our rear was replying with shriller sounds to the heavy German howitzers which were booming away, and some two hundred yards to the north of us one found its mark. Turning south we motored alongside the Yser canal to Ramscapelle and Pervyse—smaller villages than Nieuport, but as complete ruins; no single house to be seen with intact roof or walls unpitted by bullets or quick-firers. Fierce fighting had been here but a few days before, as recent graves and still unburied corpses helped to prove. Dixmude, six miles further on, was then (November 12th) in the hands of the Germans, but the opened sluices were beginning to do their work, and twixt fire and water the enemy was securely held at bay. A signpost pointing south indicated the road to Ypres.

The previous night rumour had been rife in Dunkirk that the Germans were advancing from Dixmude and evacuation was in the air, yet Dunkirk preserved its equanimity. The town was full; it was not easy to get a room anywhere; the restaurants were crowded with the military but the civil life appeared to be going on as usual. Most nights, between 10 and 12 o'clock, a gruesome scene was to be witnessed in the sheds at the station. The ambulance train (of the cattle truck variety) brought in the wounded from the front. A sort of clearing hospital had been improvised in one of the huge station sheds. Some 200 beds had recently been installed. To these the stretcher cases from the train were borne. Many of them had not been dressed for two or more days, and were intensely septic. Cases of gas gangrene, of severe compound fracture needing immediate amputation, huge black lacerated wounds from shrapnel or shell casing, some few clean bullet wounds, bad head injuries, and a traumatic aneurysm were among the 125 grave cases evacuated from the train in one night. In another huge shed, stretched on straw, were hundreds of either slightly wounded or fagged-out soldiers, in every variety of uniform, French and Belgian, chasseurs and infantry, coal-black Turcos and Algerians, in "most admired disorder," but lying so thick upon the ground that I could with difficulty pick my way amongst them.

An ambulance train working in this region would be a veritable godsend, and permit the earlier cleansing and dressing of those maimed yet gallant victims gathered from the trenches and the field. Provided with a travelling kitchen, nourishing soups and restoratives could also be administered, moreover, urgent surgical intervention could be carried out *en route*.

As has already been adumbrated in the JOURNAL, a motor vehicle fitted up as a field theatre or surgery would be of immense service in securing the earliest practicable attention to wounds, thus reducing the number of those infected and offensive arriving at the base.

In war we witness a reversion from civilization to barbarism, from sanitation to mal-hygiene. As in space we may step from the aseptic ward to the foul, so we seem, as it were, to recede in time to the days before cleanly surgery had risen on the horizon. Our methods must be adapted to the situation. The dry dressings of aseptic surgery are an anachronism, and, except in a minority of cases, out of place. Old friends, too readily discarded, like carbolic lotion and fomentations, charcoal poultices, iodoform, and friars' balsam, come to our aid, and, while grateful to hydrogen peroxide and the recently recognized virtues of iodine, one prefers to rely on the well-tried comrades of earlier date, and of even longer reputation.

MEDICAL ARRANGEMENTS OF THE BRITISH EXPEDITIONARY FORCE.

[From a Special Correspondent in Northern France.]

GENERAL ARRANGEMENTS.

Now that the total number of casualties occurring up to a week ago has been discussed in Parliament, and that the names of various hospital bases have been freely mentioned in the daily papers, it is legitimate to describe the general British arrangements for the care of the sick and wounded in France somewhat more definitely than previously seemed desirable. When the Germans commenced their attempt to reach Calais and the British troops were transferred from the centre to the extreme left of the allied line, the call upon the activities of the Royal Army Medical Corps was rapidly and very materially increased. This was not only because the number of casualties began to multiply greatly, but also because the routes by which the wounded had previously been sent to various hospital bases could no longer well be used. At the best of times these lines were commonly encumbered by the troop trains and supply trains both of the French and the British forces, and with the British forces established in their new position they seemed less likely than ever to lend themselves satisfactorily to the rapid evacuation of the sick and wounded. Consequently a new hospital base had to be chosen, and Boulogne was the place selected. It was a bold step, considering that it was, and still is, within a relatively short distance of the actual fighting line, but was justified by the consideration that in other respects it largely fulfilled the military ideal in regard to evacuation of the wounded. It is within very easy reach of Southampton, Folkestone, and other British ports, and has excellent communications with the extreme north-east and frontier of France, and the southern areas of Belgium, by a railway line not used by the French for ordinary military purposes, and comparatively little by the British. Several hospitals, including one Red Cross hospital, were at once got ready, and by degrees the equipment of these has been perfected and their number increased. There have now been, in fact, in full work for some time past as many as three general hospitals, four stationary hospitals, one general, and one stationary Indian hospital, in addition to five voluntary hospitals, each containing 100 beds and upwards. With one exception all the British military hospitals are within a few hundred yards of the station at which the ambulance trains unload, and the same is true of one of the voluntary hospitals—that known as the Allied Forces Base Hospital, the first of those working under the general control of the Red Cross Society—which is established in the Hotel Crystol, opposite the bridge leading to the town station. Of the other voluntary hospitals, the Australian Hospital, the Women's Medical Corps Hospital—a branch of the Anglo-Franco-Belge Hospital at Paris, to whose excellence attention has already been drawn in these notes—and Sir Henry Norman's hospital, a new-comer, are established at Wimereux, on the northern outskirts of the town; while the Duchess of Westminster's hospital is somewhat further afield, the place assigned to it being Le Touquet, some fifteen miles to the south of the town. All these hospitals—military as well as Red Cross—are well housed, and the habitations of most of them are well known hotels. The exceptions are No. 13 General Hospital, which has taken over the Casino; No. 13 Stationary Hospital, which was described last week; No. 2 Stationary Hospital, which occupies a large school on the southern side of the port; and one of the Indian hospitals, this having its home on the heights above the town in a very large convent school, which was thrown out of ordinary use a year or so ago owing to its partial destruction by fire.

Various circumstances tend to render the work at these hospitals heavier than at institutions of equivalent size in Great Britain; the patients arrive at all sorts of hours, and usually several at a time, and are generally wearing the clothing in which they have been living and fighting for days on end. A large proportion of their wounds require, if not formal surgical interference, at least operative cleansing, and subsequently frequent re-dressing. Finally, their stay is not in most cases prolonged, and the

men, when sent off, have commonly to be refitted in the matter of underclothing and other garments. On the other hand, the equipment of these hospitals is excellent, and the personnel amply sufficient to meet all calls alike in the way of heavy work, such as ward cleaning and stretcher carrying, and of skilled procedures, such as nursing and operations. All of them are possessed of *x*-ray departments and well-fitted operation rooms, and at least one—the Casino Hospital—has a dental department in addition. The heavier work is done by orderlies drawn from the Royal Army Medical Corps itself or from the St. John Ambulance Corps, and the nursing by the thoroughly well trained women who constitute Queen Alexandra's Regular and Reserve Military Nursing Services, and by the equally well trained women supplied by the Red Cross Society and St. John Ambulance Association. There is no red tape in the arrangements, and any matron who considers her staff likely to be overtaxed can secure as much more assistance as she requires forthwith, and is not even obliged to send her request through the more or less numerous channels which must be pursued in peace times. Equipments of all kinds can likewise be secured promptly by the same direct methods. At several hospitals there are also a certain number of medical student dressers.

With these arrangements the character of the professional staffs of all the hospitals is in thorough keeping. Those who organized the voluntary hospitals were always men working at some well known centre of medical activity, and as they themselves were to be responsible for the actual working of the hospital which they were organizing, they have always been careful to select the right kind of assistance. Consequently there is practically no British voluntary hospital now in France whose staff does not include at least two or three men whose names are professionally known outside their immediate circle of friends and acquaintances. Nor are the purely military hospitals working either in Boulogne or elsewhere in France any less well off in this respect. The system of offering inducements to officers to specialize in one or other branch of medicine, which was adopted at the last reorganization of the Royal Army Medical Corps, has led to a considerable proportion of R.A.M.C. officers specializing in the subject of surgery, and, in addition, so soon as war was declared a large number of applications for temporary commissions were received. Many of them were young men, but there was an equally large number of men of riper experience, and the general principle adopted would seem to have been that of choosing men of recent experience either on the senior or junior staffs of well-known hospitals. The net result is that the staffs of the purely military hospitals are decidedly strong as well as large. I am not, of course, personally acquainted with all their members, but have looked up the records of a very considerable proportion of them. I have thus found them to include a large number of Fellows of one or other College of Surgeons, and at no hospital that I have hitherto visited have I met any man whose previous experience did not seem to fit him excellently for the particular work he was doing. At one hospital in particular that I have visited more frequently than any other, there are as many as four men whom I personally know in ordinary peace times as members of the staffs of certain great teaching hospitals. In view of these facts it seems indisputable that the medical arrangements at Boulogne are of a highly satisfactory kind. It is further to be remembered that a considerable number of specialists take a part in the general work without being attached to the staff of any particular hospital. There are, for example, two consulting surgeons, two consulting physicians, a neurologist, a surgeon who specializes in brain and spinal surgery, four or five bacteriologists, and a couple of ordinary pathologists; last, but not least, there are available the services of at least one instrument maker, whose duty it is to prepare any special splints that may be required.

Though Boulogne is to be regarded as the principal hospital base for the British force and the chief scene of medical activity, it is by no means the only town at which military and Red Cross hospitals are established. Apart from the numerous clearing hospitals working close to the fighting line and all doing their work under the general professional supervision of a well known consulting surgeon, now ranking as a colonel on the Army Medical Staff, there are numerous hospitals in towns at a greater or shorter distance further south. The five or six large Red Cross hospitals at Paris, to which allusion was made in a note some weeks ago, are still at work, and some twenty other hospitals are available at other towns; in fact, with one or two exceptions, they are all at work. Six of them are at Rouen, three at Havre, two at St. Nazaire, and others at Nantes, Angers, le Mans, Orleans, and Marseilles. Furthermore, in every town used by the British as a military dépôt, or for any other purpose, a detachment of the sanitary branch of the Royal Army Medical Corps is to be found at work. I have not as yet visited all of these towns, but having questioned a number of acquaintances, one or other of whom knows each of them, I am able to say that the general arrangements of their hospitals in respect of housing, equipment, and staffing, are on all-fours with those of the hospitals at Boulogne; only in respect of Rouen is any qualification of this statement required. Rouen, despite its size, is very ill provided with buildings suitable for conversion into hospitals, and consequently several of those now at work within its area are under canvas. As the army medical authorities dislike the use of tents for hospital purposes whenever it can be avoided, and as Rouen tends to be both a cold town and a wet town in winter, I am under the impression that any hospitals now working there and for which really desirable winter accommodation cannot be found will shortly be removed and re-established elsewhere.

As for the fashion in which the various hospitals that have been mentioned are being utilized, one of the purely military hospitals established at Wimereux caters largely for medical cases and has an annexe set apart for the reception of patients suffering from enteric fever, and dysentery. One of the Havre hospitals receives all the cases of venereal disease that are discovered, and one of those at Rouen—the one maintained by the Red Cross Society—is reserved for the treatment of officers. The hospitals at Orleans and Marseilles are both primarily intended for men belonging to the Indian contingent. All the others are used for general purposes, though some of them—the Crystol, for instance, at Boulogne—habitually number among their patients a larger proportion of officers than others.

The system by which all these hospitals are supplied with patients is as follows. In special circumstances, as, for instance, when the down lines are known to be unusually clear, and it is believed that a rapid run for a hospital train can be secured, the wounded are sent straight from the clearing hospitals to Paris, Rouen, or some other distant hospital base. But as a general rule hospital trains all go to Boulogne. They have to travel slowly, but despite this fact usually reach it in little over six hours, the patients meanwhile being fed, their wounds re-dressed if need be, and all due attention paid them by the medical officers, nurses, and orderlies, with whom each train is plentifully supplied. On arrival of the trains at their destination—which is the port railway station familiar to all those who in peace times habitually use the Boulogne-Folkestone route to France—the embarkation medical officers examine the lists already prepared by the medical officers in charge of each train and deal with the cases accordingly.

Primarily all the wounded are divided into "stretcher cases" and "walking cases." The latter are patients the nature of whose wounds and general condition render it reasonable for them to be allowed to move about; the former are those who either have wounds in the legs and therefore are unable to walk, or wounds so serious in themselves that no avoidable movement ought to be permitted. The stretcher cases are for the most part forthwith loaded on the waiting ambulances of the various hospitals. Each of these has its own supply of automobile ambulances, and as they are all warned well in advance of the arrival of any train they have plenty of time to send them down to bring up new cases. Stretcher cases not sent immediately to one of the local hospitals are dealt with in suitable ways. Those as to whose condition there is any doubt are admitted temporarily to the emergency ward of No. 13 Hospital, which is practically part of the port railway station itself, and is the extemporized institution described in a note last week.

On the other hand, those whose wounds are clearly not very serious in themselves and whose general condition is good are either left undisturbed in the train, which subsequently takes them on to one of the distant base hospitals, or are sent straight on board one of the hospital ships, which are always waiting at the quay side. The patients dealt with in the latter fashion are usually officers.

The quayside hospital, besides an emergency ward, has also a casualty department, and this enables it to play, to some extent, the part of a local clearing hospital in regard to walking cases. These, so soon as the order to disembark from the train is given, flock into this casualty department, where their wounds are examined and re-dressed, and the question as to what is to be done with the patient is decided. The general rule with regard to their disposition is as follows: If the men seem only to require a few days' rest and a minimum of treatment, they are sent to a "convalescent" camp on the downs above the town, to which a staff of medical officers is attached. Men whose wounds being quite slight require nothing but ordinary dressings to secure their rapid healing are also sometimes sent to this camp. On the other hand, men whose wounds, though more or less serious, may be expected to have healed completely in less than three weeks are either admitted to a local hospital or re-embarked on the train after their wounds have been re-dressed, and the men themselves more or less reclothed, and sent on to a distant base.

As for the walking cases which do not come within any of the foregoing categories, and whose wounds or general condition is of such a character that they are not likely to be well for at least three weeks, they remain in or about the hospital until the next outgoing hospital ship has taken on its load of stretcher cases from the hospitals and trains, and are then sent on board for treatment at some hospital in Great Britain. Meantime their wounds are, of course, re-dressed, or submitted to operative measures if deemed immediately desirable. At this station in addition to the feeding arrangements made by the army authorities themselves, there is a free buffet, under the auspices of the Red Cross Society, at which the men can obtain coffee, cocoa, and cigarettes, etc.; while there is a second establishment of the same kind at the town station at which hospital trains proceeding further south sometimes are detained for a short time before their final departure from the town.

How long the hospitals that have been mentioned will continue to be distributed as described, and how long the existing system of dealing with the sick and wounded will prevail, it is quite impossible to say. For one thing it is the chronic fate of the Royal Army Medical Corps in times of war to be perpetually making and perfecting arrangements for the care of the sick and wounded and then having to change them utterly owing to the progress of events. For another, really wintry weather is now setting in, and difficulties may possibly be experienced in getting the larger hospital ships, all of great size and deep draught, safely in and out of Boulogne. Furthermore, there is always the hope, and, indeed, expectation, that the German forces will be driven much further north quite soon; in this case the advanced hospital base represented by Boulogne may be moved northwards in its turn. If this be done the distant hospital bases may possibly be advanced accordingly, for it is seemingly the constant aim of the medical authorities of the army to get the sick and wounded into base hospitals as rapidly as possible, and to shorten, as far as may be, the distance over which they must be conveyed.

On rereading the foregoing lines it seems desirable to explain that the term "wounded," which is almost exclusively used, is intended to cover cases of every kind which stand in need of medical care. Each hospital train arriving from the front includes amongst its occupants a certain number of men suffering from ordinary maladies. The number, however, is relatively very small. How small it is may be gauged from the fact that at the moment of writing the actual number of sick men to wounded men under treatment in the hospitals in Boulogne—including for the moment in that term the loaded hospital ships at the quay side—is a little over one to four. Those conversant with the medical histories of most previous wars will certainly deem this fact remarkable. Furthermore, the great majority of the cases are not, from a medical point of view, of a serious order. There are very few cases of enteric fever, but a very large number of cases of rheumatism. This is very comprehensible when it is remembered that for weeks past the men have been fighting in wet trenches, and sleeping on more or less damp ground. It is also worth noting, perhaps, that a considerable proportion of the rheumatic cases prove, when inquiry is made, to be reservists—men, that is, called up for duty after leading for a varying number of years lives of much greater ease than those of ordinary soldiers. It is possible, of course, that the onset of the cold weather may change the whole medical picture—there have, indeed, already been a certain number of cases of frostbite—but I am hopeful that this will not be the case, for it is universally agreed that the men are being exceedingly well fed, and that up to the present the vast majority of the troops have shown remarkable powers of resistance.

SURGICAL EXPERIENCES OF THE PRESENT WAR.

DISCUSSION AT THE MEDICAL SOCIETY OF LONDON.

THE discussion on surgical experiences of the present war (see JOURNAL, November 21st, p. 891) was resumed at a meeting of the Medical Society of London on November 23rd, Sir JOHN BLAND-SUTTON, the President, in the chair.

Injuries of Nerves: Secondary Haemorrhage.

Mr. D'ARCY POWER said that the wounds which had come under his care were the result either of the conical bullet, of the round shrapnel bullet, of pieces of shrapnel cases, or of the explosion of large shells. He had seen no case of injury due to bayonet, lance, or sword. He instanced two cases as showing the force of impact.

An officer was wounded by a large shell, which burst within ten yards. The skiagram showed the presence of foreign bodies deep in the erector spinae. Subsequent examination proved that two of these substances were sovereigns, which had been driven out of a money belt he was wearing straight down on to the transverse process of the first lumbar vertebra, which was smashed to pieces. The coins themselves were twisted and concave; one had upon it the impression of the milled edge and part of the obverse of that which lay above it. In the other case part of the patient's diary had been driven into his thigh, and for many days afterwards he shed pieces of its leaves.

The most interesting as well as the most difficult cases were those in which there had been injuries to the nerves and the nervous system. It was necessary to decide whether the subsequent disturbance was due to damage done by the bullet in its passage, or as it lay *in situ*. In many cases this could only be determined by careful examination by a skilled neurologist acting in association with a first-rate radiographer, and the surgeon's action must be governed by their reports. If the damage was done by the bullet in transit its removal would be of no benefit, whilst if the projectile itself was causing irritation it must be removed. He held, therefore, that each case must be considered on its merits, and that it was unnecessary for surgeons to remove every bullet or piece of shell merely because it showed clearly on the skiagram. The most interesting injuries to the nervous system and nerves were those to which the non-committal name of "concussion" must for the present be applied. They had to be distinguished from laceration, haemorrhage, compression, and other tangible conditions by the fact that no gross lesion was presented by examination during life. They occurred in the peripheral nerves as well as in the spinal cord. Experience showed that *x*-ray photographs, as they were usually presented, were not infallible guides to the position or the depth of the foreign body. It might be necessary to undertake an extensive exploration before a bullet was discovered, or it might even be missed altogether. Sloughing rather than suppuration was a feature in most of the wounds, and it was interesting to observe that in many instances in which the bullet had passed completely through a limb, it was only the inlet and outlet which remained as wounds, the intermediate track having healed. The cause of the infection seemed to have acted after the injury, and not at the time. In consequence of the sloughing, haemorrhage needing ligature of the main artery in its continuity was tolerably frequent. When wounds which

had healed became painful it was necessary to reopen them, and in nearly every case the pain seemed to have been due to pieces of clothing left in the tissues, at first without causing irritation. Dry dressings in most cases had to be replaced by fomentations. Iodine had been employed extensively (1 drachm of a 2½ per cent. solution in a pint of warm water) applied on cotton wool. The iodine volatilized if the water was too hot; it was converted into an inert iodate if a starch-containing dressing was used. Much time could be saved if the gaping edges of flesh wounds were brought together by a gridiron of strapping; union by third intention, which was healing by the union of granulations, then took place, just as it did in a baby whose harelip had failed to unite at once. Mr. Power concluded his remarks by pointing out that the surgeon needed constant help from the physician, the neurologist, the pathologist, and the radiographer if he was to obtain the best results for his patient; that he must know when to stay his hand and when to operate, and that his attitude should be rather from than towards operation. It was better to lay wounds freely open than to plug or drain them.

Septic Wounds of Bones and Joints near Large Vessels.

Mr. J. Charters Symonds wished to express his entire agreement with the general principles laid down by Sir W. Cheyne, who had brought them back to the consideration of the time when septic infection was the rule, and had shown that the same conditions prevailed when wounds were exposed, and must be met by the methods originally introduced by Lister. Those who worked in hospitals in the early seventies must recall many old experiences now recurring and agree with Sir Watson's condemnation of the gauze drain when suppuration exists, of the imperfection of much of the so-called sterilization, and of the tendency of an operator to attribute failure to any cause but his own lack of watchfulness. The address he had given was a fine confession of faith, and Mr. Symonds cordially endorsed his advice to younger men to read the account of Lister's early work, accessible in those admirable volumes in the preparation of which his two old pupils and assistants, Cheyne and Godlee, took so large a part. Though the time had not come to formulate definite lines of treatment, much good might result by an interchange of experience. He proposed to confine his remarks to the question of septic wounds near the large vessels and to the management of septic comminuted fractures, and of wounds of joints already septic, for here life and limb were in peril, and the surgeon's whole purpose should be concentrated upon the saving of both, leaving refinements to a later period. The wounds of large vessels—of which two interesting examples had come under his care—and of nerves, of which there were also many, and of the lung and pleura must be omitted. The head injuries he hoped some one else would deal with.

A point that must have struck every one was the septic condition of all but the simple direct bullet wound. The cases had come under care from two to ten days after the infliction of the wound; even after forty-eight hours the wounds had been septic, and the later ones very offensive; yet the absence of toxaemia was remarkable. The temperature, even in fractures, was normal, and the pain, where one of two parallel bones was broken, trivial. The septic condition must be attributed to the length of time the wounded had lain out in the open—often two and three days before help could reach them—and to the urgency of clearing the field hospitals. There had been no time for full disinfection, such as Sir Watson Cheyne rightly desired to see, and which was hoped would now be possible owing to the shifting of the base and the better provision of hospital accommodation. Though most of the wounds on arrival were septic, this was not from the lack of careful dressing *en route*. The Belgian contingent he had seen, for instance, had all been dressed on the ship or on the train, and he paid a tribute to the admirable attention these and the other cases received in transit, involving, as it must have done, a great amount of work on the part of the medical officer in charge and chiefly of the Red Cross nurses. Why was toxaemia absent in most of these cases? Did the missile sear the tissues in its passage? Certain it was that constitutional effects differed widely from those seen in wounds of equal septicity in civil life.

In the treatment of the ordinary flesh wounds he had rested content with frequent boric acid fomentations, not even employing irrigation. In some a 10 per cent. solution of argyrol had been of service. In treating comminuted fractures by bullet or shell he believed the best plan was to be content with warm antiseptic applications.

To take the first case he was called upon to handle, a drummer in the Loyal North Lancashires with a smashed humerus. The man came in on the sixth day, in great pain, foul pus escaping from the openings, the skin inflamed and sodden, and yet the temperature was not raised. He looked ill and wasted, chiefly from exhaustion, for he had undergone the terrible hardship of the long journey to St. Nazaire. A small dependent opening was made for the better drainage and a rubber tube passed through. In doing this it was ascertained that the bone was broken into many fragments. Careful dressing once a day with gauze and wool and firm splinting led to rapid improvement. At the end of three weeks the bone had united. He left after four weeks with one sinus and a strong arm.

Another man had a bullet through the tibia, splitting off a large fragment from the front, and though a direct wound, this was septic and most offensive. Rapid union ensued here also under boric acid fomentations without any irrigation. There remained a sinus leading to bare bone, which would have to be dealt with later.

It was somewhat tempting to open up and disinfect the humerus and remove some of the fragments and again to plate or wire the tibia. The results exemplified the truth of Sir Watson Cheyne's conclusions that it was far better to leave these cases alone. Strong limbs would result though there might be a little imperfection in alignment. He had found bullet and shell wounds of the tarsus more septic and more difficult of recovery. Was this because the joints were involved, or because of the softer character of the bones? Was it wise to depart from the method of non-interference and to curette these cases, say in the third week? He had just carried out such treatment in cases of injury of tarso-metatarsus and the carpus. The immediate result in the latter was an increase in the pyrexia from 101° to 104°. In neither was the result sufficiently advanced to justify any conclusion.

While it was, he thought, generally agreed that the better method of treating these wounds was to be content as a routine practice with the application of boric fomentations and gently washing with hydrogen peroxide or some mild antiseptic, the question must in some instances arise whether more active measures should not be undertaken. He mentioned two examples, one in which a main vessel lay in the wall, and another in which a joint was involved:

A bullet entered the outer and back part of the thigh, passed forwards behind the femur, and took its exit 1 in. inside the line of the superficial femoral. There being great pain and no improvement in the septic condition, the wound was examined under an anaesthetic, the greatest care being taken to avoid injury to the surface. The femoral sheath must have been exposed, for the vessels stood out from the inner surface of the track as a rounded cord. Beyond avoiding all injury and rough irrigation the case was left, and had done well. So great was the danger of secondary haemorrhage that he deemed it necessary to have a tourniquet by the bedside and the attendant instructed in its use.

In another a ricochet bullet carrying a sharp hooklike projection from its base, tore across the line of the femoral just above the apex of Scarpa's triangle. The track, some six inches in length, discharged offensive pus. Though it was impossible to clean this wound, then some four or five days old, the recovery under boric acid fomentations took the usual time of two or three weeks.

These cases gave rise to some anxiety, and he would raise the question whether such wounds should not be enlarged to afford better means for disinfection. It was, he thought, necessary in such cases to remove any fragment of shell, bullet, or clothing with as little disturbance of the parts as possible, and to provide efficient drainage by means of a large rubber tube. This might involve an incision in a dependent part.

The liability to secondary haemorrhage would be increased if the patient had other injuries, and was also septic. If seen within a few hours of the injury and the wall of the vessel was exposed, should the artery be ligatured when the wound was being cleaned? Or, should this be deferred in the expectation that if the disinfection had been effective the danger of secondary haemorrhage had been reduced to a minimum? If the wound became septic, should the main vessel be ligatured and divided in

the wound, or was it better to combine this with proximal ligature? Or, again, was proximal ligature sufficient? He related the following as a case in point:

An officer arrived ten days after being severely wounded in three places. The left arm had been amputated in the field hospital, and showed limited suppuration. The right foot was swollen and septic from a bullet wound of the tarsus, the ankle joint, as was discovered in a few days, being involved. There was a ragged septic wound on the inner side of the knee leading deeply into the popliteal space, and the skin of the leg was also red and infected. From the popliteal wound issued most offensive pus. The patient was wasted, grey and septic, the temperature 103°, and he suffered a good deal of pain, borne with that admirable courage which all must have admired in those who had come home seriously injured. The large principle involved must be whether immediate amputation should have been performed through the thigh in this case. Should the popliteal space have been opened up and the condition of the parts ascertained? The patient improved in a general way, for three days the temperature fell, and the popliteal wound became cleaner. Then fresh infection arose, and the temperature reached 103° on the seventh day after admission—the seventeenth from the injury. On this day the ankle-joint was opened and pus evacuated. Ten days after admission, and twenty-one after the injury, slight haemorrhage occurred from the popliteal wound. This being repeated next day, Mr. Symonds opened the wound, and on passing the finger gently in there came a great burst of bleeding, and it was obvious that the main vessel had been opened. A small fragment of the nickel casing of a bullet was found lying outside the vessels. The artery was with some difficulty secured above and below the wound, and then it became obvious that the vein also required ligature. As he proposed, notwithstanding the slender chance of recovery and in view of the septic condition of the leg and foot, to avoid amputation if possible, a kangaroo tendon ligature was placed on the femoral at the apex of Scarpa's triangle as a further protection. Next day, the foot being discoloured and the leg cold, amputation was performed through the thigh. Though the condition was unfavourable in all respects, the patient was recovering. Examination of the popliteal space when the case was first seen would doubtless have revealed the injury to the vessel, seeing it was then ten days old. This would in all probability have precipitated amputation with the man less able to bear it than he was after a week's rest.

Dealing alone with these wounds in a septic condition he was disposed to think the better practice was to examine and drain, and if the artery was found to be exposed and its sheath injured, to ligature the main trunk some distance above—for example, the brachial in the case of the forearm or the femoral for popliteal injury. He did not mean to say that local ligature of the smaller vessels was not in many cases sufficient. Recently, he had to lay open the calf for smart secondary haemorrhage coming from what he took to be the peroneal artery. The bleeding point was ligatured and the wound treated successfully by the open method. There must be many such cases, and whilst amputation offered an easy, and other things being equal, a comparatively safe way out of the difficulty, it would seem reasonable in view of improved methods to go much further in the attempt to save a limb than formerly was justifiable.

Another subject where information was required was as to the best method of immobilizing and transporting cases of fracture of the femur. Of all injuries these must suffer most in transit. It might be impossible to keep them in an advanced base, and he was told that when the base was at St. Nazaire the order was that all cases should be sent home. When the wound was being cleaned, was it wise to apply a plate with a view to fixation during transit? Where the wound was large and the bone exposed, and an attempt was being made to save the limb, it seemed to him, judging from his experience of compound fractures, to be a sound practice to apply a plate. In the case of the tibia and fibula, his practice at Guy's Hospital was to plate in compound fractures, when it was otherwise difficult to secure good position. In bad cases the plate had to come out, and was sometimes exposed throughout the whole period of its employment; but it served to retain the fragments in position, while the muscles wasted and the surrounding callus formed and enabled more satisfactory dressings to be applied. In itself the plate might have done some harm, but the final result was, in the severe cases with loss of skin, better, in his judgement, than could have been otherwise secured. So that he would, did the opportunity occur, employ plating or wiring, preferably the former in suitable cases. To open up any clean bullet wound, except to secure a large vessel, was a practice which could not be defended even by the most ardent advocate of plating fractures. For transit, so far as he was able to judge, Hodgen's wire splint, designed by this surgeon during the American civil war for the very purpose, was still the best. The frame should be suspended, as Hodgen directed, from a hook at the end of the ambulance. In this connexion he fully agreed with Sir Frederic Eve that no other splint permitted the dressing of compound fractures more conveniently and with less distress to the patient. It seemed to him to possess no rival.

In discussing the value of antiseptics, Sir Watson Cheyne had done good service in bringing back to mind the merits of carbolic acid. It was good to hear that Lister's greatest exponent had not lost faith in an antiseptic with which the earliest and greatest triumphs were secured. While he had himself relied upon carbolic and mercury in the immediate treatment of compound fractures and suppurating joints, he was bound to admit that the 2 per cent. solution of iodine in rectified spirit had given remarkable results in the treatment of large lacerated wounds with or without involvement of bones. It would be interesting to ascertain the separate value of each component of this preparation. He was inclined to think that the alcohol would be found to have no small part in the beneficial results. In some form probably alcohol had been used in the treatment of wounds from time immemorial, as in the rite of circumcision. He fancied there was more than met the eye in the application of wine and oil by the Good Samaritan who might with much good reason be considered the first antiseptic surgeon on record.

Radiography.

Dr. W. IRONSIDE BRUCE exhibited a number of radiograms showing the effects of gun-shot injuries. He said that *x* rays could determine the exact position of a bullet in the tissues, and if the skin was marked it ought, theoretically, to be possible to cut down directly upon it and remove it. There were certain difficulties, however, which were encountered. (1) The distance as estimated by *x* rays, conveyed nothing anatomically as to the situation of the bullet, for this depended upon the thickness of the skin, the subcutaneous tissues, etc. (2) For localization it was necessary to make use of a vertical plane, and this should be followed absolutely at the time of operation. When, owing to surgical requirements, this was deviated from, no further use could be made of the *x*-ray localization. (3) Immediately the incision had been made the marks on the skin were no longer useful. Consequently the accurate information obtainable by *x* rays could not be utilized to the full.

Functional Blindness.

Mr. W. H. H. JESSOP said that *x* rays gave certain evidence of foreign bodies in the eye. He had been impressed by the extraordinary number of cases of patients brought over from the war who were blind. He had seen four such. Nothing was observable by the ophthalmoscope, and without treatment other than rest, perfect sight had been regained. In two others the blindness was accompanied by blepharospasm. These had also completely recovered. All had been exposed to shell fire, and, he thought, had probably been affected by it. He cited also the case of a patient who had formerly had miner's nystagmus. The man had enlisted and had been employed to drive and the nystagmus returned.

Choice of an Antiseptic.

Mr. R. P. ROWLANDS said that Sir Watson Cheyne in his valuable address had wisely confined his attention to the most vital question of all. The rapid and smooth healing of wounds was of the greatest importance to the soldier and to the country. Suppuration placed his life in jeopardy and militated against his early and complete recovery. It greatly interfered with primary or early operation for the repair of injuries of special structures, such as nerves, tendons or bones. It was well known that secondary or late operations for these injuries were more difficult and less successful.

When many men were seen returning with septic wounds, the dirty conditions under which most of the injuries were sustained must not be forgotten, and especially the unavoidable delay in treatment. It was very difficult for surgeons working under the most favourable circumstances at home, to realize the awful conditions

of the war and the unparalleled difficulties which confronted their brethren in France, who by common consent were doing such devoted and heroic work. It was a duty to offer fair criticism and to help by suggesting practical methods which might be expected to improve the results. This could be done by:

1. Laying stress on the Listerian principles which governed the successful treatment of soiled wounds; and
2. By making some definite practical suggestions which could be actually carried out under the difficult and unexpected circumstances of this war.

Sir Watson Cheyne and others had dealt with these points with great ability and detail. He would confine himself to some more general remarks. Most of the shell and shrapnel wounds were, of necessity, laden with bacteria from the skin, clothes, or from the peculiarly infective soil of Northern France or Belgium. The risk of infection from each of these sources was far greater than it was in the Russo-Japanese war. There, frequent bathing and changing into clean clothes, the absence of infective soil, and the intense cold had been all favourable circumstances, which probably accounted for the good results obtained.

It was obvious that clean and dirty wounds required very different treatment. Most surgeons were fairly satisfied with the aseptic treatment of clean operation wounds; for the less wounds were irritated by mechanical or chemical violence the better they did, and the greater freedom there was from pain.

Before the revelations of this war, most of the medical men at the front were so very familiar with the brilliant results of aseptic surgery, and had so little experience of soiled wounds, that the introduction of strong antiseptics into the wounds was abhorrent to them. They feared pain and sloughing. But dirty wounds required cleansing as soon as possible, before bacteria multiplied and invaded the tissues. This was best carried out by a combination of mechanical and chemical means. The longer the interval since the injury the more necessary were strong antiseptics which were capable of permeating the invaded tissues and inhibiting the growth of bacteria. Unfortunately strong antiseptics were useless, and even harmful after twenty-four or thirty-six hours, and a great many of the wounds could not be treated adequately within that period. In the present circumstances the antiseptic used must be strong enough to destroy spores in a short time. Strong antiseptics might prove to be particularly valuable when thorough mechanical cleansing could not be carried out owing to delay in getting to the field or base hospital. Liquified carbolic acid was certainly a very powerful and valuable antiseptic, which he had often used with advantage for earth-soiled wounds. But if its routine use were recommended, difficulties of supply and cost might soon arise. Therefore he suggested the appointment of a committee of surgeons, bacteriologists, and chemists to discuss the variety and strengths of suitable antiseptics. Their report would probably be very valuable. For sterilizing the skin his colleague, Mr. Turner, had found picric acid (1 per cent. solution) in methylated spirit at least as efficient and very much cheaper than the solution of iodine in general use. The most suitable dressing should also be discussed, for secondary infection of the apertures of bullet wounds seemed to be occurring in some cases.

As regards other details of the primary treatment, free drainage and adequate antiseptic dressing were most important. When wounds were already septic, free drainage, irrigation, baths and fomentations were the chief indications. Radical operations for the repair of nerves, tendons, and bones had to be deferred until sepsis had subsided.

In conclusion, he said that it seemed to him that hope of improvement in present results depended upon:

1. Getting the patients into the field or base hospitals earlier, especially by the use of special motor field ambulances, instead of the slow and uncomfortable horse ambulances.
2. Increasing the staff and general facilities for cleansing the wounds at the field and base hospitals. There were numbers of medical men anxious to serve in this way. The present facilities made it quite impossible to carry out the routine treatment advised by Sir Watson Cheyne.
3. More facilities for bathing and changing garments for the men in the fighting line.
4. Moving bad cases as little as possible.

Now that the base was fixed, it ought to be possible to keep the bad cases still and under observation. It was difficult or impossible to treat these cases adequately during long journeys to England. The difficulties of the organization and adaptation of the R.A.M.C. in this war had been enormous, yet, in spite of shifting bases and unforeseen circumstances, the service had been brought to a state of efficiency unequalled by that of any other army. Still, much remained to be done for the greater comfort and better treatment of the wounded. This great and rich country ought to provide everything for the sick and wounded without the aid of any outside society. Everything ought to be under one supreme head, and that head a medical man, who should have perfect freedom of action. He should be free to order as many medical men as were required for the front from time to time.

Treatment of Head Injuries.

Mr. Jocelyn Swan said that he had had experience of about 2,000 cases of men wounded from the front at the Herbert Hospital, Woolwich. He thought the chief points in the treatment of septic cases were adequate drainage and disinfection. Nearly every case was septic, and the point of greatest importance was what was the best treatment to be applied at the front. The difficulties experienced by the Royal Army Medical Corps, who were often working under fire, not only in the fighting line, but also in the field hospitals, were very great. At Woolwich, wounds, already septic, had been opened freely, washed out with hydrogen peroxide or weak permanangate solution, and drained without any attempt to sew them up until the sepsis had been controlled. The organisms most commonly found were staphylococci, streptococci, these two combined, and organisms of the *proteus* group. There had been 10 cases of tetanus. These had been treated by opening up the wound, disinfecting it with hydrogen peroxide, and injecting, by lumbar puncture, large doses of antitetanic serum. Two had died, seven were well, and one was still under treatment. He thought it wiser not to attempt an amputation when symptoms of tetanus had commenced, but to be content with opening up the wound freely. There were 3 cases of malignant oedema, and pyocyaneus infection was not uncommon. A considerable number of cases of secondary haemorrhage had occurred. Like Mr. Symonds, he had been impressed by the lack of toxic symptoms, even in cases so severe as when large collections of pus formed in the knee-joint. There were 18 examples of skull injuries where the bullet entered and passed into the brain. In five the brain had been traversed completely, and two of these got quite well after the depressed fracture had been attended to. There were several cases in which the scalp wound was very small, but much comminution of the skull had taken place, perhaps associated with cerebral abscess or subdural haemorrhage. He thought that skull injuries should be dealt with forthwith, but abdominal and thoracic injuries were often well left alone. Cases of injuries to the chest, with fluid in the pleura other than pus, did not require surgical treatment. The same was true of abdominal injuries, even if it appeared that the intestine had been traversed. He was averse to looking for bullets because *x* rays had shown their presence, except in the case of skull injuries.

Concluding Remarks by President.

Sir John Bland-Sutton said he had followed Sir Watson Cheyne's opening remarks with the keenest interest. No advance, however, could be made by simply following in the paths of predecessors. Lord Lister himself had perpetually introduced changes in his methods. The middle course was the path of safety. While taking advantage of aseptic procedures, it was impossible altogether to avoid antiseptics. He himself had given up carbolic acid because he was peculiarly susceptible to its effects. For many years he had used perchloride, but lately had taken to iodine, and was pleased with the results. It was a striking thing that, although these wounds were septic, they cleared up rapidly with fomentations, and particularly well with hydrogen peroxide; when the sepsis had subsided, foreign bodies, such as pieces

of bone, bullets, etc., could be cleared away, the wounds healing with astonishing rapidity. The highly fertilized country of the North of France contained a soil rich in micro-organisms, with many of which they were unfamiliar. The PRESIDENT announced that the next meeting of the society would be devoted to the discussion of tetanus.

AN OPEN-AIR MILITARY HOSPITAL.

The 1st Eastern Military Hospital (T.F.), Cambridge.

By ROBERT SAUNDBY, M.D., F.R.C.P.
Professor of Medicine, University of Birmingham.

THE value of open-air hospitals for the treatment of the sick and wounded was abundantly demonstrated by the experience of the Northern army surgeons in the American civil war and by the Germans in 1870–71. Florence Nightingale, with that extraordinary prescience that is the mark of genius, recognized this truth, but was unable to overcome the inertia and prejudice opposed to it. Hospitals have continued to be built to please architects and building committees, and a handsome façade is thought indispensable, so that thousands of pounds are spent on putting up monumental buildings to the glory of their founders. In times of peace these may escape criticism, but now, when the demand for hospital accommodation is two or three times that of the supply, and money is needed for so many purposes that there is none for waste, it is wise that an example has been set at Cambridge which I trust may be followed all over the country wherever more hospital accommodation is required, and that there may be no more converting buildings into hospitals which are not designed or suited for the purpose.

The whole merit of the establishment on the open-air plan of the 1st Eastern Military Hospital (T.) at Cambridge belongs to Colonel Joseph Griffiths, R.A.M.C.(T.). By singular good fortune he had been appointed officer commanding for the hospital which at that time had no existence, and when war was declared it had to be created. In the first instance temporary accommodation was provided in the Cloister quad of Trinity. Nine weeks ago the present hospital was begun, and for the last five weeks it has been in full operation providing 1,220 beds besides lodging for orderlies, kitchens, and other offices. The only building that is at present merely in course of erection is the recreation room.

This marvel of creation has been effected at a cost of £20,000, or in round figures of £17 a bed!

We are told that the new hospital to be formed by adapting the Government Stationery Office for this purpose is to cost £25 a bed, yet this greater cost will give us a hospital in the middle of London, perhaps not the best situation to select, and presumably the original cost of the building is not included. At Cambridge the site has been lent and costs nothing. It is King's and Clare's Colleges cricket ground, and the hospital is indebted to the Territorial County Association for such part of the equipment as the War Office in its wisdom deems unnecessary and will not pay for. The bread-cutting machine—an immense saving of labour—and the *x*-ray apparatus were obtained by grants from the County Association.

Before proceeding to describe the hospital one other extra may be mentioned—that is, the Research Laboratory under Professor Sims Woodhead and Mr. Corbett, where by the help of a small grant from the Medical Research Fund it is proposed to study the bacteriology of wounds.

The nurses, who are Territorial Army nurses, are housed in Selwyn College, as the War Office would not sanction a building which Colonel Griffiths proposed to erect for them of the same material, and following the plan of the rest of the hospital. So the nurses have the inconvenience of walking to and from their work, which in winter will prove to be not slight, and may induce the War Office to reconsider its decision.

The hospital building consists of ten blocks, each containing 120 beds; a straight corridor runs right through dividing the wards so that there are ten wards of 60 beds on the right and ten wards of 60 beds on the left of this central corridor, which runs north and south.

The buildings are one story high, with low-pitched roofs covered with corrugated iron. The walls are made of asbestos, set in frame work, the smooth sheets of asbestos or poilite, of an agreeable grey colour; they measure 8 ft. by 4 ft., and are perhaps a quarter of an inch thick. They are made in Holland. The wards contain two rows of beds, one against the back wall the other by the open side, these latter beds being about 2 ft. from the low breast-work. The open front is guarded by blinds of Willesden canvas, like the sunblinds of shop-fronts, which can be let down at an angle to shelter the beds from snow or rain, or in very stormy weather they can be let down so as to lie flat against the openings. The back wall of the ward does not reach quite up to the roof but leaves an opening about 9 in. in width running the whole length of the ward so as to allow through ventilation.

Each ward of 60 beds has two side wards, each containing one bed, for cases it may be desirable to remove from the general ward. There are three baths and five fixed washing stands, with hot and cold water, and three water closets. There is also a small ward kitchen, in which tea for the ward is prepared.

The wards run east and west, so that the open side in each case has a south aspect. The floors are of wood, the planks being winged and fitting closely, so that no draughts can come upwards, but there is an air space below the boards.

Each patient has three blankets, one of which is generally wrapped round him, while the other two cover him, but a fourth is supplied if needed.

The laundry work is done in the town. There is fire-extinguishing apparatus, and the orderlies are exercised in fire-drill; but in view of the non-inflammable nature of the bulk of the material used in construction, it is not thought that fire could get hold of any building before it was extinguished, and it would be very easy to remove the beds and patients in an emergency over the low breast-work or through the low doors which exist in it at short intervals.

The drainage, which was carried out under the supervision of Professor Woodhead, is connected with the town drains, and all the drains have been laid on bricks and cemented.

In addition to what has been described, there is a small isolation ward of twenty beds for gonorrhoea cases.

There is a "pack store," in which each man's kit is kept separately in numbered pigeon holes, and the clothes are sterilized by heat before being stored.

In a separate building are the operating theatre, with two tables, two anaesthetic rooms, and one *x*-ray room, the last being officered by two gentlemen, one of whom came from the Cavendish Laboratory, and the other from the Cambridge Scientific Instruments Company. Their negatives, of which specimens just taken were shown, seemed good examples of radiography, and were said to have been of great service in localizing bullets, fragments of shell, and injuries to bones.

A dispensary and a medical officers' common room are at one end of a long building, in which are also a receiving room and registrar's office.

The sleeping accommodation for 120 orderlies and sergeants of the R.A.M.C.(T.) is in buildings on the same plan, the beds being arranged in bunks, the sergeants being separated from the orderlies, and having twice as much room per man. There is a messroom for the sergeants, which is also used by them as a common room, but the orderlies have a messroom, and a common room in which they can read, or write, and smoke.

The patients in the wards are given breakfast in bed, but most who are able to do so get up and wash before breakfast. They generally go back to bed for this meal, and enjoy a smoke in bed.

As already mentioned, a recreation room for patients, 100 ft. long, is now being built, the woodwork being in position, and judging by the remarkable rapidity with which the rest of the work has been executed, will probably be ready for use by the end of the present month (November).

The kitchen, which provides meals for 1,500 persons, is staffed by five cooks and ten assistants, drawn from the kitchen staff of the colleges. The food looked excellent and most appetising; the cooking is done by gas. Potatoes are cooked in their jackets, but an equatorial strip is removed from each tuber, which greatly facilitates the separation of the skin after they are cooked. The meals are sent to the wards in trolleys, of which there are ten, each trolley holding the food for sixty patients or one ward.

There are small stores for meat, milk, etc., but as most of these are delivered daily, no great amount of space is required for this purpose.

The architect of this admirable building is Mr. Skipper, and the contractor Mr. Negus, both of Cambridge, but the inspirer of the whole, the man to whose patriotism, skill, and energy this magnificent hospital owes its inception, who has achieved this remarkable result in such a short space of time and with such splendid effect, is, as we have already explained, Colonel Joseph Griffiths, F.R.C.S., who has given up his private practice, which as a leading operating surgeon in Cambridge involves no slight sacrifice, in order to devote all his time and all his energy to the work of the hospital—a work in which he is ably seconded by Major Apthorpe Webb, R.A.M.C.(T.), the registrar.

Why, it must be asked, will not the War Office sanction the erection of similar hospitals on unoccupied land near London and other great cities, where the best medical and surgical aid is available? The motor car and the telephone have made a distance of a few miles negligible. Wimbledon Common is as accessible as the Mile End Road and infinitely better for the patients. A hospital with 2,000 beds could be built there on the Cambridge plan for £40,000, and what a boon would such an addition be in a few months when we may expect our numbers at the front to be double or treble what they are now and the casualties proportionately increased!

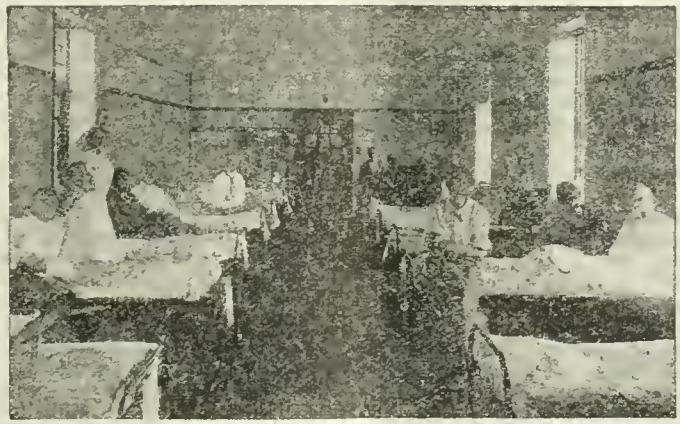
Among other places, Birmingham has ample space, in the empty land by the University buildings now occupied as the 1st Midland Military Hospital, for such an extension, and it only awaits the approval of the War Office to be undertaken by patriotic citizens who would be pleased to contribute to its equipment. We cannot believe that the example of Cambridge will be allowed to be lost.

HOME HOSPITALS AND THE WAR.

BRIGHTON.

The Extension of the 2nd General Eastern Hospital (Territorial).

By order of the War Office a very considerable extension of the size and scope of the 2nd Eastern General (Territorial) Hospital, Brighton, is being carried out. The number of beds is to be increased from 520 to 1,000, so that, in addition to wounded and sick men from the Expeditionary Force, those from the very large camps established at Seaford, Shoreham, Uckfield, Southwick, Crowborough, Portslade, and other towns, for the men of Kitchener's Army and the Territorials, may obtain any medical or surgical attention they may require.



Gordon Ward, 2nd Eastern General Hospital, R.A.M.C.(T.), Brighton.

The thousand beds are made up as follows. In the original buildings, the Brighton and Hove Grammar School, and the Stanford Road Council School fresh wards have been opened, bringing up the number of beds to 609. Two new buildings—the Howard Convalescent Home and St. Mark's Church School, close together, and situated at Kemp Town, at the extreme east of Brighton, in an open and healthy part—have been taken over, and contain respectively 73 and 160 beds. An additional building, near by, will shortly be equipped, to make up the number to 1,000.

The staff is also being enlarged. So far no additions have been made to the administrative staff, but some well deserved promotions have been gazetted. Major James A. Rooth, the Commanding Officer, has been promoted Lieutenant-Colonel, and Lieutenant Walker, the Registrar, Captain.

The medical staff originally consisted of eighteen of the thirty medical officers whose services were available on mobilization. This number, on account of the large amount of work involved, is to be increased. The establishment of non-commissioned officers and men has been raised to number 169, and the nursing staff has been increased by the addition of about forty extra sisters and nurses.

The new buildings at Kemp Town are fully equipped with operating theatre, dispensary, rooms for medical officers, etc. They are complete in themselves, and make a first-class hospital.

Up to the present eight convoys of wounded from the British Expeditionary Force have been admitted, with a total of 800 men, which includes those sent to the Royal Sussex County Hospital, the French Convalescent Home, and other places. Two convoys of wounded Belgians, numbering 181, have also been taken into the hospital. From the Territorials and Kitchener's Army there have been 938 cases. The number of deaths among the men from the Expeditionary Force is 9. Of these, 2 have been from tetanus, 5 from bullet wounds—2 of the head, 2 of the limbs, and 1 of the abdomen—1 from enteric fever, and 1 from meningitis following otitis. From the men of the Home Force 5 deaths have occurred—1 each from typhoid fever, tuberculosis of the intestine, pneumonia, chronic nephritis, and gastro-enteritis.

So far only the main operating theatre at the Grammar School has been used. Another theatre in this building is being prepared, in addition to that at Kemp Town. About 200 operations have been performed there, and of this number only 2 have been followed by fatal results, 1 after trephining for bullet wound of the skull, and 1 after short circuiting for abdominal injury by a bullet. The operations carried out were of all varieties—for example, for appendicitis, extraction of bullets, trephining, radical cure of hernia, for varicocele, for varicose veins, etc. A good many minor operations have been carried out in the wards. The *x*-ray department has been busy, about 500 examinations having been made.

The staff and all concerned in the organization and management have reason to congratulate themselves on the success of the efforts they have made to equip and maintain one of the largest military hospitals in England.

EDINBURGH.

On November 19th, and again on November 21st, parties of 100 wounded soldiers reached Edinburgh, where they were received by members of the Red Cross Society. The men of the first convoy were distributed between the Military Hospital at Craigleith and Leith Hospital, whilst those of the second went partly to the Edinburgh Royal Infirmary and partly to the Deaconess Hospital in the Pleasance. In addition to these about forty wounded soldiers are at Whitehill House, near Dalkeith. It is now no uncommon sight to witness convalescent men enjoying motor runs in the neighbourhood of Edinburgh.

The arrangements for the distribution in Scotland of wounded in auxiliary hospitals and convalescent homes has been taken over by the Scottish branch of the British Red Cross Society. All the institutions will be inspected by the society. The executive has approved of the auxiliary hospitals and convalescent homes already in use, but without any financial liability except where specifically undertaken. In future all offers are to be made to the Red Cross Committee of the county, which, if it approves, will communicate the offer to the Red Cross Commissioner for the district, who will decide which institutions are to be ranked as auxiliary hospitals, where the grant of 2*s.* a head a day will be given by the military authorities. Patients sent to convalescent homes will be such as do not require active medical or surgical treatment, and for these no grant is allowed by the

military authorities, but the executive will be prepared to consider applications from any of these recognized institutions, either as auxiliary hospitals or convalescent homes, for financial assistance. Clothing and comforts must be requisitioned for from the Commissioners, who are as follows:

Western District.—Lieutenant-Colonel R. D. M'Ewan, St. Andrew's Halls, Glasgow. City of Glasgow, Argyll, Ayr, Bute, Dumbarton, Dumfries, Kirkcudbright, Lanark, Stirling, Renfrew, Wigtown.

Eastern District.—Mr. David Wallace, C.M.G., 2, Frederick Street, Edinburgh. City of Edinburgh, Berwick, Clackmannan and Kinross, Fife, Haddington, Linlithgow, Midlothian, Peebles, Roxburgh, Selkirk.

North-Eastern District.—Colonel J. Scott Riddell, M.V.O., Boys' Brigade Hall, Crimon Place, Aberdeen. Aberdeen, City of Aberdeen, Banff, Caithness, Elgin, Inverness, Nairn, Orkney, Ross and Cromarty, Shetland, Sutherland.

Central Eastern District. Colonel W. Gordon Thomson, V.D., 38, Nethergate, Dundee. City of Dundee, Forfar, Kincardine, Perth.

MEDICAL NEWS FROM GERMANY.

Wounded in Berlin.

In Berlin twenty-five hospitals have been improvised with accommodation for about 20,000 wounded. Such buildings as the one erected for the Olympic games have been converted into hospitals, and as many as four rows of beds have been placed in each ward. To cope with the thousands of wounded factories, museums, picture galleries, and the like have been transformed into hospitals. Among these is a high school of art, where sculptures and paintings have had to give place to the wounded. In most cases the wounded have been given excellent accommodation and attention, and private munificence has supplied them with certain luxuries, among which tooth-brushes are mentioned. The severely wounded are conveyed singly from the station to these hospitals in motor ambulances, a constant stream of which is to be seen daily in and about Berlin. Many of the wounded that came from Lemberg were in a miserable condition after the long railway journey. In many cases they had not taken their clothes off for several weeks, and they left on the mind of the spectator an impression of utter weariness and collapse. Yet their courage and stolid endurance were extraordinary. In the treatment of diarrhoea much faith is being attached to cognac, to which a few drops of tincture of iodine have been added. Many of the wounded, particularly of those sent from the scenes of action in East Prussia, suffered from gonorrhoea. The largest of the hospitals is at Tempelhof, where accommodation for 1,200 is provided. The patients include officers and men from the German, French, Belgian, Russian, and English armies. Many are severely wounded, but no difference is made in the treatment of friend and foe.

German surgeons with experiences of the war of 1870 express boundless praise of the improved conditions towards which motor ambulances have contributed much in the present war. A shortage of gauze and cotton-wool is already imminent, and women and children are being urged to make surgical dressings from old linen. Letters from German surgeons at the front confirm the experiences of our own surgeons as to the deplorable frequency of tetanus following shell wounds. Geheimrat Lange writes that an amputation was performed in one case of tetanus, and that the patient was subsequently considered out of danger. He expresses great satisfaction with the results of careful fixation of limbs in fractures. He prefers the fenestrated plaster-of-Paris splints to any other form; two to three days after the application of splints the patient's temperature would be normal, even though it had been as high as 104° at the outset. He is convinced that the best after-treatment for such cases can be effected only by surgeons with orthopaedic experience and in a hospital devoted to this purpose.

Prevention of Infectious Diseases.

The military medical authorities are alive to the dangers of infectious diseases, and are on their guard against plague, which they fear may be introduced by the native soldiers from India. So anxious are they to detect this disease as early as possible, that they regard all cases of pneumonia as suspicious, and invariably examine the sputum for the bacillus of plague. Dysentery is already giving trouble in several hospitals, and it is also reported as being rife on the borders of Russia. The stools of suspects are frequently examined for dysentery and cholera, but down to the middle of October the latter disease had not been detected. Considerable difficulties were experienced in the isolation of suspected cases, and gonorrhoea has frequently broken out among the convalescents. In several places shelters of wood have been run up, and, each wall being composed of two thicknesses of wood, they have proved warm and comfortable, yet have not been costly.

Treatment of Suppurating Wounds.

Several new devices have been suggested and adopted for the treatment of suppurating wounds. Raw turpentine, for example, has been used as a dressing, and is said to cause neither pain nor irritation. Pure liquid paraffin, with or without the addition of 2 to 2.5 per cent. of iodoform, has also been advocated in very septic cases. Corrosive sublimate was also applied in a strength of 1 in 1,000, and was preferred to the weaker solutions. It is thus evident that German surgeons were carrying out antiseptic methods with much vigour.

The Treatment of Abdominal Wounds.

The Leipzig surgeon, Professor Payr, who is attached to the army of the King of Saxony, has discussed in the War Supplement (No. 2) of the *Muenchener medizinische Wochenschrift*, the treatment of abdominal wounds in war time. The victims of these wounds, he said, seldom receive proper treatment at an early date, when operative interference would be most beneficial; and at a later date, when all the resources of surgery were at the patient's disposal, he was either already on the high road to recovery, or too ill to be benefited by an operation. Fortunately the perforation of the stomach and intestines by the modern small-bore bullet was often followed by spontaneous closure of the wound, the patient recovering under conservative treatment. When laparotomy was performed some time after the infliction of the wound, coils of intestine were frequently found matted together by organized fibrin, localized abscesses, often faecal, being situated between single coils of intestine. It was not possible thoroughly to examine the wounds in such a case, and there was little prospect of establishing effective drainage. Basing himself on his experiences of perforated, gastric, and duodenal ulcers, and of multiple wounds of the intestine by Browning pistols, several cases of which he had had occasion to treat, Professor Payr made the following suggestions: He believed that when the stomach and intestines were perforated, blood, in some cases mixed with the contents of the organ, escaped into the free peritoneal cavity, tracking gradually into the pelvis, provided the effusion was not too great. It thus frequently happened that when a laparotomy was performed on the second day, no free blood was found in the upper abdomen, whereas the pelvis might be filled with it. Blood in this position usually became infected from the intestine, and was often not absorbed. In the pelvis an abscess formed, which, bursting through the surrounding adhesions, caused serious peritonitis. Faced with this possibility, the surgeon in war should, when the wound was recent, that is, only twenty-four to forty-eight hours old, and the general condition satisfactory, make a small opening under local anaesthesia through the abdominal wall just over the symphysis, large enough to admit a rubber tube as thick as the finger; this should be passed into the pelvis, and the patient should remain half sitting up or lying on his side. When operation was possible only after a considerable period, the surgeon should at once examine the pouch of Douglas from the rectum, and ascertain whether tenderness, distension, tenesmus, and disorders of micturition existed. If a definite, circumscribed swelling were detected, the sphincters should be strongly dilated and the mucous membrane above the swelling seized by two forceps, and an exploratory needle inserted between them. Altered blood, turbid exudate or pus might thus be drawn off, the evacuation being completed by making an opening with the cautery or knife, and introducing a drainage tube through it. When, however, the pouch of Douglas was diffusely distended and very painful, pelvic peritonitis must be suspected, and a parasacral opening made by enucleating the coccyx.

The retrorectal fascia should then be exposed by a longitudinal incision, and a lateral opening made into the anterior fold of the peritoneum in this position. This operation, though more serious than the one already described, could be rapidly performed with a few instruments by a skilled surgeon. The after-treatment recommended was by draining the pelvis through a tube fixed in the wound, which was kept open and lightly plugged. It does not appear that Professor Payr has hitherto been able to apply these principles extensively in the present war.

THE BRITISH RED CROSS SOCIETY.

The Situation in France.

During the past week no more doctors, orderlies, or nurses have been sent to France, as all the personnel asked for is now in the field. The shortness of the line of communications is still an important factor in facilitating Red Cross work. It renders possible the rapid transport, with a minimum of medical and surgical attention, of all who are wounded at those sections of the battle line held by British troops. There is, in fact, a considerable waiting list of surgeons whose services are not likely to be required so long as the war is waged in its present area. Should an extensive German retreat take place, a larger number of surgeons will be required. Paris is no longer an important hospital base so far as British wounded are concerned; Boulogne is their centre, that of the Belgians, Dunkirk, and of the French, Calais.

Health of the Troops.

The health of the troops continues to be extraordinarily good, especially when the severity of the weather now being experienced is remembered. There is very little typhoid fever, less tetanus, and still less gangrene. All Red Cross workers have been impressed by the excellent spirit of the British troops. They say the men are in good heart, full of confidence and good spirits. Even if they show signs of fatigue from long service in the trenches their power of recovery is marked, and they soon regain their spirits and liveliness. What impresses all the soldiers is the terrible slaughter that the Germans are undergoing—out of all proportion to the losses on our side.

The New War Hospital for London.

Rapid progress is being made with the scheme already mentioned in the Journal for the establishment of a 1,500-bed hospital in the new building being erected for H.M. Stationery Office, and further details are now available. On each of the five floors there will be accommodation for about 360 beds; each floor will be a complete hospital in itself with its own operating theatre and staff. It is intended to invite a number of leading surgeons and physicians in London to act as an honorary staff; fifty beds will be allotted to each surgeon or physician. Thus about twenty-six surgeons and eight or ten physicians will be needed. All the bacteriological and pathological work will be undertaken by the Lister Institute of Preventive Medicine. The building, which is in Waterloo Road, is found to be readily adaptable for hospital purposes. On none of the floors is there at present a single partition, so that those responsible for the adaptation will have a free hand in the planning of wards. There are several lifts; the lighting and heating installations are complete; there is a special system of ventilation and the building is fireproof.

The "Society Lady" in Red Cross Work.

Sir Frederick Treves made some observations to a representative of the Journal, to whom he gave the foregoing particulars, as to what he described as "the continued outcry against the society lady" in connexion with Red Cross work. The kind of person aimed at by those who made these comments, he said, is not encouraged by the Society. The names of some very highly placed personages certainly appear on its list of those in charge of departments, but these are ladies thoroughly experienced in public work of the kind, and, indeed, eminent in the particular branch they have undertaken. To give an example, the Countess of Dudley is doing the same work that she performed with such remarkable success in the South African war. The criticisms, however, are, we may point out, directed rather against the intrusion of amateurs into the actual work of nursing the wounded.

CASUALTIES IN THE MEDICAL SERVICES.

Army.

The official lists of casualties published since our last issue contains the name of one medical officer of the Royal Army Medical Corps killed in East Africa, and four wounded with the Expeditionary Force in France.

Killed.

Captain Cecil A. T. Conyngham, R.A.M.C., whose death in action in East Africa was reported last week, was educated at St. Andrews' College, and Trinity College, Dublin, where he graduated M.B., and entered the army in July, 1907. He was a keen athlete, and swam for Trinity when that College won the senior water polo cup in 1903. He was a member of the Wanderers' Rugby football team when it won the cup in 1906. At the outbreak of the war Captain Conyngham was stationed in India.

Wounded.

Coppinger, Captain C. J., R.A.M.C.
Irvine, Major A. W. A., R.A.M.C.
Lister, Lieutenant W. H., R.A.M.C.
Watson, Lieutenant A., R.A.M.C.

NOTES.

Medical Arrangements for the Troops in South Africa.

According to the *South African Medical Record* of October 24th a central committee has been appointed to co-ordinate the various organizations formed for the purpose of providing medical necessities for the British troops operating against German South-West Africa. Our contemporary, while approving of the action taken as likely to lessen the friction and waste of energy due to overlapping organizations—"sometimes of mere busybodies"—expresses what seems to us a natural surprise that there should not be any member of the medical profession on the committee except Sir Thomas Smartt, the chairman. Our contemporary goes on to say: "If the committee only succeeds in staving off from the military hospitals the plague of well-meaning ladies with no end of zeal and very little knowledge, who nearly drove the medical officers and Tommie Atkins mad during the Boer war, it will justify its existence. Many of these ladies might have been of untold use working outside, but inside they were a deplorable nuisance. In the same connexion, we do hope that, both in our country and in England, the door will be firmly closed on the amateur nurse."

Medical Officers Wanted.

We have received the following notifications:

Operating Surgeons.

Lieutenant-Colonel Charles Mouk, Officer Commanding the 2nd London Clearing Hospital, Duke of York's Head Quarters, Chelsea, S.W., gives notice that that unit is now being mobilized for service with the British Expeditionary Force, and requires the services of two highly competent operating surgeons to complete its surgical staff. The clearing hospital, situated a short distance behind the fighting line, receives all the wounded of a division, and is equipped to deal at once with the most serious cases. The officers appointed will receive commissions in the Territorial Force for the duration of the war.

Field Ambulances.

Lieutenant-Colonel A. G. Hamilton (R.A.M.C.T.F.), Officer Commanding Welsh Border Mounted Brigade Field Ambulance, Drill Hall, Bungay, East Suffolk, will be glad to hear from any medical man wishing to obtain a commission in the Royal Army Medical Corps (Territorial Force). There are several vacancies in the Imperial Service Unit now stationed at Bungay, East Suffolk, and in the Reserve Unit at Chester. Men joining for the period of the war only obtain an allowance of £20 for outfit, and those joining as Territorial officers for four years receive £40. In both cases a grant of £7 10s. is made for the purchase of camp kit. Pay and allowances as in the regulars.

There are several vacancies for officers in the Reserve unit of the 2nd East Anglian Field Ambulance. Applications should be made to the Officer Commanding, Colonel Blake Masson, 44, Bethel Street, Norwich, as soon as possible.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

WOUNDED SOLDIERS AND THE DUBLIN HOSPITALS.

THOUGH Dublin is provided with a large number of excellent hospitals, yet, owing to the economic conditions in the city, and the fact that it serves as a hospital centre for a large part of Ireland, the resources of these hospitals are continuously taxed to their fullest extent, and often, especially in the winter, the accommodation they provide is scarcely adequate to the demands made upon them. In spite of this they have all made an effort, and have put aside a certain number of beds for the reception of wounded soldiers; the total is about 500. Within the last month two batches of wounded soldiers arrived in Dublin, and every available bed was filled; some of the wounded have now so far recovered that they have been able to go either to their own homes or have been sent to a convalescent home, at least half the beds are still occupied, and this is likely to continue for a considerable time. When the next batch of wounded soldiers arrive, only a small number of beds will be available, and therefore either it will be impossible to receive the soldiers or a further number of beds will have to be removed from the occupation of the sick poor, for whom they are intended. In order to get over this difficulty various suggestions have been made (*a*) that a temporary wooden hospital should be erected in the Phoenix Park capable of holding 1,000 patients; (*b*) that additions should be built in the grounds of each of the Dublin hospitals with from 50 to 100 beds; (*c*) that old houses or buildings should be converted into a hospital; (*d*) that a permanent Red Cross hospital should be built. The latter suggestion is open to the objections that hospitals in Dublin are already too numerous and that the expense would be very great. The cost of converting a row of houses into a hospital would be considerable, and possibly warehouses or other buildings might be more suitable. The plan of making additions to each hospital is probably most favoured on the ground that it would not entail the setting up of new executives and practically all the Dublin hospitals have spare ground about them. The cost of separate erections would, however, be considerable, and probably the best and cheapest plan would be the erection of a temporary wooden hospital in the Phoenix Park, where the Dublin surgeons would willingly give their services if there were a sufficient number of house-surgeons and dressers to carry out the routine work. It will, however, be necessary to take action at once, as at any moment there may be an urgent demand for more beds for the wounded.

VACCINATION.

At the last meeting of the guardians of the North Dublin Union a letter was received from the Local Government Board asking whether the guardians were prepared to enforce the Vaccination Act and to institute prosecutions against those who disregarded the notice to have their children vaccinated. The chairman said that one of the guardians' medical officers had reported that there were 5,431 vaccination defaulters in his district. A guardian stated that the death-rate among children who were vaccinated was much greater than among those who were not. A proposal to hold a special meeting of the guardians to consider the question, as suggested by the Local Government Board, was defeated by 17 votes to 9, and the Board agreed to a resolution to stand by its previous antivaccination decision.

At the last meeting of the Tuam Board of Guardians, at which a similar letter from the Local Government Board was read, it was resolved that in sending out notices in future the authorities should notify that compliance was not compulsory.

ATTACK ON DOCTOR BY PATIENT.

At the monthly meeting of the Committee of Management of the Derry Asylum on November 20th the Chairman announced that one of the inmates had made an attack on their highly respected medical officer, Dr. Hetherington, who had been in their service for forty-two years, and was beloved by them all. They were glad to know that he was making satisfactory progress towards recovery. The patient murderously assaulted the doctor with a knife, stabbing him in several places. Dr. Heatherington pluckily struggled with his assailant until help reached him, and he was eventually rescued in an extremely weak state. A letter was read from Mrs. Hetherington, expressing her husband's appreciation of the prompt and skilful attention of Dr. Watson, and gratefully acknowledging the sympathy which had been extended to him by the asylum staff. Dr. John Watson, acting medical superintendent, reported that Dr. Hetherington's life was now out of danger. The necessary steps were being taken to have the inmate transferred to a criminal asylum.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

THE ST. ANDREW'S AMBULANCE ASSOCIATION IN EDINBURGH.

IN the midst of the war time the St. Andrew's Ambulance Association, which is a national association for the promotion of civil Red Cross work in time of peace, held its annual meeting on November 20th. Lieutenant-Colonel J. M. Cotterill, Consulting Surgeon to the Edinburgh Royal Infirmary and Surgeon to the 2nd Scottish General Hospital (T.F.), presided, and the annual report was adopted. In this report it was stated that the number of classes held during the year within the Edinburgh district was 94, of which 79 were first aid and 15 home nursing and hygiene; of the pupils who presented themselves for examination 1,743 had passed and had been awarded the association certificate (in the case of first year students), and the St. Andrew's Ambulance Corps now numbered 5,000 men and women. The chairman, in moving the adoption of the report, pointed out that although the primary object of the association was work in times of peace its operations were of the greatest service in war. For many years it had maintained from members of its ambulance corps a body of men to act as a reserve personnel for the home military hospitals in Scotland; at the outbreak of hostilities these men were at once mobilized, and manned the home hospitals in Scotland, relieving the men of the regular forces for duty abroad; the mobilization had been carried out in forty-eight hours. Further, at the request of the War Office, 100 trained ambulance men drawn from the corps had been mobilized for service at the front, and had left for Aldershot on October 26th. The association had also supplied orderlies to the various general hospitals, and its wagons had been placed at the service of the naval and military authorities and the British Red Cross Society. An appeal was made for increased support.

FOSSIL MICRO-ORGANISMS.

At a meeting of the Royal Society of Edinburgh on November 16th, Mr. David Ellis, Ph.D., read an interesting paper on fossil micro-organisms in the Jurassic and Cretaceous Rocks of Great Britain. He stated that some of the organic matter in the fossiliferous ferruginous rocks had been in a putrefactive condition when engulfed. He had found organisms belonging to a group akin to the modern Phycomycetes, and in the Island of Skye minute ones belonging to the Actinomyces. Near Folkestone, too, remains of fossil bacteria, in the form of bacilli and cocci had been discovered lying inside the small organic fragments of these rocks in the gault (clay and marl). That the earth, then, was not germ-free in these early days may be concluded from Dr. Ellis's investigations, and we have to think of man's enemies—who are also, let it be remembered, his friends—awaiting his advent on this planet. Possibly if man were wiser their friendliness would be more apparent.

EDINBURGH MEDICINAL WELLS.

At a meeting of the Edinburgh Geological Society, on November 18th, Mr. D. M. Tait, H.M. Geological Survey, read a paper on bores for water and wells in the Wardie shales. He pointed out that a number of wells in the neighbourhood of Edinburgh had been used for medicinal purposes in years gone. Most of them were now known only by the accounts of old writers. With the exception of the Balm Well (or St. Catherine's Well), all were in the

Wardie shales. These wells were: (1) Craiglockhart Railway Cutting; (2) St. George's Well, Stockbridge, Water of Leith (sulphurous); (3) St. Bernard's Well, Water of Leith (sulphurous); (4) Bonnington Mineral Well, on the Water of Leith; (5) The Physic Well, or Lady Well, at Corstorphine (sulphurous); (6) The Spa Well at Davidson's Mains, Barnton; and (7) Mid-Calder Mineral Well (sulphurous). All these wells in the Wardie shales were probably nearly on the same stratigraphical position within the series. In view of these facts it might be concluded that the water likely to be obtained from wells or bores on the Wardie shales was not suitable for ordinary domestic purposes.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

MANCHESTER AND DISTRICT.

THE MANCHESTER UNIVERSITY AND THE WAR.

AT a meeting of the Court of the Manchester University on November 18th, the Vice-Chancellor, Professor Weiss, described the part which the university had taken in the preparations for the war. Since war began it had continued to act in its educational capacity, and though at first it was thought that some of the buildings would be required for hospital accommodation, the military authorities had shown every desire to interfere as little as possible with the educational work. The quadrangle and athletic fields had been given up for the drilling of recruits and accommodation had been offered for Red Cross work. During the vacation a large number of students had been enrolled in the Officers' Training Corps and about 200 had applied for commissions. A new corps had been formed which had been joined by 130 recruits, and application had been made for permission to form two more platoons of 60 members each, one of which would be filled by members of the university staff. Daily lectures were being given at the university on tactics, and as the War Office was anxious that recruits should be efficient by Christmas, the Senate had decided to suspend the usual lectures on two days a week. Arrangements had also been made to enable the women members of the university to take part in Red Cross and relief work. Of last year's students alone 130 students were known to be with the forces or training in camp, and of these 80 had received commissions. In addition large numbers of past students had joined the forces and eighteen members of the staff were acting in various capacities at the front or in camp. He was sorry to say that news had been received that some of their students had been wounded and three or four killed at the front. Among these was Captain Foster, who had been seriously wounded at Mons. Captain Nugent had also been wounded, but had completely recovered.

An address had been sent to the sister university of Louvain, and a number of professors and teachers of Belgian universities were receiving hospitality at private houses through the endeavours of members of the staff. The university had also given facilities to the Belgian professors, teachers, and students to continue their studies in the libraries and laboratories of the university. As a result of the war the number of students was between 200 and 300 fewer than last year, but the entries of new students were not so few as had been expected, and in the medical department the numbers were higher than last year. The income of the university from fees had fallen over £3,000, and as the Court had undertaken that members of the staff who were at the front should not suffer financial loss in consequence, the expenses had not fallen with the income. The Vice-Chancellor added that many members of the medical staff, though they were not at the front, were giving notable service at the Whitworth Street military hospital.

The treasurer's report for the year ending July 31st, 1914, showed that the total assets of the university were £1,395,965, an increase of about £5,000 over the previous year. The receipts were £81,436, which is a decrease of £429, and the expenditure was £81,319, an increase of about £400. The war would undoubtedly seriously affect the coming year's revenue. Their income would be considerably reduced and they would have a heavy expenditure to meet on the new Arts buildings which were to cost £40,000, but it was felt that any appeal for further funds could hardly be made at present. The Court then adopted a resolution which proposed certain modifications of the statutes and ordinances in order that members engaged on active service or otherwise in the defence of the country shall not suffer any disadvantage.

THE SALFORD INSURANCE COMMITTEE AND ALLEGED OVER-PRESCRIBING.

At a meeting of the Salford Insurance Committee on November 19th it was reported from the Medical Benefit Subcommittee that the Panel and Pharmaceutical Committees had not been able to agree as to whether certain of the panel practitioners should be surcharged for alleged over-prescribing in the year 1913. The Panel Committee still adhered to its previous report, which stated that it saw no reason for surcharging any of the sixteen practitioners involved, while the Pharmaceutical Committee maintained that the cost of the prescribing by those practitioners had been in all cases above the average and in some cases excessively high. The Medical Benefit Subcommittee felt that the Insurance Committee would find great difficulty in deciding between two professional bodies, and as the Commissioners some time ago offered to meet a deputation of the three committees and to assist the Insurance Committee in coming to a decision, the Subcommittee recommended that representatives of the three committees should be sent to meet the Commissioners. This recommendation was adopted by the Insurance Committee, the Chairman and Clerk being elected to represent the Insurance Committee, while the Panel and Pharmaceutical Committees were invited to appoint their own representatives on the deputation.

WALES.

THE MEDICAL SERVICE OF THE WELSH ARMY CORPS.

WE mentioned last week that the duty of raising and organizing the medical units for the Welsh Army Corps had been undertaken, at the request of the executive committee, by Mr. Lynn Thomas, C.B., and that he was already proceeding with the establishment of three field ambulances and a sanitary company for the first division. In pursuance of the policy of giving attention to sanitary matters at the earliest possible date, a meeting of medical officers of health in Wales, summoned by Mr. Lynn Thomas, C.B., was held at Shrewsbury on November 18th, under the chairmanship of Dr. Edward Walford, M.O.H. Cardiff. The following resolutions were adopted:

1. That the medical officers of health of the counties and county boroughs and medical officers of health devoting their whole time to their official duties in Wales and Monmouthshire be formed into a national committee to assist the executive committee of the Welsh Army Corps with the object of safeguarding the health of the troops whilst at home.
2. That this committee be empowered to appoint subcommittees to deal with any matters which may be referred to them in connexion with any of the brigades.
3. That this committee recommend the executive committee of the Welsh Army Corps to form an advisory sanitary committee to assist in formulating schemes which may be considered essential or desirable for safeguarding the health of the troops.

Canada.

[FROM OUR SPECIAL CORRESPONDENTS.]

ORILLIA HOSPITAL FOR THE FEEBLE-MINDED.

THE annual report of the Orillia Hospital for the feeble-minded for the year 1913 shows that the institution was filled to its utmost capacity during the year, and that constant demands for admission were made. It has been necessary to enlarge the building by the addition of a "cottage" capable of holding two hundred women patients, and a similar building for men patients is to be commenced as soon as possible. When this is done the institution, which will then consist of a main building and four cottages, will contain accommodation for 1,200 patients, and the main building will be used as a training

school for boys and girls ranging in age from 6 to 15 years. The industrial training of children of this age has met with much success, and it has been observed that marked improvement is apparent between these ages. The girls devote a good deal of their time to needlework, and even those of low mentality can often do beautiful embroidery. The boys are employed outdoors, and in weaving and basketry. Some excellent results have been obtained from the work done in the pathological laboratory, and Dr. Evans is now engaged in carrying out a series of Wassermann tests.

HOSPITAL FINANCE.

The hospitals throughout the country are suffering from lack of funds, and many of them have been obliged to close some of their wards, and it is possible that some of them may have to close altogether.

Correspondence.

THE FUTURE OF THE LISTER INSTITUTE.

SIR,—Now that the vote of the members of the Lister Institute has been taken, and has resulted adversely to the scheme put forward by the Governing body, it may be allowable to say a word upon the controversy to which attention has already been drawn at different times in your columns.

That the proposal embodies advantages of the highest order cannot be denied. It would enable the Institute to obtain command of clinical material, a want that has been felt and acknowledged almost from its foundation; and it would, moreover, enable the Institute to co-operate systematically in researches of profound practical importance.

At the meeting held on November 18th it was fairly well shown that no *direct* interference from official sources would be attempted or permitted. But allowing this, there still remains the insuperable objection that the standard and measure of the value of the work carried out, if not solely a utilitarian one at the outset, would almost inevitably become so in the course of time. It is difficult to see how it could be otherwise in a Department receiving public money for the purpose of direct public benefit.

No one would, of course, maintain that utilitarian science is beneath any other form in dignity. It is only when the utilitarian end is viewed as the sole one worth pursuing that the true scientific ideal becomes obscured.

The fundamental fallacy underlying an exclusively utilitarian aim, even from the utilitarian side itself, lies in the arrogated possibility of foreknowing what discovery may or may not prove useful. No degree of utilitarian sagacity would have led, for instance, to the discovery of radium, the therapeutic value of which is hardly at present calculable.

Were the Lister Institute to amalgamate on the particular scheme devised, it is in this direction that it would suffer: its present freedom of research (though not, of course, absolute) would become first restricted, and then, perhaps, extinguished.

To the Medical Research scheme itself the same objection would hardly apply; it might legitimately limit its activities to direct utilitarian problems without holding the utilitarian error.

But is there no means of compromise; of profiting by the advantages of amalgamation, whilst escaping from its dangers?

The unique position of the Institute gives it a perfect right, if it thought fit, to require that under any scheme of amalgamation it should reserve an autonomous department, absolutely irresponsible to the Medical Research Committee or Governmental control. There need be no difficulty in the Institute retaining a portion of its fine buildings adequate for such a purpose, and a proportionate amount of its funds, together with its present governing body and scientific staff.

By the scheme of the Governing body the present members of the staff would be allocated to different sections of the new Institution, and could carry out work only as approved by the Medical Research Committee. But there is no reason why the existing staff should not be placed, in addition, upon, and constitute the entire staff of an autonomous department, and why each member of it might not be free at any time to work on either side; either with the other staff at a utilitarian problem of public importance, or on the autonomous side upon a subject that might not come within the approval of the Medical Research Committee.

It is to be sincerely hoped that the Governing body of the Lister Institute will not allow the verdict against their proposal to be a final one, but that it will, before so great an opportunity passes, put an amended scheme before the Members that will ensure more general acceptance.—I am, etc.,

S. G. SHATTOCK,
Professor in Morbid Anatomy in the University of London.

November 20th.

OPERATIONS OF EXPEDIENCY ON RECRUITS.

SIR,—Mr. C. J. Bond is to be congratulated on having drawn attention to a very necessary piece of surgical work, and the Leicester Royal Infirmary on having undertaken it. A month ago the managers of the Western Infirmary of Glasgow intimated to the recruiting stations in Glasgow that they were prepared to admit as urgent cases recruits bringing a note from the examining medical officer to the effect that apart from the remediable affection for which operative treatment was sought they were eligible for enlistment. The necessary funds are provided independently of the infirmary's ordinary financial resources.

It is to be hoped that Mr. Bond's letter will have the effect of starting similar arrangements in all our general hospitals. Were such arrangements made and published, there can be little doubt that, as Mr. Bond says, considerable additions would be made to the army.—I am, etc.,

JAS. H. NICOLL,
Surgeon, Western Infirmary, Glasgow.

November 23rd.

THE TREATMENT OF WOUNDS IN THE PRESENT WAR.

SIR,—In view of the controversy that is now taking place as to the value of pure carbolic acid as an application to wounds, my own experience seems to be worth recording.

Some years ago I contracted septic poisoning of the thumb in the course of attending a case of tracheotomy. The poison gained an entrance under the nail, and resulted in a very painful spreading ulceration with constitutional symptoms. I consulted Sir Watson Cheyne, who within fifteen minutes, under an anaesthetic, removed the nail, and applied pure carbolic acid freely to the entire raw surface. The wound healed rapidly, and the nail grew again with very little deformity.

This surely is an irrefutable proof of the value of pure carbolic acid. I trust that Sir Watson Cheyne's remarks on the treatment of wounds in war will have the fullest possible publicity.—I am, etc.,

C. M. ANDERSON, M.D.

London, S.W., Nov. 20th.

SIR,—After reading Sir Watson Cheyne's masterly address, and the discussion upon this subject at the Medical Society of London on November 16th as reported in the BRITISH MEDICAL JOURNAL of November 21st, there should be little need for further question of the urgent indication for prompt and thorough disinfection of all wounds in war, at the earliest moment after their infliction—but certainly within the first twenty-four to forty-eight hours.

If I may be permitted a short reference to the letters in your correspondence columns of November 21st—I am sorry Sir Victor Horsley construes a sincere compliment of mine into irrelevant banter. I regret that a surgeon of his standing, whilst strongly deprecating the use of such a valuable antiseptic as phenol, should extol such feeble antiseptic agents as alcohol and petrol. I would again ask, Has he tried these things upon himself, and what evidence has he to offer (1) against the proper use of pure carbolic acid, and (2) in favour of alcohol and petrol? Both as regards painfulness of application and efficiency as an antiseptic, there is not the slightest doubt carbolic acid is to be greatly *preferred*. The pain of a carbolic application is a matter of a few moments, and is quickly succeeded by an anaesthetic effect

which will be appreciated by the patient; on the other hand, the pain and smarting from the use of alcohol or petrol persists for a considerable time, and is *not* succeeded by any anaesthetic action. Sir Victor is proud of not being an "escharotic surgeon;" if he can show me a substance which will be equally efficacious as a germ destroyer as carbolic acid, and yet not produce even the slight superficial coagulation which phenol causes, I am willing to be converted. I do not absolutely pin my faith to carbolic acid, but having tried most of the well-known antiseptics, and even some of the less known, I have still to find its superior as a wound purifier. I would point out to Sir Victor that the coagulation on the surface of the wound which he regards as so "terrible" is, in my opinion, one of the virtues of pure phenol. It acts (1) as a protective layer preventing further ingress of germs from air, surrounding skin, clothes, etc.; (2) it has probably some effect in checking haemorrhage from capillaries and smaller vessels; (3) and, *most important*, it prevents absorption of phenol, which is a severe circulatory and nerve poison. It is probably safer to swab even a large wound with pure phenol than to wash it out freely with 1 in 20 carbolic acid; whilst to apply moist dressings soaked in 1 in 20 or even 1 in 40 carbolic over a large raw surface, and covered with a large mass of cotton-wool or other substance which interferes with evaporation, is, to my mind, a highly dangerous proceeding.

Major Galloway quotes a case of gangrene of the finger which followed upon "dipping it in pure carbolic acid and applying a strip of lint"—presumably the lint was applied whilst the finger was still wet with carbolic, and constituted a compress of pure phenol, which was kept on for an hour! I should expect gangrene to follow such a misuse of the drug, and certainly there is no comparison between this and merely swabbing a raw surface with a swab just moistened with the acid. Pure phenol should not be applied to the unbroken skin, and even fairly strong solutions of phenol should not be applied to skin or wound, and then covered with a thick or impermeable material which prevents its evaporation, otherwise a *true* escharotic action and toxic absorption will result. The second half of Major Galloway's letter is, however, a strong vindication of the use of pure phenol when properly applied, if can be used, to the cornea—about the most sensitive and vulnerable part of the human body—with impunity, and even with admitted healing virtue, it can certainly be used with confidence to other regions. The case quoted by Dr. Schofield is only like one of many I could mention where sepsis has been absolutely prevented by the use of pure carbolic acid when an undoubted contamination of a wound had already occurred. Only a short time ago a neighbouring dentist had the misfortune to run a septic instrument deeply into his hand. Picturing to himself the risks of blood poisoning, he immediately came to my surgery. I cleansed the skin thoroughly with liquid antiseptic soap, and, taking a fine probe, I dipped it into pure phenol and thoroughly applied this to the full depth of the puncture. A dry cyanide dressing was then applied. The wound healed evidently quite aseptically, and two or three days afterwards he was able to work as usual, and no disability of any kind has resulted. My experience of compound fractures has been most convincing. I have always used pure phenol and always obtained aseptic healing. In some, in which the bone has protruded and much dirt has got into the wound, thorough cleansing with carbolic has been followed by as satisfactory healing, as if the case had been one of simple fracture.

In conclusion, I doubt the propriety of calling pure phenol an "escharotic." At any rate, I have never seen a true "eschar" result from its use—that is, a scar which on healing causes cicatricial contraction. I have repeatedly used it to the interior of the uterus and occasionally to the trachea and rectum, and I have never seen the least stenosis or even functional impairment result. Even after its application to the cornea no opacity may follow. This is very different from the effect of a true escharotic—for example, a corrosive acid, like nitric acid or hydrochloric acid.—I am, etc.,

P. R. Cooper, M.D. and B.Sc.Lond.,
F.R.C.S.Eng.

Bowdon, Nov. 21st.

Sir,—In my opinion and probably in that of fair-minded men Sir Victor Horsley's reference to the late Mr. Christopher Heath in this week's Journal is not only cruel but in very bad taste.

I know of no other instance in which a dead man's reputation has been so ungenerously assailed by one who was both pupil and colleague. Sir Victor Horsley's education and years of association with men of culture should have taught him "*De mortuis nil nisi bonum.*" My experience of my old teacher and friend, the late Mr. Christopher Heath, is "*Nihil quod tetigit non ornavit.*"—I am, etc.,

Peter Broome Giles.

Bletchley, Nov. 22nd.

Sir,—Sir Rickman J. Godlee repeats his assertion that Lister treated compound fracture cases with undiluted carbolic acid "without any evil result following."

I proved in your last issue, by quoting Lister's own words, that Sir R. J. Godlee's statement was a complete misrepresentation of the facts and of true Listerian antiseptic surgery. Though, fortunately, the younger generation of surgeons cannot be deceived by this perversion of Lister's science, there remains a public duty to be done, and that is, the immediate withdrawal by the authorities of Sir R. J. Godlee's misleading and erroneous leaflet marked 24/Gen. No./3240.—I am, etc.,

Victor Horsley.

London, W., November 24th

THE PREVENTION OF TETANUS.

Sir,—Is the prevalence of tetanus amongst our wounded due solely to infection of their wounds? Presuming that a considerable proportion of them receive hypodermic injections of morphine under conditions rendering the contamination of both skin and instrument far from improbable, is it not likely that the needle may be sometimes to blame?

In India, a couple of years ago, I understood from several sources that hypodermic and intramuscular injections of quinine—so often specially indicated—had been much restricted in some districts, in consequence of the large amount of tetanus resulting presumably therefrom.

I would suggest that a small bottle of the 1 in 12 carbolic spirit mentioned in my letter in your issue of November 14th should be carried, and that the skin at the spot selected for the puncture be thoroughly cleansed with this on a piece of lint or wool, and that while a fresh piece also saturated is held pressed on the place, the soiled one be ignited and used to sterilize the needle, which should be of some non-corrosible metal, like platinum or iridium.—I am, etc.,

Stuart Oliver,
Surgeon-Superintendent, Indian Emigration Service.

Bideford, Nov. 23rd.

AMATEUR WAR NURSES.

Sir,—Dr. Eddlestone asks how it is that trained women are unable to get work from the British Red Cross Society, whilst others who have had no technical education are allowed to play the part of trained nurses to our brave soldiers. I think that the suspicion on which the question was based is groundless.

The *personnel* committee of the Red Cross is working solely on the line that *nothing is too good for our sick and wounded soldiers and sailors*, and we make it our business to see that they get the best care and skill obtainable. In conjunction with us a committee of matrons is working at St. John's Gate for the selection of nurses, and I can assure Dr. Eddlestone that these ladies do not give a second glance at the application of any woman who has not undergone three years' training at a recognized hospital and duly obtained her Certificate of efficiency. In addition, a strict inquiry is made as to the personal character of the applicant.

As a matter of fact, no nurses are now engaged by the Red Cross Society, for since its fusion with the St. John Ambulance Association the latter body takes entire charge of the nursing department, whilst the surgeons, dressers and dispensers are engaged at the office of the Red Cross in Pall Mall.

Arrangements have lately been made for the employment of a certain number of women from the Voluntary Aid Detachments of the two Societies to help in the work of the ward, the kitchen, and the store room; and with the view of preventing these persons imagining for a

moment that they are nurses—or even *probationers*—they are to be called by the somewhat unattractive name of *women orderlies*.

I regret to say that at present it is not illegal for an untrained woman to put on an apron decorated with a red cross, and to call herself a nurse—and even a Red Cross nurse—and in one way or another to approach the beds of wounded soldiers. But whatever may have been done in the past, it is now as impossible for an untrained nurse to obtain work under the British Red Cross Society as it would be for an unqualified practitioner to get his name upon the *Medical Register*. Unfortunately, there are quacks in the nursing world as there are in our own profession, but this is only one amongst the many disadvantages of living in a free country!—I am, etc.,

British Red Cross, 83, Pall Mall, S.W., Nov. 25rd. EDMUND OWEN.

SIR,—It is a pity that Dr. Eddlestone, in his anxiety that our soldiers shall be skilfully nursed, has gone out of his way to disparage a body of women who are doing excellent voluntary work.

He asks why so-called "amateur nurses" "are allowed to play the part of trained nurses," while "many hundreds of trained women are waiting for work." He will find an answer in your leading article which states that "if the waiting list was very much larger than it is, the services of all will certainly be required."

It is absurd to suggest that the Red Cross nurses "are allowed to play the part of trained nurses," if by that is meant that they occupy as responsible a position in a Red Cross hospital as a trained nurse. It is well known that the matrons and ward sisters in these hospitals are highly trained, but even in the training schools there must be probationers. Surely it is not too much to expect that an intelligent Red Cross nurse can do the work of a probationer equally well. Your correspondent's description of these nurses is a mere parody. The Red Cross nurses at present doing hospital work have been attending lectures and demonstrations by medical men and trained nurses for three or four years. They have been examined and re-examined year after year, the "paltry examination" being such as a trained nurse could not pass without previous special study. In practically all cases they have had a month or more of hospital training, and for years previous to the war they have been annually inspected, and their work reported on to the War Office by an officer of the R.A.M.C. Yet your correspondent would imply that they are unfit to make a bed or take a temperature.

When they have been "parading about the streets in indoor uniform," they have probably been making their way to a drill in some building in the next street, oblivious of their critic's angry glances.

I know of a Red Cross hospital in full work where "these sentimental women, so misguided"—some of them members of county families—are doing all the cooking with the help of a solitary kitchen maid.

Such a spirit is above Dr. Eddlestone's criticism.—I am, etc.,

Gunnislake, Nov. 23rd. ALBERT BOWHAY, M.D.

PREVENTION OF SCARLATINA.

SIR,—In reference to the statements of your special correspondent in Ireland in this week's issue of the BRITISH MEDICAL JOURNAL that scarlatina has been epidemic in Belfast since 1909; that each winter has seen an exacerbation of the disease; that already this year 1,800 cases have been notified and 277 new cases have occurred within the last four weeks, it would be interesting to learn whether the practice of rubbing the patient all over at the earliest possible moment with carbolic or eucalyptus oil has been adopted.

This method for the prevention of the spread of the disease was referred to and strongly advocated by one of your correspondents in the JOURNAL some years ago, and statistics were given which showed that where this method was thoroughly practised the result was that the spread of the disease was effectually checked.

Since this method was first brought under my notice I have adopted it in all cases of scarlet fever, and where it has been found possible to have the patient's body, including the head and limbs, rubbed with the oil not later than the second day of the appearance of the rash, and continued once daily until desquamation has ceased, no further cases have occurred in the same house, although other children have had unrestricted access to the sick room.—I am, etc.,

Liverpool, Nov. 8th. R. GARNETT SHELDON.

A MEDICAL WAR INSURANCE FUND.

SIR,—With reference to the letter from Dr. Thomarson in the issue of the JOURNAL dated 14th inst., and his suggestion that the proposed fund should be run by the Medical Sickness and Accident Society, it may be of interest to members of the profession to know what the society has done for those going on active service.

By a resolution passed at a special meeting it was decided not to charge extra premiums to members of the society on active service insured for sickness and accident benefit, and to hold them covered against all risks; those abroad to come into benefit on return to this country and to be paid if wounded or otherwise disabled from following their profession; those remaining in this country to be held covered in the usual way as if they were pursuing their ordinary vocations. Those insured for life assurance are not charged any extra premium, and are held fully covered either at home or abroad.

By this means not only will members temporarily incapacitated receive sickness benefit but also those permanently incapacitated will receive sickness benefit up to age 65, which, combined with the pension granted by the War Office, would assist materially to maintain themselves and their dependants. The society is already paying a claim from one member invalided home from the front.

In the event of a special fund being formed, as suggested, the committee have agreed to permit the staff to undertake such clerical work as is possible, and the secretary has intimated his willingness to co-operate in this and to give any advice and assistance as may be required in the formation of such a scheme.—I am, etc.,

300, High Holborn, W.C., Nov. 25rd. FRANCIS J. ALLAN, Chairman, Medical Sickness and Accident Society.

Obituary.

JOHN HARTLEY, F.R.C.S.Eng.,

SURGEON TO THE DARLINGTON HOSPITAL.

THE death of Mr. John Hartley, F.R.C.S.Eng., at his residence in Darlington on October 3rd will be very deeply regretted by many old Middlesex men, by whom he was well known and much respected. He was the second son of the late Rev. Charles Hartley, Rector of Stocking Pelham, Herts, where he was born in 1857. He was educated at King's College, London, and afterwards became a student at the Middlesex Hospital, where, after qualifying, he held the appointments of house surgeon, house-physician, and resident obstetrical assistant. He then joined his brother, the late Mr. Charles Hartley, in practice at Dunmow, Essex. He returned to London and became clinical assistant at the Royal Westminster Ophthalmic Hospital; he was afterwards appointed senior demonstrator of anatomy at the Middlesex Hospital, which post he held for five years. On his resignation the staff and pupils presented him with an illuminated address, accompanied by a clock and a cheque, as tokens of the high esteem in which he was held by them. He was a born teacher, and always loved to help where help was desired. By his own keenness he stimulated his pupils to get a thorough grip of their work, and not to pass over anything until they had mastered every detail.

He took the diploma of F.R.C.S.Eng. in 1892, and four years later succeeded Dr. E. W. Forster in practice at Darlington. About two years later he was appointed surgeon to the Darlington Hospital, which post he held till his death. For many years he spent about two hours each morning at the hospital going carefully into the details of every patient's illness. He was most patient and thorough in his examination, and having once made his diagnosis there was very little for any one else to add, and he seldom had to change his view. He always welcomed

the help of his colleagues, and was ever ready also to help them with advice or assistance in operations. He himself was a very careful operator; his knowledge of anatomy made the knife very safe in his hands. The care he had taken of his patient both before and after operation, combined with his complete system of asepsis, gave him excellent results. Having laid such a good foundation by his work in the hospital, his opinion was much valued by a large circle of practitioners both in the town and surrounding district.

The last years of his life were very busy in consultation and in surgical work. He usually went to London during his holiday, and devoted most of his time to finding out new methods and new operations, in the perfecting of which he spent himself freely and unsparingly. His enthusiasm for his work was such that he inspired his colleagues with his higher aims and carried them along with him. He was generous both to those who needed pecuniary assistance and to those of his professional brethren whom he assisted with his advice.

His geniality and straightforwardness endeared him to a large circle, and his funeral was attended by a very large concourse of mourners, including the mayor, many members of the corporation, and a large number of his professional brethren. In accordance with his own request the body was cremated at the Darlington Crematorium on October 7th. He leaves a widow to mourn his loss, but no family.

Dr. Isidore Bernard Le Gentil, L.R.C.P., L.R.C.S.Edin., a native of the Mauritius, who took his diplomas in 1886 and immediately settled in practice in Edinburgh, died on November 10th. In the poorer districts of the city, where he chiefly laboured, he was very popular; and, in addition to his private practice, he had more than 2,000 panel patients. He leaves a widow and children.

Universities and Colleges.

UNIVERSITY OF LONDON.

The following candidates have been approved at the examination indicated:

Third M.B., B.S.—R. A. Rowlands, *D. H. D. Wooderson, F. H. Bray, Henriette F. Davies, A. R. C. Doorly, J. B. Dunning, Una Griffin, F. J. Hallinan, Mary E. Harding, D. T. Harris, Jessie E. Hart, C. H. Heppenstall, R. M. Kharegat, W. M. Lansdale, L. Levene, A. C. McAllister, Helen M. M. Mackay, Ethel M. Magill, W. J. Morris, Margaret R. Paterson, Edna M. Powell, J. B. Rawlins, R. H. Simpson, Grace Stapleton, E. H. Walker, T. B. Welch.

* Passed with honours.

UNIVERSITY OF EDINBURGH.

Medical Bursaries and Scholarships.

The scholarships and bursaries in the Faculty of Medicine of Edinburgh University have been awarded as follows: *Crichton Research Scholarship in Anatomy:* Stuart Bolton, M.B., Ch.B. *Vans Dunlop Scholarship in Anatomy:* Robert Walker. *Vans Dunlop Scholarship in Physiology:* Robert Mailer. *Houldsworth Scholarship in Pharmacology:* Benjamin J. Ryrie. *Grierson Bursary in Anatomy and Physiology:* Andrew O. Ross. *Grierson Bursary in Pathology:* Andrew J. Caird, M.A. *Crichton Bursary in Preliminary Subjects:* James M'Nabb, M.A., B.Sc. *Mackie Bursaries:* William B. Ross and Robert MacGarrol.

ANNUAL MEETING OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The annual meeting of the Fellows and Members of the Royal College of Surgeons was held at the College on November 19th, the President, Sir Wm. Watson Cheyne, in the chair.

Report of the Council.

The President placed before the meeting the Report of the Council for the year 1913-14, summarized in the Supplement of the Journal for November 14th, p. 236.

Representation of Members.

Sir Victor Horsley moved:

That this thirtieth annual meeting of Fellows and Members again affirms the desirability of admitting Members to direct representation on the council of the College, which, as now constituted, only represents those members who also hold the Fellowship; and that it does so in order that the constitution of the council of the Royal College of Surgeons of England shall be in keeping with modern ideas of true representation.

Sir Victor Horsley said that the Members were treated with the grossest contempt by the Council of the College and this was shown once more by the fact that only six members of the Council had thought it courteous to meet their colleagues on the present occasion. He could not understand how the Council, year after year, could continue to adopt this attitude of contempt towards the Members. The annual report was not an inspiriting document, but it contained matters which might have been put more strongly; there were also some notable omissions. At this time last year the failure of the Council to obtain any amelioration of the conditions of service of medical officers of health was reported, and now it was said that action had been taken on their behalf. That action was really childish, especially in view of the fact that the British Medical Association had been working on this subject for a long time, and years ago—in 1909—had obtained from the Government security of tenure for the county medical officers of health, while the Council of the Royal College of Surgeons was doing absolutely nothing. It was ridiculous to come forward now and talk of what the Council was doing for the medical officers of health, especially when it had deliberately declined to do what it might have done—namely, to go by way of deputation to the Government. He could not understand why the Council so constantly declared its impotence before the world. The Council did not represent the college, and would never do so until the present resolution was carried into effect. He protested against the Council sending so-called representatives to Government Departments to speak as though they represented the surgeons of England. The Council sent three distinguished members to give evidence before the Venereal Diseases Commission, but they were not instructed in any representative sense. Yet one of them informed the Commission that he personally was against any measure which would really secure public action—that is, by medical officers of health. It was simply the witness's private opinion that nothing could be done, but he posed before the Commission as though he represented the Members of the College.

Mr. George Jones, M.R.C.S., and a barrister, seconded the resolution, and began by expressing the pleasure of the Members at the election of Sir Watson Cheyne to the presidency. The Members of the College had before them the political task of regaining the franchise they had lost. To put themselves in the position of their predecessors three centuries ago they must educate, agitate, and organize, always remembering that "Eternal vigilance is the price of liberty." The principle of representation familiar in the smallest parish councils ought to apply to the great College which had such important and valuable functions. The Council of the College represented 1,500 Fellows and no one else; the 17,000 Members had no representation whatever. There were provincial universities and bodies granting a degree in surgery, and the present policy of the Council might result in loss of strength, which would pass to those bodies. The only reason reform was not granted was that the Council had not yet seriously felt the strain of competition.

Dr. W. J. Middleton (Bournemouth) urged that Members of the College ought to have a vote: the present position was bad for Fellows, Members, and the public.

Dr. S. C. Lawrence (Honorary Secretary of the Society of Members), Dr. Brindley James (the President), and other members also spoke.

The President of the College was about to put the resolution when Sir Victor Horsley appealed to him to address the meeting. Sir Watson Cheyne replied that he did not propose to speak, but he would certainly report the matter to the Council.

Sir Victor Horsley claimed the right of reply, and said the Members did not expect the President to commit himself definitely on this occasion, but they did expect that next year the meeting would be treated with the courtesy due to colleagues.

The motion was then put, and declared carried, 41 voting in favour and none against.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

The annual meeting of the Royal Faculty of Physicians and Surgeons of Glasgow was held on November 2nd. Dr. John Barlow was President; Dr. Ebenezer Duncan, Visitor; the Treasurer is Dr. W. G. Dun; and Dr. Alexander Napier, Honorary Librarian. These and the following compose the Council: Mr. D. N. Knox (representative to the General Medical Council), Mr. Donald Duff, Mr. J. Walker Downie, Dr. David Newman, Dr. James A. Adams, Dr. A. Freeland Fergus, Dr Robert Jardine.

The Faculty agreed to give 100 guineas to the Prince of Wales's National Relief Fund and 25 guineas to the Belgian Relief Fund.

The losses by death during the year were noted: Mr. John M. Cuthbertson, who became a Fellow in 1878; Mr. John Pringle, who joined the Faculty in 1877; Dr. William Haldane, of Bridge of Allan, whose membership of the Faculty dates from 1875; and Dr. William Fenwick, of Rome, elected Fellow in 1872.

Dental Examination.

In view of the war, and in response to a requisition presented to them by candidates, some of whom are anxious to serve in His Majesty's Forces, the Royal Faculty of Physicians and Surgeons of Glasgow has agreed to hold a special dental examination. The examination will begin on Tuesday, January 12th, and will be limited to candidates who are qualified to sit for the final examination.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have been approved in the subjects indicated:

SURGERY.—‡W. Brown, ‡C. H. Fischel, *‡G. F. Malden, *‡H. R. Partridge, *‡T. J. R. Scholtz, T. R. Scott.

MEDICINE.—‡J. C. P. Bayley, *‡H. A. Cottin, *‡C. E. Clark, *‡H. Morrison, *‡H. R. Partridge, *‡C. H. Philips, *F. Simpson.

FORENSIC MEDICINE.—R. H. Chadwick, H. A. Cottin, C. S. Dobson, C. J. G. Exley, J. D. Ferguson, H. R. Partridge.

MIDWIFERY.—C. E. Clark, R. Curle, H. R. Partridge, C. H. Philips.

* Section I. ‡ Section II.

The diploma of the Society has been granted to Messrs. J. C. P. Bayley, W. Brown, C. H. Fischel, G. F. Malden, and H. R. Partridge.

The Services.

ROYAL NAVY MEDICAL SERVICE.

Report on the Examination of Candidates for Entry as Acting Surgeons, R.N.

OWING to the outbreak of war, the course for Acting Surgeons has been curtailed, the greater part of the Haslar course being eliminated, though the Greenwich course was completed.

As a consequence the places of these gentlemen on the list of Surgeons, R.N., have had to be assigned on the results of the entrance examination, with the addition of the marks gained at the examination at the end of the Greenwich course.

The marks obtained and the order of seniority are as follows:

	Marks.
H. B. Parker, M.B.	2,488
J. L. Priston	2,427
R. F. Quinton	2,365
M. J. Aitken, M.B.	2,336
J. A. Maxwell, M.B., B.A.	2,267
M. S. Moore, M.D., B.A.	2,193
*W. G. Thwaytes, M.B.	—
C. E. Greeson, M.D.	2,132
W. F. Beattie, M.B.	2,113
H. W. Fitzroy-Williams, M.B.	2,074
F. E. Fitzmaurice	2,005
T. J. O'Riordan, M.B.	1,981
J. C. Kelly, M.D., B.A.	1,970
J. M. Horan	1,886
G. M. Graham, M.B.	1,811
F. C. Hunot	1,805

* Surgeon Thwaytes, through being seconded to the Royal Infirmary, Edinburgh, did not take the Greenwich course, and therefore has been allowed to take his original place in the London entrance examination—namely, seventh.

The Admiralty prizes were awarded as follows:—Gold Medal: Surgeon H. B. Parker, formerly of London Hospital. Silver Medal and Greenwich Group Prize (pocket instrument case): Surgeon J. L. Priston, formerly of London Hospital.

AT a meeting of the Child Study Society at the Royal Sanitary Institute, Buckingham Palace Road, on November 19th, Mr. T. Percy Nunn gave a lecture on the development of the practical imagination in children. Imagination, he said, must not be confused with imagery, although imagery was one of the means by which imagination worked. Imagery, however, was not necessary to imagination; it was merely the visualizing of past scenes, and was consequently more nearly akin to memory than to imagination. Now memory might be defined as the recurrence of past experiences; but these were never reproduced exactly as they occurred, but in a more or less modified form, and this, properly speaking, constituted imagination. Imagination, therefore, was a constructive power of mind, which was capable of reproducing past experiences at will, which could select the essentials out of a mass of irrelevant detail, and weave them all into one harmonious whole. Such subjects as history, geography, and literature tended to cultivate the imagination of children; but the main object of education should be to make them familiar with the chief branches of human endeavour and progress, and for this reason handwork was a most important asset in the cultivation of practical imagination in the child. The cultivation of this faculty consisted in putting the child into touch with material things, and so giving him an opportunity to do with the material what the poet did with the spiritual. Imagination belonged to all, and its cultivation was only a question of putting people into touch with the proper medium in order that their minds might work in the natural way.

Letters, Notes, and Answers.

☞ *Queries, answers, and communications relating to subjects to which special departments of the* BRITISH MEDICAL JOURNAL *are devoted will be found under their respective headings.*

QUERIES.

UNION wishes to correspond with a British surgeon who has experience of transplantation of the ureters.

J. R. D. would be glad to know where a borderland female case can be taken in to a home. The relatives are now in reduced circumstances, and can afford to pay about one guinea a week, or not more than 30s. at most.

ANSWERS.

"BLUE STALKS" MUSHROOMS.

T. G. writes in answer to "R. S.": The mushroom called "blue stalks" or "blewitts" (scientifically *Tricholoma personatum*) is quite wholesome, and is a fair substitute for the ordinary mushroom, though the flavour is not quite so good, and it has a certain sliminess which to some people is not pleasant. It may be cooked in the same manner as the ordinary mushroom, and, like it, is best eaten fresh, although growing as it does in the cooler weather of late autumn it will keep better than the summer-growing species. Blue stalks are regularly sold in the Derby market.

LETTERS, NOTES, ETC.

AN APPEAL TO MEDICAL MEN TO COLLECT DIGITALIS LEAVES.

DR. J. GORDON SHARP (Leeds) writes: For some time I have been collecting foxglove leaves with the intention of presenting them to a local charity, in order to obviate any chance of a shortage in the future. It is not yet too late to collect, and I ask medical men throughout the country to begin at once and do as I do. The leaves should be gathered on a dry day and then placed on the top of a cupboard in the kitchen, spread out on a newspaper, and turned every day. Those who are not really acquainted with the characteristics of the foxglove should submit their batches (before drying) to the inspection of some one—for example, a local pharmacist. First-year leaves and second-year leaves are equally toxic, and leaves gathered so late as the end of November have been found to be as potent in action as those gathered in August. Personally, I do not think there will be any shortage, for the Indian Government now grows *Digitalis purpurea* very largely on the Government cinchona plantations, Nilgiris, and in 1913 Mr. D. Hooper, quinologist to the Indian Government, sent me a large bundle of leaves, from which I had a tincture made, and it proved, both physiologically and therapeutically, to be up to the standard of a tincture made from the best British grown leaves. With reference to your article on the cultivation of medicinal plants in England, it may be interesting to mention that, although I live almost in the centre of a half million town, I am able to grow in my garden almost every plant which will grow in a temperate climate.

THE MEXICAN BLANKET.

DR. R. J. RYLE (Brighton) has called our attention to the directions given by Major T. Y. Osmond, 6, Chesham Street, Brighton, in a flyleaf with diagrams for making a "Mexican blanket" for use as an improvised great coat or as an auxiliary to be worn over or under the great coat without impairing its value as an item of bedding. The blanket is folded diagonally and an oval 12 in. by 4 in. marked out in the centre of the diagonal line. Two circles, 6 in. in diameter are made on the diagonal line about 10 in. from the extremities of the oval, the marks are sewn round with strong thread or twine, though it is better to back them with canvas or tape. Openings are then cut along the diagonal line just sufficient to squeeze the head and arms through. None of the fabric should be removed as the portions between the stitches and the opening form up comfortably to the throat and neck.

A Clinical Lecture

ON THE

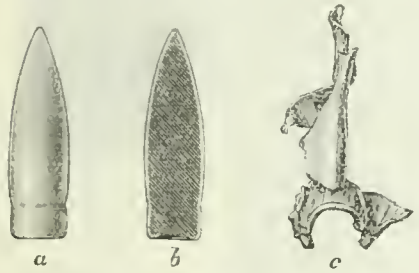
VALUE OF RADIOGRAPHY IN THE DIAGNOSIS OF BULLET WOUNDS.

DELIVERED AT THE MIDDLESEX HOSPITAL.

BY

SIR JOHN BLAND-SUTTON, F.R.C.S., LL.D.,
MAJOR R.A.M.C.(T.F.),
SURGEON TO THE HOSPITAL.

THE most mischievous instrument that can be used for the investigation of a bullet track is a probe. Mischievous, because the aperture of entrance—and of exit if the bullet has passed out of the body—soon becomes septic, and the probe conveys pathogenic micro-organisms into the deeper parts of the track. A bullet often carries sepsis-provoking germs into the depths of a wound, but a probe is sure to convey infection.



a *b* *c*

Fig. 1.—(*a*) A Spitzgeschoss (natural size); it weighs 154 grains. (*b*) A Spitzgeschoss in section, showing the lead core and the nickel covering. (*c*) The nickel covering stripped from the bullet and twisted by impact against a hard body, such as a stone. This was removed from a soldier's hand.

Until the beginning of the present war very little was known of the injuries inflicted by the sharp-pointed bullet known as the "S" bullet, or Spitzgeschoss, used by the Germans. It is sharp-pointed, and has a much higher initial velocity than bullets of an older pattern. The Spitzgeschoss has a solid core of lead enclosed in a nickel case deficient at the base (Fig. 1). It is necessary to understand the structure of this bullet in order to appreciate some of the injuries it inflicts.

The utility of radiography in detecting metallic substances embedded in the body and in the diagnosis of broken bones is beyond all question. At the 3rd London General Hospital we have been fortunate in having such a skilful and indefatigable officer as Dr. F. H. Humphris to help us. In my wards the use of a probe for investigating bullet wounds is interdicted. A careful inspection of the injured region is made with the eyes, and if there is only an aperture of entrance a gentle digital examination of the skin on the opposite side of the body, limb, head, or neck is made. In many instances the missile can be felt under the skin. Bullet wounds of the chest should always be examined in this way. When a bullet pierces both walls of the chest it may lie near the skin. If a bullet enters the chest and there is no aperture of exit, the surgeon should carefully palpate the opposite wall of the chest; if he comes upon a patch of emphysematous crackling it will be an assurance that both walls of the chest have been perforated, and it will enable the bullet to be localized and extracted. Some bullet wounds are curious in the way they traverse regions of the body where big vessels and nerves are crowded together and yet the important structures often escape injury. In the routine description of bullet wounds it is customary to state that a single bullet may make four wounds; for example, a bullet sometimes passes through both legs; in this way there are two apertures of entrance and two of exit. A hussar under my care had five wounds from one bullet. It passed through both buttocks, leaving four holes, and in passing across the interspace between the two buttocks it chipped a piece of skin off the posterior aspect of the scrotum. The soldier recovered. When a bullet lodges in soft tissue a small quantity of clear serous fluid accumulates around it. This is often a guide to the surgeon when he hunts for a bullet, either rifle or shrapnel; the sudden escape of some clear fluid into the wound indicates its lair.

A troublesome and often painful wound is caused by the nickel covering of a bullet. When an "S" bullet hits a hard object, such as a stone, and glances off, it is "deformed," the nickel covering strips, and becomes twisted into fantastic shapes (Fig. 1, *c*). When such contorted pieces of nickel penetrate the body they produce unpleasant wounds. The extensive wounds caused by such deformed bullets are responsible for some of the injuries erroneously attributed to expanding bullets. I have seen examples in the hand, groin, and foot. Occasionally the leaden core of a glancing bullet will break up into minute fragments; pellets of this kind have destroyed many eyes. The case of a shrapnel shell is sometimes reduced by explosion almost to the fineness of sand. Small, irregular fragments of such metallic sand driven with violence are fearfully destructive to eyes. Bullets often convey more tangible things into wounds than micro-organisms. If a bullet strikes a man's pocket it will carry in fragments of the things contained therein—such as matches, a button, fragments of a pipe, or a piece of a tobacco pouch, beside pieces of cloth, leather, coins, etc.

Fig. 2.—A bullet lodged under the head of the fourth metatarsal bone, which it had broken. The only evidence of injury was a red patch on the heel.

In order to convince you that every bullet wound should be submitted to radiology, the following facts will serve: A soldier in the battle of the Aisne was wounded in the heel. When he came under my care, fourteen days later, the foot was swollen and painful, but the man could stand on it. The only evidence of injury in the foot was a red raised patch at the heel. It was suggested that this soldier should be allowed to go home. I thought he had a bullet in the foot, and refused to discharge him until he had been submitted to an *x*-ray examination. A bullet lay in contact with the head of the fourth metatarsal bone (Fig. 2); the impact had broken the neck of the bone. The bullet was extracted through an incision in the sole.

The interpretation of radiographs is a matter of great interest. We must not forget that they are shadows, and,

like shadows, often misleading. For example, a soldier had an aperture of entrance over the internal condyle of the left femur. An *x*-ray examination revealed a bullet lying in relation with the condyle (Fig. 3); it required several plates to determine accurately whether the bullet was lying in front of or at the back of the bone. It was also conjectured that the bullet had turned a somersault before entering the limb. When the parts were exposed in the course of an operation the bullet was found firmly embedded in the condyle near the adductor tubercle, with the point looking towards the aperture of entrance. The bullet had turned a somersault in its flight before it struck the limb and entered the leg reversed, that is, base foremost. Fortunately the damage it inflicted was trifling, and the recovery quick as well as uneventful.

Fig. 3.—A bullet lodged in the femur near the adductor tubercle. The bullet turned a somersault in its flight and entered the thigh base first. From the radiographs it could not be decided whether the bullet lay in contact with the femur or was embedded in it.

The evidence afforded by a skiagram of the natures of the foreign body is invaluable.

A soldier was admitted with a painful wound of the big toe caused by the bursting of a shrapnel shell. A skiagram showed an irregular-shaped piece of metal embedded in the head of the metatarsal bone of the big toe (Fig. 4). The man suffered intense pain until the fragment of metal was extracted.

The same batch of wounded included a soldier who had been injured in the fighting on the Aisne by the bursting of a shell. He had an elliptical hole in the middle of the calf over the most prominent part of the fibula. The wound had become septic and small pieces of bone protruded from it. The skiagram (Fig. 5) showed that the middle of the fibula had been reduced to small fragments and a piece of metal, 5 cm. square, could be easily seen 2 in. above the ankle-joint. The wound after being daily irrigated with hydrogen peroxide solution cleared up, and with the help of an anaesthetic I enlarged the wound and removed the fragments of the bone, but failed to find the piece of shell. The search was not unduly pressed for fear of widely infecting the tissues of the leg. The soldier appeared to be making a good recovery, but twenty-one days later I noticed some oedema above the external malleolus; the skin was incised, some pus escaped, and from a loculus, near the malleolus, I removed a big fragment of copper. An ordnance officer, who examined it, expressed the opinion that it was a piece of the driving band of one of the shells ejected by the huge gun named by our soldiers "Black Maria."

Fig. 5.—A fragment of the huge shell emitted by a "Black Maria." It has reduced to fragments the middle portion of the fibula. The pieces of bone and the square of copper were removed. The soldier recovered, but his foot was in the condition of talipes equinus.

In cases where there is clear evidence that a bullet has traversed the whole thickness of the limb and left a clean punctured hole of entrance and of exit, a good radiograph gives us a picture of its track in relation to bone. The effects of bullets on bones vary enormously, and at present I am unable to satisfy myself on what these variations depend. For example, an officer was wounded in the thigh at Ypres; a round aperture of entrance was present on the front of the thigh 7 cm. above the patella. On careful palpation of the skin at the back of the popliteal space I could make out a tender spot. I suspected that the femur had been perforated by a bullet, and that the missile was probably lying under the skin on the opposite side of the limb. A skiagram of the limb proved the accuracy of this forecast. (Fig. 6.) A canal had been made by a shrapnel bullet completely through the shaft of the femur, and the bullet lay immediately beneath the skin. It was extracted a few days later.

Fig. 4.—An irregular fragment of shell embedded in the head of the metatarsal bone of the big toe.

The next bed was occupied by an officer who had received a bullet wound in the left shoulder. A round hole in the skin, immediately over the head of the bone, indicated the point at which the bullet entered, and a widely gaping elliptical opening, at a corresponding spot on the back of the shoulder, marked its exit. On admission, both wounds were septic, and a fragment of bone blocked the posterior opening. The whole limb was enormously swollen. A radiograph showed that the upper half of the humerus had been broken into a number of small fragments, and the lower half was split longitudinally. A week later I enlarged the openings made by the bullet, extracted more than thirty fragments of bone, and stuffed the cavity with lint soaked in iodine. The nerve trunks are uninjured and there is good reason to hope that this officer will obtain good, though restricted, use of the limb. Such an example of great comminution of bone is caused by a bullet that becomes "deformed" on striking a hard bone, then the leaden core breaks up and acts like a charge of shot.

A consideration of these two cases raises an important question—important because opposite opinions are expressed by surgeons in regard to the removal of missiles and fragments of bone. Some impacted missiles cause pain; others cause no pain. The soldier prefers to have the offending bullet in his pocket than in his body. This may be a matter of self-conceit. A wound or a scar must often be taken on trust; the exhibition of a bullet is something more than circumstantial evidence. The desire on the part of the patient to see the bullet sometimes leads the surgeon to take great pains to extract a bullet. I think it is good practice, in the majority of cases, to remove foreign bodies, but in this, as in surgery generally, no hard and fast rules can be laid down, experience and judgement should guide our actions. A foreign body in a wound often keeps up a discharge and maintains a fistula. The spontaneous escape of the foreign body, or its removal, is followed by rapid healing. This is equally true of a

compound comminuted fracture; free incisions and removal of minute fragments of bone are attended with relief of pain and promote healing.

In dealing with wounds caused by projectiles there are some facts that quickly impress themselves on the mind. The size of the skin wound that admits the missile is no indication of the amount of damage sustained by the tissues, hard and soft, in its track. No attempt should be made to ascertain the amount of damage by manipulation, by insertion of a finger into the wound, nor by a probe. An *x*-ray examination saves infection, pain, and much misery.

Fig. 6.—The femur of an officer wounded at Ypres. A shrapnel bullet had entered the thigh, traversed the femur, and lay under the skin in the popliteal space.

A bullet moving with a high velocity will traverse a limb and perforate a large bone like the femur and cause very little disturbance; or it may catch a nerve, an artery or a vein and produce instantly unmistakable signs. A man under my care received a bullet wound just below the angle of the left orbit, it emerged between the right styloid and mastoid processes, causing palsy of the right facial nerve. He soon became convalescent, but the facial paralysis persists. The small amount of injury that puts a soldier out of action has also impressed me. A bullet hits a man on the tip of the finger, carries off the nail, and splits the terminal phalanx. We have had many injuries of this kind; they quickly become septic, and the soldier is invalided with a whitlow for several weeks. In these apparently trivial cases an *x*-ray examination is exceedingly useful.

Incidentally references have been made in the notes of the cases in this lecture to the modes of treating septic wounds so frequent in the soldiers wounded in this war. It is of course impossible to treat such wounds aseptically. The employment of antiseptic solutions is urgent, and it is remarkable how quickly the wounds clear up under solutions of carbolic acid, boracic fomentations, and especially hydrogen peroxide. Tincture of iodine has proved very useful, and especially a combination of carbolic acid solution (1 in 60) and tincture of iodine a drachm to the pint. The wise surgeon does not put his whole trust in any routine measure whether it be styled antisepsis or asepsis. He adapts his methods to the necessity of the case. It has been suggested that the value of antiseptic methods is underrated by some surgeons and runs the risk of being forgotten, and, decades hence, some enterprising surgeon will rediscover it. The idea is unthinkable. Antisepsis cannot be rediscovered for it cannot be forgotten.

THE THRESHOLD OF DISEASE.

AN ADDRESS DELIVERED TO THE MEDICAL SECTION OF THE ROYAL ACADEMY OF MEDICINE IN IRELAND ON NOVEMBER 20TH, 1914.

BY

JAMES ALEXANDER LINDSAY, M.D., F.R.C.P.,

PROFESSOR OF MEDICINE IN THE QUEEN'S UNIVERSITY OF BELFAST, PRESIDENT OF THE SECTION.

MEDICAL science seems likely to advance in three directions—namely, first in gaining better knowledge of the causation of disease; secondly, in the acquisition of facilities for more prompt diagnosis; and, thirdly, in the discovery of improved methods of treatment. It is to the second of these topics that I propose to direct your attention to-night.

Early diagnosis of disease is, we are all agreed, a matter of vital moment. It is important mainly for two reasons—first, because the neglect or misinterpretation of early symptoms often turns a slight case into a serious one; and, secondly, because the efficacy of treatment is in many cases proportionate to the promptitude with which it is applied. Amongst the "calamities of medicine"—to use Paget's phrase—failures to make and act upon an early diagnosis take a prominent place. Time lost in the field of disease is seldom regained, and the loss is both one of safety to the patient and of credit to the physician.

Let us first glance at a few of the simplest and most obvious cases before we penetrate to the heart of our subject. Chronic dyspepsia is the blight of innumerable lives, but its first beginnings are simple enough and tractable enough. The dyspeptic, unlike the poet, *fit non nascitur*. He does not often owe much to heredity. Either he has incurred dietetic error, or he has prematurely used up his original stock of nerve force. He may have eaten and drunken not wisely but too well, or, on the other hand, insufficiently; or neglected those important aids to health which the dental art supplies; or his nervous energies may have been dissipated too soon by work, worry, or pleasure. Whatever be the cause, his digestive efficiency does not fail suddenly. The machine creaks often before it refuses to move. But the admonitions are commonly neglected. A timely warning to such persons to regulate their diet, take care of their teeth, and conserve betimes their nervous energy would save them much suffering, and, incidentally, deprive the world of a good deal of the literature of pessimism. Gout, unlike dyspepsia, owes much to heredity. It often gives warning betimes of the coming disasters to joints, kidneys, and circulation—warnings too generally ignored until the hour of nocturnal torture strikes. The late Lord Dufferin once said that his ancestors had drunk so much wine that he was obliged to drink water. Not all the scions of a gouty ancestry show a like power of self-control. An early diagnosis of a gouty tendency and of incipient gouty manifestations, and suitable action thereon, will not always banish the enemy, but they may do something to keep him at bay. The chronic bronchitic has many warnings before his malady takes final hold. The victim of chronic rheumatism commonly makes light of his malady in the stages when treatment would be most efficacious. There are obvious cases which suggest their own moral. I pass on to consider some more difficult problems.

I wish to deal with a few cases where the failure to make an early diagnosis is due, not to the carelessness of either patient or doctor, but to the inherent difficulties of the case. I have selected four examples where an early diagnosis raises problems, always difficult, sometimes insoluble, and I have purposely selected them from widely different departments of medicine. The cases are as follows:

(*a*) Endocarditis.
(*b*) Cancer of the stomach.
(*c*) Disseminated sclerosis.
(*d*) Pulmonary tuberculosis.

I believe we may study with profit the problem of early diagnosis in these four diverse fields.

(*a*) ENDOCARDITIS.

When a patient is suffering from acute or subacute rheumatism we may consider the question of cardiac involvement from three points of view. We may ask, What are the probabilities of the case, based upon statistics? or we may take account of signs and symptoms; or we may seek aid from such instrumental methods of investigation as the polygraph and the electro-cardiograph. As regards the first point, while I cannot go the whole length with Dr. Norman Moore in affirming that the involvement of the heart is an integral element in every case of acute or subacute rheumatism, I regard such involvement as extremely common in the adult and almost the rule in the child. We are justified in strongly suspecting the heart in every case of acute or subacute rheumatism, and such suspicion is specially strong in the case of the child or young adolescent. On the signs and symptoms of early cardiac involvement I need not dilate. They are familiar to you all, but I should like to press the point that even slight physical signs, a little muffling of the first sound at the apex, a trifling increase in the area of superficial cardiac dulness, a slight degree of arrhythmia, are commonly very significant. How far the polygraph and the electro-cardiograph will help us in the detection of early valvular or myocardial changes it is, perhaps, premature to say. Neither of these instruments helps to recognize mitral regurgitation, which is by far the commonest lesion in such cases. But in a certain undetermined proportion of cases of early rheumatic endocarditis there are changes in the myocardium, sometimes involving impaired conductivity of the wave of contraction, and such impaired conductivity will show itself either in the polygraphic tracing or in the electro-cardiogram.

The importance of early diagnosis in endocarditis would be difficult to exaggerate. Dr. Caton has done good service in insisting upon the necessity for prolonged rest in such cases, and the good results which may be expected from it. Careless treatment of these patients, a too optimistic attitude, a premature return to work, spell disaster in the future. Timely watchfulness will be well repaid.

(*b*) CANCER OF THE STOMACH.

The early diagnosis of this lesion is beset with the most formidable difficulties. The onset may be marked by symptoms of irritable dyspepsia and pain in the epigastrium, or by loss of weight, anaemia, and debility, or by a vague failure of the general health. I have not found the history of a previous gastric ulcer of much help in diagnosis. Marked and somewhat abrupt loss of appetite, especially for flesh meat, is a frequent and significant symptom, on which considerable reliance may be placed, if the anorexia is not otherwise explained. Loss of weight, even at an early stage, is usually pronounced, and is progressive from week to week and month to month. The examination of the gastric contents may assist. Some differences of opinion exist regarding the value of the HCl content. My experience of this test is that it possesses a real, but limited, value. In the great majority of cases of gastric cancer I have found an absence of free HCl, but it is also absent in many other conditions, such as pernicious anaemia, cirrhosis of the stomach, and in some cases of dilatation of the stomach and of chronic dyspepsia. The absence of the free acid must therefore be interpreted with caution in a doubtful case. On the other hand, no case has come under my observation where a normal acid content has coexisted with gastric cancer, though such cases have been reported by various observers. They are probably rare, and we shall hardly err in regarding the presence of free HCl as valuable evidence against the existence of gastric cancer. The bacteriology of these cases, and especially the weight to be attached to the presence of the Oppler-Boas bacillus, are still matters of controversy. Vomiting may be an early symptom, but more usually develops after some progress of the disease has occurred. Haematemesis is rarely, in my experience, an early symptom. Some epigastric tenderness may develop early, but a definite tumour belongs to the fully developed stage of the disease. I might suggest the following rule of practice: "If a patient, especially of the male sex, who is over 50 years of age, and who has previously enjoyed a normal digestion, somewhat abruptly develops a marked distaste for food, especially for flesh meats, suffers from discomfort after meals, and perhaps occasionally vomits, begins to lose weight rather decidedly, and exhibits some degree of anaemia and debility—then, in the absence of some other obvious explanation, such as alcoholism, cirrhosis of the liver, or renal disease, the suspicion of incipient gastric cancer is strong." An examination of the blood should not be omitted, although the evidence thus obtained must be interpreted with caution. Broadly speaking, the patient suffering from incipient gastric cancer develops a decided and progressive secondary anaemia. The subject of chronic gastritis or chronic dyspepsia has no constant or significant blood changes.

The question of the handling of these cases of incipient gastric carcinoma, where the diagnosis can be made with reasonable probability in the absence of tumour or other gross signs, involves a very difficult problem both for the physician and the surgeon. To procrastinate until the proof of disease is complete is a feeble policy involving a disastrous loss of time. Exploration, which is unattended by serious risk, seems justifiable, but physicians will be governed largely, in their recommendation of such procedure, by surgical experience regarding the results of the operative treatment of gastric cancer. The following figures are reported by Osler from the clinic of the brothers Mayo: In 39 cases whose condition was known who had been operated upon over five years before, 7 were alive; of 64, condition known, over four years, 13 alive; of 83, condition known, over three years, 18 alive and well.

Whether better results are likely to follow the adoption in certain cases of Schlatter's radical operation of the removal of the entire stomach the future will decide.

(*c*) DISSEMINATED SCLEROSIS.

The morbid anatomy of this affection, consisting as it does of small patches of sclerosis scattered irregularly through the brain, brain-axis, spinal cord, and sometimes the cranial nerves, prepares us for great variations in the symptoms and modes of onset of the disease. Few, if any, diseases present so varied a picture, and in few is error in diagnosis more probable or more frequent. Buzzard is probably correct in affirming that every physician is at some time or another mistaken in relation to the early diagnosis of the disease. When early diagnosis is in question we must dismiss from our minds the classic picture of disseminated sclerosis as described in textbooks—namely, intention tremor, nystagmus, scanning speech, and spasticity of the lower limbs. Any or all of these symptoms may be absent at this stage. Rather must we inquire for transient disturbances of vision—amaurosis or diplopia—temporary impairment of bladder control, paraesthesiae of one or more limbs, diminution of the abdominal reflexes, loss of tone of the sphincter iridis shown by failure of the pupil to remain contracted in presence of the stimulus produced by light, giddiness, emotional instability. Here we have a group of symptoms none of which, taken singly, is capable of any confident interpretation, but highly significant when taken as a whole. Transient paresis and a sense of fatigue in the legs may appear early. In a case of doubt the alternative possibilities of the case must be borne in mind. Most of the organic lesions of the nervous system are easily excluded. Paralysis agitans will hardly cause serious difficulty, the age law being commonly decisive. Hysteria is the most fertile source of error, and the difficulty of distinction is much increased by the fact that young female "disseminates" sometimes develop a seemingly hysterical psychosis. But hysteria never exhibits the group of early symptoms which has been enumerated, and at a later stage nystagmus, pallor of the optic disc, and ankle clonus make the distinction easy.

How far early diagnosis may enable us to deal effectively with disseminated sclerosis is doubtful. The causation of the disease is most obscure. There is no known toxic factor. Infective diseases, chills, shock, mental stress have been blamed, but on doubtful evidence. Syphilis has no influence. The course of the disease is so variable and periods of remission so common that treatment may easily get the credit which belongs to Nature. But it seems reasonable to hope that the early recognition of these cases, the removal of sources of nervous strain and the adoption of a well-ordered hygiene may improve the prospects of these unfortunate patients.

(*d*) PULMONARY TUBERCULOSIS.

I pass on to the most important case of all. The early agnosis of pulmonary tuberculosis is a matter of vital portance because of the frequency of the disease, and of comparative curability in the incipient stage. An mense amount of work has been done in recent years connexion with this subject, and many attempts have en made to find a short cut to a prompt and secure agnosis. I have to essay the difficult task of evaluating ese methods, which time is not available to describe in tail.

We may attempt to solve the problem of the early agnosis of pulmonary tuberculosis by the following ethods:

1. By an analysis of symptoms, history, and physical gns.
2. By an examination of the sputum.
3. By radioscopy and radiography.
4. By the tuberculin tests of Koch, von Pirquet, Moro, id Calmette.
5. By an examination of the blood after the method of rneth.
6. By agglutinin and precipitin reactions on the lines of idal's valuable test for typhoid fever.
7. By the fixation of complement test on the lines of assermann's well-known test for syphilis.
8. By the opsonic index method.

Most of these methods are too familiar to you to require ny description. Arneth's method is, however, new and ot widely known, so some account of it may not be appropriate. Briefly, this observer hopes to find a iagnostic clue to tuberculosis, and to its activity and ourse, in changes which he describes in the neutrophile eucocytes. Arneth divides these cells into five groups, amely, those in which the cells have one, two, three, four, ve or more nuclei. He finds that in health these groups orm approximately 5 per cent., 35 per cent., 41 per cent., 7 per cent., and 2 per cent. In the very earliest stage of ulmonary tuberculosis, when the general health is still naffected, these various groups preserve their normal ratio, ut so soon as signs of general infection occur this ratio s disturbed. The first group rises to 15 per cent., the econd to from 36 per cent. to 46 per cent., while the third roup falls slightly, and the fourth and fifth groups fall more ecidedly. In more advanced cases with active symptoms he first group rises to from 28 per cent. to 52 per cent., the econd group to from 37 per cent. to 53 per cent., while the hird group falls to 10 per cent., and the fourth and fifth roups tend to disappear altogether. It is claimed for his method that it gives us an accurate indication of the ntensity of the infection and of the reaction of the atient's organism, and that hence it affords a useful uide to prognosis. In favourable cases, where recovery is n progress, the condition of the neutrophile leucocytes is aid to tend to revert to the normal.

Arneth's method is comparatively new, and has not een extensively tried in this country. It is attractive, nd may contain some amount of promise, but it is not asy to believe that the changes in the leucocytes which re, no doubt, reactive in character, are quite specific for uberculosis in contradistinction to other infections. As I have not tried the method, I pass no judgement upon it.

Radioscopy affords interesting information in cases of pulmonary tuberculosis, but there is still a good deal of doubt as to its value in incipient cases, and the interpretation of the skiagram is often a matter of great difficulty. Amongst the earliest changes are a fine mottling in some of the characteristic areas, the dark lines due to the peribronchial fibrosis usually present, and, especially in children, the shadow cast by swollen bronchial glands. Impaired movements of the diaphragm are likely to develop later. Unfortunately the sources of fallacy are numerous, and the skiagram does not help us to differentiate between old healed lesions and recent active lesions. The method is one which appeals to the *x*-ray expert and the pulmonary specialist, but is not likely ever to become generally available.

The various tuberculin tests, regarding which such high hopes were once entertained, have proved disappointing. A little reflection will convince us that they suffer from an inherent and incurable defect. They all depend upon the principle that the organism once infected by tuberculosis has become hypersensitized to the action of tuberculin. But this hypersensitization may depend upon the presence of an obsolete and healed lesion in lung, or gland, or bone. As 70, 80, or 90 per cent. of our city populations—the exact figure does not affect the argument—are, or have been, the subjects of tuberculous infection, a positive reaction to tuberculin gives us little information of real value, and may easily mislead as to the correct interpretation of the case before us. To put the matter in another form, tuberculin reactions do not distinguish between tuberculous *infection* and tuberculous *disease*, which is precisely the point which is really at issue. A negative reaction may be allowed some weight, but in ordinary city practice a positive reaction is the rule.

I need not say anything about the value of a routine examination of the sputum. The discovery of tubercle bacilli is decisive, and bacilli may be found in quite early cases, although at this stage their absence, and, indeed, the entire absence of sputum, is quite common.

The attempt to discover a reaction based upon the agglutinins and precipitins in the blood of tuberculosis patients—that is, a reaction analogous to Widal's valuable test for typhoid fever—has so far led to no fruitful result, and there seems to be no probable future for this method.

The latest suggestion of a specific test for tuberculosis is on the lines of the well known Wassermann reaction which has proved so useful in the recognition of syphilis. The theory is that the serums of tuberculous patients contain an antibody capable of fixing complement in the presence of tuberculin. Positive results have been claimed for this method in proportions varying from one-quarter to three-quarters of the cases. It is affirmed that a negative result goes far to exclude tuberculosis. This method is quite new; it is still in the experimental stage, and it would be premature to express any opinion upon its probable usefulness.

The opsonic index method, the technique of which is now generally known, seems to yield interesting information in the hands of the pathological expert, but the results are very conflicting, and the method is unsuitable for general adoption.

A review of the foregoing methods will probably convince us that no sure short cut to a summary diagnosis of incipient pulmonary tuberculosis is at present available. Laboratory methods may give us a valuable suggestion or a useful caution; they can seldom afford definite guidance. We are not yet absolved from the necessity of basing our opinion in large measure upon a careful study of history, symptoms, and signs. Let us inquire where we stand to-day in reference to these matters. Two types of incipient cases rise before the mind. In one type the examination of the chest is wholly negative; in the other, slight but significant departures from the normal are present; in both symptoms, perhaps slight and not very characteristic, will be found. What are we to say of these cases where symptoms excite suspicion, while signs are negative? A vague failure of general health in a young adolescent may have many explanations, but the suspicion of pulmonary tuberculosis will be strong where we find the syndrome of loss of weight, slight afternoon pyrexia, cough, and acceleration of the pulse. There is often a history of slight haemoptysis, which the patient frequently assures us "came from his throat" or "was due to his teeth." To this symptom much weight may be justly attached. Night sweating is occasionally an early symptom, and when present is most significant. Digestive disturbance may appear early and may strengthen the diagnosis, but it is often absent. On these points there will probably be no difference of opinion.

Acute divergence of view emerges, however, when we ask the question, What are the earliest physical signs of tuberculous invasion of the lungs? A formidable list of authorities might be quoted who maintain that the earliest signs are auscultatory. Strümpell says, "The auscultatory signs in the beginning of the disease are in general more certain and easier to recognize than those from percussion." Cornet says, "In the earlier stages of the disease percussion does not help very materially." Wilson Fox says, "Percussion at the apex is often unaffected in the early stages." West says, "The physical signs yielded by auscultation are not only the earliest to be detected but remain throughout the disease the most important." Osler says, "Dullness is rarely present in early cases." In sharp conflict with the above views we

have the opinion of an imposing array of observers who insist that the earliest signs are those yielded by percussion. Aufrecht affirms that percussion "offers positive information much sooner than auscultation." Krönig says "it is a very widespread error to expect to find the earliest physical signs by auscultation." In England D. B. Lees and Clive Riviere have warmly advocated a similar view. Powell says cautiously that "at this stage (namely, the incipient stage) the physical signs are but slight; the percussion note at one apex is slightly impaired and the respiration weaker, the inspiration being wavy or even jerking. There are usually a few rhonchi present, which, if limited to that apex, are very significant." My own belief is that auscultatory changes are in general prior to any appreciable muffling of the percussion note, and of auscultatory changes I believe the earliest to be a modification of the respiratory murmur either in the direction of weakness or harshness, with commonly some disturbance of the respiratory rhythm. Crepitation comes later.

The early diagnosis of pulmonary tuberculosis in young children is a separate problem, and one of no little difficulty. In these patients tuberculous infiltration of the lungs does not commonly show that preference for the apices which is so constant a feature in the adult. The disease is more diffusely disseminated or may specially affect the roots of the lungs. The tracheo-bronchial glands are frequently involved, and may afford useful physical signs. The symptoms are often marked, and progress rapid. The physical signs often trouble us not by their latency or deficiency, but rather by their abundance and by the difficulties attending their interpretation. The problem which most often arises is this: the child has a broncho-pneumonia, arising out of one of the exanthemata or otherwise, and is doing badly. The question is whether the pulmonary condition has been throughout or has become tuberculous. In many of these cases physical signs are indecisive, and symptoms are capable of more than one interpretation. Osler hardly exaggerates when he says that in some of these cases time and the results of treatment alone can decide the diagnosis. The examination of the sputum, when it can be obtained, may, of course, settle the problem. I would suggest the need for caution when dealing with obscure pulmonary conditions in young children, and the desirability of not prematurely affixing the tuberculous label. Goodhart is undoubtedly right in holding that a good many suspicious cases ultimately clear up and come to nothing.

Before dismissing the subject of the diagnosis of early pulmonary tuberculosis I would like to record my conviction that quite early cases are in the majority of cases amenable to treatment. The human body, in spite of superficial appearances to the contrary, is really somewhat tolerant of tuberculous infection, but to succeed we must begin operations before gross physical signs have developed. Many years ago I had occasion to visit that veteran of our profession, Sir Hermann Weber, and our conversation ran mainly on the subject of pulmonary tuberculosis. As I parted from him at his own door his last words to me were "Get them early." In that, and not in any novel or heroic methods of treatment, lies at once our safety as physicians and our best hope for humanity.

Time will not permit us to consider in detail the numerous other cases where an early diagnosis is a matter of vital moment or is beset with peculiar difficulties. But I should like to emphasize my conviction that in researches in this field, both from the clinical and the pathological standpoint, lies one of the best hopes for the future of medical science. The public must learn that for disease to be countered successfully it must have early recognition and timely treatment. Our hospitals are full of the wrecks of humanity, which we may, indeed, often patch up with more or less success, but which can never be restored to integrity.

Prevention is best; early diagnosis is next best; late diagnosis is too often only a *pis aller*. How different from their usual fate would be the destiny of the diabetic, the tabetic, the subject of granular kidney or of arthritis deformans, if these conditions were recognized at their earliest manifestations! But the diabetic commonly only seeks advice when thirst, polyuria, and progressive emaciation can no longer be ignored. The tabetic regards his early pains as "only rheumatism." The victim of granular kidne waits until his headaches, dyspepsia and visual trouble force themselves upon his reluctant attention. Th arthritic makes light of early symptoms which too surel portend ultimate disablement. We must take care tha to the ignorance of the public is not superadded any negl gence on our part, any cavalier treatment of apparentl trivial ailments, any neglect of significant symptom The out-patient room of one of our great hospitals is a excellent field for learning to distinguish promptly b tween the trivial and the essential, between some triflin ailment and the slight but significant manifestations grave disease. It is a field to which the beginner and th junior student are, with curious perversity, often assigne Rather it is the advanced student who has learnt his bus ness in the wards and has already accumulated some fun of practical experience who will there find his natur sphere and opportunity.
