It is clear that we shall err greatly if, to quote the words of Kipling, "We are afflicted by what we can prove, we are distracted by what we know"; and if we allow our sense of the boundless complexity of the human organism to engender undue timidity in interference.

That in proportion as we know more we can better diagnose disease, and can the more prudently and efficiently help our patients, daily experience teaches us. The immense progress of surgery in recent years, which has resulted from the strictly scientific work of Pasteur and Lister, impresses profession and laity alike, but the advances of medicine can challenge comparison even with those of surgery.

Modern diagnostic methods enable us to recognize diseases of which our fathers never dreamed, and to detect the more familiar maladies in those early stages in which they are most amenable to control. So long as they are used in conjunction with the older clinical methods, and not merely as short cuts to diagnosis, they prove unqualified boons. Nor can it be questioned that the range of efficient treatment is being extended widely.

But let us not forget how much we owe to the work done by our fathers with the less efficient methods at their disposal. We begin where they left off; the harvest which we are reaping they sowed; thanks to their advances we are able to advance yet further. If they knew less than we do, they had one great advantage over us, in that they had more time for thought.

That the progress of medicine has been more rapid in recent years than ever before is due to the cumulative advance of science as a whole. Modern physics and chemistry, and the borderland science of physical chemistry, have rendered possible modern physiology and pathology, and upon the foundations thus provided is being raised the stately edifice of a modern medicine in which the scientific spirit shall have freer play than heretofore. Just as the spirit which animated those who worked and those who taught in the humbler buildings of the ancient Marischal College finds in these noble halls more ample opportunity and wider scope.

Address in Surgery

DELIVERED AT THE

EIGHTY-SECOND ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION

BY

SIR JOHN BLAND-SUTTON, F.R.C.S.,

SURGEON TO THE MIDDLESEX HOSPITAL.

THE SURGEON OF THE FUTURE.

The perusal of addresses in surgery delivered at annual meetings of the Association during the last ten years leaves an impression on the mind that some of the surgeons who delivered them resembled proud conquerors on a battlefield, vain of their victories, brandishing their swords, and sighing for more foes to vanquish. Accounts of battles contain sickening lists of the killed and wounded and longer lists of those who die from infectious diseases in camps; records of surgical procedures always contain a mortality bill even for the most trifling operation.

The art of surgery is probably as ancient as the art of war, and is practised by warlike savages who have never been influenced by civilization. The antagonistic callings of the soldier and the surgeon have been markedly modified by the progress of science. It is believed by many that the ingenuity exercised in the invention of methods for destroying life will make war impossible, and the discovery of the causes of diseases and the perfection of preventive medicine will render physicians and surgeons unnecessary. The belief in each instance is futile. Soldiers and surgeons will be required as long as civilization endures; but their methods have undergone great changes, and greater are impending. Gunpowder revolutionized warfare; the discovery of anaesthetics and the invention of the microscope completely changed surgical methods. The enormous impetus which the discovery of anaesthetics gave to surgery threatened to extinguish it as an art, for post-operative suppuration and pyaemia became endemic plagues in all populous cities where the surgeon plied his craft. It was on this unfavourable flood that some of the most notable ventures of modern surgery were launched, but their progress was slow. Traditions and methods die hard! A famous surgeon told me that when he began to perform operations under chloroform an old pupil of Guy's Hospital came in to see a leg amputated under the new conditions. When the surgeon pointed out the merciful nature of anaesthetic sleep and the change it had wrought in the methods of removing limbs, the old fellow sighed, and said he had a fancy for the old ways, and liked to see some blood and sawdust about! Sir William Fergusson delivered some lectures on the progress of anatomy and surgery at the Royal College of Surgeons, England, in 1855, and described operations performed at that date in London in this rough and ready style. You will acquit me of exaggeration when I state that the arena of an operating theatre in the first half of the nineteenth century smacked of the bull ring, and the board in the old operating theatre, that bore a notice regarding the reservation of the arena for the surgeons and the two first rows of stalls for privileged spectators, recalls the notices *Sol* and *Sombra* in the Plaza de Toros.

In the early stage of a great discovery few men perceive its significance. When anaesthesia began to make progress, although surgeons recognized its importance, many years elapsed before it was fully utilized. Chloroform had been in constant use for operations before its usefulness in the reduction of dislocations was recognized. Operating theatres had iron bars and racks fixed to the walls and ring-bolts let into the floor for the attachment of cords and pulleys employed in the forcible reduction of dislocated shoulders and hips. In the Middlesex Hospital the dislocation fixtures and tackling were abolished with the old operating theatre in 1895. To-day a dislocated hip is reduced with the help of chloroform without pulleys, almost in the twinkling of an eye. When done expertly it resembles a conjuring trick. Let me briefly describe an actual case to show what harm sometimes followed the use of pulleys in reducing a dislocated hip. In 1889 the chief officer of a ship had his hip dislocated by a derrick-boom falling upon him during a voyage in the Atlantic Ocean. The captain attempted to reduce it. As a preliminary the patient drank half a bottle of brandy and fifty drops of laudanum. Being drunk he was fastened by a perineal band to a ring-bolt on the deck and ten seamen under the superintendence of the captain hauled steadily on the leg. Their efforts were unavailing. Four days later the ship touched the Canary Isles and the officer was sent ashore; the head of the thigh bone was promptly reduced by a surgeon under chloroform. On recovering the patient was unable to walk without pain. When the limb was extended he felt a pricking pain down the back of the thigh to the knee, then it divided and "one stream of painful sensations" ran down the back of the leg and the other along the front of the leg to the toes, and the sailor found it hard to kick against the pricks. I saw him in London and came to the opinion that the efforts of his shipmates had broken the rim of the acetabulum and a spicule of bone interfered with the great sciatic nerve. By means of an incision in the buttock the nerve was exposed as it issues from the great sciatic foramen. I found a hook-shaped piece of bone on the rim of the acetabulum in such a position that its sharp end pricked the nerve when the limb was extended. This piece of bone was removed. The officer recovered and reported himself in good health twenty years afterwards.

The utility of chloroform in the diagnosis of hysterical contractures, phantom tumours and spurious pregnancy was its last merit to be appreciated. The surgery of the viscera is one of the remarkable extensions that followed the introduction of anaesthetics. Abdominal organs such as the spleen and omentum were removed when extruded through accidental rents made by knives, spears, swords, scythes, sickles, cart-wheels, or similar forms of violence, and extruded intestines were returned with success centuries before the discovery of ether and chloroform. Caesarean section was successfully performed in Roman times, and many a child, to use Shakespeare's phrase, "was from his mother's womb untimely ripp'd." This form of delivery has been effected by midwives, and butchers; by a patient on herself, and by the horn of a mad bull; in some instances mother and child survived. The success that followed this inartistic mode of delivery is instructive: forty years ago Caesarean section had an astounding mortality when performed by surgeons, whilst the spayer and gelder carried out his calling with almost invariable success. Lister unravelled the riddle. To-day wounds made and closed in the course of a surgical operation unite with a certainty that ceases to attract attention. Surgeons rarely pause to think on what would happen if surgical wounds failed to heal. In the pioneer days of abdominal surgery the incisions often failed to unite and such patients frequently died. I shall later on place facts before you to show that failure of intestinal wounds to unite is one cause of the high mortality following operations for cancer of the colon. Union of healthy intestine takes place quickly and perfectly.

New Diseases and the Plagues of Egypt.

We marvel to-day at the frequency of the disease called appendicitis that became endemic in great centres of civilization in the last quarter of the nineteenth century. This disease occurred sporadically, and had been known as perityphlitis and iliac abscess for many years, but the cause of the present epidemic has not been discovered by pathologists or bacteriologists. A study of the history of diseases shows that they wax and wane. In the fourteenth century lepers were common, and leper houses as numerous in Europe and the British Isles as lunatic asylums

to-day. Leprosy lingered longest in Scotland. I thought it probable, reflecting on the prevalence of leprosy in Iceland and Norway, that there may be some lepers in the northern islands of Scotland. I have been assured on reliable authority that there is no leprosy in the Orkneys. Whilst pondering on the absence of this disease in Britain, doubts arose in my mind on reading in Lord Strathcona's will (*Times*, May 28th, 1914) a bequest of £5,000 to the Right Hon. John Burns for a home for fifty lepers in the United Kingdom, none of the sum to be expended upon lepers coming into the kingdom.

In Europe generally, leprosy diminished greatly without any recognized cause in the fifteenth century, but its decline was coincident with a great increase in syphilis. One disease tramples out another. In the vegetable world grass, and what we call weeds and the Bible tares, choke the nobler plants. When from accidental causes weeds are held in check, the suppressed plants revive and flourish again. It was a great discovery to detect the part played by insects as unconscious pimps in the fertilization of flowers. No one can doubt that the disappearance of many species of flowering plants, and variations in the abundance or the scarcity of particular species of flowering plants depend not merely on favouring conditions of weather, but on the abundance or scarcity of the insects that act as vectors of the precious pollen from the flowers of one plant to the flowers of another of the same species. Diseases supply parallels. To-day we are staggered by the important observations that many infections are conveyed from man to man, man to beast, and from beast to man by insect agency. Flies act as vectors of the parasites of sleeping sickness, gnats spread filaria, malaria, and yellow fever; fleas infect man with plague, and bugs can convey the leprosy bacillus.

The famous plagues of Egypt fraught with such important consequences to the Israelites were intensified by flies. When the narrative is considered in the light of modern knowledge, it is a fair inference that the dust storm which fouled the Nile water and rendered it undrinkable, killed the fishes, and caused the frogs to take refuge on the land. The dead fishes and frogs provided breeding places for flies, and they hatched out in myriads.

During the last decade the fly has come to be regarded as a conveyer of disease, and the indictment is very strong. The biting fly conveys parasites in its proboscis, and the common non-biting fly carries on its body, legs, and wings the infective agents of typhoid, tuberculosis, ophthalmia, and perhaps small-pox. The sequence of the Mosaic visitations is significant; the plague of flies was followed by a murrain among beasts and boils and blains on the Egyptians. The death of the children was the last plague, and it is the last to be explained by modern science. Dr. E. H. Ross was medical officer in Cairo in 1909. He tells us the spring of that year was ushered in by a heat wave on May 1, and the temperature rose to 102° in the shade. Fourteen days later the greatest plague of flies ever remembered appeared in the city. Food, milk, and fruit were contaminated by them. In two months 3,000 children under 5 years succumbed to enteritis—a disease due to infection.

It is not an unreasonable assumption that the death of the Egyptian children, which induced Pharaoh to let the children of Israel go, was due to an epidemic of infantile enteritis spread by an enormous swarm of "divers sorts of flies."

One of the greatest plagues which troubled surgeons and destroyed millions of lives is known as suppuration or pyosis; it was spread widely by surgeons. When Pasteur discovered the cause of fermentation and Lister gave this discovery a practical application in the daily work of the surgeon, it was not suspected for many years that the most dangerous items in a surgical operation were the infected instruments and fingers of the surgeon. The importance of this observation cannot be overestimated; surgeons admit its truth by wearing sterilized rubber gloves when performing operations.

The Microscope in Surgery.

It is usual to ascribe the remarkable progress of surgery to the discovery of anaesthesia and the perfection of methods designed to prevent wound infection, but we must not forget that most important was the invention of the microscope; without its assistance the minute bodies which effect such great changes in organic and inorganic nature, and cause so many varieties of infective disease in animals and plants, would have remained not only hidden but unsuspected. This important instrument of research, perfected by earnest workers mocked at as "brass and glass men," is now indispensable in clinical research. Every improvement in the construction of the microscope has led to an increase in knowledge of the cause of disease. It has also become a means of popular instruction and amusement. Even embryologic processes are displayed to interested pleasure seekers on cinematographic films in "picture palaces," and school children are instructed in physiology, including the microscopic features of the blood. The numerical estimation of blood corpuscles is a regular exercise for the clinical clerk, and corpuscles are scrutinized in the laboratory by experts with microscopes as diligently as physicists examine the solar disc with teleseopes for sunspots. Specks in the white and in the red corpuscles, barely visible to the highest powers of the microscope, may have more influence for evil on the health of a community than a sun spot big enough to be visible to the naked eye exercises on the weather.

Derangements of the functions of blood-forming organs, especially red marrow, and the significance of an excessive production of leucocytes has come to be so thoroughly appreciated by surgeons that under certain conditions an excessive proportion of white corpuscles in the blood is a more emphatic bar to a surgical operation than sugar in the urine. It is in this direction that the increase of pathological knowledge, especially the form of it called clinical pathology, will influence operative surgery in the future. The light microscopic studies of the blood throw on leukaemia acts as a danger signal to the surgeon when contemplating the removal of an enlarged spleen. The extirpation of a leukaemic spleen is always followed by death, and this experience is crystallized in practice, for an abdominal tumour resembling a spleen always suggests a blood count.

The Influence of Chemiotherapy on the Surgery of the Central Nervous System.

Disease was formerly regarded as something that entered the body, and the idea of evil spirits, or devils, entering men and women led, even before the dawn of Christianity, to surgical practice consistent with such belief, for there is evidence that the skulls of epileptics were trephined to afford incarcerated evil spirits a chance of escape. Fifty years ago our knowledge regarding the physical condition of the brain and spinal cord was of an elementary kind. It was the custom to teach that the cerebro-spinal fluid served as a waterbed for the brain in order to preserve it from harmful concussions. In my student days this teleological explanation tickled my fancy, and I suggested to the lecturer on anatomy when he waxed enthusiastic, after the style of Hilton, on this wise precaution of Nature, that the explanation was absurd, for the relative bulk of brain and cerebro-spinal fluid resembled an ironclad in a duck pond. Now cerebro-spinal fluid is used as a medium for inducing temporary paraplegic analgesia—a method of conscious anaesthesia of great advantage to the surgeon when he is called upon to operate in conditions where a general anaesthetic would be attended with unusual risks. The diagnostic importance of cerebro-spinal fluid obtained by lumbar puncture is not only great but its utility is increasing. Examination of samples of the cerebro-spinal fluid obtained by tapping the spinal theca is a routine in diagnosis. Flexner's demonstrations, that the olfactory nerves are routes by which the microbes of influenza and cerebro-spinal fever infect the central nervous system, add a new interest to the physiology of these remarkable secretory organs in the brain called "choroid plexuses."

In discussing influenzal meningitis he tells us that the fluid secreted by the choroid plexuses in infected monkeys contains an antiserum which escapes by the meningeal veins, and it may become possible to arrest the development of bacilli in the blood by means of compounds injected into the cerebro-spinal fluid. Here is a method of specific therapy unsuspected in our wildest dreams—Science transforming the cerebro-spinal fluid into a pool of Bethesda! Enterprising surgeons are now devising

methods by which they can "trouble" the pool to the best advantage. No one can doubt that bacteriologists are in their methods as ingenious as surgeons. Crowe and Cushing ascertained that urotropin (hexamethylenamin) given by the mouth is excreted into the cerebro-spinal fluid and inhibits the growth of pyogenic bacteria. Surgeons turn this observation to practical account; it is now the custom to administer urotropin internally two or three days before an operation on the brain or spinal cord, and continuing it for a few days afterwards. Post-operative meningitis occurs occasionally in spite of it!

Orr and Rows have found that micro-organisms use neural lymphatics as routes for infecting the cord. Thus a bedsore or any septic area of the skin can lead to an infection of the spinal cord at a spot corresponding to the roots of origin of the implicated nerves. This will intensify the interest of surgeons in neuritis complicating septic lesions. The brilliant demonstrations that spirochaetes use the lymphatics of nerves as avenues for invading the spinal cord will modify the treatment of syphilitic diseases of the cord.

Intrathecal injections of salvarsan, in common with all arsenical compounds, irritate the spinal cord. To overcome this difficulty salvarsanized serum obtained from the patient is injected into his cerebro-spinal fluid and tolerated. This is a good example of practical ingenuity.

The results of surgical enterprise on cerebral tumours are unsatisfactory; the mortality is great and the condition of the survivors in many instances sad. The indefiniteness of gliomatous formations makes them extremely unfavourable for operation, to say nothing of the difficulty in localizing cerebral tumours in non-motor areas. It is probable that compounds will be discovered that can be injected into the cerebro-spinal fluid and cause gliomas to shrivel in the same way that gummas disappear under potassium iodide, mercury, or salvarsan, and thus abolish some of the most uncompromising operations of modern surgery.

Surgical Gambling with Malignant Disease.

Investigations of the minute structure of morbid growths have been mainly useful in separating the so-called benign tumours from those which inevitably destroy life. Thirty years ago the two groups were regarded as distinct. It is true that type forms can be distinguished as innocent or malignant, but each genus of the so called innocent group, with the exception of lipomas, contains species in which the histological features of innocency shade away into those indicating malignancy. This is a matter of great importance when a declaration of malignancy entails the sacrifice of an organ, or a limb. The horror patients entertain of malignant disease, and the stigma they think it imprints on the family reputation, leads to willing submission when the surgeon offers operative treatment. It is an impression deeply ingrained in the profession that the presence of malignant disease justifies an operation, however extensive or dangerous, for its relief. Let us satisfy ourselves that surgical gambling with malignant disease is justified. There are two organs in the body often the seat of cancer and often attacked by surgeons—the uterus and colon—in connexion with which this question may be fairly considered.

The results of removal of the uterus for cancer in its neck are by no means uniform even when the conditions are apparently similar. The microscopic features of cancerous growths do not help in explaining variations in the clinical course of the disease. There are intrinsic and extrinsic factors concerned in estimating the malignancy of uterine cancer which have only recently been appreciated. Our predecessors in the art of surgery recognized a remarkable alteration in the appearance of patients the subjects of advanced malignant disease, which they expressed by the phrase "cancerous cachexia." This "bad habit" of body has no special relation to cancer; it is due to the entrance into the circulating blood of toxic substances secreted by the bacteria and cocci which colonize cancerous growths in exposed situations. The relation of bacteria to cancer is a matter of first-rate importance to the surgeon, and influences his work very markedly. I find, as a rule, that non-ulcerating cancers of the breast are sterile. Cancer of the tongue usually swarms with streptococci, and the neck of a uterus when cancerous is colonized by staphylococci, or streptococci, and the *coli* group. This led me to make bacteriological investigations of the necks of cancerous uteri before undertaking their removal; I quickly found that the fate of a patient submitted to operation for this disease depends not so much on the skill of the surgeon as on the nature of the infecting micro-organism. Many patients submitted to hysterectomy for cancer of the neck of the uterus die within a few days of the operation from septic peritonitis, pulmonary embolism, or acute bacteriaemia if the cancerous tissues are colonized by streptococci.

In the general hospitals of London during the year 1912 the mortality of radical hysterectomy for cancer of the neck of the uterus varied from 10 to 48 per cent. This forms a striking contrast to hysterectomy for fibroids of the uterus, for the mortality of this operation in the general hospitals of London is about 2 per cent., the difference being almost entirely due to the presence of bacteria and cocci in the cancerous tissues. It cannot be too emphatically stated that the virulence of cancer, as a rule, depends on its septicity, and cancers in exposed situations are rapidly destroyed by bacteria.

Sepsis in Relation to Cancer of the Large Intestine.

The relationship of sepsis and cancer is an important matter for the surgeon. During the last ten years there has been great activity in developing radical measures for the treatment of cancer of the large intestine. The results are not gratifying. Resections of the caecum, or portions of the colon, are attended with a high rate of mortality, and of those who survive operation early recurrence or dissemination is the rule. Surgeons know this, and in order to improve the results of operative treatment painstaking investigations have been made on the distribution of the blood and lymph vessels of the colon. In spite of much admirable work and surgical enterprise, cancer of the large intestine is as opprobrious to the surgeon as hysterectomy for cancer of the neck of the uterus to the gynaecologist, and for the same reason—sepsis. The mortality of radical operations for cancer of the caecum and colon in London during 1912 was 30 per cent. In the London Hospital, during the years 1901–11, resection of cancerous portions of the large bowel was performed on 95 patients; 49 recovered and 46 died (Sir Frederic Eve). In these days of boastful surgery this may be called a superlative death-rate.

The radical method of dealing with cancer of the colon consists in free resection of the cancerous portion in favourable cases; this requires a complicated operation for the reunion of the bowel, entailing a sutural junction that must be not only water-tight but gas-tight. One of the first requisites for immediate union is the absence of pyogenic bacteria. In operations for intestinal anastomosis success depends on early and firm union of the apposed surfaces of the bowel. There is nothing more amazing in relation to the healing of wounds than the rapidity with which peritoneal surfaces join when they are carefully sewn together with sterile sutures. In regions of the gastro-intestinal tract free from pyogenic bacteria union occurs after surgical operations safely and quickly; thus a gastro-jejunostomy in the hands of competent surgeons is devoid of risk from septic peritonitis. How different the picture for radical operations performed for cancer of the colon! Septic peritonitis destroys the lives of at least 30 per cent. of those who submit to it. Death is due to septic peritonitis from infection during operation, leakage at the junctions, or failure of union due to the colon bacillus and its congeners.

Cancer of the colon is an extremely insidious disease; in the early stages it is symptomless, until it becomes septic or obstructs the flow of faeces, then the patient complains of pain. When cancer becomes septic, it sloughs and bleeds. Infected cancer impairs the patient's health, because the toxins brewed by the schizomycetes colonizing it enter the circulation. Colic cancer sometimes leads to abscess when it is infected by the *coli* group. The frequency with which visceral cancer mimics inflammatory conditions and misleads physicians and surgeons alike is due to sepsis. The appreciation of the causes of failure in the surgical treatment of colic cancer should exercise some influence for good. Statistics indicate that the risks of operations performed for cancer of the colon are as great as for the operations of general surgery in pre-Listerian

days, with this difference—the mortality of that period was due to sepsis from infection of the wound that often arose from the use of dirty sponges, instruments, sutures, and the septic fingers of the surgeon and assistants. In operations on cancerous viscera the diseased tissues are already infected and taint the fingers and instruments of the surgeon, hence the danger of such operations.

SURGICAL COQUETRY.

It is by no means uncommon to see surgeons clad in sterilized overalls, gloves, caps, masks, and top boots resecting a cancerous segment of colon swarming with pyogenic micro-organisms. This can only be described as surgical coquetry. Some of our methods for destroying bacteria in the course of an operation are almost as clumsy as attempts to kill fleas with bludgeons.

In order to improve the results of operations for visceral cancer means must be devised for sterilizing them, or a specific remedy found for cancer. There are indications that both methods will be available. Cancerous organs are sometimes submitted to the action of radium as a preliminary to operation, and histological examinations of malignant tumours affected by radium emanations show that the gamma rays find distinctions in tissue cells imperceptible to the microscope. We need a compound which can be introduced into the circulation to destroy streptococci and its kind. This is no idle dream. Huxley suggested that it would become possible in view of the discoveries in therapeutics "to introduce into the economy a molecular mechanism which like a very cunningly contrived torpedo shall find its way to some particular group of living elements, and cause an explosion among them, leaving the rest untouched." This sounded fantastical in 1881, but Ehrlich has discovered "molecular mechanisms" more subtile. There are drugs (organotropic) which injuriously affect the organs of the body and fasten on them like aniline staining reagents cling to special tissues. He speaks of compounds that injure the intestinal tract of mice, and they die of profuse diarrhoea. Sometimes the red blood corpuscles are attacked, and the animal dies of severe anaemia. Curious drug affinities occur in the central nervous system; in mice the vestibular nerve is attacked, and they gyrate like Japanese waltzing mice. The derivatives of phenylarsin acid attack the optic nerve, and large doses of atoxyl produce blindness.

What surgeons urgently need is a molecular compound which will either kill the bacteria and cocci that colonize cancer or neutralize their harmful toxins in the same way that salvarsan renders spirochaetes inert without destroying the organs or tissues of their host.

THE SURGEON OF THE FUTURE.

In pre-Listerian days the path to surgery lay through the dissecting-room. A thorough practical knowledge of the anatomy of man was and is indispensable to a sound surgeon. Many surgeons whose names are prominent in the history of surgery—from John Hunter to Fergusson—taught anatomy by dissection. Surgeons no longer act as demonstrators of anatomy or conduct *post-mortem* examitions; the principles of antiseptic surgery forbid such occupations. The practical training in the dissecting-room and *post-mortem* room teaches men something they cannot learn from books—the appreciation of tissue; this means, in plain terms, the power to recognize organs and tissues, normal and abnormal, at sight or by touch in the course of an operation.

Surgeons are of two types, they are either craftsmen or biologists. The surgical craftsman invents variations in technique; metal plates, wires and screws for bones; or fancy methods of suturing wounds. Some expend their ingenuity on surgical cutlery and improve the knives and needles. The utility of a simple tool such as the clip forceps is inestimable. In spite of much ingenuity among surgeons, an ideal ligature material awaits discovery. Clever contrivances like the laryngoscope, bronchoscope, and cystoscope have revolutionized special branches of surgery. Another useful instrument, the oesophagoscope, requires for its successful use a surgeon with the instincts of the sword-swallower and the eye of a hawk. Recently through the kindness of my colleague, Alfred Johnson, I witnessed through the cystoscope a stone slowly extruded from the vesical orifice of the ureter.

The biological surgeon studies pathology in its broadest aspect and investigates, in the laboratory, problems of morbid anatomy and bacteriology. The diagnostic value of reports issued from the laboratory by the pathologist and the bacteriologist, to be of value, must be estimated with the help of clinical experience. If the surgeon has had no experience in bacteriological methods he must accept the reports from the laboratory with the hopefulness of a patient swallowing physic compounded from a prescription he does not understand and which he is often unable to read. The training of surgeons in clinical pathology is of great importance, and it requires little foresight to recognize that for men ambitions to attain high places in surgery the high road lies through the pathological institute.

Morbid histology has been and still is of great use in classification, diagnosis and prognosis of morbid growths; for a knowledge of their cause new methods are required. For these we fix our attention on the men along the skyline—bacteriologists, experimental physiologists, physiological chemists, and physicists; the future lies with them. As it is of the utmost importance that surgeons shall have a practical knowledge of clinical pathology, it becomes essential to bring the wards, operating theatres, and laboratories into the closest intimacy. From this union of workers means will be found for curing diseased organs by chemiotherapy rather than by extirpating them. Until the right compound for curing cancer has been discovered, surgeons will continue to excise cancerous viscera, and this makes it more necessary to discover means for ridding cancer of pyogenic bacteria.

The skill, ability, and dexterity with which surgeons remove a kidney, the uterus, or perform extensive resection of the intestine, great and small, can be witnessed almost daily in the splendid hospitals of large cities, but surgical effort is handicapped by streptococci and the *coli* group, which are very resistant to chemiotherapy. There is something fascinating in submitting septic morbid growths to what Ehrlich picturesquely terms a "bacteriological siege." Our difficulty is to destroy these seeds of disease without serious damage to the organs and the delicate tissues in which they flourish. The antiseptic solutions employed against bacteria are powerful cell poisons. We need therapeutic agents which destroy parasites but do not kill the tissues of the host. Acute minds are busy with these problems, and surgeons may hope to remove visceral cancer with no more risks than attend gastro-jejunostomy or hysterectomy for fibroids.

The magical effects of salvarsan on the lesions of syphilis, acute and chronic, lead us to hope that this compound will assist in the elimination of cancer of the mouth and tongue, for in these situations cancer is often engrafted on chronic syphilitic lesions. It is reasonable to believe that within a few years surgeons will notice a marked decrease in the number of men with cancer of the lips, gum, tongue, and pharynx, and of women with cancer of the vulva. The extinction of these forms of cancer will relieve surgeons of some of the most distressing and unsatisfactory operations they are called upon to perform.

In regard to the cure of malignant disease, there is most hope in chemiotherapy. In detecting the cause of cancer histology has proved a false dawn, but, like that peculiar light which precedes the dawn in the tropics, it is very fascinating. Who can tell how long we shall have to wait for the real dawn! We need not despair; the zeal, enthusiasm, and acumen of laboratory workers fills us with the hope that the ideal of all practitioners of medicine and surgery is attainable—the control of all forms of infective disease.

THE Russian Imperial Duma has voted in favour of the proposal to establish a Faculty of Medicine in the University of St. Petersburg.

WE learn from the *Journal of the American Medical Association* that the trustees of the University of Pennsylvania have voted in favour of admitting women to the medical college of the university. The new regulations will take effect in the autumn of the present year.

THE latest "A. F. pamphlet" supplies a description of methods that have been found useful in organizing and conducting local movements in favour of humane slaughtering. Copies (price 2d.) can be obtained post free from the Animals Friend Society, York House, Portugal Street, Kingsway, W.C.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

TWIN TUBAL PREGNANCY WITH TUBAL ABORTION OF ONE TWIN.

E. P., a multipara, aged 33, was admitted to the Royal South Hants Hospital on April 28th, 1913, suffering from severe uterine haemorrhage. There was a history indicative of six months pregnancy, abdominal tumour to about the level of the umbilicus, and milk in the breasts. No fetal heart sounds were heard. The os was patulous, but very little else could be made out on vaginal examination, owing to excessive tenderness. As the patient was having continuous haemorrhage, it was thought advisable to empty the uterus without delay. She was anaesthetized and placed in the lithotomy position. On passing a sound I noticed that its direction did not correspond with the axis of the tumour, nor did it pass as far as I expected. A bimanual examination under the anaesthetic showed the tumour to be distinct from the uterus. A diagnosis of tubal pregnancy was made, and the abdomen prepared with acetone and iodine for laparotomy.

I opened the abdomen from umbilicus to pubes a little to the left of the middle line. A large dark-coloured tumour was exposed with omentum adherent to its upper pole. The adhesions were easily separated, and then, having packed abdominal swabs around the mass, I opened it freely. A quantity of old blood and clot escaped, and passing my hand into the cavity I extracted a fetus. There was no sign of life; using the umbilical cord as a guide, I easily found the placenta in the antero-inferior portion of the gestation sac, and stripped it from its site. As I brought it into view I saw another umbilical cord springing from the same placenta. This I traced out, and found another fetus free in the peritoneal cavity, and situated just below the liver. It was as large as the fetus first removed, but showed signs of degeneration in the toes of one foot. I ligatured the uterine artery near the fundus, and then removed as much of the gestation sac as possible. The oozing from the walls of the sac, and especially the placental site, was rather alarming, and I could only arrest it by gauze packing. This I used freely round a tube which I passed to the bottom of the sac. The abdomen was then closed in layers. The patient made a slow but uninterrupted recovery, and left the hospital on June 18th.

The interest of the case, apart from the rarity of the condition, would seem to centre round the position of the second fetus. It seems improbable that a fetus of such size could escape past abdominal swabs, at the time of operation, unrecognized. The length of each fetus was about 7 in. It is possible that tubal abortion of one embryo had occurred at an earlier date, and that the anastomosis in the fused placentae had been sufficiently strong to nourish the intra-abdominal fetus until some factor brought about the death of both embryos.

I am indebted to Mr. Shettle, the senior surgeon of the hospital, for his kindness in referring the case to me, and also allowing me to publish the result.

Noel Braham, F.R.C.S.Edin.,
Late R.M.O. Royal South Hants and Southampton Hospital.
Southampton.

Reports of Societies.

ASSOCIATION OF REGISTERED MEDICAL WOMEN.

At a meeting on Tuesday, July 7th, Dr. F. May Dickinson Berry in the chair, Dr. E. Bolton gave a summary of 19 cases of tuberculous disease of the female generative organs that she had collected from the records of the New Hospital for Women. During the last ten years 75 cases of tubal disease had been operated upon, and of these 19 had been microscopically determined to be tuberculous in nature. She held that the diagnosis of tuberculosis was sometimes very difficult. As regards symptoms, menorrhagia and metrorrhagia were marked and amenorrhoea was rare. Among the married women sterility was a very noticeable feature. Pathological findings in the uteri removed showed evidence of tubercle in 66 per cent. of the cases, and she was of opinion that for this reason it was wiser to remove the uterus. Dr. L. Lepper having demonstrated specimens and microscopic preparations from some of the cases described, Dr. Louisa Garrett-Anderson agreed that the difficulty in diagnosing tuberculous from non-tuberculous conditions of the adnexa was very great. She had found that prolonged anaesthesia in these cases was sometimes followed by tuberculous chest trouble. Dr. Maud Chadburn also described the difficulties arising in diagnosis. She had found tuberculosis localized in the tubes in the routine examination of a woman who came for treatment of varicose veins, and who did not complain of pelvic trouble. The symptoms usually complained of by those suffering from tuberculous pelvic disease were menorrhagia, amenorrhoea and sterility, and very rarely pain. She advocated early surgical treatment and the removal of all obvious disease, preserving the uterus and ovaries whenever possible. Dr. Hilda Clark gave her experience of diagnosis and treatment by means of injections of tuberculin. In one case the distorted tubes had resumed their normal contour; dysmenorrhoea was frequently improved. Dr. Forrester-Brown drew attention to the good general condition and appearance of a woman who had undergone operation for severe tuberculous disease of the adnexa.

Reviews.

AMERICAN WORTHIES OF MEDICINE.

Professor Howard A. Kelly has compiled a *Cyclopaedia of American Medical Biography*,[1] the object of which is to give a short account of every medical worthy who has lived in the United States and in Canada. By "worthy" he means one who has won distinction either as an original thinker or writer, or as a teacher or leader in medicine. Others, too, are included, such as pioneers who did great work with insufficient means and assistance in the border countries in the early days, and men who after taking a degree have not practised medicine, but became eminent in some other branch of science. There are also a few biographies of men who have done no special original work, but who widely influenced their fellows by their strong personality. The book, which contains sketches of more than 1,200 worthies, closes with December 31st, 1910.

Some interesting articles on special subjects serve as an introduction to the lives. From an essay on anatomy by Dr. C. R. Bardeen, we learn that Philadelphia was the first place where anatomy was studied in the United States; New York came next. The first teacher of practical anatomy was Thomas Karl Wallader, who had worked under Cheselden, and who in 1730 or 1731, made dissections and gave demonstrations for the instruction of two or three students. Dr. Valentine Mott, who about 1806 was demonstrator of anatomy at Columbia, has recorded his experiences as a resurrection man. On one occasion he drove in disguise a cart containing eleven subjects from a burying ground, sitting on the bodies and "proud," he said, of his "trophies." In a paper on surgery Dr. Martin B. Tinker claims among the pioneer work done by Americans, spinal anaesthesia, the modern operation for hernia, excision of the Gasserian ganglion, and decortication of the lung for old empyema. Philip Syng Physick first advised the use of animal ligatures in 1816; he used ligatures of buckskin, rolling them under a marble slab; he cut them close and left them buried in the wound. About ten years later Jameson made a number of experiments on animals which he thought showed the superiority of animal ligature material. Tinker says that Benjamin Winslow Dudley was one of the first to trephine successfully for the relief of epilepsy. He operated on his first case in 1819 and reported 6 successful cases in the *American Journal of the Medical Sciences* in 1832. Benjamin B. Simons is credited with the first operation for brain abscess; it was reported in the *Carolina Journal of Medicine, Science, and Agriculture,*

[1] *A Cyclopaedia of American Medical Biography. Comprising the Lives of Eminent Deceased Physicians and Surgeons from 1610–1910.* By H. A. Kelly, M.D. In two volumes. Philadelphia and London: W. B. Saunders Co. 1912. (Roy. 8vo, pp. 969; illustrated. 42s. net.)

vol. i, 1823. About one-half of the whole number of operations on the Gasserian ganglion so far reported are said to have been done by Americans, and a complete tabulation of all recorded cases of brain tumour operated upon down to 1903 shows that nearly one-third of something over 300 brain tumours then reported had been operated on by American surgeons, with a proportionately large number of successful cases. Intubation as a substitute for tracheotomy was introduced by O'Dwyer. McDowell performed the first ovariotomy in 1809, and afterwards operated in 13 cases with eight recoveries. Professor Howard Kelly gives an excellent review of the work done in America in gynaecology and obstetrics, and Dr. Alfreda B. Withington gives an account of women in medicine in America, in which she says that Elizabeth Blackwell, who recently died, lived to see 7,399 women physicians and surgeons in America. Thomas Shastid contributes a critical essay on medical jurisprudence.

Of the biographical part of the *Cyclopaedia* we can speak with high praise; but it is impossible to review such a work in detail. We therefore only take a few selected lives as specimens. The account of Oliver Wendell Holmes is excellent, and eminently readable. It is quite rightly dealt with from the medical rather than the literary point of view. Crawford Williamson Long is credited with the first use of ether as an anaesthetic, though he did not make it known to the medical world. Professor William H. Welch, therefore, says that while the credit of independent experiment and discovery need not be withheld from Long, we cannot assign to him any influence upon the historical development of our knowledge of surgical anaesthesia or any share in its introduction to the world at large. As Sydney Smith said, it is not the man who stumbles on a new truth, but he who by crying it from the housetops gets it accepted, that is the real discoverer. The account of W. G. T. Morton is very brief, and scarcely does justice to the man or to his work. Of Elisha Perkins, whose name is known in connexion with the once famous tractors, there is a good account, though short, but it is odd to read that "it was owing to the exertions of *one* Dr. Haygarth, of Bath, England, that the idea of any healing power resident in the tractors themselves was refuted." The younger William Pepper was a man into whose life manifold activities were crowded; among his most important works were the reorganization of the University of Pennsylvania, and the establishment of a great museum and free library.

The lives are all commendably short, and the more important of them are "documented" with abundant references. Owing to the number of authors, they are inevitably unequal in execution, but altogether they are very interesting. The whole book is a record of splendid achievement in every province of medical science, and gives the impression of great activity, often along original lines, and of freshness, vigour, and originality in the men whose work is recorded. The book is illustrated with several portraits.

ALCOHOLISM AND ITS EFFECTS.

THERE is a certain fitness in noticing the two works cited in the footnote in one article.[2] Dr. CLIFFORD'S Raper Memorial Lecture is an eloquent denunciation of the evils associated with the traffic in alcoholic beverages, and a glowing account of the advantages of total abstinence. In addition to quotations from the writings of numerous professional men of distinction, Dr. Clifford remarks (p. 7) that "it is no longer a guess that total abstinence is the royal road to longevity," and cites the statistical data of certain insurance companies which maintain separate classes for abstaining and non-abstaining members. Mr. PHELPS'S pamphlet consists for the most part of a pungent criticism of this species of evidence. Mr. Phelps quotes some observations by Dr. Dwight, medical director of the New England Mutual Life Office, which indicate the statistical complexity of the problem. One passage from Dr. Dwight's remarks may be cited. He says:

> We divide them (that is, the insured lives) into the total abstainer, rarely use, temperate, and moderate. By "rarely use" we mean the man who says that he, perhaps, twice a year at a dinner drinks two glasses of champagne. While we have every reason to believe that this is an honest statement, it is not quite fair to say he is a total abstainer. Otherwise they are divided by the individual's own statement—in many instances incorrect. In many instances the total abstainer is a total abstainer because he has to be and has been advised to be, but take them as they run, we find the total abstainer with a mortality of 59 per cent. of the American table—these are rough figures; rarely use, 71 per cent.; temperate, 84 per cent.; and moderate, 125 per cent. If we let these figures stand as they are it is accumulative evidence to demonstrate that we ought all to stop drinking the next minute, and that we ought to divide our applicants into abstainers and non-abstainers; but let us see what the effect of tobacco is. We find that the total abstainer from tobacco has a mortality of 57 per cent. as against 59 per cent. when he is a total abstainer from alcohol; that the rarely use is 72 per cent. as against 71 per cent. from alcohol; that the temperate is 84 per cent. as against 84 per cent. for alcohol; and that the moderate is 93 per cent. as against 125 per cent. for alcohol. In other words, the mortality on the total abstainer from alcohol is almost absolutely the same as that on the total abstainer from tobacco. It may be said that a man is usually a total abstainer from both, but he is not necessarily so. It does mean, I think, that we are describing the same kind of groups, the same type of man, the same conservative type of man in the total abstainer from both kinds. Then to show you the numbers—we find that out of 180,000 cards, 42,700 were total abstainers from alcohol—at least, they said they were—while the total abstainers from tobacco were 41,100, almost exactly the same number; 13,000 rarely used tobacco, while 20,000 rarely used alcohol. I only bring them up as they are, simply as a suggestion that before we accept all total abstainers on a different premium, or before we talk very much about doing it, we had better be sure that it is all due to total abstinence from alcohol or tobacco, and we had better go a good deal further in our investigations in our attempt to make these groups homogeneous before we here as an Association or as individuals advocate very strongly the wide separation between total abstainers and those who rarely use.

This passage very clearly brings out the difficulty which some statisticians have felt in assessing the importance to be attached to the quoted differences in mortality between abstaining and non-abstaining sections. It would also appear to be necessary to allow for occupational differences in the sections and the amount of experience available is not sufficient to allow of much subdivision. Mr. Phelps calls attention to the marked variations from quinquennium to quinquennium in the relative mortalities of the temperance and general sections of the United Kingdom Provident Institution. Thus the percentage excess of the general section was 25.1 in 1866–70, 45.2 in 1871–5, 42.9 in 1876–80, and only 29.4 in 1881–5. For the most recent period (1906–10) the figure is 27.7. Such large fluctuations make it difficult to draw simple inferences from the figures.

In the concluding pages of his book, Mr. Phelps criticizes with extreme severity certain abolitionist literature and legislation, but these remarks have not any direct bearing upon conditions in this country. While some passages in Mr. Phelps's book would have lost nothing had they been worded less strongly, he deserves credit for once more calling attention to the rash manner in which statistical conclusions are drawn. Dr. Clifford in the lecture under notice roundly asserts that "Half the crime of the country is directly due to drink, and a further fourth is indirectly incited by it." But, in a work by Dr. Charles Goring, entitled, *The English Convict*, recently issued by His Majesty's Stationery Office, with a preface by the chairman of the Prison Commission, the author concludes (p. 277) that "alcoholism is not directly related to crime but only indirectly, through its relation to defective intelligence."

We do not desire to underrate the evils associated with the excessive indulgence in alcohol, but a sense of those evils constrains us to protest against exaggerations, which in the long run must tend to discredit the temperance movement in the eyes of impartial persons.

HORMONE THERAPY.

PRACTICAL medicine has gained a great deal in recent years by the introduction into therapeutics of the principles contained in the various ductless glands. *Hormone Therapy* is the term used by Dr. HARROWER[3] to express the "therapeutics of the ductless glands and internal secretions," an idea more or less conveyed by the name "opotherapy" borrowed from the French. Dr. Harrower believes that

Price 4d.) *The Supposed Death-Rates of Abstainers and Non-Abstainers and their Lack of Scientific Value.* By E. B. Phelps, M.A., F.S.S. New York: Thrift Publishing Company. 1913. (Pp. 30.)

[3] *Practical Hormone Therapy: A Manual of Organotherapy for General Practitioners.* By H. R. Harrower, M.D. With a foreword by Professor Dr. A. Biedl (Vienna). London: Baillière, Tindall, and Cox. 1914. (Demy 8vo, pp. 503; 8 figures. 15s. net.)

the medical men of America and England do not take advantage of hormone therapy as much as they should, and he has written his book in order "to broaden the therapeutic horizon and to stimulate the reader to include in his armamentarium such of the hormones as are of proved utility." He has endeavoured to collect from the literature all references bearing on the therapeutic use of the many animal extracts now on the market—the hormones derived from the pancreas, spleen, liver, bile, thyroid gland, thymus, kidney, suprarenal and pituitary bodies, epiphysis cerebri, testis, ovary, placenta, lungs, lymphatic and carotid glands, and so forth. An appendix contains a most useful glossary of some of the many new names and words applied to these various animal extracts, and a table of the doses and diseases in which they are to be administered. Numerous references to the literature are given at the end of each of the thirty-four chapters of the book.

Dr. Harrower is to be congratulated on the skill with which he has put together the results of his study of the very extensive literature of hormone therapy. He does not set out to give his own clinical experiences with the multitude of preparations he mentions, but is satisfied to quote their eulogies from the current medical literature, largely from various French, German, and Italian periodicals, and he seems at times to be perhaps a shade uncritical in his quotations or appreciations. None the less he has collected a great quantity of valuable matter bearing on the therapeutic uses of glandular and tissue extracts, and his readers will surely thank him for countless useful hints and suggestions in the treatment of acute and chronic diseases. The book is clearly and concisely written; it may be warmly recommended to the attention of all medical practitioners.

HEALTH TEACHING FOR THE PEOPLE.

THE series called "People's Books"[4] includes a set dealing with matters relating to everyday life. They cover a large variety of subjects, and the writers for the most part have been selected for their special knowledge and also for the sanity of their views. It is this that gives them their value for popular guidance. Dr. ALEXANDER BRYCE, in a volume on *Dietetics*, expounds briefly but lucidly the principles underlying nutrition, and he has given a personal character to the book by setting forth his own views on important points. He is not a faddist, recognizing that what is one man's meat is another man's poison. While admitting that vegetarianism has many advantages to some persons, his experience of vegetarians of all classes has not convinced him that they are stronger, healthier, longer lived, better tempered, or in any way better than the average mixed feeder who takes moderation and regularity as his rules of life. He says that in too many cases the effects of a pure vegetarian, or fruitarian, diet is disastrous. This statement does not apply to those who take animal protein in the shape of eggs and of milk and its products. But even they, though in health and vigour quite up to the average of the mixed feeder, are, except in a few isolated cases, not conspicuous for vitality, "energy" in the fullest sense of the word, initiative, or outstanding merit in the ordinary affairs of life. The uric acid craze he thinks has been overdone. Dr. Bryce's small book is throughout marked by a spirit of common sense, and may be read with advantage by members of the medical profession.

Dr. HUGH S. DAVIDSON'S *Marriage and Motherhood*, described as a wife's handbook, gives a popular description of the signs and symptoms, hygiene, and complications of pregnancy and labour, with information as to the newly born child and its deformities and diseases. It is eminently sensible and practical, and may be warmly recommended to those for whom it is intended. It may be mentioned that the author preaches the advantages of a large family, one being that the children are happier in themselves and pleasanter to other people.

The Baby, written by a university woman, is marked by good sense and motherly tenderness. It is written in simple language, not overloaded with medical details, and may be recommended as a safe guide for all mothers.

In *Youth and Sex* the dangers and safeguards for girls and boys are described by Mrs. SCHARLIEB and Mr. F. ARTHUR SIBLY respectively. Mrs. Scharlieb's part of the book could scarcely be bettered. Mr. Sibly, we venture to think, in his zeal for purity, rather exaggerates the danger which he exposes. At any rate, he gives one the impression that the larger part of boy life is taken up with thoughts about sex, and the longings and practices that grow from that habit of mind.

G. SPILLER'S *Training of the Child* is intended to meet the demand which is said to exist for a manual of home education dealing with the moral and intellectual training of children. It is all very well intended and mostly very sound and sensible, but the feelings of the average man or woman on reading it might be expressed in an adaptation of the words of Rasselas on hearing of the qualifications required for a poet: "Thou hast persuaded me that it is impossible to be a parent." All this talk of training and making the child walk in the way it should go is excellent in intention, but we have a suspicion that it must tend to the production in many of a moral invertebracy which will in time sap the efficiency of the nation.

In Mr. WATT'S little book on *Psychology* the attention of the reader is directed mainly towards the study of experiences, their analyses, description, classification, and connexions. We can commend it as a sound and lucid introduction to psychology.

Dr. A. M. HUTCHISON gives a clear account of the phenomena of *Hypnotism*, and treats psychotherapeutics in a temperate and rational spirit. The applicability of suggestion to education is discussed in an interesting manner; the author always stimulates thought, even if he sometimes fails to convince.

Of Mr. J. ARTHUR HILL'S book on *Spiritualism and Psychical Research*, all we can say is that it has not convinced us that there is any scientific proof of the reality of the phenomena of spiritualism. However interesting the subject may be to persons of a mystical turn of mind, it may be doubted whether it is worth the serious attention of any one who has work to do in this world.

MEDICINAL AND DIETETIC PREPARATIONS.

Coloured Chloroform and Ether.

DR. P. F. BARTON, M.A., M.B. (Wimbledon, S.W.), writes: There are definite dangers due to the fact that chloroform and ether are similar in appearance, and only to be distinguished by their weight and smell. Now that so much ether is given by the open method, different coloured drop bottles are sometimes used, but this does not prevent chloroform being put into the ether drop bottle by mistake. The greatest danger of all is when chloroform has been by mistake put into a Clover's inhaler. I have heard of two fatal accidents from this, and almost witnessed a third myself. The profession has become accustomed to coloured antiseptics, and provided the colouring reagents are absolutely innocuous to the patient, are permanent, and do not affect the properties of the chloroform and ether, there is much to be said in their favour in the case of anaesthetics. At my suggestion, after some months of experimenting, Messrs. Duncan, Flockhart and Co. have succeeded in producing a pink chloroform and a green ether which are perfectly satisfactory, and which they are now prepared to dispense if they are asked for them. The mixture of equal parts shows a clear brown. I have exposed them to sunlight for some weeks without their fading, and used them frequently with perfectly satisfactory results. I gave the ether by the open method for over two hours a few days ago, using the same piece of lint, and found it perfectly satisfactory, and have found the pink chloroform equally good. Probably chloroform is never mistaken for ether in hospitals or in the practice of the professional anaesthetists, but surely such a mistake ought to be made absolutely impossible. At times anaesthetics are given in a bad light, with indifferent assistants, and for an exacting surgeon, who is inclined to flurry the anaesthetist. The green used for the ether is a pure vegetable product, 1 in 1,400; the red in the chloroform is an aniline product 1 in 200,000.

CLINICAL CONGRESS OF SURGEONS OF NORTH AMERICA.

THE Clinical Congress of Surgeons of North America—to give the full and correct title—which is being held in London during the present week, is the fifth session. The previous meetings were held in Chicago on two occasions and in Philadelphia and New York. The meeting has been essentially a clinical one, and from 9 a.m. to 5.30 p.m. each day of the week there have been operative clinics and demonstrations in the hospitals. The institutions which have co-operated in providing the clinical programme included seventeen general and fifteen special hospitals, the intention being to afford the visiting surgeons an opportunity of seeing the surgeons and specialists of London at work in their own hospitals according to their accustomed routine and in their own environments. Care was taken to prevent overcrowding at the hospitals; admission to the various clinics and demonstrations was strictly by numbered tickets, which were issued only up to the capacity of the room in which the clinic or demonstration was given.

The members of the Congress dashed *in medias res* on Monday morning, July 27th, at 9 o'clock by visiting the operating theatres of the several London hospitals contributing the large clinical programme arranged for that day.

Formal Opening.

The formal opening of the Congress was held in the Grand Hall of the Hotel Cecil on Monday evening. The meeting was largely attended, every seat being occupied.

Sir RICKMAN GODLEE, in his capacity of Honorary Chairman of the London Committee, gave a brief address of welcome, in which he expressed regret that several well known London surgeons were unavoidably prevented from taking part in the Congress owing to the annual meeting of the British Medical Association unfortunately taking place during the same week.

Professor J. B. MURPHY, the President-elect of the Congress, introduced to the meeting the American Ambassador, the Hon. WALTER HINES PAGE, who gave a most cordial welcome to the American surgeons.

Professor MURPHY then introduced to the meeting, Dr. W. L. RODMAN, President of the American Medical Association, who brought greetings from that association to the medical profession in this country.

Presidential Address.

The proceedings concluded with a presidential address by Professor J. B. MURPHY entitled, "Arthrodesis and bone transplantation; its limits and technique."

Operative Treatment of Ulcer of Stomach.

Professor A. VON EISELSBERG of Vienna read a paper entitled, "The choice of the operative method for ulcer of the stomach." The paper was discussed by Sir WATSON CHEYNE and Mr. JAMES SHERREN.

Suture of Levator Ani in Perineorrhaphy.

On Tuesday, July 28th, Dr. HENRY JELLETT (Dublin) read a paper on "The suture of the levator ani muscle in perineorrhaphy operations." He pointed out that the levator ani muscle was an essential constituent in the support of the pelvic floor. The operation had not come into general use owing to its supposed difficulty, and also because it was thought to be attended by a certain amount of danger; both these objections he believed were erroneous. Certain writers had introduced unnecessary complications in their description of the operation, which was really a very simple one. Mention had been made by some authorities of two muscles—the deep transversus perinei and the levator ani. The deep transversus perinei had had much importance attached to it, and had been mistaken for the levator ani in certain cases. During the operation it was isolated and divided transversely, and the two portions of the levator ani thus exposed carefully sutured; the divided transverse perinei muscle was also sutured before the completion of the operation. Professor Krönig had said that the deep transversus perinei muscles were sufficient to reconstitute the pelvic floor. Dr. Jellett thought that some bundles of the lower and inner edge of the levator ani became separated from the rest of the muscle, and had received this special name, and he had no hesitation in saying, from the examination of patients and the appearances at operation, that the so-called transversus perinei muscle must be a part of the levator ani. He outlined the steps of the operation, and mentioned that care should be taken to avoid the accumulation of blood in dead spaces. He said that large vessels should be ligatured, and that the haemorrhage was largely controlled by rapid operation and accurate suturing. Further, to obliterate dead spaces between tissue layers the vagina should be carefully packed with iodoform gauze, a special retractor being necessary for this purpose. He believed that routine suture of the levator ani muscles was an essential feature of this type of operation; that it was always practicable, except when the muscle had become atrophied, and that it was neither difficult nor dangerous to perform.

The discussion was opened by Dr. F. J. MCCANN, who agreed with Dr. Jellett in the advocacy of routine suture of the levator ani muscles. He showed also that the displacement of the levator ani fascia would cause weakness, and that this must be sutured in addition. He gave a detailed description of an operation for a case of severe prolapse, and showed that it might be necessary to excise the vaginal vault, and even the cervix, to restore the vagina to its normal size. The levator ani should be exposed and sutured. The essential points of the operation were to keep the rectum back in its normal position, and to unite two solid columns of tissue in front of it and behind the vagina. Haemorrhage must be absolutely arrested, and suturing must be accurate. He did not think that it was always necessary to plug the vagina with gauze.

Certain Derangements of the Knee-joint.

Mr. ROBERT JONES (Liverpool) read a paper on this subject. He said the most common derangement was an injury to the internal semilunar cartilage, which, owing to its being more fixed and bearing greater pressure, was more frequently lacerated than the external cartilage. In certain cases an injury to the internal cartilage might give rise to symptoms on the outer side of the joint. The proportion of cases of injury of the internal cartilage to those of the external was about eight to one. The symptoms at the time of the accident were sudden pain and inability to extend the leg; this occurred immediately after the accident. "Locking" of the joint was usually noticed, but not always. The accident usually took place when the knee was flexed, but might occur in extension. The points of maximum tenderness were over the internal lateral ligament and the anterior bone of the semilunar cartilage. Treatment of this lesion at the time of the accident was immediate and absolute reduction of the displaced cartilage and the subsequent prevention of any latent strain on the joint until the ligaments and cartilage had had time to recover. Reduction was accomplished by fully flexing the joint, rotating the tibia inwards, and then extending the limb, the patient being encouraged to co-operate. The knee should be maintained in full extension, completely at rest, from four to five weeks. Further, the patient should be kept recumbent as long as there was any effusion or pain in the joint. Aspiration might be necessary, and massage was a useful adjunct to the treatment. The fear of adhesions forming in the joint from the enforced immobility had been exaggerated. If the patient presented himself at a later date the history of recurrent attacks of synovitis and "locking" were valuable points in the diagnosis, also there was usually some tenderness over the cartilage and pain on hyperextending the joint, also the site of pain was always a fixed point. With regard to other lesions which might give rise to similar symptoms, he mentioned synovial fringes, loose bodies, and the presence of osteomata near the joint, but the diagnosis was generally made clear by careful examination, attention to the history of the accident, and by radiography. Operative interference should not be undertaken for the initial injury, but in all recurrent cases in people who had to lead active lives, especially when their occupation led them into positions of danger. Age was not a contraindication. He also pointed out that tuberculosis and rheumatoid arthritis occurred in certain cases not operated upon. He then outlined the technique of the operation, and insisted on the importance of asepsis and gentleness of manipulation. Successful cases might be allowed to walk in fourteen or fifteen days after operation.

Another injury which might occur was rupture of one or both crucial ligaments and fracture of the tibial spine. These injuries could usually be treated by rest in full extension, though subsequent operation might be necessary.

Mr. A. H. TUBBY, in opening the discussion, said the great factor in producing the displacement of the semilunar cartilage was undue lateral strain on the joint, and often occurred in patients suffering from genu valgus and contraction of the tendo Achillis. The treatment in early cases was the reduction of the displacement under an anaesthetic and immobilization in plaster-of-Paris for from three to six weeks, after which limited flexion and extension might be permitted on suitable apparatus. The amount of the early effusion after the accident was a guide to the nature of the injury. Walking should not be permitted as long as pain was present. Operation was necessary in those who could not afford the time or apparatus necessary and in those who were compelled to lead active lives. As to the operation itself, asepsis was extremely important, the patient's own skin being a special danger.

Mr. ROBERT MILNE described the various types of injury of the cartilage, and pointed out that if there was a history at the time of accident of a rapid effusion into the joint and great pain, this could not be due to a torn cartilage alone, but was due to strain or rupture of the internal, lateral, and crucial ligaments, which were subjected to great tension when the cartilage became nipped between the articular surfaces and caused locking of the joint. He showed slides illustrative of certain derangements of the knee-joint, and pointed out that foreign bodies in the joint might become calcareous and grow, owing to the deposition of calcium salts from the synovial fluid.

Transplantation of Ovaries.

Professor TUFFIER (Paris) read a paper on this subject. The grafting of ovaries from one patient into another was difficult, but might become successful with the improvement of technique, and possibly some chemical substance might be found to protect the implanted ovary from the action of the phagocytes. He described the procedure of grafting the patient's own ovaries into the subperitoneal fatty tissue, the uterus being left *in situ*. The graft could be made in the neighbourhood of the uterus or elsewhere. The method of doing this was as follows: The abdomen was opened, adhesions broken down; the ovary, tubes, and glands were isolated; the ovary was then dissected out and embedded in a pouch formed in the subperitoneal fat. The Fallopian tubes were then removed. Complete haemostasis was important and asepsis was absolutely necessary, otherwise the grafts became cystic or sclerosed. If necessary, the gland could be divided into two parts and each portion engrafted. The implanted ovaries remained inactive for about three or four months after operation and symptoms of climacteric commenced, then for four or five days the ovary became painful and menstruation recommenced. There was usually a period of six months between the operation and the establishment of menstruation. He spoke in high terms of the success of the operation, and mentioned that the fatty tissue of the abdominal wall was not a good site for the graft, owing to the pain, tenderness, and swelling at each menstrual period. He exhibited slides showing that the grafts were healthy and contained active ovarian tissue of good vitality three years after operation. As the result of his observations he advanced an interesting theory of menstruation; he thought that each month there was a gradual accumulation of a chemical substance in the blood, and that when this reached a certain concentration it acted on the ovary and started the menstrual flow and the excretion of the substance. If it was allowed to accumulate menopause set in. As a proof of this he had caused menstruation to occur in a patient by injecting the serum taken from another woman the day before menstruation began.

Operations for Cancer of the Larynx.

On Tuesday, July 28th, Professor E. SCHMIEGELOW of Copenhagen read a paper on "The results of operations (laryngo-fissure) for cancer of the larynx." He gave statistics showing the excellent results which could be obtained by operative measures when cancer attacked the vocal cords. The reason those results were not more frequently obtained was entirely due to the fact that the cases were not diagnosed early enough—hoarseness, the all-important clue, being allowed to continue without an expert examination of the vocal cords being made until it was too late to operate. In the majority of the cases in the tables given by Professor Schmiegelow the disease was situated in the centre of one or other vocal cord. In the extrinsic, as distinct from the intrinsic, cases of cancer of the larynx, the growth was more soft and the glands were more readily infiltrated. He warmly recommended the operation of splitting the larynx, commonly known as laryngo-fissure. Professor Schmiegelow briefly outlined his procedure. He preferred a general anaesthetic of ether with morphine. A low tracheotomy was performed and the thyroid cartilage was then split. The part was formerly packed from below to keep the saliva away. He had given up the tamponading which he originally practised and closed the wound at the time of the operation. The patient could feed early, and perhaps on the same day, and leave his bed on the second day. He was in favour of removing the tracheotomy tube before the patient left the table. One patient he had operated upon fourteen years ago was not only alive and well, but since the operation had travelled as far as the North Pole.

The paper was discussed by Sir STCLAIR THOMSON, who made an appeal for expert examination of the vocal cord in any case of hoarseness which did not clear up within three weeks.

On July 29th, at King's College Hospital in the throat department, Sir STCLAIR THOMSON exhibited the following cases of laryngo-fissure for intrinsic carcinoma of the larynx:

DEMONSTRATION OF CASES.

CASE I. *Epithelioma of Larynx: Laryngo-fissure: Recurrence: Complete Laryngectomy. No Recurrence after Five Years.*—Male, aged 45. February 25th, 1909: Epithelioma of right vocal cord, which was mobile. No glands. Laryngo-fissure under chloroform anaesthesia. No Hahn's tube employed, and no tracheotomy tube left in. November, 1909: Recurrence; removal of entire larynx, with first two rings of trachea. No recurrence after a lapse of nearly five years. Patient breathes through the mouth and has a fair voice by means of a modification of von Bruns's artificial larynx. He can lift quite heavy weights, sleeps well, has a good appetite, smokes 2 oz. of tobacco a week, and thinks nothing of cycling 10 miles. (Case published *in extenso* in the BRITISH MEDICAL JOURNAL, February 17th, 1912.)

CASE II. Male, aged 63. Intrinsic cancer of the larynx; laryngo-fissure. No recurrence four years after operation.

CASE III. *Intrinsic Cancer of the Larynx: Laryngo-fissure. No Recurrence after One Year and Eight Months.*—Female, aged 55; had been hoarse for eight months. Right vocal cord replaced by reddish cauliflower growth. Large portion removed by indirect method for microscopic examination and found to be epithelioma. November 28th, 1912: Laryngo-fissure under intravenous infusion of ether and hedonal. No Hahn's tube. No tracheotomy tube left in. The removed tissue was found to be free of any sign of epithelioma. Evidently the growth had been entirely removed by the mouth.

CASE IV. *Intrinsic Cancer of Larynx: Laryngo-fissure. No Recurrence after Nine Months.*—Male, aged 58. Had had increasing hoarseness for twelve months, with pain in the right ear, before October 17th, 1913. Posterior three-quarters of the right vocal cord was replaced by a cupped and granular infiltration. Cords moved well. No glands. Wassermann reaction negative. No tubercle bacilli in sputum. A portion of growth removed through the mouth displayed features of an undoubted squamous-celled carcinoma. November 10th, 1913: Laryngo-fissure under chloroform anaesthesia. No Hahn's tube, and tracheotomy tube not left in. The removed growth showed a typical squamous-celled epithelioma. Patient sitting out of bed next day and swallowing with ease. Went home ten days after operation. This patient's voice was remarkably loud and strong. As nine months had elapsed and the larynx was soundly healed, experience warranted the assertion that there was now no fear of recurrence.

CASE V. *Intrinsic Cancer of Larynx: Laryngo-fissure. No Recurrence after Eight Months.*—Male, aged 44. Had been hoarse for nearly six months before he was seen in November last. Epithelioma of left vocal cord, confirmed by microscopic examination of portion removed through the mouth. December 1st, 1913: Laryngo-fissure under chloroform anaesthesia. No Hahn's tube employed, and no tracheotomy tube left in. Patient out of bed and eating solid food in twenty-four hours. He has a good strong voice.

CASE VI. *Intrinsic Cancer of the Larynx: Laryngo-fissure. Shown Two Months after Operation.*—Male, aged 52. Had been hoarse for five months before being seen on May 12th, 1914. All the right vocal cord was occupied by a knobby, irregular growth with white spots on it like coagulated milk. The movement of the cord was almost abolished. May 20th, 1914: Laryngo-fissure under chloroform anaesthesia. No Hahn's tube. Growth found to extend back to and include the vocal process and also to the subglottic region. It had likewise invaded the ventricle of Morgagni. As the patient was very

congested and embarrassed with catarrh the tracheotomy tube was left in for three days.

CASE VII. *Intrinsic Epithelioma of Larynx; Laryngo-fissure. Shown Five Weeks after Operation.*—Male, aged 58. Voice never clear, so difficult to say how long he had been husky. Right vocal cord quite immobile and converted into a pink growth of a rough surface. June 22nd, 1914: Laryngo-fissure under chloroform anaesthesia. No Hahn's tube. Tracheotomy tube left for three days. Patient sitting out of bed and eating solid food within twenty-four hours, and went home within a week from operation. Growth extended into subglottic region. Proved to be epithelioma.

Intranasal Surgery of Lacrymal Apparatus.

Dr. J. M. WEST of Berlin followed with a paper entitled, "The intranasal surgery of the lacrymal apparatus after an experience of over 225 operations." He stated that dacryocystitis occasioned blindness more frequently than any other form of sinus disease. He then gave in detail the features of his operation, drawing attention to the points in which it differed from other operations for the relief of obstruction, inflammation and disease of the tear passages. In his operation he spared the inferior turbinate body inasmuch as it had an important physiological function. He dealt with the tear sac alone and did not further interfere with the nasal duct, the principle of the operation being that underlying the method of opening any abscess. He removed the lower half of the diseased sac, which amounted to opening the abscess at its lowest point.

Dr. D. R. PATERSON of Cardiff discussed the paper. He dealt with the question when the operation might be done and might be left alone, and drew attention to the fact that Nature sometimes assisted and brought about the same result that was obtained by art. He quite agreed that in suitable cases excellent results could be obtained.

Congenital Atresia of the Post-Nasal Orifice.

Dr. CHARLES W. RICHARDSON (Washington) read a paper on this subject, which was discussed by Dr. DUNDAS GRANT, of London.

EPSOM COLLEGE.

MORE than usual interest was taken in the celebration of Founder's Day at Epsom College on Saturday, July 25th, as it is the last time on which the present Head Master, the Rev. T. N. H. SMITH-PEARSE, will preside, after being in office for twenty-five years. In recognition of the services thus rendered, the President of the College, Lord Rosebery, kindly attended and gave away the chief prizes for the year. Among those present were the Treasurer (Sir Henry Morris), the Chairman of the Council (Sir William S. Church), and Sir John Broadbent, Mr. Stanley Boyd, Dr. F. de Havilland Hall, Dr. Guthrie Rankin, Dr. Septimus Sunderland, Dr. Frederick Taylor, Dr. W. Essex Wynter, and other members of Council.

In his valedictory address the HEAD MASTER reviewed the progress of the College since his appointment, referring to the increase in the number of boys, the scholarships to Oxford, Cambridge, and the London hospitals, which had been won, and the extension and improvement of the College buildings. He expressed his appreciation of the support which had always been given to him by the Council of the College; he referred in warm terms to the help freely rendered to him by the staff and by other officials at the College; and dwelt on the fact that a deep debt of gratitude was owing to his wife.

After a recital of the prizes, scholarships, and honours won direct from the school since last Founder's Day, the chief prizes were distributed by Lord ROSEBERY, who afterwards delivered an address on the "Formation of character." He observed that any boy who found after leaving school that he had taken from it no serious result of his studies would decide that he had made a mighty bad bargain of his time, and would find good cause to have remorse for his life. The years spent in school were far more important in the formation of character than all the years spent afterwards. The school moments decided whether the boys were going to be men in the highest sense of the word, or whether they were going to pass through life as atoms. There was only one way by which the character of a man at its best showed itself, and that was by his manners. Of course this was not an infallible way, as he had known many excellent people who from shyness had the most execrable manners, and he had also known scoundrels with the most charming and fascinating manners, given to them for much the same reason as the web was given to the spider. But those were not the manners he referred to; he meant those simple, manly manners which were the index of a straightforward character. They should make their manners worthy of their character, and their character worthy of their manners; the two processes went hand in hand. He did not know of any profession in which manners were of so much importance as in the noble profession of medicine. Those who had been attended by a doctor must have realized the difference between the one who came in with a gloomy and austere expression, with bills of mortality condensed in his countenance—enough to take the heart out of the most courageous patient—and the doctor who instinctively seemed to spread a sunny atmosphere through the room the moment he opened the door, giving the patient a feeling of hope and encouragement. If the first doctor was the best in the world and the second was only third-rate, he would a thousand times rather have the third-rate doctor with his genial manners, except, perhaps, for an occasional consultation.

At the close of his speech a cordial vote of thanks to Lord Rosebery was proposed by Sir HENRY MORRIS, who laid special emphasis upon the interest taken in the College by Lord Rosebery as a near neighbour. This was seconded by Sir WILLIAM CHURCH and carried by acclamation.

After the proceedings in the schoolroom refreshments were served to a very large number of visitors in the College grounds; the Officers' Training Corps paraded in the course of the afternoon, and a gymnastic display was given by the school.

ROYAL COMMISSION ON VENEREAL DISEASES.

THE following is the official report issued to the press by the Secretary of the Commission:

Venereal Disease in Working Men.

Sir John Collie at the forty-eighth meeting of the Commission gave the results of some observations he had recently made in connexion with 2,176 men referred to him for medical report. The 2,176 men were divided into three classes: (1) 1,119 whom accident or illness had overtaken; (2) 557 apparently healthy, but required to pass medical examination before entering employment; (3) 500 of the same class as the second division, but who also submitted themselves to the Wassermann test. Of all three divisions 106 were found to be suffering from venereal disease. In the first two divisions in connexion with which clinical evidence was relied upon, 60, or 3.8 per cent., were found to be infected; in the third class, where the Wassermann test was applied, 46, or 9.2 per cent., were shown to have had syphilis.

The 500 cases of those apparently in perfect health (as evidenced by a thorough physical examination) were taken consecutively as they presented themselves for examination, and no selection was made, except that working-class people over 21 years of age only were chosen; 103 of the 530 had served in the army or navy, and of these 24, or 18.9 per cent., gave a positive Wassermann reaction; the percentage of positive reactions in the remainder of the 500 was only 6.

Sir John Collie stated that the figures probably did not represent the full extent of the existence of the disease, for the men examined were of a somewhat superior artisan class.

An interesting feature of the investigation was the fact that the Wassermann test showed a positive reaction in as many as twelve, sixteen, and nineteen years, and in one case as late as twenty-nine years after infection, and long after all recollection of the infection had disappeared.

Syphilis and Gonorrhoea in the Female.

Mr. Frederick McCann, Surgeon to the Samaritan Free Hospital for Women, said that it was of the utmost importance that syphilis and gonorrhoea should be regarded as common female ailments, for which the same facilities for treatment should be available as for other female ailments without any special stigma being attached to

them. If proper facilities for in-patient and out-patient treatment were provided, the special aspects of these diseases would to a large extent disappear.

Systematic instruction in the early local signs of syphilis and the signs and symptoms of gonorrhoea was much required; this instruction should be given at the special hospitals for women and in the gynaecological departments of the general hospitals.

It was essential that gonorrhoea should be regarded as a serious disease in both sexes, especially in women, and that prompt and effectual treatment was required. The medical profession could do much in this respect by impressing upon patients the gravity of the disease and the necessity for curative treatment.

Venereal Disease in Glasgow.

Dr. Chalmers, Medical Officer of Health for Glasgow, gave supplementary evidence with reference to the experience of the Health Committee of the Corporation of Glasgow. He stated that ophthalmia neonatorum was made compulsorily notifiable in Glasgow in 1911, and that in the beginning an attempt was made to supervise the cases at the homes. It was, however, soon apparent that there was definite need for provision being made for hospital treatment. Arrangements had accordingly been made for this treatment, and it had been necessary in some cases to provide also for the reception into hospital of the mother.

Their experience had shown that a proportion of children affected with ophthalmia neonatorum also suffered from congenital syphilis, and that the resultant defects in vision were greatest when the diseases were concurrent. In the period ending December, 1913, of 463 children suffering from ophthalmia neonatorum, 13.6 per cent. were found also to be syphilitic.

With regard to syphilis generally, the Corporation of Glasgow had made arrangements for placing opportunities of obtaining a Wassermann test at the disposal of any practitioners who desired it; and in view of the information required with any specimen sent for examination, it had been arranged to pay a fee of 2s. 6d.

Between September, 1913, and June 25th last 953 equipments for the purpose of obtaining a Wassermann test had been issued to practitioners by the Corporation.

Dr. Chalmers was of opinion that no form of compulsory notification of venereal disease, whether for any group of persons or of cases, would effect its object. His view was that the public required not compulsion but education; and he thought that the issue of an authoritative statement showing the danger to life in after-years of syphilis contracted at an earlier period, and of the disastrous effect on children, would help to form an educated public opinion, which would at least induce those who might contract the disease to seek effective treatment, even if it failed in the ultimate purpose of inducing them to avoid exposure to it.

The main problem at the present time was the organization of means of diagnosis and treatment.

LITERARY NOTES.

The *Journal of Parasitology* is the title of a new American publication devoted to medical zoology which will be issued quarterly from the press of the American Medical Association. It is intended to be a medium for the prompt publication of research notes on animal parasites. The editorial board consists of Franklin D. Barker, University of Nebraska; Charles F. Craig, Medical Corps, U.S. Army; William B. Herms, University of California; Brayton H. Ransom, U.S. Bureau of Animal Industry; William A. Riley, Cornell University; Allen J. Smith, University of Pennsylvania; John W. Scott, University of Wyoming; Charles W. Stiles, U.S. Public Health Service; Richard P. Strong, Harvard University; John L. Todd, McGill University; Robert T. Young, University of North Dakota. The managing editor is Dr. Henry B. Ward, University of Illinois.

The *Hamburgische medizinische Ueberseehefte* is the title of a new periodical published under the editorship of Professor Brauer, Director of the Eppendorf Hospital at Hamburg, and Dr. C. Hegler of the same institution. Among the collaborators are Professor Albers-Schonberg of Hamburg, Excellenz Professor Behring of Marburg, Excellenz Professor Ehrlich of Frankfort, Dr. Simon Flexner of New York, Professor Alb. Plehn of Berlin, and Professor Unna of Hamburg. Its special purpose is to keep German doctors in foreign countries in close touch with the work that is being done at home. The first number contains a paper by Professor Behring on disposition and diathesis.

The *Pan-American Surgical and Medical Journal*, the first number of which appeared on June 27th, is the official organ of the Louisiana State Medical Society. The editors-in-chief are Drs. Waldemar T. Richards and Adolph O. Hoefeld. For the benefit of Central American readers a part of the new periodical will be printed in Spanish.

While Sir James McGrigor was deputy inspector of the Northern District there was an outbreak of typhus among the Royal Dragoons quartered at York. It struck him that convalescents were discharged too soon to barracks, and he therefore decided to see every man in the hospital before he was discharged. On one occasion when inspecting the men whom it was proposed to discharge he noted one of them who appeared to him to be very ill. No symptoms of fever, however, could be discovered, and it was found that the man had been in hospital recovering from a flogging. On examining the back it was seen to be perfectly healed. Nevertheless McGrigor directed that he should be kept under observation till the next inspection. Before the time for that had arrived McGrigor says he learnt that the Radicals in York had excited a great commotion there because a man who had been flogged had died, and that they had insisted on the exhumation of the body and vowed vengeance against the commanding officer and the surgeon. On arriving at York McGrigor found that a coroner's inquest was sitting in the hospital barracks on the very man whom he had regarded with suspicion. It proved that on the evening of the day when McGrigor had examined him the symptoms of typhus, which was doubtless incubating at the time, showed themselves, and the disease rapidly proved fatal. McGrigor found the jury taking evidence when he hastily made his appearance before them. The rest of the story may be told in his own words:

> After announcing myself, my office, and rank, I offered myself for their examination; their answer was, "You are one of the party concerned; you want to get the doctor and colonel off, but they shall go to the castle." On examining the face of the corpse, and the largely sloughing ulcerated state of the loins and sacrum, I in vain assured them that the appearances were those common in fatal cases of low fever; that punishment was never inflicted in that quarter, and that I myself could swear to the man's being perfectly cured of his punishment before he was seized with the prevailing fever. But all would not do. Several vociferated, "You are a party concerned; you are not a proper witness; we will not take your testimony." In this state of affairs I was quite at a loss what to do. I learned that the members of this inquest were determined to bring in a charge of murder against Colonel De Grey and Dr. Irwin, and to commit them to the castle of York. I rode to Colonel De Grey's lodgings in York, where I found him and his wife in the utmost agony at the proceedings, he wringing his hands and pacing the apartment in agitation. On leaving, quite at a loss what to do, I fortunately met Mr. Atkinson, the celebrated surgeon of York, in his carriage. I related the circumstances to him, and he hastily took me into his carriage, and drove to the barracks. I could have found no individual in York so fit and so able as my friend Atkinson to extricate us all from this terrible dilemma. He was a hearty, honest fellow, with much blandness of manner, of unbounded kindness and humanity, held in great estimation for his professional talents, very hospitable, and of very liberal principles—a feature in his character which made him regarded by the Radical party of York as one of their chief men. I shall never forget his entry into the room where the inquest was sitting. They all stood up on his appearance, and he forthwith began to rate one and all of them in set terms: "You rascals! do you know what you are doing? You a jury! pretending to investigate the cause of the poor man's death, and refuse the evidence of the only competent witness that you could have! You deserve, every one of you, to be sent to the castle." Then, addressing a humble looking person there, whom they had been examining, and who proved to be a little druggist in York, he continued: "And you, you rascal! What know you of wounds and punishments? Go back to your counter." Upon inquiry, we found that the druggist, upon looking at the sloughing ulcer on the sacrum, had deposed that to be the evident cause of death, and that the man had died of excessive punishment. Mr. Atkinson desired them instantly to go on with my examination, which they did in the most respectful manner, while he stood by, and my detail clearly exonerated the colonel and the doctor. On my calling some time after this upon Colonel De Grey, he told me with horror that two of the jurymen had called on him for something to drink his health upon his escape from being lodged in York Castle!

ROYAL MEDICAL BENEVOLENT FUND.

AT the last meeting of the committee twenty cases were considered, and grants amounting to £208 voted to the applicants. The following is a summary of the cases relieved:

Widow, aged 65, of M.D.Dubl., who practised in India, Ireland, and London, has endeavoured for twenty-four years to earn a living by keeping a boarding house, but has never really made a profit or been able to save. One daughter, who helps at home. Voted £10.

Daughter, aged 44 years, of M.D.Heidelb. and F.R.C.S.Eng., who practised in London, impossible to do any regular work in consequence of ill health. Earns a little occasionally by painting. Voted £12 in twelve instalments.

Widow, aged 62 years, of M.R.C.S.Eng., who practised at Burnley and Caister; since husband's death has acted as house-keeper to her brother, a clergyman, who has just died, and is now without home or means. Voted £10 in two instalments.

Daughters, aged 49 and 52, of M.R.C.S.Eng., who practised at Kingscliffe; only income about £25 each, and until recently this had been supplemented by occasional work as governesses, but for the last few months unable to obtain employment. Voted £5 each.

Daughter, aged 51 years, of M.R.C.S.Eng., who practised in London. Only a very small annuity and health very indifferent. Voted £5.

Daughter, aged 57, of M.R.C.S.Eng., who practised in Norfolk. Guardian spent all capital, and only income £13 per annum given by relative. Health bad. Relieved six times, £30. Voted £5.

Widow, aged 52, of L.R.C.P.Lond., who practised in London. Endeavours to earn living by letting rooms, but has not been very successful recently. Wants a little help for repairs to house. Relieved once, £12. Voted £10.

Daughter, aged 33, of M.D.Dubl., who practised at British Guiana and Middlesex, is suffering from her glands and her teeth require attention, consequently too ill to work. Relieved eight times, £80. Voted £10.

Daughter, aged 75, of M.R.C.S.Eng., who practised at Doncaster. Too old to work and only income old age pension. Relieved twice, £30. Voted £18 in twelve instalments.

Daughter, aged 67, of M.R.C.S.Eng., who practised at Rendcomb. Health very indifferent and quite unable to work. Relieved twelve times, £178. Voted £18 in twelve instalments.

Widow, aged 48, of M.R.C.S.Eng., who practised at Hexham and London. Endeavours along with her daughter to earn a living by taking in boarders, but not successfully. Stepson helps a little. Relieved five times, £60. Voted £12 in twelve instalments.

Widow, aged 65, of M.D.Glas., who practised at Dennistonn. Has a small pension from the Elder Fund, and son pays rent of house. Takes in boarders in the summer but does not get sufficient to make it pay. Relieved six times, £54. Voted £12 in twelve instalments.

Daughter, aged 58, of L.R.P.C.Edin., who practised in North London. Health very bad and unable to work. Recently received a pension of £40 from the Mercers Company. Relieved eight times, £83. Voted £5.

Daughters, aged 42 and 50, of L.S.A.Lond., who practised at Sydenham and Plumstead. The elder suffers from migraine and the younger is an epileptic, both unable to work. Recently lost mother who had a small pension. Joint income only £45 per annum. Relieved eight times, £83. Voted jointly £18 in twelve instalments.

Widow, aged 64, of M.D.Edin., who belonged to the R.A.M.C. Suffering from cancer and has been operated upon. Small army pension, but sufficient to provide necessary nourishment. Relieved once, £6. Voted, £10.

Widow, aged 69, of M.R.C.S.Eng., who practised at East London, and who died last year, leaving her quite unprovided for. Health very bad. Five children, but none able to assist. Has a pension from the Fishmongers' Company of £30, and total income about £45. Relieved once, £12. Voted £12 in twelve instalments.

Widow, aged 64, of M.D. St. And., and M.R.C.S.Eng., who was engaged by the Stepney Union. Tries to earn a living by taking in lodgers, but cannot make enough to live on. Four children, none able to help. Relieved eleven times, £132. Voted £12 in twelve instalments.

Widow, aged 48, of L.R.C.P. and S.Edin., who practised at Stamford Hill. Suffering from cancer, and has been operated upon and quite unable to work. Has one daughter aged 17 years who earns a few shillings weekly. Has no income. Has been helped by the Guild. Relieved twice, £38. Voted £18 in twelve instalments.

A special emergency grant of £1 was also made to an urgent case.

Contributions may be sent to the Honorary Treasurer, Dr. Samuel West, 11, Chandos Street, Cavendish Square, London, W.

THE first international congress for the investigation of questions relating to sex will be held at Berlin on October 31st, November 1st, 2nd, 3rd and 4th. Almost all civilized countries will be represented and more than one hundred communications have been already promised. For information relative to the congress application should be made to Sanitätsrat Dr. Moll, Kurfürstendamm, 45, Berlin.

EIGHTY-SECOND ANNUAL MEETING
OF THE
British Medical Association.

THE SECTIONS.

BRIEF SUMMARY OF PROCEEDINGS.

THE nature and scope of the work of the different Sections will appear from the following short summary of the proceedings. A full report of the discussions and of the various papers read in the Sections will be published in due course.

Wednesday, July 29th, 1914.

SECTION OF ANATOMY AND PHYSIOLOGY.

BEFORE the proceedings commenced Dr. Calder, as local secretary, read a letter from the President, Professor Reid, regretting and explaining his absence, and welcoming the members to Aberdeen. On the motion of Professor J. Kay Jamieson, Professor MacWilliam was unanimously voted to the chair. Dr. Robertson (Glasgow) opened the scientific proceedings by reading a paper on the phylogenetic development of the bulbar and ventricular septa of the heart, in which she described and compared the conditions obtaining in elasmobranch, dipnoan, reptilian, and mammalian hearts. She pointed out that these septa appeared in association with the development of a pulmonary system of respiration and circulation and the consequent need for the separation of the oxygenated and non-oxygenated blood streams. She next described two cases of cardiac malformations in which the great efferent vessels both arose from the right ventricle, due to the interventricular septum being placed on the left of the vessels, a condition which the author believed was secondary to a dilatation of the right auricle and a consequent excessive torsion of the heart. Dr. Ivy McKenzie (Glasgow) read a paper on the reptilian heart and its significance in the interpretation of the co-ordinating muscular systems in the mammalian, in which he described the development of the sinu-auricular and auriculo-ventricular nodes and bundles from their corresponding rings in the lowest vertebrates in association with the processes whereby (1) the auricles became divided by a septum and (2) the sinus became gradually enveloped by the expanding auricle. He showed that in the phylogenetic development of the heart the original sinu-auricular ring became divided into the sinu-auricular node and the auriculo-ventricular node. Dr. McKenzie also contributed the results of further researches on the anatomy of the bird's heart, and stated that there was no structure in the bird's heart resembling the bundle of His. The sinu-auricular bundle could, however, be displayed with the utmost ease in the hearts of certain birds—for example, the guillemot—but it was to be looked for at the junction of the inferior vena cava with the right auricle. Dr. Thomas Lewis (London), in discussing these papers, thought a sharper distinction should be drawn between the auriculo-ventricular and sinu-auricular nodes than what Dr. McKenzie was willing to allow, and pointed out that whereas stimulation of either vagus affected the former equally, stimulation of the right vagus had a much more powerful effect on the latter than had stimulation of the left vagus. Professor MacWilliam (Aberdeen) read a paper on cardiac fibrillation and its relation to the action of chloroform. He regarded cardiac fibrillation as the most common cause of death in chloroform administration, and as being dependent on irregular or intermittent administration. His observations had been chiefly made on the cat, an animal peculiarly prone to such forms of cardiac failure. Dr. Goodman Levy (London) read a paper on ventricular fibrillation, the cause of death under chloroform, in which he confirmed Professor MacWilliam's conclusions, but laid greatest emphasis on the importance of giving sufficient of the anaesthetic. He considered that most deaths under chloroform were due to the anaesthesia being too light. Drs. Melvin and Murray (Aberdeen) gave the results of some observations on blood pressure, in which they

attached great importance to the estimation of the diastolic pressure. The diastolic index was given as the beginning of the fourth phase, and attention was directed to the frequently prolonged duration of that phase in normal young adults. Dr. Strickland Goodall, F.R.S.Edin. (London), gave an account, in a paper on some instrumental variations in the human electro-cardiogram, of certain very carefully recorded electro-cardiograms taken on normal adults to show how the tracings varied according to the position of the subject, the kind of electrode used, the speed of the motor, and the size of the slot. Mrs. Tribe, B.Sc. (London), described a number of experiments performed for the purpose of demonstrating the existence of vasomotor nerves in the lungs. The method of investigation employed was that of perfusing the lungs with defibrinated blood, and recording the outflow from the pulmonary veins before and after the injection of adrenalin.

Section of Dermatology and Syphilology.

The President, Dr. Alfred Eddowes, opened the proceedings in a short speech in which, after returning thanks for the honour conferred upon him, he expressed the sympathy of the Section with their Honorary Secretary, Dr. Christie, who was only now convalescent from a severe illness. He announced that the discussion on syphilis would be held jointly with the Section for Naval and Military Medicine and Surgery. Dr. Norman Walker, Dermatologist to the Royal Infirmary, Edinburgh, opened a discussion on the need for more method in the treatments of lupus and ringworm. He said that during twenty-two and a half years' service at the Royal Infirmary he had had 1,054 cases of lupus and he wished he could think that 100 had been cured. The usual custom of the patients was to attend a few times and then disappear for an indefinite period. Girls would seek treatment for cosmetic reasons for perhaps a few weeks previous to marriage. In private, on the other hand, the cases, not so numerous relatively to other cases as in hospital—1 in 80 as against 1 in 30—attended for treatment more persistently, and in consequence with far better results. The difference between the two classes of case depended on the fact that the poorer classes experienced no discomfort from the disease, while those better educated understood more fully its nature, and were more sensitive to the disfigurements caused. As regards the methods of treatment he employed, Dr. Walker expressed himself as in favour of scraping when combined with other methods, especially after treatment with uranium nitrate, which was both caustic and radio-active. *X* rays, he considered, gave good results, but were to be avoided, owing to the liability of the patients to contract epithelioma. He had almost abandoned the Finsen lamp for the Kromayer. Tuberculin as a 5 per cent. ointment deserved greater consideration than it had received. Its use lay largely in relieving contractions. Turning to ringworm and favus, Dr. Walker said he had experience of 3,426 and 482 cases respectively. The favus had increased very rapidly when notification and *x*-ray treatment were first instituted, but had now greatly diminished. The ringworm cases had increased greatly in numbers since 1902, when they were only 100, and were now, when systematic *x* ray treatment had just begun, at their height. Dr. Norman Walker expected that the numbers would now follow the course taken by the favus cases. Finally, he called attention to the recent regulation of the Local Government Board ordering the notification of lupus, and said that this placed a great and powerful additional weapon in the hands of the medical profession. He advocated the notification of all cases for their own sake in order that they might be followed up and efficiently treated, not because they were a public danger. In fact, he did not consider them to be such. The President spoke in favour of surgical measures in early cases, especially excision. He also advocated yellow oxide of mercury as of value in releasing contractions. Dr. Goodwin Tomkinson advocated the use of small doses of *x* rays in conjunction with salicylic acid plaster and mild cauterization. He deprecated scraping and extolled heliotherapy. Dr. Haldin Davis dwelt on the value of excising all early patches of lupus and the importance of early diagnosis. He also recommended special schools for children suffering from ringworm. Dr. Winkelried Williams said that patients suffering from lupus should avoid alcohol and be treated locally with permanganate of potash. Dr. Bolam thought that lupus was emphatically a disease of the poor. He advocated sanatorium treatment. Dr. Milne advocated scraping for lupus and croton oil for ringworm. Dr. MacCormac referred to the hot-air treatment employed by Ravaut of Paris. He also advocated the surgical treatment of dry forms of lupus, especially in early cases. Dr. Norman Walker replied. Dr. Green and Dr. Meachen also spoke.

Section of Diseases of Children including Orthopaedics.

After the opening of the meeting by the President, Dr. John Thomson (Edinburgh), Mr. T. H. Openshaw (London) introduced a discussion on congenital dislocation of the hip. He favoured the view that the condition was due to abnormal intrauterine pressure. Treatment, he said, should be commenced as soon as possible after the diagnosis had been made. Results varied directly with the age of the patient. The older the child, the more deformity and the less good the result. For patients under 5, the head of the femur should be put into position under an anaesthetic. For those over 5, a preliminary tenotomy of the restraining muscles was necessary. He did not think it ever possible to replace the head directly into the acetabular cavity, but by its retention at the acetabular site it subsequently attained its correct position, if kept in contact with the acetabulum for a sufficiently long time—about six months. He expressed himself as greatly satisfied with the results of Lorenz's method, and thought that the bad results and failures were chiefly due to the post-operative position being continued for too short a period. For a certain group of cases an open operation was required. Into this group fell those for which Lorenz's method had failed, those over 12 years of age, and those with a great degree of external rotation. He thought that, as the condition became better known, and cases were recommended for treatment earlier, the proportion of cases not treated by Lorenz's method would be very small. Dr. Laming Evans spoke of the value of radiograms in this connexion. He recounted the differences to be found in affected joints from those in the normal, emphasizing especially the shape and position of the acetabulum and its boundaries, and exhibited a series of skiagrams demonstrating the changes which occurred with re-formation of the acetabular cavity. He agreed with Mr. Openshaw as to the importance of operation as early as possible. Mr. John Fraser said that untreated cases did not usually survive longer than 40 to 45 years of age. It was commoner in some countries than others. In France it occurred unusually frequently, and that had been ascribed to the extension of the legs of the baby after birth and their retention in that position by bandage, a customary procedure by the midwives in that country. Mr. Alexander MacLennan (Glasgow) thought more than three months was necessary for moulding to take place. It was very uncommon to diagnose cases younger than 18 months, and the usual tests proved fallacious. Reliance had to be placed on *x* rays. He did not agree that intrauterine pressure was the cause. Mr. Andrew Fullerton (Belfast) related an instance of dislocation occurring in one hip some time after dislocation of the other hip in the same child. Dr. Simpson expressed the view that the deformity was primarily one of the head of the femur, and that the dislocation was secondary. He raised the question as to the connexion between anterior dislocations of the hip and the commoner ones. He also agreed that the case should be treated early and thought that the prognosis was favourable up to the age of 8. Mr. Paul B. Roth thought treatment should begin as soon as the child could walk. Dr. E. Henderson (Westmorland), among 11,833 school children, had found 15 cases of congenital dislocation of the hip. Mr. B. Bankart (London) spoke of his own method of treatment. He emphasized the importance of internal rotation for the second position of fixation, of avoidance of preliminary traumatism of muscles, and of putting up both hips in the Lorenz position when one side was affected. Mr. T. H. Openshaw having replied, Mr. Paul B. Roth read a paper on the treatment of torticollis, in which he advocated the subcutaneous method of

division. The evidences of the ill effects of this method were very slight. He did not regard it as a serious or dangerous operation, as he did the open method. He thought that retentive measures were quite unnecessary. He also contributed a paper on the practical treatment of lateral curvature of the spine, which was discussed by Mr. A. MacLennan (Glasgow), Mr. F. H. Allfrey (Southwick), and Mr. John Fraser (Edinburgh).

SECTION OF ELECTRO-THERAPEUTICS AND RADIOLOGY.

OF the two specialities covered by the title of the Section, the former, that of electro-therapeutics, occupied the entire field on the first day of meeting. The President (Dr. Samuel Sloan) opened the proceedings by introducing a distinguished visitor from abroad, Professor Stéphane Leduc, of Nantes, through whose experimental research, Dr. Sloan said, the ionic treatment of disease had now become an established practice. Professor Leduc devoted his address to a subject which he has made peculiarly his own, namely, the galvanization of the brain. He regarded it as surprising that diseases of the brain were those for which electricity was least employed. For a long time the brain was considered inaccessible, or nearly so, to electrical currents, whereas it was the fact that the brain was quite exposed to such action, as it was not protected by the superposition of conducting tissues, such as a muscular layer, which would divert the current. Professor Leduc laid down some rules for the utilization of the continuous current upon the cerebral region, and said that the current had proved useful in all the changes of cerebral nutrition for which he had applied it. After this introductory address the proceedings resolved themselves into a general discussion on the therapeutic value of high-frequency currents. Dr. Sloan urged that these currents, when used judiciously, had an influence upon the circulation, immediate and remote, penetrating also into the deeper tissues, and, moreover, influencing the brain, as was evidenced by the psychic effects involved. Dr. W. F. Somerville (Glasgow), speaking out of an experience of high-frequency extending over twelve years, said that his best results with these currents had been in cases of neuritis, for the most part affecting the branches of the cervical and brachial plexuses. Dr. E. P. Cumberbatch (London) discussed the surgical side of high-frequency treatment — namely, the diathermic effect of such currents, which was particularly valuable as a means of bringing about the destruction of diseased tissue and new growths. For his own part, he did not see why diathermy should not be applied to operable malignant growths, preparatory to surgical operation, so as to coagulate them and seal up their channels of spread. A number of speakers gave instances of high-frequency treatment within their own experience, and more than one expressed the view that for various conditions—such as enlarged glands, acne, and rodent ulcer—the use of x rays was more simple than diathermy, as well as more absolute and less dangerous. Dr. W. J. S. Bythell (Manchester) thought that as a section of medicine they ought to be very careful that they did not get a reputation for tinkering with a great number of different diseases by a great number of different methods. A further discussion on the subject of electricity in the treatment of neurasthenia was introduced by two papers, one by Dr. Agnes Savill and the other by Dr. W. F. Somerville Dr. Savill's paper was to some extent a philosophical treatise on neurasthenia, which she discussed in turn from the standpoint of two opposite camps —those who regarded the neurasthenic condition either solely or primarily as a disease of the mind, and therefore responsive only to psycho-therapeutic treatment, and those who regarded the nervous symptoms of neurasthenia as secondary to disordered physical processes, a condition responding best to physical methods of treatment. On reviewing all the cases she had seen, Dr. Savill came to the conclusion that when the neurasthenia had a psychic cause, and the source of the trouble was still existent, physical means of treatment could not cure. In the same way, psychic methods would fail in cases of toxic neurasthenia, even when the mind of the patient was at rest. Electricity would do more than most drugs, or than diet alone, but it could not perform miracles. Dr. Somerville also, while stating that he had not the slightest doubt as to the value of electro-therapeutics in general, and of high-frequency currents in particular, said that as the predisposing and immediate causes of neurasthenia were complex, and as the symptoms were complex also, it was foolish to regard any particular treatment as specific.

SECTION OF GYNAECOLOGY AND OBSTETRICS.

THE Section opened under the presidency of Dr. Haultain, who after briefly welcoming the members and visitors, at once called on Professor Archibald Donald (Manchester) to open a discussion on the treatment of fibromyomata. Dr. Donald practically confined his remarks to operative treatment and its results, but expressed the hope that the discussion would not be limited to the particular points on which he touched. He considered that expectant treatment should be given up in all cases causing symptoms, and that palliative measures, such as curetting, were never of service. Vaginal hysterectomy was not advised for fibroids. In regard to abdominal work, myomectomy was the operation of choice if it proved possible. Enucleation was useful also as a preliminary to hysterectomy, particularly in intraligamentary tumours. He preferred subtotal hysterectomy, but was not dogmatic on the point; he considered the risk of malignant disease in the cervical stump as illusory. The mortality in his last 309 cases (during the last four and a half years) was 2.9 per cent. As to his technique, he favoured removal of the tumour within clamps as a first step, followed by interrupted suture of the broad ligaments. He invariably removed both ovaries, as they were often degenerated and cystic or liable to become so. The most serious post-operative complication was thrombosis, but he had found that this yielded to the most scrupulous asepsis and to efficient "team" work in the conduct of the operation. Dr. Donald concluded with a strong protest against the use of x rays, basing his disfavour on the difficulties of diagnosis, the presence of complications, the impracticability of judging thus early of the results, and on the possibility that operation undertaken at a later date might be rendered more difficult. Professor Gauss (Freiburg) unfortunately was unable to be present, but his paper was read by the Secretary. Long series of cases of "fibroids and metropathy" were recorded showing the improving results as the technique of filters and crossed-fire was developed. In the last series of cases there had been neither deaths nor recurrences. The discussion which followed was notable for a general agreement with Dr. Donald, and more particularly for a disparagement of x rays. Professor Kynoch (Dundee) was alone in suggesting a "wait and see" policy as regards this treatment. Professor Murdoch Cameron (Glasgow) surprised many by his advocacy of bare-handed technique in operating; all others favoured rubber gloves, sleeves, and masks. Dr. Purslow (Birmingham) suggested that hysterectomy should be total in cases where the cervix was badly eroded—not from the point of view of possible malignancy but to arrest discharge. Many favoured resection of ovaries to their removal, but there was nothing said in favour of transplantation. Among those taking part were Drs. Hastings Tweedy, Nigel Stark, Beckwith Whitehouse, Professor Watson (Toronto), Sir John Byers, and the President. Professor Donald, in his brief reply, stated that removal of both ovaries was judged best not from theory but from practice.

SECTION OF LARYNGOLOGY, RHINOLOGY AND OTOLOGY.

THE excellent attendance at the opening of the Ear, Nose, and Throat Section showed the interest which the ordinary members were taking in the splendid programme provided by the authorities. It was also very pleasant to notice many prominent specialists from all parts of the kingdom. The opening was most convivial, and a happy, almost holiday-like spirit seemed to possess the members, and thus held out excellent prospects of valuable and instructive proceedings. The President first referred, with great regret, to the unfortunate clash with the Clinical Congress now in progress in London. Proceeding with his address he spoke of the great advances which had been made in this special branch during the past year, referring especially to suspension laryngoscopy, diathermy,

and intratracheal administration of ether—all of which had opened out huge fields for the scientific specialist. The only room for regret, in regard to these new methods, was the fact that none had emanated from British scientists. Mr. Harmer (London) then read his paper on diathermy in the treatment of inoperable growths of the nose and throat; he held out splendid prospects for this treatment, as also did Dr. William Hill (London), who stated that diathermy and radium would probably be found of great associative value. Dr. Hill, finding his subject too long for the time allotted him, finished by showing several *x*-ray pictures of stricture of the oesophagus on the screen. Dr. John Macintyre (Glasgow) then advanced the claims of *x* rays, stating definitely that some of these cases, though pathologically malignant, were not so clinically. The discussion was then started by the President, and continued by Dr. Watson-Williams, Mr. Somerville Hastings, Dr. Pegler, Dr. Syme, Mr. Livingstone, Mr. Faulder, and Mr. O'Malley. The openers having responded, the proceedings closed.

Section of Medical Sociology.

The responsibility of the State as regards venereal disease was the subject for discussion in the opening session of the Section of Medical Sociology on Wednesday, July 29th. The President, Dr. John Gordon of Aberdeen, in an opening address, spoke of the close relations which had grown up between the medical profession and the State since the introduction of the Poor Law in 1842, culminating in the passage of the National Insurance Act, 1911. On the practical experience of medical officers of health and practitioners social reform and new legislation dealing with health must be based. The recognition by the British Medical Association of medical sociology as a special department of medicine was evidence of a sincere altruistic spirit in the profession. Dr. A. K. Chalmers (Glasgow) opened the discussion on venereal disease. He described the efforts made in Glasgow—a little earlier than in other parts of the country—to grapple with the problem of treatment, and gave examples of the statistical results obtained to show how impossible it was at present to dogmatize as to the prevalence of venereal disease. Treatment should be free and national in character; on the Glasgow figures it would cost about 30s. for each adult. Professor E. Pontoppidan of Copenhagen described the public measures taken in Denmark, and summarized the experience there as showing (1) that the State regulation of prostitution had been a failure, (2) the State regulation of venereal diseases by compulsory measures had been a failure. The fight must be left to the medical army, with the least possible assistance from the penal code and the police. Dr. Louise McIlroy favoured a system of confidential notification of hospital returns remitted to the Royal Commission, which should be kept in being for several years. Treatment should be given in general hospitals in such a way that no stigma would attach to patients. Dr. Lachlan Grant claimed that by a readjustment of social conditions the prevention of prostitution was possible. Mr. T. Jenner Verrall urged the importance of the medical profession being sure of its ground before recommending to the public a definite line of policy. A mistake might put the question back 100 years. Dr. Helen Wilson discussed the difficulties of the relations between practitioners and patients in regard to sexual diseases. Sir John Collie said the question of confidential notification was under the serious consideration of the Royal Commission. He was averse from it because sufferers might resort to quacks rather than subject themselves to notification. If this occurred notification might tend to spread disease, owing to treatment at the early infectious stage being neglected. Dr. Clippingdale (London) contributed a historical note as to measures taken in Aberdeen for the treatment of syphilis in 1493.

Section of Medicine.

After a few words of introduction, the President, Dr. F. J. Smith (London), called on Dr. Harry Campbell to open the discussion on headache. He began by defining the area in which headaches might be felt, and enumerated various morbid cephalic sensations which should be distinguished from headache and called dysaesthesiae—such as tightness, lightness, heaviness of the head, bursting feelings, giddiness, confusion. A centre for headache might be presumed to exist in the inferior part of the post-central gyrus. Asking why headache was so common, Dr. Campbell gave a number of the pathological and mechanical causes that might underlie its distribution and occurrence. Finally, he drew attention to the connexion between the cerebral centre for cephalic sensibility and the special sense centres; they would account for headaches due to bright lights, loud sounds, and the like. Finally, after suggesting a classification of headaches, he mentioned those due to faulty digestion in some form or another, and put in a plea for the carnivorous diet. Dr. C. O. Hawthorne (London) commented upon the limitations of our exact knowledge of such things as biliousness, high blood pressure, and alimentary toxaemia. Free leeching of the temple was a cure for many headaches in full-blooded persons. The early morning headache of children, with or without vomiting, might be due to optic neuritis. Dr. L. H. Pegler (London) referred especially to nasal headaches, or headaches caused by nasal disease, and noted that there was no particular character enabling the nasal headache to be distinguished from all others. The relief of nasal obstruction might cure headache. He also spoke of the importance of proclivity in the occurrence of headache. Contact between intranasal surfaces might cause headache; so might veno-lymphatic stasis; so might malaëration of the blood; so might inflammatory conditions, all in the nose. Dr. F. C. Eve (Hull) spoke of the toxaemic headaches so commonly caused in the administration of tuberculin, and of the relation of the pressure of the cerebro-spinal fluid to pains in the head. The Chairman (Dr. F. J. Smith) spoke of the headaches seen often in medical men, cured by mercury and iodide. He spoke highly of the inunction treatment of specific ailments of little severity. Dr. H. Campbell, in reply, referred to the fact that Wassermann's reaction might be absent and the cerebro spinal fluid normal in cases of active syphilis. Dr. J. S. McKendrick (Glasgow) then read a paper on splenectomy in relation to the treatment of anaemia. He noted that the spleen was not, apparently, an organ essential to normal life, and that surgeons nowadays had the skill to remove pathological spleens without any great danger to life. Professor L. P. Phillips (Cairo) described the successful treatment with benzol of a case of splenomedullary leukaemia. It was a powerful poison, and so must be administered to patients with great care. Sir William Osler (Oxford) then gave a classification of the cases of splenic enlargement with changes in the composition of the blood, drawing particular attention to those in which splenectomy was indicated. In these patients, after years of apparently good health, the liver might suddenly enlarge, and then splenectomy might well be advisable. Dr. J. R. Charles (Bristol) related two cases of splenectomy and a case of spleno-medullary leukaemia treated with benzol. The result was excellent in all, but in the third case the improvement was but temporary. Dr. Lea (Manchester) referred to experimental splenectomy in animals and its influence upon the course of experimental tuberculosis. Dr. T. Wardrop Griffith (Manchester) then gave a lantern demonstration on two cases of patency of the ductus arteriosus. The Section was attended by some ninety members and visitors.

Section of Naval and Military Medicine and Surgery.

Surgeon-General P. H. Benson, I.M.S., took the chair in the absence of the President, Surgeon-General W. Maxwell Craig, R.N., who was prevented by illness from attending. The proceedings opened with a vote of condolence, proposed by Surgeon-General Benson and seconded by Colonel C. N. Melville, R.A.M.C., which was unanimously adopted. Fleet Surgeon D. Walker Hewitt, in a paper on the treatment of wounded in naval warfare, pointed out the differences that exist between the conditions of war on sea and on land—differences which affect the nature of the wounds inflicted, the method of their treatment, and the surroundings in which it has to be carried out. Naval medical officers had to recognize that a man-of-war was a fighting machine and could not by any process of ingenuity be turned into a floating hospital. Arrangements

made on behalf of the wounded had, therefore, to be subservient to fighting efficiency. The first step should be the organization of an efficient first-aid party especially instructed in the hand transport of wounded men. First aid, usually so called, must be carried out in dressing stations under cover. The dangers of primary haemorrhage were rare and far less than that of sepsis from contamination of the wound by the soiled hands of the bearer party. It was impossible to expect men, in the confusion and hurry of fighting, to examine injuries carefully and apply dressings skilfully. Early removal by skilled bearers was the first requisite. Dressing stations were fitted up in the larger ships, but it was difficult even in these to get situations easy of access, protected by armour and not too hot; these difficulties were accentuated in smaller craft. Surgeons and wounded should not be too much kept together, but scattered as much as possible. In ships too small to carry a surgeon he suggested that three or four of the crew should be carefully trained in first aid by short spells of work in naval hospitals. After an action well-equipped hospital ships were a necessity, and removal of wounded from ship to ship should be frequently practised in peace, so that delay might not be caused in war. Sir James Porter emphasized the importance of practising the removal of wounded at inspections and other times, insisting particularly on the necessity of dealing with large numbers of men. Captain Max Page, R.A.M.C. (S.R.), read a paper on gangrene in war, derived from his experiences in the Balkan war. He divided gangrene into five varieties—namely: (1) Due to interference with blood flow; (2) traumatic; (3) infective; (4) vasomotor; (5) due to the effect of high explosives. The fourth type, attributed to disturbance of the vasomotor system, resembled frost-bite in its nature; half the cases suffered from cholera, and all gave a history of exposure to cold, wet, and famine. This form had been attributed by some observers to pressure from tight putties or the consumption of ergotized rye, but, Captain Page thought, on insufficient grounds. Lieutenant-Colonel E. M. Wilson, C.B., in a paper on employment of ex-soldiers and sailors in civil life, dealt specially with those trained in medical duties. These men belonged to the Reserve of either the sea or land forces. Their technical skill was apt to fade if not kept in practice. Medical men could do a great service, not only as to the men, but also to the nation, by finding employment for these men. The Army and Navy Male Nurses' Co-operation, 11A, Welbeck Street, supplied men of this class, and they could also be found through the R.A.M.C. Records Office, Aldershot. Sir James Porter confirmed what Colonel Wilson had said, and emphasized the importance of the work performed by these agencies.

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE.

DR. F. W. MOTT referred to the great loss which the Section had sustained through the death of Dr. William Reid of Oxford, who had been elected one of the vice-presidents of the Section. Dr. Mott opened the discussion by reading a paper which was illustrated by a lantern demonstration. The following is a brief outline of the principal points with which he dealt: (1) The importance of the study of the pathology of general paralysis and tabes (in the light of recent researches) in respect to their diagnosis and treatment. (2) Syphilis a disease of the lymphatic system. The lymphatic systems of the brain and spinal cord in relation to the mode of entry of the spirochaetes or their toxins into the central nervous system. The cerebro-spinal fluid, a secretion of the choroid plexus, in relation to the pathology of parenchymatous syphilis. The importance of the condition of the fluid in relation to diagnosis and treatment. (3) The existence of spirochaetes in the central nervous system in relation to the pathology of parenchymatous syphilis. The infection of the central nervous system, the evidence of its occurrence, the time of its occurrence, latency. Personal observations on a series of 100 cases of general paralysis, in which spirochaetes were found in the brains in 65 per cent. (4) The correlation of cortical spirochaetosis with the morbid histological changes and phenomena of neuronic irritation and destruction, with their attendant clinical signs and symptoms. (5) Experiments on animals in relation to the therapeutic action of mercury and arsenobenzol compounds. (6) Theories regarding the causation of parenchymatous syphilis: (*a*) Modification of the spirochaete and evidence thereof; (*b*) the hypersensibility of the neurones; (*c*) a lowered resistance of the neurones. (7) Neuro-recidive, or Herxheimer's reaction in relation to treatment by salvarsan. (8) Recent developments in the treatment of parenchymatous syphilis by intrathecal injection of salvarsanized serum and of hypertonic solution of neo-salvarsan. The results in general paralysis. Dr. Plaut (Munich) pleaded for further experimental research by inoculation with syphilis of anthropoid apes, to discover whether there is evidence of varieties of spirochaetes from the biological standpoint or whether a biological peculiarity can be recognized in these animals acquiring late syphilis of the nervous system by reason of their reaction to the spirochaete in the earlier stages of syphilis. He indicated many of the problems which yet remain unsolved, and laid special stress on the fact that the cure of general paralysis can only be accomplished by fighting against the spirochaete, and that this fight must be begun in the first stages of syphilis. The discussion was continued by Dr. T. Mackintosh and Mr. McDonagh. Sir Clifford Allbutt, Dr. S. A. K. Wilson, Dr. Aldren Turner, Dr. Grainger Stewart, Dr. Campbell Thomson, Dr. Ford Robertson, Dr. T. J. Thomson, and Dr. D. W. Falconer took part in the subsequent discussion; and Dr. Mott replied.

SECTION OF OPHTHALMOLOGY.

DR. C. H. USHER, President of the Section, having briefly opened its proceedings, a discussion on the choice of a cataract operation was commenced by Mr. E. E. Maddox. The first consideration, he said, should be safety, and a preliminary iridectomy should take the premier place. Its chief disadvantage was the presence of a cicatrix when the incision for extraction was made. This could be almost entirely overcome by using a very short and narrow broad needle. The combined operation as regards risks was midway between the preliminary iridectomy and the simple method. He greatly preferred to do the bridge operation of Desmarres, for after the operation the eye was quite safe. Lavage was most useful, but the use of india-rubber tubes was not permissible. Simple extractions give the best visual results. One great disadvantage about intracapsular operations was the need of a specially skilled assistant. Dr. Casey A. Wood (Chicago) thought that mature cataracts in otherwise healthy eyes did well by any method. In incomplete cataract complicated by other diseased conditions of the eye preliminary iridectomy should be done. Major McKechnie, I.M.S., advocated Smith's method of intracapsular extraction, and greatly emphasized the fact that a very large incision, including at least half the cornea, was essential. The zonule of Zinn was not tough, and easily gave way. Mr. Bickerton (Liverpool) much preferred the combined operation. Mr. Devereux Marshall (London) favoured the simple operation followed by iridectomy if necessary. Dr. MacGillivray (Dundee) was a strong advocate of the subconjunctival method of extraction, and did not like sutures. Mr. Montagu Harston (Hong Kong) spoke in favour of Smith's method. Mr. J. Herbert Parsons (London) advocated the performance of a peripheral iridectomy. Dr. R. A. Reeve (Toronto) did a good many operations without iridectomy, but always used capsule forceps. Dr. Hill Griffith (Manchester) thought the combined operation the safest and best; so also did Dr. Harold Gifford, at all events so far as European and American patients were concerned.

SECTION OF PATHOLOGY AND BACTERIOLOGY.

AFTER a few brief introductory remarks by the President (Dr. W. S. Lazarus-Barlow) a discussion on the action of radiations on cells and fluids was opened by him. He pointed out that the action of radiations upon cells and fluids must be considered from two points of view both having important bearings upon clinical medicine. On the one hand, the effect of relatively large quantities of radiations was important owing to the probability that rays (radium, *x* rays, and mesothorium) were destined to play an important part in the treatment of new growths; on the other hand, the effect of minute quantities was important because a claim had been made for their efficacy

in the treatment of certain diseases on balneological lines. His experiments dealt with the total action of radium doses eight times as great as those previously employed, and he regarded the columnar cells and subcutaneous tissue as one complex and the squamous cells and subcutaneous tissue as another complex. His experiments showed that the time and quantity factors of the radium dose played markedly contrasting parts, on which he laid great stress. He irradiated two rats—one for 108 minutes with 92 mg., another for 240 minutes with 38 mg., and then killed them nine days later. It appeared that in the case of the mucosa and submucosa, the smaller quantity of radium, acting for the greater length of time, produced the more profound changes. The exact converse held in the case of the cutaneous and subcutaneous tissues, in which the inflammatory reaction and destruction of squamous cells was greater in the case of the rat exposed to 92 mg. for 108 minutes. He concluded that undesirable damage would be better eliminated by keeping the quantity factor of the "radium dose" high in the case of the columnar cell complex, whilst in the case of the squamous cell complex it would be better eliminated by keeping the quantity factor of the "dose" low and the time factor high. Dr. Beckton then narrated some experiments to support his view that the action of rays was manifested only through the tissue glands and not directly on the tissues, for he could find no change in Altmann's granules after irradiation. Mr. Morson gave a lantern demonstration of histological preparation, showing the rapidity of degeneration in tumours after irradiation, and the fact that spheroidal and columnar celled growths responded best of all. He laid stress on the striking effect of treatment, and at the same time the effect of excessive dosage. Dr. Russ had carefully analysed the effect of the alpha, beta, and gamma rays on Jensen's rat tumour, and on *S. pyogenes aureus*, and found a most striking variation in the results, considerably longer exposures being necessary to sterilize the bacteria than to affect the tumour, and this was much more marked in the case of the *x* rays than the others. Dr. Price Jones had dealt with *in vitro* plasma cultures which were markedly affected, in as far as the mitoses were concerned, but he pointed out that the spread of tissue which might even occur in non-radiated tissues was the same as the increase of mitoses. The discussion which followed dealt with these points, and in his reply the President pointed out that the suggestion to introduce radio-active substances into the body fluids only emphasized the boldness of the empiricist in dealing with emanations whose danger could only be suspected. He also mentioned the difficulties in the way of research, owing to the scarcity of radium and its high price. The rest of the session was occupied with a discussion on the bio-chemistry of immunity reactions. This was opened by Dr. Carl Browning, who gave a general survey of the present position, and pointed out the large gaps in existing knowledge. Drs. Thiele and Embleton contended that complement was really a ferment, and did not act quantitatively by combining with antigens; also that there was no true specificity of bacteria, but that in the serum of animals dying from any kind of bacterial infection the same toxic substance could be demonstrated. Dr. Mackenzie Wallis dealt with the "protective ferments" of Abderhalden and their relation to immunity. Major A. G. McKendrick brought the discussion to a close with a paper on the compound lysins.

Section of Pharmacology, Therapeutics, and Dietetics.

The proceedings of the Section of Pharmacology, Therapeutics, and Dietetics were opened by an introductory address from the President, Professor J. Theodore Cash, F.R.S. He sketched briefly the history of the Section, pointing out that it had met five times in the last six annual meetings, and sixteen times previously, on an average of once in two years. This increase in the frequency of the meetings of this Section corresponded with the growing importance of the subject of pharmacology in the medical curriculum and with the increased development of pharmacological teaching and laboratory equipment in the various medical schools. Among other points he advocated the use of the metric system in dosage, on the grounds of bringing laboratory work and clinical work into closer relation, and also with a view to bringing this country into line with other nations. He foreshadowed the introduction of the metric system in the new *Pharmacopoeia* as an alternative to that at present in use. The general business of the Section began with a discussion on recent advances in the relationship between chemical structure and pharmacological action, which was opened by Dr. J. M. Fortescue-Brickdale (Bristol). He emphasized the great difficulties of correlating structure and action, pointing out that those difficulties arose mainly from the biological side, and that the action of complex substances could only be determined experimentally in each case, though a new body having close structural analogy to one of known action would probably act in a similar manner. He then proceeded to discuss the methods by which alterations in chemical structure might affect the action of a substance. Dr. McWalter (Dublin) and Dr. Grünbaum (London) and the President also contributed to the discussion. Papers by Dr. F. J. Charteris (Glasgow) on the action of colloidal palladium in obesity; by Professor C. R. Marshall and Dr. G. B. Killoh (Dundee) on the bactericidal action of colloids of silver and mercury; and by Dr. J. A. Gunn (Oxford) on the pharmacology of the isolated human uterus and Fallopian tubes, concluded the work of the Section for the day.

Section of State Medicine and Medical Jurisprudence.

The first meeting of the Section of State Medicine and Medical Jurisprudence was opened by the President, Professor Matthew, M.O.H. Aberdeen, with a short introductory address, in which after referring to the apparent incongruity between the subjects which were combined in this Section, and the dissociation of the subject of medical sociology from that of State medicine, he suggested that in another year there should be a clearer definition of the relation between these subjects, and that a more appropriate designation for the combined Sections would be that of Preventive Medicine. He mentioned that the University of Aberdeen had recently appointed a full-time lecturer in public health, and that the combination of the chairs of Public Health and Medical Jurisprudence would cease when he relinquished his present appointment. He made special reference, from the point of view of medical jurisprudence, to the study of the criminal, remarking that since lunacy began to be recognized as a disease or a physiological defect the ordinary lunatic received more humane and just treatment, and there was a closer study of the psychology and genesis of the criminal. He concluded by saying that it was in this connexion that the union of State medicine and medical jurisprudence might, after all, find its justification. A discussion on the reform of vital statistics, with special reference to death certification, was opened by Sir Victor Horsley, F.R.S., who maintained that the *Nomenclature of Diseases*, which bore the imprimatur of the Royal College of Physicians, was largely responsible for the confusion existing on the subject of death certification. This work was essentially ridiculous in its terminology, for it was not really a nomenclature of diseases, but a list of symptoms. As instances of the absurdity of the volume, he mentioned the inclusion of hysteria, neuralgia, and neuritis as causes of death, and stated that in 1911, 57 persons were stated to have died from hysteria, neuralgia, and sciatica, and no fewer than 501 from "neuritis." These were, of course, really deaths from alcoholism. He therefore proposed that the Association should move in this matter, and produce a real nomenclature of diseases from which all the old loose terms and archaic names were expunged. The Association had drawn up a scheme, the principles of which were laid before the Registrar-General ten years ago, but nothing was done, and nothing probably would have been done had it not been for the fact of the appointment of the Venereal Diseases Royal Commission. Dr. Bruce (Dingwall) advocated the sending of certificates of death by general practitioners direct to the medical officer of health in the first instance. Dr. J. C. Dunlop (Register House, Edinburgh) stated that the *Nomenclature of Diseases* was not an official book in Scotland, and he thought Sir Victor Horsley laid too much stress on its influence in encouraging ill-defined terms. He did not think that the Registrar-General's office should be attached to a Ministry of Public Health, as legal knowledge was quite as important as medical in the office of the Registrar-

General. Dr. F. E. Wynne (M.O.H. Wigan) gave various instances of the absurdity of the present classification of the nomenclature of diseases, and pointed out that the confusion was due to an endeavour to classify causes of death on an anatomical instead of on a pathological basis. He suggested that there should be a special section for diseases of the ductless glands, and that the term "croup" should be altogether deleted. Dr. Chalmers (M.O.H. Glasgow) advocated the adoption of uniformity in national and local returns. After some remarks from Drs. Boyd (Pretoria), McCall, Murray (Stornoway), and Laffan, Sir Victor Horsley replied to the remarks of various speakers and moved a resolution advocating reforms in the national statistics of life and death and a confidential system of death certification. This was seconded by Dr. Bond and passed unanimously. The meeting concluded with a paper by Dr. McWalter (Dublin) on the necessity for reforming the coroner's inquest, and a paper on legal investigation of causes of death in Scotland by Dr. W. G. Aitchison Robertson (Edinburgh).

SECTION OF SURGERY.

WHEN Mr. Scott Riddell, M.V.O., President of the Section, took the chair at the first meeting of the Section there was a large and keenly interested audience, and after a few words of welcome to the City of Bon Accord the scientific business was begun. Mr. W. G. Spencer (London) led a discussion on the etiology and treatment of squamous-celled carcinoma of the tongue and floor of the mouth. Surgeons, he said, had recognized that there was a pre-cancerous stage, which was characterized by a recognizable lesion lasting generally longer than three months before it became actually cancerous. This lesion was a subepithelial small round-cell infiltration, which was mainly of inflammatory origin, but some of whose cells appeared to be derived from epithelium. When these cells were sufficiently numerous proliferation was noticeable. The term "pre-cancerous" was too indefinite; this period of small round-cell infiltration should properly be included within the cancerous period. Microscopic examination alone, performed preferably within the operating theatre or its immediate vicinity, at the time of operation was the only real method of recognizing early epithelioma. The operative treatment of these lesions depended upon the amount of involvement of the tongue. Early cases could be treated by local operations, excision of the ulcer; later cases could be dealt with only by extensive operations, such as Crile's block dissection; inoperable cases should be treated by continuous use of non-irritating antiseptics to disinfect the ulcerated surfaces and by the use of drugs to relieve pain. The paper was illustrated by many references to cases and by microscopic slides. Professor Kay Jamieson (Leeds) described the anatomic distribution of the lymphatic vessels of the tongue and glands of the submaxillary and cervical regions. He drew particular attention to the course of lymphatic vessels from the tip of the tongue, down the fraenum, close to the periosteum of the inner surface of the jaw to the submental glands, and sometimes passing them to glands of the lower deep cervical group. The lymph vessels in the tongue itself sometimes, in passing downwards, crossed over to glands on the other side. The jugulo-digastric and the jugulo-omohyoid glands were glands deserving special mention from their constancy. Mr. J. F. Dobson (Leeds) was associated with this investigation, and had as a result advocated that for the thorough treatment of any advanced case of tongue cancer with gland involvement nothing short of Crile's block dissection was adequate. Some cases showed that it was not necessary, nor sometimes even practicable, to remove all the large lymphatic trunks. Mr. C. P. Childe (Southsea) said he had been driven to perform extensive operations by clinical experience of recurrence. He operated by first removing the gland area and at the second stage removing the tongue. He strongly advocated education of the public in the early recognition of possible cancerous conditions, and presented members of the Section with copies of a leaflet drawn up for that purpose, published by the borough of Portsmouth. The discussion was carried on by Mr. McAdam Eccles (London), Mr. Hey Groves (Bristol), Dr. T. K. Dalziel (Glasgow), Professor Caird (Edinburgh), Mr. Lucas (Birmingham), and many points regarding extent of glandular involvement, etiology, and operative methods raised. Mr. Spencer having replied, Mr. Sidney A. Boyd read a paper on newer indications for removal of the spleen, and discussed various diseases demanding this operation. Sir William Milligan's paper on some practical considerations in the diagnosis and treatment of cerebellar abscess was most attentively followed, as new suggestions were made on methods of diagnosis and on the route of attack on these lesions. Mr. W. I. de Courcy Wheeler described the subsequent history of three cases of aneurysm of the abdominal aorta operated on by him by Colt's method.

SECTION OF TROPICAL MEDICINE.

PROFESSOR R. SIMPSON, C.M.G. (London), in his opening remarks, referred to the first meeting of the Section of Tropical Medicine in Edinburgh some sixteen years ago, and to the epoch-making paper of Manson and the brilliant work of Ross, which they first made public at that meeting. He also dwelt on the urgent need for the prosecution of sanitary reforms in the tropics, and then called on Fleet Surgeon Bassett-Smith, C.B., R.N., to read a paper on kala-azar and allied conditions, which presented a summary of present knowledge on the subject. Under the term "leishmaniasis" Fleet Surgeon Bassett-Smith included (1) all general diseases caused by the *Leishmania donovani*; (2) all the superficial infections caused by *Leishmania tropica*. The epidemiology of Indian kala-azar was considered to be coextensive with the Mediterranean infantile form, with which it was now generally held to be identical. He regarded the superficial leishmania, "Oriental sore" and "espundia" as being identical infections, since cases of naso-pharyngeal leishmaniasis had been found in Italy, where the former disease was also common. Professor Gabbi (Rome) recorded a number of observations which to his mind effectually disproved Basile's contention that the dog-flea, *Ceratophyllus fasciatus*, is the natural conveyer of the *Leishmania* infection between the dog and man. He was inclined to explain the discrepancy between Basile's experiments and his own and those of Wenyon by the failure of the second observer mentioned to exclude the spontaneous development of leishmaniasis in his experimental animals. In the discussion which followed, Dr. D. E. Anderson (London) referred to his observations on "uta," a dermal leishmaniasis of Peru, formerly considered to be syphilis. Dr. P. H. Bahr remarked on the absence of kala-azar from Ceylon, where the conditions were so similar to those of Southern India. Professor Ferguson (Cairo) referred to a form of tropical splenomegaly which was excessively common in Egypt, and in which he had failed to find the *Leishmania*, and in which excision of the spleen apparently rapidly effected a cure. Captain Marshall, R.A.M.C. (London) and Professor Gabbi concurred that such cases were in their experience common enough, but that in the terminal stages of true kala-azar, and *Leishmania* was apt to disappear from the liver and spleen. Dr. MacCallan (Cairo) read a paper on the ankylostomiasis campaign in Egypt, and concluded by saying that it was proposed to make an ankylostomiasis survey of each province and to clear up a number of disputed points, such as the absence of "ground itch" in the heavy infected districts. Dr. Sandwith (London), in the discussion, referred to the results obtained with the oil of chenopodium in ankylostomiasis in Sumatra and the Malay States. He considered it extraordinary that the drug had proved to be of so little avail in Egypt. He referred in complimentary terms to the interest taken by Lord Kitchener in this work. Professor L. Phillips (Cairo) said that in his experience eucalyptus oil, castor oil and chloroform water had given results nearly as good as those of thymol. Professor Ferguson (Cairo) read a preliminary communication on the effect of the accumulation of *Bilharzia* eggs in the spinal cord, when they are found in the posterior columns and in the ganglia cells of the cornua. Curious nervous phenomena, spastic paraplegia, incontinence of urine, and trophic ulcers are observed in these cases during life. The morning ended with a short paper by Professor L. Phillips (Cairo) on the inefficiency of small doses of emetine in effecting a cure in amoebiasis. He advised a three weeks course of emetine injections combined with saline aperients.

British Medical Journal.

SATURDAY, AUGUST 1st, 1914.

THE PRESIDENT'S ADDRESS.

In his Presidential Address, which is published at p. 221, Sir Alexander Ogston gives a most interesting review of the growth and development of Aberdeen in its civic as well as its academic aspect. It is well known that he has given much attention to the archaeology of Scotland, and therefore he can speak with special authority on the early inhabitants of that region. He shows how from a small settlement in a remote and almost inaccessible part of the coast of the North Sea where the people earned a hard living by fishing, it grew into the flourishing city of which an account has already been given in the JOURNAL of January 3rd, 1914. To what an extent the fishing trade has now grown visitors will be able to see for themselves; it is, as the President says, one of the wonders of the world. Aberdeen has now many other flourishing industries, and its trade, as Parson Gordon said at the end of the fifteenth century, is still with "Norroway, Swethland, Denmark, Pole, Germany, Holland, Flanders, France, Spayne and England." It was made a royal borough by Gregory King of Scots as early as the ninth century. Its development was doubtless hindered by its exposure to attack from without, for it was never a strongly fortified place, and consequently it was frequently taken and retaken in the almost perpetual wars which raged up to the middle of the seventeenth century. It was always a place of importance, and even up to the end of the sixteenth century might, but for its remote situation, have been the capital of Scotland. Kings resided in it and Parliaments were held there. In 1511, when Queen Margaret, sister of Henry VIII and wife of James IV, visited Aberdeen, her favourite poet, Dunbar, celebrated the event in verse, calling the city—

> Blythe Aberdeen, thou beryl of all Townis,
> The lamp of beauty, bounty, and blytheness.

Allowing for the exuberance of the poet's fancy, the account of the Queen's reception shows that in the early years of the sixteenth century the town could make a brave display of welcome and hospitality.

It was shortly before this time that a notable development in the importance of Aberdeen took place. This was the foundation of the famous university, which has made its name known all over the world as a training ground of men who have helped to do the work of the empire and have enlarged the boundaries of knowledge in every sphere of intellectual activity. The divine thirst for learning had, indeed, existed in Aberdeen from a much earlier period, for already in 1262 there was a grammar school, which has existed more or less continuously ever since. In 1483 there came to Aberdeen as Bishop of the See a man who was to make the light of wisdom glow with a brighter flame, and place it in a high place where it could be seen of all men. This was William Elphinstone, a man skilled in all the learning of his time and full of enthusiasm for its diffusion. He was a graduate of Glasgow, and had been both student and teacher in the universities of Paris and of Orleans, then celebrated as a centre for the study of law. Before going to Aberdeen Elphinstone had already distinguished himself in diplomacy, and acquired a great influence over the mind of King James III, and later of his successor. He had held high office in the kingdom, and had been entrusted with important embassies. Elphinstone was keenly interested in education, and Sir Alexander Grant suggests that to his inspiration was due the Scottish Act of 1496, which required all barons and freeholders to have their eldest sons instructed in "Arts and Jure."[1] By that measure it was enacted that all barons and freeholders in Scotland should send their eldest sons to the grammar schools from the time they were 8 or 9 years old. At these schools they were to remain till they had "perfect" Latin. They were then to proceed to the schools of art and law, where a course of three years would qualify them to administer law and justice to the parts of the country to which they belonged; the object of this was that the poor "should have no need to seek our sovereign Lord's principal Auditors for each small injury." This was, in fact, as Sir Alexander Ogston points out, the curriculum of a university. Moreover, it seems, as he says, to prove that to Elphinstone belongs the credit of having anticipated by several hundred years the introduction by the State of the principle of compulsory education. Hastings Rashdall says that from this act it is clear that Elphinstone aimed at making his university a school of law. It is still more clear that his aim was the education of a grossly ignorant clergy. In the Bull of Foundation, which by his influence was obtained from Pope Alexander VI in 1495, the state of things in the region about Aberdeen is described as follows: "In the northerly parts of the Kingdom of Scotland there are certain parts divided from others and cut off by firths and lofty mountains, wherein lived rude and illiterate men almost savages, who on account of their great distance from spots where there are schools of learning, find it dangerous to travel to places where letters are studied. So ignorant are they that persons cannot even be found capable of reading the word of God, teaching or administering the sacraments." The Pope praises "the priceless pearl of knowledge," which, besides giving a clear understanding of the "secrets of the universe, raises those of humble origin to the highest rank." This, though only the formal style of such Bulls, recalls what Gaisford, Professor of Greek at Oxford, said in praise of classical knowledge, that it gave its possessors a sense of superiority to their fellows. The remedy for the intellectual darkness which prevailed in the remote places referred to by the Pope was said to be the foundation of a Studium Generale Literarum, and the Pope points out that if a university were established in the illustrious old town of Aberdeen (*inclita civitate veteri Aberdonensi*), which is near to the wild places described, "many men of that kingdom and especially of those parts, ecclesiastics as well as laymen, would gladly give themselves to the study of letters."

Sir Alexander Ogston gives a most appreciative sketch of the personal character of Elphinstone, who was certainly one of the greatest men of his time, not only in Scotland but in Europe. Besides founding the university he reformed the clergy, built the great steeple of his cathedral, and showed himself a *pontifex* in the literal sense of the word by projecting the building of the old Bridge of Dee, then the only way of communication with the town from the south, and leaving materials and money which he had collected to his successor, Bishop Dunbar. Elphinstone's work on his cathedral has long

[1] Hastings Rashdall, *Universities of Europe in the Middle Ages*, vol. ii, part 1, p. 309. Oxford, 1895.

disappeared, but the university of which he was the begetter remains and has developed beyond the dreams of the founder. An account of the University of Aberdeen was given in the JOURNAL of January 10th and 17th, 1914.

Readers, therefore, need only be reminded that Elphinstone founded what is now King's College, a remarkable feature in it being that he laid the foundation of a medical faculty, the first in Great Britain. The mediciner, James Cuming, was not a priest, but a married man and a regular graduate in medicine. Whether he actually taught from a university chair is not known, but it is clear that he practised medicine, for there is a record of the salary paid him by the town. Cuming died in 1521 and was succeeded by Robert Gray, who was also a doctor of medicine. Ferrerius of Paris speaks of Aberdeen in 1534 as the most celebrated seat of learning in Scotland, and among the early teachers makes a complimentary reference to Gray.

Sir Alexander Ogston points out, as a proof of Elphinstone's sagacity, that in the foundation of the university he sought for help, not from the great magnates whose influence might have overshadowed it to the detriment of its growth, but from the burgesses, the lesser nobility and gentry. We know from modern instances that the pious founder may be a serious hindrance to the work for which he supplies the material equipment. Of the development of the University of Aberdeen, of the foundation of Marischal College, and of the final fusion of the two colleges in 1860, enough has already been said in previous articles. Visitors will see for themselves into what a noble temple of medicine Marischal College has grown from very humble beginnings: its laboratories and provisions for teaching are surpassed by none in the kingdom. The school itself, since the colleges were made into one university, has thriven marvellously. Every year it sends out a number of well trained doctors to do their work in civil life and in the services. It has in recent times been the intellectual cradle of many original investigators; we need only name Patrick Manson, Arthur Keith, and William Bulloch of the London Hospital. Among the most eminent of living men connected with Aberdeen is Sir Alexander Ogston himself, who, as a teacher and a surgeon, has always manifested independence and originality of thought, and who, though retired from the battle of professional life, stands at the head of the surgical profession in Scotland. Throughout his career he has been a true leader in modern surgery, and many generations of students hold his name in veneration. Though he makes no mention of himself it is well known to all who know anything of the University of Aberdeen during the past thirty or forty years how large a part he has played in bringing it into the front rank among the medical schools of Great Britain.

CHEMISTRY AND MEDICINE.

DR. A. E. GARROD'S Address in Medicine (p. 228) gives an admirable summary of the present relations of medical science and chemistry. As he points out, the aims and operations of many of the different branches of science are nowadays inextricably intertwined. Physiology, pathology, bacteriology, therapeutics, and chemistry, to name only the most important contributors to medicine, have become to a large extent interdependent sciences, borrowing from and lending to one another with the utmost freedom. One result of this great enlargement of their boundaries has been that the medical investigator is nowadays bound to have some special bias, to look out upon the field of medicine from his own standpoint, whether as a chemist, a physiologist, or an expert in one or another of the branches of pathological science. Dr. Garrod, as is well known, has won distinction as an investigator of the problems of physiological and pathological chemistry, and is therefore peculiarly well fitted for the survey of medicine from the chemical point of view. And nobody but a trained chemist can hope to understand the incredibly complex divagations made by the science of organic chemistry during the last decade or two, notably under the leadership of Emil Fischer, to whom Dr. Garrod makes appreciative reference, and Paul Ehrlich. As has always been the case, the progress made in chemical study has answered certain questions that it set out to solve, but in answering them has raised countless further and more complicated questions; thus the contemplative student of experimental knowledge can see repeated and verified every day the fable of the immortal hydra and its nine heads—when one is down another comes up for solution to take its place. Pathological chemistry is now more than ever before beset with knotty problems presented to it for elucidation by the bacteriologist and experimental pathologist, many of them, so far as our present knowledge and means of research go, frankly insoluble to-day, whatever they may be to-morrow.

Much has been done to solve the question of the constitution of the proteins, the carbohydrates, and the more complex fatty substances met with in the animal economy, and we may fairly be said to have a sound, if still incomplete, working knowledge of the structural units out of which many of these bodies are built up, for all their infinite variety. But the path of the pathological chemist is no longer set in these comparatively easy places. The bacteriologist and experimental pathologist now cry out for information about substances far less well defined than the proteins of everyday life that are the main constituents of living or dead protoplasm. Nowadays research is busied with the composition and properties of such elusive substances as toxins, antitoxins, hormones, chalones, the secretions of the ductless glands, or ferments, and with the processes of life or disease occasioned by their manifold actions and interactions. In fact, the chemist is being called upon for precise information about substances justly characterized by Dr. Garrod as "intangible entities revealed as yet by single properties," identified by criteria that must appear wholly inadequate to the chemical mind, in spite of the fact that even such flimsy knowledge as we have about them is mainly inferential and based upon circumstantial rather than upon direct evidence.

The complexity of the questions that have to be answered may be illustrated by a consideration of the proteins of foodstuffs. Time was when the digestion and absorption of the proteins appeared to be a straightforward matter. It was thought that they were broken down by the digestive juices into simpler but still highly complex fractions, such as albumoses or peptones, absorbed as such, and as such built up again into similar proteins in the animal body once more. But nowadays we have changed all that. The infinite variety of animal proteins is now recognized. Animals of different genera contain different proteins, built up, no doubt, of more or less similar atomic complexes in ultimate analysis, but having these atomic complexes in different numbers and differently arranged within their protein molecules. The bricks of which the

protein edifice is constructed—to use a coarse analogy—may be similar, or even apparently identical, in different kinds of animals or different genera of plants, but the ways in which the bricks are utilized to build up the different protein molecules are not the same. Not only so, but even in the various organs and tissues of each animal these bricks are put together differently. And thus we learn that the very proteins which perform identical functions in different animals are not themselves identical, but differ from genus to genus, from species to species, and differ the more widely the further the several species are separated from each other in the evolutionary scheme.

As a further complication, it seems from Abderhalden's work on the protective ferments and cytolysins that each tissue protein bears not only this specific generic stamp, but also a second stamp derived from the particular organ from which it is derived. It appears probable that the two liver proteins, for example, respectively derived from the sheep and the dog, while exhibiting specific ovine or canine differences, agree in containing in their molecules some particular group of atoms that confers on both the peculiar hepatic impress. The elucidation of these and similar problems of the constitution of the proteins is of the greatest importance to the pathologist who wishes to understand the widespread phenomena of anaphylaxis, for example, or of immunization, and also to the pathologist in search of explanations for the narrower errors of metabolism such as those shown by cystinuric or alcaptonuric patients. Yet it is to the pathological chemist that we must look, in the last instance, for their solution.

Want of space makes it impossible to refer to the many other metabolic problems set out and in part answered by Dr. Garrod in his masterly survey of the wide field he has set himself to traverse. He makes abundantly evident the extreme delicacy of the chemical processes whereby the metabolic processes of the human body maintain the integrity of their balance, the complexity of the methods of defence employed by Nature in the presence of disorder or disease. He encourages the modern physician to cultivate a healthy scepticism, not unchecked by the positive results of scientific research, in estimating the effects of drugs and diets in the treatment of disease, quoting an excellent apophthegm of that iconoclastic mystic Paracelsus: "Nature is the physician, not thou. Thou must learn of her, not of thyself." It is true that Paracelsus was one of the last men in the world to follow such a plan himself in his own practice; but of the soundness of his advice there can be no question. When we administer a serum or a vaccine, or the extract of an endocrine gland, we are copying Nature's methods and using her weapons; the hope is that such empirical therapeutics will be placed on a more scientific footing as our knowledge of the chemistry of the living body increases.

THE ADDRESS IN SURGERY.

Sir John Bland-Sutton has taken as the subject of his address (p. 235) The Surgeon of the Future. To place his forecast in the strongest light, he begins with a backward glance at the surgeon of the past. The discovery of anaesthetics and the invention of the microscope, he says, completely changed surgical methods. Of the immense influence of anaesthesia in the development of surgical handycraft there can be no doubt. The horrors of surgery in the days before means were found of drowning the patient's sensations in unconsciousness are beyond description. A distinguished physician, who had to submit to an amputation, has left a record of his feelings which was published by Sir James Simpson;[1] it is worth quoting: "Of the agony occasioned I will say nothing; suffering so great as I underwent cannot be expressed in words, and thus fortunately cannot be recalled. The particular pangs are now forgotten; but the black whirlwind of emotion, the horror of great darkness, and the sense of desertion by God and man, bordering close upon despair, which swept through my mind and overwhelmed my heart, I can never forget, however gladly I would do so. . . . Before the days of anaesthesia a patient preparing for an operation was like a condemned criminal preparing for execution. He counted the days till the appointed day came. He counted the hours of that day till the appointed hour came. He listened for the echo on the street of the surgeon's carriage; he watched for his pull at the door-bell, for his foot on the stairs, for his step in the room, for the production of his dreaded instruments, for his few grave words and his last preparations before beginning; and then he surrendered his liberty, and, revolting at the necessity, submitted to be held or bound, and helplessly gave himself up to the cruel knife. The excitement, disquiet, and exhaustion thus occasioned could not but greatly aggravate the evil effects of the operation, which fell upon a physical frame predisposed to magnify, not to repel, its severity."

Nor was it only the patients who suffered. Men like Cheselden, John Hunter, and Abernethy used the knife with reluctance and dislike, and Charles Bell generally passed a sleepless night before a critical operation. In a letter under date March 23rd, 1805, he says: "I am just returned from witnessing an operation. . . . I cannot bring my mind to leave surgery in the state it is now practised. . . . Yet, being bound to certain rules, a *spectator* merely, it was torture to me." It is difficult for the present generation to conceive that there were surgeons who held that pain was a useful stimulus; but on this ground the use of chloroform was forbidden by the principal medical officer of our army in the Crimea.

It may be admitted that anaesthesia has certain disadvantages which may be called defects of its qualities, but we think Sir John Bland-Sutton has overstated the case when he says that, in consequence of its introduction, post-operative suppuration and pyaemia became endemic plagues in all populous cities, dogging the footsteps of the surgeon. The production of suppuration as a necessary part of the healing process in wounds, except in the rare cases in which union took place by first intention, had always been aimed at by the surgeon till antisepsis taught him a better way, and pyaemia with hospital gangrene had raged as a devastating scourge in hospitals long before the discovery of any sweet oblivious antidote to the pain of the surgeon's knife. John Bell, writing in 1801, quoted an ancient French author, who said: "A young surgeon who is bred in the Hôtel-Dieu may learn the various forms of incisions, operations too, and the manner of dressing wounds; but the way of curing wounds he cannot learn. Every patient he takes in hand (do what he will) must die of gangrene." That was the state of things long before the day of anaesthesia, and such it continued to be till the demon was finally exorcised by the genius of Lister.

With anaesthesia and antisepsis gradually broadening into the principle of asepsis, the surgeon of the old type—whose practice might be summed up in the

[1] *Collected Papers on Anaesthesia*, etc., Edinburgh, 1871, p. 86.

familiar formula, "Cut through everything that's soft, saw through everything that's hard, tie everything that bleeds"—faded out of existence, and his place was taken by a man of an altogether different mould and temperament. Men whose intellectual power made them well fitted to advance knowledge formerly avoided surgery because its inevitable accompaniments jarred on their sensibilities. When anaesthesia mitigated these horrors, such men were attracted by the nature of the scientific problems which surgery presents and the definiteness of the issues with which it has to deal. Having gazed through the microscope on the Pacific of a new pathology, they went forth to do things undreamed of by their rude forefathers. In considering the causes of the progress of surgery in the past half-century, the men behind the weapons must be taken into account as well as the means of research.

Surgeons, Sir John Bland-Sutton tells us, are of two types—they are either craftsmen or biologists. Craftsmen to a greater or lesser extent they must always be, but in this direction there is a limit set to possible advance. But in pathology and chemiotherapy the field of progress is illimitable. As Sir John Bland-Sutton truly says: "It requires little foresight to recognize that for men to attain high places in surgery the high road lies through the pathological institute." He has himself given the best evidence of the faith that is in him not only by his own career, for he approached surgery through pathology—there were no institutes then—but quite recently by presenting to the Middlesex Hospital, with which he has been so long connected, an institute of pathology, now nearly complete, comprising clinical, research, and teaching laboratories and a museum. A necessary condition of progress is that the wards, operating theatres, and laboratories should be brought into the closest intimacy. If the time has not yet come for saying *Cedant arma togae* there can be no doubt that it is approaching. The surgeon of the future will work with chemical compounds rather than with the knife. The brilliant results of salvarsan have shown the way not merely to the cure of syphilis but also, we may perhaps hope, to the destruction of the seeds of cancer and other diseases without damage to the organs and delicate tissues in which they grow. The ideal of the surgery of the future is that expressed by Huxley in an address to the International Medical Congress in 1881, when he expressed the hope that the advance of therapeutical knowledge would make it possible "to introduce into the economy a molecular mechanism which like a very cunningly contrived torpedo shall find its way to some particular group of living elements and cause an explosion among them, leaving the rest untouched." As Sir John Bland-Sutton says: "What surgeons urgently need is a molecular compound which will either kill the bacteria and cocci that colonize cancer or neutralize their harmful toxins in the same way that salvarsan renders spirochaetes inert without destroying the organs or tissues of their host."

A few years ago it seemed as if the line of progress in the art of healing lay in the gradual transformation of what was once called medicine into surgery; parts of the body which had, till times comparatively recent, been held inviolable by the knife were gradually invaded by the surgeon. Now there are signs that the tide of this revolution is on the turn, and if the surgeon cannot altogether cease to be a craftsman he must, if he is to gain complete mastery of many of the diseases that are even still subject only to the final arbitrament of the knife, put on the armour of the physician.

That the surgery of the future will be to a large extent chemio-therapy is a consummation devoutly to be wished for. It is a dream, but then it must be remembered that it is the dream of one who is himself a craftsman of the highest order. Moreover, it inspires hopes which should encourage workers to strive with redoubled vigour to wrest from Nature the secrets which she has so jealously kept throughout past ages.

ANNUAL MEETING NOTES.

Prolegomena.

The first impression left by Aberdeen is one of spaciousness, solidity, and orderliness, and this is not altered by further experience of the city. Nearly all the streets are wide, and there is such an air of cleanly newness about the whole place that it is difficult to realize that it has behind it a crowded history of many hundred years. There are slums to be found, but they are difficult to realize as slums, because the houses of the slum dwellers are so solidly built and the children playing around them look such healthy little mortals. It is, in fact, on its bare-headed, bare-legged, fresh-coloured children, on its shawl-clad women, and its occasional groups of robust-looking fishermen that Aberdeen depends for such local colour as it possesses. But perhaps the most striking thing of all is to find that one can step out of Aberdeen itself on to a magnificent expanse of sandy shore. The word "step" is used advisedly, for, literally, the very centre of Aberdeen's civic, educational, and commercial activity is divided from a very remarkable natural shore only by a few houses and a street that can be traversed on foot in half a dozen minutes. Between the actual beach and the town limits is a broad strip of green turf, part of which is used apparently as a free golf link, and, except for the presence of one large building, the passage of an occasional tramcar, and a distant view of the harbour lighthouse, there is nothing whatever to suggest the proximity of a great town. This nearness to the sea, coupled with the fact that the shore is not bespattered with artistic villas, is a great addition to the amenities of Aberdeen and a health asset of quite exceptional value. However, it is Aberdeen as a place for a great gathering such as that of the British Medical Association at its annual meetings that is really in question. On this it is sufficient to state that it is lending itself admirably to the needs of the situation. The beautiful edifice known as Marischal College provides ample accommodation not only for the work of the Sections, but of the Council and the Representatives, while the Advocates' Hall, which has been lent for use as a reception room, is distant not more than 150 yards, and is a spacious and luxuriously furnished building. Furthermore, those who represent the hosts of the Association on the present occasion, namely—Sir Alexander Ogston, his first lieutenants, Drs. Thomas Fraser and F. K. Smith, and the chairmen and secretaries of the various committees—have, as will appear in subsequent notes, made the fullest use of all the natural advantages offered by Aberdeen and its general characteristics.

General Arrangements.

The general arrangements are on all-fours with those of previous meetings, but the making of them has been accompanied by unusual difficulties. Scotland does not indulge in bank holidays, but it does, it seems, break off work occasionally not for a day, but for a whole week at a time. One of these occasions was last week, during which neither man, woman, nor child in Aberdeen was disposed to pursue the normal tenor of existence. Fortunately, however, the officials of the meeting, not forgetting the approach of this holiday, took time by the forelock, with the result that, despite all initial difficulties, everything so

far as the visitors are concerned has been working smoothly. The Representatives, on their assemblage on the 24th inst., found everything ready for them, and the balance of preparations were completed by the time ordinary members began to arrive on Monday and Tuesday. Moreover, the Reception Committee, headed by Professor Matthew Hay, with Drs. H. M. W. Gray and H. E. Smith as his honorary secretaries, appear to have drilled in advance all the members of their subordinate staff, for although these were new to work of the kind there has been a happy absence of confusion at the reception room. A further example of the general forethought exercised is the fact that those who arrived in Aberdeen by train found that the Hotels and Lodgings Committee, whose chairman and honorary secretaries are Dr. John Gordon, Dr. F. Philip, and Dr. James Robertson respectively, had opened an office at the station and were ready to help them in the task of finding quarters should they not have done so in advance. On first thought it might seem as if a city such as Aberdeen would find it easy on ordinary commercial lines to house a thousand or more visitors of the professional class, but owing to the presence of many ordinary visitors at this time of the year and other causes, this was not the case. In fact, had not the hospitality of Scotland been a good deal more than proverbial, the position would have been very difficult. As things are, a very large proportion of members attending the meeting are the private guests of Aberdeen's medical and other citizens. It need scarcely be added that there is a good deal of other private hospitality in progress quite apart from the round of entertainments and amusements that the Local Entertainments Committee (chairman, Dr. G. C. Ogilvie Will; vice-chairman, Dr. Albert Westland, and honorary secretaries, Drs. W. F. Croll and W. C. Souter) has been able to arrange. These cater for all tastes, and are on a most elaborate scale. The afternoon occupations include lawn tennis, squash rackets, golf, cricket, visits to hospitals and local industries, and a series of expeditions to various spots of antiquarian interest within easy reach of the town; while for those less energetically inclined there are a series of garden parties, the first of which was given on Wednesday by the Lord Provost, Magistrates, and Town Council of Aberdeen. On Wednesday evening the Court and Senate of the University were at home at Marischal College, and at the hour we go to press an entertainment given by the President and members of the Aberdeen Branch is in progress at what is locally known as the Music Hall, while a general reception and dance, provided by the same hosts, is to follow on Friday evening. Furthermore, the need of occasional repose has not been overlooked, three of Aberdeen's principal clubs having arranged to allow members of the Association to avail themselves of their accommodation. The annual dinner, which is taking place at too late an hour to be more than mentioned this week, has been arranged by the Dinner and Luncheons Committee, whose chairman and honorary secretary are Dr. John R. Levack and Dr. William Brown respectively. It may be stated in advance, however, that Scotland's reputation in the matter of skill in culinary connexions is well sustained by Aberdeen, cleanly tea-shops and luncheon rooms being plentiful. The food, in fact, is so good that members of the Association will certainly not return home hungry. Tired, however, they will certainly be if they take advantage of half that Aberdeen has offered them in the way of social entertainment and active amusements, not to speak of mental recreation and scientific discussions.

Church Services.

Church services always form a part of the proceedings of the Association at its annual meetings, but the day and time on which they take place tend to vary. This year Wednesday was the day chosen, and the hour was the unusually early one of 9 a.m. The more definitely official ceremony was that held in the West Parish Church of St. Nicholas, this being attended by the President and principal officers of the Association, who marched to the church from Marischal College, preceded by the Corporation of the city of Aberdeen. The sermon was preached by Professor Thomas Nicol, D.D., Professor of Biblical Criticism in the University of Aberdeen, and Moderator of the Church of Scotland for the year 1914, and the lessons for the day were read by Drs. John Gordon and Thomas Fraser respectively. Taking as his text Luke xxii, 27, "I am among you as He that serveth," Professor Nicol said that there was a tradition that the Chinese sage and philosopher, Confucius, on being asked to describe the whole duty of man, answered with a single word, "Serve." The fullest and loftiest exemplification of the truth thus conveyed had been given to the world by our Lord Jesus Christ. Service was the most characteristic note of His life, and it was also the sum total of the duty which He required of all who bore His name. The words which were spoken in the upper room and were recorded by the evangelist and beloved disciple St. Luke suggested for brief consideration the example, the mission, and the motive of the finest and noblest service that could be rendered to God and man. As for the example, this service Bacon, in his *Advancement of Learning*, had called seeking "the glory of the Creator and the relief of man's estate," and "the servant" was in the Old Testament one of the prophetic titles of Jesus. He laid aside the glory He had with the Father from all eternity to become a "bond-servant," and He gave obedience to His Heavenly Father's behests, carrying that obedience to the limit of death upon the cross. His earthly life was full of gracious ministry from its commencement to its close, and the gospels were full of the services which occupied His three years of public ministry. His whole life, in fact, was lived in the encompassing element of service and His discourses to His disciples enforced it. On the night when He took the Last Supper with the twelve, He rose from supper and having laid aside His garments and taken a towel and girded Himself, He poured water into a basin and washed the disciples' feet, and wiped them with the towel wherewith He was girded. "I have given you an example," He added, "that ye should do as I have done unto you." By this He recommended that self-denial which was not afraid to stoop to the most menial offices. He exhibited that reverence for what is lowly which is the distinguishing feature of the truest greatness. His death as an example for mankind was the glory and fulfilment of His word, "I am among you as He that serveth." This was His supreme service to His brethren and mankind, and it was this which had crowned Him eternally with glory and honour. As for the mission, the example of service offered by Christ came home with especial directness and power to those who in each generation called themselves His. They formed the great and holy fellowship called the Church, and the mission of this was to continue Christ's ministry, carry out His purpose, and furnish channels for the distribution of His compassion and redeeming grace to the miserable and the sinful. But while the Church occupied this high position in her corporate life, it was permitted to all to share her ministry of help and service, whether in a personal or a professional capacity. Furthermore, the mission to seek the glory of the Creator and the relief of man's estate could nowhere be found better exemplified or more worthily adorned than in that noble profession whose representatives were now assembled in force in the city of Aberdeen. It was a joy to recognize and extol the varied, efficient, and Christ-like service rendered by them in fighting sickness and disease, and in bringing relief and alleviation to the pains and woes of suffering humanity. All must freely admit that the many unselfish and unremunerated services of medical men, the courage which carried them often into the very valley of death, their

discoveries, which, like those of Sir J. Y. Simpson, had often blessed humanity on a large scale, and the fashion in which they applied skilled and highly trained intelligence to the investigation of disease and the search for its remedy, and thus brought about a reduction of the death-rate and the more general diffusion of health in many communities, were exemplifications of the spirit of Him who said "I am among you as He that serveth." As for the Motive, those who served did so because they loved, and "they loved because He first loved them." Man could not give up the incarnation, the historic life, death, resurrection, and ascension of the Son of God and yet retain those desires for social progress, those impulses towards self-sacrificing benevolence and altruistic service which flow chiefly from the example of Christ and were sustained by His living spirit. Humanity in its active aspects of pity for suffering and patient service for fellow men had the surest pledge of its continuance as a moral force in the Divine Fatherhood and the revelation of God in Christ stooping to the lowliest of services. In the medical profession not less than in the more directly sacred profession of the ministry, men would draw their most potent inspiration from Him who came not to be ministered unto, but to minister, and Who said to the disciples Whom He trained and commissioned to continue His ministry "I am among you as He that serveth."

At the same hour—9 a.m.—Mass was celebrated at St. Mary's Cathedral by His Lordship, Dr. Æneas Chisholm, Roman Catholic Bishop of Aberdeen, an address being subsequently delivered by the Right Rev. Monsignor Meany. This proved to be of so succinct a character that we are able to reproduce it practically in full. Taking as his text Ecclesiasticus xxxviii, 6, Monsignor Meany said: The thought which naturally rises in my mind when I see you gathered round this altar is to welcome you in the name of the Church, which established at Aberdeen the first Chair of Medicine in this country. Aberdeen is proud to acknowledge that she owes to the illustrious Bishop Elphinstone the foundation of that chair. It is fitting that you should to-day, under the guidance of Elphinstone's successor, thank God for an act of wisdom and beneficence which brought science and mercy to our forefathers. What the plight of those forefathers must have been in their time of sickness is painfully revealed in a quaint contemporary Statute of English Law. It was found in England that "common artificers, smiths, weavers, and women practised physic and surgery, to the high displeasure of God, the great infamy of the faculty, and the destruction of many of the King's lieges" (3 Henry VIII, ch. 11, 1511). If that description is a true account of the state of the medical profession in England at the opening of the sixteenth century, I fear that our ancestors in the North must have suffered even more than their English neighbours, and no doubt they learnt to be grateful to the fostering care of the Church which, for the relief of human misery, introduced systematic study of the healing art. In those days doctors were examined and licensed by Bishops. But if your Bishops to-day cannot claim to exercise such a versatility of knowledge, they do claim, and the Church of God with them, to encourage and promote your studies, to bless and to extol your work. So in the Holy Sacrifice we implore for the deliberations of your Congress the protection and the enlightenment of God. We pray that God may grant you deeper insight and extended resource, for we understand on the authority of the Word of God Himself that "the Most High hath given knowledge to men that He may be honoured in His wonders" (Ecclesiasticus xxxviii, 6). To you such knowledge does not mean the mere acquisition of learning. It signifies much more. It means for you the possession of a gift which manifests to you the wisdom, the power, the love of God. It involves for you the ability and the will to honour God by applying to the infirmities of men the wonders of God, of raising up for His glory those who are sick and wounded along the way of your life. This suggests to me that for years I have longed for an opportunity of saying publicly how much I value the help given to me in the course of my ministry by doctors who are not of our faith. It has never been my good fortune to work with a Catholic doctor. But I have everywhere, both in country and city, met with the most devoted assistance, advice, and sympathy from the medical men whom I have been privileged to know. I have found them ungrudgingly charitable to the poor. I have found them tender and delicate in their thought for the poor. I have found them interested, far beyond the strict sphere of medical work, in the welfare of the poor. I have found that they looked with eyes of reverence on the ministration of the Church, that they appreciated the place of a priest at the bedside of a patient, that they warned me when religious rites were necessary or expedient. And I desire to say here with all the solemnity worthy of this sacred place, and in a sense of profound gratitude, that the world does not know, and could not estimate if it did know, the immense debt which our people owe to the medical profession. Besides, we priests ourselves, when illness comes upon us, have ever at our command the services of those medical men to attend us, to soothe us, to cheer us. I know there is some etiquette, some unwritten law which places us on the free list of doctors, but my experience has been that we were tended with a minute and searching care, with assiduity, and a refinement of intelligent kindness that no words can express, and no payment reward. It is a pride and a pleasure for me—a duty which I am thankful to discharge—to offer some belated tribute to your noble colleagues. I should like to make you the messengers of our gratitude and our respect. For yourselves, I have only two thoughts to put before you. "The Most High has given you knowledge that He may be honoured in His wonders." "To whom much is given, of them much shall be required." What is required of you is that in the midst of your work, in your studies you should keep a supernatural outlook—see with the eye of faith "the invisible things" of God, from your understanding "of the things that are made." Cultivate divine patience when you are confronted with the mystery of suffering. Strive to grow day by day in forbearance when you are in touch with the querulousness, and helplessness, and unreasonableness of the sick, for "patience hath a perfect work."

A service was also held in the Cathedral Church of St. Andrew, where an address was delivered by the Lord Bishop of Aberdeen and Orkney. In the Book of Revelations, he said, there was described as standing in the midst of the new Jerusalem a tree whose never-failing supply of fruit was for meat and its leaves for the healing of the nations. This detail served to recall the fact that the work of the medical profession was not merely noble, it was also sacred. He who devoted himself worthily to it served not only his fellow creatures, but also in a special sense his God. The history of the healing art reached back to the dim primaeval days, when man sought blindly for the first-rule remedies for his hurts and his diseases; and as knowledge of the ancient world grew wonder increased at the accumulating evidence of medical and surgical skill in bygone days. Still, it had been reserved for those living in the present age to behold the most wonderful developments in this direction. It had been justly claimed that in little more than a century a united profession working in many lands had done more for the race than had ever before been accomplished by any other body of men. So great had been these gifts that appreciation of them had almost been lost. Vaccination, sanitation, anaesthesia, antiseptic surgery, the new science of bacteriology, and the new art in therapeutics had effected a revolution in civilization to which the extraordinary progress in mechanical arts was alone

comparable. A medical man of the present day had more than a long and splendid ancestry behind him. His work was one which called forth many of the finest qualities of the human character, such as patience, self-control and equanimity, hope, strength, and cheerfulness; last, discernment and sympathy mingled with firmness and humanity based on knowledge. The good physician or surgeon gave to his patients more than medicine or skill. He imparted from the resources of his own character impalpably and yet really the healing influences of his own higher self. On the other hand, what lessons—sometimes saddening, sometimes uplifting—must he carry away from the silent confessional of the sick bed; what revelations of character, what unmasking met him there as human nature faced bravely or otherwise the pains of sickness or the approach of death! Rightly, then, was the physician honoured; that was due to him, and rightly has time been found at this busy congress to meet in the House of God. Let the thought go forth with them that their profession is a sacred one. Let their ideal be as high as Heaven itself. Let them not be satisfied to do their work in a mere rut, which could only deepen as the years went on. Let their work find its supreme inspiration in the vision of God upon His throne, and the Tree of Life, whose leaves are for the healing of the nations.

The Representatives.

The Representative Meeting did not actually commence in the train, but the "Flying Scotsman" on Thursday was highly medicated. At King's Cross, London; York, Newcastle and Edinburgh, so many Representatives joined the train that a "quorum" was formed long before reaching Aberdeen. A good many were crossing the border for the first time, and from remarks made it was clear that some among them had not specialized in geography. Lunch and dinner were served in the train, the demand for food being greater than the supply in the case of those who waited for the second sitting down. It was an ideal day and the long run "beside the seaside" was greatly enjoyed. On Friday, at 10 a.m. precisely, the Representatives assembled in the Mitchell Hall, which graces the magnificent College, credibly described by the guide book as the "largest granite building in the world." There were many familiar faces and when the talking began not a few familiar voices. Work began promptly, but a certain number of members did not seem happy as to the positions they had taken up and eventually established themselves in the galleries on either side; the fronts of these are of beautifully carved wood, the upper portion of the walls and the roof being built of dull polished Correnie granite. The roof is a particularly fine piece of Gothic architecture, studded with electric lamps. At the east end, behind the chair and platform, is a magnificent historical window, representing in stained glass the history of Aberdeen University since its foundation, pictures or arms of principal, rectors, and other eminent men connected with the College, being incorporated in the scheme. Such was the "setting" of the meeting. The surroundings created an atmosphere of harmony and grace altogether inconsistent with tumult and vexatious discussion. Good humour prevailed. To sum up general results, old Representatives declare that the Aberdeen meeting has done much to strengthen the Association and encourage unity in the profession. An excellent group was taken by a local photographer on Friday in the College Quadrangle. Some amusing incidents reminiscent of never-to-be-forgotten student days created diversion on this occasion. The Representatives' Dinner, which owes its introduction to a happy inspiration dating back some years, duly followed in the evening, when Mr. Verrall presided over a gathering of about 150, the Aberdeen guests being Dr. Thomas Fraser, Dr. F. K. Smith, and Dr. Pirie. The drinking of the usual loyal toasts was the only formal after-dinner proceeding, but the names of those ready to contribute to a general entertainment were sent up to the chairman, and much talent for song, recitation, and tale telling was disclosed. By way of getting through Sunday the local executive had made arrangements for an expedition to Cruden Bay. The morning was dull, cold, and threatening, and in the circumstances it was somewhat surprising to find such a large number of ladies and Representatives at the station. A special train (Great Northern of Scotland) left punctually at 10.30, arriving at Cruden Bay at 11.15. Many members were soon on the links, and the round was so enjoyable as to induce many to take a second round after lunch. The sands at Cruden are a special feature. That important element, the weather, did not bear out the early morning foreboding, and, greatly to the delight of all, the afternoon was bright and the sunset beautiful. Lunch and afternoon tea were served at the Railway Hotel. Many strolled for miles along the beach, some in the direction of the Scaurs and others to Bullers o'Buchan, past Slains Castle, from which Dr. Johnson wished to see a shipwreck. Altogether the outing was a pleasant and enjoyable relief from the strenuous preceding days at the Representative Meeting. Dr. Scott (Aberdeen) acted as cicerone to the party. Work was recommenced on Monday, and by 6 p.m. on Tuesday evening the Representative Meeting of 1914 was at an end.

Lady Visitors.

The arrangements for the comfort and entertainment of ladies accompanying members to the meeting are in charge of a general committee, formed solely of ladies, and five subcommittees, and are of a most extensive character. Apart from accommodation at the General Reception Room, a kind of club for their benefit has been constituted in the rooms of the Aberdeen Medico-Chirurgical Society, and a flat in the very centre of the town has been lent for the purpose of allowing those staying outside the town to change their attire before attending evening entertainments. A further distinctive feature of this year's meeting is the formation of a corps of lady guides. Lady visitors have also been made honorary members of the Aberdeen Ladies' Golf Club, and two matches have been arranged for them. Furthermore, four tennis clubs have placed their courts at their disposition from 10 a.m. onwards. The formal amusements provided for ladies in particular commenced as early as Tuesday morning, when a certain number were invited to visit the Aberdeen Art Gallery under the cicerouage of Mr. Alec Fraser, and others to visit the Day Nursery and the Maternity Hospital. On Wednesday morning there was an attractive exhibition of Highland dancing and bagpipe playing in the ball-room of the music-hall, as well as an expedition in private motor cars to Drum Castle, and visits to institutions of special interest to women within the limits of the city itself. Among the institutions to be visited by them in the course of the week is one which, so far as we are aware, has no counterpart in England; it is a home for widowers' children. The arrangements in view for Thursday and Friday are of a corresponding character to those on Wednesday, one especially interesting item on the first of these days being an examination of St. Machar's Cathedral, under the guidance of the Rev. Dr. Bruce M'Ewen, and a visit to King's College Chapel and Library, conducted by the Rev. Professor Cowan and Miss Robertson. The convener of the Ladies' General Committee, which numbers nearly ninety ladies, was Mrs. Harrower, and its honorary secretary Mrs. Carter, while Mrs. Thain was convener of the Games and Entertainments Subcommittee, Miss Pirie and Miss Westland being its honorary secretaries. The arrangements for visiting institutions have been made by Mrs. G. B. Esslemont and Mrs. Glegg, those for morning drives by Mrs. Hay and Miss Grainger Stewart; and Mrs. G. Williamson and Mrs. H. M. W. Gray have taken charge of the tea and reading room

arrangements. At the time of going to press the full fruits of their work still remain to be seen, but, judging by the success of the arrangements on the first three days of the week, lady visitors seemed certain to leave Aberdeen with the happiest of memories alike of their hostesses and of the city itself.

FOREIGN GUESTS.

JUST before the President delivered his address on Tuesday evening there were presented to him a number of foreign guests and delegates and other representatives of Branches of the Association beyond the seas, and as in former years this ceremony proved a popular feature. The list of foreign medical men selected for the honour included Professor Karl Gauss of Freiburg, who has come over for the purpose of describing the results he has obtained by the *x*-ray treatment of fibroids; Professor Stéphane Leduc of Nantes, a leader in the field of electricity in its relation to cerebral physiology; Dr. E. Pontoppidan, Professor of Medical Jurisprudence at Copenhagen; Dr. Clemens von Pirquet, Professor of Pediatrics at Vienna; Dr. Umberto Gabbi, Professor of Tropical Medicine at the University of Rome; Dr. Karl Jung, Professor of Psychiatry at the University of Zürich; Dr. Alban Bergonié, Professor of Biological Physics and Medical Electricity at the University of Bordeaux; Dr. H. Morestin, Professor of Surgery in the medical faculty of the University of Paris, and Surgeon to the Tenon Hospital; Dr. Rist, one of the Physicians of the Laënnec Hospital, and Professor of Clinical Medicine in the same University; Dr. Fritz Frank, Professor of Midwifery at Cologne; Professor D. S. Demetriades of Athens; Professor Adelf Onodi, the laryngologist of Budapest, who has been the guest of the Association on more than one previous occasion; and Dr. J. R. Macleod, Professor of Physiology at Cleveland, U.S.A. Most of these bear names which are already well known to members of the Association through references to their writings in the pages of the BRITISH MEDICAL JOURNAL itself, or in its Epitome of foreign literature relating to medicine and surgery and their various departments.

REPRESENTATIVES OF OVERSEA BRANCHES.

By no means all oversea Branches of the Association were represented at the meeting, but a sufficient number of them figured on the list of presentations to bring vividly to mind the fact that members of the Association are now to be found in organized groups in practically every part of the world. Particularly well represented were Indian and Australasian Branches, the names of members of Middle Eastern Branches outnumbering those of Australasia by just one. Most of those on the South Indian and Madras list were members of the Indian Medical Service; they included Lieutenant-Colonel R. H. Elliot, Major F. F. Elwes, Captain J. Forrest, Major E. M. Illington, Captain A. C. Ingram, Lieutenant-Colonel R. K. Mitter, Captain D. S. A. O'Keeffe, Major T. H. Symons, and Major C. G. Webster. The Bombay Branch sent Major E. F. Gerden Tucker; the Punjab Branch, Captain S. H. Lee Abbott and Lieutenant-Colonel H. Smith; the Burma Branch, Lieutenant-Colonel J. Penny; and the Malaya Branch, Drs. G. A. Finlayson and P. Fowlie. As for the Australasian list, it was made up as follows: there were six members of the New South Wales Branch—namely, Drs. George Allan, W. H. Crago, L. Herschell Harris, E. T. Thring, J. Grenville Waine, and A. Murray Will; and two from the South Australian Branch, Drs. A. A. Lendon and H. Swift; two from the Victorian Branch, Drs. H. Cordiner and Hamilton Russell; one representative of the West Australian Branch, Dr. H. O. Teague; and one each from the Tasmanian and New Zealand Branches respectively, namely, Drs. Hugh Armstrong and A. A. Martin. Apart from these six, Branches of the Association situated in different parts of Africa—north, east, and south—were represented by delegates; while there were also present at the meeting, we believe, several medical men from the West Coast. Confining ourselves, however, to the official list, this included the names of Drs. M. N. McFarlane and D. M. Tomory, of the Orange Free State and Basutoland Branch; of Drs. J. J. Boyd and A. W. Sanders of the Pretoria Branch; of Dr. Julius Petersen, of the Cape of Good Hope Branch; of Drs. P. P. J. Ganteaume and R. J. Love of the Border Branch and Natal Branch; of Dr. C. A. Wiggins of the East Africa and Uganda Branch; and of Dr. Llewellyn Phillips of the Lower Egypt Branch. The extreme east and the extreme west—namely, China and Canada respectively—also found place on the list, the latter being represented by Dr. R. A. Reeve, Professor of Ophthalmology at the University of Toronto; and the former by Drs. C. T. Griffin and G. M. Tharsten; while the Mediterranean sent Dr. A. W. Dowding of Gibraltar.

HONORARY DEGREES.

AMONG those upon whom the University proposes to confer honorary degrees at a meeting of the Senate on Friday are understood to be Mr. W. T. Hayward, Consulting Surgeon to the Children's Hospital, Adelaide, South Australia; Mr. T. J. Verrall, Sir Victor Horsley, Dr. Archibald Garrod, and Sir John Bland-Sutton. The degree to be bestowed is the Doctorate in the Faculty of Law.

THE WAR AND THE MEETING.

THE outbreak of a war in the Balkan area, which is creating such confusion in the Chancelleries of Europe and such disturbance on the markets of the world, is not leaving untouched even the Annual Meeting of the Association. In anticipation of what has actually occurred, more than one Continental authority who was expected to take part in the work of the Sections thought it wise to abandon the project, and one at least—namely, Professor Onodi of Budapest—had to leave Aberdeen almost as soon as he had arrived on news reaching him that mobilization of the Austro-Hungarian army had been ordered.

PRESENTATION TO PROFESSOR STEPHENSON.

THE successful portrait of William Stephenson, Emeritus Professor of Midwifery, was on view on Monday, and was presented to him on Tuesday afternoon at a large gathering of his old pupils and other members of the medical profession wishing to do him honour. The presentation was made on behalf of the numerous subscribers by Professor Matthew Hay, and, in acknowledging it, Professor Stephenson mentioned that of his old boys, as he called them, as many as eight were, or had been, Professors of the University of Aberdeen.

PATHOLOGICAL MUSEUM.

MEMBERS found that the Pathological Museum Committee, under the able chairmanship of Dr. G. M. Duncan, had prepared an effective array of specimens illustrative of the work in various sections together with other specimens relating to recent work in the fields of tropical medicine and the physiology and diseases of the circulatory system. We propose to deal in detail with individual Sections and specimens in a later issue, but it may here be stated that on a preliminary survey we were especially struck by a Section illustrative of recent research, which is a newcomer to these annual exhibitions.

HISTORY OF MEDICINE.

PERHAPS, however, the most noteworthy exhibits of all were those which had been collected and arranged by Dr. W. J. Dilling. They set forth the history of medicine from early Egyptian times. Especially striking was a large collection of portraits of eminent medical men of the past arranged in alphabetical order from Abercrombie to

von Ziemssen. For this unique collection of engravings the Pathological Committee was indebted to Mr. J. F. Kellas Johnstone of Aberdeen.

Annual Exhibition.

The annual exhibition this year is very happily situated, the two rooms devoted to it being next to that occupied by the Section of Electrotherapeutics and Radiology and in Marischal College, which is housing all the Sections. There have been larger exhibitions at some previous annual meetings, but none at which the skill and resource of manufacturers in seizing on every fresh suggestion in the way of treatment, and making it practically available to every one, has been better illustrated. All classes of medical and surgical appliances, drugs, foods, furniture and laboratory apparatus are well represented; the characteristic of the exhibition as a whole being, perhaps, its strength in stalls devoted to modern medical literature. The exhibition, in short, serves once more, as a kind of illustrated edition of the advertisement pages of the medical journals and as a mine of new ideas to those who are too much absorbed in the daily cares of practice to have time regularly to study their Journal from end to end. As a special sign of the times it may be observed that one stall this year is devoted to books and pamphlets dealing with prostitution and the prophylaxis of venereal diseases, the holder of this stall being the British Branch of the International Abolitionist Federation. There is, however, practically no stall on which is not to be seen some novel example of the services rendered to science by manufacturing art. It is to be hoped, therefore, that all members will contrive to visit the exhibition, since occasions are rare on which so much that is new can be seen and thoroughly examined with so little trouble. The exhibition was kept open during the reception given by the university authorities on Wednesday evening, and will not close until 6 p.m. on Friday night. At a later date we hope to give detailed account of some of the more interesting things which were on view.

The Sections.

The sixteen Sections among which the scientific proceedings of the meeting are divided began work promptly on Wednesday, and are being well attended. It is generally agreed that at no previous meeting has the accommodation provided for them met the needs of the situation more satisfactorily. Some account of the discussions held in each Section on the first day will be found elsewhere in this issue. The atmospheric conditions prevailing during the week have added considerably to the anxieties of those in charge of the meeting, and increased the labours of all concerned by necessitating the provision of protection from the weather at garden parties and the like. Fortunately, however, there has been no interference, up to the hour of going to press, with the enjoyment by visitors of the multiplicity of arrangements made for their benefit. No rain has fallen during the day, and the profusion of flowers, excellently fresh strawberries, and other fruit grown in the open air, are serving as evidence that the relatively low temperature and overcast skies are quite abnormal samples of Aberdeen weather in the summer time.

The Irish Graduates' Luncheon Party.

The luncheon at which it is the hospitable habit of the Irish Medical Schools' and Graduates' Association to entertain many guests during the annual meeting of the British Medical Association took place this year at the Grand Hotel, Aberdeen, on Wednesday, July 29th, under the chairmanship of Dr. W. Douglas, president of the association. Among the guests, in addition to the Chairman of Council, the Chairman of Representative Meetings, and the Treasurer of the British Medical Association, were Dr. Chisholm, Roman Catholic Bishop of Aberdeen, and several other distinguished clerics. After the toast to the King, given by the Chairman, had been honoured with special warmth, the toast of the British Medical Association was proposed by Dr. F. E. Wynne and acknowledged by Dr. J. A. Macdonald; the toast to the Irish Medical Schools' and Graduates' Association was proposed by Sir James Barr and acknowledged by Dr. Crampton, who said that he believed it was the only association in which Irishmen of all political opinions and religious views met on common ground without any risk of misunderstanding. He mentioned that of the 120 foundation members of the association as many as 25 still survived.

A Temperance Crusade.

For over forty years past a breakfast organized by advocates of total abstinence has formed a standing feature of all annual meetings of the British Medical Association, and members received an invitation to one as soon as they arrived in Aberdeen. It took place on Thursday under the chairmanship of Mr. Alexander P. Forrester-Paton, President of the Scottish Temperance League, which on the present occasion shared the position of host with the National League, and later we hope to give an account of some of the speeches that were delivered when the breakfast was over. This event, however, was not the only evidence of the activity of the temperance party, for on the Sunday preceding the meeting, or rather, on the Sunday intervening between the commencement of the Representative Meeting and the assemblage of ordinary members, a large number of addresses were delivered by members of the medical profession. Some of them took the place of sermons at ordinary services at places of worship, and others were delivered at special meetings. The following list of the titles of some of the addresses will perhaps sufficiently indicate the line taken by the speakers as a whole: Does alcohol increase efficiency? (Dr. G. A. Pirie); Recent changes in the use of alcohol in the treatment of disease (Mr. C. W. Cathcart); National efficiency and drink (Dr. J. Mackie Whyte); The influence of moderate quantities of alcohol on the functions of the brain (Dr. James Ritchie); Alcohol and nerves (Dr. A. B. Olsen); Some lessons from a medical man's experience; (Dr. A. W. Russell); Medical reasons for temperance (Mr. J. Furneaux Jordan); Drink in hot climates (Dr. P. E. Giuseppi); Alcohol and its power (Dr. Robert Milne); Alcohol as seen by a Christian medical man (Sir Alexander Simpson); Concerning arguments in favour of alcohol (Dr. W. L. Reid). The special meetings included one for women, at which Lady Horsley presided, and Dr. Mary Sturge delivered an address, entitled, "What shall I drink?"; while at another special meeting for women Dr. Beatrice Webb spoke on alcohol in relation to the health of girls. Sir Victor Horsley addressed the Young Men's Christian Association on alcohol as the enemy of brotherhood, being introduced to the meeting by Professor Matthew Hay, who described what could be done with the amount spent annually in Aberdeen on alcoholic beverages if it were devoted to local improvement schemes.

On Thursday, Sir Alexander Ogston was entertained at luncheon by his old house-surgeons and dressers.

The number of members registered up to 3 p.m. on Thursday was about 1,000; there were also some 500 ladies present.

Professor J. C. Bose, of Calcutta, will deliver a lecture before the Royal Society of Medicine, on October 30th, on the modification of response in plants under the action of drugs. Professor Bose hopes to illustrate his lecture by the demonstration of experiments upon sensitive plants which he will bring with him.

THE TITLE OF "PROFESSOR."

WHEN Matthew Arnold held the chair of poetry at Oxford his delicate sensibility was offended by the title of "Professor," which he thought derogatory, as it was associated in this country with conjurors and exhibitors of "ghosts." It has fallen much lower than this, for we have ourselves seen on a hairdresser's shop at a watering place on the South Coast the description "Professor of Trichology." In Germany, however, the title of "Professor," if not quite so sacrosanct as that indicating the rank of an army officer, carries with it considerable prestige. Certain revelations made recently by a member of the Reichstag as to the existence of a regular traffic in honours caused a great sensation in Germany, where apparently the sale of titles as a means of replenishing the war chest of a political party is not so familiar to the public mind as it is in some more democratic countries. An eminent surgeon long since gathered to his fathers used to be known as the "Solicitor-General" from his insatiate appetite for orders, but the most eager seeker for such honours here would not dream of asking for the title of "Professor of Medicine." He might indeed try to get the office, but that is another matter. It would seem that of all titles made in Germany "Professor of Medicine" is the most costly. The best and most expensive brand is the Prussian. It must be remembered that "Professor" in Germany is a title which may be conferred by the Emperor as a distinction independent of any connexion with a chair in a university. From documents published in the *Vorwärts* it would appear that a good many Prussian doctors have actually bought the title. The procedure is said to be quite simple for any one who is prepared to pay the price asked. The candidate first hands over £280 to some one who, like Bunty, can pull the strings; then he must publish a small treatise on some medical subject. He need not trouble about the value of this contribution to professional literature: that is considered of no importance. The thing is only intended to save the face of the authorities who dispose of titles, by showing that the candidate has given some attention to medical matters. We may without rashness hazard a guess that the aspirant to the title of "Professor" could get some one else to write the book—for a consideration—as used to be done in the case of theses for the degree of Doctor. From Jews and foreigners a bigger price is asked. The moral appears to be that a German professor unattached need not be accepted as an oracle of medicine on the mere strength of his title.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

The Midwives (Scotland) Bill.

THIS bill has now passed through the Standing Committee on Scottish Bills, and is to a great extent in line with the corresponding Act applying to England.

Under the first clause, after January 1st, 1916, no woman, except as certified under the Act, shall take or use the name or title of midwife or any other equivalent title, and penalties are imposed for so doing. After January 1st, 1921, no woman "shall habitually and for gain attend women in childbirth otherwise than under the direction of a registered medical practitioner, unless she be certified under this Act." No woman can be certified under the Act unless she has complied with the rules and regulations laid down under it, and no woman certified under the Act can employ an uncertified substitute, and no certification under the Act provides any right or title to be registered under the Medical Acts and to assume any title implying the same.

Clause 2 enumerates the institutions which can provide certificates in midwifery and gives powers to the Central Midwives Board of Scotland to recognize such other institutions as they may approve.

Clause 3 sets up the Central Midwives Board: Three persons to be appointed by the Lord President of the Council, two of whom shall be certified midwives practising in Scotland; four persons are to be appointed, one by the Association of County Councils for Scotland, one by the Convention of the Royal Burghs of Scotland, one by the Queen Victoria Jubilee Institute for Nurses (Scottish Branch), and one by the Society of Medical Officers of Health; five registered medical practitioners are also to be appointed, one by the University Courts of the Universities of Edinburgh and St. Andrews conjointly, one by the University Courts of the Universities of Glasgow and Aberdeen conjointly, one by the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow conjointly, and two by the Scottish Committee of the British Medical Association. It is further provided that every five years after 1920, the Board shall retire from office together, and shall be eligible for reappointment.

Under Clause 4 the Board may represent to the Privy Council that it is expedient to modify the constitution of the Board in various ways, but before giving consent to the modifications recommended the Privy Council shall cause the representations to be laid before both Houses of Parliament.

Clause 5 details the duties of the Midwives Board relating to the regulating of the issue of certificates and the conditions of admission to the roll of midwives; the course of training and conduct of examinations; admission to the roll of women already in practice as midwives at the passing of this Act; the supervision of their practice; the conditions under which they may be suspended; the appointment of examiners; the provision of a roll of midwives and the removal of midwives from the roll, and other matters.

Clause 6 relates to the power of the Board to frame rules suspending midwives; and under Clause 7 the Board may, if it think fit, pay certain expenses incurred by midwives who appear before it.

Clauses 8, 9, and 10 relate to offences.

Clause 11 relates to the reciprocal recognition of midwives; and under Clause 12 a midwife who is aggrieved by any decision of the Board is entitled to appeal therefrom to either division of the Court of Session within three months after the notification of such decision.

Clause 13 relates to the provision of the expenses of midwives presenting themselves for examination.

Clause 14 provides what the roll shall contain.

Under Clause 15 the Board is authorized to appoint certain officers; and under Clause 16 it is provided that the local authority of every district in which the Act is operative shall, on the commencement of this Act, be the local supervising authority for that district, and the duties of the local supervising authority are set out in this clause. They relate to the general supervision over the midwives practising in their area; to the investigation of charges against them and the reporting of such charges to the Board; to the suspension of midwives and the notification to the Board of removals and changes of addresses. The local supervising authority may delegate its duties to subcommittees.

Under Clause 17 an officer appointed by the authority may enter at reasonable times lying-in homes which he has reason to believe are conducted for profit within the district.

Clause 18 requires the midwife to give certain notification of her intention to practise, and Clauses 19 and 20 provide penalties for misstatements.

The local supervising authority under Clause 21 may contribute towards the training of midwives.

Clause 22 is an important clause from the point of view of medical men, as it relates to the conditions under which fees can be paid to medical men who are called in by midwives, and it may be of interest to give the clause in full:

22. *Medical Assistance in Case of Emergency.*—(1) In case of an emergency as defined in the rules framed under Section five (1) (*c*) of this Act, a midwife shall call in to her assistance a registered medical practitioner, and the local supervising authority shall pay to such medical practitioner a sufficient fee, with due allowance for mileage, according to a scale to be fixed by the Local Government Board for Scotland, and such fee shall cover one subsequent visit.

(2) It shall be a condition of the payment of such fee that the medical practitioner so called in shall state in his claim to the local supervising authority the nature of the emergency.

(3) The midwife shall report forthwith to the local supervising authority each case of emergency in which she has called in a registered medical practitioner to her assistance, stating the nature of the emergency and the name of the medical practitioner.

(4) The local supervising authority shall have power to recover the fee from the husband or guardian of the patient as an alimentary debt, unless it be shown to their satisfaction that such husband or guardian is unable by reason of poverty or ill-health to pay such fee.

The remainder of the clauses up to the last—Clause No. 30—relate to definitions and sundry minor matters; and under Clause 25 it is provided that any expenses under this Act payable by the local supervising authority shall be defrayed out of the public health general assessment.

The Housing Bill.

The Government's Housing Bill was read a second time without a division on Friday, July 24th. In introducing the bill, Mr. Runciman explained that there were two parts of it—the one dealing with the provision of cottages in agricultural districts and the other relating to the provision of cottages for workmen in the direct employment of the State, particularly at Crombie and Rosyth. It was evidently anticipated by Mr. Runciman that, in view of the state of public business, it might only be possible to secure the portion of the bill dealing with Rosyth, and with the housing of Government employees in other places. In the subsequent debate it was indicated that this might possibly be the fate of the bill. The Admiralty desires to provide 3,000 cottages at Rosyth, which will involve the spending of something like £1,000,000, including the cost of sewers, roads, and other necessary improvements. Mr. Runciman dealt with the small progress which is being made in the provision of cottages in agricultural districts, and he pointed to the financial and other difficulties which frequently stand in the way of private landowners in providing the necessary cottage accommodation, and he gave some interesting illustrations as to the inactivity of local authorities in respect of administering the powers which they possess under the law at present. In many parts the question of housing has never been raised at council meetings, and has received brusque treatment when it has been raised. The fear of increasing the rates, the fear that if the provision of houses were started in one district it would lead to the demand in another, the difficulty of obtaining land and the fear of interference with private enterprise—are all contributory reasons. Under the bill, the financial provision will be at the disposal of local authorities and of public utility societies of approved kind which do not operate for private profit. In the case of the local authorities, the whole of their capital expenditure may be provided by the State on approved schemes. In the case of the public utility societies nine-tenths of their capital expenditure may be provided by loans covering a minimum period of forty years and a maximum period of sixty. There is to be no sinking fund charge in the rent on the cost of the land. The cottages generally are to be provided with gardens. It is anticipated that, as has already been the case in some areas, County Committees will be set up, with which the Board will deal in the main. For the present it is proposed that £3,000,000 should be set aside for the purposes of the provision of cottages in agricultural districts, and it is intended that they should be let at economic rents. Mr. Forster, Mr. Prothero, Mr. George Roberts, Sir Arthur Griffith-Boscawen, Mr. Aneurin Williams, Mr. Long, and other members joined in the discussion, which, while critical in detail, was on the whole friendly to the bill. The bill was finally committed to a Committee of the whole House on a division of 214 votes to 84, and the necessary money resolution passed through its Committee stage.

Fatal Accidents in Factories.—Mr. Morrell asked the Home Secretary whether, in view of the large and continual growth in the number of fatal accidents occurring in factories and workshops in recent years, he would grant a return of all such accidents for the past year showing the name, age, and occupation of each person killed, with date of accident, cause of accident, and description and name of owner of factory or workshop in which the accident occurred, similar to the list of fatal accidents contained in the reports of inspectors of mines and quarries; and would he require the insertion of such particulars in future reports of the Chief Inspector.—Mr. McKenna in reply said the subject of a return by the Departmental Committee on Factory Accidents took the view—with which he agreed—that what was important was the preparation of careful analyses of the accidents in particular trades or districts. Tables giving detailed information for specific trades had been published in the annual reports of recent years—as, for example, for cotton spinning in 1909, shipbuilding in 1910, locomotives and motors in 1911, and iron and steel foundries in 1912—and other trades would be dealt with in the same way. Statistics in this form should, in his opinion, be much more valuable for purposes of prevention of accidents than unclassified particulars of individual accidents spread over the whole body of miscellaneous industries. In reply to Lord H. Cavendish-Bentinck, Mr. McKenna said they were constantly taking legislative steps to diminish the number of fatal accidents.

Mortality of Seamen (Committees).—In reply to Mr. Peto, Mr. Robertson said the Committee was purposely made small in number, and limited to officers of the three Government Departments primarily concerned—the Board of Trade, the Local Government Board, and the General Register Office. He did not think it would serve the purpose in view to enlarge the Committee so as to include representatives of the large number of bodies which might be interested in, or have personal experience of, the matter before the Committee.

Suffragist Prisoners (Forcible Feeding).—Mr. Jowett asked the Home Secretary whether he consented to receive a deputation from the Forcible Feeding Protest Committee of Medical Men on July 15th, at 4 p.m.; and whether that deputation withdrew, and for what reason.—Mr. McKenna: I had consented to receive a deputation as described in the question. The deputation brought with them a reporter, and stated that they desired to publish the proceedings. I had understood that they wished to represent certain views to me personally, and I should have been glad to listen to them; but, inasmuch as the subject involved the discussion of the cases of individual prisoners then undergoing sentence in Holloway, I could not agree to be a party to a public discussion with them of such cases. The deputation then withdrew.

Removal of Prisoner to Bucks County Asylum.—Mr. Wedgwood asked the Home Secretary whether Harry Humphries was sent to the Bucks County Lunatic Asylum because he hunger-struck in prison; and who were the doctors who certified him insane, and how long he intended to keep him in this asylum.—Mr. McKenna: This man was transferred from prison to an asylum in pursuance of a certificate of insanity submitted by two magistrates and two registered medical practitioners under the Criminal Lunatics Act, 1884. He will remain under the provisions of that Act till the expiration of his sentence in February next, unless he should be remitted to prison or discharged from then. The reports before me do not justify the adoption of either of these courses at present, but the case will be further considered in due course.

Medical Officers and Sanitary Inspectors.—Mr. C. Bathurst asked the President of the Local Government Board whether he proposed to issue before the end of the session a general order which would secure for district medical officers of health and sanitary inspectors greater security in the tenure of their office; and, if so, when such order would be issued.—Mr. Herbert Samuel said the matter was still under consideration. He hoped to be able to come to a conclusion on it at an early date.

Indoor and Outdoor Relief (Ireland).—In reply to Mr. Ffrench, Mr. Birrell said the numbers of paupers in workhouses and on outdoor relief on January 2nd, 1909, were 44,035 and 56,501, respectively. The numbers in workhouses and on ontdoor relief on July 4th, the latest date for which the information was available, were 32,554 and 37,792 respectively. The reduction in the numbers was doubtless largely due to the Old Age Pensions Acts.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

LIVERPOOL.

Opening of the "Sir Alfred Jones" Tropical Ward in Royal Infirmary.

This ward, with its annexe for students, was opened with great *éclat* on July 23rd, by the Countess of Derby, who was presented with a gold card case as a souvenir of the occasion. Its establishment has been rendered possible by the will of the late Sir Alfred Jones, founder of the Liverpool School of Tropical Medicine. A sufficient sum was left, not only to build the new ward, but also to erect the adjacent new laboratories. The latter are now in course of construction. Sir Thomas Barlow assisted at the ceremony, and there were also present the Earl and Countess of Derby, Mr. F. C. Danson (Chairman of the School), the Lord Mayor and Lady Mayoress, Sirs Ronald Ross, W. H. Lever, the Vice-Chancellor of the Liverpool University, and many others interested in the work of the school. The new ward is a one-storied building, so arranged as not to interfere with the access of light and air to the other wards of the hospital which are above it. The entrance is from the corridor leading to the main staircase, in proximity to the casualty department on the other side of this corridor. The ward is 15 ft. high, 25 ft. wide, and 42 ft. long, affording cubic contents of 1,575 ft. to each of the 10 beds contemplated. The laboratory for students—an apartment 40 ft. by 20 ft.—is placed on the north side, thus giving a suitable light for microscopical work—and there is a small serving room between it and the ward.

All the internal walls are faced with glazed bricks of quiet colour, with coved angles at floor and ceiling, and the ward is floored in oak blocks. The other paving, being in terrazzo, is in keeping with the rest of the hospital. The outer walls are built of rustic brick with terra-cotta dressings, also in harmony with the main building. The heating is by low pressure steam, with fresh air inlets, and hopper-topped windows for ventilation. Electric lighting has been installed throughout.

The building was designed by the late Mr. Francis Doyle, architect to the hospital, and the work has been completed by his brother, Mr. Sidney Doyle, and staff, with Messrs. Travis and Wevill as contractors.

After the formal opening ceremony, on the invitation of Mr. Danson, about fifty guests lunched at the Adelphi Hotel. Following the loyal toast, the company in silence drank "The Memory of our Founder, Sir Alfred Jones." Afterwards Sir Thomas Barlow, in reply to the toast of his health, discoursed interestingly on the importance, from the imperial point of view, of the work in which the school is engaged.

MANCHESTER AND DISTRICT.

Manchester and District Radium Fund.

The great success that has attended the appeal of the *Daily Dispatch* on behalf of the radium fund is shown by the fact that though £25,000 was the sum originally aimed at, the fund now stands on July 27th at over £29,000, and donations are still coming in, while a number of the collecting boxes have still to be returned. The total for Manchester alone is well over £25,000, apart from subscriptions from neighbouring towns. The contribution of Bury, for example, is over £2,600, and other towns have sent in various amounts. Last week the Manchester Y.M.C.A. promoted a radium fête and carnival, and though on account of the stormy weather some of the attractions had to be abandoned, a cricket match was played and the proceeds are expected to be considerable.

At a meeting of the Radium Committee on July 20th, a hearty vote of thanks was passed to the proprietors of the *Daily Dispatch* for their invaluable services in bringing the fund so prominently before the public, and for the vast amount of trouble they have taken in order to secure the sum of money necessary to carry out the scheme. The question of the appointment of an expert radiologist was considered, and the appointment left in the hands of Sir William Cobbett, Professor Rutherford, Professor Wild, and Sir William Milligan, who will report to to the general committee. A letter was read from the Oldham Hospital asking that it should be allowed to participate in the benefits of the scheme, and it was decided to suggest that Oldham might make a contribution to the fund of about £2,500, and in that case might be a sharer in the scheme. It was also resolved to spend a further sum of £10,000 in the purchase of radium to be delivered as early as possible, and when the full amount now on order is obtained Manchester will be in possession of about 1,600 milligrams of radium bromide.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

Caledonian Medical Society.

The Caledonian Medical Society held its annual meeting in Glasgow on July 24th. Dr. J. T. Maclachlan was elected president for the current year; Dr. S. Rutherford Macphail of Derby, president-elect; and Drs. W. A. Macnaughton and D. Rorie, editors of the *Journal*. The President in his address dealt with diseases of parasitic origin. He appealed to the large cities to appoint at least one expert to devote his entire time to the elucidation of the cause of any single infectious disease, and predicted the final annihilation of all infectious diseases that afflict humanity.

The annual dinner of the society was held in the evening. Sir David McVail, in submitting the toast of the Society, said that their records gave a great deal of evidence of high culture in the medicine of the Highlands. He thought they were right in having a society which upheld Celtic medicine and the credit of the Celtic past of the population of this country. On the subject of Celtic medicine the society had a large number of papers which by themselves would make a most interesting volume. The Chairman, in reply, said that the society was formed in 1878 by a small but enthusiastic band of medical students in Edinburgh. At the present moment the membership was nearly 300, scattered over Scotland and England and the Dominions across the sea. The society was chiefly concerned with ancient Celtic literature regarding medicine and cognate subjects.

Anderson's College Medical School, Glasgow.

The calendar for the Anderson College of Medicine for 1914–15 has now been issued. Its preface states that the college dates back to the year 1800, and it has provided a medical education at a cost suited to the circumstances of many who could not otherwise have been able to prosecute the study of medicine, and who had been an honour to the profession. It is also recorded as a notable fact that the college had given fourteen professors to the University of Glasgow, of whom one at present held office. The curriculum provides for a complete medical and dental education.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

Dublin: The Civic Exhibition.

Abderhalden's Exhibit.

There is at present on view in the Food Section of the Civic Exhibition now held in Dublin the celebrated exhibit prepared by Professor Abderhalden of Halle, and shown at the Dresden International Health Exhibition in 1911. It represents the actual cleavage products (*Bausteine*) in exact quantities which he obtained from several proteins, such as caseinogen, gliadin, globulin, etc. It has never been out of Germany before, and is of such value that it is hardly likely ever to visit this country again. Professor Abderhalden lent it to Professor W. H. Thompson, who is in charge of the Food Section of the Exhibition, and it will be on view till the end of August.

Teeth and Medical Inspection.

On Monday, July 20th, the free dental inspection at the Civic Exhibition began during the visit of forty-seven

girls from St. Mary's, Donnybrook, Girls' School. Mr. Bermingham, secretary of the committee of dentists in charge, examined several of the children's teeth, and gave a short talk on the proper care of the teeth. A committee of fourteen dentists has volunteered their services, and some of them will be in attendance every afternoon from 4 to 6 and on Friday evening from 8 to 9 to give free dental inspection to any child desiring it. It is specially wished that the children should be under 10 years of age. This dental inspection is an exhibit typical of part of the work of the dental clinics of Ireland receiving grants from the educational authorities. There are 49 of these clinics in Ireland, of which 13 are in county Dublin. Dental inspection is the only part of medical inspection carried on in Ireland. Of the 201 children examined in Ireland, 192 needed treatment, and there was an average of 5 teeth decayed per child. The need for dental inspection is shown by the fact that while only 4 per cent. of the children at the age of 7 have decayed teeth, 75 per cent. of the children at the age of 13, who have not previously been inspected, have decayed teeth.

On the previous Saturday thirty-two babies and children were brought by their parents to take advantage of the free medical inspection afforded in the Child Welfare Section. The examination of the older children is the same as carried on in English schools by a doctor to discover physical defects which may be interfering with the normal growth. The examination of babies done at the exhibition is an illustration of the work of baby clubs carried on in Ireland by the Women's National Health Association. It consists not only of medical inspection of a baby, but of a conversation with the mother on the subject of the feeding of the child.

Correspondence.

THE FUTURE OF THE LISTER INSTITUTE.

Sir,—With reference to the annotation in the last number of the Journal on the future of the Lister Institute, I desire to point out that the governing body of the institute have decided by a majority to recommend to the members, that the Lister Institute should be presented to the nation on certain conditions, and placed under the control of the National Medical Research Committee. It lies with the members of the institute to accept or reject such a proposal, and doubtless a meeting of the members to consider this matter will be held in the near future. In the meantime I wish to state I regard such a proposal, involving as it does, the cessation of the activities of an independent organization, and the centralizing of pathological research under parliamentary control, as so prejudicial to the interests of scientific research in this country, that I have felt compelled to resign the chairmanship and membership of the governing body.—I am, etc.,

London, W., July 27th. John Rose Bradford,
Late Chairman, Governing Body, Lister Institute.

Sir,—I have heard with astonishment the proposal to destroy the Lister Institute and hand over its building and its endowment to a Government Committee. The article on this subject in the Journal of July 25th states that "the chief object of Lord Iveagh and his advisers in offering the Lister Institute to the Medical Research Committee" of the Government is to enable that Committee to utilize the funds available under the Insurance Act for some other scheme. I do not, of course, know how far the writer is entitled to represent Lord Iveagh. But I must protest altogether against the notion that it is possible for Lord Iveagh to offer the Lister Institute to anybody. The Lister Institute was constituted (as I know from having taken an active part in its earlier incubation) by the contribution of funds from Sir James Whitehead's Mansion House Committee in aid of the Pasteur Institute, from the Berridge Trustees, from subscribers to the Jenner Memorial and other sources, and by the free gift by the late Duke of Westminster of the land on which it stands. All this took place before Lord Iveagh made his generous gift to the institution.

But I am sure that Lord Iveagh himself does not suppose that he can give at one time and take away or "offer" to give away at another time (as your contributor assumes) the endowment which is the chief source of income to a greatly valued scientific institution.

There are many individuals who have had to do with the building up of the Lister Institute who will resent most deeply the attempt to convert this independent home of research into a convenience for a Government board. The National Medical Research Committee has something like £50,000 a year to expend. If it requires buildings similar to those of the Lister Institute surely it can pay for their construction. They will not be in excess of requirements. I feel confident that nearly all, if not all, men of science and most members of the medical profession will agree with me in desiring that the Lister Institute shall remain what it is—an independent centre of research free from Government control.

It is unhappily the fact that Government "aid and control" of scientific institutions invariably means—in this country—the waste of money which should go to the scientific purposes of an institution—by its diversion to a a body of clerks, superintendents, directors and secretaries—and the mismanagement of the scientific enterprises which are undertaken. Unconditional gifts or grants in aid, on the part of the Government are on a different footing and were, until recently, the welcome form which such aid took.

I do not mean to say that the present organization and management of the Lister Institute are satisfactory. It certainly requires remodelling, as the present suicidal attempt shows. Such a remodelling can be effected. But I hope and believe that the members of the corporation to which the Lister Institute and its property (amounting altogether to some £400,000 in value) belong, will not accept the proposal to "give away" their trust to a Government Committee. A majority of them will, I hope, remain firm, and keep the Lister Institute as an independent institution. The transfer has to be submitted to the members of the corporation before it can be effected, and to be voted by a three-fourths majority of them. The present list of members of the corporation contains about ninety names. It is to them that all who are opposed to the strange proposal of Dr. C. J. Martin for destroying the institution of which he was made director a few years ago should address their arguments.

The small governing body of the Lister Institute in which this proposal has arisen consists of only twelve persons, who are not members of the working staff of the Institute, some of them not even men of expert knowledge. Even so, I am informed that the chairman of the governing body, Sir John Rose Bradford, secretary of the Royal Society, was so much opposed to the proposal to destroy the Lister Institute and hand over its property to the Government that, when the proposal to do so was voted by that body against his pleading, he very properly resigned the chairmanship and his membership of it. Thus the medical profession and the body of ninety ordinary members of the Lister Institute will observe that the proposal to abolish the Institute is already actively opposed, and that they must now be vigilant and keep an eye on the proceedings of officials if they desire to preserve the Lister Institute for the purposes for which its various founders (as well as Lord Iveagh) intended it. The small governing body has shot its bolt and is condemned by its own chairman. It is for the general body of members now to take up the matter and support the late chairman of the governing body. I would suggest that an informal meeting of the members should be called before the day when they will be asked to vote.—I am, etc.,

London, S.W., July 27th. E. Ray Lankester.

STATE REGISTRATION OF NURSES.

Sir,—In the discussion which took place recently at a meeting of the British Medical Association on the State Registration of Nurses, I see that Mr. Garstang, of Altrincham, said that "unanimity already existed on this question except for the party led by Lord Knutsford."

This strikes me as a very original way of arriving at unanimity by simply disposing of the opposition. Unanimity may be said to exist on Home Rule, except for the party led by Mr. Bonar Law! And upon most questions, except for the opposition, there is unanimity! The whole point is whether the opposition is sufficiently numerous or important to be considered.

I have just sent out a Protest against the Registration Bill, worded as follows:

We, the undersigned, wish to make our most carefully considered protest against the bill, No. 88, introduced into Parliament by Dr. Chapple and others, to regulate the qualifications of trained nurses and to provide for their registration. We believe that this bill would be a source of danger to the public by inspiring a false sense of security, and detrimental to the true interests of the best nurses, by introducing an undesirable standard of uniformity.

Up to date I have received signatures to it from over

300 matrons of hospitals, including the matrons of the London, St. Bartholomew's, St. Thomas's, Middlesex, St. George's, St. Mary's, King's, Westminster, Seamen's, etc.,
100 matrons of institutions and nursing homes,
15 matrons of Poor Law infirmaries,
3,000 nurses.

It is also signed by over 200 medical men, many of them the leaders of the profession, whose opinion on any question of nursing is of the utmost value.

In the face of such opposition from people deeply interested in and experienced in the training of nurses it is very unlikely that the bill will ever become law, and I hope that Mr. Asquith's advice to the Registrationist Deputation may be considered—that is to say, that some attempt should be made to arrive at a reasonable solution of the question more or less acceptable to both sides. I should be only too glad.—I am, etc.,

KNUTSFORD.

Knebworth Hall, Royston, Herts,
July 29th.

THE BRITISH MEDICAL ASSOCIATION AND THE MEDICAL PROFESSION.

SIR,—In the issue of July 25th, p. 206, two letters expressing a desire to divide the activities of the Association into departments, and to reduce the subscription, appear. One adds that the *Lancet* is run at a profit for £1 1s. per annum, implying that the JOURNAL is run at a loss. Now in 1913 the BRITISH MEDICAL JOURNAL cost in all £39,966, the receipts for it being £23,932; no doubt the writer thinks there is a loss of £11,034. But that is not a fair comparison, for no account is taken of the 24,376 members to whom if the price of the JOURNAL were charged at £1 1s. per annum in the accounts, £25,594 would be added, making total receipts £54,526, or a profit of £14,560. The *Lancet* also did not gain £1,650,000 for the profession working the National Health Insurance Act.

Personally I am not on the panel, but in the United Kingdom 9,459 members are, while 6,106 are not, showing that the panel men pay by far the larger amount towards "building up the panel system."

Again, no member of the Association was ever in danger of being "compelled to become a trade unionist." Your correspondent is confusing the recommendation of the Council that the "Special Fund" should become a trade union (this body being necessarily entirely separate from the British Medical Association), which recommendation has been reversed by the now sitting Representative Meeting, which decided the "Special Fund" should be administered as a trust or other organization not being a trade union.

Should the Association be divided into (1) scientific and (2) political sections the cost of working would necessarily increase and the scientific members would soon be entirely out of touch and sympathy with the political, especially if *no* political matter was included in the JOURNAL but reserved entirely for the SUPPLEMENT, which the second correspondent desires supplied *only* to the political members.

The profession will only be united if the "Association takes immediate and prompt action" is the opinion expressed in the second letter.

Now "The Association" is *every member*. If the writer means to say that only if each member takes "immediate and prompt" personal interest and participation in all that *is being done* can the profession be united, then I vehemently endorse every word, for I have expressed that opinion times out of number; but I fear he means that imaginary "Association" which is supposed to exist somewhere "up in London."

As a matter of fact the British Medical Association is like a toothed wheel, which should be driven by a motive power acting upon the teeth, and so revolving the whole upon an axle at the hub; whereas, if we imagine the motive power to be the intellectual interest of the members produced by an adverse environment, the teeth to be the members, and the hub the central authorities at 429, Strand, what is expected is that the hub shall drive the wheel, the teeth of which are (many being composed of lead or some material easily bent) deflected in many directions, and some keep breaking off (that is, resigning) upon the least extra strain produced by the efforts of the hub to turn the wheel. I ask what kind of action can result, and how can it be prompt or immediate? To leave simile, let the members pay for whole-time medical organizers, who can keep them in touch with what is actually going on—what efforts are being made in London, what policy is being attempted, so that, having a clear idea of all these, *they* may take immediate and prompt action to back up those who are working hard for them under adverse circumstances.—I am, etc.,

HARDING H. TOMKINS,
Representative, South-West Essex Division;
Member of Special Fund Committee.

Leyton, N.E., July 25th.

SIR,—Dr. Charles Gibson informs us the fight for the partial recognition of the rights of the profession cost the Association a large amount, to which many subscribed, and, with the increased subscription, caused a loss of about 2,000 members. A terse statement, but, in my opinion, very unfair. "Partial recognition of the rights of the profession." The answer to this is obviously, "The pledge and what became of it." "To which many subscribed" would more accurately be rendered "promised subscriptions," as, within my knowledge, some men who promised to subscribe were contented to let matters rest at the promise when, through our Amphioxus attitude, we were routed.

The Association possessed the key of the citadel and we stole it from the Association. I am an out-and-out opponent of the trade union idea; but I can answer the question why a member of the Association is compelled to become a trade unionist. Simply on account of the apathy of his colleagues. This Division (Beds) has been canvassed upon this question, and the percentage of replies is an eye-opener to anyone really interested in the future of the profession. The idea of splitting the Association into sections does not commend itself to my mind. Dr. Arthur Todd-White adduces reasons for not splitting up into sections which appear to me to be adequate. If the profession failed to be united on the question of the National Insurance Act—and optimistic indeed is he who still hopes to see a united profession—it is difficult to see how a man can be wholly scientific or wholly political. Like medicine and surgery they cannot be divorced. A scientific question may arise which depends largely upon political action for its settlement.

With regard to the Representative Meeting—so-called—it *must* be unrepresentative as regards the great body of practitioners, a large percentage of whom take no practical interest in the welfare of their profession; but it is representative of the active members of the Association, who often, at great personal inconvenience, attend the Divisional meetings, not merely to record a personal view of the subjects under discussion, but to discuss them with their colleagues, and, by the interchange of opinions, arrive at a reasoned conclusion. It is only by meeting men of all shades of opinion and having a free and open discussion that we can hope to arrive at a decision which, communicated to our Representative, expresses the view of the majority of the members of the Division which he represents.

At the present time, notwithstanding our recent experience and the fact that danger ahead stares us in the face, a few enthusiasts turn up at our meetings, the majority of their colleagues remain at home, and are so little interested in the subjects under discussion that they fail to send even an excuse for their absence.

Even if every medical practitioner joined the Association I doubt very much, from past experience, whether we should be in a position to say that the decisions arrived at even approximately represented the opinions of the profession as a whole.

Apathy is our stumbling-block.—I am, etc.,

S. J. ROSS.

Belford, July 27th.

Medico-Legal.

STEVENS v. BRITISH MEDICAL ASSOCIATION.

THE hearing of this case was continued on July 23rd. The action was brought by Mr. Charles Stevens, managing director of Stevens and Co., Limited, for damages for a libel alleged to have been published by the defendants in *Secret Remedies*. The defence was that in so far as the statements complained of were statements of fact they were true, and that otherwise they were fair comments on matters of public interest.

A report of the first six days' proceedings was published in the JOURNAL for July 25th.

The plaintiff appeared in person; the defendants were represented by Mr. Colam, K.C., and Mr. Dickens (instructed by Messrs. Hempsons). Mr. Kimber (instructed by Messrs. Dod. Longstaffe, Son, and Fenwick) watched the case on behalf of Sacco, Limited.

On July 23rd, Dr. Dyke Acland recalled, was further cross-examined by the plaintiff. He said the question whether he would accept the results of a layman's experiments depended on who the layman was. He would have accepted Pasteur's experiments when he was a tadoner as he believed he was endeavouring to ascertain the truth. Dr. Bulloch was one of the greatest authorities on tuberculosis, and any experiment performed by Dr. Bulloch was such that it might be depended upon. The witness then gave certain figures showing the result of treatment at Midhurst. When he spoke of the disease being arrested he meant that the general health was completely restored. Sanatoriums did not only take early cases; a man with a large cavity might be much better than one with tubercle dissemination all over the lung. Statistics taken over the whole life could not be safely compared with those taken over a particular period. They often admitted patients to Midhurst who, they thought, would not improve, but they admitted them to see whether they would improve. He (witness) was not an expert on silicosis. That was a form of miners' phthisis, but coal-miners' phthisis was not silicosis. All miners' phthisis did not end in fibrosis.

In re-examination he said that the tables which Mr. Stevens had put to him were tables of far advanced cases. Referring to Mr. Stevens's experiments with the rabbits he said that the very fact of there being pus present ought to give rise to suspicion of contamination.

At the conclusion of the re-examination, plaintiff drew attention to certain letters whereby it had been agreed between him and the solicitors for *Truth* that an action for libel which was pending against that journal should stand over until the decision in this case.

In reply to Mr. Colam, the learned judge said his ruling was that this was a matter of public interest.

Mr. Colam having addressed the jury and the plaintiff having replied, Mr. Justice Shearman summed up as follows:

Summing Up.

Mr. Justice Shearman: Gentlemen of the Jury,—This, as you know, is an action for libel brought by Mr. Stevens against the British Medical Association, and it is an action brought upon one of a series of articles which appeared in a newspaper called the BRITISH MEDICAL JOURNAL, which articles were substantially reprinted in a book. The plaintiff comes here and asks for damages because he says his reputation has been wrongly assailed.

Gentlemen, there are two questions I have to leave to you, and one will take a very short time to explain. It has been well settled law in this country for a great many years that it is not for the judge, but for the jury, to say whether the words complained of are libellous or not. A libel means something which conveys an imputation upon the character of the person who brings the action. I cannot say, but it is for you to say, whether there is something in this book which is libellous; and that question will not take you very long to decide. The plaintiff comes and says, "They call me an impostor"; and Mr. Colam says, "We are justified in our comment by saying 'He cannot prove what he states.'" So that you may very well come to the conclusion that apart from the defence of fair comment there are matters derogatory to the plaintiff's reputation in these words, but it is a matter I have to leave to you. If you came to the conclusion that they were not attacking the plaintiff's character, but only his medicine, there would not be such an action. If you came to the conclusion that the words attack his character as well as his goods (he has not brought an action for an attack upon his goods, but upon his character) then you will answer: Yes, these words are libellous; in other words, that they convey an imputation upon the plaintiff.

Then, gentlemen, the real matter begins, because the defendants say, "If we have made an imputation we are justified in doing it by what is called the law of fair comment." Now, gentlemen, that leaves this serious question for you to decide. Before I deal with the evidence I want to instruct you in what I conceive to be the law. It is a very important principle in this country that a man's character shall not be improperly attacked. A man's good character is his property, and no one has any right to attack his character. That is one excellent principle; but, gentlemen, there is another very excellent principle too, and it is that this is a country where, when matters of public interest arise, everybody shall be at liberty freely to express his own mind in honest criticism. That, gentlemen, has been called in other terms the right of free speech. It is not confined to newspapers, but it is open to you, or to me, or to any of us. It does not apply when we are dealing with purely private matters, but when we are dealing with matters of public interest that right of free speech or comment applies. That is another important principle. It is important that a man's character should not be wrongly attacked. It is important that a man should have a free right to criticize matters of public interest, and it is when those two principles come into conflict that the difficulty arises.

The law, I understand, is this: It is for the judge to say whether this is a matter of public interest. I decide that it is a matter of public interest. I do not think any one can question it, because any question involving the treatment and cure of tuberculosis and the medical interest of large bodies of persons is a matter which can be freely discussed. Therefore that point does not arise.

That being so, it is not for me, but it is for you, to decide whether it is fair comment, and, if I may respectfully say so, that is a sensible principle of law. It is not for one person who sits as a judge to decide, but it is for twelve people selected from amongst the citizens of the city where the case is tried, and they have to say where the line is to be drawn between the two principles of attacking the character and the right of having free speech on matters of public interest. For a great number of years it has been left to the gentlemen of the jury to say, having regard to all the facts of the particular case, Have the defendants gone beyond the line of fair criticism, or are they within the line? That is the question which you have to decide. Bearing in mind that one jury, as we know (we know very little about the previous case), have disagreed about it, I hope you will carefully apply your minds and, if possible, come to an agreement upon this matter.

Gentlemen, there is one other thing I ought to have called your attention to with regard to deciding what is fair comment. Some people think it is not fair comment, and cannot be fair comment, to attack a person's character. That question has been decided in the courts too, and it has been decided in a court to which we all have to pay respect. What are the principles which a jury ought to apply? I am going to read what one of the judges of the Court of Appeal on this matter said. He said: "The defence of fair comment assumes that the matter to which it relates would be defamatory if it were not protected by the defence of fair comment." Then he says: "A fair and bona fide comment on a matter of public interest suffices to protect that which would otherwise be defamatory. Comment which tends to prejudice may still be fair; it may convey imputations of bad motive so far as the facts truly stated justify such an imputation." In other words, if the facts which people prove in court justify the imputation that they have made, it may be fair comment. "It is for the jury to say whether the facts justify the imputation or not. The fault here is that that question has never properly been left to them. The question for the jury is whether the comment, in their opinion, is beyond that which a fair man, however extreme might be his views in the matter, might make honestly and without malice, and which was not without foundation." Gentlemen, to put it in a shorter sentence, it means this: You first have to decide when you look at these words what imputation is made. It is for you, and not for me, to decide what is the exact imputation. Then you have to decide how much the defendants have proved, and, bearing in mind what they prove, do you think, on the facts which you believe to be proved, that the defendants have done anything more than fairly comment upon a matter of public interest? You will say if you think they have done more and gone out of their way to make an attack which was not justified by the facts. You may find it is not fair comment on the facts proved before you, and which have been proved in the course of the case—not merely the facts which were before the man who wrote the article, but upon all the facts which have been proved before you by the witnesses while you have been sitting in the jury box; if you come to the conclusion that certain facts are proved which would warrant the imputation made in that article, then you can find for the defendants. It is for you to say Aye or No; looking at the facts, do you think this is fair comment, realizing that comment cannot be fair if the imputation or comments rest upon untrue facts? But if they rest upon true facts and they do not go beyond fair comment you can find for the defendants. I think that will explain to you what the law is upon the matter.

It is not for me to tell you exactly what imputation is conveyed in the words I am going to read. A case very much like this was tried not very long ago, when the judge instructed the jury as to what is the meaning of the word "quack," which I believe is one of the words used here. The higher Court said that it is for the jury to decide what it means, or rather what it means when it is used in a particular sentence. I cannot therefore tell you what this means. You have to make up your minds, and having done that, you have to look at all the facts and say whether the defendants have or have not gone beyond the limits of fair criticism—that is to say, honestly commenting upon the true facts. There is one other matter about the law and then I will pass away from it. I do not want you to form any opinion, that because I have had to pull up the plaintiff frequently for doing things which he ought not to have done, that shows I have prejudice against him. It is my business to see that the only evidence put before you is what is actually evidence. One cannot have in these

courts people coming forward and saying, "Oh! somebody told me so-and-so, and so I repeated it." There would be no limit or end to such evidence. Someone might come forward and say, "I saw Smith in the morning and he told me he had seen three ghosts. I saw Jones in the afternoon and he told me he had seen six ghosts." You might consider that that was evidence that there were nine ghosts walking about the place. The answer is that the first man may be a liar, or the other man may have told him lies. We cannot have what other people say because we only listen to witnesses who go into the box, who can be seen, so as to judge after cross-examination whether you believe their evidence to be true or not. That is why from time to time I had to have little arguments with the plaintiff about the matter, but I was simply doing my duty in getting the evidence confined within the proper legal limits.

Now let us apply ourselves to the problem we have to solve. I have said to you all I am going to say about the law on the point, but there is one other point. It is impossible for a judge in summing up the evidence, unless he reads it from his notes, which would not make you very much wiser, to do so without making comments of his own upon the facts. As I understand the law, a judge is entitled and indeed it is his duty, to make comments upon the facts sometimes if he thinks that he ought to make them. If you disagree with what I say you are at liberty without any offence to disregard it, because the facts are for you and not for me; but I am entitled, where certain matters come up, to call attention to certain things in the facts. If you get from that what my views are upon the matter you may avail yourselves of them and adopt them, or disregard them as you think fit.

Now let us look at this alleged libel. Will you turn to it, because I am bound to read the passages complained of? Gentlemen, in one way you have to recollect this: that it has been said somewhere here that this gentleman, the plaintiff, is carrying on a campaign. It may equally fairly be said that the defendants are carrying on a campaign. They are exercising their undoubted right and duty in saying, "We are tackling the subject of proprietary medicines and calling attention to a large number of them, and doing our duty to the public in calling attention to the men who sell these proprietary medicines and the methods which they display." What you have to consider in this case is whether in the words which these people write about a matter obviously of interest to the community, they have used here anything more than legitimate criticism upon the man who sells this cure, and the methods which he has of selling it, because both of them are attacked or appear to be attacked. But it is for you and not the judge to say what the imputation is.

The beginning of the chapter is: "Nostrums and quack medicines vary greatly in the extent to which they constitute deliberate fraud." They do not say deliberate fraud as to this, but say there are all sorts of gradations, and the early part of the article goes on to say that some contain something of value, but not very much. Then come these words: "But with other proprietary medicines it is quite clear that the makers cannot in the slightest degree believe in the claims they make." You will have to consider whether that is not the keynote of this case, and whether the whole matter is, Does the plaintiff believe in the claim he makes for his medicine? It goes on: "The 'remedy' in these cases is some substance or mixture devoid of medicinal activity, or possessing some slight therapeutic property having no relation to the disease for which the nostrum is put forward as a cure. It is often, indeed, for inert preparations"—That is, preparations which have no medical effect at all—"that the most extravagant and emphatic claims are made; the makers, and the advertisement writers whom they employ, are untrammelled by any necessity of squaring their statements with the real properties of the thing to be recommended, and having set out consciously and deliberately to deceive, they are able to give their whole attention to telling the most effective stories in the most plausible manner, and reaping the maximum of payment for the minimum of expenditure. People who are ill or suffering are to be frightened with impressive pictures of the aggravated suffering and premature death that await them unless they take the 'only cure' in question, therefore let them be frightened thoroughly. Careful suggestion will induce people who are not ill to believe that they or some of those dear to them are in the early stages of some disease; therefore let everything possible in the way of striking advertisements, personal letters, and repeated assertions be utilized to produce the result. It is the victim's money that is wanted; therefore let the price be fixed high, and the advertisements be written up to it. If it should be discovered by correspondence that so much cannot be cajoled or frightened out of an individual sufferer, the price can be reduced gradually as 'special concessions,' in return for which testimonials may be extracted. Of quack medicines the sale of which is conducted more or less on these lines, two examples are described in this chapter, and other examples will be enumerated later." In other words, gentlemen, it does not undertake to apply everything to them, but generally on these lines. They begin by saying, "Where the makers cannot in the slightest degree believe in the claims they make." That is the class of medicine they are dealing with.

Then I need not read to you what they say about Tuberculozyne. Dealing with Stevens's Consumption Cure they go on to say: "The sale of another preparation advertised as a cure for consumption, Stevens' Consumption Cure, is conducted in a very similar way, but this time the herbs are said to be African, and the odd names they bear certainly have a Kaffir flavour. The vendor considerately warns the public against American quacks"—I do not think I need read the whole of that, it is about American quacks, because I am going to refer in a moment to what Stevens does. "But Stevens has somewhat bettered his instruction, and his letters and circulars have a character of their own due to the effrontery of his attitude toward the medical profession." Then it proceeds to make this attack upon him: "The circular continues: 'The great drawback to my cure, so far as the medical profession is concerned, has always been the fact that I would not reveal its formula. This is now done away with; its formula is 80 grains of umckaloabo root and 13½ grains of chijitse to every ounce, prepared according to *British Pharmacopœia* methods.' The farce of revealing a formula by the employment of such fancy names as these is one of the oldest dodges of the quack medicine man, and no such names as 'umckaloabo' and 'chijitse' appear in any available work of reference on pharmacy. Inquiries made in various parts of South Africa have been negative, experts in native matters being unable to ascertain that the names were known. Further, the Native Affairs Department of Cape Colony has caused inquiries to be made in the Transkeian territories into the question whether the native tribes there resident had any knowledge of 'umckaloabo' and 'chijitse,' or of their reputed medicinal properties. The result of the inquiry was entirely negative. Nothing was known of any such plants, nor was it even possible to identify their names. Smith's *South African Materia Medica*"—That is a medical work, of course—"contains no record of any such names as 'umckaloabo' and 'chijitse.'" There is an end of that.

Then I think I may turn on to page 28: "Stevens' Consumption Cure. This is advertised as manufactured only by C. H. Stevens. The price is 5s. per bottle, containing 2½ fluid. oz. This preparation does not appear now to go under any other name than that of 'Stevens' Consumption Cure.' As regards its past history, the following extract from *Truth Cautionary List* for 1908 is of interest." This article was published in 1903, and the *Truth Cautionary List* is a book cautioning the public against people who are to be avoided. This is the extract: "Stevens, C. H. The proprietor of a remedy for consumption which has been put on the market in South Africa and England under the name of Sacco, and later in South Africa as Lungsava, the recipe for which is stated to have been long in use amongst the Kaffirs and Zulus. In connexion with the advertising of Sacco in England, an article which appeared in *Truth* was circulated in a mutilated form, omitting a condemnation of its sale as an absolute remedy for consumption. Stevens has acquired a number of testimonials from medical men who must now regret their precipitate action. He is now in England on a new campaign." Gentlemen, people who publish a thing and repeat it are bound themselves to justify it either by justification or by fair comment; and the fact that the defendants have printed from *Truth* shows that they have to undertake to satisfy you that their extract is also fair comment.

Next follow a number of circulars which I will not read but I commend them to your notice. Probably you have read them. I do not read them *in extenso* now, because you will find that I have to read some extracts from them in the number of things which have been put in. The gist of that I may pass over for the moment and come to page 32, which is the formula. Upon this you have heard a good deal of evidence, and I want you to specially pay attention to the words. The second paragraph which you have heard so often is this: "The medicine was a clear red liquid, and analysis showed it to contain, in 100 fluid parts, 21.3 fluid parts of alcohol, 1.8 parts of glycerine, and 4 parts of solid substance; this solid substance contained about 1 part of a tannin and 0.2 part of ash, the remainder being extractive." "Extractive" was given in evidence by the medical men as being the stuff that resulted from the chemical analysis, the residuum which was left after the chemical process had been gone through. Then it goes on to say this: "No alkaloid was present, and no other active substance could be detected." In other words, they say: Here are certain ingredients of which there are four parts, of which one part, or roughly one part, is tannin, and the other three parts, or 75 per cent., is something which is inert. That is the meaning of it: "No alkaloid was present, and no other active substance could be detected." The medical and chemical witnesses say that in this class of vegetable, what are called the active, as apart from inert, parts are nearly always alkaloids, and that three of the four parts left were proved to have no alkaloid in them; and the analyst practically says, "I do not know what they are."

Then he goes on to say this about krameria, and it is for you to say what is meant by these words: "The solid substance agreed in all respects with the solids of decoction of krameria, or a mixture of this decoction with a little tincture of kino." Krameria, we know, is a thing which is a slight astringent, and produces some kind of red colouring, although possibly a different red colouring to this; and kino is another kind of drug, which is of the juice of a tree, but they are both vegetable products used in medicine. Then it goes on to say: "The solid substance agreed in all respects with the solids of decoction of krameria, or a mixture of this decoction with a little tincture of kino. The formula thus appears to be approximately: Rectified spirit of wine 23.7 parts by measure; glycerine 1.8 parts; decoction of krameria (1 in 3) to 100 parts by measure, or it may be made with tincture of krameria. Estimated cost of ingredients for 2½ fluid ounces, 1½d."—that is to say, if it is krameria.

Now, the plaintiff says that the statement here that this is made of krameria is libellous; in other words, the comment founded upon it is not true. In reply to that, the defendants say, "*It* is not a statement that it is made of krameria; it is a statement in which a man honestly making a criticism upon a skilled analysis put before him might say, 'The nearest I can get to it is krameria.'" And, gentlemen, you will notice it says, "The formula thus appears to be"—he does not say it is so and so, but is approximately so and so. There are the words; it is for you to judge. The plaintiff says: It wrongly accuses me of having krameria. It seems to me, and it is for you to judge—I am going to say what I have to say about the chemical evidence very shortly, because I have looked at it very carefully, and I can sum it up to you in a very few sentences—it seems to me that if these three parts of umckaloabo are just as otiose as the three parts of krameria, it does not much matter whether it is krameria or whether it is umckaloaba or whatever it is. If you have a medicine, and say that 10 per cent. of it is rose-water, when as a matter of fact 10 per cent. of it was orange-water, and rose-water and orange-water had exactly the same effect, it might occur to you that it would be difficult to say what complaint can be made about it. But if, on the other hand, umckaloabo has some extremely active substance in it which krameria has not, the matter would be very different.

This is substantially what the chemists say about it. Three chemists were called on behalf of the defendants. They all say that this medicine has 1 per cent. of tannin, that it has glycerine, that it has alcohol, and that it has a trace of ash, but they say they cannot find out what the rest is. And two of the chemists say the same thing on behalf of the plaintiff: that since this dispute started we have taken the different medicines provided by the defendants for us to analyse, and we find the same thing; we find a certain amount of tannin, we find a certain amount of glycerine, and we find these solid parts too. But, testing the solid parts of the umckaloabo as well as the solid parts of the krameria, the chemists on behalf of the defendants say: "We find equally that they are inert." Or, rather, they put it in this way: We cannot find any trace of anything active in them at all; there are no alkaloids. There is something else which I do not quite appreciate called glucosides, but they do not find them. They say: "We do not find here any active part whatever." If you come to the conclusion that the solid residuum parts of umckaloabo—the 75 per cent. which is in dispute—are equally harmless and inert in one and the other, you may think it makes very little difference. On the other hand, if you come to the conclusion that the solid parts have something in them which is active, although it cannot be found, you might think differently.

Now let me turn for a moment to the evidence of the two chemists, quite well-known, able, and competent people, who were called on behalf of the plaintiff—Mr. Parry and Mr. Cassal. This is what Mr. Parry says about the matter. He gives his particulars, and after giving his analysis the two chemists say: "We applied other tests and we found that there was no krameria." They say: "We applied tartrate of antimony, and that, by producing a particular colour, showed that there was no krameria there." Mr. Cassal says the same, that they applied two tests to show that it was not krameria. But after the evidence was concluded I asked a question of Mr. Parry. I wanted to get out what the difference was, and this is the note I have of what he said: "The residuum"—that is the part which is different—"shows no definite signs of being either active or inactive; I cannot identify it: but there are many drugs which do not contain any definite sign of activity which nevertheless have medicinal activity." That throws us back rather into the region of mystery. Both he and Mr. Cassal say: We show there is no krameria here, but neither of them can point to any definite stuff in this which contains any medicinal activity at all as distinct from the mixture with krameria in it; that is to say as discovered chemically. They say they cannot find it. There may be drugs, and they say there are drugs, which contain medicinal activity although they cannot trace them. On the other hand, there are plenty of things which contain residuum which is actually inert. But it is pointed out on behalf of the plaintiff: "We show it is not krameria." It is pointed out on behalf of the defendants: "Oh, yes, but you do not show that there is in fact anything there except perfectly otiose matter which is different from krameria." Mr. Parry and Mr. Cassal were not asked the question, but still it may be there although they cannot find it. Therefore, so far as the plaintiff's drug is concerned, his own experts say: "We cannot identify anything there which shows it has any active property; chemically we cannot produce any evidence that it has anything but otiose matter other than that which is in the analysis in the book. That is the position with regard to the analysis. You may very probably come to the conclusion, having regard to the tests made by these two chemists who were set to work to prove that there was no krameria, that the chemical analyses which they provided show that it had no krameria in it. Mr. Cassal says: I saw it prepared from the brown stuff, and nobody has been called to say that the brown stuff is krameria, and you may say you do not believe that the brown stuff is krameria; and Mr. Cassal has been called, who said that he saw it made up of that brown stuff, whatever it may be. With that I will pass away from the chemical evidence.

Now let me come back to the main question, apart from the chemical question, whether this is fair comment on the plaintiff and his methods of selling Stevens's consumption cure. With regard to that, the first thing you want to know is, what has he been doing? What are his circulars? I have a bundle of them here. I do not intend to read them all, but there are one or two to which attention has been called on both sides. They all run to a very large extent on the same lines. This one has turned up with a good many patients, and it is as follows: "There are so many termed 'consumption cures' made up in various forms and advertised to cure pulmonary tuberculosis, asthma, and other chest diseases, in such flowing language, which have all been proved failures, that everything seen advertised will naturally be considered just another swindle with suffering humanity its victim; if there were any other means of proving my cure, and letting the world know it, I should never resort to newspaper advertising; still, any one reading my advertisements will readily see how they differ from others puffing remedies for the same ailments that I guarantee to cure." In looking at the bundle of these circulars you will have to consider how far what is said in this article is justified, because in the article they say that Stevens begins by attacking other cures, which he calls sham cures, and says they are all shams: "I guarantee to cure." Then he says: "It is preposterous to claim the ordinary drugs that are known to every chemist even, to cure this disease, just because they are given a fancy name, and advertised by a Polish or a German Jew; it is not only preposterous, but a wicked swindle." In other words, he says that other people who are advertising these cures are making preposterous claims, and that their claims are a wicked swindle. Then he talks about an American quack. Then he adds this: "I do not say in my advertisements 'Consumption can be cured,' 'Consumption is curable,' or any such evasive remarks, but I say, 'I will guarantee to cure you if you are consumptive, or return your money in full,' and that my terms are 'No cure, no pay.'" Then he goes on: "The African herbs which my cure is prepared from have never been used by any white doctor or chemist before I introduced same to civilization a few years ago. These herbs are original and have defied our cleverest analysts to discover the active principles they contain"—in other words, this is a bag of mystery, no clever analyst in England can tell what is in it, but there it is, and with this stuff I am going to cure consumption. Then he says: "The proof is here for anyone to see. Is there another remedy in the whole world that is claimed to cure consumption backed up by hundreds of English, Irish and Scotch doctors like mine is?" When one hears of the hundreds of English, Irish, and Scottish doctors, one wonders why they have not appeared in court; but it is for you, you have to consider whether this man is making these claims here honestly such as he really believes in. Then it goes on: "'No, there is not,' and I only want a Royal Commission formed to test it publicly on admitted cases of consumption, to enable me to claim the big rewards offered to the first man discovering a cure for this insidious disease." Then a little lower down he says: "To bring my cure to its present state of perfection it has cost me many years of ceaseless toil, untold hardships in a wild and unexplored country where life is held very cheaply, and thousands of pounds in hard cash. I am here to prove my cure for consumption regardless of all cost, and no unfortunate sufferer shall be denied it because they are too poor to pay for it." In dealing with these things you will consider whether they are candid or whether they are catchpenny advertisements, and whether the criticism made by the defendants is or is not justified by the sort of way in which this man is recommending and putting his cure before the public. Then it says: "Should it make you sick, that shows it is going to do you good—sickness is a sure sign that the tubercle-bacillus (germ of consumption) has a thorough hold of your system, and that a war is being waged between the disease and my treatment." Then in another place he says: "I only returned to England a few weeks ago to prove my cure to the satisfaction of the British Government." You will judge what that means. The statement is that he has come back to prove his cure to the satisfaction of the British Government.

The next one I have, and again I will go through it very shortly, is this: Stevens circulated a paragraph from *Truth*, and when one comes to look at it there is no substantial dispute about it. *Truth* published an article against him, and then he came up with certain doctors and *Truth* altered their tone. I will not read them to you now, they were read to you on the first day. The article in *Truth* then went on to say: "Although we have altered our tone and it looks as if there was something in it yet it is absurd to say, and he has no business to say, it is a cure for consumption." Upon that, this man without any permission from *Truth*, cut out all the laudatory parts, leaving out the part which said that he had no business to use it as a cure for consumption. This is the circular advertisement: "*Truth* and my discovery. Many people believe everything in the newspaper. *Truth*, to be in keeping with its name, so extracts will be interesting to them. Mr. Labouchere's articles are too long to reproduce at length, but to give you an idea what he has said about my treatment, I will give a few extracts," and he gives you an idea of everything that was said on one side and nothing that was said on the other side. That is another thing that was circulated broadcast, and which you may think is a justification for the reprint in *Truth* which appears in the article, or rather a true fact upon which their comment might have been founded.

Then the next thing is this circular with the hand upon it, and which says it is a tuberculous hand which he has cured, and he says, "This cannot lie." It is called "From a photograph of the tuberculous hand of Mr. Alfred Williams," and then underneath it is another photograph taken three weeks

later. You have seen the original photograph, and you find that this photograph of the tuberculous hand is not a photograph of the tuberculous hand at all, but a photograph of what an artist has depicted as a copy of somebody else's tuberculous hand, but it is circulated to the public as if it is the real hand, and that is how he cured it. As a matter of fact this is not a real photograph of the hand at all. We have seen the photograph, and it does show a strongly marked tuberculous hand, but one wants to know why the photograph could not have been printed and not the picture. Then another thing which was distributed was the analysis by Mr. Lord. Sometimes things are done irregularly. The only evidence about him is that for certain duties which the plaintiff mentioned, for making examination of sputums for him, he was being paid thirty shillings a week. Never mind whether he was paid anything else. He was a man in Stevens's employment. He was not, as far as I know, a man with a degree; he was not a medical man. This analysis of his was circulated in very large numbers. At the top it says: "Mr. J. P. Lord, Analyst and Bacteriologist, Consulting Bacteriologist to the Councils of Carshalton, Cheam, Dorking, Epsom, Ewell, Leatherhead, Maldens and Coombe, Sutton, etc." That looks to me very much like some rural district council which is multiplied about seven times over—I do not know. If you know the neighbourhood you will know that they are all about the same locality, and whether each of these ten councils are likely to have a consulting bacteriologist is for you to judge. It says: "Some fifteen months ago I had submitted to me, by a physician, a bottle of a lung specific, made by Mr. Charles E. Stevens, of Wimbledon, with a request to determine whether the medicine contained any harmful ingredient. After a careful analysis I was able to assure him that it was perfectly innocuous. Since then several medical men to my knowledge have used this specific and have found that their tuberculous patients have derived great benefit from it. In one case a tuberculous ankle, which was doomed to amputation, has been saved." This analyst and bacteriologist has probably put in here something which somebody told him, possibly what the plaintiff told him, one does not know, because Lord has not given us the benefit of going into the witness-box, and the plaintiff has not put him there. That is all we know about him. Then: "Inspired by these successes, the users of this remedy have again submitted ordinary samples from the commercial stock to me for further report, and by the courtesy of the discoverer I have been provided with samples of the raw material." He appears to have been in the discoverer's employment, but this analysis was written as if he was a bacteriologist who by the courtesy of the discoverer had been given some particulars. That you must bear in mind. None of this is decisive, but you have to bear it in mind as to how far these facts which are not in dispute justify the criticism which is directed to them by people who are writiug a series of articles against the owners and advertisers of patent medicines.

There are a lot of other forms. One that I have is lithographed.

Then comes a newspaper advertisement in November, 1911—an advertisement which deals with sanatorium treatment. This is the only thing one need say about sanatorium treatment, that, whether sanatoriums are good or bad, I can quite understand that doctors of the highest eminence in the country are looking to sanatoria as a real alleviation of consumption at the present day. I am talking of it as we know it from the amount of public money which is being spent on them. One can quite understand medical men taking a certain line with regard to sanatoria, but we are not trying the benefits of sanatoria in this case, neither are we trying the efficacy of Stevens's medicine, we are trying the question whether the plaintiff has been libelled, or substantially whether these remarks which have been made by the defendants are or are not within the limits of fair comment. That to my mind is all we have to do with sanatoria in this case. The plaintiff says: "Sanatorium treatment. We all know that a great number of the supposed sanatorium cures only remain well for a few weeks or months after leaving these institutions, and as a matter of fact, the general health only is somewhat improved, the disease still being in the system just the same. The BRITISH MEDICAL JOURNAL in its issue of November 12th, 1910, showed clearly from well kept statistics that after five years' sanatorium treatment and supervision less than 3 per cent. were able to follow their occupation, and if only three out of every 100 consumptive patients are able to follow their work after five years' treatment and supervision (and it is well known that sanatoria only accept patients in the early stages) what grounds have we for calling sanatorium treatment a 'Cure' for consumption? 'A landslide to the grave' would be a better and more correct term." Now, what is said on behalf of the defendants is this: You are trying to foist your medicine upon these people; these are poor people who would be ordered to sanatoriums. You are telling them that sanatorium treatment is no good; have five shillings worth of my medicine instead. Dr. Acland, whose evidence I will deal with presently, says: These figures are preposterously absurd; I have figures showing that we arrest the disease in over 50 per cent. of the cases, and how Stevens can come and say that only 3 per cent. ever go back to their work one does not know. The only figures put in to justify these figures by Mr. Stevens himself are forty-eight tables, which he put in this morning, and it turned out that one of them—No. 27—only dealt with nine very bad cases, and saying that they contradicted Dr. Acland, who gave us the whole figures for ten years from one particular sanatorium. People who live in glass houses must not throw stones, and people who make attacks upon sanatoriums and say they are landslides to the grave, when they come here, it is for you to say whether they are not rather squeamish in having attacks made upon their own medicine, which is being sold at five shillings a bottle as an alternative remedy for consumption to sanatoriums. So much for that.

There are a great many of these advertisements, but they all run on practically the same lines. Here is another: "When your doctor and the specialist have told you they can do no more for you, sanatorium treatment, open air, and change of climate failed to give you relief, and the disease is slowly but surely devouring all except your soul and bones, send a postcard to Charles H. Stevens, 204, Worple Road, Wimbledon." You will consider again whether the defendants cannot found upon that the statement that they are practising upon the fears of patients in getting them to take his medicine.

Then here is another: "Consumption. The new cure. If you are a Consumptive yourself, never mind if your doctor and the specialist have told you they can do no more for you—sanatorium treatment, open air, and change of climate failed to give you relief—send a postcard to Mr. Charles H. Stevens, 204, Worple Road, Wimbledon, for full particulars of this new cure, and records of the wonderful recoveries it has brought about; or, if you will give him details of your case, he will send you a supply of it (the cure) on the 'No cure, no pay' principle."

Then we know that the plaintiff enters into bonds, and he has told us that when he enters into a bond not to get paid at all unless he cures, he wants £25. The advertisement, however, does not say that. The advertisements always say, "No cure, no pay." "We guarantee to cure everything." "Whilst it positively destroys the germs of consumption so quickly, is perfectly harmless even to the most delicate constitution, and any one suffering from this dreaded disease can have a supply of it sent post free to any address on the 'No cure, no pay' principle; that is to say, it need only be paid for if perfectly satisfied with the benefit received from it, and the patient considers the progress made warrants its continuance."

Then there is another in February, 1908, from the *News of the World*, which is, I believe, a penny weekly paper. "Consumption. No Cure, No Pay. These are the extraordinary terms Mr. C. H. Stevens gives with his new South African Cure for Consumption. He has cured thousands of hopeless cases in Africa and elsewhere during the last four years, and will guarantee to cure you if you are affected with any complaint of the chest, or will return your money in full if you do not improve in health to the satisfaction of your own doctor. He (the discoverer) only returned to England a few days ago after many years absence to prove his cure to the satisfaction of the British Government."

Then here is another: "Consumption. A guaranteed cure. I will make a present of ten pounds to every patient suffering from his lung I undertake to cure if I fail to do so, and will treat any patient free of charge who cannot afford to pay."

Then there is another in 1910. "Consumption. A guaranteed cure. This may sound too good to be true, but it is a fact, and I will make a present of £10 to every patient I undertake to cure if I fail to do so, and will treat any poor sufferer free of charge who cannot afford to pay. There is no catch or trickery about this offer. An absolute cure for the Great White Plague has been found, and I—the discoverer—am offering it to all who are unfortunately afflicted. A large and ever increasing number of medical practitioners in the British Isles are using the cure, and it alone, in the treatment of their tuberculous patients. I am also treating doctors' wives, sons, and their intimate friends, so if you have any symptoms of this terrible disease write to me at once; never mind if you cannot afford to pay me a single penny, for I am going to prove that my discovery is a positive cure for consumption, no matter what it costs; and if you are too poor to pay, all you have to do is to get your local doctor to watch the speedy recovery you will most probably make."

You, gentlemen, will consider whether the meaning of those advertisements is not that he has what is called and used to be known as an infallible cure. What is said by the defendants is that this man undertakes to do things which he knows he cannot do. That is the gist of the libel, but it is not for one side or the other side, or for me, but for you, to look at the words used and say what the imputation is, and whether what has been said of him has been justified.

Then there is one other in which he says this is a general tonic and will cure any broken-down system: "Stevens' Consumption Cure is a vegetable germicide, fatal to all disease germ growths, but acts as a strong tonic; is a blood purifier, stomach cleanser, and a nerve stimulator; one will readily understand that it must be all these to cure consumption and build up a broken-down system entirely by itself."

Those, gentlemen, are substantially the articles. In another case he says that in a few months, and in another case he says in six months, he will undertake to cure every external case and every pulmonary case. First of all he says in six months, and then he says in a few months. In other words, the gist of the advertisement—so the defendants say—is that no case is incurable; and in the witness-box Stevens said: Unless a man has one leg in the grave I will undertake to cure him. He is here before the public saying: Those are the professions I make, and what is said by the defendants is: Those professions he cannot possibly believe in.

Now before I part from the written circulars there is one other matter that counsel has commented upon, and it is this.

Before these articles were written by Mr. Harrison, who is one of the chemists called on behalf of the defendants, he wrote to Stevens for a bottle of this medicine, and the result of his writing for a bottle was that he had a series of letters sent to him following up the inquiry. Mr. Harrison wrote for a bottle for the purpose of his analysis, but, I suppose, that was not known to the people in charge of the office, and the result is that having sent the bottle he does not say, The bond will be for £25, otherwise I shall want payment in advance, but he says: "When the amount to be paid for the cure is mutually agreed upon you can pay it over to a bank manager or some responsible person, only to be paid to me in case a complete cure is effected to the satisfaction of your own doctor in the time I state; if this is not done your money is returned to you, for my terms are 'No cure, no pay.' If you decide to give my treatment a trial you may please yourself whether you send for one week's treatment at a time or for the three months' course at the reduced price." Then the bottle is sent. That is followed by another letter from Stevens in which he says, "Your local doctor will admit to you that he has nothing at his command to destroy the tubercle bacillus, neither does he know anything that will do so without killing the patient at the same time, and it is this missing link which I claim to have discovered." I do not think there is any question that he is not saying, "I can cure consumption because this is such a very fine tonic that it will build up your body and enable you to throw it off," but "I can kill the tubercle bacillus." If that is the issue, does he really believe that his medicine will kill the tubercle bacillus and that it will really cure every kind of complaint because it can kill every possible germ? If that is the imputation — you must not take it from me that that is the imputation, because you will have to judge the words for yourselves,—but if that is the imputation you will have to bear in mind some of the large body of evidence which is more or less material to that issue. We are not trying any particular issue about consumption in this case. We are only trying the question whether this is fair comment or not on the plaintiff. But to throw some light on the matter we have heard a great deal of evidence which to me has been very interesting and, I dare say, to you too.

Now I will pass away for the moment from the different prospectuses and letters which were written, merely saying that if you desire to see them when you come to consider this matter I will put them all into one bundle and you shall have them.

There is this remark that I can make. Juries are absolute masters as to whether they believe evidence or not. It is open to you on a medical matter, if you think fit, to disbelieve Dr. Acland and to believe the plaintiff when he contradicts him. It is entirely open to you, but I feel constrained to make this remark, that although it is fair criticism of doctors—and doctors are subject to criticism the same as every other person who is or is supposed to be an authority—although it is fair criticism to say that doctors are conservative and are prejudiced and will only deal with professional people, if you pursue that argument to its logical conclusion and say that because a doctor will only listen to professional men, you are to disregard what they say in favour of Tom, Dick, or Harry, who have never had the smallest medical experience from the beginning of their lives, we are getting perilously near a gross absurdity. Any of you gentlemen, or any member of the Bar, or anybody, may say that a particular judge perpetrates an injustice; it may be accurate, or it may not, but to say that because a judge may perpetrate, or sometimes perpetrates, an injustice you could get a better judge by going out into the street and picking up a crossing sweeper and say he is untrammelled by prejudice—that is something like the argument that appears to have been put forward here. We have had before us Sir Richard Douglas Powell, Dr. Acland, and one or two other doctors, and you have listened, I am sure, very attentively to their evidence, but I do want to summarize what they have said about the matter. A great deal of what they have said I do not think is questioned. Doing my best to summarize it, it is this: Consumption is in fact due to a particular bacillus, the tubercle, and it arises as a specific form of disease. When a part of the body—I am dealing with the lung for the moment—gets inflamed, the tubercle finds a home and it produces a specific disease; and the medical men who have studied this matter for years have arrived at the conclusion that they know of no drug taken through the blood that will kill it. They say it cannot be compared with other bacilli. There has been a large advance in medical science lately by the aid of the microscope, and the discovery of these different kinds of bacilli—they are not visible to the naked eye; one hears of putting a million of them on a threepenny bit—they are things that can only be discovered by the most powerful instrument, and can only be treated by the most delicate and most careful manipulation—and it is found out now that this disease, which was an ordinary lung disease, is really due to this parasite, the tubercle, and they say that this is an extremely tough and wiry customer —I am using very unscientific language now—other bacilli, they say, can be got rid of more easily, but not so the tubercle; not only is it more lively in itself, but the trouble is that if you get it into the lung, or wherever you get it, it proceeds to destroy the tissue round about, and prevents the blood getting at the tissue, and the result is that doctors say: We do not use the word "cure," but we say we arrest it, and it may be arrested so that the man will live the course of his natural life; in one or two cases the man can cough up the actual stuff and get rid of it once and for all, and the other case is to build up an antibody, do something to the germ by which something can be pushed against the bacillus which reduces it to inertness and kill it in that way. But they say: As regards killing it with drugs, we know of nothing that can do it, because it is so extremely lively that if you put anything into the blood which would kill it you would at the same time kill the patient; and they say that at the present time nothing is known to science, and to the medical men in England who have been studying this matter, that will do it. The plaintiff, on the contrary, says: I have found it; my chemist cannot tell you what the substance is, and they cannot say whether the residuum, which they cannot describe, is inert or active, but still there it is. Dr. Acland said frankly that there are one or two things you can cure. He said that quinine is employed in malaria, but there the bacillus is in the blood, and when the quinine gets into the blood you get at the bacillus direct. And the same with that horrible disease, syphilis. There is apparently some cure now called salvarsan. The germ being in the blood, it is able to be got at and can be partially killed by using a strong arsenical combination and administering it directly into the blood. But, says Dr. Acland, that cannot be done with tubercle bacilli because tubercle bacillus is not floating about in the blood, but attaches itself to the surface of the hand or knee or other part of the body, chiefly the surface tissue of the lung, and when it does attach itself in that way it is difficult to get the blood to it at all, because it corrupts the part around it and prevents the blood from getting to it. That is what they say, and they say that, as far as human medical knowledge goes at present, there is no known drug which can do anything like kill the bacillus by being administered through the stomach. That is what they say with their present knowledge. They do not say these things are impossible: no scientific man says anything is impossible, but in the present state of medical knowledge (say the eminent doctors called on behalf of the defendants) there cannot be such a thing—at any rate, there is no such knowledge at the present day. In other words, if you are going to do it you have to do what to our knowledge is a miracle—that is to say, something incomprehensible. On the other hand the plaintiff says (and I am going to call your attention to his evidence presently): "Oh, yes, I can do it because this is a germicide and will kill it."

That brings me now to the point of Dr. Bulloch's evidence. It seems to me to be extremely important evidence, but the weight of it is entirely for you. The plaintiff says: I can cure this case because I can get at the bacillus, and there is something in my drug, whether the chemist can identify it or not, which will cure it. And he says: the stream of people whom I have brought before you, and whom I have cured, shows that I can get at it, and can get at it by killing the germ. In that way Dr. Bulloch's evidence comes in. Dr. Bulloch, we know, is Professor of Pathology to London University, and has spent many years of his life, as he told us, in experiments of this kind, and Dr. Acland says he is one of the greatest living authorities on tubercle. Dr. Bulloch got some tubercle bacilli, both that taken from the cow or bull and that taken from the man, and he conducted a number of experiments. There were certainly five, if not more. I have notes of five experiments. He says: I put this bacillus into the medicine as it is taken by the patient, 1 in 100; but in order to be sure, I took it undiluted, and with my delicate instrument I actually got this tubercle bacillus of the cow and the tubercle bacillus of the man and plunged it into your germ killer, and there it was for fifteen minutes, for six hours, and for six days, and after that time there was the little beggar alive and kicking. If you believe that you may consider that puts an end to the claim made for this medicine that it is a germicide. The physician tells us there is nothing known to science which can do it. The bacteriologist says: Here is your stuff which you say is a germ killer; you say once it gets through the blood the tubercle is killed; here is the tubercle; I hold it in the stuff one hundred times strong for six days, and I produce a basket full of the stuff I have got and it remains alive. That is a matter which may occur to you to be of extreme importance as showing that it cannot cure in the way of killing the germ. When you take a dose of this stuff into the stomach or lung, or knee, or whatever it is, you cannot get it undiluted, and, says Dr. Bulloch, six days is the longest I looked at it; but here was some of the stuff, partly bovine and partly human, 100 per cent. strong; I left it for six days, and it was still alive. Now how is that met? To meet that Mr. Stevens gives some evidence of his own. He has been into the witness-box. We have not heard from him that he has had any medical training or knowledge. At any rate, until he took up the sale of this medicine all one knows of him, according to his own account, is that being a consumptive, as he says, he went out to South Africa and he was immediately cured in the picturesque way he described. We know that he invented a revolving target; we know that he had a cycle agency; and we know that he has been dealing in these medicines, and for some years now has been selling this particular thing. But he says he got different tubercles and operated upon them himself, examined them himself, and he gave you the results of his experiments—taking two plates and rubbing them together; but he flatly contradicts Dr. Bulloch. He says: I have bred some rabbits, and, although I have not a licence to vivisect at all, I actually performed vivisection upon them. He seems to have been the sole anaesthetist, the sole vivisector, as well as the sole bacteriologist and sole microscopist, and I felt constrained to ask him why was not somebody else there, and he said: It is against the law to conduct vivisectional experiments without a licence, and one is horrified to hear that this man has been doing it, if he has done it. But

as regards the microscopical part of it, he has had at his disposal Mr. Cassal and Mr. Parry, or people of the same kind, who are chemists, but there are other bacteriologists to whom he might have said: Here is the tubercle bacilli, try it in this medicine, and give me the result of your experiment. If he was anxious to meet Dr. Bulloch on his own ground, and, one hesitates to say, fairly to put this to the test, why should he not have got some such report? I mentioned Dr. Bulloch. He put this into guinea-pigs. Dr. Acland says: One experiment on guinea-pigs I do not attach any importance to, and I am not suggesting that you should attach so much importance to the experiment on guinea-pigs as to the variety of experiments that Dr. Bulloch made on seeing the tubercle bacillus plunged into this stuff and leaving it there; but as to the other part of Dr. Bulloch's experiment, when the plaintiff had to deal with it, and if he genuinely desired to put this stuff to the test—here is the bacillus, I plunge it into my medicine and it immediately shrivels up—one would have thought that some scientific men whose position and knowledge would carry respect could have been called to say so. The only test we know of is the test applied by the plaintiff himself, alone by himself, in the way he has described. So much for the scientific aspect of the case.

That, gentlemen, substantially represents the defendants' view as to the efficacy of this medicine. What does the plaintiff say on the other side? Here comes in a strong part of his case. He brought in succession before you patients, twenty-nine in all, and it may appear to you that every one of those patients were not what I may call people who have their teeth out and pretend to like it, but it may occur to you that they were all people who had the most genuine belief that they had been cured by this medicine; and you may say: Here are all these twenty-nine people, they were people who suffered from tubercle in the lung, people who suffered from tuberculous abscess, people who had tubercle in the knee, and people who had it in the glands. A great many of them had had it for years, and they have come here to tell you that they had had it for years. I do not want to undervalue their evidence by not reading it to you, because you will recollect how many days were spent by a procession of people who came up and told us their histories; and I think it is fair on behalf of the plaintiff to say that I do not think the actual history of the symptoms was questioned very much by the defendants; they do not dispute the facts. We had twenty-nine of these people called. I dare say he could have produced 129. One wants to be quite fair to the plaintiff. I do not say for a moment that he should go on calling hundreds and let this case last for a month; but there is this comment to be made, that if he produces twenty-nine or thirty he would produce his best specimens—a man would be a fool who did not; I am not saying it against him at all—a man naturally produces his best specimens. He says: Here is a large body of people; their history shows that they have received genuine benefit from this medicine, and that is a matter you have to consider. On the other hand, the view of the defendants is this: Here is a man, his receipts for some years were £2,000 a year; he is probably doing a very large business in the sale of these bottles of medicine, which cost 5s. each, or £2 12s. 6d. for a three months' course of treatment. There are thousands of people treated, and one knows that some must die; one would naturally expect it. We have had it in evidence that one person who gave evidence at the last trial as being cured has had a relapse and has since died. That evidence is met by the doctors on behalf of the defendants in this way. They say it always is Nature that cures. As regards the abscess, they take the view that the man took the medicine at the same time as the abscess burst, and when the abscess was got rid of there was nothing to prevent the patient getting well. That accounts for a certain number of the cases. As regards pulmonary cases, what they say is this: When these are cured or when development is arrested, it is done by the interference of the force of Nature. If the tubercle is arrested, it is by a sudden bettering of the condition of the patient which forms an antibody, which neutralizes the poison in the disease which is in the lung; and it is said these are coincidences, these are cases where you have had sanatorium treatment, and granted that the patients get very much better after they had the medicine, they say, to use the old Latin motto, "Because it is after this, it is not necessarily in consequence of this." Those cases are met in that way. That is the answer to all those cases. I do not want to belittle the evidence which has been put before you by not reading it to you, but I have read it very carefully, and you will recollect that it relates to a large variety of cases, one in the knee and others in different places. The plaintiff's case is that the proof of the pudding is in the eating, the proof of the efficacy of his medicine is in the results. As against that, the defendants say: Although that is your case, the whole knowledge of science at the present day shows that your claims are untenable, and the number of cases you have dealt with and the number of doctors who have sent certificates in which they have said the patients got better and they afterwards got worse would enable the jury to come to the conclusion that you (Stevens) know perfectly well that when you say it will always cure, that it is a specific and infallible remedy for every kind of consumption, you know you cannot carry out what you promise. That is the case on the defendants' side.

There is another body of evidence that I want to deal with, and that is the evidence with regard to what this stuff is, and incidentally it may throw a good deal of light on the matter as to how far you trust the plaintiff's evidence. Do not think that I am giving you any suggestions. You are obviously the best people to judge of this matter, but one cannot pass over the letters which were suddenly produced by Mr. Colam yesterday, when the plaintiff at the conclusion of his case went into the witness-box. The story he gave was this. He says: I was in the last stages of consumption, and, acting on the advice of my doctor, I went to South Africa. You will recollect the story. He says: I went out there and I went to the market place and met an old Dutchman, and he said: "I know somebody who will cure you," and he took him up country and left him in a sort of improvised tent on poles, and a native came with the stuff and boiled some of the stuff and gave it to him, which made him violently sick three days in succession, but he was permanently cured in three weeks. Then he says: I came back to England at once and went to Dr. Pilley. With regard to the story in Africa it rests entirely on his own evidence; and how far it is accurate is entirely for you to say—whether you believe it or how much of it you believe. He says: I came back and I tried to get people interested in it, and I went to Dr. Pilley. Unfortunately Dr. Pilley cannot be found in any medical directory. All that one knows of the plaintiff, then, is that, according to his own account, he is back again in a little while practising, giving this consumption cure to people as a sort of charity, at the same time carrying on a cycle agency, and according to his own view, it was not until the cycle agency came to grief through an unfortunate fire that he began to start this as a business. Up to that time he said it was rather a hobby, that he got some of it and gave it to people who wanted it, and he was doing it charitably. All that rests on his own evidence entirely. Then he says: I started it as a business and I made £5,000 or £5,000 a year. You heard his evidence as to that, and how out of that £6,000 he gave £5,000 away in charity. That is the evidence he gave, and that again rests entirely on his own word. Why should he give it away in charity? He said he went to the Jewish quarter; "they were starving, and I was compelled from my humane views to give this away"—greatly to his credit, but it all rests on his own evidence. According to him, he was making a large income in the first year, and that is how he disposed of it.

Then he is cross-examined, and it is suggested that all this story about the Dutchman and the pot of umckaloabo and his knowledge of the cure is pure fiction, because it is put to him as a matter of fact: Do not you know a man called Weimann? is not this Weimann's cure? did you not buy it off him? were you not partners? No, he said, nothing to do with it. The course the cross-examination took was something of this sort: Have you ever sold any other medicine? No. Have you ever been interested in any other medicine? No; I have not been interested in any other medicine. And then it appeared that he had been interested in a bubonic plague cure and a rheumatic cure, according to his view. With regard to that, I want to read to you these letters in the year 1903. In November, 1903, Stevens writes to Weimann: "Dear Mr. Weimann, Many thanks for herbs but am very sorry that you didn't send me a few lines also to let me know how you were all keeping. Nevertheless I trust you are keeping well and all enjoying good health and that Joey's arm is by this time quite better. The medicine I have titled 'The South African Microbe Killer,' dispensed by V. Weimann, Herbalist, Maclean Town."—It is said that is obviously the microbe killer, and the name first attached to it is Weimann's name.—"A friend of mine in Cape Town Mr. Baliotra, of Cadenza and Co. Strand Street, is a brother-in-law to the London Consumptive specialist. Three weeks ago he, Mr. Baliotra, sent him a packet of the herbs, from me with the request that he should try it. If this report is good and I have every confidence that it will be, all the consumptive hospitals in England and Europe also are in time sure to try it. Mr. Dunlop will call on you about Xmas or New Year, whether I can get or not, I am a wee bit afraid that I won't be able to, for it will mean at least a week travelling there and back and as have just taken over new premises, am up to my eyes in work. Would dearly love to spend another evening in your rural but delightful homestead. . . ." I do not think there is anything more in that letter. Then there is another letter on July 15th, 1903, from Stevens: "Dear Mr. Weimann,—Please send some more consumptive medicine as soon as possible, as much as you have time to get. I have twenty-three samples to send away to England and Scotland, besides very urgent cases in town here; one sample to a niece of Lord Cromer. Love to all, and please don't disappoint me." It is said that this shows that this is really Weimann's medicine, and that the origin of the whole thing is Weimann. Then here is another letter, on September 28th, 1904: "I have just received your epistle and the 65 lb. of herbs. Am very pleased that you are getting more of them, as we expect a big run on them in a short time. I sent the remaining two halves of notes last evening, so you should get them on Friday, and I shall send the halves of three £5 notes with this and the remainder by the next post. I shall then be in debt to you for"—so much, and he sets out the list, £29 5s. Then he says: "I made a mistake before; you will be in my debt for 3 lb. instead of me in your debt for 1 lb.; or I will consider that I owe you for 3 lb. less than your next parcel contains. Yes; I noticed two days before I left East London what a cold rain you were getting."

Then, gentlemen, this is the letter of September 28th, 1904: "I would like very much if you would send me a few pounds of the leaves by themselves as there are such a number of people here with colds on the chest, and I believe you said that they were much better by themselves for it. I don't believe that

any of the roots or the leaves grow down in this part at all as there doesn't seem to be the proper kind of soil for them. As soon as I can convince the medical profession that this is a cure there is somewhere about a million pounds offered as prize money for the first person that brings a consumptive cure to light which you may depend that I shall claim. I only want half of this Mr. Weimann and I shall see that you get the other half. As soon as this is done both our fortunes are made. Don't speak about it in the meantime; keep it quiet in your district. It may take a few months and it may take a year, but it is sure to come. Hoping you are all quite well, with kindest regards."

Then, gentlemen, this is one of the earlier letters, of April 28th: "This is the first opportunity I have had to write you at my leisure since receiving yours of February 22nd. You say you will not mention the names of the herbs and that you are going to give it up. Well, I am sorry that you mistrust me. I don't know that I have done anything to warrant it. It may give you a good deal of trouble and put you to some expense, but I don't consider that you have gone to more than half the trouble or a quarter the expense that I have. Such things I do not begrudge one bit, but if you are willing to forfeit your outlay I am not. The money I have spent on your medicine I shall get back ten thousand times over if it takes me years to do it." That is one of the passages. Another passage is: "I really think that some outsider has persuaded you not to give me the names and quantities of those herbs." The real date is April. That is the letter I have. Gentlemen, I need not trouble you with these other letters. You recollect the cross-examination. You may or may not come to the conclusion that the origin of this medicine is that this man took up Weimann's medicine. Another letter was read, in which he said that times were very hard, and he could not send the money. If that is so, it seems very odd that there were the £5,000 being distributed in charity then or very shortly after that time. That is the correspondence, and you will bear in mind that correspondence.

The Plaintiff: Would your lordship point out that that was three months later, where the shortness of money was said to be, and after litigation had commenced?

Mr. Justice Shearman: Yes, I said so; it was soon afterwards. Gentlemen, you may recollect with regard to this that one of the issues which may come before you, according to the interpretation which you put upon the letters, is the bona fides of the plaintiff. Possibly as to the criticism it does not matter very much whether he got it from Weimann or from a Kaffir. This is all one has about it, but it is worth noticing at the last trial (we can only deal with what occurred at the last trial which is given in evidence at this trial) nothing was said about Weimann, and an extract from the shorthand notes of the last trial has been read, in which he said a native concocted the drugs for him. He was not asked anything about Weimann and nothing was said about him, but what is now said is this, that if this story about the native who was in a picturesque garment and boiled the stuff which made the plaintiff sick for three days was true, it would have been brought forward as an advertisement, because it would have been the best catchy thing to catch the public by saying, "Here was I dying of consumption and I took it myself." But until it comes into court the thing was not mentioned, and then there is the history given with regard to Weimann showing the plaintiff is inquiring what are the names of the drugs, and saying, "I am going on with it even if you want to stop and there is a million in it." That means they are doing it, and very legitimately, for the purpose of obtaining money, not as philanthropists, and they do not say it is for philanthropy. It may throw some light upon the matter if you come to the conclusion that the account given by the plaintiff is not strictly accurate, because that may help you in arriving at a conclusion as to whether he really believes some of the claims he is making with regard to this. If Weimann merely, as he says, grew this stuff and he knew all about it before, and he had it many years before from the native who boiled it in a pot and gave it to him, it may help you a good deal if that story is true, and it may throw some light on whether he really believed those extraordinary things about the efficacy of this medicine. But if you do not accept that story, and you think the origin of this comes from Weimann, it may throw a considerable light upon this medicine which Weimann and he got together and were trying to work as a patent medicine. You might have the idea that he had less belief in its efficacy if it was somebody else's drug which he took up as a commercial business.

Gentlemen, so much, then, with regard to umckaloabo. I have dealt with the medical evidence, and perhaps I should have dealt with the patients and dealt with one or two of the doctors he called. Several eminent doctors were called on the one side, but the plaintiff himself called some doctors. He called Dr. Grün, and Dr. Grün was obviously a believer for some time in this, and seemed to be a believer in it now, and he said he had used it with efficacy. He said, "I thought it was the best thing I had," but recently he was trying something else. That one has to bear in mind with regard to Dr. Grün. Then one has to bear in mind that if this man says he has hundreds of testimonials from doctors, it is very curious that they have not come up.

The Plaintiff: The defendants have prevented them coming up in many cases.

Mr. Justice Shearman: Gentlemen, that is a remark I am sure you will not pay attention to—to have the notion that a doctor, a professional man, will not come up if he believes this is good for humanity. It is a remark made before and commented upon. I do not mind it being made, because the plaintiff is here in person. You will attach what weight you think fit to the remark—that hundreds of the medical profession are terrified and will not come up. Dr. Sames came up. His view was this, if I recollect it rightly. He says, "I have still belief and hope in it, and I think something can be done with it." Then there was a Dr. Jameson who came up who had ordered it for somebody else, and taken it himself, and it had cured him as a wizard cured. He was his own patient. The only other doctor was Dr. Bennett, about whom I want to say something. Dr. Bennett was a man who came up and said, "I produce this herb," and I was anxious to find out who he was, or what his business was. He said he had practised in Liberia. He produced his commissiou, and the commission was made out to Mr. W. B. McPhee, and he said McPhee was his clan name. Why he should call himself Bennett when his real name was McPhee I do not know. I do not think he throws very much light upon the matter. It may be true that this drug never came from Liberia at all; he may have deceived the plaintiff as much as he deceived anybody else. It does not seem to me to throw any light on the matter. He was a curious witness. He produced this thing. He said he picked it among some pineapples in June in Liberia, and we are in July, and he brought it over in a Saratoga trunk. He said it had leaves, and I called attention to this fact myself; he said he had pounded up the leaves and used it for colds. I said, "Why did you bring it without leaves?" He said he had the leaves, and he could bring them, but he has disappeared into the *Exigkeit*, and we do not know where he is. He is a man who says he knows umckaloabo, but at present the fact that there is a stuff called umckaloabo rests upon the plaintiff, Captain Bailey, and this witness.

The Plaintiff: My lord, they admit that it does exist. Mr. Colam has admitted umckaloabo does exist in Africa.

Mr. Justice Shearman: I am telling you what the evidence is. All the evidence I know of, whatever Mr. Colam says, is the evidence of the plaintiff, the evidence of this man Bennett McPhee, and the evidence of Captain Bailey. Captain Bailey says he knows the name, but he says he did not notice the thing particularly. He says, "I think the word means cure for a clot of blood." He says it was used as a styptic and antiseptic. An antiseptic means a germ killer. He said, "I know they take it for chest troubles," and he says "I think the words mean cure for clot of blood." He said it was very hard to know the formation of the Kaffir words altogether. I suggested that perhaps it meant it would cure the bleeding, but he said no, he thought it was a clot of blood out of the chest. Then he said, "The sort I am acquainted with is a kind of tuber or bulb." Mr. Colam has made a good deal of comment about the Spanish onion, but I think that has been a bit overdone. Captain Bailey said it was a kind of tuber or onion. He said, "I looked at these things, and they looked very much the sort of thing which the natives used," and he said it was of a reddish colour. Then he says that he is now a journalist and writer, and that he has seen it in the early Eighties in Griqualand West, and that a man grazed his leg, and two other men chewed the stuff up and gave it to him, and it had a remarkable effect; and he said that they gave it when they have coughing. He said that part of it they used as a poultice, and then he said that the Bennett root seemed to him to feel like a young one. He was a little doubtful about it, but he gave his blessing to the root which was produced by Dr. Bennett. That is the evidence that there is a drug known to the natives which the natives use which is called umckaloabo. With regard to Mr. Bennett, if you accept his evidence, he says in one passage of his evidence that he gave it in a thousand cases, and never used it himself. Whether I took him down correctly I am not quite certain, but he eventually said it was the leaf, and then you recollect what happened. I do not know what importance you would attach to Dr. Bennett, but at any rate it is clear now from Mr. Cassal's evidence that the medicine that is supplied is made of this stuff which has been produced here, and evidence has been called that this stuff which is here is stuff which has been shipped in considerable quantities for a good many years to the plaintiff, and I think you will probably assume that that is what he makes the medicine from. It comes from an African herb, and there is evidence that you can identify it with umckaloabo. Whether it is the same umckaloabo, or the same stuff as the native gave to the plaintiff when he was under the tent, or whether it is the stuff that Dr. Bennett indentifies does not matter. There is strong evidence that it is an African herb.

With regard to the medicine I have only this to add in summing up, and then I shall have gone roughly through the evidence in the case. It was first sold in Capetown as "Sacco." Apparently there was trouble in Capetown. It was made into a company. For a long time I was trying to get at how "Sacco" was sold over here, but at last we got what one would suspect, namely, that "Sacco" is on the market as well. Then the plaintiff and those associated with him went to Johannesburg, and according to his account he was the victim of a persecution by the doctors there, but as he opened an Institute of Preventive Medicine, one can understand he got into trouble for practising as a doctor, or, as it is termed, "doing acts which are reserved for doctors." At any rate, he got into trouble. Then it was opened as "Lungsava," and there an alteration was made, and then, gentlemen, there appears on the scene this stuff chijitse, and that appears to have been mixed with it. But what effect is to be attributed to it, or why it is mixed with it, or whether it is mixed with it to distinguish it from "Sacco" I do not know. It is called an improvement, but what effect is

attached to that drug one does not know, because they claim for umckaloabo all the benefits, and it is the umckaloabo which is supposed to be the germ killer, and why it is added, or on whose advice it is added, one does not know. Then it is called "Lungsava." Let me summarize it to the best of my ability. There was a gentleman named Wightman (this is from the admissions of the plaintiff), and he sent "Sacco" to a number of people, and letters were sent, which came to this effect: "Will you try my medicine, and send me a confidential report as to how it goes on?" The result was that a number of people who tried it said that the patients got better, and they sent letters on the condition that they were treated as confidential. They were addressed to Mr. Stevens, although Mr. Wightman got them, because it was in Mr. Stevens's name that it was sent. Then "Lungsava" was brought out, and I think one is entitled to remind you of this. "Lungsava" is brought out, and they are trying to bring it out as a company. It is said that the prospectus was not issued to the public, but privately to friends. Whether there should be a lower code of morality in getting money out of your friends or the public does not matter; but at any rate it is a prospectus under which they are trying to get money. The prospectus contains a number of certificates given by doctors when they were asked to try "Sacco" and report confidentially, and extracts are given and they appear on this prospectus. It is pointed out by Mr. Stevens that if you looked in the prospectus that is explained. The British Medical Association eventually wrote to all these doctors saying "Have you authorized this advertisement of your name for 'Lungsava'?" It is pointed out by Mr. Stevens on this prospectus that these advertisements were given for "Sacco," and so it is, gentlemen, in a sense, like this: Here is the prospectus of "Lungsava" "For private circulation only," the capital is £10,000, divided into 10,000 shares of £1 each. Down at the side it says, "With regard to the virtues which 'Lungsava' possesses, any subscriber may go to the South African Institute of Medicine." These people called themselves the South African Institute of Medicine. Then it says that the list attached are only a few of the British medical epistles received about Mr. Stevens's original discovery, "Sacco." Of course, if you read it you will find these are given to a different medicine, although only different, I daresay, by the addition of the green stuff to the red stuff—but there it is. The British Medical Association wrote to these people, and they all said they were scandalized at the improper use of their names. A good many wrote back. I do not want at this late hour to read you the letters, but here is a bundle if you wish to consider them [exhibiting same]. There are about thirty writing and saying they did not authorize it. But you may take it roughly, so as to put it to the advantage of both sides: roughly it appears that the most of them were extracts from real accounts and reports which have been given, but they had been given under the circumstances which I have told you of. Roughly it proves, on behalf of the plaintiff, that they did write the things which are here, but not the whole of them. Mr. Colam has pointed out that in some of them, although they publish early letters which were favourable, they did not publish later latters which said the patient had died. Mr. Colam said, "Here are a couple of cases which said the patient had just died. Why did you go on advertising those when you knew the patient had died?" The plaintiff said, "I never had those letters." He apparently had the good fortune to have the favourable letters brought home by Wightman, and not the unfavourable letters. That is the history of it. This medicine has been going on, and has been sold for a long time since.

I am not going to trouble you with the letters, because I am sure you have heard them. Just as I passed over in detail the twenty-nine cases that come up one way there were also cases given on behalf of the defendants. They were questions of correspondence. There was the case of the man with silicosis of the lungs where he died after being assured that he had every chance of getting well. That is substantially it—there was a chance of getting well. There was another case where medicine was supplied, and the man died, and the widow sued and got the money back. There was a third case whom this man diagnosed and told him he had got consumption, and a doctor said he had not got anything of the sort. Against those you will set the large number of people who have come up and said "I took this medicine because I had consumption, and I was improved through it." Gentlemen, I think substantially treating it in compartments to the best of my knowledge I have gone through the mass of evidence which has been dealt with.

Let me in leaving this case and these documents to you finally sum this up. Although one has been discussing the history of consumption and the present knowledge of it, and although one has been discussing the effect of this particular drug, yet you have to confine yourselves very closely to what the real issue in this case is, and I come back to where I started. Having regard to all the evidence that has been given, all that is proved with regard to the value of this medicine, the effect it has had on patients, what doctors have said for and against it, to the entire conduct of the plaintiff since he took this medicine up to make a livelihood out of it, and having regard to what has been proved to your satisfaction in that matter, will you now turn to these articles here in this book, and say whether, having regard to what has been proved in this case, you think these articles are or are not a fair comment? That is the one and simple issue which you have to try which is of importance. Now which is it? If you come to the conclusion that the things that have been proved are not true facts so as to be a proper foundation for the comment and attack upon the plaintiff that has been made, then you will find for the plaintiff. If, on the other hand, you find that the facts that have been proved in your judgement afford ground for the comments—that is to say, it is fair criticism and justified by the proved facts, then you will find a verdict for the defendants.

But if you find a verdict for the plaintiff, and if you answer the question by saying that this is libellous and not fair comment, then, and then alone, arises the third question as to damages. The question of damages is purely a matter for the jury, and not a question of comment on the part of the judge. One has always to give some moderate and reasonable sum in such a case. The plaintiff, indeed, here says, "I am not out for damages, but to clear my character." That does not mean that he is not to have any damages, but they are to be kept moderately within limits. In dealing with damages you have to recollect that if you make a violent and unprovoked attack, founded on untrue facts, juries may properly give heavy damages. If, on the other hand, you think the defendants have just exceeded the line and the conduct of the plaintiff has not pleased you, although the defendants have exceeded the line, then the damages may be small. This is a matter which is within your province. That is all I want to say with regard to the degree of damages. This point only arises if you find the matter goes beyond the limit of fair comment. I am sure you will consider this very carefully. This is a responsibility which always rests upon juries who have to try questions of fair comment, because you represent the public; you are taken from the public. You are not laying down a law, but you are laying down a standard which you think right and proper for comment in the circumstances of the particular case. It is for you as members of the jury to fix that standard, and you have to say whether, having regard to the facts, this is within the standard of permissible fair comment by people writing in the public interest, or whether it is outside it. If it is inside it, it means a verdict for the defendants; but if it is outside it, it means a verdict for the plaintiff, with such damages as you may consider proper.

The Plaintiff: Will your lordship explain one more thing to the jury, and that is about the onus being upon the defendants and not myself?

Mr. Justice Shearman: No, I do not propose to add anything more.

The Foreman of the Jury: Would your lordship write down the questions which we have to answer?

Mr. Justice Shearman: Yes, there they are.

(The judge here handed the written questions to the jury, who retired at 4.42 p.m.)

Mr. E. G. Kimber: My lord, in the absence of the jury, would your lordship allow me to explain that I am instructed on behalf of the "Sacco" Company?

Mr. Justice Shearman: I see you were instructed, but I am afraid I cannot hear you. I think your duties are confined to saying you represent the "Sacco" Company.

Mr. E. G. Kimber: I see it appeared in your lordship's summing up what my connexion as between this company and the plaintiff was.

Mr. Justice Shearman: I note your appearance.

Mr. Stevens, having regard to your last remark about the onus, I should like to tell you why I did not pay attention to it. It is because it is wrong. If you look at that passage at the bottom of the page I think the onus is the other way, but I am uncertain about it. (Handing book to the plaintiff.)

(The jury, after an absence of eighteen minutes, returned to the court.)

The Associate: Have you the questions and answers?

The Foreman of the Jury: Yes. (Handing same.)

The Associate: Gentleman, are you all agreed?

The Foreman of the Jury: Yes.

The Associate: Are these the answers to the questions submitted to you?

The Foreman of the Jury: Yes.

Mr. Justice Shearman: To the first question, "Are the words complained of libellous?" the answer is, "No." Then, "Are they fair comment upon matters of public interest?" "Yes."

Mr. Dickens: I ask for judgement with costs and a certificate for a special jury and the costs of the previous hearing.

Mr. Justice Shearman: Yes.

Thank you gentlemen. I am very much obliged to you for your services.

The Plaintiff: May I ask for a stay of execution of costs in view of an appeal, my lord?

Mr. Dickens: Your lordship will put Mr. Stevens under some sort of terms?

Mr. Justice Shearman: It is only costs.

Mr. Dickens: The costs are a very large sum, some £2,000. They ought to be paid.

Mr. Justice Shearman: I give you judgement, Mr. Dickens, and I do not think, as it is only costs, I can grant a stay.

Mr. Dickens: If your lordship pleases.

The Plaintiff: Thank you very much, my lord.

Mr. Dickens: Your lordship grants a certificate for the special jury in each case?

Mr. Justice Shearman: Yes. The costs of the first trial automatically follow the result of the second.

Mr. Dickens: Yes, I suppose they do. I mention it so that Mr. Stevens should understand.

WORKMEN'S COMPENSATION CASES.

Obesity.

THE claim of a man for compensation on the ground that having to lie up after an accident he had grown too fat to follow his employment as a miner (BRITISH MEDICAL JOURNAL, March 14th, 1914, p. 630), came before the House of Lords on July 17th. The Sheriff Substitute had found that the incapacity for work had ceased, but the Court of Session by a majority had remitted the case to the Sheriff Substitute to fix compensation. The House of Lords was unanimous in allowing the appeal from the decision of the Court of Session. Lord Loreburn, who delivered judgement, said that if the House had to act upon the merits of the case, he would draw the conclusion from the evidence which had been drawn by the Court of Session. But the only point raised before the arbiter was whether the incapacity of the man resulted from his injury. The arbiter found that it had not, and the House must confine itself to the question, was the conclusion of the arbiter one to which a reasonable man could come? He thought it was. He found that the incapacity of October, 1913, did not result from the accident of October, 1910, and the arbiter's award must be restored.

INSANITY AND CRIMINAL OFFENCES.

IN charging the Grand Jury at the opening of the July Sessions of the Central Criminal Court, the Recorder, in dealing with the case of Sydney Smith, charged with the murder of a newsvendor, pointed out that the accused man, when arrested, threw away some papers. One of these papers stated that he had been improperly detained in a lunatic asylum, and it appeared to him that the best thing he could do to call attention to the matter was to shoot an old man of 70, who would not be very likely to live very long. The case, the Recorder said, afforded a little insight into the ways in which lunatics were dealt with in this country. The accused man had twice been certified as insane. The man had been in an asylum and was discharged as cured, had a further outbreak, and was again sent to an asylum, and again released. He thought that the greatest possible care should be exercised with regard to such persons. At every session of that court he saw the extreme danger of prematurely releasing persons who were under confinement in asylums.

At the trial on July 22nd, before Mr. Justice Darling, Smith was found guilty but insane at the time he committed the act, and was ordered to be detained during the King's pleasure. The jury, in giving their verdict, called attention to the evidence that the prisoner, at the time he committed the crime, was on leave for a month from a private asylum, by permission of the Board of Control. He had some years ago been under treatment in the same institution, but was not dangerous, and was discharged as cured. He then obtained employment, and for twelve years worked so well that he earned a pension. The judge said he could not make any observation about the suggestion of the jury. The case would, no doubt, be reported in the newspapers, and those who had power to alter the law in that respect would see what the view of the jury was.

The Services.

ANNUAL TRAINING OF GLASGOW UNITS.

THREE field ambulances of the Lowland Division, together with the Lowland Mounted Brigade Field Ambulance and the Divisional Clearing Hospital, are encamped at Shewalton, Ayrshire, for their annual training. The total strength of the camp is 768 officers and men and 112 horses, and of this number over 90 per cent. remained for the full fifteen days' period. The usual training in field ambulance work was carried out during the first week, and the units were inspected at work by Colonel D. J. Mackintosh, M.V.O., the Assistant Director of Medical Services; by Colonel Hickson, the Inspector of Medical Services; and by the General Officer Commanding-in-Chief, General Sir J. S. Ewart. On July 22nd the competitions were held in tent-pitching, stretcher drill, riding and driving, first aid, etc., for the Brodie Cup, Glasgow Units' Cup, and other prizes. In the afternoon of the same day sports were held, and these were attended by a large gathering of military and civilian friends. The camp will not finish until August 3rd.

Obituary.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are Dr. Fasbender, professor of gynaecology at Berlin, aged 71; Dr. J. W. Gleitsmann, for many years professor of laryngology and rhinology at the New York Polyclinic Hospital and Medical School, aged 73; Dr. Luigi Griffini, professor of pathology in the University of Genoa; Dr. Simon Marx, formerly lecturer on obstetrics at the New York Post-graduate Medical School, aged 50; Dr. A. L. Mason, associate professor of medicine at Harvard and senior physician to the Boston City Hospital, aged 72; Dr. Eberhard Nebelthau, extraordinary professor of internal medicine in the University of Halle, and formerly director of the medical policlinic in that town, aged 50; Dr. O. G. Ramsey, professor of obstetrics and gynaecology in the Medical Department of Yale University, aged 44; Dr. G. F. Reinhardt, professor of hygiene in the University of California, and formerly president of the State Board of Medical Examiners of California, aged 45; Dr. Jeremiah Clark Stewart, professor of the principles of surgery in the University of Minnesota, Minneapolis, aged 60; and Dr. George Strawbridge, sometime professor of otology in the University of Pennsylvania, aged 68.

Universities and Colleges.

CONJOINT BOARD IN IRELAND.

THE following candidates have been approved at the examinations indicated:

FIRST COLLEGE.—*Helen G. Rea, J. J. Brennan, T. C. K. Coleman, T. Cooney, J. Danaher, T. L. Dolan, P. J. Filose, S. A. Gailey, M. J. Griffin, J. A. Hamilton, G. A. Henderson, B. F. Honan, L. M. Leventon, F. L. Macdowell Norah McCormick, R. G. J. McCullagh, P. J. G. McDonnell, P. J. McGing, M. R. Morris, M. C. Myerson, R. H. Von Nauman, R. H. Newman, M. O'Brien, V. R. O Connor, J. C. Rowan, J. C. Rutherford, I. N. Ryan, S. T. Wills.

SECOND COLLEGE.—M. Bradley, G. Dunne, D. H. Ferris, A. F. E. Harbord, F. B. Harrison, H. Hurst, A. Mahony, E. McCarthy, T. P. MacDonnell, D. B McEniry, H. L. Mooney, B. J. Mulligan, G. C. F. Roe, J. C. Smyth.

THIRD COLLEGE.—H. M. Alexander, T. A. Buchanan, M. Burke, F. Coffey, M. Dockrell, K. Elmes, H. Graham, B. Hirson, H. K. Kevin, C. A. R. McCay, J. McGuire, T. Moore, J. P. Pegum, F. J. Power, A. T. Rhatigan, C. W. Robinson, G. C. L. Woodroffe.

FINAL.—R. A. Austin, R. M. Alcorn, R. J. Brookes, F. Byrne, W. P. Cooney, T. L. Enright, A. B. Foott, S. H. Good, C. W. Joynt, J. Lanigan, A. Merrin, W. J. J. Mulcahy, C. Murray, J. J. O'Connell, H. V. O'Donoghue, L. S. O'Grady, G. M. C. Powell, M. Shipsey, N. A. K. Sparrow, F. M. D. Taylor, J. J. Walsh.

D.P.H.—*D. M. Barry, R. Cramb, H. R. M. Ferguson, P. E. Harrison, A. F. Kennedy, A. C. Lorena, R. J. May, C. G. Sherlock.

*Passed with honours.

Public Health AND POOR LAW MEDICAL SERVICES.

MEDICAL OFFICERS OF HEALTH AND PRIVATE PATIENTS.

MEDICAL OFFICER.—It is no part of the duty of a medical officer of health to examine a patient suspected to be suffering from an infectious disease. If a medical officer of health who is in private practice sees a patient for this purpose he is entitled to his usual fee.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Blackburn.—The Medical Officer of Health, Dr. J. Coote Hibbert, estimates the population of the county borough of Blackburn at the middle of 1913 at 133,931. The birth-rate was 21.7 per 1,000, and the death-rate standardized for sex and age was 17.1 per 1,000. The infant mortality-rate was 148 per 1,000 births. This last rate was nearly 20 per 1,000 above that of 1912. In one of the wards of the borough the rate was, however, as low as 59 per 1,000, though in one other it was as high as 229, and in two others it was 223. Investigations were made with respect to nearly all the deaths of children under 1 year of age, and it was found that 37 per cent. of the mothers were employed in the cotton industry. In nearly 20 per cent. of the cases investigated the children were nursed out. A pavilion containing 26 beds at the Blackburn Fever Hospital is now used for the treatment of tuberculosis, and during the year 119 patients were admitted. Of this number, 103 were insured persons. The average stay in the hospital of the 91 patients who were discharged during the year was sixty days. In the case of 25 patients discharged no improvement was said to have taken place, and as regards 6 patients the disease was advancing. Eight patients died during the year. The number of cases of phthisis notified during the year was 230, and there were 88 deaths from the disease. The phthisis death-rate was thus only 0.65 per 1,000. Of other forms of tuberculosis 104 cases were notified, and there were 49 deaths. Of the 2,923 children born during 1913, more than one-half were not vaccinated, and of the children born during the last five years exemption certificates were obtained with respect to as many as 6,348. Referring to this large number of exemptions, Dr. Hibbert points out that should small-pox be introduced into the borough there will be a great risk of an extensive outbreak unless the early cases are immediately brought to the notice of the Health Department and their prompt isolation effected.

Medical News.

THE annual meeting, motor-car tour, and luncheon of the Brussels Medical Graduates' Association will be held at the Earl's Court Hotel, Tunbridge Wells, under the presidency of Dr. Fielden Briggs, on Saturday, August 8th, at 1.30 p.m. Members are invited to bring ladies. Tickets, price 5s. (not including wine), may be obtained from the Honorary Secretary, Dr. Arthur Haydon, 29, Broadhurst Gardens, Hampstead, N.W.

A POST-GRADUATE course of clinical medicine will be held in the autumn at the Hôtel-Dieu, Paris. The course, which is under the direction of Professor Gilbert, will be essentially practical; it will extend from Monday, September 28th, to Saturday, October 10th, and will comprise thirty lectures and demonstrations. These will be given by MM. Maurice Villaret, Dumont, Hirscher, Bénard, Chabrol, Lippmann, Paul Descomps, Deval, Pierret, Grivot, Guilleminot, Dausset, Jomier, and Durey. Those who attend will have the opportunity of personally examining the patients, handling apparatus, and making preparations in the laboratory, and a certificate will be given at the end of the course. The fee is 100 francs (£4). Application should be made to M. Deval, chef de Laboratoire, Hôtel-Dieu, Paris.

As has already been stated in the JOURNAL, the fourteenth French Congress of Medicine will be held at Brussels on September 30th, October 1st, 2nd, and 3rd. The congress is under the patronage of the King and Queen of the Belgians, and the honorary presidents are MM. Berryer, Minister of the Interior, and Poullet, Minister of Science and Arts, and M. Klobukowski, French Minister at Brussels. The actual president of the congress is Dr. Henrijean, professor in the Medical Faculty at Liége; the vice-president is Dr. Bordet, professor in the Medical Faculty of Brussels. The questions proposed for discussion are cardio-vascular syphilis; vaccinotherapy in general, and in particular vaccinotherapy of cancer and typhoid fever; the therapeutic value of artificial pneumothorax; lipoids in pathology. The general secretary is Professor René Verhoogen, 22, rue Joseph II, Brussels.

IN the annual report for 1913 of the medical officer of health for the Port of London, Dr. Herbert Williams, reference is made to the efforts that have been made by the Port Sanitary Authority, though without avail, to obtain greater powers than already exist for the protection of the country from the introduction of small-pox. In view of the large and increasing number of unvaccinated persons now to be found in this country the Port Sanitary Committee suggested to the Local Government Board that power should be given to Port Sanitary Authorities to visit and inspect all persons on board ships arriving from ports at which small-pox was known or suspected to exist if situated within fourteen days steaming of ports in this country, and that there should be the same powers and penalties as at present exist under Orders of the Local Government Board relating to plague, yellow fever, and cholera. In support of the suggestions of the Port Sanitary Committee, Dr. Williams was able to give various instances in which cases of small-pox had managed to creep into the country owing to a person having become infected at a foreign port and arriving in England within the limit of the incubation period of the disease.

LAST December a gunner belonging to an artillery regiment stationed at Bourges was admitted into the military hospital in that city with symptoms of acute inflammation of the appendix of three days' duration. Dr. Gary operated at once, and M. Bonel, who has reported the case (*Bulletins et mém. de la Soc. Anat. de Paris*, March, 1914, p. 112), states that the peritoneal cavity contained much fluid, "turbid rather than purulent," and with a distinct faecal odour. The vermiform appendix was greatly enlarged and sloughy, and there was a perforation close to its attachment to the caecum. There was no faecal collection or foreign body in its canal. The coils of intestine were washed with ether after Morestin's method—now much employed in France—the abdominal cavity dried by means of compresses, and a drainage tube inserted. The patient did very badly until the fifth day, when a big *Ascaris lumbricoides* in a state of maceration came away through the tube. Convalescence followed, and was only interrupted by pulmonary symptoms on the fifteenth day. According to Guiart, the parasite in this type of appendicitis is the direct cause of the disease—the inoculating agent, in fact. Authorities on intestinal worms seem not quite sure that the perforation is directly caused by the lumbricus. Raillet considers that it irritates a point in the mucosa, and that a perforating ulcer develops.

Letters, Notes, and Answers.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Aitiology, Westrand, London.* The telegraphic address of the BRITISH MEDICAL JOURNAL is *Articulate, Westrand, London.*

QUERIES.

SEA-WATER asks for advice as to the cause and treatment of the following condition: A man on one occasion paddled with his children in the sea; half an hour later his legs began to swell rapidly, the swelling extending as high as his legs had been immersed and ending abruptly. The swelling diminished slowly, and it was a week before he was able to walk properly. On another occasion he ran on damp sand in his shoes and stockings; presently he noticed the swelling beginning—the swelling on this occasion was not so severe as on the previous occasion. One child has developed the same peculiarity. There is no tendency to oedema under ordinary circumstances.

ANSWERS.

SEA BATHING AND SKIN IRRITATION.

W. M. writes: I would suggest to "F. I. W." to advise his patient to take a fresh-water bath one or more times to which sufficient carbonate of soda has been added to make the water slightly alkaline. I suffer from intolerable itching and desquamation, particularly of the legs, after sea bathing, but have always found the soda bath sufficient to arrest the condition complained of.

LETTERS, NOTES, ETC.

THE MEDICAL DIRECTORY.

MESSRS. J. AND A. CHURCHILL (7, Great Marlborough Street, W.) write: The annual circular of the *Medical Directory* has been posted to every member of the medical profession. Another copy will be forwarded on request, should the first notice have accidentally gone astray. We should be glad if practitioners will kindly co-operate in returning the forms to us promptly, so that the entries may be as accurate as possible. To meet the convenience of purchasers, the *Directory* will be on sale this year early in the month of December.

A CLINICAL TEST FOR THE ESTIMATION OF GLUCOSE.

DR. J. BARKER SMITH, L.R.C.P., writes: I am sorry that Dr. G. C. Parnell (BRITISH MEDICAL JOURNAL, July 4th, p. 12) has taken so much trouble to investigate glucose in urine by coloured glasses after caramelization by liquor potassae. Because a full complement of gradations of yellowish-brown colour, fifty gradations between water and sherry colour, was published in *The Hospital Gazette* so long ago as December 10th, 1892, in serial articles in which the estimation of the caramelization was made by colour, also by oxidization. If Dr. G. C. Parnell will run a weak solution of acid permanganate into a weak solution of potassium iodide, he will find that he can strike the yellowish-brown tint of caramelized glucose, maltose, lactose, etc., almost with the same facility as a chord in music. For some years past I have found it convenient to use a few discs of coloured glass, but here, again, I get my gradations quite easily, and these are also *en rapport* with the chemical gradations. As regards the term, "thoroughly boiled," using a weaker solution of potash and boiling exactly one minute, I found the time of boiling made a considerable difference. It may be that he has solved the bullet-like discharge of the tube contents when equal volumes of liquor potassae and urine are used, by a careful selection of size of test tube; it was this difficulty which made me use a weaker potash solution. I am quite sure that Dr. Parnell would not have made this departure had he known the extent of the work already done and published during the last twenty years in various medical and technical papers.

The Popular Lecture

DELIVERED AT THE

EIGHTY-SECOND ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION

BY

J. ARTHUR THOMSON, M.A., LL.D.,

REGIUS PROFESSOR OF NATURAL HISTORY, UNIVERSITY OF ABERDEEN.

VIS MEDICATRIX NATURAE.

Allow me first to thank the Council of the British Medical Association for inviting me—a zoologist—to give what is at any rate called the Popular Lecture. This is not so irrelevant as it seems, for the links between zoology and medicine are many and ancient. There was a time, indeed, when the physician bore without reproach the name of a small animal which he carried about with him in a tube in his pocket—to wit, the leech—the only animal that has given its name to a profession; but the links are even closer to-day. Thus, such creatures as the trypanosomes of sleeping sickness and the plasmodia of malaria are certainly zoological property, and every medical man knows the importance of the fly on the wheel of the chariot of civilization. I propose to lecture for about half an hour, and then in the dimmer light to show some interesting slides.

It is said of one of the most brilliant men of science of to-day that the only use of the title that he gives to a lecture is to indicate what subject he is certain not to speak about; and to some extent this reproach applies to my title—the Healing Power of Nature, *Vis Medicatrix Naturae*. The subject is so large that I must leave many sides of it untouched, and other sides of it hardly touched at all.

Thus, the title might well enough apply to the healing virtues that there are in many natural substances, in the interesting old simples that simple peoples (and people) still use.

But I must not be drawn aside by this attractive theme, save to remark that we should not scoff *too* loudly at the old prescriptions. Have we not lately rediscovered that more than one snake carries in its gall bladder a sure antidote to its own venom? Is not the old advice that the coward should eat of the lion's heart, so that he might be brave, echoed in the modern treatment of a cretin with the thyroid extract of a sheep? Is it not like a leaf out of an old book to read that a clever use of pituitary extract enabled a successful examinee the other day to add in a short time to his height the few inches that were required in order to secure a post for which he had proved himself otherwise eligible? It looks as if by taking sufficient thought we could add a cubit to our stature.

The title, the healing power of Nature, might also refer to the extraordinary capacity that many living creatures have of healing their wounds and regrowing lost parts. One of the Big Trees or Sequoias, which was a seedling in 271 B.C., suffered a burn 3 ft. wide when it was 516 years old, and spent 105 years in folding its living tissues over the wound. When it was killed, at the age of 2,171 years, it was engaged in healing a third great wound 18 ft. wide and about 30 ft. high. A sponge can be cut up and planted out like a potato; it may be minced and pressed through a sieve without losing its power of regrowth. An earthworm thinks nothing of regrowing a new head or a new tail; and a snail has been known to regenerate its horn and the eye at the tip of it even unto forty times. The curtailed lizard grows a new tail, and a stork can replace the greater part of its bill. For various reasons there is not much regenerative capacity in man; we can regrow our hair—often a million cells in a day—but we cannot regrow a tooth or a single nerve cell. Yet I must not be drawn aside by this attractive theme, further than to remark that one of the most interesting facts in regard to the regenerative capacity—Nature's power of healing—is its adaptive distribution. It tends to occur in those animals and in those parts of animals which, in the natural conditions of their life, are particularly liable to non-fatal injury. Long-legged and lanky animals like crabs and star-fishes usually show much of it; a self-contained globular animal like a sea-urchin shows little. The chameleon is one of the few lizards which cannot regrow its tail, for it keeps it safely coiled around the branch. Another very interesting fact is that what is regrown is not always quite true to pattern—the crab does not always get an eye for an eye, but it may be an antenna for an eye. The lizard does not always regrow its own tail, but its grandfather's, so to speak. There is a great secret here, but this is not the time to probe it.

Another very interesting aspect of the healing power of Nature is the way in which organisms defend themselves from injurious intruders, or parasites, or poisons. Every one knows of the garrison of amœboid cells which defend us so effectively; of the antitoxins by which the living cells checkmate toxins; of the way in which the liver is always trapping poisons. It would be very interesting to discuss for a little the immunity which some animals, like the hedgehog and the garden dormouse, enjoy in respect of snake poison, for here the healing power of Nature is seen in very fine prophylactic expression. But I must not be drawn away from my theme.

The title, *Vis Medicatrix Naturae*, might also well enough apply to the part Nature plays in hygiene—a most alluring subject: how the sunlight is the most universal, economical, and effective destroyer of many disease germs; how various bacteria and infusorians make a clean thing out of an unclean; how the earthworms keep the soil sweet; how there is over the world—on land and sea—a body of scavengers of all sorts and sizes who clean up while we sleep, and how many external parasites which we call repulsive are doing their best to keep things tidy and in their places. But I must not be drawn aside by this attractive theme, beyond remarking that there is much truth in the old saying, *Medicina curat, Natura sanat*—Medicine cures, Nature keeps well.

The title, the healing power of Nature, might also refer to the fundamental healthfulness of wild Nature. There is no Medical Association among animals. Pathological variations are pruned off before they have time to catch on. Disease is inconsistent with natural selection; it is almost unknown in wild life. Parasites are common, but most of them do little harm until some change of distribution brings them into new hosts. Then there may be a brief and fierce epidemic. Of course, domesticated animals and cultivated plants have many diseases, but we are speaking of wild Nature. Disease is relatively rare and always transient, and while there may be senescence, there is no senility. Man and his dependants have a monopoly of that. This is an idea of profound importance, but I must not be drawn away from my theme.

What, then, do I mean to-night by the healing power of Nature? I mean to refer to the way in which Nature ministers to our minds, all more or less diseased by the rush and racket of civilization, and helps to steady and enrich our lives.

1. My first point is that there are deeply-rooted, old-established, far-reaching relations between Man and Nature, which we cannot ignore without loss. Man was cradled and brought up in touch with Nature, and he must ever return to her, like the wandering birds whose life is never full till, moved by an organic home-sickness, they come back to nest in the old home where they were born. Like Antæus of old, who lost his strength when lifted up, man becomes weak when he is kept off the earth—whether by poverty or by riches—but gains fresh force when he gets his feet on the solid ground of Nature once more. "On the solid ground of Nature trusts the mind which builds for aye." In a period of evolution which has been mainly urban we miss our contact with Nature; most of all, perhaps, in youth, for it remains true of the child who goes forth every day, that what he sees becomes part of him for a day or for a year, or for stretching cycles of years. It is, I submit, a condition of sanity to know the country and the seasons, the hills and the sunrise, the birds and the flowers; to know—not merely to read about—the sting of the wind-driven snow and the changeful music of the sea. . . . There would be less "psychopathology of everyday life" if we kept up our acquaintance with the bonnie briar bush and the cry of the whaup on the moorland.

> To make this earth, our hermitage,
> A cheerful and a pleasant page
> God's bright and intricate device
> Of days and seasons doth suffice.

2. We need to keep in touch with Nature in order to

get the fundamental impressions of power, of largeness, of pervading order, of universal flux, of intricacy. We need it to keep alive in us that light of life which we call the sense of wonder. We have put ourselves beyond a very potent *vis medicatrix* if we cease to be able to wonder at the grandeur of the star-strewn sky, the mystery of the mountains, the sea eternally new, the way of the eagle in the air, the meanest flower that blows, the look in a dog's eyes. Of course, there are wonders and wonders, changing with the age of the individual and with the age of the race. As Keats lamented, the rainbow has never been quite the same since Newton looked at it with his discerning eye, and the sunbeam that steals through the gap in the shutters and dances on the floor and walls and roof of our room is not such a wonder to us now as it was some fifty years ago. But new wonders have taken the place of the sunbeams of our childhood, and so let it ever be. Science is always pushing the curtain back a bit, but if the half-wonders go, the wonder remains—the fundamental mysteriousness of Nature. You remember what Coleridge said: "All knowledge begins and ends with wonder; but the first wonder is the child of ignorance, while the second wonder is the parent of adoration." Some one said to me the other day that he could not understand a man really seeing the life of an anthill and remaining irreligious. "The undevout astronomer is mad." It is a high ambition to seek to be able to say:

> It is enough if through Thy grace
> I've found naught common on Thy earth:
> Take not that vision from my ken.

3. The healing power of Nature is manifested thirdly in the beauty that is everywhere. There is no place where this voice is not heard, unless man has obtruded noisily. Excepting prize pigs—though I am assured by enthusiasts that even they have their aesthetic points—and other living creatures which bear the marks of man's fingers—all finished organisms are artistic harmonies, pleasing to the unprejudiced eye, especially when seen in their natural setting. A hippopotamus at the Zoo may not be what you would call pretty, but see him in the Nile as Job saw him—Great Behemoth!—with his ruddy hide, in the shade of the lotuses, in the covert of the reeds and fens. "His strength is in his loins and his force in the sinews of his belly, the muscles of his thighs are knit together, his bones are pipes of brass, his limbs are like bars of iron. He is the chief of the ways of God."

There is no doubt as to the healing virtue of beauty. Even the bower bird feels it in its display of bright shells and flowers. Why beauty has this power is a difficult question with a complex answer. The renowned physiologist, Sir John Burdon-Sanderson, expressed his belief that most of the beautiful things in the animate world please us in part because of their fitness or adaptiveness. Some beautiful objects please us because of their associations, often established in early years; others awaken prehistoric memories, as in the repulsion that many good people have for snakes. Others, like the swallow flying south, to warmer lands and coasts that keep the sun, set our imagination working pleasantly. These are some of the reasons for our enjoyment of the beautiful. But there is another, and a very interesting reason, which I may illustrate with reference to colour.

The sensation of colour is physiologically associated with chemical changes in our eyes. Natural combinations of colour induce changes that are pleasant, being eurhythmic, partly because we are not unprepared for them, but more deeply because the colours of living creatures are themselves expressions of normal vital processes, of consistent and congruent processes, which result in the deposition of pigment. The colour may be enhanced by or may be altogether due to structural features—fine lines and bars and rings—which may be accurately described as the ripple marks of rhythmic growth, which please us just like the regular recurrence of certain phrases in music. Muddy colour—such as man often makes—is a discord; it is almost physically painful; it demands what we may call "the impossible" from our eyes. But there is no muddy colour in wild Nature.

In any case Nature spreads before us a rich and ever-changing beauty feast, and, as Dr. Chalmers Mitchell has well said: "Pleasure in her ways, rather than a cold comprehension of them, is Nature's surest gift to us."

4. Another healing virtue in Nature is to be found in its perennial interest. It claims our attention; it arouses the curious spirit. It leads us on and on like the tales of the thousand and one nights. It stretches our brains, so full is it of unsolved problems; but not insoluble, for Nature always gives some reward. We have spoken of the harvest of a quiet eye, but the discoverer has a keener joy, whether in finding an unrecorded flower or bird in a parish, or seeing a new star in the heavens, in reading the riddle of gossamer or discovering radio-activity, in disclosing the new world of the deep sea, as the *Challenger* explorers did, or an even newer and larger world, as Charles Darwin did on the famous Columbus voyage of the *Beagle*.

5. There is healing, too, for our unrest in the progressive disclosure of the orderliness of Nature. Ours is no phantasmagoria of a world, but a Systema Naturae. Wherever you tap organic Nature, Romanes said, it seems to flow with purpose. More and more we can formulate events; often we can predict them; sometimes we can control them. We are parts of a reasonable world, which voices reason and listens to reason. On the tomb of Fraunhofer, one of the founders of spectroscopy, by which we discover the composition of the heavenly bodies, there are inscribed the words "Approximavit Sidera." He brought the stars near. And that is what science is ever doing. When we think of the way in which man, minister and interpreter of Nature, has annihilated distance, has made the ether carry his messages, has coined wealth out of the thin air, has harnessed electricity to his chariot, has almost solved the problem of flight, and is advancing to the control of life itself, we are sure of his rationality, and of Nature's as well. We come back invigorated to the old Aristotelian doctrine that there is nothing in the end which was not also in kind in the beginning. In the beginning, therefore, was the Logos, implicit in the nebula, as now in the dewdrop. It slept through the evolution of plants and coral-like animals, but with dream-smiles which are a joy for ever. It found more expression in the structure and behaviour of the freely moving animals, and became explicit at last in the reasoned discourse of man. But it was present as part of reality throughout the whole process of becoming.

6. But Nature speaks to our moral as well as to our intellectual ear. It was an incomplete survey of the facts which led Huxley to see in organic Nature only a vast gladiatorial show, a dismal cockpit, a war from which there is no discharge, and to maintain that Nature has no word for man save "Struggle on, each for himself, extinction take the hindmost"—a thesis obviously congruent with a competitive industrial age. That Nature thus speaks no one can doubt, for we can observe the singling and sifting that goes on continually, but we are apt to turn away before Nature has finished speaking. She has certainly another counsel to offer besides that of whetting teeth and sharpening claws.

Professor MacGillivray of this university once counted the feathers in the nest of the long-tailed tit, and found 2,379. This is a diagram illustrative of the fact that the limitations and difficulties which enforce struggle and competition may sometimes be transcended and overcome by increasing parental care and mutual aid. In many races of animals success has been the reward of subordinating individual interests to those of the species. When we look into the facts we find that an extraordinarily large part of the energy of life is spent not on self, but for others.

It seems that Nature is continually taking advantage of her children's capacity for self-forgetfulness. Thus, along the mysterious line of instinctive evolution, many insect-mothers spend themselves in producing the next generation and providing them with a substantial nutritive legacy; it is their meat and drink to do this, and often they have not even the reward of getting a glimpse of their offspring. This is one of Nature's ethical diagrams. Nature stamps not only the beautiful but the good with her approval; and when we carefully consider the process of natural selection, Nature's sifting in the struggle for existence, do we not get from it a deep and ancient ethical message—that the individual must be content to subordinate himself to the species, even to lose himself in its progressive life?

7. I admit that Nature's music does not cease on a merry chord, but I think it has a healing power.

It is not a small thing, forsooth, that we are part and parcel of an order of Nature which has evolved for millions of years like a long drawn out drama to finer and finer issues; that the process of evolution has the unity of an onward advancing melody; that all through the ages life has been slowly creeping—and occasionally quickly leaping—upwards; that while there have been many mysterious losses of even branches from the great arbor vitae, the flowers have become finer. There was a time when there were no backboned animals; then fishes appeared, then amphibians, then reptiles, then birds and mammals, and then man—every age going one better than its predecessor.

Is it not full of meaning that in the course of the ages there has been a progressive evolution of the nervous system, an increasing elaboration of behaviour, and a gradual emancipation of the psyche? The bird is more of an agent than the worm—more of a free agent; and the world has greater value to the bird than to the worm. Some simple creatures have only one reaction to all stimuli—one answer to every question; but how complex is the life of the ant on the instinctive line of evolution and of the dog on the intelligent line! Since the beginning of life there has been a growing appreciation and mastery of the world. Is it going to stop?

With increasing familiarity we are apt not to wonder enough at the great process of world-becoming. Finer actors have appeared on the crowded stage, and the situations have become more and more intricate. Just as corpuscles probably became what we formulate as atoms, and atoms molecules, and molecules colloids, and colloids protoplasm, and protoplasm organisms—keeping for the moment to one side of the shield—so organisms have gone on increasing in complexity, and they are at it yet. A great web has been ever passing from the loom of time—hunger and love are its warp and woof—but the pattern has become more and more intricate, and it sometimes seems as though it were picturing to us a story.

Again, we are familiar with the idea of the past living on in the present, like the unsounded letters in words, like unopening button-holes and unusable buttons on our clothes, like offices whose holders have no responsibility save that of drawing their salaries. So the baleen whale's past lingers in the two sets of useless teeth which it has before it is born. The dog's history is echoing when it turns round and round at night on the imaginary herbage of the hearthrug, and the bird's reptilian ancestry is betrayed when the puffin moults its bill or the grouse its claws. We, too, are walking museums of relics—antiquarians in spite of ourselves. Some of the antiques, like the appendix vermiformis, are troublesome anachronisms; others, like the notochord, serve a purpose in development, and then pass practically away; while others, like the ear-ossicles, are transformed almost beyond recognition into new and important structures.

But must we not go much further and recognize what no one perhaps has fully appreciated, that there is a principle of conservation in Evolution. In a very literal sense, the higher animals are heirs of the ages.

Organisms have evolved by a trial and error method; they experiment organically, instinctively, and intelligently; above all, perhaps, in the mysterious ante-natal life of the germ cells they experiment in self-expression—just as water vapour does in snowflakes, but far more subtly. What are called variations and mutations in biological language are the organism's experiments in self-expression, and these are the raw materials of progress.

The organism proves all things, but the other side is that it holds fast that which is good. Great gains once made are not held lightly. Species become extinct and races perish, but important organic inventions are carried on by some collateral lineage. It was probably some ribbon worm that first manufactured haemoglobin—the all-important red pigment of the blood. Many backboneless animals of higher degree on different lines of evolution have not got it, but the invention was too good to lose; and everyone knows that it was retained on collateral lines, and that all backboned animals from fishes onwards have red blood. Or again, the most primitive and in a way most puzzling kind of locomotion is that of the amoeba gliding in the pond. Is it not a most suggestive fact that our health from day to day and the development of our nervous system are absolutely dependent on this self-same amoeboid movement?

For millions and millions of years there was throughout Nature no voice of life at all—nothing to break the silence but the thunder and the cataract, the waves on the shore and the wind among the trees. The morning stars sang together and the little hills clapped their hands, but there was no voice of life at all. The long-lasting silence was first broken by insects, but they never got beyond instrumental music. It is to the amphibians in the Carboniferous Age that we must look back with special gratefulness, for they were the first to get vocal cords, and, interestingly enough, a moveable tongue. With them animate Nature found a voice.

Now, in a much deeper sense, we may perhaps say that for millions and millions of years Nature was speechless—never more than groaning and whispering as it were. It was in Man first that Logos began to be articulate. In science and art and their applications, such as medicine, we hear it clearly. Shall we not say, then, with Whitman, "Prais'd be the fathomless Universe, for life and joy, and for objects and knowledge curious."

I conclude my brief study of some aspects of the *vis medicatrix Naturae* by quoting a few aphorisms from Goethe's well-known rhapsody on Nature.

We live in her midst and know her not. She is incessantly speaking to us, but betrays not her secret.

She rejoices in illusion. Whoso destroys it in himself and others, him she punishes with the sternest tyranny. Whoso follows her in faith, him she takes as a child to her bosom.

She wraps man in darkness, and makes him forever long for light. She creates him dependent upon the earth, dull and heavy; and yet is always shaking him until he attempts to soar above it.

I praise her and all her works.

She has brought me here and will also lead me away. I trust her. She may scold me but she will not hate her work. It was not I spoke of her. No! what is false and what is true, she has spoken it all. The fault, the merit, is all hers.

Everyone sees her in his own fashion. She hides under a thousand names and phrases, and is always the same.

I praise her and all her works. She is silent and wise; I trust her.

In a paper published recently in the *Chemist and Druggist* Mr. C. A. Hill, B.Sc., F.I.C., has given in tabular form the results of the examination for purity of some thousands of samples of pharmaceutical chemicals; the tests were carried out in the laboratories of the British Drug Houses, Limited. The samples were examined during the four years 1910 to 1913; the most important of the impurities tested for were lead and arsenic, but a table is given of miscellaneous impurities, such as mineral matter in citric and tartaric acids, chloride in potassium bromide and iodide, acidity in sublimed sulphur, etc. The limits which have been adopted for the permissible amounts of lead and arsenic are in most cases those recommended by the Committee of Reference in Pharmacy for adoption in the *British Pharmacopoeia*, but the author favours less stringency in regard to the amount of lead permissible in citric and tartaric acids and cream of tartar. The standard recommended by the Local Government Board is a maximum of 20 parts of lead per million in all three substances; the Committee advised a maximum of 5 parts for citric acid and cream of tartar, and 20 parts for tartaric acid; Mr. Hill states that the results he presents show that it has been possible to obtain sufficient supplies of materials conforming to these more stringent requirements, but in view of the considered statements of prominent manufacturers that the removal of traces of lead so as to conform to a more severe standard than 20 parts per million is a matter of sufficient difficulty to affect the cost of production, and to an extent disproportionate to the benefit involved, he appears to incline to the official adoption of the Local Government Board standard. Presumably, the samples described in Mr. Hill's tables represent all those offered by makers to a pharmaceutical wholesale house, and it is satisfactory to notice that in a very large number of cases the percentage of the samples conforming to the requirements was 100, and that only in few cases did it fall very materially below this.

EIGHTY-SECOND ANNUAL MEETING

OF THE

British Medical Association.

Held in Aberdeen on July 29th, 30th, and 31st.

PROCEEDINGS OF SECTIONS.

SECTION OF MEDICAL SOCIOLOGY.

JOHN GORDON, M.D., C.M., President.

PRESIDENT'S INTRODUCTORY REMARKS.

I THINK that I might claim with justice that the medical profession has been and always must be an important force in the development of the State. To the profession falls the duty of safeguarding the health and energies of individual citizens, and to the citizens fall the many duties which the State demands.

The main objects of our profession have been to prevent disease or to cure it, and although in the darker ages much of the medical work was empirical and feeble, still the efforts that were made were honestly conceived and boldly carried out.

Side by side with the great ideals and glory of the profession there has grown that deep love of humanity, that personal feeling for human woes and happinesses that has rendered the name of "family doctor" one with the name of "family friend." The child patients that have become healthy men and women, and good citizens, have been a pride to the physician, and to him the parents turned for the word of participation in praise or blame, or for guidance. It has ever been the struggle of the physician to weed out of the daily lives of the people whatever makes for disease, and to guide them into what strengthens, what helps resistance, what makes for moral and physical well-being, and the full measure of capacity.

The physician of to-day and the physician of a century ago differ little in individual outlook—that is, in the attitude of the professional man to the individual patient. The great difference lies in the collectivist outlook of the present-day physician, who, while no less a humanitarian than his predecessors, realizes more keenly the economic value of health to the State, and surveys his practice and keeps note of the chain of cause and effect with a view to the larger issues in the hands of the State and county and municipal authorities. The earliest official connexion between the State and the medical profession came with the introduction of the Poor Law in 1842. It was evident from the investigations of specially appointed Commissioners that disease was most prevalent among the poor. The Commissioners reported that all epidemics and all infectious diseases were attended by charges immediate and ultimate on the rates, and they said that it was a "good economy to incur charges for preventing the evils where they are traceable to physical causes." On the introduction of the Poor Law system, it soon became apparent that many of the epidemic diseases originated where men, women, and children lived in poverty, degradation, and vice of all kinds. These areas were hot-beds, where the manure was unwholesome food, dirt, dejecta, and the neglect of the simplest sanitary laws.

It was not possible for these poor people, who were devoid of knowledge, of money, even of energy, to help themselves out of this estate of misery and disease. Nor was it sufficient that the work of redemption should be undertaken by private voluntary workers. Slowly it became clear that the work had to be done by organized State efforts. In increasing degree State control has come to be exerted in almost every department which has any connexion with public health, and simultaneously the medical profession has been called to assist more and more in the prevention, amelioration, and cure of disease.

The attention of the profession has been directed towards the study of illness as a social sore, able to be combated at its origin or even removed, and this same attitude of close observation is widely diffused among the general public. Remedial measures now embrace not only the appeal to "medicines," but also the appeal to local authorities to improve the housing of the people and train young people in habits of cleanliness and purity of life. The trend of social work no less than the work of the medical profession has been towards careful scientific study and treatment, and the formulating of preventive measures.

We cannot overestimate the beneficial results which have streamed from the works of Pasteur, who in 1858 solved the problem of infection. His works early began to penetrate the minds of all those who were devoting themselves to the health of the community.

The fact that numerous diseases sprang from living vegetable organisms was shown by Lister and Koch, while speedily other observers descried that living animal organisms produced other groups of diseases. It followed that if both these vegetable and animal organisms could be eliminated, or their dire effects neutralized, the corresponding diseases would be removed, or at least diminished in their severity.

In the administrating of public health the important advances were made by the creation of a new central authority—the Local Government Board—and the appointment of medical officers of health throughout the country, to render skilled assistance in the detection of areas of disease and the removal of causes, and generally help in the initiation and development of agencies to secure the health of the people. The State also turned its attention to the protection of childhood and youth, and has never ceased its efforts to devise suitable and effective legislation with this end in view.

I need only recall one or two of the various Acts that have come into operation for the betterment and preservation of the health of the people, such as the Nuisances Removal and Diseases Prevention Act, the Mines Act, the Factory Acts, the Food and Drugs Act, the Regulation of Child Labour, Water Supply, the Public Health Acts, the Sanitary Act, the School Board Act, the Medical Inspection of School Children, the Mental Deficiency and Lunacy Act. To each of these there has been linked the scientific knowledge of the medical profession. The pivot on which the successful working of these Acts turns is the conscientious care and the applied skill of physicians and surgeons.

Possibly the crowning effort which Parliament has yet made is the passing of the National Insurance Act in 1911. It has for its fundamental principles the bringing of financial assistance to employed manual workers when they from sickness are unable to continue their work, and the giving of medical aid and drugs and appliances when they are ill.

Sixteen millions of employed people have by this Act been placed under medical care, and possibly in a short time an even greater number of wives and children will be added. The relation between the medical profession and the State has thus been knit more intimately than ever before.

The Act also includes valuable provisions for research work by skilled medical investigators, and this must in due time have a powerful influence in the prevention of many diseases, as well as in the methods of treatment.

Last year the Government appointed a Royal Commission to carry out an investigation into the extent and prevalence of venereal diseases in the country, and one result of this commission is to be the establishment of a special council to deal with the subject along preventive and remedial lines.

Following the introduction of Wassermann's test for syphilis there has been opened a new light on many forms of disease which formerly were obscure in their origin. Especially is this true in neurology. And so widespread is syphilis and so subtle in its effects of wastage of strength and life that it calls for urgent and firm control. It cripples and decimates our population to an extent that was not formerly appreciated. It may be expected that whatever schemes are evolved as a result of this investigation, the medical profession will respond to the call made by the State for active and careful co-operation in the treatment of this scourge on its physical side, while the moral aspects will fall to be dealt with by social workers and educationists.

One of the most promising features of recent legislation in our own and many other countries is the fact that the medical expert has been incorporated into the educational system. By the skilled vigilance and wise guidance of

the medical inspectors of school children, many ailments ought to be detected in initial stages, and lives and capacities of great value preserved to the nation.

The general practitioner is in a position to contribute much of value to the constructive work of reform in social conditions and the treatment of disease. His daily routine brings constantly under his observation the influence of individual tendencies and particular environments as factors in the history of human ailments. Within the last twenty years a vast amount of detailed knowledge has been accumulating among medical men with regard to temperamental and sociological considerations, while scientific research is forging onward and conveying one truth and another as deciphered in the laboratory into the domain of recognized fact. At the same time there is scattered through the length and breadth of the land our trained body of general practitioners, familiar with the living daily truths of existence in the homes where ailments develop and are tended, and this same body is well fitted to link together the learning of the university and laboratory with the administrative departments of the State, the burgh or county councils, insurance committees, sanitary offices, dispensaries, and sanatoriums. The alert, awakened minds of the doctors can do much for the nation, and there is not one among us who would not say "I will."

It is on the practical experience and everyday knowledge of medical officers of health and practitioners that social reform and new legislation dealing with health must, in the main, be based. The day was when each general practitioner valued his experience mainly as a personal asset in his diagnosis and treatment of patients. Now the practitioner values it quite as much from the point of view of any help it may be to the profession at large, and to the nation, and rejoices to know that the observations and statistics in one locality and another will be compared, and general results obtained that will serve to guide all who are working in various ways for the raising of the standards of public health, morality, and national efficiency.

The recognition of medical sociology as a special department of the great subject of medicine is in itself evidence of a sincere altruistic spirit in the profession. When the British Medical Association some years ago instituted this department it to all intents and purposes publicly allied itself with the country's social administration and the demand for better conditions of housing and living among the people, for a healthier and purer tone of life in all social ranks.

This Section of Medical Sociology is designed to afford opportunity for the discussion of any special knowledge acquired in medical practice or by research which would be calculated to assist in the solution of problems of public importance. This year our programme includes the consideration of medical service under the Insurance Act, the responsibility of the State as regards venereal disease, and the duty of the State towards the early environment of the child, all of which will be dealt with from the two-fold aspect of medical experience and administrative considerations.

DISCUSSION ON THE RESPONSIBILITY OF THE STATE IN CONNEXION WITH VENEREAL DISEASE.

OPENING PAPERS.

I.—A. K. Chalmers, M.D.,

M.O.H. City of Glasgow and Glasgow Port Local Authority.

In introducing the subject Dr. Chalmers explained that he was unacquainted with the view which Dr. Robertson, who was originally to have done so, would have taken. He thought, however, no better form of introduction could be found than in that part of the President's remarks in which he had made reference to the responsibility of the State for the welfare of the individual. For, after all, the function of preventive medicine and medical science generally was to relieve the individual from such inefficiency as resulted from disease and environment.

Public attention had been directed to venereal disease as a cause of physical deterioration, and one of the first questions was to ascertain its prevalence. He doubted whether any one was in a position to say definitely what amount of venereal disease existed in this country at the present time. Death returns did not help us, in a direct way at least, and applying the ratio of positive reactions obtained from selected populations to the whole population was, in his opinion, quite misleading. In an indirect manner, however, death returns did afford some kind of indication. For example, in 400 deaths of infants occurring in ten years frankly attributed to syphilis he found that no fewer than 67 per cent. occurred in the first three months of post-natal life, 21 per cent. in the second three months, and only 12 per cent. between the sixth and twelfth month. This preponderance of the cases in the first quarter was, of course, in keeping with what had long been recognized regarding the association of miscarriages with syphilis. Some information, again, was thrown on the question of prevalence by inquiry into the frequency of stillbirths and miscarriages, and again one found a gradation between both and the infantile death-rate of a district, which again was related to its sanitary condition, and was highest in the poorer districts. The significant thing was that syphilis as a frankly stated cause of death seemed also to have a similar grading: but although this might be taken as indicating a higher proportion of congenital syphilis in such districts, he thought some part of the difference lay in the more efficient treatment which was sought in the districts better able to pay for it.

It seemed to him desirable that all the efforts that were being taken to ascertain the prevalence of the disease should endeavour to distinguish between acquired and congenital syphilis. During the past winter Dr. Elliot, one of the resident physicians at Ruchill Hospital, Glasgow, had endeavoured to ascertain the proportion of children responding to the Wassermann test among those who were admitted for scarlet fever and measles. The object of this inquiry originally was to ascertain whether the anaemias which are so common in children from poorer districts were related to syphilis. The result in that direction was negative, but the proportion reacting to the Wassermann test was about 8 per cent., and might be compared with 3 per cent. which represented the proportion of infants displaying clinical evidence of the disease in over 4,000 brought to the infant consultations. Again, there was a contrast between both of these figures and the rates presented in over 700 samples of blood examined by the Wassermann test from patients whose symptoms were obscure; this percentage amounted to 38. Of all three he thought the 8 per cent. the more likely as an index of congenital syphilis.

Another figure which might help to a conception of the prevalence of the disease was to be obtained from the number of children suffering from ophthalmia neonatorum where syphilis was present as a complication. It might be said that ophthalmia was present in from 9 to 11 per 1,000 births, and of these 13.7 per cent. were complicated with syphilis. He found, for example, that of 524 cases of ophthalmia 72, or 13.7 per cent., were also syphilitic, but this varied from 8.5 per cent. in the non-gonococcal cases to 19.8 per cent. in gonococcal cases, and when one contrasted the result on the eyes in both the injury was very obvious, and he submitted a table to show this:

Ophthalmia Neonatorum: Results of Treatment.

Result.	Non-gonococcal.		Gonococcal.		Also Syphilitic.	
	Cases.	Per Cent. of Total.	Cases.	Per Cent. of Total.	Cases.	Per Cent. of Total.
Cured	227	98.4	151	87.2	42	66.8
Defective vision	3	1.2	21	12.2	15	23.7
Totally blind ...	1	0.4	1	0.6	6	9.5
	231		173		63	

This being the state of matters which fell to be dealt with the question for the consideration of the meeting was how means of recognizing the disease were to be extended to the population generally, and how the disease was to be treated. In both cases he thought this must be free. He

believed the local authorities should organize the facilities for both, but many obvious reasons might be adduced in support of the suggestion that a considerable proportion of the cost should be supplied by the State. An estimate of the probable cost of this might be made by assuming the 8 per cent. which he had shown as the ratio of congenital syphilis, and applying it to the population generally. In children the proportion of salvarsan required represented roughly three-sevenths of what was required in adults, and if one took 20s. as approximately the average cost of this, and applied it to the population generally it would seem to mean that in every million of population £80,000 might represent the cost of the salvarsan required, and the total cost to the country in one year readily run into $3\frac{3}{4}$ millions. If drastic treatment of this sort could be relied upon as likely to protect the population from the worst physical effects of this scourge he believed the national advantage would well outweigh the cost.

II.—ERIK PONTOPPIDAN, M.D.,

Honorary Member Royal Society of Medicine, Lond.; Chief Physician to Rudolph Berghs Hospital, Copenhagen.

PUBLIC MEASURES AGAINST VENEREAL DISEASE IN DENMARK.

IN Denmark the principle of public and free treatment of venereal patients has been the rule for more than a century, but the methods followed were somewhat inadequate. In 1874 the laws and regulations were codified and provided for the right of any person infected to be treated at public expense and at the same time imposed the duty upon him of undergoing treatment. To a certain extent the hospital facilities were adequate, but the provisions for public ambulatory treatment were scanty. This aspect of sanitary measures was the more neglected because it was thought that the most reliable defence against venereal diseases was the regulations providing for the police supervision and preventive sanitary control over prostitutes. In Denmark, as in most other countries outside England, the State considered its responsibility as regards venereal disease to be covered by a strict enforcement of the regulations, and the medical authorities were mostly of the same opinion.

The evidently unsatisfactory results, however, aided by the discussions at the international conferences in Brussels in 1899 and 1902, and the criticism by competent medical authorities caused the system to crumble down by its own weakness and want of convinced supporters. By a law passed on March 30th, 1906, all control over prostitution was entirely abolished and replaced by strict rules, enforced on all venereal patients. The change was complete; the professionals escaped supervision, while the amateurs were controlled and punished.

The new system was not at all well received by the medical profession. The Minister of Justice, who introduced the law, evaded all consultation of the medical authorities; according to his somewhat cynical expression he did not expect to receive the answer he wanted, and so he preferred not to ask at all. This explained why the law, if literally applied, would be on many points impracticable, a vexation for doctors and patients. Only the firmness and common sense of the medical profession, by practically eliminating the bad points, saved the good points and made the system work reasonably.

The first three paragraphs of the new law contain mainly rules permitting the police to secure public order and decency. Loose women without work can be punished as vagrants, and any person inciting to debauchery or causing public scandal is liable to imprisonment. The keeping of brothels is strongly punished. The advertising of objects to prevent conception is prohibited.

According to paragraph 4, any person knowing or supposing himself to be suffering from venereal contagious disease, who has sexual intercourse with another, shall be liable to imprisonment—in aggravating circumstances, with hard labour—and this penalty is extended also to married intercourse. This clause, which formerly had been applied only in very few particularly grave and clear cases, was after 1906 taken up by the police authorities to a much greater extent, and particularly applied to prostitutes arrested for different offences. The difficulties in defining the contagious state (both generally and in each case), and in proving the accused guilty of "knowing or supposing" his state, soon showed the application of the clause on a large scale to be impracticable, and resort to it was soon restricted.

Paragraph 5 is the old corner-stone of the Danish law regarding venereal disease, and it was continued from the Act and Regulations of 1874. It gives every person suffering from the said disease the right, whether rich or poor, to claim medical attendance at the public expense, and imposes the obligation to submit to such treatment, unless he can prove to be otherwise under proper attendance. The difference, as compared with pre-1906 times, is mainly that the opportunities for treatment have been improved and increased, while the compulsory measures have been very much extended.

Paragraph 6 orders the doctor, when danger of contamination makes it necessary during or after treatment, to give the patient notice to appear before him at fixed times, unless another qualified doctor testifies to have taken over the case. This notice is to be given on a particular form; if the patient does not act according to it, the doctor has to send an intimation to the public health officer, who orders the patient to appear in the public consulting office, if necessary through the police. This arrangement—which, carried out to the letter, would make of the physician an informing police inspector—has from the beginning met with strong disapproval from the medical profession. We want to retain our position as our patient's trustee and know that retaining his confidence is necessary to our work, lest we frighten the patients away and make the law counteract its own ends. That is why in my private practice I have never given an official notice, and accordingly have never had to notify any case of disobedience. Most of us act more or less in the same way, and this is well known by the authorities, who, however, apparently do not think it opportune to enforce the rules. In public practice—in hospitals and public consulting rooms—the quality of the patients and their relations to the medical attendant are different, and the operation of the rules is more stringent and may be considered in suitable cases sensible and beneficial.

Paragraph 7 orders the doctor to make the patient acquainted with the nature and the contagiousness of the disease, and the possible risks, judicial and otherwise, concerning marriage. This obligation is generally discharged by the physicians, except that the official forms are mostly avoided as they are somewhat brutal; they are replaced by better-worded communications.

Paragraph 9 deals with the nursing question. No child suffering from syphilis may be placed with a wet nurse if this is not its own mother, and no wet nurse suffering, or suspecting herself to be suffering, from the disease may suckle the child of another woman. A child is to be considered as suspected of suffering from syphilis when any of its parents have contracted syphilis less than seven years previously and three months having not yet elapsed since the child was born. It is easy to see that this law was made before the Wassermann test was known; it also illustrates the difficulty of fixing a definite term in regard to disease. Doctors know that cases are not always safe after seven years.

Paragraph 10 deals with compulsory examination. The police are entitled to apply this to any person accused of professional prostitution as a trade, of *racolage* and the like, of contamination by sexual intercourse or nursing. If consent is refused—which is very seldom the case—the court of justice is appealed to.

Paragraphs 11 and 12 define the different provisions for public examination and attendance, which in most towns and in the country are performed by the local health officers, while in Copenhagen the municipality has to supply a sufficient number of visiting doctors, who are to give daily consultations free of cost to anybody suffering from venereal disease. Copenhagen since 1906 has had twelve public consulting physicians located in different areas, each giving daily free consultations at fixed hours, in the forenoon or in the evening. The number of patients treated has been about 4,000 men and 1,000 women a year, the number of consultations 30,000 to 40,000 a year. In the commencement the doctors were paid per consultation (3 kroner for the first and 1 krone for each following visit), and the expenses went up to about 60,000 kroner a year; later the physicians received a fixed salary of 2,000 kroner a year, and now the cost—medicine, etc., included—

amounts to about 40,000 kroner a year. About 1,200 to 1,500 patients are treated free of cost in polyclinics, mainly connected with the hospitals, so it might safely be said that two-thirds of the venereal patients receive free advice and treatment in Copenhagen.

The facilities for hospital treatment have been augmented since 1906; besides the venereal wards in the communal hospital (about 120 beds), the Rudolph Berghs Hospital, formerly used solely as a lock hospital for prostitutes (200 beds), has been reopened as a dermato-venereal hospital, also with 120 beds for venereal patients. These two hospitals receive the bulk of the cases from Copenhagen, but even this number of beds, about 1 bed to every 2,000 inhabitants, is hardly sufficient for the demand. During recent years about 2,000 patients a year have been treated here with about 70,000 sick days, and as each day costs about 3½ kroner, the annual cost amounts to about a quarter of a million kroner. The venereal patients are treated, housed, and fed just like the other sick people, except that some of them require a little stricter discipline.

According to paragraph 14 persons under treatment at the public expense are not allowed to leave the hospital unless dismissed by the physician. Offenders are punished with imprisonment for periods from twenty days.

I have tried to define the main lines of the public measures against venereal disease in Denmark, and to show how they are worked. I have limited myself chiefly to Copenhagen, because this town is the only area where the diseases are frequent; the smaller towns, and particularly the country, with their 2 million of population, contribute only 20 per cent. of the total.

The vital question is, What are the sanitary results? If you consult statistics, you at once meet the old difficulty that they are open to different explanations and conclusions. Of all statistics, those concerning venereal diseases are perhaps the most questionable and the least reliable. There is no doubt that the yearly number of cases collected through the weekly notifications from the physicians to the Board of Health showed a very marked increase from 1906 to 1911. This may not necessarily mean a real augmentation of actual cases, but might be due to the extended and liberal facilities for free medical treatment.

By specially considering the cases of epididymitis, a complication which necessarily has been treated mainly in hospital, it is found that the cases have decidedly augmented in recent years, which leads to the conclusion that simple gonorrhœa has actually been more frequent. The cases of gonorrhœa in women have decreased very much since 1906, the explanation being that formerly the prostitutes were forcibly sent to hospital, now they avoid it, and the women generally do not care to go for hospital treatment, and only to a small extent to other treatment for gonorrhœa. Most entries, therefore, come through the police. As regards syphilis, the case is different; this disease is treated in hospital to almost the same extent as formerly, and this does not look as if syphilis were actually decreasing. Syphilis congenita, which is usually treated in hospital, has hardly shown any tendency to decrease.

I regret to be obliged to state that these statistics, such as they are, and perhaps of limited value, at all events do not support the hopes of the promoters of the new sanitary system. The number of cases of syphilis and venereal disease in Denmark has not been reduced. The State regulation of prostitution has been a sanitary failure. The State regulation of venereal diseases by compulsory measures has been the same. I believe in extensive treatment, and still more in hygienic and preventive measures, which last may be the road of the future. The State has used till now the weapon of prohibition, but I believe the fight against these diseases must be left to the trained medical army, with the least possible assistance from the penal code and the police.

III.—Louise McIlroy, M.D., D.Sc.,
Senior Assistant to the Muirhead Professor of Gynæcology, University of Glasgow.

Dr. Louise McIlroy remarked that there was no use in talking in definite language about the prevalence of venereal disease: the available information was too vague. Panic must be guarded against; with the Royal Commission sitting, and lay journals and books dealing with the matter, the impression was fostered that there was a vast amount of disease of this kind. Death certificates were useless as indications of the incidence of the disease, and they would continue to be so until a confidential death certificate was introduced. Medical practitioners had no right to say that such-and such an individual was not suffering from venereal disease unless they had applied laboratory tests. Clinical diagnosis was of very little use except in very obvious cases. There must be a system of confidential notification of the disease, but not to the local health authority. Her suggestion was that the present Royal Commission should be continued for five or six years, and hospital returns should be supplied to it, the form adopted being of a confidential character. This would avoid the necessity of returning particulars of cases in private practice. As to the effects of venereal disease upon the community, Dr. McIlroy gave particulars of investigations in the Glasgow Royal Infirmary into the number of stillbirths, premature births, and cases of sterility; she remarked that this question had a very important bearing upon the decline of the birth-rate. In the out-patient department a blood test was taken in every case in which the patient was willing, and in the first 100 cases the Wassermann test gave a positive reaction in the enormous percentage of 43 instances. No one would believe the results, although they were most carefully taken. Two hundred more blood tests were made, and at the end of the third hundred the percentage was somewhat reduced, being between 30 and 40 per hundred. In the case of gynæcological patients the offspring were examined and it was noted that negative mothers often had positive offspring. Dr. McIlroy urged that the notification of any form of miscarriage or abortion was imperative. As to the necessary education of the community, the method to be adopted was a vexed question. Should sex education be given in the schools or at home? She thought any discussion of such questions in the school was out of the question; this instruction should be given by the parents and by no one else. It might be retorted that parents knew nothing about it, but, until a comparatively few years ago, medical knowledge on this subject was very slight. Now that wider knowledge had reached the medical profession, it would percolate to the rest of the community. As to treatment, the only way to eradicate venereal disease was to make treatment free and attractive, and to take away from it every stigma. If the lock hospital system were abolished and hospitals under the direction of the local authority were substituted, very little would be gained, because a stigma would soon attach itself to the new institutions. Cases should be treated in the general hospitals—not necessarily side by side with other cases—but the wards in which they were treated should not be specially labelled. As to the cost, if the State was willing to spend £80,000 on tuberculosis, it ought to be willing to spend as much on stamping out venereal disease, which did so much to produce degenerates and criminals, and to fill the insane and blind asylums. At the end of perhaps ten years the State would probably find that its expenditure had resulted in a saving of money. Names and official forms should be kept out as far as possible in dealing with cases, but the question how much control should be exercised over a sufferer from venereal disease was an important one, having regard to the danger of infection being conveyed to the rest of the community. Cases had come to her knowledge of a woman covered with syphilitic sores deciding, in spite of all arguments, to return to her work, which it was found consisted of wrapping tissue paper round oat cakes in a factory. A man in a highly infective state, examined in an out-patient department, was subsequently seen in a public tea-room drinking tea out of an ordinary cup. These cases should be under some control, and there should be a penalty against unqualified persons who treated the disease, as well as against those who knowingly communicated the disease..

IV.—Lachlan Grant, M.D., D.P.H.Edin.,
Bacteriologist, Northern Districts Committees, Argyll County Council.

ESSENTIAL PREVENTIVES OF PROSTITUTION.

Prostitution is not primarily a medical problem any more than it is a religious or a police one. Its implications and ramifications are too great to be embraced under any one sectional heading, and it is bound up with

many other questions—social, economic, national and international. Nevertheless it is the bounden duty of all medical men to take cognizance of all aspects of the problem and to throw the weight of their authority and influence on the side of the real basic reformers. It is for us as men and as physicians to probe it to the very bottom, and never to be satisfied until the root causes are discovered and adequately dealt with.

The extirpation of venereal diseases is inseparably bound up with the prevention of prostitution; and so with some other aspects of social and moral disease, none the less hideous for being invisible to the physical sight. The hydra-headed monster touches society at all points, and in spite of the efforts of the best elements in our civilization, reinforced by repressive laws, it has continued to increase in every civilized country until we see threatened, not only civilization, but the existence of the race itself. Much may still be done to mitigate its horrors by a more stringent application of the law and by further legislation and an educational campaign. A more summary procedure against procurers and so-called white-slavers is called for; also raising the age of consent and the prohibition of employment of girls in street vending and other dangerous avocations. And what is of vast importance under any circumstances—a well thought out system of graduated instruction for boys and girls in sex and hygienic matters with warnings as to some dangers in the outside world.

Any form of State guarantee or provision of supposed safeguards must naturally act as an encourager rather than a deterrent, and amount to a justification and perpetuation of the institution. In our own country, at all events, any form of State recognition or revival of the Contagious Diseases Act may be ruled out as impossible and contrary to the spirit of the times.

All countries have tried to combat the evil with numerous laws and regulations backed up by philanthropic agencies, and they have *all* failed to stem the tide of immorality and disease. Most reformers and investigators now see that a new point of view is necessary, and this applies specially to the medical profession. We come more into contact with the phenomena than any other class, and have the data to make an exhaustive diagnosis of the social as well as the individual organism. Those who are inclined to take a more or less pessimistic view of society and regard prostitution as a necessary evil, inherent in the nature of things, are bound to admit it is a universal scourge that threatens the existence of the more stable elements of civilization; and the onus lies on them to reconcile their position as ordinary citizens with their position as members of a scientific body. For my part I am bold enough to say that what is morally wrong and socially unjust can never be justified on grounds of expediency.

In our day the burning questions are not so much religious and political as social and economic, and just as the churches and other organized bodies are forced by the pressure of events to extend their boundaries and widen their horizon, so must we, as the organized army of public health, admit the economic aspect of moral, mental, and physical disease as a prime factor in the problem, and act accordingly. All investigators who reach the basic facts discover the same thing—that prostitution is fundamentally of economic origin—and eventually find themselves up against the same economic impasse. What is wanted is a practical recognition of the doctrine that we are all members of the social organism, and individually and collectively responsible. No further Royal Commissions or investigating committees are required to discover the main facts we medical men are already cognizant of; and the responsibility of the State to deal with them, all, or most of us, are prepared to admit.

With a few exceptions sexual prostitution may be set down to poverty and ignorance. From the poor and the working classes are drawn the vast majority of the recruits for white slavery. None of us will say that any one class of the community is naturally more vicious than another, and that the labouring classes are more immorally inclined than the middle or upper classes. In fact, taking individual for individual, and considering the differing environments and opportunities, I think the workers show up best. Nine-tenths of the problem is one of environment, and what Bernard Shaw once said is universally true, that "what is wrong with the poor is their poverty." Poverty is accountable for much of the ignorance that hinders moral and intellectual progress, and ignorance reacts in aggravating the conditions that make for poverty. Both must be grappled with, and in attacking one we attack the other. The recognition of women's economic independence, and, at all events, the same equality of opportunity as is claimed for men, will place them in a position of safety for commanding their own destiny in life, thus freeing them from the pressure of want, and the temptation to sell themselves for the means of subsistence. To bring this about will require a new outlook as to the meaning of life, and far-reaching legislative measures to give it effect. It will involve a searching criticism of our entire commercial and industrial system, and of the relations of the individual to the community and of the mother and the child to the State. There must be an adequate income for all workers, male and female, and a minimum standard of comfort for every citizen. Among the legislative and economic measures required are a national housing scheme insuring ample space and sanitary details in conformity with the highest standard of health and morals; a generous endowment of motherhood and the encouragement of reasonably early marriages; free medical advice and nursing; more stringent control of conditions under which females are employed, and prohibition of their employment in dangerous or degrading occupations such as in chemical works and coal mines; abolition of the half-time system and employment of young girls as vendors in the streets or public places; laws to control the conditions of domestic and farm service—from which a large proportion of the victims of prostitution are drawn. And there is clamant need of reforms that will encourage the people to remain on the land and prevent the wholesale flocking of the young people to the towns and cities.

Apologists for prostitution sometimes say it is a safety valve for male passion, without which no virtuous woman would be safe anywhere. As conditions exist, there is some truth in the contention, but the most hopeless pessimists among us cannot salve our consciences sufficiently to accept as a permanent institution that tens of thousands of girls shall be yearly sacrificed as a bribe to lawless passion to keep its hands off decent women. This cannot be so, and while preventing the supply of victims of the traffic, we must also try to prevent the demand for them arising. The economic and legislative measures I have referred to would have a deterring and educational influence on men, and the inculcation of a higher ideal of womanhood, motherhood, and home life, accompanied by juster social conditions, would, in time, eliminate the worst elements in sexual immorality and create in the minds of young men a feeling of disgust for the brothel and the woman of the street. Celibacy, if voluntary, may be right for the few, but for the vast majority it is an evil, and doubly so when made compulsory owing to artificial social and economic conditions. Make these conditions more human; enable young men to marry honourably and get rooted to family life before they become *blasé* and cynical; make the education of our young more of moral discipline and less of devil-take-the-hindmost competitive intellectualism; let us openly denounce the vulgar and brutish ideas about woman that blunt the finer susceptibilities of so many men. If society will do these things, the demand for illicit and unnatural sexual indulgence will shrink into a negligible quantity and prostitution and all its horrors will be a thing of the past.

Legislation can do much, and economic justice still more, to effectually combat prostitution and its resulting disease and crime, but it is also essential to educate public opinion and so dispel the prevailing ignorance on sex matters. Parents, as well as children, require to be enlightened, and school teachers and clergymen should be active, intelligent allies of the official guardians of public health. A special department in a well-organized Ministry of Health concentrating on the prevention of prostitution and venereal disease could do much. Supplemented by the co-operation of the educational authorities they could strike at the very roots of the evil. There is just as much need for special machinery to deal with prostitution and venereal diseases as for tuberculosis, cancer, insanity, and small-pox—even more so, as prostitution is also a form of moral rottenness more dangerous to society than any purely physical disease.

The time has certainly come for special concentration on this problem, and the responsibility lies on the State to provide the machinery and the sinews of war.

On the educational side systematic teaching must prevent girls and boys growing up dangerously ignorant of their bodily functions and the main facts of reproduction. We must have a network of schools of motherhood throughout the country and ensure that no young couples will blindly rush into matrimony and acquire knowledge and wisdom through a painful course of blundering, dear-bought experience, and that no parents would fail in their duty to their children and evade the natural questions of daughters and sons. A universal campaign to educate public opinion in these respects is one in which the medical profession must naturally take a leading part, and to all the related movements from the economic and legislative side it must lend the weight of its influence, prestige, and experience. If the facts are faced and courageously dealt with the problem of prostitution and its ramifying evils, making for race degeneracy, will be well on the way to an adequate solution in accordance with the highest ideals, the newer civilization, the social conscience, and modern medicine.

DISCUSSION.

Dr. Helen Wilson (Sheffield) urged that methods of dealing with the problem must not only have regard to the foci of infection but to the conditions which tended to propagate disease. There was great difficulty in teaching sex hygiene to boys and girls; they should hear nothing of venereal disease at that early age. It was a question whether the parents were ready to give teaching; a beginning must be made, not in the schools, but in educating adults. This would be one of the objects of the National Council, just formed under the presidency of Sir Thomas Barlow. The community attended to the physical sanitation of streets and factories and places of amusement; it should also attend to their moral sanitation. The responsibility for dealing with the disease must be left to the medical profession, in whose hands also was very largely the problem of individual education. Had the medical profession so far rightly conceived its duty to individual patients? Besides diagnosis and treatment, the doctor owed to the patient the warning necessary for guarding against future consequences to himself, and also for protecting others from infection. These warnings must cover several years. In the case of a woman, she should be told that in all future pregnancies, at whatever interval, she should put herself under medical observation and treatment. In the case of a married woman it was very difficult to give warnings. She believed it was usual for the medical profession not to tell a married woman what was the matter with her in these cases, but was it possible for her to carry out warnings unless she was told definitely? She knew what was said on the other side. Silence was observed out of compassion; it was urged that one did not want to break up the home. The probability was that sooner or later the woman would find out, and the true course (following the rule of doing as one would be done by) was to leave the decision to the wife. In a great many cases, though indignant the wife would forgive, but a modern woman wanted to do her own forgiving and not have it done for her by the doctor. In dealing with employees in large works who might infect others, there was a difficulty that firm dealing in regard to segregation might drive people to resort to quackery. Thus any breach of old principle of professional confidence would defeat its object.

Mr. T. Jenner Verrall remarked that it was only lately, through the notification and supervision of tuberculosis, that the public had been launched on a course of tolerance of public examination of these questions in any degree. The reluctance on the part of the public to countenance public measures with regard to tuberculosis would be enormously increased on the question of syphilis. First, the public would declare the absolute necessity of the medical profession being quite sure of its own position before it tried to teach others. As had been remarked, the profession was only just arriving, by modern and precise means of diagnosis, at a certainty of position for itself. Until the profession was quite clear on certain questions of latent syphilis, it would only run the risk—if it attempted to speak confidently—of deluding the public into the idea that it could offer safety when, in fact, it could not. At what stage ought teaching on the duties in sex hygiene to be inculcated? It ought to be earlier than was previously the case, and at present it ought to be done through the parents, and not the schools. Parents, patients, and the community generally needed teaching, a great deal more than they at all realized, of their duties to others as well as to themselves. He was quite certain that doctors had not gone to the lengths they ought to have done in this regard; they had not said what they ought to have done as to what a patient should or should not do after he left their hands. More outspoken treatment was not only justifiable, but their duty. As to what would be the ultimate results of the efforts the profession might make in combating venereal disease, much would depend on establishing a perfectly good case. For instance, the question of statistics was vastly important, inasmuch as the subject was a delicate one. The public would submit with reluctance to these matters being dealt with openly, and if the profession made the least false step, and, for example, dealt wrongly with the statistics, it would probably throw the whole matter back a hundred years. He was prepared to go to the fullest lengths in the open treatment of these diseases, provided always that the advance was cautious and that they did not run the risk of having it said, "You acted on panic and you did not prepare your way properly." He hoped that the ground would be thoroughly prepared before a campaign was initiated in the public interest.

Dr. L. A. Parry (Brighton) commented on Dr. McIlroy's statement that she found 30 to 40 per cent. of unselected patients in her clinic suffering from syphilis as diagnosed by laboratory tests. This was one more very potent argument against allowing the teaching of the laboratory to outweigh clinical knowledge. Did any one believe it was possible that nearly 40 per cent. of 300 unselected gynaecological patients were suffering from syphilis? These figures immensely exaggerated the prevalence of the disease, and he deprecated the bringing forward of laboratory statistics which could only mislead. He agreed with Professor Pontoppidan that no diminution of venereal disease would be brought about by Act of Parliament. It must be by education and raising the general moral tone of the people.

Dr. Laura S. Sandeman (Aberdeen) urged the desirability of removing the stigma from treatment of venereal disease. Patients should not be regarded as outcasts. In regard to insured persons, it would tend to diminish the disease if venereal patients were sure that sickness benefit would be paid. The fact that doctors had to refuse it—in other words, to certify that a patient was suffering from venereal disease—immediately raised a question in the house as to the nature of the illness for which sick benefit was refused. This tended to make patients chary of asking for advice at the stage when it would be most useful. It must be remembered that a great number of patients suffering from syphilis and gonorrhœa had acquired it innocently, and therefore should not be deprived of benefit nor have the nature of their illness disclosed to their societies. The number of acute venereal cases requiring sick benefit was small as compared to the number of paralytic and chronic rheumatic cases, of which it was practically certain that venereal disease had been the primary cause, and yet for which the societies paid heavily. If treated in the acute stage, the saving both financially to the societies as well as with regard to the ultimate health of the individual and his posterity and the spreading of infection among his fellow citizens would be incalculable. The State must make itself responsible, and should give every facility for diagnosis and treatment to patients suffering from these illnesses, the burden of which should not be thrown on charitable institutions. She was in favour of confidential notification by such a plan as giving a number and initials to the medical officer of health, the patient to be told that no further inquiry would be made provided he reported himself as often as his medical attendant considered necessary, but that should he fail to do so his name and address would have to be given. Some would ask of what use would this

notification be. She believed it would give the medical profession greater authority in dealing with the disease, because sufferers would learn that the law regarded the disease as infectious. In notifying a case the practitioner might be required to fill up a schedule with a few particulars as to the nature of the illness; this would be useful to another practitioner taking charge of the case if the patient removed to another neighbourhood. Special methods must be adopted in the case of an insured person changing his doctor. Surely a Government that had allotted such enormous sums of the country's money to the improvement of the health and physique of the nation, would not hesitate at the extra expense in fighting a vastly greater cause of impairment of the nation's vitality than even tuberculous disease.

Sir JOHN COLLIE, as a member of the Venereal Commission, said the question raised by the last speaker was having the very serious consideration of the Commission. Personally he was very much opposed to notification for this very simple reason: that at the early stage, which was the infectious stage, most sufferers from venereal disease would be tempted not to consult general practitioners but quacks. Having their diseases untreated that stage would be a fruitful source of spreading the disease. Witness after witness before the Commission had agreed with this view, and he thought it would be a very serious step to take at this stage without very serious consideration of the question in all its phases, and as to whether notification would not tend really to spread the disease, thus counterbalancing the advantages of getting statistical information as to prevalency. He did not think the amount of latent syphilis present in the community was quite realized. Quite recently he took 500 strong, able-bodied, healthy working men over 21 years of age, and thoroughly examined them as for life assurance. He then asked each to allow him to take 5 or 10 c.cm. of his blood, and Dr. Mott kindly submitted the specimens to the Wassermann reaction. Sir John Collie said he was rather surprised to find that of the whole 9.2 per cent. gave a positive reaction. Many had been in the army and navy, so he took a separate list of those. The percentage from army and navy men worked out at 18, and of civilians 6. It was interesting to note that a large proportion of these men, though urged to submit to salvarsan treatment (for which he had arranged facilities) declined to undergo it, and unfortunately, of those who did, the vast majority after a subsequent test still gave a positive reaction. Some of them had had the disease 12, 16, 19, and, in one case, 29 years. It was a very open question whether the mere fact that the reaction was positive was an indication of serious mischief, but that was a question which was *sub judice*.

Dr. CLIPPINGDALE (London) recalled the interesting fact that the Town Council of Aberdeen was the first public authority in these islands to attempt by legislative edict to arrest the spread of syphilis. There could be little doubt that syphilis reached Scotland direct from the Continent without passing through England, and in Scotland it was known by the name by which it was known in France—that is, "grandgore," or the "great disease." It apparently came to Scotland by sea, but whether it reached Leith or Aberdeen first would probably never be known. The Scots, with their usual prudence, took prompt means to suppress the disease. It only became rampant in Europe in 1493, after the return of Columbus from conquering the West Indies, yet as early as 1497 the Aberdeen Town Council by ordinance required all "licht weman" to "decist fra thar vices" on pain of being branded on one cheek and "banyshed of the toune"; and a few years later a return was ordered to be made of all infected persons and an injunction issued to those persons to abstain from visiting meat markets, bakeries, breweries, and laundries. The example set by Aberdeen in 1497 was followed six months later by the Corporation of Edinburgh, which issued a similar edict. In England the first attempt to deal with this disease seems to have been made in 1506, when the "stews" (harlots' houses) in Southwark were suppressed. For more than 400 years, however, no further attempt had been made by public authority in these islands to deal with a malady so loathsome and so lethal.

DICUSSION ON
A STATE MEDICAL SERVICE *v.* A PANEL SYSTEM.

OPENING PAPERS.

I.—Sir JOHN COLLIE, M.D., J.P.,

Member of Advisory Committee, National Insurance Act; Medical Examiner, London County Council.

At the present juncture, for every person of the industrial classes insured under the National Insurance Act, there is one uninsured, for whom, with the exception of the Poor Law service, there is no free medical provision of any description. That is to say, 12,000,000 persons—men, women, and children of the working class—get no benefit from the National Health Act. We have to recognize the fact that no Government, Liberal or Conservative, is likely to extend the panel system to women and children at the present rate of remuneration for medical men. Thousands of medical practitioners, chiefly in the country districts of England and Scotland, are giving faithful service under the Act, and administering medical benefit to the best of their ability with the means at their disposal. But in many parts of London, and in the poorer quarters of some of our large towns, panels are too large; the doctors are overworked, consequently the quality of the work of necessity has suffered. Unfortunately, many doctors on the panel are now called upon to treat a large number of trivial ailments. One doctor in a poor class London district states that in one week last winter he saw 320 people with colds in their heads; this seems inconceivable, but when I tell you that he and his five partners have close on 7,000 on their panel, it is more credible. Some doctors attend as many as from 90 to 92 per cent. of the persons on their panel lists in the course of the year. Dr. Cox stated that last year from 65 to 70 per cent. of those on the panel lists all over England were seen by the medical men on the panel. This is more than twice the number which was calculated for when the Act was framed. Dr. Salter stated at a public meeting in London that he saw on an average 168 patients a day. He said this worked out, allowing a nine hour day, at the rate of three and a quarter minutes for each patient, of which one and a quarter minutes were taken up in clerical work. The patients had to wait on an average for two and a half hours.

Think what all this means to the doctors. One doctor in Bermondsey who had 2,800 patients on his list had not been out of the borough for nearly a year, and worked every day, including Saturday and Sunday, from 9 a.m. to to 11.30 p.m. This is not medical practice, it is commercialism of the worst type and justifies the sneer that "the ancients tried to make the practice of physic a science and failed, and that we in modern times tried to make it a trade and had succeeded." The competition between doctors for patients has led sometimes to undue readiness to give certificates, and other distinctly undesirable practices. The London Insurance Committee appointed medical referees; they examined 2,000 cases sent by the approved societies; of these 460 did not attend when asked to, 769 were found fit for work, and 771 unfit—that is, 62 per cent. were found to have been, to put it mildly, lingering on the threshold of work. Every one of these received a weekly certificate.

It has been said by one who is a strong advocate of the panel system that it is good because "medical men compete with one another for increasing remuneration by pleasing the patients." It is just this necessity of pleasing patients which makes the administration of the Act so difficult.

The profession is handicapped by: (1) Division in its ranks. Fortunately I am not called upon to discuss this. (2) Lack of organization to deal with disease. A game of musical chairs in which the most scientific do not necessarily succeed in getting places. (3) Lack of appliances and institutions. It is well known that the hospital accommodation is painfully insufficient for the needs of the community. In London, at any rate, there are long waiting lists; many have to wait months before being admitted, and even for operations sometimes as long as ten or thirteen weeks. A friend who is attached to the special department of one of the metropolitan hospitals tells me that he has patients who have been waiting

twelve, fifteen, and even twenty months for operation. (4) Lack of opportunities for post-graduate study.

The State referees and consultants and the nursing service foreshadowed in Mr. Lloyd George's last Budget will, in time, do much to ameliorate these conditions, but surely it is an injustice that the State should subsidize a nursing system for the poor which does not touch 12,000,000—mostly women and children—of exactly the same class of the community. It seems almost inconceivable that the present maternity benefit does not touch uninsured mothers, who have now in consequence of the Act actually to pay increased fees! It is open to question whether, in the poorer districts of large cities at any rate, the Gordian knot should be cut by the appointment of whole-time medical officers with graduated salaries to cope with these difficulties. The Majority Report of the Poor Law Commissioners indicates that the medical treatment amongst the poor is inadequate, and the Minority Report advocates a State Medical Service.

I am adverse to the nationalization of medicine, and I see no necessity, at present at any rate, for a wholesale State Medical Service, but I think that such a medical service is urgently called for in poor industrial areas of large towns, where medical men are scarce, and, on the other hand, in sparsely populated districts—for example, in the Highlands—where it cannot be worth a practitioner's while to go long distances to see a single patient. In many rural districts a State medical officer must of necessity be only a part-timer.

In Bermondsey, with a population of 130,000, there are only 32 doctors—that is, one doctor to every 4,000 people, whereas Hampstead with a population of 80,000 has 168 doctors, or one doctor to every 478. Obviously some system is needed whereby both insured and uninsured will reap the full advantage of medical benefit. Such a step must inevitably come, and when it does will lead to the co-ordination and development of the various public health services. I deprecate violent changes of any sort, and when the changes which I believe are inevitable do come, I hold strongly that vested interests must be recognized. Those who elect to join a national medical State service and who by doing so necessarily relinquish private patients, and who fail to sell their interest, must be compensated by the State. Any other arrangements obviously would be inequitable.

I do not press for a complete whole-time State service; a part-time service would in certain districts work contemporaneously with the present panel. The danger, of course, is the creation of a "rich man's" and a "poor man's" doctor, and a cleavage of the profession which would be undesirable in the last degree. I am strongly of opinion that the term "panel doctor" should not be used and the words "general practitioner" substituted on all occasions. But I believe that a recognized civil service with the advantages and status I shall presently define would prevent any such disaster.

There is, however, one *sine qua non* in such a service, and that is that the medical officer must be well paid, have a good position, and the number of patients allotted to him must not be excessive. I have yet to learn that salaried whole-time medical officers of health are not enthusiastic, progressive, and capable, and that the fact of their not being paid by fee has militated against their attaining their deservedly high position. The salaries for whole-time service would be graduated, and there would be, as in the army and navy, positions of increasing responsibility and remuneration.

Facilities would be provided for modern methods of diagnosis, such as the Wassermann and Widal reactions, *x* rays, microscopic examination of tumours, and bacteriological methods generally. The advantages of a complete service would include advice of consultants, and some arrangement would necessarily be made for augmenting the present inadequate hospital accommodation which now so seriously embarrasses general practitioners. Doctors paid fixed salaries by the State would be a great deal more independent of the general public. To medical men the advantage would be obvious; the State service would entail regular hours and regular holidays, more time for the home, for post-graduate study, a permanent freedom from the anxiety caused by fluctuations of income; in fact, entire freedom from the commercialism of the present system, and finally a pension at the end of the service.

C

One of the objections urged against even a modified State service is that the doctor would become an official. I freely admit that a reversion to the official type in the administration of sick benefit would be disastrous, but surely, as Dr. Brend pointed out in the June number of the *Nineteenth Century*, the training of the doctor, both as a student and when in practice, his association with suffering, the intimate relationship that necessarily obtains between him and his patient, preclude the possibility of his ever becoming hidebound with red tape. He would still be a clinician, not an administrator.

The authority to whom I have just referred points out that the strongest argument in favour of free choice of doctor lies in the alleged necessity of psycho-therapeutic influence being brought to bear upon the patient by the doctor of his choice. These cases are mostly functional, and therefore less important, and it goes without saying that sound surgical acumen, even when associated with the absence of the *suaviter in modo* so dear to the lover of a bedside manner, is really more valuable than many of those qualifications which make for success, but which most of us despise. Then again, can the personal relationship necessary for psycho-therapeutic treatment ever be established in a large poor-class practice, where there are thousands on the panel list? After all, I do not believe that the personal element is so strong in this class of medical practice. Does not the Scholastic Clerical and Medical Association, which exists very largely by means of its introduction of one practitioner to succeed another in general practice, flourish and pay a good dividend?

There is no free choice of doctor in the army or navy and we hear no complaints. (Dissent.) The medical institutes, which the working classes so favour, and the worker's club, allow no free choice. People who are sent to hospital do not in general decide which ward they shall go into, and, consequently, who shall attend them.

II.—H. H. Mills, M.D.,
Kensington.

All who have studied political thought during the last twenty years have realized the increase of that consciousness of collective responsibility which calls for action by the State.

For example, one need only recall the great number of Acts of Parliament referring directly or indirectly to the public health. By far the most important measure recently introduced was the National Health Insurance Act. In framing this measure two courses were open to Parliament—one was to build up from the beginning an absolutely new *ad hoc* organization, the other—and I venture to think the better one—was to use, modify, and extend existing organizations already concerned with the problem which the Act was intended to solve.

As regards medical service under the Act, it was, in my opinion rightly, decided to extend and amplify existing methods of practice already adopted by the medical profession. The scheme in the beginning was necessarily incomplete, and Sir John Collie, as well as the other members of the Advisory Committee, was perfectly aware that subsidiary and complementary service were in contemplation from the first. Provision of a nursing service, clinics, medical referees, and facilities for pathological research are now being established.

The State by assuming responsibility for certain payment for what is really a part-time State system has established a certain control. This control, exercised through the Insurance Commissioners and Insurance Committees, is at present at its minimum, and surely it is wise to watch carefully how one scheme works before launching an entirely different one. In any case it may confidently be said that if one great pillar of the Act—the scheme of medical benefit—is destroyed, then inevitably the other great divisions of the Act will fall also, and the administration of sickness benefit, and the approved societies will all be merged into one national State controlled service. This possibility is already occupying the serious and anxious attention (and resistance) of representatives of approved societies.

The system of establishing in every insurance area a list or panel of doctors who are willing to treat insured persons under certain conditions was accepted by the British Medical Association—the only body with authority

to speak for the profession in the matter. It was undoubtedly the hope that by this means practically all the general practitioners in the country would give their help to this national scheme. In many parts of the country this hope has been fulfilled. In a comparatively small number certain difficulties still exist.

The British Medical Association, after the Representative Meeting at Swansea in July, 1903, appointed a Committee to investigate conditions of contract practice. The Committee presented an interim report at Oxford in 1904, and a full report at Leicester in 1905. The conclusions ratified in 1906 were that under contract practice of any kind there ought to be free choice of doctor from the list of those willing to serve. This is, of course, the panel system; and this panel system, with its free choice of doctor for the insured and its right of refusal of an insured person by the individual doctor, furnishes that elasticity of working which approaches most closely to the best traditions of medical practice in the past. A busy skilful doctor who has attracted to himself a large practice among the well-to-do classes naturally could not be expected to attend many of the working class; but, in order to show his sympathy with his medical brethren whose work lies almost entirely amongst the industrial workers, he could, without any loss of dignity, consent to treat, for example, the insured domestic servants of his richer patients. This elasticity is in great contrast to an absolutely rigid system which a whole-time salaried service presents. When it is considered that in a few years the dependants—wives and children—of insured persons will come into the scheme of insurance, it seems imperatively necessary for all doctors to join in the establishment of a truly national health service, which, so long as it retains its independence, shall be the finest in the world. But Sir John Collie would like to see the whole population mapped out with mathematical and military precision into brigades and battalions, each with its medical officer. Such a suggestion is entirely contrary to all our national characteristics, and free choice of doctor would be impossible.

Launched in his career as a State medical officer, the doctor would see before him a number of years of work at a fixed salary, with the certainty that at the end of a given time a retiring pension would be given to him, and I can imagine no more dreary round than such a system would develop. I admit that the pension idea is an attractive one, but a pension scheme could be, and will be, easily arranged on an insurance basis for all doctors on the panel. Those of us who have friends in the navy or army—or, indeed, any institutional service—must have been struck with the constant assertion that work was in a groove, that their mental and professional activities were atrophied on account of the limited range of their outlook. The panel doctor, on the other hand, has acquired a new independence, a new feeling that he is a factor in the social development of the people among whom he works.

The art of medicine is somewhat akin to the practice of religion. Human trust and confidence are things which cannot be measured by any scale, but they are real factors in the treatment of disease. Establish your rigid system and immediately reasons for discontent with that system will be conceived. I am convinced that the panel doctor, now that he is independent, will prove to be keenly progressive in his social ideals. I do not care to what political party he belongs, he is destined to mould the social legislation of the near future, whereas if he becomes a salaried civil servant he will be allowed to have no voice in any political question.

Less than two years ago the medical profession was in the throes of a revolution, but slowly the consciousness has come that the course ultimately taken was the right one. At the time when the noise of battle had scarcely subsided, and the combatants had come to realize that their differences were but transitory, Sir John Collie came before such an important body as the Faculty of Insurance—largely composed of approved society representatives—meeting in London last February, and gave us his opinion on a salaried State Medical Service. The ideas were not new, and at the time that he spoke various suggestions were actually under consideration for extending the scheme of medical benefit which he criticized so severely. Sir John Collie had every right to hold what opinions he chose—and to vary those opinions as often as he liked—but when as an active politician (he is Liberal candidate for Devonport) he actually suggests to the Government that in two short years they should scrap the whole organization of the present medical service, we, as a profession, have a right to inquire what authority he has for such a suggestion. His remarkable series of changes of opinion during the year 1912 are not calculated to give us confidence in his judgement.

Another revolutionary change is not asked for either by the profession, or the public. The Insurance Committees are getting into their stride and working more efficiently every month. On very high authority I am able to state that the number of complaints throughout the country—never very high—is rapidly diminishing. The defects in the scheme are being remedied by the establishment of a consultant, referee, and other services. The shortage of institution beds in the country is a serious matter in which Parliament will be compelled to intervene, and the scheme of medical benefit will not be complete until ample provision is made. Private charity is not and never has been adequate for providing sufficient institution beds for the needs of the sick population, and the question of hospital reform and in-patient accommodation is one of the greatest importance—but that problem is, I venture to think, entirely separate from the question at issue.

Sir John Collie asserts that it would be an economy for the State to establish a complete salaried service, and in doing so he exemplifies to the full the contrast between the attitude of a politician and that of a doctor whose chief concern is not State economy, but the interest of the individual patient. It is certainly not economical to keep alive many people who, as Mr. Bernard Shaw would say are "better dead," but the duty of the doctor is to save the individual life, even though it costs the State more than it is economically worth. It can safely be asserted that doctors in industrial areas are being paid at a far better rate than hitherto. Good pay will undoubtedly attract good workers, and there is ample evidence that in London at least there is a migration of doctors into densely populated areas hitherto insufficiently supplied with medical men. In one area of London comprising four boroughs with a population of 700,000 where nearly all the doctors are on the panel, seventeen new practices have been started since the Insurance Act came into force.

One of the great advantages of the panel system is that the unsuccessful doctor will not be encouraged, as people will not remain on his list. Whereas were he once appointed as a whole-time State servant it would be very difficult to move him. Sir John Collie alleges that "the doctor with the greatest readiness to give certificates is the most successful." This charge is absolutely unwarranted. The most successful doctor is the one who cures his patients. It is unjust to make such a sweeping assertion. In a few instances—often out of charity—a doctor has given his certificate too readily, and there are undoubtedly a small number of unscrupulous doctors who, either to serve their private ends, or through hostility to the Act, have behaved in a way which should subject them to some form of discipline. The question of certification is often exceedingly difficult. To begin with, there is no rigid definition of what incapacity for work may mean, and again, it is not easy for a doctor to tell his patient that he is a liar. There are also many borderland cases which, if treated injudiciously, would become valetudinarian, and it is only by tactful treatment with sufficient rest that such cases can be persuaded that their best chance of recovery is a return to some form of occupation.

The rate of sickness amongst women is proved to be in excess of the actuarial estimates. Until this was ascertained, this also gave colour to the suggestion that the doctors gave certificates to the women too freely. This excessive sickness, this amazing amount of suffering now for the first time revealed, is rightly being met by an increased grant, and I can imagine no better way of spending money than to secure adequate rest and treatment for the prospective and actual mothers of our race.

Another oft-quoted objection to the panel system is the unequal distribution of insured persons among the doctors on the panel. This difficulty is, I understand, hardly existent in many parts of the country. But in London, owing to circumstances connected with the action of what

I may call without offence the "die hard" section of the profession, many doctors coming on the medical list rather late have found it difficult to obtain their share of the insured persons in their district.

But the significant fact that less than 12,000 of the insured population of a million and a half in London did express a desire to change their doctor last year suggests that, on the whole, the insured persons are fairly well satisfied with their treatment. It will be the duty of the London Insurance Committee at the proper time to advertise the fact that insured persons at the end of each year can change their doctor if they wish.

Lapses on the part of a small percentage of the doctors were in no way caused by the panel system; they would equally occur under any system. They are brought to light—and a good thing, too—because for the first time these poor people have a tribunal of easy access to listen to their complaints. If complaints were invited against any of the professions—the legal or clerical, for example—one wonders whether the percentage would be so low.

It is necessary to refer to the condition of the drug fund. In many parts of the country the cost has exceeded expectations. This very grave matter needs the most earnest attention of the whole medical service. We must honestly admit that three-fifths of the drug taking is both unnecessary and harmful. It is unfortunately true that in the past people were encouraged to come to the doctor, and the only tangible return for their fee was a bottle of physic. All that has to be unlearned by the people, but we can look hopefully forward to a few years hence, when drug prescribing will have diminished as much as the prescription of alcohol—formerly so commonly prescribed in large quantities at our hospitals.

III.—R. C. Buist, M.D.,

Dundee.

The influences that move our preference to one or another form of medical employment are so varied that they cannot all be weighed in the same balance. An aesthetic "derogatory" may not be fully countered by a financial *quid pro quo*. We may, however, agree that the ultimate value of any form is somehow to be tested in the manner in which work is rendered under it, and for clearness sake confine our attention to the psychological conditions of medical practice. Let us accept as fundamental the fact that our normal attitude to our various acts is conditioned by habit, and that this is the product of the character we inherit and the civilization we accept from our predecessors. Were there no other conditions the dispassionate observer would find the social picture unvaried from year to year and from aeon to aeon. We, by inspecting the ports of entry for agents of disturbance, may forecast the directions of divergence under their action.

In medicine the tradition of the elders is thoroughly safeguarded. The student, reduced to hypnotic anaesthesia by the formal lecture, is for three or more years submitted to continuous inoculation, and no honeyed heterodoxy will pacify the examining Cerberus that guards the portals of the profession. But let us look at the psychology of the relation between doctor and patient in the individual act of medical attendance to discern, if we can, the influences that determine its ultimate character. On the part of the doctor we have three instincts we may call compassion, curiosity, and cupidity, which give respectively a humane, a scientific, and a mercenary character to the medical act. Each has a reflex in the patient's desires for sympathy, for relief, and for economy. Mingle the three in due proportion and the conditions of practice are ideal, and what we are in search of is the system which most readily affords such an ideal apportionment.

Exchange of service for service, conveniently symbolized by the cash nexus, is not peculiar to but is fundamental in the relation of doctor to patient. The work which the doctor renders must be fairly balanced by an adequate share of the satisfactions of life. If this foundation be unevenly laid any superstructure will be unstable. Yet it will be granted that the more constantly this foundation is present to consciousness the less satisfactory is the structure. Profession and public have been so long accustomed to the formula, "One attendance, one fee," that many have sustained a rude shock in the transition to the panel system with the formula, "One patient, one payment," the patient being potential and the payment actual. Yet though it has not always been easy to trace the individual payment from patient to doctor, we have seen the quarterly insurance cheque, even belated, received with satisfaction. Any general comment on the results notes that, especially in populous areas, so great are the inequalities in the remuneration received and the responsibilities undertaken by individuals that there is sometimes doubt whether the remuneration can be earned or the responsibilities discharged. In view of this many contend that we should make the still further change to a salaried service where the responsibilities could be reasonably distributed. In this the commercial relation to the individual patient would be still less direct and the cash nexus would tend to become entirely subconscious.

Of the correlation of sympathy and the desire for it we learn much from cases where these are magnified to abnormality. Exaggerated desire for sympathy is pathognomonic of the cases described as neurotic, where the nervous mechanism is working badly, though no structural change can be detected. Exaggerated compassion may make the doctor anxious to prevent his patient feeling the wind that blows while he overlooks some gross clinically discoverable condition, such as albuminuria, of which she is unconscious. The condition in the patient is a disease, what is it in the doctor? A too vivid perception of the cash nexus has sometimes been suggested, and it must be admitted that were the dependence on the individual subconscious we should expect exaggerated compassion only in those cases where it expressed a congenital bias. Whatever be the truth on this point compassion for the sufferer is not peculiar to the medical relation, and if the hysterical patient makes a special appeal for professional recognition it is probably that she may by our authority enforce the slavery she demands from her surroundings and in which the doctor is himself sometimes involved. Is there fear that in any conceived system of medical employment compassion would die out in the medical profession? Is not a desire to heal one of the strongest impulses to the selection of medicine as a profession, and is not the sympathy it expresses inborn in the doctor? Undue development of it is an infirmity of systems of individual employment.

What medicine can give on its scientific side is of it and it alone. It is here that any system of medical organization must be known by its results. Here there is no room for parade. We must bring knowledge to relieve our patient and guide him back to the full efficiency of life from which he has fallen. Curiosity is warranted if it can probe and solve the problems presented by body and mind and by the conditions of life under which they have arisen, and that system is best under which this practical curiosity can have fullest and freest play.

What conditions must such a system embody? Can we agree upon a few? (1) Freedom from financial anxiety. Is it possible to provide this and leave adequate stimulus to exertion? (2) Reasonable limitation of the amount of practice. Is not leisure essential not merely for thinking but for maintaining the bridge from the research laboratory to the bedside? If the doctor's knowledge is not progressive, is his practice likely to be so? (3) There should be no inducement to subject the doctor's standard of knowledge to that of the patient. The patient's choice of doctor depends on many factors, but his main interest is to have an assurance that the doctor's knowledge is adequate to the discovery of his ailment, to its relief and to the prevention of its recurrence, and already to an extent greater than the profession had hitherto realized he has shown his readiness to accept an official guarantee.

The interpretation of history is so often biassed that it might be dangerous to inquire what conditions have most contributed to what we to-day recognize as scientific medicine, but does the product of hospital and laboratory compared with the much more widespread individual practice cause misgiving as to the prospect of future fruit, even though we may have to travel still further from the older form of medical practice?

If, then, our science is safe and compassion inevitable, need the profession concern itself about subsidiary issues that make one or other system socially convenient? Whatever system we are to have, we must see to the

security of its financial basis, and we may safely leave the character of our work to the humanity of our common character and the peculiar scientific interest of medicine.

IV.—MICHAEL DEWAR, M.D.,

Edinburgh.

AFTER carefully considering most of the arguments which have been brought forward by its advocates for the institution of a State Medical Service, I frankly admit that something can be said in its favour, as can usually be said of any proposition put forward by any party, yet to my mind all the arguments seem to be inconclusive and unconvincing. In my study of the question it appears to me that the advocates of a State service base their claims on three main points:

1. That the panel system is a failure, and, inferentially, that a State service is the logical sequence.
2. The advantages of linking up the various medical services of the community—public health, hospitals, Poor Law, and the general practitioners—in one national service of whole-time officers under a Minister of Public Health.
3. The advantages of a system of preventive treatment under such a service, as opposed to what is termed—perhaps a little sneeringly—curative treatment.

In passing I may be allowed in a few words to dispose of one or two other arguments which are used in its support: (*a*) Circumscribed working hours—eight hours a day—and time for research work; (*b*) a definite salary increasing by promotion; (*c*) pensions. These are simply an alluring bait dangled before the eyes of the profession. The first is impracticable under any system worked by general practitioners, owing to the uncertain nature of their work; while the second and third are just what I say, and could only be enjoyed by a moiety of the profession. In discussing the three main arguments which I have already mentioned I will not traverse and repeat (so far as I can avoid them) the criticisms of the BRITISH MEDICAL JOURNAL of January 17th last, with almost every word of which I agree, or the observations of others. I will not even use German-made arguments, but will content myself with the British-made article.

1. That the panel system is a failure. Is it a failure?

I am of opinion that after eighteen months' working of the Act, which involved one-third of the population of the country, nine millions of whom, being people who were never accustomed to a system of medical and sick insurance, and the co-operation of members of the medical profession, who had to learn and accommodate themselves to the provisions and new conditions of the medical service, the panel system has been a wonderful success considering the limited time it has been in existence, and that certainly it is not the failure which it is attempted by some to make out, and it will be for the advocates of a State service to prove up to the hilt that it is a failure. The conditions of the present service—I speak as I find them—are not unduly irksome or burdensome, and the remuneration is fairly good, if one takes into account three factors: (1) The usual rate of charges per visit among the working class in private practice; (2) the absence of book-keeping; and (3) the absence of bad debts. It would even be considered fairly satisfactory by practitioners in country districts if there was a little more generous mileage rate. The existing mileage rate is one of the blots on the present system, and this feature will have to be reconsidered in the future, under whatever service doctors come to be placed.

Surely the men who have been working the Act are best fitted to judge as to the benefits which have accrued to a big majority of insured persons, who in pre-insurance days never received anything but sporadic dispensary treatment, and very often not even that, as is well known to every one, and, as to the further development of the system, I would ask the State service advocates not to be led away by the reports of some parts of London, and the East End especially, as these areas are only a portion of the system. In our own Edinburgh area, and, as far as I can learn, in the whole of Scotland, the Act is working well; there have been very few complaints by insured persons against doctors, and the majority of these have been proved to be of a frivolous nature. I say it is a pity, and, I may almost add, a shame, that before the system in force has had a sufficient time to prove its worth and justify its usefulness, a number of medical men can be found who hurriedly condemn it, use all their influence to sweep it away, and make an endeavour to replace it by a system which is not favoured by a large majority of thinking men. They do not realize what they are doing, as a whole-time State medical service would be bad for the insured persons; it would deplete, and in many cases destroy, the practises of a large number of practitioners in cities and large towns, and it would be fatal to the existence of the smaller friendly societies, because either State societies would be established or the administration of sick benefits placed on economical grounds in the hands of the large collecting societies.

A State service would necessarily abolish the great principle of "free choice," which was fought for strenuously and granted by an overwhelming majority in Parliament. Is it considered now that we were wrong in fighting for that principle? I know well enough that the State service men are of opinion that free choice would not be abolished, and that they use all kinds of sophistry to support their opinions. But in the same breath they simply give themselves away by declaring that they stand for utility and not for sentiment, and as free choice is a matter of sentiment, it must give way before the superior utility of a whole-time service. It is ridiculous to say that there would be a perfect "free choice" in a State service, and then to say it must be swept away.

As regards the argument that a State service would be a better system for the working man and his dependants—for it is assumed that the dependants must be included in such a service—we have only to take stock of the Poor Law system, the old post office service, the police service when under the medical officer of health, and other services. What will the insured person say when he realizes what a State service means? I leave that to its advocates to answer. Again, under a whole-time service only a small portion of the medical profession will be able to participate in its fruits. Take Edinburgh as an example. There will be something like 250,000 people who will come under the service. As the city will likely be divided into small compact areas, each under a whole-time officer, it will not be far from the mark to say that 100 doctors will be quite able to overtake their medical attendance; 2,500 persons under the present remuneration means £375 a year, but as each officer will be offered £600 to £700 a year or less, one of two things will happen—either the surplus will be given in extra benefits, or the 2s. 6d. will be withdrawn. Then they talk about time being available for research work. May I ask if much research work has been done in the past by 85 per cent. of the men engaged in whole-time appointments? It is only the few who are fitted by inclination, or possess the necessary ability to carry on research work, and even then this can only be done satisfactorily in laboratories by men who are doing little else.

II. There is a good deal to be said in favour of the second argument—the linking up of the various services. But I would ask again if this linking-up process cannot be brought about under the present system? Will it be beyond the wit of man to arrange for consultants being employed, nurses being made use of, laboratories being established, and treatment centres being instituted just as well under the panel system as under a State service, and even a Minister of Public Health being appointed, who would co-ordinate the work of the various Commissions? I do not argue the latter point, as I consider it would be bad for the whole country to put the supreme control of such a gigantic undertaking under one man, especially when Commissioners have already been appointed for each country, who understand the needs and requirements of those they have in charge. At least, I know that the Commissioners for Scotland have succeeded in organizing and administering the affairs in Scotland a great deal better than any bureaucracy in London could do. They have made themselves acquainted with the most minute details; and put themselves to no end of trouble to find out things, which would never have been done by any official in London. It was a wise thing the Government did when they adopted the plan of devolution as regards the Commissions in each country. Is this all to be changed and overturned at the bidding of a few men, clever though they may be?

Give the present system time to work out its own salvation, and I believe it can be done successfully if every insurance practitioner would only realize his obligations and come to a proper sense of his duty in carrying out the provisions of the Act in a proper and faithful manner. I maintain that if the panel system ever becomes a failure it will not be due to five-sixths of those who have undertaken the work, but to the one-sixth through whose carelessness and irregularities the majority will suffer.

III. Preventive treatment. A good deal is being made of this aspect of the question. State service advocates blandly assume that by making use of preventive medicine all the ills of the human frame will be done away with, and there will be little or nothing left to cure. This statement is based on the words of several speakers and writers. In connexion with this there are two points to which I may allude:

(*a*) The idea that the work of the doctor, whether in private or insured practice, is not in a great measure preventive is very much to be deprecated. Personally I may say that my custom during the course of my private practice has been mostly of a preventive nature, and under the Insurance Act conditions it is very much more so, as I have greater opportunities of seeing cases of illness among the working class at an earlier stage than in pre-insurance days.

(*b*) I may be wrong in assuming that it is the intention of the State service advocates that the whole-time men would under such a system be mainly occupied in visiting their people's homes, examining each individual for latent diseases, and investigating the home conditions. At least, that is what I am led to understand. This would practically be inquisition and in part performing the duties of the public health officials. The idea is impracticable and utopian. The man who undertakes the care of 2,000 or 3,000 persons would find his time fully occupied, especially in an eight-hour day, in the curative treatment, as long as human nature is as it is, without spending his time in parochial visitations. They are assuming that doctors will be archangels, and certainly our experience of whole-time appointments in the various public services does not encourage the entertainment of such laudable actions. Under these circumstances you must have preventive men as well as curative men, and then there would be chaos.

I appeal to the advocates of a State service to wait a while, to cease this senseless agitation for a time, until the present system, which can and will likely be amended in many ways, has had a sufficient time to get into full working order and justify its usefulness. If, then, it is found to be useless and not able to carry on the work for which it was established, it will be open, and justifiably so, to the advocates of a State service to press for its establishment with all their might. At present they are not justified in so doing.

DISCUSSION.

Dr. A. C. Farquharson (Durham) remarked that Sir John Collie had said that the issue lay between a panel system and a State Medical Service. Was it possible to have an issue between something which existed and something which did not exist? Did the presumed defects in one system create extraordinary perfections in some system not defined? Sir John Collie said he did not press for a whole-time service; a part-time service would do. What was the panel system but a part-time service giving the individual practitioner freedom? For this reason the panel system was to be preferred to the fetters of a wonderful system providing regular hours and pensions, but taking away the individuality which had come down to the medical profession through the centuries. If a State Medical Service were established, would it be in competition with the general medical profession? If the State set up a system for the whole nation it would derogate the right of individuals to enter into contracts with one another, and thus it would interfere with personal liberty. He was not convinced that the co-ordination and administrative efficiency that the exponents of a State Medical Service claimed would be brought about would in fact occur. He was a firm believer in the panel system; the Act was working with huge success in Durham, and the dispensing was done at a cost of under 1s. 6d. per insured person.

Dr. Milson Russen Rhodes (part of whose contribution was read in his absence by Dr. David Rorie, one of the honorary secretaries of the Section) urged that the principles of a State preventive medical service were that the medical profession should become the servant of the community, and not as now of individual patients, and, on the other hand, that every member of the community should give a fair share, or equivalent, according to his income, for the services he, as a member of the community, had thus received towards his health. Whatever step the Insurance Act had taken in this direction, it could only be regarded as a crude step in the evolution of an efficient and responsible system of a State preventive medical service. The nation would soon realize that the general practitioner should be the household teacher of preventive treatment and medicine, and not stand, as in the old private practice system, merely for the principles of curative and palliative treatment. When the nation came to demand this he trusted that the profession would lead, rather than be driven by, the inevitable evolutionary process of collective State action. The new order would involve sacrifice on the part of the profession, but he did not believe it would hesitate on this account. Dr. Rhodes restated the principles on which, in his opinion, a State Medical Service should be formulated; these he set out in the British Medical Journal of April 20th, 1912.

Mr. E. B. Turner (London) said he held the view that of two evils one should choose the least. What would be the effect of a State Medical Service on the community, the sick person, and the profession? As to the community, he held that the service would not be a good one; competition was necessary to get the best out of a man. A civil service department, hidebound in officialdom, was not the best method of Government control of an individualistic profession such as that of medicine. The State had never done anything as well as it had been done by private effort—witness the telephones. As to the position of the sick person under a State Medical Service, the patients must be allocated to the doctor of the district, whether they liked it or not. He was against those who said the personality of the doctor had nothing to do with it. The personal magnetism of the doctor was an enormous factor, whether the ailment were functional or organic. The public medical service officer would tend to look to the health of the State rather than to that of the individual. If he were the individual he would rather the doctor looked to his health. It had been said that the rank and file in the army and navy services did not complain at being treated by the doctor allotted to them. When the change from the system of regimental surgeon to the Royal Army Medical Corps took place there were bitter complaints. Supposing a State Medical Service were started, how would promotion be arranged? If it were by nomination by the powers above, would not this open the door to gross nepotism and political favouritism? If promotion were by the ordinary routine of a Government office, the man who gave least trouble to his superiors and proved himself a docile machine would come to the top. All individuality would be crushed out. If the factors which make a first-class practitioner—brains, personality, sympathy, tact—were stretched on the Procrustes bed of officialdom a maimed and truncated spectre would arise. Independent of the public, the State doctor would sink to the position of the school-board man and the tax collector, instead of being the friend and adviser of his patients. The man who would rise would be the man in the groove, provided he had had the wit to choose the groove which led to the top. This was not the ideal of a learned profession. Panel work was partly a State service. The practitioners were under regulation and controlled by those who for the most part were their inferiors in intelligence, education, and station, but the panel system was far more elastic than a State service. The ideal system, however, was a free untrammelled practice, in which a practitioner could give of his best under the stress of strenuous competition, in intimate relations with his patients, whom he was free to decline, and who, in turn, could dismiss him—a condition in which a practitioner was compelled to advance with the times and keep himself in the forefront of modern

science. There were still thousands of doctors who were striving for these ideals, and many of them thought with himself as to the two systems under discussion—"A plague on both your houses."

Dr. CHARLES FORBES (Aberdeen) gave some reasons for thinking that a State Medical Service was rapidly becoming a question of practical politics. The present Government had practically committed Parliament to guaranteeing "adequate medical treatment" for insured persons and their dependants. If the panel system for 13½ million insured persons cost, say, 12½ million, what would the profession consider fair remuneration for providing really adequate treatment for, say, 35 million persons? Wives and children required more treatment than men, and if 12s. a head were taken as the minimum demand the cost would be 37½ million; add to this the cost of what the State must ultimately provide for expert assistance in diagnosis and treatment—institutional treatment where imperative—and a sum was reached that would appal the taxpayer. The claim for a State Medical Service was that it would provide adequate treatment more economically and efficiently than any possible extension of the system of capitation payment. When approved societies saw they could not regain control of medical benefit, they would bring their great political influence to bear in favour of a State Medical Service. When adequate treatment came to be enacted by Parliament for insured persons and dependants a State Medical Service offered the most efficient and economic system, with greater economy for the sickness funds of approved societies, and generally more efficient organization for both prevention and treatment. What was to be the attitude of the Representative Body of the British Medical Association towards this question? As an insignificant general practitioner he assured the leaders of the profession that if a majority of panel practitioners were offered salaried service by the State they would ask: (1) What compensation does the State offer me for disturbance of vested interests? (2) What conditions of service do you offer? (3) What terms do you offer? If favourable answers were given to these three questions, three-fourths of the panel practitioners would become State servants to-morrow. If the Association entered the political arena on this question with its hands tied, it would be a disaster for the profession and the country. The Association secured everything the profession gained in the panel fight, but if the British Medical Association and the new Federation were to be turned into propagandists to fight for the continuance of the panel system as against a State Medical Service, then the profession would have a greater defeat than it suffered in the last campaign.

Dr. J. C. MCVAIL, Vice-Chairman of the Scottish Insurance Commission, expressed his indebtedness for the invitation to attend the proceedings of the Section, especially as he was sure it would be profitable to hear the views expressed on this subject. He was glad that it seemed to be realized that the Commissioners were doing their best to act fairly in the administration of a difficult Act. Under the Act the doctor came in as a private practitioner with the primary object of doing his very best for the patient; the medical practitioner was always at his best when dealing with a patient as an individual. Taking it for granted that a majority, as indicated by the discussion, were in favour of a continuation of the panel system, it was important that they should do their utmost to make it a success. Linked up with the success of the panel system there was undoubtedly a necessity for very careful certification. The doctor had to think not merely of the financial interest of the patient, but of the society. Doctors had to see that societies had their attention sufficiently directed to cases where benefit should be obtained by means of the Workmen's Compensation Act. Societies might not always be aware, otherwise than through the medical attendant, that a case of ophthalmia was probably traumatic ophthalmia, due to injury during employment. It was not a doctor's duty to be a judge of morals, and to say whether a disease was due to misconduct or not, but it was his duty to set down unflinchingly the nature of the disease, and leave others to decide whether it was a disease of misconduct or not. If he had a case of gonorrhœa he was not to call it urethritis or salpingitis, and syphilis must not be called a disease of the liver or any other organ. Further, a doctor had to be careful to certify that a man was fit for work on the actual day that he decided the man was so fit. He must not postpone the date, because the man urged that he did not want to begin work in a broken week. A single day's extra sickness of every insured person in Scotland meant to the societies the loss of £40,000 to £60,000.

Dr. L. J. PICTON (Stockport) thought that if the view indicated by Mr. Turner were taken, of "a plague on both your houses," the medical profession must give some indication of the form in which it desired medical benefit to be modified. Little as he sympathized with the exponents of a State Medical Service, they had a point in their favour in that they did attempt to deal with the question of taking in the dependants. Supporters of the panel system must say how they would deal with dependants under the panel system. The Act raised definitely, and by its general tendency, the hope in the minds of the public that the dependants would be taken in. The question of treating them was entirely one of expense, and he could not see how they were to be included under the present system except at a cost which the community could not bear. A means of eliminating a source of heavy claims upon the sick fund would be to require the individual to bear the cost of small illnesses, the State only to come in for long illnesses, somewhat on the lines of motor car insurance where one obtained a considerably reduced rate by agreeing to pay the first £5 damage oneself.

Mr. WISHART (Chairman of the Aberdeen Insurance Committee) expressed the view that if the medical profession wished to retain control of the administration of medical benefit it must come forward with remedies for existing defects, and particularly it must deal with any practitioners who accepted more persons than they could properly attend. If the profession did not deal with these matters, the approved societies would press for a State Medical Service. Instead of requiring 40 or 50 patients to wait in ill-ventilated surgeries, a direct incitement to disease, why did not practitioners group themselves and have a well-equipped waiting-room with a nurse and dresser? He believed a State Medical Service was coming in some form, and he would like to see the doctors in control of it.

In reply to a question by Dr. T. CUMING ASKIN, Mr. WISHART said there were a few doctors in Aberdeen who had large numbers on their lists.

Sir JOHN COLLIE, replying on the discussion, remarked that he never said the panel system was a failure; he had pointed out that in the poor districts of large cities whole-time medical officers might best be able to cope with the difficulties which undoubtedly existed. He did not think the profession properly appreciated the difficulties that would arise when the extra half-crown voted by Parliament came up for revision, and the dependants were proposed to be included.

THE SECTIONS.

BRIEF SUMMARY OF PROCEEDINGS.

SECTION OF ANATOMY AND PHYSIOLOGY.

Thursday, July 30th.

PROFESSOR WILLIAM WRIGHT (London) on this day gave the results of a histological examination of the alimentary canal in the elephant, and showed a series of photomicrographs illustrating the anatomy of the various parts. He drew attention particularly to the structure in the regions of the cardiac and pyloric orifices of the stomach, and in the region of the ileo-cæcal valve. He also showed a specimen of the temporal gland in the elephant, and a number of photomicrographs illustrating its structure. He pointed out its resemblance to the sweat gland, the mammary gland, and the lacrymal gland; its tubules and ductules were, however, more constantly lined

by two layers of epithelium than was the case in these above-mentioned glands in man. The papers were discussed by Professor Jamieson and Drs. Goodall, Earle, and Gladstone. Dr. Goodall asked if the writer had considered the distribution of elastic tissue, and mentioned that in most animals there was a distinct deposit of elastic tissue before each of the sphincters. He believed that the nodule of lymphoid tissue shown in the section of the stomach was more constant in carnivora than in herbivora. Mr. Norman J. Calder was the next speaker; he described a number of rare anatomical anomalies, including: (1) An abnormal band in the right auricle of the heart in the line of the sulcus terminalis, and probably a separated portion of the crista terminalis; (2) an accessory retrosternal thyroid gland; (3) varieties of the falx cerebelli, with corresponding markings on the occipital bone; (4) a thoracic duct opening into the venous system on the right side; and (5) an extra-apical lobe of the right lung, with no special relationship to the vena azygos major. Mr. George Riddoch (Aberdeen) subsequently demonstrated a dissection of the sympathetic system of a full-time fetus, pointing out more particularly the differences it presented, from the usual descriptions of the system in the adult. Mr. Sidney Boyd (London) then described a congenital anomaly of the duodenum, in which the duodenum passed from the pylorus outwards behind the hepatic flexure, and emerged as a coil of jejunum lateral to the ascending colon, thence passing down into the pelvis. Professor J. Kay Jamieson (Leeds) showed a number of specimens in which the lymphatics had been injected with Prussian blue. He further demonstrated the mode of injection. Dr. R. J. Gladstone (London) then showed a case of congenital absence of the left kidney and ureter. The testis, epididymis, deferent duct, and seminal vesicle of the same side were present, but imperfectly developed. Both suprarenal glands were present. The right kidney was enlarged to double the size of the normal. This, he demonstrated, was a pure hypertrophy, the enlargement being due to an increase in size of the constituent elements —namely, the pyramids, tubules, and glomeruli—and not to an increase in their number. Dr. Gladstone also showed a case of congenital absence of the appendix of the caecum. After drawing attention to the extreme rarity of the condition, he described five different grades of the deformity, starting from complete absence of both caecum and appendix and ending with that in which the caecum is normal and the appendix only is wanting. He believed these different types to be due to arrest of development at corresponding stages in the growth of these organs. Mr. F. K. Dalziel (Glasgow), in the discussion, described a case which he had recently met in which the left kidney lay immediately in front of the right kidney.

Friday, July 31st.

On the third morning Dr. Hugh Maclean gave a demonstration of a method for the estimation of sugar in a small amount of blood: 2 c.cm. of blood are taken, to this 7 c.cm. water, 14 c.cm. dialyzed iron, and 1 c.cm. saturated aqueous solution of sodium sulphate are added. The mixture is filtered by pressing through filter paper by means of a cloth, and the sugar estimated by a modification of Bertrand's method. Dr. Cathcart thought this was a very valuable communication, particularly on account of its rapidity. He regretted that the permanganate titration had to be adopted, as it was difficult to get workers to adopt a uniform end point. Mr. E. S. Edie gave the result of certain experiments on the action of enzymes. He found that if an excess of pepsin were added to a small quantity of trypsin the digestive action of the latter was markedly inhibited. This inhibition was not due simply to the presence of protein attached to the pepsin. Other considerations suggested that it was due to the pepsin being able to combine with protein in alkaline solution, but not to digest it. The action of a small quantity of trypsin was thus inhibited, owing to there being a very small proportion of the substrate free to combine with this enzyme. In a similar manner an excess of trypsin inhibited the action of a small amount of pepsin on protein in an acid solution. Professor Macleod reported some recent researches on sugar metabolism, concerning the possibility that in cases of experimental hyperglycaemia a certain proportion of the glycogen in the liver is broken down, not only into dextrose, but also into other substances. Histological examination of the liver stained by Best's method showed that the glycogen had become discharged as a colloidal substance, probably dextrin, into the blood vessels. In another series of observations it was found that large amounts of lactic acid were discharged into the blood of the hepatic veins after local anaesthesia of the liver, produced by clamping the vessels. Dr. Hugh Maclean said, in reference to the possibility of the presence of intermediate substances in the blood, that he had attempted to find evidence of these by the estimation of sugar in the blood before and after hydrolysis. In no case was there any change. Mr. A. D. Gardner reported the results of certain experiments on the sugar of blood and urine. He found that whereas glycolysis always occurred in normal human blood, in the blood of seven patients suffering from diabetes it was largely or entirely absent, although in mild cases of the disease glycolysis might equal or exceed the normal value. Dr. E. P. Cathcart read a communication on the influence of carbohydrate on metabolism. He pointed out that the so-called isodynamic law was of limited application, and that for normal metabolism carbohydrates were absolutely essential. He cited a new series of experiments which he had carried out, in which he described the effect of the replacement of given amounts of olive oil, in cases where the oil was the sole foodstuff given, by approximately isodynamic amounts of pure glucose. Professor Macleod pointed out that Dr. Cathcart's results were fully confirmed by those of Professor Ringer of Philadelphia. He was of opinion that further investigations on these lines would probably enable them to treat cases of acidosis more satisfactorily than they did at present. Mr. J. B. Orr and Mr. David Burns described the influence on metabolism of excessive water ingestion. They concluded that excessive ingestion of water did not produce the appearance of creatin in the urine, that the apparent decrease in the excretion of creatinin recorded under these conditions was fictitious, being due to an error of analysis caused by the great dilution of the urine, and that excretion of creatin was not a necessary consequence of the catabolism of tissue protein.

Sections of Dermatology and of Naval and Military Medicine and Surgery.

Thursday, July 30th.

Mr. McDonagh opened a joint discussion on the treatment of syphilis, and pointed out that till the cause of a disease was known its treatment must be empirical. He held that the *Spirochaeta pallida* was not the actual cause of syphilis, a sexual cycle and the production of spores being also necessary. The tendency of all protozoal diseases was to spontaneous cure, and, though treatment might do much to cut short the life-cycle, the host himself did more. Salvarsan could kill the spores in the early stage; later it killed only the gametes, the causes of the symptoms. Early diagnosis was therefore more than ever important. Coming to the use of salvarsan, Mr. McDonagh agreed that the best method of administration was the intravenous one, injections being made at intervals of not more than seven days; he preferred shorter intervals of four days. Spasmodic administration much lessened its efficacy. It was not efficacious in congenital syphilis. In primary syphilis he gave five injections of neo-salvarsan, and then mercury; in secondary syphilis nine injections and mercury for two years. Intrathecal injections must be used with caution in general paralysis and without much hope of success. Colonel Gibbard followed with a paper on the same subject, relating his experiences in the Military Hospital, Rochester Row. He said that three years ago, when he addressed the Association on the same subject, the question was whether salvarsan was a specific remedy for syphilis or not. To-day the question was not whether it should be administered, but how and when. He mentioned the great success in preventing relapses experienced in the army. In the pre-salvarsan days 371 cases showed 315 clinical relapses in the first year of treatment; now 285 cases treated with salvarsan and mercury showed only 9 relapses. After nearly 4,000 injections no fatality had occurred. The question of the minimum amount of treatment was

difficult, and very important from the economic aspect, since every addition made to the number of injections in a course of treatment made a difference of hundreds of pounds. The general practice was to give two salvarsan injections and nine mercurial injections, the former at either end of a nine weeks period, the latter weekly during it. Drs. Tomkinson, Nixon, McCormac and McWalter took part in the discussion that followed. Captain C. Webb Johnson, R.A.M.C.(T.F.), in a paper on common ailments in camp, said that the insignificant points were more often of most importance from the point of view of efficiency. He thought that the medical examination of recruits should be much stricter than it often was; there was a great temptation to pass men as fit to fill up the ranks which must be strongly resisted. The throat and mouth should be carefully examined, particular attention being paid to the teeth. The general physical conformation was also important, and the moral character also paid attention to, especially as regards drink. All recruits should be examined before going to camp. Close attention should be paid to the feet, boots and socks, and periodical inspections of the feet made. The alimentary system also demanded attention. Colonel Melville, Lieutenant-Colonel Kelly, and Dr. Baxter took part in the discussion.

SECTION OF DERMATOLOGY.

Friday, July 31st.

FIVE papers were read on the concluding day, the first of them being by Dr. Goodwin Tomkinson (Glasgow), who dealt with four cases of Lahore sore. The patients were a father and three children who had come from Sialkote in the Punjab. The lesions, which were all on the left side of the face, had lasted a year, and had been treated locally with carbon dioxide snow and *x* rays. Dr. Tomkinson had sections made and films stained. In the films the *Leishmania tropica* was found, thus establishing the diagnosis. The author called attention to the fact that all the patients were in the habit of sleeping in the open air in the right lateral decubitus position, without the protection of mosquito nets. This suggested that the infective agent was probably conveyed by a biting insect of nocturnal habits. The President advised local treatment with salvarsan. Dr. Cranston Low said he had had one case of the disease, but had not been able to find the parasite. Mr. J. E. R. McDonagh (London) read a paper on the *rationale* of the Wassermann reaction. The principal conclusions at which he arrived were as follows: (1) That the Wassermann reaction was an adsorptive phenomenon. (2) That traces of amino-acids interfered largely one way or the other with the reaction. (3) That there was no necessity to employ all the words recently coined in connexion with immunity work. Accurate chemical and physical terms were needed. (4) That the complement and the antibody were nearly if not quite identical. (5) That the antibody was a cellular product which was set free to circulate in the body fluids. Dr. Nixon (Bristol) said it was important to replace the provisional theoretical terms "antigen" and "antibody" by terms representing definite physical and chemical properties. Dr. Winkelried Williams (Brighton), in a paper on keratodermia blenorrhagica, pointed out that the disease was rare in this country, but that he was reporting the fourth case—the second under his own observation. This case was peculiar in that it did not appear until ten years after the patient had been infected with gonorrhoea. Like most other instances of the disease, this case was associated with severe gonorrhoeal rheumatism. This rheumatism had been diagnosed as rheumatoid arthritis until the correct diagnosis of the skin condition led to the necessary alteration in the diagnosis of the joint affection. Subsequently treatment with gonorrhoeal vaccine led to the complete cure of the patient both of the eruption and the arthritis. This showed the valuable light that might sometimes be thrown on obscure cases of arthritis by dermatology. Mr. Haldin Davis (London) read a paper on infantile eczema in which he expressed himself strongly against the view that it owes its origin to a diathesis, and favoured the theory of external irritation. He considered that children with severe eczema were likely to die of other diseases more readily than children with normal skins. As regards treatment, he had recently been much impressed by the beneficial effects of small doses of *x* rays, given at intervals of a fortnight. In view of the difficulty of keeping young babies quiet and preventing them from wriggling, he gave them just enough anaesthetic to put them to sleep. Of eight cases, five were practically cured. He only used the method in very severe cases. Hence he had not as yet collected many. He believed he was the first to apply *x* rays to these cases. The President said he believed in keeping the child's face wrapped for several days at a time in a single dressing of ointment. Dr. Norman Walker agreed with much that Dr. Haldin Davis had said. He had a strong affection for the old-fashioned tar in the form of lotion. Although he believed that external causes were of first importance, he found the old-fashioned mercurial purge of great value. Dr. Nixon said that eczematous children were liable to die of status lymphaticus or pulmonary diseases. Circumcision was often advisable in eczematous male infants. Dr. McWalter (Dublin) and Dr. J. Crabbe (Holloway) also spoke. Dr. Cranston Low, who objected to the term "eczema," regarded these cases as really seborrhoeic dermatitis and obtained good results from sulphur and ichthyol treatment. Dr. McWalter (Dublin) read a paper on the use of antimony in syphilis, a drug he had been using for fifteen years. He also used it in other diseases. The President, in closing the proceedings, desired especially to thank Dr. McLatchie for his work as Secretary, work which had been exceptionally heavy owing to the illness of Dr. Christie, and work which had been exceptionally well executed. Dr. Norman Walker proposed, and Dr. McWalter seconded, a vote of thanks to the President. This was carried with acclamation, and the proceedings then terminated.

SECTION OF DISEASES OF CHILDREN, INCLUDING ORTHOPAEDICS.

Thursday, July 30th.

DR. A. E. GARROD, opening a discussion on the thymus gland in its clinical aspects, said that the thymus was essentially a gland of childhood. He narrated the experimental results which had followed thymectomy in animals, the most striking results of which were changes in the osseous system similar to those of rickets. Thymus feeding had not been able to prevent these changes. A form of "cretinoid" idiocy had been ascribed to absence of the thymus. He then spoke of the conditions which accompany hyperplasia, dealing with the clinical varieties—"thymic death," "thymic asthma," and "status lymphaticus." He had not seen an undoubted case of thymic asthma, and thought that such cases must be very rare. Deaths in status lymphaticus could not be ascribed to the effect of pressure. Paltauf had placed the subject on a broader basis, relegating the enlargement of the thymus to the position of one factor only of a general constitutional state. He dealt with the symptoms and pathology of status lymphaticus, pointing out that many of the signs were inaccessible to the clinician. Status lymphaticus played a part in Addison's disease and Graves's disease. The treatment at present had been chiefly concerned with the large thymus and the removal of the gland or its reduction by irradiation with *x* rays. Possibly, if it were proved that the defect was one of internal secretion, administration of one or other of these might bring beneficial results. Mr. Alexander MacLennan (Glasgow) recounted his experiences in the removal of the thymus gland for various morbid conditions. He advocated thymectomy as a preliminary to partial removal of the thyroid gland for Graves's disease. He had removed the thymus in eight cases. Mr. D. P. D. Wilkie (Edinburgh), in a paper on acute appendicitis and status lymphaticus, laid stress on the importance of the latter state in relation to operations in acute abdominal conditions, and narrated cases of appendicitis which had been rapidly fatal and in which status lymphaticus was found after death. The subject of status lymphaticus appeared to have an abnormally low resistance to acute abdominal infections, and there was a particular reason for the avoidance of chloroform as the anaesthetic in such cases. Dr. Charles McNeil (Edinburgh) said that the special feature of status lymphaticus was that a small "noxa" produced an uncommonly great reaction of tissue cells. He thought that death in this condition was due to infection of a fulminant form, the virulence of which

infection was referable to the constitutional state of status lymphaticus. In the second part of his paper he dealt with "scrofula" as defined by Escherich, Morro, and others. He held that in status lymphaticus there was an accentuated reaction to tuberculosis also. Professor Noel Paton spoke of the thymus from the side of physiology, recounting experiments by thymectomy on guinea-pigs. Very little result followed. The thymus enlarged after castration, a fact which was well known in the meat trade. Professor Paton had produced these effects in guinea-pigs. If the thymus were removed the testis grew more rapidly. There was a close connexion between the thymus, sex glands, and body growth. The thymus could not be considered as an organ essential to life. The discussion was continued by Dr. J. H. Thursfield, Dr. D. B. Lees, Dr. Frederick Langmead, Dr. Leonard Findlay, and Dr. D. Watson Geddie. Dr. A. E. Garrod having replied, Dr. Leonard Findlay and Dr. Madge Roberts contributed a paper on some manifestations of congenital syphilis and its treatment. They referred to the condition of eczema which one of them had described in syphilis; 37 cases in all had been seen, and each gave a positive Wassermann reaction. In a series of 11 cases of congenital heart disease a positive Wassermann reaction occurred in 7 of the patients, and in the mothers of 2 others. Of 15 cases of cerebral diplegia in which a history of injury was obtained the Wassermann reaction was positive in 5, and in 10 where there was no history of injury; 4 gave a positive reaction. They spoke of mental deficiency, and had found a positive Wassermann reaction in 59 per cent. of such cases. These figures were evidence of the inefficiency of the present methods of treatment. They advocated the use of the scalp veins for intravenous injection of neo-salvarsan. The mortality of the cases they had treated with salvarsan and mercury was considerably less than that of those treated by mercury alone.

Section of Electro-therapeutics and Radiology.

Thursday, July 30th.

The principal discussion on the second morning related to the comparative value of *x* rays and radium in the treatment of malignant growths. It was opened by Dr. F. Hernaman-Johnson (Darlington), who dealt largely with the physics of the question. He pointed out that a few years ago physical science would not commit itself to the proposition that it was possible, even in theory, to design an *x*-ray apparatus which should give out rays identical with the gamma rays of radium. That attitude had now changed. It was known definitely that by using a suitable anticathode, and discharging against it negative particles moving at about 120,000 miles a second, the necessary conditions would be fulfilled. It was at any rate certain that in cancer the therapeutic effects of hard filtered *x* rays closely approached those of radium, but so long as the *x* rays they used still differed considerably in penetrating power from the hard gamma rays of radium, they must admit that cases occurred which, even apart from questions of correctness of application, were better dealt with by the latter agent. Radium therapy, however, was simply *x*-ray therapy writ large, and when it was divorced from electro-therapeutics no small loss resulted. A second paper, dealing more strictly with the clinical side of the subject, was read by Dr. John Macintyre of Glasgow, who pointed out that in a great many cases the site of the disease and its depth in the tissues determined the choice of the agent; the state of the patient and the history of the case also had to be taken into account, and the widely differing form of the two agents also had something to do with the advantages and disadvantages of each. It was furthermore of importance to remember the expense involved in the purchase and use of radium, although one great advantage which radium possessed was in the collection of emanation. Dr. James R. Riddell (Glasgow) reported certain cases to support the view that hard *x* rays have an action on certain malignant tumours very similar to the action of heavily filtered radium, and that the action was selective in the sense that its final result was the destruction of the malignant cells, while the surrounding fibrous tissue was irritated and stimulated to increased growth. Dr. W. S. Lazarus-Barlow (London) detailed some experimental researches in order to show that when one had determined the quantity of radium and the time of exposure which would give good results in dry cutaneous carcinoma, the quantity of radium must be increased, and the length of exposure diminished, in order to get the optimum results in the case of columnar-cell carcinoma. Among other speakers, Dr. Frank Fowler (Bournemouth) called attention to the poor equipment of many *x*-ray departments, which made it out of the question to compare the results in any way with those obtained by means of radium; and Mr. Hall-Edwards (Birmingham) said that recent developments in *x*-ray treatment had at least rendered it possible to get rid of the large sloughing and offensive surfaces which had been the necessary accompaniments of malignant growth. The papers read during the morning included one by Dr. W. C. Oram (Liverpool) on the subject of the radiographic detection of gall stones. He drew the conclusion that some gall stones were likely to be too transparent for *x*-ray demonstration even under the most favourable conditions. Dr. J. R. Riddell showed diagrams of an *x*-ray tube so designed that either a converging or a parallel beam could be made use of; and Dr. E. P. Cumberbatch (London) gave a demonstration of a condenser discharge apparatus for muscle testing. A cinematograph exhibition concluded the morning's work. Dr. John Macintyre showing the first *x*-ray cinematograph film ever made, together with some recent examples of work in this direction. These latter illustrated the movements of the stomach after a bismuth meal, the successive pictures being made with exposures of one-three-hundredth of a second.

Friday, July 31st.

At the conclusion of the combined discussion with the Sections of Medicine and Diseases of Children, another discussion took place in the Section of Electro-therapeutics and Radiology on the subject of *x*-ray diagnosis in gastro-intestinal conditions. Dr. A. F. Hertz, in an opening address, confined himself almost exclusively to appendicitis, and urged that no case of appendicitis ought to be operated on without a preliminary *x*-ray examination. The evidence to be obtained by means of *x* rays was both direct and indirect. Directly, the appendix itself could be seen in at least 50 per cent of cases, and probably in a much larger proportion. The actual method of examination depended upon palpation with the screen; by manipulating the caecum and pushing it in various directions so as to separate the ileum from the caecum one could frequently see the appendix. Dr. Hertz discussed the *x*-ray appearances, and also the signs on palpation indicative of diseased appendix. The indirect evidence obtainable by *x* rays had regard to the various reflex effects which the appendix had upon the alimentary canal, and particularly upon the stomach. Dr. G. A. Pirie (Dundee) pointed out certain indirect radiographic signs of appendicitis, and Dr. O. Grünbaum (London) suggested the use of collodion for coating a bismuth pill, the advantage being that the pill did not disintegrate until the contents of the stomach became acid. Dr. E. Duncan (Glasgow) considered that the appendix was much maligned, and did not produce as much mischief as was alleged. Dr. Hertz, in replying, criticized an expression which had been used in the course of the discussion, namely, "atonic constipation." There might be deficient peristalsis with normal tone, and normal peristalsis with deficient tone.

Section of Gynaecology and Obstetrics.

Thursday, July 30th.

The subject for this day's discussion—the management of pregnancy and labour in contracted pelves—was opened by Dr. Henry Jellett (Dublin) and Professor Frank (Cologne). The former confined himself to the second degree (2¾ in. to 3¼ in.) of symmetrical contraction, and discussed its treatment under the headings of (1) induction, (2) Caesarean section, (3) pubiotomy, and (4) craniotomy. He was not greatly in favour of inducing premature labour; although the recognized methods were easy, they were all more or less uncertain, and the possibilities of infection were large. It was an operation for special conditions alone. Caesarean section was good, except that it prevented any demonstration of the voluntary powers of the patient, and "once done always done." It was specially serviceable in elderly primiparae. He considered pubiotomy the operation

of choice and to be particularly indicated in young primiparae. When this operation was performed every opportunity was given the woman of escaping any further operation, and there was a permanent increase in the measurements which was very obvious in later labours. The main arguments against it were, first, the prolonged labour and secondly the possibility of lacerations. A record of 19 cases was given showing complications in 9; in 2 there was necrosis and extrusion of the fragment of pubes between the section and the symphysis, but this led to no difficulty in locomotion; craniotomy should be limited to dead children. Professor Frank, who apologized for speaking in German, discussed his simple and safe operation of subcutaneous symphysiotomy. The only instrument necessary was a narrow knife; and compression afterwards prevented haematomata. He recommended it more especially for multiparae with middle degrees of pelvic narrowing. It was advisable to delay its performance till the os was dilated and to allow Nature to complete the delivery. It was a useful operation for the delivery of the aftercoming head. Contraindications were discussed and tables analysed. In 155 cases the previous history of the patients showed 23 per cent. of live births, whereas with symphysiotomy 94 per cent. was obtained. For primiparae with the same degrees of contraction he advocated extraperitoneal suprasymphyseal Caesarean section. Dr. Shannon (Glasgow) interposed his analysis of cases in Professor Kerr's wards in the Glasgow Maternity Hospital during the years 1909–1913; 27.5 per cent. of contracted pelves were found in a total of 1,291 cases. Full details were given of the methods of diagnosis and treatment, but these did not lend themselves readily to summary. It was obvious, however, that craniotomy was given a somewhat larger sphere of usefulness than is usual. Kerr's modification of Pinard's method of estimating the proportion between the head and the pelvis was described. Dr. Hastings Tweedy (Dublin) emphasized the difficulties of pelvimetry. He considered extraperitoneal section an admirable operation and viewed with much disfavour craniotomy of a living child merely because there had been several vaginal examinations. Professor Murdoch Cameron (Glasgow) expressed a great contempt for statistics, and agreed with Dr. Jellett and Dr. Tweedy in regard to craniotomy. He preferred Caesarean section to pubiotomy. Professor Kynoch (Dundee) considered it inadvisable to time labour by the clock. In cases where natural delivery appeared improbable he had found Walcher's position useful. He was sorry to find induction so severely criticized, believing, as he did, that the failures were due less to the method than to its performance. He had recently been much impressed by the simplicity of symphysiotomy in the hands of Professor Frank. Sir John Byers and Dr. Oliphant Nicholson also spoke. Dr. Jellett, in reply, pointed out that he had discussed the question from the standpoint of modern midwifery and not from the point of view of what a general practitioner might be compelled to do. He therefore preferred pelviotomy to induction. The best test of the proportion between head and pelvis was given by the former, which postponed operation to the last moment. He was inclined to forecast a prophylactic pubiotomy during pregnancy.

Friday, July 31st.

The first paper of the last day was read by Dr. Leith Murray (Liverpool). It dealt with acidosis and the nitrogen partition in pregnancy, and expressed regret that even in maternity hospitals urinary examinations were not as full as might be. Three simple quantitative tests were described which could be applied by a relatively inexperienced worker in a clinical laboratory: (1) Mathison's for ammonia, (2) Groat's for total nitrogen, and (3) Hart's for acetone-complex bodies. A discussion of the possible value of the data obtained followed. An increased ammonia coefficient was not necessarily indicative of an acidosis, but might, and often did, represent a change in the liver either degenerative or necrotic. A few elementary points in relation to acidosis in general were given and the question raised whether even an estimation of the acetone bodies was a true measure of the condition. The speaker was inclined to agree with Sellards that the only true test was one of tolerance to alkali. If the body were in no need of fixed bases, any alkali introduced would be eliminated and the urine become alkaline; but if there were a need for fixed bases, it would remain in the body and the reaction of the urine would remain unchanged. This test was, in addition, a therapeutic measure, and also gave a clear indication of the cause of a high ammonia coefficient, whether from a disorder of the protein metabolism or as a purely compensatory process. The results in 80 cases of normal and toxic pregnancy were given. In symptomless pregnancy the coefficient rose steadily towards the end, ranging between 2.2 per cent. and 12 per cent. Exceptionally still higher ratios were observed during labour. Hyperemesis, eclampsia, pre-eclampsia, and nephritis in pregnancy were reviewed in turn, and a comparison made between the ammonia ratio, the acetone bodies, and, in some of the cases, the tolerance test. The difficulties of interpretation were admitted and a plea put forward for a further study of the subject. Dr. Beckwith Whitehouse (Birmingham), Dr. Russell (Glasgow), and the President joined in discussing the paper. Dr. Tennyson Smith (Kent) followed with an interesting narration of a case of rupture of the uterus through the scar of a previous Caesarean section. The woman had been in labour for fourteen days before the rupture occurred. The fetus was in the abdominal cavity, with much blood clot, and hysterectomy was done eight and a half hours after the rupture. The patient made a good recovery. Some discussion followed as to the site of the rupture and the best suture material for uterine wounds. The President contributed some further observations on the treatment of eclampsia by veratrone. Cases, both in eclampsia and in the pre-eclamptic state, were recorded showing the very favourable results that had been obtained with this drug. The blood pressure and pulse immediately fell in every case, and the quantity of urine rapidly rose; diaphoresis was marked, and there was in almost every instance an immediate cessation of fits. The depressing action of the drug in doses of $\frac{1}{2}$ to 1 c.cm. was very temporary in eclampsia, although in other conditions it appeared more potent. This in itself was suggestive that the drug was in some measure a real antidote. Experimental work on cats showed that veratrone stimulated the afferent fibres of the vagi. The work of the Section closed with a vote of thanks to the President, proposed by Emeritus Professor William Stephenson.

SECTION OF LARYNGOLOGY, RHINOLOGY, AND OTOLOGY.

Thursday, July 30th.

THERE was again an excellent attendance at the Nose, Throat, and Ear Section, and the subject chiefly under discussion was one of much interest. There is probably no more contentious subject in otology than oto-sclerosis. Mr. Gray, who had charge of the etiological and pathological aspect of this disease, showed some really excellent diagrams and screen pictures. He further freely acknowledged the difficulty of stating the exact nature and cause of this disease, especially as to whether it be a bone change, pure and simple, or whether it be neurotrophic. It was an exceedingly instructive paper. The clinical aspect was then dealt with by Mr. Fraser, who especially mentioned a probable catarrhal origin in some cases. Again the Section showed its appreciation of the thoroughness of the speaker's work. The various methods of treatment were then discussed by Mr. Jenkins. He stated definitely that, in his opinion, no known treatment was of any curative value in true oto-sclerosis. An excellent review of the claims made on behalf of the system of treatment known as auditory re-education was then supplied by Mr. F. F. Muecke. It included a detailed account of much work done by him on the subject at the London Hospital, and showed that the results were not satisfactory. The discussion was then taken up by Dr. Watson-Williams, Dr. William Hill, Mr. Syme, Dr. McKenzie, Mr. Jenkins, and Dr. Booth, and the openers suitably replied. All the speakers were unanimous in their opinion of the value of the opening papers. The morning's work concluded by a paper by Dr. Dimitrios Dimitriadis, which was read on his behalf by the Secretary, and gave an account of the wounded during the last two Greek wars, with special reference to the ear, nose, and larynx.

Friday, July 31st.

The Section was again indebted to Mr. J. S. Fraser (Edinburgh), who showed some splendid epidiascopic

pictures demonstrative of the pathology of labyrinthitis. The spread of infection from the middle ear and antrum could be followed with great ease, so excellent and instructive were the slides. The pathology of the various diseases of the middle ear and labyrinth must surely have made a great advance during this congress. Dr. Watson-Williams (Bristol) then gave a demonstration on the intranasal operations for frontal sinus disease. First touching briefly on the historical aspect, showing pictures of the methods and instruments of the various Continental and American specialists, he went on to explain—largely by means of excellent *x*-ray pictures—his own method, describing the possible dangers of the operation, and pointing out the best way to avoid them; he laid great stress on keeping to the outer side of the vertical plate of the middle turbinate. After him Dr. William Hill showed Good's raspatory, for which he claimed good results. Sir William Milligan then raised the point of the greater safety of the external operation in the hands of specialists other than those specially skilled in the internal method. Dr. Watson-Williams suitably replied, stating that this method increased the field of frontal sinus operation, but in no way replaced wholly the external operation. But he differed from Sir William in regard to the relative danger of the external and the intranasal method which he advocated and practised, and which was comparatively easy to perform and nearly devoid of danger with reasonable care. The next paper was by Dr. Brown Kelly (Glasgow), who dealt with the difficulties and dangers of exploratory puncture of the antrum of Highmore. Cardiac failure, shock, abscess of cheek, cocaine poisoning, toxaemia, various reflex disturbances (probably via the tenth nerve), and an embolism, were among the dangers mentioned as having occurred during or immediately after puncture of the maxillary antrum. The President having congratulated Dr. Kelly on his paper, the discussion was started by Dr. Pegler, and continued by Mr. Faulder, Dr. Watson-Williams, Mr. Somerville Hastings, Dr. Gogarty, Dr. Hill, Dr. Booth, and Mr. Gray and the President. The next demonstration was on a new form of an extending broncho-oesophagoscope. Sir William Milligan explained his very useful invention, and was congratulated by the President, Dr. Hill, and Dr. Brown Kelly on the advance that it represented. Owing to the late hour Dr. Hill omitted reading his paper, but demonstrated the special instrument which he and Dr. Elphick had devised to minimize the haemorrhage in tonsillectomy. He apologized for bringing out yet another instrument for the tonsils, but claimed that the excellent results obtained more than justified his action. Mr. O'Malley spoke of the experience he had had with his own instrument, stating that he had had practically no bleeding in his cases. Further speakers described their methods in attacking this surely the most unfortunate organ of the human body. The concluding paper was on the latent empyemata of nasal accessory sinuses. Dr. O. St. J. Gogarty made out an undoubted case for a thorough examination of these sinuses in cases of obscure headache and other equally obscure head symptoms. The discussion was undertaken by Dr. Williams, Dr. Killen, Mr. Gray, and Dr. Peterkin. Dr. Booth then moved a very hearty vote of thanks to the President, who had done so much for this Section both scientifically and socially. He also referred with great pleasure to the fact that so many able men had come from London and the big provincial towns despite the great counter-attraction in London.

Section of Medicine.

Thursday, July 30th.

On the second day a discussion on the treatment of phthisis by artificial pneumothorax was opened by Dr. Rist (Paris), who remarked on the general uniformity of the methods now employed, and noted that spontaneous pneumothorax was habitually fatal when it occurred in bilateral phthisis. It was necessary, therefore, to confine the production of artificial pneumothorax to patients with one sound or nearly sound lung; and in determining the soundness of a lung it was essential to employ the *x* rays as well as the usual clinical methods of examination. He dwelt on the difficulties met with in interpreting the pictures yielded by the *x* rays; experience was of the highest importance here, and waiting in order to be able to examine the case again after a few weeks. Among the patients most suitable for artificial pneumothorax were those with cavities in one lung; Dr. Rist laid stress on the frequency with which cavities appear early in phthisis. Any progressive unilateral pulmonary tuberculosis was suitable for the treatment; caseous tuberculous pneumonia was often vastly improved by it, if not cured. Artificial pneumothorax was sometimes the only successful treatment for haemoptysis. It must be remembered, however, that the presence of adhesions could not always be made out beforehand; Dr. Rist was of the opinion that artificial pneumothorax should always be attempted in cases where it was indicated. The common complication of the treatment was a pleural effusion, seen in perhaps half the patients; often, however, the effusions were small, and not often did they need to be tapped. These effusions always contained tubercle bacilli; when small, they often showed eosinophilia. Use of the *x* rays showed a number of curious movements in the diaphragms of patients with artificial pneumothorax, and also curious movements of the heart. Dr. H. de C. Woodcock (Leeds) then read the paper by himself and Dr. J. A. M. Clark on artificial pneumothorax. He gave details of the methods of administration they employed, and the precautions that should be taken if shock was to be avoided. Severe haemoptysis cried out for the treatment; a series of cases in which artificial pneumothorax was employed was detailed. Dr. G. Lucas (Banchory) suggested that the term "nitrogen compression" should be substituted for "artificial pneumothorax," in the interest of the patients and their mental repose. He asked Dr. Rist a number of questions on practical points. Dr. F. Eve (Hull) referred to the simplicity of the apparatus that might be used, and gave a few practical details of his own procedure. Dr. C. Riviere (London) deplored the backwardness of Great Britain in the employment of this method of treatment. He gave his own experience of its use, detailing one case in which pulmonary oedema and death followed it. He expressed doubt whether early tuberculosis could be treated by collapse with advantage. Dr. W. M. Crofton (Dublin) referred to cases of early pulmonary tuberculosis, in which the *x* rays failed to display the site of the infection; he also disagreed with Dr. Rist's statement that caseous pneumonia was almost necessarily fatal. Sir William Osler (Oxford) summarized the present position of pneumothorax treatment, and added remarks on the occurrence of pleural effusion as a complication; he asked if the effusion was not really due to puncture of the lung. The President thanked Dr. Rist for his excellent paper, and drew attention to the importance of symptoms rather than physical signs in tuberculous patients. Dr. Rist, in reply, answered a number of points and questions raised by previous speakers; he regarded the pleural effusions occurring in the course of the treatment as due to extension of the tuberculous process to the surface of the collapsed lung. Dr. D. D. Brown (Harrogate) then read a paper on rheumatoid arthritis, comparing the medical and surgical standpoints. The disease was increasing, he said, and he gave a classification of its etiology. He always sought for a primary focus of infection in the patients and devoted much attention to its treatment. Creosote and guaiacol seemed to him the best drugs to employ, with thyroid extract. He did not regard the disease as incurable by any means. Dr. G. H. H. Almond (Bath) gave a general account of the disease and the lines on which it should be treated by physicians, surgeons, and orthopaedists. Dr. W. M. Crofton asked for further details as to Dr. Brown's lines of treatment. Dr. C. O. Hawthorne (London) called for more definite and more scientific evidence in proof of the statements made by previous speakers. Dr. Brown spoke encouragingly of the use of bacterial cultures and vaccines in suitable cases. Dr. W. Aldren Turner (London) next read his paper on the outlook in epilepsy. Cure he regarded as the arrest of the fits while the patient was able to earn his living, or at any rate enjoyed normal mental activities. The curability of a case should be determined largely by consideration of the mental condition. Any sign of dementia rendered the outlook very unfavourable at any age. Dr. W. Haig (Crieff) gave an account of the rapid relief of acute lumbago obtainable by manipulation and active movement. Deep thumbing of the lumbar muscles

followed by free movement of the lumbar joints, were said to enable the patient to return to work at once. Dr. F. Eve (Hull) read a paper on acute atrophy of the thyroid, occurring shortly before death in a woman treated for exophthalmic goitre during six years. He discussed the influence of horse serum in checking morbid cytolytic processes. About sixty persons attended the meeting of the Section.

SECTIONS OF MEDICINE, OF DISEASES OF CHILDREN, AND OF ELECTRO-THERAPEUTICS AND RADIOLOGY.

Friday, July 31st.

AT a joint meeting of these Sections, Dr. F. J. Smith in the chair, Dr. D. B. Lees opened a discussion on tuberculosis in children by emphasizing the frequency of its occurrence, the utility of *x*-ray examinations in the diagnosis, and the importance of careful and methodical physical examination by the ordinary physical methods. Particular stress was laid on the results obtained by careful percussion of the front and back of the chest; six dull areas characteristic of tuberculosis and not any other infection—influenzal, pneumococcal, and so forth—could always be found early in tuberculous patients. In patients with spasmodic asthma dull areas behind, corresponding to enlarged bronchial glands, could be defined. It was advised that careful percussory records of these six typical dull areas should be made every month. In infancy and childhood tuberculosis tended to spread by the lymphatics much more than it did in adults; an odd fact hitherto unexplained was that in the young the right lung was attacked much more frequently than the left. Asthma and croup might be caused by the pressure of enlarged lymphatic glands at the root of the right lung especially. Stress was laid upon the necessity for skiagrams taken by the shortest possible exposures; the importance of the peribronchial fibrosis and the calcified glands so common in pulmonary skiagrams was minimized; attention was to be concentrated on the finer apical mottlings. The difficulties introduced by mixed infections, so common in children, were discussed, and Dr. Lees concluded by commending once more to the general practitioner the method of careful percussion in the early diagnosis of phthisis in the young. Dr. C. Riviere (London) stated that the common form of tuberculosis in infants and children was the lymphatic or glandular. Interscapular dullness, particularly when confirmed by the skiagram, was a valuable diagnostic proof of tuberculosis at the root of the lungs; Dr. Riviere stated as a new fact that this dullness occurred on the right side only, and explained this dullness as due to pressure on the right pulmonary artery. The physical signs in true phthisis were, he asserted, quite different; and he laid greatest stress on the evidence afforded by the lightest possible percussion. His own areas of dullness were different from those described by Dr. Lees, however. Dr. Ironside Bruce (London) gave an account of the *x*-ray examination of the chest; skiagrams were essential, and the exposure should be as short as possible. The patient should hold his breath while the exposure was made; any movement of the diaphragm during the exposure led inevitably to loss of fine detail. Dr. F. C. Eve (Hull) gave an account of the physical signs of phthisis as met with in a large town. Dr. D. McNeill (Kirkwall) expressed his difficulty in believing in the value of the areas of dullness described by Dr. Lees, as evidence of pulmonary tuberculosis; he thought, too, that enlarged lymphatic glands in the neck afforded no good proof of phthisis. Dr. D. Lawson (Banchory) spoke of the necessity for combining all methods of examination in the diagnosis of phthisis, and asked a number of questions relative to the *x*-ray examination of patients suspected of phthisis. Dr. F. Langmead (London) spoke of the necessity for discovering means to determine whether pathological lesions found by the various methods of physical examination were evidence of active disease or no. Dr. E. E. Prest (New Cumnock) emphasized the importance of general evidences of illness, symptoms rather than signs, in the daily routine of determining whether a child suspected of phthisis was in need of treatment. Dr. D. Barty King (London) dwelt on the difficulty of finding definite evidence of phthisis in many of the children that had been actually certified as having tuberculosis, and recounted a case diagnosed as phthisical by the skiagrapher that proved *post mortem* to be non-tuberculous. The President laid stress upon the importance of studying the patient rather than the physical signs, holding that the clinical aspects of the matter were often neglected. Dr. Lees, in reply, upheld the utility of his areas dull on percussion, as evidence of old as well as of active tuberculosis. Dr. Riviere, in reply, distinguished between tuberculous infection and tuberculous disease, and answered a number of the points raised by other speakers. Dr. Bruce also replied, deprecating excessive interpretation, in a clinical sense, of the appearances shown in skiagrams. After the conjoined meeting, attended by over 120 members, had come to an end, Dr. F. C. Eve (Hull) and Dr. A. H. Lister (Aberdeen) read their papers to a much diminished meeting in another place.

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE.

Thursday, July 30th.

AT the second meeting of the Section, Dr. Jung, Professor of Psychiatry at the University of Zurich, opened a discussion on the importance of the unconscious in psychotherapy. The unconscious he defined as "the sum of all psychological events which are not appereceived." It contained, he said, all the psychic events which were unable to pass through the threshold of consciousness because of their lack of the necessary intensity. As an example of this he cited the case of a worthy merchant who, according to his conscious view, was happily married, successful, self-respecting, hard-working, enlightened, artistic, public-spirited; but though unaware of it himself he was careless, also forgetful of his wife's requests, minimized his income to income tax authorities, had misgivings about transacting business on Fridays because superstitious. These were compensating unconscious vices, and there might exist in such an individual unconscious compensating virtues also, but the effect of either was liable to be influenced by essential hereditary dispositions, as also by the existence of motives for virtuous or vicious actions. In general, in normal individuals, the result of the functioning of the unconscious was to produce a balance, all extreme conscious tendencies being toned down through effective opposite impulses in the unconscious. In abnormal persons it was otherwise; in them the functioning of unconscious processes broke through into the conscious mind in an abnormal manner and disturbed the adaptation of the individual to his environment. A normal person could unconsciously utilize his unconscious psychic tendencies to correct any one-sided conscious attitude, but the abnormal individual could not do this; he might even increase his one-sidedness by defending himself against his own compensating influences, and the result was a great lack of harmony between his conscious and unconscious attitudes. The unconscious began to obtrude violently on his conscious mental processes, and did so in forms which were altogether unacceptable to him so far as his conscious mind was concerned. This unacceptability of form was due to the distortion inevitably undergone by the compensating influence before it could make headway against the resistance of his unconscious mind, and to the necessity of the compensating influence presenting itself in the language of the unconscious—that is to say, in psychic material of the most heterogeneous and fantastic nature. A second paper on the same subject by Dr. Jones was read on his behalf by Dr. Eder. The latter, as also Dr. Constance Long, read papers, and these and the preceding were discussed by Dr. Leslie Mackenzie, Dr. Crichton Miller, Dr. Stein, Dr. H. J. Mackenzie, and Dr. Mott.

[In regard to the proceedings of the Section on the first day there was an unfortunate clerical error. The President referred to the death of Dr. James Neil of Oxford, and not as printed last week, page 250.]

SECTION OF OPHTHALMOLOGY.

Thursday, July 30th.

MR. J. HERBERT PARSONS (London) opened the discussion on the hygiene of reading and near vision. He traced the development of reading and letters, and pointed out that it was only within the last thirty years that the subject had been studied from a scientific standpoint. The effect of

illumination was very important, but glare had but little real effect, in spite of the fact that it was very distressing to be exposed to it while working. Dr. MacGillivray (Dundee) said he had never seen organic mischief result from defective light. Dr. F. W. Edridge-Green (London) said that lack of peripheral illumination caused headache and distress in reading, and for this reason he deprecated the use of reading lamps. Dr. Parry (Hove) spoke of bad illumination in schools, and Dr. R. A. Reeve (Toronto) mentioned the bad effect of highly glazed papers. Mr. Devereux Marshall (London) did not believe that electric light was bad for the eyes, but since its advent people used their eyes so much more and overtired them, and then blamed the light. Dr. A. J. Ballantyne (Glasgow) thought that rash statements as to the evil effect of bad light on the eyes should be carefully avoided. Dr. Marion Gilchrist (Glasgow) spoke of the evil effects of badly fitting spectacles in children. Dr. Montagu Harston (Hong Kong) stated that in the tropics people often worked most of the day in artificial light because of the heat, when blinds had to be drawn. Mr. Parsons having replied, the discussion on the teaching of ophthalmology to medical students was opened by Dr. A. Maitland Ramsay (Glasgow). He pleaded for a more thorough recognition of the necessity for every student having to pass an examination as well as to attend a course on ophthalmology for their ordinary medical and surgical degrees. Mr. M. L. Hepburn (London) thought that teaching should be very practical, and he deprecated set lectures. All students should be taught to recognize errors of refraction, though not necessarily to correct them. Miss E. M. Maxwell (Dublin), Dr. Montagu Harston (Hong Kong), Dr. Hill Griffith (Manchester), Mr. A. F. MacCallan (Egypt), Dr. MacGillivray (Dundee), Dr. R. A. Reeve (Toronto), and Dr. Casey A. Wood (Chicago) spoke of the practice of teaching adopted in the universities with which they were connected, and on the recommendation of Mr. T. H. Bickerton (Liverpool), seconded by Dr. MacGillivray (Dundee), a resolution was passed urging the necessity of an examination for all medical students in ophthalmology.

Friday, July 31st.

Dr. A. Hill Griffith, in a paper on cases of later infection after Elliot's operation, described one in which a suppurative irido-cyclitis caused destruction of the eye two years after the operation. He mentioned that 28 cases had been recorded, and that a colleague of his had had one case, but he thought that there must be many more cases which had never been recorded. He disenssed the operation, and thought that a conjunctival flap should be cut as thick as possible. Mr. Devereux Marshall said that he looked upon all cases of cystoid scars as containing a potential cause of mischief. He described a case of infection occurring one year after an irideetomy for glaucoma which developed a cystoid scar. Professor H. Gifford (Omaha) agreed that any eye with a fistula in it was liable to infection from the conjunctiva, and as a precaution against this he advised the routine use of an antiseptic lotion to the eye. Mr. J. Herbert Parsons (London) was surprised that late infection did not occur more frequently. He thought that a large flap was essential, which should not cut down as far as the cornea at each end. The trephine should be as far as possible in the cornea, as Elliot recommended. Dr. Montagu Harston (Hong Kong) thought that suppuration in cavities, such as the accessory sinuses, was a great source of danger. Dr. A. J. Ballantyne (Glasgow) strongly advocated a large and thick conjunctival flap. Dr. Casey A. Wood (Chicago) had seen suppuration commence at the margin of the flap, one three weeks after operation, and one six months after. Dr. A. Maitland Ramsay (Glasgow) said the flap should not be cut to the periphery. Dr. James A. Wilson (Glasgow) thought thin flaps dangerous, and thick flaps were far safer. Neither Mr. Bickerton nor the President had ever seen cases of late infection. Dr. F. W. Edridge-Green (London) read a statistical paper on the results of the new Board of Trade sight tests. It clearly demonstrated the bad results as regards colour-vision tests, many normal-sighted persons being rejected. Mr. J. Herbert Parsons (London) defended the Board of Trade tests, and Mr. Devereux Marshall adversely criticized them. Major McKechnie (I.M.S.) thought the Edridge-Green lantern was a scientific instrument, and he failed to see the use of retaining the wool test. He thought that a standard should be fixed. The work of the meeting concluded with a paper by Dr. James A. Wilson (Glasgow) on the factor of heredity in short sight.

Sections of Pathology and Bacteriology and of Pharmacology, Therapeutics, and Dietetics.

Thursday, July 30th.

At a large joint meeting under the presidency of Professor Cash, F.R.S., a most valuable and interesting discussion on the pathology of heart function was opened by Dr. Thomas Lewis, who in view of the impossibility of dealing with the entire area of so rich a field of work decided to confine his observations to those curious disorders of the heart's action which are disturbances of the regular sequence of chamber contractions. He submitted the thesis that there exists no direct knowledge of disordered rhythmicity or disordered conductivity in the human heart, using these terms in their special senses, and that Wenckebach's classification of irregularities of the heart, based as it is upon Engelmann's hypothesis, rests upon an insufficiently secure foundation. He put forward for discussion the point that auriculo-ventricular heart-block is conditioned by interference, be it through direct, nervous, or chemical channels, with the auriculo-ventricular conducting system, and specially with the auriculo-ventricular node and bundle. He adduced arguments to support his proposition that certain of the preparatory processes which precede the normal contraction on the one hand, and the extrasystolic contraction on the other, were essentially different, and that these which preceded the latter were of a kind foreign to the physiological heart. He held that there was no proof that abnormal nerve impulses playing upon a normal heart might be responsible for extrasystoles of the higher types of disorder, but that there was evidence that nervous impulses playing upon a supersensitive or irritable organ did provoke these curious contractions. By galvanometric records he showed that in a normally stimulated contraction of the cardiac muscle the type of curve given from two separate leads, placed adjoining, was similar, but in the case of the fibrillating heart the curves were in character in no wise comparable; from this he deduced that in the normal contractions there is no independent activity of the cardiac muscle fibres, whilst in fibrillation the fibres are working independently of each other. Sir James Barr then set forth some formulas by which he maintained that the work and output of the heart could be calculated, and described a therapeutic treatment which he used, and in the efficacy of which he exhibited an attractive degree of faith. He based this treatment on views of cardiac physiology, which did not seem to the meeting to be in keeping with modern knowledge, and concluded his remarks by an attack on the work of the modern school and on all those who had come to be regarded as specialists in this particular field. The discussion was continued by Dr. Ivy McKenzie, who agreed with Dr. Lewis that the general circulation played a part which must not be overlooked in the production of heart failure. Other speakers were Dr. A. J. MacWilliam, Dr. F. W. Price, Dr. W. J. Ritchie, and Dr. A. Goodman Levy, the latter describing a toxaemic condition which produced heart-block, and which had come under his notice while testing the effect of large doses of chloroform.

Section of Pathology and Bacteriology.

Friday, July 31st.

Dr. Penfold opened a discussion on the variability of bacteria. He held that recent studies showed that not only fermentative power but also all culture and serum reactions are subject to variation. This variation and selection had been shown to occur within the body in the course of infection; while in the laboratory the precise factors in the environment effecting the selection had been individually examined. He showed that the facts so far established affected (*a*) bacterial classification, (*b*) the recognition of bacteria, the standards adopted by the hygienist, epidemiologist, and the clinical bacteriologist; (*c*) the vaccinist, whether he be engaged in immunizing patients or in producing serums for passive immunization. Dr. M. C. W. Young continued the discussion, and demonstrated a remarkable series of cultures and illustrations to

support her contention that the tubercle bacillus was a most pleomorphic organism. Dr. Lazarus-Barlow made use of his acquaintance with radium, which he had found in appreciable quantities in bouillon, to put forward a hypothesis to account for some of the variations found in bacteria. Dr. E. C. Hort urged the abandonment of artificial media for the preparation of vaccines for purposes of treatment. He and Dr. Ingram had been employing whole normal human blood with encouraging results. Dr. Crofton instanced variations in acne bacillus and leprosy bacillus, and emphasized the importance of autogenous vaccines because of the greatest variant of all, namely, toxicity. Dr. Wilson (Belfast) mentioned some cases of bacterial variation which had come under his own observation, particularly with reference to *B. coli* of urinary origin, *Streptococcus faecalis*, and the diplococcus of meningitis. Dr. John Teacher described a diphtheroid organism which had undergone variations. Dr. Benham spoke on the importance of using correct media. Dr. Hort then read a paper on the recognition of haemic infections of the urine from a clinical and experimental standpoint. He had adopted this method of investigation because of the familiar experience that attempts at blood culture frequently failed, even when patients are most certainly suffering from blood infections. By using proper media—and on this he laid great stress—he had been able to diagnose lobar pneumonia in a few hours and typhus fever in a few minutes. Drs. Findlay and Martin then communicated a paper on the effects of daylight and drying on the human and bovine types of tubercle bacilli. Their experiments indicate: (1) That diffused daylight rapidly robbed both bovine and human types of tubercle bacilli of much of their pathogenicity for the rabbit when the bacilli were dry, but if the bacilli were allowed to remain moist the action of daylight was less marked; and (2) that drying *per se* had little influence in one week. Drs. Cruickshank and Moyse then read a paper on the presence and significance of nitrites in urine, and held that the most common cause of such nitrituria was an associated urinary infection, generally of the *B. coli* group. A paper by Drs. J. M. Morgan and J. H. Teacher on aneurysm of aorta due to bacterial infection was accompanied by a demonstration of specimens, with notes of the clinical aspects of the case. All the cases were characteristically illustrative of endocarditis. The session was brought to a close by some apt remarks by the President.

SECTION OF PHARMACOLOGY, THERAPEUTICS, AND DIETETICS.

Friday, July 31st.

THE chief business on the concluding day was a discussion on the pharmacology and therapeutics of animal extracts. The discussion was opened by Professor Noel Paton (Glasgow), who dealt with the general physiological aspects of internal secretions, and by Dr. O. F. F. Grünbaum (London), who gave a detailed account of his own experience of the therapeutic value of certain animal extracts. Both speakers advocated caution in drawing conclusions from the effects of treatment of certain diseases with animal extracts. Both Dr. Grünbaum and the speaker who followed him had failed to obtain any good effects from the use of a parathyroid extract in paralysis agitans. The discussion was continued by Dr. A. F. Hertz (London), who dealt chiefly with the treatment of asthma by adrenalin, pointing out its advantages and advocating the use of small doses. He was followed by Dr. J. A. Gunn (Oxford), who mentioned some points in the action of adrenalin and pituitrin, which he had observed in experiments. The President (Professor J. Theodore Cash) in summing up stated—what was generally felt—that the interchange of opinion on this subject between the clinician and the laboratory worker had been stimulating to both. Papers were read by Dr. Albert Wilson on the treatment of cancer with goat's serum; by Dr. J. Chowry Muthu on the effect of diet in the treatment of pulmonary tuberculosis; and by Dr. Charles Gibson on the influence of food upon national character. The proceedings of the Section concluded by a demonstration given by Dr. J. A. Gunn to the joint Sections of Pharmacology and Surgery, in which he showed the effects of certain drugs on an isolated human appendix removed four hours previously.

SECTION OF STATE MEDICINE AND MEDICAL JURISPRUDENCE.

Thursday, July 30th.

THE business of this Section on the second day was entirely devoted to the subject of tuberculosis in its various aspects. The first paper was by Dr. J. T. Wilson (County M.O., Lanarkshire), who dealt chiefly with the provision of institutional treatment and outlined the schemes which were being adopted in his county. He mentioned the difficulty of dealing with working men in such institutions, as those who had a wife and family and were earning good wages were often very reluctant to accept institutional treatment. Working men were also not very amenable to discipline, and it was difficult to persuade them to go to working colonies. In his opinion, better housing for the working classes was one of the most important factors both in prevention and in domiciliary treatment of tuberculosis. There ought to be some arrangement for treatment of patients who were "strongly suspected" by practitioners of being affected with tuberculosis; they were entitled to this under the provisions of the Astor report. Dr. McGregor (Tuberculosis Medical Officer, Glasgow) gave details as to the administration of a tuberculosis scheme in the City of Glasgow, with special reference to tuberculosis dispensaries, of which there were six, serving seven separate areas. In his opinion, the ratio of beds in sanatoriums to the number of the population proposed by the Astor report—namely, one for every 5,000, was far too small. In Glasgow they were supplying 500 beds for hospital cases and 250 in sanatoriums, which gave a proportion of one bed to 1,500 persons for pulmonary tuberculosis alone. They were also giving special attention to the needs of tuberculous children. Dr. Buchan (M.O.H. Bradford) considered that Scotland was distinctly ahead of England in the administration connected with tuberculosis. He thought that the statement in the Astor report alluded to by Dr. McGregor as to the proportion of one bed to 5,000 of the population was most unfortunate. In Bradford, with a population of 300,000, they provided for 100 cases in a sanatorium, 100 in hospitals, and 50 beds for surgical cases; this provision was far too small for their requirements. He considered that cases of surgical tuberculosis should be dealt with on sanatorium lines. Dr. Guy (Tuberculosis Medical Officer, Edinburgh) discussed the various alleged causes of the decline in the tuberculosis death-rate, mentioning the ebb-and-flow theory, the theory of gradually acquired immunity, and the decline owing to the segregation of advanced cases in workhouses. In his opinion none of these accounted altogether for the decline, which he attributed to three factors: (1) Progress in sanitation; (2) social uplift; and (3) educational advancement. He advocated a concentration of forces—namely, the harmonious co-operation of medical officers of health and tuberculosis medical officers, and suggested the universal appointment of efficient veterinary inspectors to deal with the milk supply. Dr. Jessel (Wigan) read a paper on the organization and management of a tuberculosis dispensary. Dr. Esslemont professed a profound distrust of domiciliary treatment, and considered that the best way to attack the problem was to congregate tuberculous persons in large communities of the nature of garden cities, where all sorts and conditions of employment could be carried out by the sufferers, each person doing the work for which he or she was best fitted, and receiving payment for work done. Papers were read by Dr. Chowry Muthu (Wells) on tuberculosis in India; by Dr. E. E. Prest, on sanatorium benefit and the position of sanatoriums in their relation to the treatment of chronic cases of pulmonary tuberculosis; and by Dr. W. M. Crofton (Dublin) on preventive inoculation of tuberculosis and the possibility of this on a large scale. Dr. Crofton, being an ardent advocate of tuberculin treatment, was naturally enthusiastic as to its efficacy. Mr. Macrae, County Tuberculosis Officer, Aberdeen, detailed his experience of tuberculin treatment in the case of 6 children, 5 of whom were immensely improved at the outset as compared with 6 control cases treated on ordinary lines, but at the end of nine months the 5 children improved by tuberculin were dead, while the control cases were all alive. Dr. McWalter (Dublin) expressed himself as profoundly disappointed with sanatorium treatment, of which he had much experience, and suggested that phthisis was less frequent among tobacco smokers, eaters of garlic and

onions, and those who consumed lime-salts in the form of brown bread or lime-containing water. Dr. Laffan (Cashel) dwelt on the difficulty of getting milk in country districts, and considered that poor people ought to be entitled to obtain it from farmers at a reasonable price. Other speakers were Drs. Watts, Milne, Thomson, Murray, Hennessy, and Gold; and Dr. Wilson and Dr. McGregor briefly replied. A special point brought out by several speakers was the great educational value of sanatorium treatment, and there was general agreement that prolonged sanatorium treatment should only be adopted in early or curable cases, but that the educational value of sanatoriums was very great in chronic cases, in which, however, a stay limited to six weeks was recommended.

Friday, July 31st.

There was a pretty full programme for the last day's session of this Section. Several papers of high scientific value were read, but they were preceded by an interesting discussion on malingering. This was opened by Sir John Collie who, in the course of his paper, drew special attention to the influence of the mind on the body as an important factor in the detection of fraud in accident claims, and gave details of several cases illustrating this point. In each of the cases mentioned the functional disease originally induced by shock and suggestion was caused by powerful counter-suggestion, by forcing, as it were, into the patient's consciousness the idea that he was quite capable of doing his work if he only knew it. He believed that in that class of case occupation of some sort was the cure required. The whole secret in treatment lay in getting the patients to adjust their mental processes to their environment. Unfortunately, as a rule, it was exceedingly difficult in the case of a working man who had met with an accident to re-educate him to control the field of his consciousness, but it was impossible to cure him until he learnt that his external sensations must not dominate him. Frequently the happening of an accident so perverted the mental outlook of the victim that he persistently dwelt upon and exaggerated all his unusual sensations, which in course of time came to fill so large a portion of his field of consciousness that to a certain extent he genuinely believed he was not fit for work. In cases which were contested, the "law's delay" accounted for a great deal of prolonged disability and the development meanwhile of functional disease. While waiting for a settlement, and especially while waiting for the trial of his case, the workman had little or nothing but his health to think of; he was unable to concentrate his thoughts on anything but his body, and hence became a prey to all sorts of pains and discomforts and sensory stimuli which he would in other circumstances ignore. When confronted with those difficult cases, the first and all-important step to take was to make as certain as possible that there was no organic disease present. That was by no means easy, as certain organic diseases in their incipient stages closely resembled hysteria, neurasthenia, or still more the hybrid hystero-neurasthenia. The most likely diseases to cause mistakes were disseminated sclerosis, general paralysis of the insane, and tabes. The point many were apt to forget was that a serious disability was none the less existent because it was psychic in origin. Speaking generally, the more an accident resulted in actual physical injuries, such as broken bones and so forth, the less likelihood there was of serious nervous sequelae, especially if the case was wisely treated from the first. It had been his practice for some time to induce insurance companies for whom he acted to send their milder cases to a trained masseur, who supplied not only massage but psycho-therapeutic treatment in the form of candid advice and encouragement to use the affected joint. The seven cases he sent to Maida Vale Hospital for Nervous Diseases, where they received admirable psycho-therapeutic treatment. That institution alone had within the last few years cured between one and two hundred cases of the class referred to. If all medical men would conscientiously and fearlessly perform their duty in accident cases an enormous reduction would be made in the burden that was thrown upon employers, and the large increase in the compensation charge would be greatly reduced if not entirely wiped out. Dr. L. A. Parry (Brighton) dealt with the difficulties of diagnosis, but was convinced that with sufficient experience and careful examination a proper opinion could be formed in the great majority of instances, and quoted some cases in support of this opinion. He complained of the careless way in which medical certificates were often given, and thought that if a consultation of all the medical men engaged in a case could be held before court proceedings, the lamentable spectacle of medical men differing from each other on every point in the witness-box would be avoided. Dr. Hennessy (Clogheen) took exception to Sir John Collie's reference to "haphazard" doctors, as he considered that the so-called "haphazard" doctor was in most instances in a better position to judge whether a patient was malingering or not than the society doctor. He referred to the class of medical men in Ireland known as "medical advisers," whose functions were chiefly directed to keeping down the amount of money paid in sickness benefit apart from the merits of the case. He instanced cases of a "medical adviser" certifying a case of Bright's disease as fit for work without even examining the urine, and another certifying a man suffering from appendicitis as fit for work who, in the course of a few days, had to be operated on. Dr. Drury (Halifax) thought there was a danger of exaggerating the evil of malingering. It was no new thing, but had been brought into special prominence by the Insurance Act. In his opinion workmen were no more inclined to malingering than other members of the community, and there were many cases of malingering in their consulting rooms. He objected very strongly to the regulations of the Insurance Act which required medical men to state in the certificate on the first day of illness the name of the complaint from which the insured person was suffering, as it was obvious that in many, if not in most, cases a definite diagnosis was impossible at such an early period. He pleaded for a better understanding between the medical profession and the insurance societies. Sir John Collie, in replying, said that he was strongly in favour of consultation between the doctors on both sides in accident compensation cases, but the difficulty was that there was nearly always some fighting spirit on one side or other which absolutely refused to concede any point whatever. Dr. Buchan (M.O.H. Bradford) read a paper on the period and duration of infectious disease, which was discussed by Drs. Paterson, Morris, Milne, F. E. Wynne, and Clements. Dr. Robert Milne read a paper on the prevention of infectious disease, which was discussed by Dr. Rusk (Belfast). Papers were also read on anaphylaxis in the antitoxin treatment of diphtheria by Dr. Macrae; on intracellular parasites in acute measles and scarlet fever, by Dr. E. H. Ross; and on the advisability of suitable steps being adopted by the State and municipal authorities to secure the earlier treatment of persons suffering from cancer, by Dr. C. P. Childe.

Section of Surgery.

Thursday, July 30th.

An interesting preliminary to the ordinary work of the Section was the proposal of the Chairman, Mr. Scott Riddell, to send a message of greeting to the great clinical surgical congress now meeting in London. When Mr. Robert Jones rose to introduce the discussion on the surgical treatment of arthritic deformities a large audience had assembled. Mr. Jones pointed out that every case of arthritis was a potential but preventable deformity, and in this branch of medical work, as in others, prevention was of much more importance than correction. The essential symptom of arthritis was limitation of movement. His experience in tuberculous diseases even in the active stage was that correction of the deformity did not tend to result in general dissemination. He divided ankylosis into two varieties, unsound and sound; in the former the angle of flexion would be increased by use, in the latter it would not. In osseous ankylosis osteotomy was specially applicable in the femur. He thought that osteoplastic operations on the adult spine were to be encouraged. In regard to arthroplasty great credit was due to Murphy for his enterprise in this branch of operative work; it was of little importance what material was used as the interposing flap, but it was of great importance that the technique should be perfect and that sense of proportion should be preserved. Stability of the limb

after arthroplasty was of more moment than mere movement. Arthroplasty in tuberculous ankylosis was not so successful as in ankylosis after other infective processes; so that in these cases operations below the joint—such as pseudo-arthrosis of the hip—were most suitable. Arthroplasty of the knee was not encouraging. In severe osteo-arthritis of hip-joint, where the chief symptom is pain due to friction, the removal of excrescences and the performance of arthrodesis was successful. In the discussion which followed Mr. Max Page spoke of the difficulties in treatment of tuberculosis of the shoulder in children. Mr. Hey Groves described a method of employing a bone graft from the upper end of tibia to strengthen the junction of the two bone surfaces in excision of knee. Mr. H. M. W. Gray, in describing his method of applying the tibial bone graft to spinous processes in spinal caries, held the opinion that the graft grew with the patient. Professor J. T. J. Morrison urged the use of spinal anaesthesia as a means of preventing the undoubtedly severe shock of these operations. Papers were read by Mr. Hey Groves, who demonstrated some new methods employed by him in the operative treatment of fractures, and by Mr. A. Don, who showed that a portion of rib formed a convenient, easily obtained, and readily applied splint for cervical vertebral disease. The mechanics of the human foot, from an engineer's point of view, were discussed and demonstrated in interesting fashion by Professor Rowell of Leeds. Mr. Rowell is a professor of engineering, and brought a fresh mind to the problems of flatfoot and high heels.

Friday, July 31st.

The popularity of Mr. H. M. W. Gray and the interest in the subject of the development of the shockless operation attracted the largest audience of all the meetings of the Surgical Section. Mr. Gray's introductory paper on anoci-association—a phrase whose unattractiveness and obscurity were referred to by more than one speaker—contained the results of his personal experience of over twenty years. He had come to regard local anaesthesia as the chief, the most important factor in the prevention of pain and shock; general anaesthetics, narcotics, and other precautionary measures were merely adjuvants. Novocain in one-quarter to one-half per cent. solutions was non-poisonous. Ether and to greater extent chloroform exerted undesirable toxic effects on brain cells and therefore disposed to shock. Crile's method, as generally practised, was inadequate. The author's own method was briefly sketched. Short preparation of the patient was important; long preparation meant loss of vasomotor tone and owing to the strain—cerebral anaemia. To exclude external impressions a hypodermic dose of omnopon and scopolamine was administered and the patient's eyes covered by lint and the ears stopped with cotton-wool. Local anaesthesia was accomplished by nerve blocking and local infiltration. For an abdominal operation requiring a long paracentral incision, five or six skin blebs were made with a fine needle, through the blebs with a thicker, longer needle—first the line of incision and then the lateral abdominal parietes down to the peritoneum were infiltrated—the quantity of local anaesthetic being from 100 c.cm. to 200 c.cm. Pain in the deeper layers was dealt with by another local injection, and further injections might have to be made into the peritoneal attachments of the organs to be operated on, even, as in appendicectomy, into the peritoneal cavity itself in that immediate neighbourhood. While the operation was proceeding insignificant quantities of ether might require to be given. He emphasized the extreme safety of this whole procedure, and also the extraordinary sense of well-being of patients and the absence of pain after the operation. For a year he had used Hoffmann and Kochmann's preparation novocain ¼ per cent.; potassium sulphate 4 per cent., and twelve drops of synthetic adrenalin to each 100 c.cm., and he was quite satisfied that it was the best combination. In over 2,000 abdominal operations during the past three years only two suffered from shock. Several speakers, including Dr. Ogilvie Will and Mr. Fergusson in the discussion were able to corroborate Mr. Gray's statements as to the efficiency of the method. Mr. Cuthbert, Mr. Wheeler, and Mr. Hey Groves hoped to give Mr. Gray's methods extended trials. Mr. Miles pointed out that there was danger in their being carried away by a phrase. He thought that crispness and quickness in operating were important factors in preventing shock, and he had by no means lost faith in general anaesthetics, even chloroform. Professor J. T. J. Morrison strongly advocated a more extended use of spinal anaesthesia. The rest of the session was taken up with reading of papers. Mr. A. Fullerton (Belfast) dealt with the successful treatment of two cases of intravesical growth by the high-frequency current. Mr. Hey Groves demonstrated a simple inexpensive apparatus for maintaining the Fowler position. This consisted of a frame to be laid on the ordinary bed frame below the mattress and so adjusted that the upper half and the portion opposite the knees could be elevated or depressed at will. Dr. G. H. Edington described a method of opening the abdomen for appendicectomy. Mr. Max Page and Mr. D. P. D. Wilkie read papers on acute appendicitis, appendicular abscess and appendicular obstruction. In connexion with this Section Dr. J. A. Gunn gave a demonstration in the Pharmacology Department on the action of certain drugs on the isolated human vermiform appendix, a specimen having been obtained from the infirmary earlier in the day. A telegram containing fraternal greetings from the Clinical Surgical Congress being held in London was read to the Section and received with applause. Mr. Scott Riddell's able and kindly conduct of the Section was acknowledged by a cordial vote of thanks.

SECTION OF TROPICAL MEDICINE.

Thursday, July 30th.

THE second day's work began with a paper on the education and official position of the sanitarian in the tropics which, in the absence of its author, Colonel King, I.M.S.(ret.), C.I.E., was read on his behalf by Mr. Cantlie. The author pointed out that in sanitation extreme specialization was necessary; though this fact was generally recognized in temperate regions the needs for such specialization were more urgent in the tropics. The British Empire extended over 11,000,000 square miles, out of which more than half and containing a population of 350,000,000 was situated within the tropics. In the tropics the sanitarian had not at his disposal all the expert advice in different branches of science which he could command in England; more usually he was expected to be an expert surgeon, gynaecologist, pharmacologist, and sanitarian, rolled into one. The plan at present being adopted by the Committee of the London School of Tropical Medicine of a post-graduate course in tropical sanitation was excellent, and there would be a large and increasing demand in the future for men trained in this manner. As regards organization, it was essential that the head sanitary officer in a tropical colony should not be subordinate to the principal civil medical officer, who should confine his attention to curative medicine, but he should be responsible directly to the Government itself—in fact, the officer responsible for public health matters should be a member of the governing body. A diagram was then exhibited demonstrating the author's idea of the organization of a sanitary department and its complete separation from the department of curative medicine. Professor Simpson, C.M.G. (London), agreed to many points in Colonel King's paper, but he was quite unable to associate himself with the proposal of extreme specialization in the training of sanitary officers. He considered a preliminary general medical education to be essential; not only did the student in this manner learn the natural history of disease, but it brought him into contact with all classes of people, and he was thereby enabled to develop that sympathy so characteristic of medical men in general. Dr. Campbell Graham (Deli, Sumatra) spoke appreciatively of sanitation as applied in that colony solely as a result of private enterprise. The work initiated by Drs. Schüffner and Kuenen in that colony had reduced the death-rate from 80 to less than 12 per mille during the last fifteen years. He considered these figures very striking. Dr. D. E. Anderson (London) expressed himself as fully in agreement with Professor Simpson's views. Colonel Penny, I.M.S. (Burmah), said that the necessity of complete separation of the sanitary from the general medical department was now being generally recognized in India. Mr. J. Cantlie (London) was very much averse

to excessive specialization as proposed by Colonel King. He put forward the following resolution, which was seconded by Colonel Woolbert, I.M.S. (ret.), and passed:

> Whilst agreeing with Colonel King in his admirable scheme for the creation of separate curative and preventive medical departments in the tropics, this meeting considers that there should be no interference with the general education of medical students, but that the specialization in hygiene should be entirely a matter of post-graduate training and work.

No less than five papers dealing with sandfly fever followed: The bionomics of Maltese *Phlebotomi*, by Captain Marett, R.A.M.C.; Sandfly fever, by Colonel Birt, A.M.S.; Sandfly fever, by Captain Graham, I.M.S.; Sandfly fever in Italy, by Professor Gabbi, Rome; and Sandfly fever in Peshawar, by Captain Houston, I.M.S. The essentials of these papers did not differ in any way. The symptomatology of the fever is the same, whether it occurs in Italy, Malta, or Chitral. Captain Marett gave a detailed account of the life-history and habits of the *Phlebotomi* in Malta. The larvae, he said, flourished in rubbish, and fed on the excreta of wood-lice, lizards, and bats. The adult lived but seven days, and died after oviposition. In Malta they appeared in numbers in May, but decreased in July and August, increasing again towards the autumn. Apparently three species—*papatasii*, *minutus*, and *perniciosus*—were capable of conveying the fever virus. Professor Gabbi's communication dealt with the appearance of this fever in Messina after the earthquake of 1908; he said it was now popularly known as the "fever of the rubbish."

Friday, July 31st.

Mr. J. Cantlie (London), in opening the discussion on colitis and post-dysenteric conditions, said that there was a tendency of anatomists to minimize the importance of the sigmoid flexure which he regarded as an organ as separate and distinct as the pancreas, it merited a position as the most important portion of the intestinal canal, it was one of the narrowest parts of the tube but widened out where it joined the rectum; at this point there was a definite valve, as distinct as the os uteri, which he had designated the sigmo-rectal pylorus: this when stimulated by the passage of faeces caused a desire to empty the bowel. He elaborated an eloquent plea for the more extensive use of the sigmoidoscope in the diagnosis of post-dysenteric ulcerations especially affecting this part of the intestinal tube. These ulcerations could be plainly seen and rapidly healed when touched up with pure carbolic acid; other preparations had proved quite unsatisfactory. He deprecated appendicostomy and lavage of the intestinal canal. The dilatation of the sigmo-rectal pylorus itself by passage of the sigmoidoscope in many instances sufficed to ameliorate the condition. In some cases he recommended opening the upper part of the sigmoid colon above the stricture and direct lavage. He considered the prompt treatment of these cases as of great moment, as he was assured that in a proportion of cases the seat of ulceration became malignant. As the only reliable drug of use in this condition he recommended Crook's colloid silver, which could be given by the mouth or introduced through the rectum; as it was non-toxic, the quantity given as a dose was immaterial. Dr. D. E. Anderson (London), in a paper on the comparative diseases of the British West Indian Colonies, analysed the Colonial Office health reports for the last four years. Amongst other interesting facts, he pointed out the number of blackwater fever cases in British Guiana in 1913, that the amount of dysentery was proportionate to the amount of typhoid fever in any one colony, and the great reduction in the number of yaws cases in Jamaica since the introduction of salvarsan. Vomiting sickness, he said, was extremely common in Jamaica, and 96 cases were reported there in 1913. Montserrat and the Bahamas were by far the healthiest islands in the group. Dr. P. H. Bahr (London) described as misleading the statistics published in the colonial reports, and on this Dr. Sandwith and Mr. Cantlie agreed. Dr. Williamson (Aberdeen), concurring, pointed to the official list of diseases which had to be filled in as being the cause of the evil. A paper on beri-beri, the rice theory, and recent criticisms was read by the Secretary in the absence of the authors, Drs. Fraser and Stanton (Kuala Lumpur, F.M.S.), who pointed out that experiments on human beings with regard to the etiology of beri-beri were the only ones which could be considered at all reliable. The evidence in favour of beri-beri being an insect-borne or a place disease had quite broken down, similarly the theory of an infective micro-organism had received no confirmation; on the other hand, the application of the general principles, as a result of Fraser and Stanton's inquiries, had resulted in the eradication of beri-beri in the Orient. Dr. Campbell Graham (Sumatra) said he had seen cases of beri-beri in Sumatra, in spite of and subsequent to new alterations of diet, the patients being persons in whom no food deficiency could be suspected. Dr. Sandwith (London) and the President agreed that beri-beri was the result of a one-sided diet, like scurvy, but registered their opinion that the damage to rice as the result of weevils, moulds, and other insects might have a definite bearing on the etiology of the disease. Dr. P. H. Bahr (London) read a paper on sprue, in which he put forward the infectiousness of the disease and certain new views on its etiology. He regarded it as an intestinal toxaemia, of which the thrush fungus (*Monilia albicans*) was the main organism concerned. Mr. Cantlie and Dr. Simpson were inclined to agree with the general conclusions of this paper. Owing to lack of time, the important paper by Dr. Scott (Jamaica), on vomiting sickness, had to be curtailed. The disease was of exceptional interest, as it appeared to be confined to the island. The author concluded that it was a septicaemia by some organism which could not be cultivated on the ordinary culture media. Dr. Sandwith proposed and Mr. Cantlie seconded a congratulatory message from the meeting to Sir Patrick Manson, G.C.M.G., and this was passed by unanimous consent. The meeting closed with a vote of thanks to Professor R. T. Simpson, C.M.G., the President, and to the energetic local secretary, Dr. C. A. Williamson.

CLINICAL CONGRESS OF SURGEONS OF NORTH AMERICA.

Perforation in Typhoid.

On July 29th Dr. George E. Armstrong (Montreal) read a paper in which he stated that 50 to 75 per cent. of deaths from typhoid fever were due to surgical causes. The incidence of perforation varied in different years and in different epidemics, and was less common in Germany than in America. One-third of all the deaths from typhoid fever were caused by perforation. It was of rarer occurrence in children than in adults. The most common site was at the base of a well-defined ulcer, and its size varied from a pin-point to that of a stout lead pencil. The usual situation was somewhere in the terminal two feet of the ileum, and unless the perforation occurred between the layers of the mesentery it was always fatal unless operated on. Early operation was very important, and the difficulties of diagnosis made this hard to carry out in every case. Early diagnosis was therefore a matter of moment, and the usual statements in the textbooks gave erroneous impressions. The first indication of a perforation was usually pain, which occurred in 75 per cent. of cases. It was of the nature of a sudden cramp, and was persistent. It was most often generalized, or, rather, less frequently localized to one of the abdominal regions; often it was so slight as to be overlooked, unless the patient's attendants had been specially warned. In a few cases it might not be present at all. The second symptom was a small change in the expression and appearance of the patient; this occurred in 65 per cent. of cases. There was a sudden marked change for the worse in the patient's general condition. Tenderness was present in 88 per cent. of cases and was often generalized; it might be most marked on the anterior wall of the rectum; 85 per cent. of the patients were rigid. No value could be attached to the absence of liver dullness unless the liver had been carefully marked out from the beginning of the illness and the dullness had suddenly disappeared. A fall of temperature was rare, but pulse changes were always clear and became more rapid in 95 per cent. of cases. Diagnosis should not always be waited for; a few cases which had not perforated would therefore be operated on occasionally. Persistent pain and sudden change for the worse always called for operative interference. Operation was best carried out

under local anaesthesia. The perforation, which was usually easily found, should be closed, and other perforations looked for, and doubtful ulcers should be infolded. Resection of the gut was rarely necessary. The pelvis should be drained and the abdominal wall, which often showed a tendency to delayed healing, should be sutured with some non-absorbable material and the sutures left in for twenty-one days. With the earlier diagnosis and operation recoveries were increasing in number; he had 50 per cent. recoveries in a recent series.

Sir ANTHONY BOWLBY, in discussing the paper, said the death-rate from typhoid fever had diminished steadily with the increase of sanitation, and was now very small. In war time, however, the incidence was higher. In cases of perforation there was no hope of recovery unless the ulcer was operated upon. Diagnosis could generally be made sufficiently early, but sometimes the abdomen might be opened and no perforation found. Operation should always be performed as a routine measure if perforation were suspected. Difficulty of diagnosis was often caused by the severe condition of the patient. It should be more generally recognized that 25 per cent. of deaths from typhoid were due to perforation, and that 3 per cent. of all typhoid patients perforated. It should therefore be remembered that every case of typhoid fever might require prompt surgical treatment at any moment. The pain in this condition was in proportion to the mental activity of the patient. It was often acute in onset, then subsided, and then returned spasmodically. It was excited by handling the abdomen or by the movements of the patient. It never actually yielded to sedatives, but the onset of toxaemic sleep might give rise to errors. Any sudden persistent pain, or a local or general tenderness or rigidity were significant signs. The abdomen might be flaccid. The pulse nearly always increased and lost volume rapidly in bad cases. A blood count was useful, as a rise in the leucocyte count would occur an hour or so after perforation, but the count must be made regularly so that the rise might be noticed. A rigor might occur and should be carefully investigated. Operation was borne well by typhoid patients as long as quickness and gentleness of manipulation were insisted upon.

Dr. J. B. MURPHY called attention to the two important points mentioned in these papers. The first, that the death-rate due to perforation had been reduced to 50 per cent.; and, secondly, the great diminution of the total number of cases, due to increased and better sanitary measures. In this connexion he paid a personal tribute to the late Mr. Hart, editor of the BRITISH MEDICAL JOURNAL.

Exophthalmic Goitre.

Dr. C. H. MAYO (Rochester) read a paper on this subject. He said that a few years ago operation was undertaken only in advanced cases, which had been under medical treatment for a long time; consequently the results were bad, and the operation became discredited. There was a definite connexion between the function of the thyroid gland and certain other organs in the body, notably the sex organs, and derangements of the thyroid might have marked influence on the function of these other glands. The menopause often showed many symptoms akin to myxoedema on the one hand, and hyperthyroidism on the other; further, there were the temporary enlargements of the thyroid body at puberty, at the menstrual periods, and on other occasions. The thyroid body had more to do with deferring old age than any other gland. There was probably a good margin of safety in the amount of the gland present in the human; one-sixth of the gland was probably enough to maintain an adult in health, and one-third a child. The importance of the organ was indicated anatomically by its very large blood supply. The secretion of the gland was first deposited into the lymph spaces, and then passed into the veins, and so into the general circulation. The contamination of the water supply by intestinal bacteria from another case of goitre had been thought to be the cause of goitre; and a peculiar diplococcus had been isolated in cases of exophthalmic goitre. Iodo-thyroglobulin contained a fair proportion of iodine, which was influenced by giving the patient iodine in any form. The action of the colloid was probably to absorb the secretion and deliver it up slowly into the circulation. Thus in exophthalmic cases there was very little colloid, in normal persons rather more, and in simple goitres a great deal, indicating the retention of secretion. The less percentage of iodine in the gland in exophthalmic cases was owing to its having escaped into the circulation, the amount in the blood being increased. Kendall had divided the secretion into three separate toxins, one of which poisoned the muscular system, another the nervous system, and the last the circulatory system, and the amount of each individual toxin determined the type of the disease, the muscularly weak, the extremely nervous, and the cardiac type. The thyroid gland could never be transplanted so as to functionate, because the sympathetic nervous system could not be joined up. Seven thousand cases of goitre had been operated on in the Rochester Clinic; nearly one-half of these were of the exophthalmic type, and in over 90 per cent. of them the clinical diagnosis was borne out by the pathological findings. Exophthalmic goitre was always associated with hyperplasia of the thyroid body, and a distinction must be drawn between these cases and those in which a goitre of the adenomatous variety suddenly began to give rise to exophthalmic symptoms. This was due to a toxic degeneration of the gland and consequent hyperthyroidism. If the symptoms of Graves's disease set in in a case of simple goitre it meant that hyperplasia of the gland was occurring. Cystic adenomata never gave rise to symptoms; only the solid forms of adenoma did this. The treatment was medical—by *x* ray, the injection of boiling water, the ligature of the superior thyroid artery, usually on the left side and under novocain, and, lastly, by partial thyroidectomy in suitable cases. In extreme cases of exophthalmos excision of the superior cervical ganglion of the sympathetic should be carried out. Simple ligation of the vessels caused the patients to put on weight and made the bad cases much better, and so prepared them for further operation.

Mr. JAMES BERRY testified to the value of Dr. Mayo's work on this subject. To obtain good results in these operations it was necessary to avoid operation when there were any acute symptoms of hyperthyroidism, and also to avoid operation on all advanced cases. Advanced cases might be improved by ligation of the vessels which was a very valuable proceeding. Partial thyroidectomy could be carried out in cases of early Graves's disease, and in cases of ordinary goitre with some symptoms of Graves's disease in addition. The latter variety could almost always be cured by operation, but were not true cases of exophthalmic goitre. He had had a small mortality in the cases of partial thyroidectomy for true Graves's disease. There was no mortality amongst the cases treated by ligature. As to the after-treatment it was very important to give the patient abundance of fluid.

Cancer of the Breast.

On Friday evening Dr. W. L. RODMAN (Philadelphia) read a paper on this subject in which he said that twenty years ago surgeons believed that innocent mammary tumours were exceedingly rare, and gave slightly too much prominence to the sarcomata. Only about 1 to 2 per cent. of breast growths were sarcomata. Abnormal involution of the gland with hyperplasia and cyst formation was probably the most important subject at the present time. The diagnosis between this condition and cancer was often very difficult, but it should be remembered that abnormal involution was usually bilateral whilst cancer was unilateral, that abnormal involution was usually painful from the beginning, but that cancer was not so, except in its later stages, and lastly that just before menstruation the symptoms of abnormal involution were generally exaggerated whilst cancer remained unaffected; if these points were borne in mind the difficulties of diagnosis became lessened. The idea that cancer of the breast usually occurred after 40 years of age must be given up, as quite a large percentage of cases occurred before that age. Dimpling of the skin through involvement of the deep trabeculae was a very important sign, and he described various ways in which this sign could be elicited. Retraction of the nipple depended upon the location of the tumour, and its importance had been exaggerated. Acute carcinomatous mastitis, which was often mistaken and treated as an inflammatory condition, was an exceedingly deadly disease; it was rather more common in

non-pregnant than in pregnant women, and he thought that it should not be operated on, as life was not thereby prolonged. The discharge from the nipple gave valuable evidence as to the nature of the growth; a dark, sanguineous or granular discharge pointed to carcinoma; pure blood was almost diagnostic of papillary cyst-adenoma, but it must be remembered that the latter tumours had a marked tendency to become malignant. Cutting into a growth was the direct cause of immediate dissemination, so that a piece of the tumour should never be removed for microscopical examination unless it was possible to cut accurate frozen sections at the time, when the tumour could be removed immediately if carcinoma were found. He described in detail his operation for the removal of the breast. The important points of this were the incision, the wide dissection of fascia and muscle both in the direction of the axilla and epigastric angle, the necessity of always working towards the growth from healthy towards unhealthy tissues, and finally, the need for gentle handling of the breast to prevent expression of carcinoma cells, which could easily occur; 72 per cent. of his cases had remained well after operation, and he regarded late recurrences of growth many years after operation not as recurrences but as fresh infections of cancer in persons who had already been proved liable to this disease.

Mr. W. Sampson Handley said a tumour supposed to be a fibro-adenoma occurring in a patient over 40 was more often than not a carcinoma, which was sometimes very mobile. Surgery could only advance along the lines mapped out by pathological research. Cancer of the breast spread to a certain extent by the lymphatics to the axillary glands, but the chief spread was by "permeation" in the deep fascia; the growth passed out in a centrifugal manner along the small lymphatic tubules of the deep fascia. When this had spread for a short way a reparative inflammatory process set in, the lymphatic became fibrosed, and the cancer cells destroyed, except for about 5 mm. at the head of the advancing column; the process thus spread out in an ever widening circle, scattered nodules making their appearance where the reparative process had failed. He had been able to demonstrate the advancing edge microscopically. The area to be excised at operation should therefore be approximately circular with the growth at the centre. He showed slides illustrating many of the above points.

(To be continued.)

MOTOR NOTES FOR MEDICAL MEN.

By H. Massac Buist.

OVERHAULING THE CAR.

At the present moment, when many medical men will be reflecting that they may be called upon, in the discharge of duties connected, directly or indirectly, with mobilization, to undertake journeys much longer than those they usually have to make, it may be opportune to consider a few points in connexion with the preparation of the machine for such work. The fact that the machine is doing quite well in its daily runs in connexion with the doctor's work does not mean that it will not require some special attention before undertaking a series of extended runs from one point to another away from the district in which the owner resides.

Cars are curious things, in that, as far as matters of habit go, they seem to be alive. Thus a car may work quite reliably day after day for weeks at a spell, doing a given series of rounds, calling a halt every mile or two, as does the average doctor in the course of exercising his profession. But if the same car be asked to go fifty or seventy miles without a halt it is ten to one that some minor part of the mechanism fails in the most annoying manner, leading to a breakdown involving a loss of hours. This is so even in the hands of manufacturers, as instance the manner in which experience over a period of years is necessary to enable a maker to produce a competition car that will do brilliantly well in hill climbing efforts, speed trials on the sands, or short distance races at Brooklands, and which will also stand the racket of a race of from 300 to 500 miles. If motor manufacturing be considered along those lines, it will be found that there are in the world to-day only about a dozen firms which know how to combine efficiency with endurance in a manner that can be at all relied on in that way. Since it is so for the manufacturer, how much more is the marked difference likely to occur in the case of the private owner who has no factory behind him. By drawing the attention of doctors to some of the phases of production and of the manufacturing industry, as occasion arises, useful work may be done in the way of putting producer and user in touch with each other's problems.

Difference between Brief and Lengthy Runs.

While, therefore, on the one hand, it should be neither necessary nor desirable to send the car for its annual overhaul before starting, on the other the machine will want looking over in a more special fashion than is done ordinarily in connexion with its daily work in the doctor's service. Under those conditions it does not go long enough at a spell to run any serious risk of damage even should there be insufficient oil in the back axle or gear-box, or lack of grease in the universal joints. In most such cases ample warning would be given by way of gradually-increasing squeaking. Before starting out, however, all those points should be specially checked. It is besides as well to unscrew the valve caps and have a look at the condition of the engine's interior in regard to carbon deposit. If there is at all much of this, the motor ought to be cleaned out by the Cyclean process. It must be remembered, however, that this is of no use if the under portion of the valves themselves require grinding in, for the motor will only soot up again within 500 miles. When having this process applied by the local licensee, moreover, it is as well either for the owner to stand by his car or for his man to do so. It has been my experience that, had I not been by, on one such occasion all the paint work on the dashboard would have been blistered when it came to doing the last cylinder. The average garage mechanic seldom thinks of what other part of the vehicle is going to be affected by work he is doing on the particular portion of it that occupies his attention.

Remember the Temperature.

Assuming, therefore, that the motor is clean and that it will be given a reasonable chance of keeping clean by drawing off the oil from the base chamber—if the design is such that it is contained there, as is the general manner—that it has been replenished with new and clean supplies, and is not suffering from loss of compression, and that all water connexions and other points where leaks might occur have been looked over, a start may be made with a fair certainty of having no motor trouble. When motoring in summer weather, especially when running anything from thirty miles upwards at a spell, it should be had in mind that the engine is working under quite different conditions from either winter weather or the ordinary doctor's service. In both those conditions the engine rarely gets heated up sufficiently for the oil to get really thin; whereas when doing a long run the motor is warmed in a manner which of course makes it far more efficient, so that the driver is thoroughly delighted with the power it is giving; but this often has an accompanying penalty, in that the lubricating oil gets very thin and is far more apt to foul the cylinders in that condition. This particularly applies to the manner in which a great number of manufacturers design their oil ways; they are quite satisfactory when the lubricant is thick, but are not so when it becomes thin. It is therefore essential to start in summer time with a clean engine.

Give Heed to Propeller Shaft Joints.

In regard to chassis in general, apart from such all the year round attention as the filling of grease caps at regular intervals, it is as well to pay particular heed to the universal joints in connexion with the propeller shaft. Unfortunately, the design of these details in the average car is such that, with the body-work on, the word accessibility is a mere euphemism. Many a time, too, when getting these joints filled up with grease, by putting the car over a pit one has found that in replacing the leather or other forms of covering, the joint made is so indifferent that the grease merely gets spewed out on

to the running boards and under part of the body-work, so that after going a very few miles no more lubricant is left than if no pains had been taken to replenish it. Therefore it is particularly essential to look to it that the grease put into the joints at either end of the propeller shaft is adequately secured in the covering to those connexions. If these parts are run dry, sooner or later a broken propeller shaft joint will be sustained, than which there is scarcely any form of motor accident more dangerous. If the fore end goes it drops like a pole, which the back axle has to jump. I have seen an ugly accident of that sort in connexion with racing, though fortunately the occurrence is very rare with touring cars, because, as a rule, there is considerable squeaking by way of warning. This risk of breakdown can to a certain extent be guarded against by having a strap so set underneath the propeller shaft as to catch it in the event of its dropping. These remarks, in any case, apply only to such cars as have open instead of closed propeller shafts. There are, of course, a large proportion of cars designed on these principles.

TYRE POLICY.

Brakes should be gone over, particularly with a view to ensuring that they are acting in an absolutely compensating fashion, the pull being equal on either back wheel. It is as well to take up any slackness of the steering, and particularly to supply all steering joints with ample lubricant. Next, as the car stands in the garage, the wheels should be checked for alignment. If a wheel be ever so little out of truth tyres wear in extraordinarily quick time.

Runs longer than those usual in the execution of the doctor's daily work demand also attention to the pneumatics. A tyre that is fairly well worn will nevertheless probably run quite satisfactorily for weeks, doing short journeys of anything from a few hundred yards to three or four miles at a spell, because in such circumstances the tyres rarely get hot, and in addition they are not highly stressed. But if run for scores of miles at a spell they are bound to get hot, and on long runs the pace is likely to be greater than when driving about in the ordinary course of professional work. Therefore, the medical man will be in pocket, in place of out of it, by taking off all tyres showing any appreciable wear, and replacing them with new covers before starting out on a run the length of which cannot be foreseen. The old covers can be brought into use again afterwards, and worn to the ordinary limits.

The really economical motorist is the man who uses his tyres, for whatever particular work he may be engaged on, just short of the limits of trouble occurring. It may seem wasteful to discard covers a little early, but in these days, when they can be retreaded practically under guarantee as to mileage to follow, the motorist will be well advised to have such work carried out rather on the early than on the late side. Let a thing go a little beyond the margin, and no amount of repair will ever make a satisfactory job of it. The extent to which tyres should be blown up depends entirely on the speed and on the car. Nobody can give advice that shall be of general application. Happily, however, if he will but inquire, the firm making any tyre used by the individual motorist will give him the best advice their experience dictates.

ANTIDYSENTERIC VACCINATION.

By W. BROUGHTON-ALCOCK, B.A., M.B.Cantab., M.R.C.S.,
Pasteur Institute, Paris.

AT this critical period of international conditions haste compels me to omit all matter not of immediate practical interest, and I trust those authors who have devoted some time to this study and have made known their interesting observations will comprehend the omission of reference to their work. I hope at some future date to write a more complete article.

After recognizing from practical experience on man the impracticability of the employment of heated Shiga bacilli in subcutaneous injections in single or multiple doses, I tried several other methods, and at length arrived at a most simple and practical one, which I trust may render service should the occasion for its use arise during the present war. Any race of *B. dysentericus* may, when treated, be so employed. The strains of Shiga alone, of all varieties of dysentery bacilli at the Institute, show in man an extreme reaction, this being due to their endotoxicity, which is present in both recent and old laboratory strains, living and dead.

This is the method: Take then a twenty-two to twenty-four hours' culture of *B. dysentericus* on a test tube of peptone agar, wash in saline 0.9 per cent. and centrifugalize, dilute the deposit in 2 c.cm. fresh saline; heat to 56° C. for one hour, count or otherwise numerate the bacilli per c.cm., and place the 2 c.cm. in 20 c.cm. normal, heated, pooled (two or more) human serums or 10 c.cm. normal heated horse serum. Let them remain together overnight. If I use the former, I place the mixture in the ice house, so that any possible spirochaete may be destroyed. After *well* centrifuging twice (the second time after adding saline to wash the bacilli), the deposit is mixed with 0.9 per cent. saline, so that 1 c.cm. contains 350 million bacilli to the c.cm. Preventive injections are to be made four at a time, and when possible in the afternoons; first dose, 1 c.cm., that is four injections of ¼ c.cm. each made in the left side of the back over muscular tissue, and where the braces or kit to be carried do not press (not in the arms). The skin is well raised, and injection made *into the loose subcutaneous tissue*. The second dose of 2 c.cm. follows about eight or nine days later in similar fashion, ½ c.cm. quantities, on the right side. A third similar dose may be made.

I have been similarly preparing very endotoxic strains of Paratyphoid B, also A, typhoid, cholera, and *B. proteus*, etc., some for treatment, and have seen during the last year some most satisfactory results from therapeutic inoculations of typhoid and *proteus* bacilli.

The reactions most carefully followed have never in over 200 subjects been marked or inconveniencing. This reduction in both local and general reactions to the untreated micro-organism is really striking. In the last series of 75 preventive injections in a dysentery-infected service of a lunatic asylum there was but one subject who showed high fever the night of the injection; he, however, slept well, and the temperature was just over normal in the morning. My object in giving only 1 c.cm. for the first injection is to avoid too great a general reaction in the rare hypersensitive patient.

Results.—All subjects I have vaccinated live in endemic areas; so far there have been no cases among them.

Serological Examinations.—By contrast, with the patients of earlier series who to the same dose of untreated Shiga bacilli showed determinable specific ambocepter and agglutinin properties in their serums, the serums of the subjects who had even three doses of bacilli treated by normal serums showed no fixation of complement nor increased agglutination. I have previously (*Académie des Sciences*, May 7th, 1912) made known such observations when applying specifically sensitized typhoid vaccines to man (Besredka principle).

These comparative findings in the serums of subjects after vaccination by bacilli treated with prepared specific horse serums, and in those after bacilli treated with normal human or horse serums are interesting.

Dopter (*Annales de l'Institut Pasteur*, 1910), after reviewing the literature of vaccine work with dysentery bacilli, has shown that the Shiga bacilli treated with specific antiserum give early and prolonged immunity in mice and avoid the negative phase that follows injections of untreated bacilli.

In the method I have above described will be noted the marked simplicity and rapidity with which a vaccine may be made—and used prophylactically and therapeutically—from the first pure culture of the particular micro-organism that is causing an epidemic, despite the numerous varieties in any group. On the valued suggestion of Dr. Roux, the eminent director of the Pasteur Institute, I have been trying the utility of a vaccine made by the addition of heated human serum and later adding saline without centrifuging after the micro organisms have been acted on by serum. This procedure simplifies technique, but my work is too recent to draw conclusions.

PROFESSOR ABDERHALDEN has accepted an invitation to become director of a research institute which is to be erected in Berlin.

British Medical Journal.

SATURDAY, AUGUST 8th, 1914.

THE WAR: SOME IMMEDIATE DUTIES.

It is a clear duty of all members of the medical profession who remain at their ordinary civilian work to see that those medical men who have pledged themselves in advance to serve the country in any such emergency as has now arisen shall not suffer in their civilian practices, and that their patients shall be looked after. The country has to meet a situation such as it has never before been called upon to face, for events moved less swiftly in the Napoleonic wars, and we must all stand by the men who are taking their places in the first fighting line.

The Royal Navy is fully mobilized, and the medical officers—Staff Surgeons and Surgeons—of the Royal Naval Volunteer Reserve have been called up. This Reserve consists of civilian practitioners who have been trained to the special work of a naval surgeon in time of peace. They are now on duty, many of them at sea.

As the Territorial Force has been mobilized, a large number of medical practitioners who hold commissions in that force have left their civil practices and joined the units of which they are members. There are fourteen mounted brigade field ambulances and forty-two field ambulances forming part of the fourteen divisions into which the Territorial Force is distributed. These officers are no longer civilians; they are under military orders, and must go wherever the division to which they belong is sent.

In Southampton, in Exeter, and in London steps have already been taken which we venture to suggest might well be imitated all over the country. In Southampton, where it appears that about one-half of the doctors in active practice are liable to be called up, a meeting of the medical profession was held on August 4th, when it was resolved: "That this meeting of the medical profession loyally undertakes to safeguard the interests of those of their colleagues who are called to leave their practices in the service of their country, and also undertakes any medical duties for the sole benefit of the absentees." A committee was appointed to carry out this resolution, and immediately issued a notification asking each doctor liable to be called away for duty to make any arrangements he could with practitioners in his neighbourhood, and offering, should he be unable to do so, itself to make such arrangements. Insured patients attending the surgery of a deputy doctor will be shown a printed list of doctors remaining in the town, and will be referred to one of them for treatment. Poor Law doctors also are asked to do the necessary parish work of their absent colleagues. In Exeter the Chairman of the Division of the British Medical Association, Dr. Arthur C. Roper, in the absence of the Divisional Secretary, Dr. Eager, who is an officer of the First Wessex Field Ambulances, and was in camp, summoned a special meeting of the Exeter Division for August 6th, in response to a requisition signed in anticipation of the declaration of war, to decide what steps should be taken to provide the public with adequate medical attendance in the absence of many medical men on military duty, to save those medical men so absent from financial loss, and to discuss any other business arising out of the situation. Dr. Roper, in calling the meeting, pointed out that the matter is one which affects practitioners in rural districts as well as those in towns, and that it is within the knowledge of some of those who signed the requisition that mobilization of the Territorial Force will practically denude some country districts of doctors. In London a special meeting of the Panel Committee has been summoned for August 7th, when it will be proposed that steps shall be taken to secure the medical treatment by practitioners on the panel of insured persons on the lists of those of their colleagues who are absent on military duty, and have been unable to make suitable arrangements. It will also be proposed that practitioners on the panel for the County of London shall express their willingness to undertake, free of charge, the medical treatment of necessitous dependants of reservists on their lists who have been called to the colours, and of insured persons who have become unemployed as a result of the war.

The Insurance Commissioners in England have issued a circular letter[1] to all Insurance Committees, pointing out the necessity of making arrangements of the nature of those indicated above, but it will obviously be well that the profession in each locality should take the initiative, as the provision for insured persons will be only a part of what should be done.

In addition to the medical officers in the Territorial Force, constituting the Territorial field ambulances, there are those who constitute the Sanitary Service, and they have all now become available for military duty with the divisions. The Territorial Force has also twenty-three general hospitals in the chief centres throughout the country, and a medical staff for the organization of fourteen clearing hospitals. The staffs of the general hospitals will not at present be expected to do more than test and stand by their organization, so that they may be in a position at once to admit sick and wounded should they be called upon to do so.

Offers of service from senior students for employment as dressers are coming in, and suitable applicants will be engaged; the Navy already has some actually afloat. The regulations for the entry of these Surgeon Probationers into the Royal Naval Volunteer Reserve will be found at page 318. These young men ought not to be allowed to suffer in their careers. The time spent in this way

[1] Supplement, p. 143.

should be reckoned as part of their clinical training, and it would be well that the General Medical Council should take the initiative by intimating to the licensing authorities that such a course would in the circumstances be proper. The Council might possibly make some general regulation which we have no doubt would be accepted by all the licensing authorities.

Both the navy and the army have a reserve of nurses. Nearly every one of the large hospitals undertook some years ago to supply each a certain number of nurses when called upon in an emergency, The response to-day has been, it is hardly necessary to say, ready and prompt. The selection is made by the matron of the hospital, subject to the approval of the navy or army authorities.

Offers of service are pouring in to the medical departments of the navy and army. Individual offers by untrained persons are rather embarrassing; the spirit is admirable, but efficient help can be given only by trained persons working in organized bodies. The Voluntary Aid Detachments which have been constituted in most parts of the country during the last few years are responding well to the call upon them, and individuals—men or women—who have not already some place in the organization of the Admiralty or War Office can best serve at the present time by joining the Detachment in their neighbourhood or, if necessary, helping to organize one. There is room in such detachments not only for trained nurses, but for cooks, attendants, and orderlies, and arrangements should at once be made locally to prepare, for the reception of convalescents, country houses whose owners may be willing to offer them for this purpose.

The Admiralty has received numerous offers of vessels to serve as hospital ships. We understand that all such offers will be noted, but we question very much whether they ought to be accepted. The multiplication of small hospital units is doubtful policy, and a yacht capable of accommodating only, say, eight or ten patients would not make any appreciable addition to the official provision, and might cause anxiety. Such boats might eventually be of some assistance in supplementing the Admiralty carrier ships which will bring sick and wounded from the hospital ships of the fleet at sea to the base hospitals ashore. In present circumstances offers of convalescent accommodation will be more highly appreciated. The sick and wounded will be landed as rapidly as possible at naval base hospitals, and it will be important to have facilities for drafting convalescents from these hospitals to suitable places in the country as rapidly as possible.

The Admiralty has issued notices, published at page 317, stating that it is prepared to receive applications for temporary service as surgeons in the Royal Navy. Applicants must not be more than 40 years of age, and should apply to the Director-General, Medical Department of the Navy, Admiralty, S.W. The pay offered is 22s. a day with allowances, and equipment allowance for uniform. We understand that the response has already been very considerable, but that applications will still be received. Applicants by letter will be notified when to attend at the Medical Department of the Admiralty, where they will be examined as to their physical fitness for the service.

The War Office has also issued a notice that it is prepared to enlist civilian surgeons, and the particulars are given in the official document printed at page 319. The age of the civilian surgeons enlisted must as a rule not exceed 35 years, though in special circumstances individuals may be accepted up to the age of 40. Those accepted will have the rank of lieutenant in the army, and must engage for twelve months or until their services are no longer required. They will receive 24s. a day inclusive of all money allowances except travelling allowances and expenses when travelling on duty. They will receive a gratuity of £60 on the termination of their engagement if they have rendered satisfactory service. We understand that a large number of applications have already been received, but that the list is still open for immediate service, and that the names of later applicants will be recorded to be called upon in the future as required.

The British Medical Association has, through the Chairman of Council, notified the Prime Minister that it is ready to make use of its machinery to assist the Government in any appeal it may desire to make to the medical profession. The response to the first announcements that civilian surgeons were needed for the navy and army has been immediate, and will probably within the next few days prove ample for present needs, but the offer of the Association will stand good for the future, and no man can say what that future has in store, nor how great the sacrifices we may be called upon to make in the life and death struggle which has been forced on the country.

ANNUAL MEETING NOTES.

When we went to press last week the annual meeting at Aberdeen was still in full progress. We were able, however, to supply an account of a good many of its general features, including a report of the work done at the Representative Meeting and a summary of that which the sixteen Sections did at their opening session. In the present issue will be found summaries of the work of these Sections on the two concluding days, together with a detailed account of the proceedings of the Section of Medical Sociology on all the three days that it met. The Supplement, amongst other matters, contains an account of the annual dinner and of the graduation ceremony. A general reference was made last week to the Annual Exhibition of foods, drugs, instruments, books, and sanitary appliances, and a detailed account of some of its more interesting contents will appear in a later issue.

The Curtain.

The meeting at Aberdeen is now but a memory, yet one so pleasurable and bright that it must always serve as a striking background to corresponding recollection of the dramatic events which have since occurred and are still occurring. Never has a curtain at a theatre fallen and risen between scenes presenting a greater contrast than those at Aberdeen on Saturday and Sunday respectively. On Saturday the weather was bright and sunshiny, and

the pleasure portion of the meeting was only just ending; on Sunday there were torrents of rain, the streets were thronged with people bidding farewell to hundreds of fisher folk summoned to rejoin the navy, and many of the local officers and their visitors were deep in study of mobilization orders and making other preparations for active service. But though the curtain has fallen on the Aberdeen meeting, and all minds are turned forward rather than backward, it is still right to summon before it some of the leaders among the Association's late hosts and assure them of the success of their efforts and of the valuable and pleasurable results to which these led. Far away as is Aberdeen, and despite the counter-attraction offered by the meeting of American surgeons in London, the attendance at Aberdeen was fully up to the average of annual meetings, and never have members felt themselves more welcome. They had reason, in short, to realize that Aberdeen's ancient war cry, "Bon accord," is not merely a motto, but a rule of conduct which all Aberdeen's present citizens are ready to observe. The President of the Aberdeen Branch, Sir Alexander Ogston, now President of the Association itself, was well served by all his officers, and more especially by his two secretaries, Dr. Thomas Fraser and Dr. F. K. Smith, on whose energy and ability in the performance of their work the success of the meeting largely hinged. As we noted last week, the arrangements made for the work of the Sections were admirable, and for the ease and comfort with which they did their work those who attended the Section meetings have special reason to be grateful to the executive members of the Reception Committee—namely, Professor Matthew Hay, its chairman, and Drs. H. M. W. Gray and H. E. Smith, its honorary secretaries. How well done was the work of the Dinner and Luncheon Committee, whose chairman and secretary respectively were Dr. John R. Levack and Dr. William Brown, those who attended the annual dinner can amply testify. As for entertainments, all possible desires were most fully anticipated by the committee which had this work in hand, headed by Dr. J. C. Ogilvie Will as chairman, and Dr. Albert Westland as vice-chairman, while Dr. W. F. Croll, who also arranged the cricket match, was its very active secretary. In this connexion should be mentioned also Professor Cash, who took in hand the transformation of Marischal College on the evening of the University reception, and on other occasions was ever ready to render courteous service to all whom he could aid. In the matter of excursions and expeditions Aberdeen outvied—if that be possible—officials of all previous meetings, and the plans made in respect of them were not only well devised but ably carried out by Dr. George Scott and Mr. G. H. Colt. Another of Sir Alexander Ogston's officers was Mrs. Carter, who, in addition to playing the part which might be expected of his daughter, contributed largely to the success of the arrangements made for the benefit of ladies attending the meeting. As we mentioned last week, these were of an exceptionally thoughtful kind, and for the comfort enjoyed by their women-folk members are especially indebted to Mrs. Williamson and Mrs. Gray, who took charge of the arrangements for afternoon tea at the Ladies' Club established in the rooms of the Aberdeen Medico-Chirurgical Society; Miss Baughan, who was in charge of the very useful information bureau and a corps of lady guides; and Mrs. Hay and Miss Grainger Stewart, who arranged the morning motor drives which were so thoroughly enjoyed.

Garden Parties.

The Association received an official welcome on behalf of the Lord Provost, the magistrates, and the Corporation of the city of Aberdeen at the general meeting on Tuesday evening, and on the following day it received a second but less formal welcome from the same body at a garden party given in Duthie Park. It was this affair that led off the round of entertainments, and, like those which succeeded, it proved a brilliant success. Apart from other advantages, this party gave members of the Association an opportunity of meeting Aberdeen citizens, for many of these joined in the proceedings, and the whole gathering numbered upwards of 3,000 persons. The weather was a little cold, but the threatening rain was seemingly kept off by the presence of several huge marquees, so nothing occurred to mar the pleasure of the afternoon, which was spent promenading in this beautiful park, inspecting its hothouses, and listening to music. Two bands were playing in different parts of the grounds, and not the least interesting feature of the afternoon, to those who came from the south, was the presence of over a dozen pipers, who at intervals during the afternoon played spirited marches and rousing strathspeys and reels. On the following day there were three further garden parties, and these, though not on so large a scale, were even more enjoyable in view of the excellence of the weather. Two of them took place at a little distance from Aberdeen, so the guests were taken out and brought home by special trains. One of these was given by Mr. and Mrs. Duncan Davidson at their beautiful home at Inchmarlo, near Banchory, a chamber concert forming part of the proceedings; the second was given by Dr. and Mrs. Lawson at the well-known sanatorium named Nordrach-on-Dee, and the other by the directors of the Myrtle Hydropathic. Two further garden parties took place on Friday, the weather again being admirable. One of these was given at Banchory House by Sir David Stewart, the guests being taken out by motor charabancs. The other took place at Parkhill House, Dyce, the host being Mr. J. E. Crombie, the guests going out and returning by a special train. Many garden parties have been given at previous annual meetings, but none in more beautiful surroundings or by hosts who took greater care in providing for the comfort and entertainment of their guests.

Evening Entertainments.

The University of Aberdeen did not content itself with placing its beautiful buildings at the disposition of the Association and conferring honorary degrees on five of its members; it expressed its goodwill in a third and equally practical fashion by entertaining the Association at a reception on Wednesday evening. The guests arrived very promptly, and for nearly an hour from 8.30 onwards the staircases which lead to the Mitchell Hall were thronged. It was in the ante-chamber to this hall that they were received by their hosts, and having made their bow they passed on into the hall itself, where an organ recital was in progress. At 9 p.m. a string band began to play, and before very long an informal dance was in progress. This entertainment proved to be so popular that, large as is the Mitchell Hall, there would have been no room for dancing had not the adjoining museum been open, and had not supper parties commenced in the rooms devoted to the University Union at quite an early period of the evening. On the third of the four days that the meeting nominally lasts there took place the annual dinner of the Association, of which an account will be found in the Supplement, but, mindful of the fact that not all members care to attend dinners, and that very few of the ladies present at annual meetings are actually members of the Association, the Branch made arrangements for an entertainment at the theatre, and this proved to be of a most enjoyable kind. Its general features were those of variety shows all over the world, but two items were probably entirely new to almost all of those present. These were a diving performance given by Miss Lily Smith, the well-known swimmer, and her two sisters, and the remarkable feats performed with the stock whip by an Australian known as Captain Jack Kelly. The last evening entertainment of the week took place on Friday, Sir Alexander Ogston and the members of the Aberdeen

Branch being again the hosts. This was a reception given in two buildings and a large marquee, all three being decorated with great taste and connected together for the nonce by canvas corridors. It was one of the cheeriest evenings and best arranged entertainments that we remember in a long experience of annual meetings. One hall was given up to general music, and one to conversation and exchange of experiences in regard to the events of the meeting; another hall and a marquee to supper parties, and a fourth hall to dancing, and a number of small rooms to smoking and the like. The dancing began soon after nine o'clock, and was so enjoyed both by those who danced and those who merely looked on that ladies were pressed into service to play the piano when the ordinary programme was complete. Some pipers were also present, and played for the many who took part in the eightsome reels, two of which were danced in the course of the evening. The net result was that guests were so loth to leave that it was long past midnight before this party was really at an end.

EXPEDITIONS.

THE north-east corner of Scotland is rich in localities specially attractive on account either of their archaeological interest or picturesque beauty, and those able to snatch a few hours during the week were offered very wide choice in the matter of expeditions to such places. Apart from visits which are commonly arranged for tourists in Aberdeenshire by the various railway companies, the Excursions Committee, with the co-operation of a large number of medical men in different hamlets, planned not only for Saturday but for other days of the week a whole series of special expeditions. The scheme, indeed, was so comprehensive as to be almost bewildering in the number of alternatives that it offered, the special leanings of the archaeologically inclined, of the lovers of the picturesque, and of students of history being all equally consulted. Many of the places were visited by individuals armed with the permits that had been secured from the factors of the owners of the various estates by the Excursions Committee, and others were visited by groups. On the Thursday, for instance, there was an expedition to a prehistoric British fort on the Bennachie mountain, the party, which travelled out in a motor coach, being met at Inverurie by Dr. W. Henry of Kemnay, Drs. Forbes and Nicol of Inverurie, and Dr. A. E. L. Gray of Meikle Wartle, who guided them up to the fort by a prehistoric road known as the Maiden Way. Before starting they were entertained at luncheon by Mr. and Mrs. George Smith, of Pittodrie, and were refreshed with tea on their return by the same hosts. On the same day another party, on the invitation of Sir Alexander Baird and the medical men of Stonehaven, visited a Roman camp and some Druidical circles near the latter town, as also the famous Dunottar Castle, and a wonderful nesting-place for sea-fowl some two miles to its south. Dr. W. A. Macnaughton, of Stonehaven, kindly acted as their cicerone throughout the day. On Friday, again, there was a very successful expedition of the same order, this leading the party to Kildrummy, an ancient royal residence, and to Craigievar Castle, which is reputed to be the oldest inhabited edifice of the kind in Europe. The party was very kindly provided with luncheon by Dr. J. A. Simpson, of Alford, and with tea at Kildrummy Castle by its owner, Colonel Ogston. The largest expedition of all was to Balmoral Castle and Braemar, which were visited on Saturday by a party of nearly two hundred. Dr. John Innes represented the Excursions Committee on this occasion; Dr. Scott, its chairman, being detained in Aberdeen on Army Medical work, and the party was greeted at Ballater by Dr. Alexander Hendry, who is surgeon to his Majesty's household at Balmoral; while at Balmoral itself, where luncheon was served, it was received by Mr. Michie, the King's Factor. On the same day Mr. G. H. Colt took out a party to visit a vitrified prehistoric fort, some Druidical circles, a ruined castle, and other objects of interest near Huntly, those who had the opportunity of taking part in this expedition being guided throughout the day and entertained to luncheon and tea by Drs. Wilson, Garson, and Watson (all of Huntly), and their wives, and also by Colonel Mellis, who lives in the same district. Other places visited during the week by the courtesy of their owners were Muchalls, Crathes, and Drum Castles; while Dr. J. E. Skinner and Dr. James Lawson of Duncelt made arrangements for those who desired to visit the Barmekin of Echt, a prehistoric hill fort in their locality. Other Aberdeenshire medical men who kindly placed their services at the disposition of members wishing to visit antiquities or places of other interest hard by were Dr. W. I. Fortescue of Kingcausie, Dr. G. C. Burgess of Forfar, and Drs. W. L. Millar of Forres and Rannie of Culter. On Saturday also a number of members crossed country to Inverness on an expedition, of which an account in some detail will be found in the SUPPLEMENT to this issue.

INDUSTRIES.

AMONG the many industrial enterprises thrown open to the examination of members were some of an entirely novel order to the great majority of visitors. A large number, for instance, were greatly interested by what they saw at the Rubislaw quarries, one of those which have helped to obtain for Aberdeen the title of "The Granite City." Many of the same party subsequently visited the granite sculpture works of Mr. Arthur Taylor in Jute Street, where they had an opportunity of examining a statue of King Edward VII recently completed by Arthur Drury, R.A. It is to occupy a site near the railway bridge, and there was some diversity of opinion as to the artistic effect and durability of the oxidized silver ornamentation designed for the royal vestments. Two large parties also visited the fish market in the early morning, and besides being present at the fish auctions had the main features of Aberdeen's leading industry explained to them by Dr. Bowman, of the Marine Research Department.

SPORT.

IT need scarcely be said that there were plenty of opportunities for golf at Aberdeen, and many members took advantage of the courtesies offered them by the Royal Aberdeen Golf Club at Balgownie, by the Deeside Golf Club, and by the owners of the links at Murcar and Balnagask. It was at Balgownie that the competition for the Ulster Cup took place. There were 72 players, and the winner proved to be Dr. D. Barty King of London, who, with a handicap of 6, ended 1 up on bogey (80). Second came Dr. K. Gillies (Inverness), who, with a handicap of 5, ended "all square." The next five all tied at 2 down. They were Drs. A. M. Mitchell (4), C. B. Gerrard (4), E. H. Spittal (5), S. G. Luker (9), and Mr. Albert Lucas (5). There were also putting and approaching competitions for ladies, the winner of the former being Mrs. Eddowes of London, and of the latter Mrs. Haig of Aberdeen. The general golfing arrangements were well carried out by Dr. Alexander of Kingseat Mental Hospital, while Miss Pirie and Miss Westland looked after the interests of lady visitors. There was likewise a cricket match between Aberdeen and an eleven representative of the Association. It ended in a draw, but thanks only to the fact that Aberdeen declared its innings at a close after making over 200 for two wickets down.

THE POPULAR LECTURE.

THE Popular Lecture was delivered by Dr. J. Arthur Thomson, M.A., LL.D., Regius Professor of Natural History in the University of Aberdeen, in the Mitchell Hall, Aberdeen, on the last evening of the meeting, Friday, July 31st. Neither the audience nor the lecture were perhaps strictly of the character connoted by the word

"popular," but at any rate lecturer and audience were thoroughly in sympathy and the applause was frequent. The lecture is published at page 277 of the JOURNAL. The exhibition of a number of zoological slides at the conclusion of the lecture was much enjoyed. Dr. Thomson had a neat phrase or quotation from the poets for all the wonders of Nature's handiwork displayed on the screen, and at the conclusion an expression of thanks to him was carried by acclamation.

The Temperance Leagues.

The National Temperance League, which this year was associated with its sister organization, the Scottish Temperance League, held its forty-fifth annual breakfast conference in connexion with the British Medical Association on July 30th. The chair was taken by Mr. A. P. Forrester-Paton, who expressed the admiration felt by the leagues for the work being done by the medical profession in relation to temperance reform. Among other speakers, Mr. John Turner Rae presented a message from the Science Education Committee of the National Temperance League, emphasizing the importance of further researches into the nature and cure of inebriety in amplification of the evidence presented ten years ago to the Inter-Departmental Committee on Physical Deterioration. Some of the lines that such a research might take were indicated by Mr. McAdam Eccles, among them being an endeavour to determine the lowest percentage of alcohol in the blood which will produce distinct physiological and pathological effects in normal subjects. The proceedings concluded after a vote of thanks to the hosts had been put to the meeting by Mr. T. H. Bickerton, of Liverpool.

Among those who entertained visitors during the week were Dr. Reid, medical superintendent of the Royal Asylum, who, with Mrs. Reid and his assistant medical officers, received nearly 200 guests on Thursday afternoon and showed them over the whole premises, refreshing them afterwards with tea and the music of two bands. On the same day there was also a kind of "at home" on a large scale at the Royal Infirmary, where the guests were received by the chairman of its managing board and by Professor Mackintosh, Professor Marnoch, and other members of the medical staff.

The membership ticket this year took the form of a folded card bearing a pen-and-ink sketch which conveyed an excellent idea of Aberdeen Harbour at sundown, with the trawlers moored to the quay. Inside was a capital map of the main streets of Aberdeen and a ground plan of Marischal College, showing the distribution of the rooms devoted to sectional meetings.

AN IMPORTANT PUBLIC HEALTH APPOINTMENT.

The West Hartlepool Town Council recently decided that the public health work of the county borough, the school work and the work under the Tuberculosis Order, should be carried out in future by a whole-time medical officer of health, with the assistance of a whole-time assistant medical officer. We are surprised, however, to learn that instead of proposing to pay to the senior officer a salary such as would attract practitioners of experience and standing in the profession, it is offering a commencing salary of only £400 for the combined duties in question. The Local Government Board as representing the public, and the British Medical Association as representing the medical profession, have repeatedly expressed the opinion that in the public interest the work of medical officers of health, where circumstances permit, should be carried out by practitioners who are not engaged in private practice. While of this opinion the Association and, we believe, the Local Government Board, fully recognize the value of the work which has been and is being done by many medical officers of health who have been working at the same time as private practitioners. Experience has, however, shown that there are disadvantages attending this system, for circumstances may arise in which the private interests of a general practitioner conflict with the public duties to be performed by a medical officer of health. Moreover, an officer whose whole time is given to public appointments is more likely than a general practitioner to possess the special knowledge of public health law and administration which the duties increasingly thrown on medical officers of health render essential. The Legislature has recognized the necessity of special qualifications in public health by making it incumbent upon county councils and on the councils of districts with a population of over 50,000 to appoint as medical officer of health a medical practitioner who, in addition to the ordinary qualifications, possesses a diploma in public health. Recognizing these facts, the councils of nearly all the county boroughs and of many other large districts have, with great benefit to the public, appointed as medical officers of health practitioners with special qualifications and experience in public health matters, and have made it a condition that they shall not engage in private practice. The West Hartlepool Town Council must therefore be congratulated upon the step it has taken, but it appears, unfortunately, to have overlooked the fact that the Local Government Board has, in the interests of the public health, strongly recommended that the salary of whole-time principal medical officers of health should in no case be less than £500 a year. In the present case not only is the officer to be appointed to be entrusted with the care of the health of a population of over 60,000, but with the responsible work of school medical officer and tuberculosis medical officer to the county borough, both of them appointments demanding special expert qualifications. For the combined appointment in the case of an important county borough such as West Hartlepool it is obvious that the interests of the public health cannot be efficiently safeguarded by the appointment of an inadequately paid official, and in the interests of the public, quite as much as in those of the medical profession, we must protest against the inadequacy of the suggested salary. We note that the Hartlepools Division of the Association has unanimously passed a resolution to the effect that the salary for the combined appointment should be at least £500—a resolution which will be thoroughly endorsed by the Association and the profession throughout Great Britain. The post calls for the appointment of an expert administrator, and it is certain that the town council cannot secure suitable candidates for it at the salary proposed, which is substantially less than that paid by the large majority of county boroughs throughout the country. Indeed, to go no further than the neighbouring borough of Hartlepool, with a population of only 20,000, and where, since it is not a county borough, the duties of the medical officer of health do not include those of tuberculosis medical officer, a salary of £400 is paid for work less onerous and responsible. The risk of appointing inadequately paid officials is inefficient service, and in matters of public health such a step is a fatal mistake in public policy. We trust that in the interests of the large community which it represents the West Hartlepool Town Council will reconsider its decision, especially as the question of finance involved is comparatively insignificant.

INTERNATIONAL DENTAL FEDERATION.

The International Dental Federation, or permanent organizing bureau of International Dental Congresses, met in the University of London on Monday, August 3rd. Mr. W. B. Paterson, F.R.C.S., L.D.S.(London), President, was in the chair, and delegates from various National Dental Associations comprised in the Federation attended and spoke of the progress of dentistry in their several countries during the past year. A marked diminution in

the number of delegates was observable by reason of the outbreak of war. No representatives of Austria, Germany, France, Holland, Belgium, or Denmark were present. The Vice-Chancellor of the University of London, Sir Wilmot Herringham, attended the meeting, and welcomed the Federation on behalf of the University. The President reviewed the work of the Federation in matters of dental hygiene, connected with school clinics, the army and navy, and public health generally, since the last International Congress, held in Berlin in 1909. He also dealt with the work of organization of the sixth International Dental Congress, which was opened at the university on the following day. At the conclusion of the President's address the following delegates spoke: Dr. W. T. Brophy (Chicago), on behalf of the United States, referred to the rapid progress now being made in the various municipalities throughout the States in the establishment of school dental clinics. Dentistry for the army and navy had been put upon a sound footing, and dentists ranked in equality with medical men. Dr. E. T. White (Brisbane) spoke of the forthcoming Australian Dental Congress, and extended a welcome. Dr. Eudore Dubeau (Montreal) dealt with the subject of unqualified practice and the steps successfully taken in Canada for its suppression. Dr. Vincenzo Guerini (Naples) could not report any forward dental movement in Italy during the year. Dr. Sten Hager (Stockholm) mentioned several improvements in school dental clinics undertaken by the Swedish Government, which were pioneer efforts in their way. Dr. Florestan Aguilar (Madrid) instanced various Government Acts passed for the betterment of public dental hygiene; in particular, the appointment of dentists as health inspectors in their own specialty, with the same magisterial powers which medical men who are medical health inspectors possess in Spain. Dr. John S. S. Burnett (Monte Video) recounted the steady growth of dental education in his city, and stated that the dental school there now had some seventy pupils. Professor S. P. Pickerill, Otago University, New Zealand, dealt also with dental education, more especially as it related to the teaching of medical students in dental pathology, to enable them to appreciate dentistry in relation to oral sepsis. Dr. E. C. Kirk (Philadelphia) related the results of a census of opinions on the question of didactic lectures for dental students, the general trend of which suggested that the dental schools of the United States did not value didactic lectures of the old-fashioned type, and that the time had arrived for their suppression as part of a dental curriculum generally. The Vice-Chancellor, in a speech which brought the proceedings to a close, drew upon his experiences of congress organization in connexion with the International Medical Congress of 1913, and compared them with those of the Federation. He referred to the similarity between the duties of the permanent bureau of International Medical Congresses established at the Hague and the duties of the International Dental Federation. In speaking of those other duties performed by the Federation not connected with congress organization, he emphasized the importance, in connexion with dental education, of gaining the ear of Governments and authorities by repeated presentation of their views. It was only by a system of constant hammering in of their ideas that they could hope to attain to what was wanted. Later in the day the Federation revised its rules, fixed the next, or seventh, International Dental Congress to be held in Spain in 1919, and decided to meet in San Francisco in 1915.

THE International Ophthalmological Congress, which was to have been opened at St. Petersburg on Monday, August 10th, has been postponed. The information has been received by Mr. Walter Jessop from Dr. Germann (St. Petersburg), secretary of the congress.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

Sick Policemen.

DR. ADDISON asked the Home Secretary whether his attention had been called to the inadequacy of the arrangements existing at present in the Metropolitan Police for the treatment of members of the force; whether a number of the men who went on the sick list during a year, but who were not ill enough to be sent to an ordinary hospital, were accommodated in section houses or their own lodgings, where there were no proper facilities for their nursing or attention; and what steps he proposed to take to improve the present arrangements.—Mr. McKenna said that the arrangements now in force in the Metropolitan Police district for the medical care of sick police had been carefully devised with a view to giving them the most efficient care. All cases of illness in which nursing was required were sent at the cost of the police fund to the hospital nearest to the home and friends of the sick officer, unless treatment in a special hospital was recommended. Officers suffering from minor ailments were treated by the divisional surgeons, of whom there were 182, in their own home or lodgings, like ordinary private patients, or, if they resided in the section houses, in the sick-rooms provided there. Officers requiring rest and care during convalescence were sent at the cost of the relief fund to a convalescent home at the seaside.

Dr. Addison also asked the Home Secretary whether, in consequence of the inadequacy of the facilities provided for the treatment of sick members of the Metropolitan Police, he would consider the advisability of the establishment of an isolation ward and proper facilities for open-air and other suitable treatment of suspected or early cases of tuberculosis and the proper provision of police hospitals in suitable districts; and whether he was aware that for the City Police force of 1,100 men there was an institution with four wards and thirty-two beds, whilst in the Metropolitan Police force of 21,000 men there was no provision of this kind whatsoever.—Mr. McKenna replied that prompt measures were taken in cases of suspected or early tuberculosis in the Metropolitan Police; arrangements had for some years been in existence by which such cases were at once transferred to suitable hospitals or sanatoriums for observation or for treatment. The hospital established for the City Police force no doubt served satisfactorily for a comparatively small force concentrated in an area of one square mile, but to establish special hospitals to serve the whole metropolitan area of some 700 square miles would be a most costly expedient and would not yield such good results as the present system, under which sick police had the benefit of treatment in the great hospitals of London, which placed at the disposal of the sick the services of the most distinguished surgeons and physicians of the metropolis. For every man in hospital a subscription of 1 guinea a week was paid out of the Police Fund.

Female Factory Inspectors.—Mr. Morrell asked whether the number of women and girls employed in factories and workshops in the year 1907, the last year for which such figures were available, was more than 1,850,000, or, approximately, 37 per cent. of the total number of persons so employed; whether this percentage had since been maintained; and whether, in view of the fact that there were at present only twenty women inspectors out of a total of 217, he would consider the desirability of making further additions to the staff of women inspectors.—Mr. McKenna said that the figures were correct, except that the present number of lady inspectors was twenty one out of a total of all grades of 223; but it was not to be supposed that the inspection of factories where women were employed was confined to the women inspectors. On the contrary, it was shared by all members of the staff, from the chief inspector downwards. The Home Office had, however, been steadily increasing the number of the lady inspectors—three had been added in the last eighteen months—and that policy would be continued.

Scotland.

[*FROM OUR SPECIAL CORRESPONDENTS.*]

July Post-Graduate Teaching in Edinburgh.

The second fortnight in July has now been definitely included in the autumn vacation post-graduate courses in medicine in Edinburgh in connexion with the University and the Royal Colleges. During the two weeks ending August 1st, special courses in obstetrics and gynaecology and in diseases and defects of children have been held. In both the numbers attending were restricted (to 10 in the former and to 25 in the latter) on account of the clinical side of the teaching, and both were open to women (as indeed are all the post-graduate classes). The attendance was satisfactory; and to the graduates a well-filled day was offered in both courses, in fact, teaching began at 10 a.m. and continued, with a short interval, till 5 p.m., whilst in the obstetrical section there were opportunities given for seeing the operative work in the Royal Maternity Hospital at night. The August course of internal medicine is now in progress.

A Maternity Convalescent Home.

This home for the treatment of recently-confined women and their infants at Shandon, on the shores of the Gareloch, founded and endowed by Mr. A. F. Yarrow, accommodates six mothers, each having a room to herself. Preference is given to patients from the Glasgow Maternity Hospital, and to the wives of workmen from Messrs. Yarrow's works. Each patient remains for a fortnight. The institution will be open all the year round, having a very sheltered situation for winter residence, and will prove a valuable adjunct to the Maternity Hospital of Glasgow. It was formally opened on May 30th last. The consulting physicians are Dr. Robert Jardine, of the Royal Maternity Hospital, Glasgow, and Dr. Leonard Findlay, of the Royal Hospital for Sick Children, Glasgow; the visiting physician is Dr. Arthur Downes, of Helensburgh.

Royal Edinburgh Hospital for Incurables.

At the annual meeting of the members of the Incorporation of the Royal Edinburgh Hospital for Incurables, held within the Longmore Hospital on July 28th, the chairman (Mr. D. M. Westland) intimated that in order to meet the need for extension the managers had purchased a property adjoining their Cottage Hospital at Liberton. It had been resolved to take all the phthisis cases to that hospital, so as to leave room in the Longmore Hospital itself for the increasing number of cancer patients. The chairman appealed to the public for financial assistance. This proposed transference of the phthisis cases to Liberton has already been referred to in the Journal (vide British Medical Journal for July 11th, p. 93).

Ireland.

[*FROM OUR SPECIAL CORRESPONDENTS.*]

Dublin University Post-Graduate Classes.

The post-graduate classes organized in connexion with the School of Physic, Trinity College, Dublin, will be held this autumn between September 14th and October 3rd. Instruction will be given in medicine, surgery, gynaecology, diseases of the eye, ear, throat, nose, and skin, pathology, anatomy, physiology, *x*-ray work, and urology. Professor John Joly, Sc.D., F.R.S., has kindly undertaken to give a lecture on radium to medical practitioners on one afternoon during the course.

Honour for Irish Doctor.

More than forty years after the close of the Franco-German war, the French Government has issued its handsome "Médaille Commémorative de la Campagne de 1870-71." Many of those who would have received this decoration have passed away. Of those who served in the Anglo-American Ambulance during those terrible days at Sedan, Paris, and Orleans Dr. Charles E. Ryan, Glenlara, Tipperary, is one of the few survivors. He has received the Brevet and Decoration from the French Minister of War, bearing the Seal of the Chancery of the Legion of Honour, May 7th, 1914. For his services to the wounded in the same campaign Dr. Ryan had conferred on him at the close of the war the Military Cross of Louis II of Bavaria, and also the Bronze Cross of the French Ambulance Society. In his work, *With an Ambulance in the Franco-German War* (John Murray), Dr. Ryan has given an account of his experiences with both armies during that tremendous struggle.

Gunshot Wounds in the Dublin Hospitals.

Owing to the unfortunate collision between the military and the mob in Dublin on Sunday afternoon, July 26th, a large number of cases were admitted to the Dublin hospitals suffering from gunshot wounds, most of them inflicted by rifle bullets. The majority of the patients were taken to Jervis Street Hospital, which is situated close to where the firing took place; two patients, an old man and a woman, were dead when brought to the hospital, and a third died about an hour after admission. Over twenty cases of bullet wounds were treated at this hospital, besides cases of bayonet wounds and other injuries, many of which were so serious as to necessitate detention in hospital. A few other cases were admitted or treated in some of the other hospitals. Some fourteen cases in all were detained in the hospitals suffering from bullet wounds; so far they are all progressing favourably, and it is not expected that there will be any further mortality.

The late Sir Christopher Nixon.

At the annual meeting of governors of the Royal Veterinary College of Ireland on Thursday, July 30th, there was an unusually large attendance of governors, and a resolution of condolence was adopted with the family of the late Right Hon. Sir Christopher J. Nixon, Bart., M.D., who had been President of the college since its foundation, and to whose untiring energy its establishment and success was in a great measure due.

England and Wales.

[*FROM OUR SPECIAL CORRESPONDENTS.*]

MANCHESTER AND DISTRICT.

The Manchester Royal Infirmary.

An interesting ceremony took place at the Manchester Infirmary last week, when the chairman of the board of management, Sir William Cobbett, presented certificates and medallions awarded by the Queen Mother of Greece to nurses from the infirmary for their services to the wounded in the Greek-Turkish and Greek-Bulgarian wars of 1912 and 1913. The medallions showed a small silver cross, and the certificates, which were in Greek, described the donor as the "High Protector of the Red Cross." Of the ten nurses who went out to the wars one, it was stated, was still in Greece, but most of the others received the awards personally, and were congratulated by the chairman on having undertaken an onerous and dangerous duty which had been heartily and fully appreciated.

At a meeting of the board of management, a resolution was cordially adopted congratulating Sir William Milligan on the honour of knighthood recently conferred on him. The chairman announced that the donations for the Central Branch now amounted to £22,466 towards the £25,000 required. He said that the radium fund had for some time been almost monopolizing the attention of the public, and, in order not to interfere with that, no special efforts had been recently made to push the claims of the Central Branch. The radium fund was now an accomplished success, and he hoped that within the short time that must elapse before the opening of the Central Branch the donations would be sufficient to put it on a sound financial basis.

Ophthalmia at Swinton Schools.

The extent of the epidemic of ophthalmia at the Manchester guardians' schools at Swinton appears to have been somewhat exaggerated, although its seriousness cannot be denied. At present there are about seventy children suffering from ophthalmia and other affections of the eye. Many of the cases are quite mild and all are

being treated in a temporary building quite separate from the general buildings, so that none of the cases come into contact with any of the healthy children. Several years ago the guardians appointed an ophthalmic surgeon, who periodically examines the eyes of the children and removes to separate accommodation every child whose eyes are in any way affected, and no child is allowed to return from the ophthalmic building until the surgeon is satisfied that there is no possibility of recurrence. About three years ago the number under treatment for diseases of the eye was over 150, but since then there has been a gradual diminution, which is undoubtedly owing to the careful treatment and isolation. The guardians have applied to the Local Government Board for sanction to purchase an estate where better accommodation may be made for these cases, the cost being estimated at about £7,250.

Canada.

[FROM OUR SPECIAL CORRESPONDENTS.]

CANADIAN MEDICAL ASSOCIATION.

THE annual meeting of the Canadian Medical Association opened at St. John, New Brunswick, on July 7th, under the presidency of Dr. Murray MacLaren. About 280 members were in attendance. After the addresses of welcome, which were delivered by the Hon. Josiah Wood, the Lieutenant-Governor, and the Hon. J. D. Hazen, Dr. MacLaren delivered the presidential address. In it he reviewed the history of the early visits of medical men to the province of New Brunswick and to the city of St. John, from the visit of De Monts and Champlain in 1604, when so many of their party fell ill with scurvy, to the visit of La Tour and the landing of 3,000 Loyalists on May 1st, 1783, who founded the city of St. John; among them were a number of medical men. The Canadian Medical Association met at St. John for the first time in 1873 and again in 1894. It was interesting to note that at the latter meeting the topics discussed included a Dominion Medical Act, interprovincial registration, and a uniform standard of medical education for the various provinces of the Dominion. All these questions had since been solved. In speaking of the organization of the association, the President urged that the constitution should be altered to meet needs as they arose. He referred also to the wish expressed by many members that a weekly journal should be published by the association. In concluding his address, Dr. MacLaren paid a tribute to the splendid work being done in Canada by the Army Medical Corps. At the present time there was an organized service of 700 medical officers and 1,800 non-commissioned officers and men ready for the field. The presidential address was followed by the address in medicine, delivered by Dr. Thomas McCrae, Professor of Medicine at the Jefferson Medical College, Philadelphia. He impressed upon his hearers the necessity for patient observation and the importance of careful routine examination and inspection. He reminded those present that it was only by drawing correct inferences from the knowledge obtained by such observation and inspection that a true diagnosis could be arrived at. "The eye sees only what it is trained to see," therefore a physician must train every sense; he must accustom himself to careful observation and reflection, and he must not rely too greatly upon the perfection of instruments. The address in surgery was delivered by Dr. J. Rutherford Morison, Professor of Surgery at the University of Durham, who chose for his subject "The teaching of surgery." Dr. H. Jellett, of the Rotunda Hospital, Dublin, delivered the address in obstetrics, the title of which was, "The present relation of theory and practice in the treatment of genital prolapse." On Thursday evening, July 9th, an able address on "Health problems in Canada" was given by Dr. Charles A. Hodgetts, Medical Adviser to the Commission of Conservation. This address was open to the public. Dr. Hodgetts deplored the lack of uniformity in the laws relating to public health in the Dominion of Canada. In 1871 public health was allowed to lapse to the various provincial Governments, and now each of the nine provinces controlled public health under a different statute law, and without any reference each to the other, or to the Dominion as a whole. He advocated strongly the formation of a federal department of public health and the publication of vital statistics for the whole Dominion.

In accordance with the suggestion offered by the President in his address, it was resolved that the constitution be amended to allow a provincial society to hold its annual meeting even should the annual meeting of the Canadian Medical Association take place in that province. In the past Ontario has been the chief sufferer in this respect, as the meetings of the Canadian Medical Association have been held at places in that province more frequently than in other parts of the country. It was resolved also that the British Government be requested to provide for a careful examination of all intending emigrants to Canada before embarkation. Thus the emigrant would be saved much distress and annoyance and the expense of deportations would be avoided to a great extent. A further resolution was adopted to petition the Government to establish a Federal Department of Public Health.

A large number of papers were read in the various sections, the reading of which was followed with keen interest. Clinics were conducted by Dr. George E. Armstrong of Montreal, Dr. Thomas McCrae of Philadelphia, and Dr. Max Einhorn of New York. The next convention will take place at Vancouver. The president-elect is Dr. R. E. McKechnie of Vancouver.

The annual meeting of the Canadian Medical Protective Association was held on July 9th, in connexion with the meetings of the Canadian Medical Association. Dr. R. W. Powell, of Ottawa, was re-elected president.

On Wednesday, July 8th, a luncheon was given to the members of the Canadian Medical Association by the local Branch of the British Medical Association, and on Thursday a luncheon was given by the St. John Branch of the Canadian Medical Association.

ONTARIO COLLEGE OF PHYSICIANS AND SURGEONS.

The annual meeting of the Medical Council of the Ontario College of Physicians and Surgeons was held in Toronto on July 7th and 8th. The most important matters that came up for consideration were the Workmen's Compensation Act and the regulation of the "practice of medicine." It is important that a clear understanding should be arrived at as to the exact legal definition of the phrase "practice of medicine," and that legislation should be secured to limit the activities of those who practise the various "pathies," many of whom have had no proper training in any of the branches of medicine. A resolution was adopted that a list be drawn up of all those who might be considered as claiming to be medical practitioners, and the whole matter was referred to a joint committee, consisting of members of the executive committee, the legislative committee, and a representative of the teaching bodies. The Workmen's Compensation Act for the province was discussed at some length, and the hope was expressed that as the Act became operable some provision for the payment of a medical man would be made. Mr. F. W. Hinsdale, who has been engaged in work connected with workmen's compensation in the State of Washington, was of opinion that there were good reasons why no provision for first aid had been made, particularly as the Ontario Act was somewhat of an experiment. He reminded his hearers that under the provisions of the new Act it was unnecessary to determine the fault, which, of course, in many of the cases did not exist, the accident being attributable to no fault, but rather to chance; and he was of opinion that the fact that the workman received, instead of merely 20 per cent., the full sum paid by the employer, would be a guarantee in itself that the physician's bill would be paid.

The provisions of the Examination Act were altered to allow a teacher to conduct an examination in any subject; previously he could not examine in the subjects taught by him. It was resolved also that the Canadian Medical Council be requested to make Toronto an examination centre alternately with Montreal, irrespective of the examination centre in the Western Provinces. A vote of condolence was passed to Hon. Dr. R. A. Pyne on the death of his brother, Dr. A. R. Pyne, and to Dr. E. E. King on the death of his daughter.

The officers elected for the year 1914–15 are: President, Dr. James McArthur, London; Vice-President, Dr. H. S.

Griffin, Hamilton; Registrar, Dr. J. L. Bray, Toronto; Solicitor and Counsel, H. S. Osler, K.C., Toronto; Public Prosecutor, John Fyle, Toronto; Official Stenographer, George Angus, Toronto; Treasurer, Dr. Wilberforce Aikens, Toronto. The next annual meeting will be held in Toronto on July 6th, 1915.

Correspondence.

THE FUTURE OF THE LISTER INSTITUTE.

SIR,—I am instructed to inform you that all members of the Lister Institute will shortly receive a statement from the governing body, giving details of their proposal for the amalgamation of the resources of the Lister Institute with those at the disposal of the Medical Research Committee. The recommendations of the majority of the governing body will be submitted to the members of the Institute at a meeting which will take place early in October.

In the meantime members will no doubt suspend their judgement on a proposal the details of which have not yet been placed before them.—I am, etc.,

London, S.W., August 4th. CHARLES J. MARTIN, Director.

SIR,—We beg to bring to your notice the proposed amalgamation of the Lister Institute of Preventive Medicine with the Government Medical Research Institute created in connexion with the Insurance Act. In other words, it is proposed to hand over the Lister Institute—the representative in England of the Pasteur Institute of France—to a Government Committee. The Lister is the only institution in England devoted to pure research in medicine, where men can spend their whole time in working at the natural history of disease with a view to its prevention. It is elastic in its constitution and free from the inevitable restrictions of a Service-run department, so that any one who has an idea or theory in regard to the prevention of disease can be given advice and working facilities, and so put his idea or theory to the test of experiment. The Lister is also a place where any member of the staff can have pupils—and as a matter of fact, students come to it from all parts of the world—or give lectures on his special subject and so spread knowledge.

2. However right and proper it may be for the State to maintain an institute for medical research, it is surely desirable that there should be in the country at least one establishment in which researches can be pursued independently of the State and its officials. The Lister Institute is the only place adequately equipped to fulfil this function in the United Kingdom.

3. If the work turned out by the Institute were so poor in quality and meagre in quantity that its continued existence were a discredit to science, the last argument would lose its force so far as the Lister Institute is concerned, but as a matter of fact—the present governing body themselves being the witnesses—the quality of the work done is excellent, and there is an increasing tendency for research workers to resort to the Institute for instruction and laboratory facilities. Such hospitality will be absolutely out of the question if the Institute is compelled to house two complete staffs, the nominees of the Government Committee and the present staff of the Institute.

4. It may be said that the amalgamation will lead to the better utilization of the Institute's resources, and that it is not economical to have two separate research institutes in London. History has again and again taught that Government-controlled institutes of this kind tend to become stereotyped and inelastic. The fire of enthusiasm burns low under the damping effect of bureaucracy, "which is sure to think that its duty is to augment official power, official business, or official numbers, rather than to leave free the energies of mankind." Success in research depends upon freedom of initiative. It is a matter of common knowledge that in Germany a research worker who has the choice between a university post and a post in a Government research institute, invariably prefers the university post. If in the future it is found that there is no room in England for the two institutions, then a fusion might take place. Let us wait and see how the new Government scheme works.

5. Does any man imagine for a moment that it will be possible to carry out the objects of the Institute under the new régime? Let us rehearse these objects:

(*a*) To undertake or aid scientific research into and study of the causes, prevention, and treatment of disease in man and animals, the study of biology in any form, or any other science in its relation to the health of man or animals, the study of any agency or discovery affecting or likely to affect human health, the study of the composition, properties, and powers of any article of food or drink, or medicine, the study of air, water, animals, vegetables, minerals, and chemical substances in their possible relation to human health, and to provide a place or places where research and study may be carried on for the purposes aforesaid.

(*b*) To provide instruction and education in preventive medicine to medical officers of health, medical practitioners, veterinary surgeons, advanced students and others.

(*c*) To prepare and to supply to those requiring them such special protective and curative materials as have been already found or shall in future be found of value in the prevention and treatment of disease.

(*d*) To treat persons suffering from disease or threatened therewith, in buildings of the Institute or elsewhere, as out-patients, especially in cases where similar treatment cannot conveniently be obtained at any London hospital, but nothing herein contained shall authorise the establishment of a residential or in-patient's hospital.

The governing body at that time included the late Lord Lister, P.R.S., Lord Iveagh, F.R.S., Lord Rayleigh, O.M., F.R.S., and the late Professor Sir John Burdon-Sanderson, F.R.S., Regius Professor of Medicine of the University of Oxford.

6. In conclusion, is this Institute, with its high ideals and illustrious founders, to perish in this premature fashion as the result of a policy of timid pusillanimity, under whatever fine phrases the surrender may be concealed? If so, then the one institution in England wholly devoted to independent research in preventive medicine will disappear. After amalgamation there will no longer be room for the encouragement of private research, or for pupils, or for the diffusion of knowledge by lectures or demonstrations. Instead of being out of earshot of the hurly-burly of politics, it will be competent for any member of Parliament to question the work and policy of the Institute at any time and the way in which public money is expended. In our opinion it is a suicidal policy and will not be to the real benefit of preventive work in disease in England.

F. W. ANDREWES, M.D., F.R.C.P.,
Lecturer on Pathology, St. Bartholomew's Hospital; Professor of Pathology in the University of London; Member of the Council of the Lister Institute.

DAVID BRUCE, Surg.-Gen., A.M.S., Kt., C.B., F.R.S., F.R.C.P.,
Member of the Governing Body of the Lister Institute.

A. R. CUSHNY, F.R.S., M.A., M.D., LL.D.,
Professor of Pharmacology and Materia Medica in the University of London; Member of the Lister Institute.

W. S. GREENFIELD, M.D., F.R.C.P.,
Late Professor of Pathology and Clinical Medicine, Edinburgh University; Member of the Council of the Lister Institute.

A. S. GRÜNBAUM, M.D., Sc.D., F.R.C.P.,
Professor of Pathology and Dean of the Faculty of Medicine, University of Leeds.

E. RAY LANKESTER, K.C.B., D.Sc., F.R.S.,
Member of the Council of the Lister Institute.

JAMES RITCHIE, M.A.Oxon., M.D.Edin.,
Irvine Professor of Bacteriology, University of Edinburgh; Superintendent, R.C.P. Research Laboratory, Edinburgh.

W. J. SIMPSON, C.M.G., M.D., F.R.C.P.,
Professor of Hygiene in King's College, London; Member of the Council of the Lister Institute.

STATE REGISTRATION OF NURSES.

SIR,—Lord Knutsford's criticism of the statement by Mr. Garstang, the Chairman of the Medico-Political Committee, shows once more that his lordship cannot understand the difference between a constitutional opposition

and a factious opposition, such as that which he has got up against the State registration of nurses.

The action taken by our Association, after many years of hard work and close consideration, has been confirmed over and over again in committees and Representative Meetings, including the one just closed. It is supported by all the nurses' associations in England, Scotland, and Ireland, and the bill which he seeks to hinder has been agreed upon by all these bodies and is being put forward by a joint committee representing all these bodies.

Finally, it has been warmly supported at all open meetings of nurses during the past twelve months, and the only meeting, where Lord Knutsford appeared in opposition, carried it against him by a large majority. Against these constitutional procedures he dares to put the opinions of private individuals, collected by himself, on a circular containing several incorrect assertions and no argument.

This is precisely the sort of thing I protested against Mr. Asquith doing when the last deputation went to him on the subject. I pointed out to Mr. Asquith on that occasion that these *ex cathedra* opinions, collected by Mr. Holland (as he was then), were merely bureaucratic, and could not for a moment be quoted against the constitutional resolutions of the British Medical Association and other representative bodies.

The very matrons Lord Knutsford names as objecting to the bill I myself visited a few months ago, and found them profoundly unacquainted with registration by the State. They knew none of its purposes nor of the great advantages it offers to every trained calling. All they feared was a loss of controlling influence. Even this I showed them was a delusion, and that their personal influence and control of their nurses would be unaffected. —I am, etc.,

London, W., Aug. 4th. VICTOR HORSLEY.

*** We have received from Mrs. Bedford Fenwick, President of the Society for the State Registration of Trained Nurses, a long letter putting forward very similar arguments, for which we are unable to find space.

THE UNIVERSITY OF LONDON.

SIR,—Your editorial comment on my letter to you of last week breaks new ground at its close in a personal attack upon myself. You say that on May 30th, 1912, the Senate adopted a resolution "welcoming the efforts of Lord Haldane and other friends of university education in London to raise funds towards the present and future needs of the University," and you accuse me of rejoicing in the failure of these efforts. This, I think, you will admit is a somewhat serious charge to make in a journal which is widely read by the medical graduates of the University who have done me the honour of electing me three consecutive times to represent them on the Senate. I am at a loss to understand on what evidence you found the charge, and I hope, at any rate, that the following explanation will convince your readers that it is baseless. The efforts of "Lord Haldane and other friends," etc., date from a letter addressed by Lord Haldane to Sir Francis Trippel, published in the press in March, 1912, in which Lord Haldane approved a proposition by Sir Francis Trippel to raise a fund to purchase the Bedford site for the University; and he named, among others, three trustees of this fund—Lord Rosebery, Sir Francis Trippel, and himself. In response to the public appeal certain donations, which have remained anonymous, were announced, and Lord Haldane, in a letter published in the *Times* of May 9th, 1912, declared that some of these donations carried "conditions which were inconsistent with the gifts being used by the University as at present constituted." Sir Francis Trippel has contradicted this later statement, and Lord Rosebery wrote to the Vice-Chancellor on March 20th, 1912, that when he accepted the trusteeship he was not aware that any site had been fixed upon, and that he supposed that the most that had been done was to accept offers of money for a site to be offered to the University; and that he had not as Chancellor committed either the University or himself to anything except to being trustee for certain sums collected for the benefit of the University.

The Senate were further assured by one of their most influential and respected members who was supposed to be deep in the counsels of Lord Haldane that the fund which was being raised by "Lord Haldane and other friends," etc., was not, in fact, hedged in by the stipulation that the University should choose the Bedford site, and on this understanding a carefully worded resolution was passed without a division on May 30th, 1912, emphasis being laid on the fact that the Senate regarded themselves as free to make their own choice. You have omitted the last clause, which is of crucial importance in this connexion; the whole resolution runs as follows:

> That the Senate welcome the efforts of Lord Haldane and of other friends of University Education in London to raise funds towards the present and future needs of the University, and have referred to a special committee the consideration of the most suitable site for the University.

The Bedford site was subsequently considered in detail and rejected decisively by this committee and by the Senate, and another site was recommended, but on October 21st, 1912, in an interview with the Vice-Chancellor, Lord Haldane made it clear that the anonymous money for which he was spokesman would not be available for this site, whereas the Drapers' Company at the same time announced that their proffered donation of £60,000 would be so available.

In July of last year Lord Haldane, in a correspondence with the Vice-Chancellor, again made it clear that the efforts of "himself and other friends," etc., were absolutely conditional on the selection of the Bedford site by the University, notwithstanding that he was aware that this site had been rejected by the Senate and by their Sites Committee. It is, therefore, evident that the Senate were misinformed at their meeting on May 30th, 1912, and that their resolution wrongly described the efforts of "Lord Haldane and other friends," etc., as being directed to "raising funds towards the present and future needs of the University"; these efforts are more accurately described as being directed to removing the University from its present advantageous financial position as regards its tenure of its premises from the Treasury, to a site condemned by its governing body after exhaustive investigation.

Removal of the University to the Bedford site, upon which Lord Haldane thus lays a strange personal insistence, would be very much in the interest of a particular school of which Lord Haldane is a life governor, but would be detrimental to the University as a whole. Moreover, as Sir Philip Magnus, member of Parliament for the University, pointed out on the morrow of Lord Haldane's letter of May 9th, to which I have referred, Lord Haldane's action in accepting offers of money "under conditions which are inconsistent with the gifts being used by the University as at present constituted," tends to restrict the freedom of Parliament and to prejudice the situation in favour of a policy for the reconstitution of the University in accordance with the recommendations of the Royal Commission of which Lord Haldane was chairman, a policy which still has to get the sanction of Parliament, and whose prospects of getting that sanction become increasingly remote. For these reasons I am free to admit that I, in common with the large majority of my fellow graduates, am not sorry that these efforts, which are in no sense disinterested efforts for the general benefit of the University, have failed. You have seriously misrepresented my position in this matter, and I trust that you will give me this opportunity of correcting the effect of your statement, which conveys an entirely false impression calculated to injure me with my University constituents.—I am, etc.,

London, W., July 28th. E. GRAHAM LITTLE.

THE WAR: A PRACTICAL OFFER.

SIR,—There are many of the medical profession who will be unable to go to the front and engage in active work for their country.

I am ready to attend all soldiers, sailors, their wives and families, of whatever rank, without making any charge, and have already commenced to do so.

There are others all over the country who are doubtless ready to do likewise. Can we not have the names sent in and organize accordingly? I am willing to act in any secretarial capacity.

Moreover, there are those on whom the war will heavily fall and who will not be in a position to pay medical fees—to these we might well extend like services.

Care must be taken not to interfere with the patients of other men, but this could surely be readily arranged.—I am, etc.,

London, S.W., August 5th. LINDLEY SCOTT.

*** We venture to suggest that any such plan as our correspondent proposes would best be instituted by the medical profession in each locality. The British Medical Association in its Divisions affords a basis for such local action and at the same time a means of co-ordination.

The Services.

CALL FOR TEMPORARY SURGEONS AND SURGEON PROBATIONERS (STUDENT-DRESSERS).

ROYAL NAVAL MEDICAL SERVICE.

SURGEONS for temporary service in the Royal Navy are required. They will be paid 22s. a day, *plus* allowances and equipment allowance for uniform. Their age must not exceed 40 years.

Surgeon Probationers in the Royal Volunteer Reserve—that is to say, senior students to act as dressers—are also required.

Application should be made to the Director-General, Medical Department of the Navy, Admiralty, S.W.

A considerable number of applicants have been accepted, but the lists are not closed.

The regulations for Temporary Surgeons and Surgeon Probationers are as follows:

REGULATIONS FOR THE ENTRY OF SURGEONS FOR TEMPORARY SERVICE IN THE MEDICAL DEPARTMENT OF THE ROYAL NAVY.

SURGEONS who may be temporarily employed in the Royal Navy in time of War or Emergency to meet the requirements of the Service will be appointed under the following regulations:—

QUALIFICATIONS.

To be registered under the Medical Act as qualified to practise Medicine and Surgery in Great Britain and Ireland.

To produce certificates of good character.

To be reported physically fit after medical examination.

Age not to exceed 40 years.

PAY AND ALLOWANCES.

Full Pay.		*Half Pay.*	
A day.	A year.	A day.	A year.
22s. 0d.	£401 10s. 0d.	10s. 0d.	£182 10s. 0d.

NOTE.—Half pay is for sickness and extra leave only.

To be granted thirty days' advance of pay on joining a ship after appointment.

To receive the same allowances as are payable to permanent Officers of their rank.

Lodging money at the rate of £50 a year is usually allowed when employed on shore without Quarters in the United Kingdom, and £24 a year in lieu of rations. In cases, however, of temporary employment on shore, the lodging and provision allowances will be at the rate of 3s. 6d. and 1s. 6d. per day respectively.

If Quarters are provided in a Medical Establishment, an allowance is granted in lieu of provisions, for self and servant, and for fuel and lights at the rate of £39 a year in the United Kingdom, and £103 a year abroad.

UNIFORM.

Each Surgeon to provide himself as follows:

1. Frock coat, waistcoat, and trousers.
2. Undress coat.
3. Uniform cap.
4. Mess jacket and waistcoat.
5. Sword and undress belt.

All as specified in the Uniform Regulations.

To cover the above each officer accepted for service will receive an Equipment Allowance of £20, payable on the officer's being called up for active service.

The following instruments must be provided by the Surgeon:

A Pocket Case of Instruments.

A Stethoscope.

Three Clinical Thermometers.

MESSING.

Surgeons will be allowed, when attached to ships in commission, the ordinary Ship's rations; but will have to pay about 2s. a day towards the maintenance of their Mess as Ward-room Officers.

PENSIONS FOR WOUNDS AND TO WIDOWS, ETC.*

In the event of Surgeons engaged for temporary service being wounded in His Majesty's Service, Gratuities or Pensions, varying in amount according to the injuries sustained, will be granted, on the basis of the awards in similar cases of Naval Officers.

Should Temporary Service Surgeons be killed in action, die within two years of wounds received in action, or meet their death by acts of the enemy, the following Pensions and Allowances will be granted to their widows, children, etc.:

	Widows.		Children up to the Age of 18 for Boys and 21 for Girls.		Widowed Mothers dependent on their Sons, if the Latter left no Widows or Children.	Orphan Sisters dependent on their Brothers, if the Latter left no Mothers, Widows, or Children.
	Killed in Action.	Drowned, etc., by Acts of the Enemy.	Killed in Action.	Drowned, etc., by Acts of the Enemy	Killed or Drowned, or Suffered Violent Death by Acts of the Enemy.	Killed or Drowned, or Suffered Violent Death by Acts of the Enemy.
	£	£	£	£	£	£
Surgeon..	80	65	12 to 16	10 to 14	50	50

In addition to the foregoing Pensions, the widows and children of officers killed in action will be granted the following Gratuities:—

Widows—One year's Pay of their husband's corresponding rank in the Royal Navy.

Each unmarried child, under the age of 21, one-third of the Gratuity paid to the widow.

These Pensions and Gratuities can be given only in cases of injury or death caused by acts of the enemy and not on account of injury, disability or death which may result from carrying on the ordinary duties of the Service.

CONDITIONS OF SERVICE.

To engage for six months certain, but the liability to serve will be limited to five years.

To serve when and where required from the date of signing the Declaration.*

To be liable to immediate discharge for misconduct or incompetency.

To rank with, but after, Surgeons in the permanent Service.

To be under the general rules of the Service as regards discipline, etc.

To receive two calendar months' notice of services being no longer required.

To be granted a gratuity of two calendar months' pay on discharge if not discharged for misconduct or incompetency.

Voluntary resignation of appointment will be allowed subject to the convenience of the Service, but the gratuity of two calendar months' pay on discharge will be thereby forfeited.

The following form of Declaration and of Schedule of Qualifications will be required from Candidates:

DECLARATION.*

Christian and Surname at full length. I .....

.....

a Candidate for temporary service as a Surgeon in the Royal Navy, do hereby engage for general service, and attest my readiness to proceed on duty abroad whenever required to do so, upon the terms specified in these regulations.

I Declare—1st. That I am ..... years of age, and that I was born on ..... 18—, at .....

2nd. That I am †.....

.....

3rd. That I labour under no mental or constitutional disease or weakness, nor any other imperfection or disability which can interfere with the most efficient discharge of the duties of a Medical Officer in any climate.

4th. That I am registered under the Medical Act in force as duly qualified professionally, and that I hold the following Diplomas, etc., in Medicine and Surgery:

.....

.....

Signature.....

Date.....

N.B.—A mis-statement by a Candidate will invalidate any

* Unmarried candidates will be preferred.

* It should be distinctly understood that Candidates entering their names are not liable in any way to serve until they have signed the Declaration, which they will only be called on to do when their services are required.

The entering of names is simply for the convenience of communicating with Candidates quickly.

† Here insert "of pure European descent and the son either—

"(*a*) of natural-born British subjects; or

"(*b*) of parents naturalized in the United Kingdom."

NOTE.—If any doubt should arise upon this question the burden of clear proof that he is qualified must rest upon the candidate himself.

subsequent appointment, and cause forfeiture of all privileges for services rendered.

Medical School .....

* *Present Address* .....

† *Permanent Address of Parents or near Relative* .....

NOTE.—The Certificates of Birth *(not of Baptism)* or Declaration thereof made before a Magistrate, of Medical Registration, and of Character *(up to date)* must accompany this declaration.

By Command of their Lordships,

W. GRAHAM GREENE.

Admiralty,
October, 1911.

REGULATIONS FOR THE ENTRY OF SURGEON PROBATIONERS, ROYAL NAVAL VOLUNTEER RESERVE.

QUALIFICATIONS.

Medical students attached to a leading Medical School who have passed their Intermediate Examination in Anatomy and Physiology, but are not fully qualified medical practitioners are eligible for these appointments.

2. Candidates for appointment must be of pure European descent, and the sons either of natural-born or naturalized British subjects. They must be not less than 18 nor more than 25 years of age, and must be certified to be physically fit for the Naval Service.

3. Applications for entry must be made upon Form R.N.V. 26 (see Appendix) and submitted through the Admiralty Volunteer Committee for the consideration of the Admiralty.

RANK AND UNIFORM.

4. Surgeon Probationers rank with Sub-Lieutenants, R.N.V.R. and their uniform is the same as for Officers of that rank, without the "circle" on the cuff denoting Officers of the Military Branch, and with one row of red cloth on the sleeve. An allowance of £20 in aid of outfit will be granted to Surgeon Probationers on completing their first course of training afloat, or their first Hospital Course. In the event of an officer resigning before he is fully qualified, he will be liable to refund this allowance. No further allowance for outfit will be granted in the event of subsequent promotion to the rank of Surgeon, R.N.V.R.

PAY AND ALLOWANCES.

5. While under training afloat Surgeon Probationers receive pay of 5s. a day and, if required to join a Ward Room Mess, Messing Allowance of 1s. a day. While undergoing a Hospital course they receive pay at the same rate, and also Hospital allowance at the usual Naval rate, that is, £39 a year.

6. When called out for active service Surgeon Probationers will be paid 5s. a day, and in addition 2s. a day special allowance, together with the usual allowances payable when under training.

TRAINING.

7. Surgeon Probationers are required to undergo courses of training, and to obtain certificates from the Medical Director-General of the Navy that they have been instructed in their duties and have taken full advantage of their instruction. The courses of instruction comprise one period of from 14 to 28 days (at the Officer's option) at a Naval Hospital, and a similar period afloat. The Hospital Course must be taken first.

EMPLOYMENT.

8. When called up for actual service the duties of Surgeon Probationers will include the following:

First aid on board fighting ships.
Transport duties on shore.
Clinical dressing.
Clerical duties at the Naval Hospitals and on board Hospital Ships.

They will be liable to serve either ashore or afloat, as may be directed by the Admiralty, and wherever the Admiralty may have need of their services, on the understanding that so far as practicable these services shall be confined to Home Waters and the Mediterranean and to Base Hospitals, Hospital Ships, and Hospital Carriers.

COMPENSATION FOR INJURIES.

9. Officers who may receive hurts or wounds whilst on active service in the Royal Navy, or whilst undergoing training, will receive the same pensions and allowances as those to which Officers in the Royal Navy of corresponding rank would be entitled in similar circumstances.

RELINQUISHING APPOINTMENT.

10. Upon obtaining full qualification as medical practitioners, Surgeon Probationers will be required to give up their appointments, but may at their option and subject to the approval of the Admiralty—

(*a*) Enter as candidates for appointment as Surgeons Royal Navy. Such candidates will be credited at the entrance examination with additional marks on a similar scale to that now laid down for candidates who have served in the Officers' Training Corps, viz., one per cent. of the maximum number of marks allotted will be credited to candidates in possession of the Hospital Course Certificate, and two per cent. to those in possession of the certificate for the Man of War Course.

(*b*) Enter as Surgeons R.N.V.R., either attached or unattached.

* Any change of address to be notified to the Director-General, Medical Department of the Navy, Admiralty, London.

† This address is required for communications during an Officer's absence from England, when on service.

R.N.V. 26.

ROYAL NAVAL VOLUNTEER RESERVE.

ROYAL ARMY MEDICAL CORPS.

CALL FOR CIVILIAN MEDICAL PRACTITIONERS.

THE War Office notifies as follows:

Civilian medical practitioners desiring to serve at home or abroad as surgeons with the army should communicate with the Secretary, War Office, London, S.W.

Gentlemen accepted for such service will be granted the temporary rank of lieutenant in the army and must fulfil the following conditions:

1. They must be registered practitioners.
2. They must engage for a period of twelve calendar months or until their services are no longer required, whichever shall first happen.
3. Their pay to be 24s. a day, inclusive of all money allowances, except travelling allowances and expenses when travelling on duty.
4. They will be granted free passages to and from any country abroad to which they may be sent.
5. They must devote their whole time to military service.
6. They will receive a gratuity of £60 at the termination of their engagement if they have rendered satisfactory service.
7. They should not exceed 35 years of age, but in exceptional circumstances gentlemen between 35 and 40 may be accepted.
8. They must furnish
   (*a*) A medical certificate showing that they are in good health, of sound constitution, and fit for hard physical work.
   (*b*) A statement of any previous service with the army.

(c) A recommendation as to character from a person of position and responsibility.
(d) A certificate as to age.

We understand that a number of applications have already been accepted, and that the names of all those not at once engaged will be placed on a list. They will be called upon if and when required.

Public Health AND POOR LAW MEDICAL SERVICES.

SCIENTIFIC RESEARCH FOR THE LOCAL GOVERNMENT BOARD.

The President of the Local Government Board has authorized the following researches to be paid for out of the annual grant voted by Parliament in aid of scientific investigations concerning the causes and processes of disease. These are in addition to the investigations already announced.

1. An investigation of the details of the technique in carrying out Wassermann's reaction for the diagnosis of syphilis. The Army Council have consented to permit Major Harrison, R.A.M.C., to carry out this investigation. He will act in collaboration with a subcommittee of the Pathological Section of the Royal Society of Medicine.
2. An investigation by Mr. H. J. Gauvain, in collaboration with the Board's pathological staff, into the cutaneous tuberculin reactions of cases of tuberculosis of bones and joints of bovine and human sources.
3. A continuance of the investigations of Drs. Twort and Mellanby on infantile diarrhoea, with special reference to the conditions governing the absorption of toxic substances from the alimentary canal.
4. A further investigation into the causes of stillbirths by Drs. C. J. Lewis and Dale.

Universities and Colleges.

UNIVERSITY OF LONDON.

The following candidates have been approved at the examinations indicated:

Second M.B., Part II.—Girdhar C. Agarwala, F. M. Allchin, Ruth Balfour, C. H. D. Banks, J. A. Birrell, Alethea J. Bolton, G. W. J. Bousfield, L. J. F. Bull, P. C. L. Carrier, Hester M. Church, P. S. Clarke, P. N. Cook, C. J. C. Cooke, Gunaratnam F. Cooke, Dorothy T. Daintree, R. C. Davenport, P. G. S. Davis, *L. S. Debenham, J. D. Dyson, T. S. Evans, Marjorie E. Franklin, W. B. Gabriel, Iris Harding, *A. G. Harsant, F. K. Hayman, N. N. Haysom, G. W. Heckels, *W. A. Hewitson, F. G. E. Hill, E. A. Holmes, J. W. Hyatt, *J. Joffe, T. John-Thomas, M. H. K. Kaue, V. J. F. Lack, N. M. Lewis, R. T. Lewis, E. E. Lightwood, Marguerite F. J. Lowenfeld, P. S. Marshall, M. W. H. Miles, Marie M. A. Moralt, *A. Morford, J. J. Murphy, Sinnethamby Muttiah, N. Olivier, Margaret S. Palmer, V. J. E. C. del S. Perez y Marzan, B. H. Pidcock, T. D. Pratt, J. A. Pridham, W. M. Abdul Rahman, P. R. Riggall, G. F. Rodrigues, W. R. Rowlands, T. C. Russell, S. N. Scott, W. R. J. Scroggie, Nirendra M. Sen-Gupta, M. Shimberg, R. G. Simpson, W. Steadman, Ellen Sylk, K. R. Traill, M. B. M. Tweed, Rustam N. Vakil, S. Vidot, Phillis E. Webb, Lotty Weihermann, O. Williams, G. S. Wilson, C. Young.

M.D. (*Branch I, Medicine*).—†J. L. Davies, E. P. Evans, C. J. Marshall, E. S. Miller, Margaret G. Thackrah. (*Branch III, Mental Diseases and Psychology*).—C. S. Read. (*Branch IV, Midwifery and Diseases of Women*).—Maud F. Forrester-Brown, Edith M. Guest, Susie E. Hill, F. J. Humphrys, R. Montgomery, A. W. Owen, Mary C. Scott. (*Branch V, State Medicine*).—H. L. Hopkins. (*Branch VI, Tropical Medicine*).—M. F. Reaney.

M.S. (*Branch I, Surgery*).—H. Gardiner, V. Glendining, N. C. Lake, P. H. Mitchiner, A. H. Todd, J. B. T. Wilson.

* Passed with distinction in one or more subjects.
† Awarded a University Medal.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

An ordinary meeting of the Comitia was held on Thursday, July 30th, at 5 p.m., the President, Sir Thomas Barlow, Bt., K.C.V.O., being in the chair.

Members.

The following gentlemen, having passed the required examination, were admitted Members of the College:

Adolphe Abrahams, M.B.Camb., L.R.C.P.; Cuthbert Delaval Shafto Agassiz, M.D.Aberd.; Harold Wordsworth Barber, M.B.Camb.; Frederick Charles Davies, M.B.Camb., L.R.C.P.; Arthur Geoffrey Evans, M.B.Camb., L.R.C.P.; Herbert Thomas Evans, M.B.Oxon.; Thomas Lionel Hardy, M.B. Camb., L.R.C.P.; Sohrab Shapoorji Vazifdar, L.R.C.P.; Henry Owen West, M.D.Lond.

Licences and Diplomas.

Licences to practise physic were granted to ninety-seven gentlemen who had passed the required examination.

Diplomas in Public Health were granted jointly with the Royal College of Surgeons to thirty-nine gentlemen who were recommended by the Examiners.

Murchison Scholarship.

The Murchison Memorial Scholarship was awarded to Charles Jennings Marshall, M.B.Lond., of Charing Cross Hospital.

Bissett-Hawkins Medal.

The President reported that the Bissett-Hawkins Memorial Medal had been awarded to Sir Ronald Ross for his distinguished work in connexion with malaria.

Congress on Neurology at Berne.

Dr. F. W. Mott was appointed delegate from the College to an International Congress on Neurology, Psychiatry, and Psychology, to be held at Berne, September 7th to 12th next.

Examination in Practical Pharmacy.

A letter was read from Dr. A. R. Cushny, F.R.S., Examiner in Practical Pharmacy (retiring), laying before the College his views on that examination. It was decided to appoint a committee to consider the questions raised in this letter.

District Nursing.

A letter was read from Sir Arthur Downes, chairman of a committee concerning district nursing in London, asking that a representative be nominated to serve on a central council consisting of representatives of those engaged in district nursing and of others interested in the question. Sir Dyce Duckworth was appointed.

Gift.

The gift of a china tea service was received from Dr. Frank Shuttlebotham, Milroy Lecturer for this year. The cordial thanks of the College were directed to be sent to Dr. Shuttlebotham.

Censors.

The following were elected Censors: Drs. Percy Kidd, Howard Henry Tooth, C.M.G., Theodore Dyke Acland, Sir Wilmot Parker Herringham.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An ordinary Council was held on July 30th, when Sir W. Watson Cheyne, Bart., President, was in the chair.

Issue of Diplomas.

Diplomas of Membership were granted to ninety-five candidates found qualified at the recent examinations.

Diplomas in Public Health were granted (jointly with the Royal College of Physicians) to thirty-nine candidates found qualified at the recent examinations.

Regulations for the Fellowship Examination.

The Universities of Bristol and Wales and the Imperial University of Japan were added to the list of universities whose graduates in medicine and surgery may present themselves for examination for the Fellowship without first becoming Members of the College.

Recognition of Institutions.

The following institutions, which had been visited by members of the committee, were added to the list of institutions recognized by the Examining Board in England for instruction in chemistry and physics—namely, Cranleigh School; Lower School of Laurence Sheriff, Rugby. Queen Elizabeth School, Cranbrook, was removed from the list of institutions recognized by the Board for instruction in chemistry and physics. The South African College, Capetown, was recognized as a school of anatomy and physiology for the courses required for admission to the Second Examination of the Conjoint Board, and the Imperial University of Japan was added to the list of universities whose graduates in medicine are admissible to the Final Examination of the Conjoint Board under the conditions of Paragraph IV, Section III, of the Regulations.

Egyptian School of Medicine.

Dr. J. A. Ormerod was appointed Visitor to the examinations of the Egyptian School of Medicine for the last period of examination.

Sir Gilbert Blane Medal.

This was awarded to Surgeon Gilbert Francis Syms, R.N.

Conference on District Nursing.

The President reported that he had nominated Sir Alfred Pearce Gould, K.C.V.O., to serve on a central council for London, which was now being established.

PRELIMINARY EXAMINATIONS IN SCOTTISH UNIVERSITIES.

A draft ordinance has been prepared by a joint committee of the four Scottish universities proposing to constitute an Entrance Board consisting of sixteen members, four from each university. It will replace the existing joint board which meets in rotation for one year at each of the university seats under a new chairman, a new secretary, and with new members. The proposed board would be a stable composition with a permanent seat and permanent officials. The board would arrange for the conduct of simultaneous preliminary examinations in St. Andrews, Glasgow, Aberdeen, and Edinburgh, and in other places if thought desirable. It would also have the power to define the method, scope, and standards of examinations subject to any general regulations.

LONDON SCHOOL OF TROPICAL MEDICINE.

THE following candidates have been approved at the examinations held at the end of the forty-fifth session:

*†A. C. Munro, †C. Bonne, †J. M. Stenhouse, †J. S. Webster, G. W. Maconachie, W. M. Shepherd, W. M. Strong, J. C. Watt, B. H. Wedd, H. G. Waters, Miss O. N. Walker, J. Baeza, A. C. Anderson, N. S. Deane, L. S. Holmes, A. G. McPhedran, J. V. Shirgaokar, C. Sivasithamparam, R. K. Mitter, C. H. Barlow, R. B. Jackson, I. A. Rahman, W. J. Dixon, C. K. Attlee, S. Elias, K. B. Dastur, A. G. Fletcher.

*Awarded the Duncan and Lalcaca medals.
†Passed with distinction.

Medical News.

OWING to the dislocation of business due to the war it has been necessary to curtail this issue of the JOURNAL, and the same course will probably have to be followed until conditions become normal, especially among manufacturers of paper.

WE are asked to state that the library and offices of the Royal Society of Medicine will be closed for cleaning until September 1st.

THE Board of Control announces that the Secretary of State has approved of William Rees Thomas, M.D., for appointment as Medical Superintendent of the State Institution for Mental Defectives at Moss Side, Liverpool.

THE Worshipful Company of Drapers of the City of London has made a grant of £500 a year for three years in aid of the work of the Department of Applied Statistics at University College, London, including the Galton Laboratory of Eugenics and the Drapers' Biometric Laboratory.

A SERIES of clinical demonstrations will be given during August and September at the London Hospital. The course will commence on August 10th, when Dr. Wall will deal with pulmonary tuberculosis; on the following day Dr. Grünbaum will demonstrate diseases of the blood; on Wednesday abdominal diseases will be taken by Dr. Miller; on Thursday Dr. Thompson will deal with diseases of the nervous system; on Friday Dr. Lewis Smith will demonstrate common cardiac conditions; and on Saturday Dr. Hutchison will give demonstrations on selected cases. Members of the profession will be admitted on presentation of their private cards. The demonstrations will be at 2.15 p.m. daily, except Saturday, when they take place at 10.15 a.m.

THE committee of the Cancer Hospital has decided to establish a post-graduate course in radio-technology and a combined laboratory and lecture room is, therefore, being included in the new extension now approaching completion. It is hoped that the laboratory will be opened by the autumn. It is proposed that the course shall extend over a period of two months, the fees being moderate. The lectures, illustrated as far as possible by models and experiments, will include two by Dr. Robert Knox, director of the electro-therapeutic department of the hospital, upon the clinical applications of radiations, and six by Mr. C. E. S. Phillips, F.R.S.E., dealing with the physics of the subject. The electro-therapeutic department will be open on three afternoons in each week, and experience may be gained there in the treatment of cases under the supervision of Dr. Knox. The laboratory course and experimental work will be under the direction of Mr. Phillips.

WE are glad to be able to announce that the dispute regarding the Victoria Hospital, Blackpool, has at length ended in a sense entirely favourable to the contentions of the medical profession in that city. The settlement came about as the result of two long meetings between the Board of Management, the Mediation Committee, and the representatives of the medical men. It then appeared that the sole medical stipulation with which the board did not feel itself in a position to comply was that relating to the retirement of Dr. Molloy, and, finally, it was resolved that the difficulty should be met by the Board of Management resigning *en masse*. It was agreed that such resignations should take effect at a meeting of subscribers to be held shortly, and it is understood that on the new board then to be elected Dr. Molloy will not seek appointment. The Blackpool Division of the British Medical Association and the medical profession as a whole in that locality have exhibited a striking degree of solidarity and restraint throughout the whole contest, upholding their views with admirable moderation and firmness, and all parties alike are greatly to be congratulated on a return to a normal condition of affairs.

Letters, Notes, and Answers.

☞ *Queries, answers, and communications relating to subjects to which special departments of the* BRITISH MEDICAL JOURNAL *are devoted will be found under their respective headings.*

LETTERS, NOTES, ETC.

MEDICAL OFFICERS FOR WAR SERVICE.

DR. R. DOUGLAS DOBIE (London, W.) writes: So great will be the need for surgeons in the present crisis, that I make no excuse for putting forward the following suggestions:

1. That all candidates for medical degrees who have failed during the last examinations, should be re-examined immediately on their weakest subjects, and if they pass be given their qualifying degrees or diplomas.

2. That the last examination results should be revised, and all those candidates who failed by narrow margins and are anxious to be of service, shall be at once given their degrees or diplomas.

This would considerably increase the number of surgeons available in the present critical emergency, both for active service and hospital relief. Needless to say, all the candidates have received an up-to-date training, and have only come forward for their qualifying examination after their professors and teachers had been satisfied with their work.

TREATMENT OF SYPHILIS.

DR. J. C. MCWALTER, LL.D. (Dublin) writes: Replying to "J. L.," who asks for a treatment for syphilis other than salvarsan, I follow the advice of Neisser, who states it is important to combine several antisyphilitics in small doses for a long time, and I give 1 gr. each of sulphide of antimony, calomel, and quinine with a ¼ gr. of capsicum every night. This should be continued for six months with occasional intervals of a week; afterwards, small doses of potassium iodide for three months longer will complete the cure. Should any sequelae appear, minute doses of arsenic (Donovan's solution) will remove them.

THE SPECTROSCOPE IN TROPICAL MEDICINE.

FLEET SURGEON W. E. HOME, R.N. (Victoria, B.C., Canada) writes: Dr. Sorensen, a Dutch doctor at Flores, an island near Borneo, has published in the *Archiv für Schiffs und Tropen. Hygiene* a very interesting story showing the value of the spectroscope in medicine. He has to deal with a great many cases of malarial fever. He noticed in the BRITISH MEDICAL JOURNAL in 1908 that urobilin always appeared in the urine in cases of malarial fever. He got a spectroscope to show its absorption bands in urine that he might be able more quickly to diagnose his cases. He devised a method for estimating by dilution the quantity of urobilin in the urine, and on his scale the quantity was usually between 2 and 10. One day he found a case which showed urobilin 120. He examined the patient (who was being treated as an out-patient) more carefully, and found he was feeling pretty well but was slightly jaundiced. He thought a great haemolysis must be going on, suspected the onset of blackwater fever, and put him to bed. As the patient had had 15 gr. of quinine on each of the preceding days he was given no more. That night the patient began to suffer from haemoglobinuria, which lasted two days. It was only a slight attack, and the patient made a rapid convalescence, leaving the hospital in ten days to get married. Since that case Dr. Sorensen has seen 15 cases of blackwater fever, all slight—all detected by spectroscope before haemoglobinuria had occurred. None of them were serious as none got any more quinine; none caused any anxiety either to the patient or to his physician. There is added this dramatic history. Three days before Dr. Sorensen obtained his spectroscope a case of blackwater fever came up for treatment. That case died, as such cases so frequently do. The spectroscope has not done anything so striking in medicine before. Here it is not merely assisting in the clinical examination of cases but absolutely saving life, clearing up a much disputed point in pathology, the cause of blackwater fever, and preventing disease. If only other doctors in regions tormented by blackwater fever will repeat these observations, as they should, we may find we have secured by the spectroscope a great advance in tropical medicine.

EIGHTY-SECOND ANNUAL MEETING
OF THE
British Medical Association.

Held in Aberdeen on July 29th, 30th, and 31st.

PROCEEDINGS OF SECTIONS.

SECTION OF MEDICAL SOCIOLOGY.

JOHN GORDON, M.D., C.M., President.

DISCUSSION ON THE DUTY OF THE STATE TOWARDS THE EARLY ENVIRONMENT OF THE CHILD.

I.—W. LESLIE MACKENZIE, M.D., LL.D., F.R.C.P.E.,
Medical Member of the Scottish Local Government Board.

1. *Ante-natal Care.*—A few days ago, in answer to a question, the Prime Minister announced that the new grants for baby clinics and infant clinics would be in the control of the Local Government Board of each country. The grants for schools for mothers would be in the control of the Board of Education. The administration of the grants for maternity and pre-maternity has not yet been formally announced. It is now certain, however, that a considerable amount of imperial funds will be devoted to the ante-natal and post-natal care of infants and young children. At present no public assistance of any kind is available to the expectant mother unless she is destitute and sick. Maternity benefit under the Insurance Act is a birth allowance, not a pregnancy allowance. No doubt the sicknesses incidental to pregnancy entitle an insured woman to sickness benefit, but this is not the same as the care of pregnancy as such.

The case for ante-natal care is to be found in the reports of the various congresses on infant mortality; but it has been put with overwhelming force by Dr. J. W. Ballantyne in his paper on ante-natal causes of infantile mortality, including parental alcoholism, read at the first National Conference on Infantile Mortality (1906).[1] Recently the syphilitic factor has been emphasized. In Scotland two public authorities—the City of Glasgow and the Middle Ward of Lanark—have made arrangements for free application of the Wassermann test. Possibly other authorities have done the same. There are many other causes of infantile mortality that are capable of ante-natal prevention or mitigation: for instance, ophthalmia neonatorum. How far ante-natal prevention may extend can only be decided by experience; but some scientific ground for new proposals is now available in the infant mortality returns issued annually as part of the Reports by the Local Government Board. Detailed causes of death are now more elaborately classified.

It is, therefore, no straining of the facts to say that a great amount can be done to prevent sickness in the prematernal state, and that there is abundant need for consultation centres for expectant mothers. It may be hoped that the official application of the new grants, along with the service of the voluntary bodies, will result in an effective organization for ante-natal care.

2. *Birth.*—Up to date, the only statutory restriction on the mother is contained in Section 61 of the Factory and Workshops Act, 1901: "An occupier of a factory or workshop shall not knowingly allow a woman or girl to be employed therein within four weeks after she has given birth to a child." This affects only the workers in factories and workshops. The question has been raised whether the period of four weeks after a confinement of the mother is sufficient to safeguard the health of the mother and child. It is a further question whether a period of rest should precede confinement. This is a matter for expert discussion. Meanwhile, birth and the sequelae of birth are more or less safeguarded by the Notification of Births Act, including the notification of dead births. This Act has not been universally adopted either in England or in Scotland; but it has been adopted by local authorities representing a considerable majority of the population in both countries. The Local Government Boards have power to extend the Act by order to any locality, and there is a general agreement that the Act should be universalized.

Out of this Act has arisen the system of health visitors. In Scotland, probably the largest expansion of the health visiting idea has occurred in Edinburgh, where, under the general guidance of the medical officer of health, the work of the official health visitor is supplemented by the voluntary work of some three hundred women. Meanwhile, in England the registration of midwives has enabled the local supervising authorities to exercise some control over the management of birth. In Scotland no registration of midwives is yet enforced, but the bill for the training of midwives has already passed the House of Lords, and is about to receive its third reading in the House of Commons. These two Acts, combined with the general powers of the Public Health Acts, afford a basis for effective administrative control of the infant's environment at birth. The new grants-in-aid ought thus to make possible an effective system of dealing with the newborn.

3. *Health Visiting.*—In the organization of a health visiting scheme it is desirable that the statutory health authority should be the organizing nucleus of the voluntary organization: otherwise, the system is apt to be good or bad according to the enthusiasm or apathy of two or three individuals. No one would now think of leaving typhoid fever or small-pox, or even tuberculosis, entirely to the accidental presence or absence of voluntary service. But the care of birth and infancy is equally a national obligation. How best to fulfil the obligation will be a matter for discussion, but I have indicated the machinery now available.

4. *Infant Clinics and Milk Dépôts.*—Dr. McLeary's work with infant milk dépôts in Battersea and his book describing the system established a case for the infant milk dépôt. The Goutte de Lait and infant consultations of Paris, no less than the Coullet restaurants for nursing mothers, leave no doubt as to the preventive effects of careful preparation of milk and proper feeding of the nursing mothers. In one or two places milk dépôts have been dropped because sterilized milk tends to produce scurvy in the infant. This, however, is still a disputed point. Whatever be the final conclusion as to the destruction of milk ferments by heat, the question of the proper preparation of milk for infants is unaffected. It is certain that many mothers require better feeding and all infants require milk. It is equally certain that the uncontrolled milk market does not provide, on a sufficient scale, for the provision of clean and prepared milk. In Berlin an admirably organized voluntary service, working with the public bodies, does make a serious effort to meet the needs of the infant population. How far the effort succeeds I cannot tell, but in this country there is certainly room for development.

The problem of the crèche is incidental to the conditions of labour. If is a question worth discussing whether the crèche for children still at the nursing stage is not a direct cause in keeping down the wages of working women. Apart from this, however, which is a fundamental question, the crèche, wherever it exists, is an immense relief to the working women. It is a natural adjunct of the baby and infant clinics. It is simply the nursery of the working woman's home.

5. *Pre-School Age Clinics.*—The environmental dangers to children at the ages of 1 to 5 are very great. The relative immunity of the under 1 year infant passes away and the chances of infection are enormously multiplied. School clinics have shown that, in many cases, the defect or ailment discovered at entry to school is already old. It is at the pre-school age that prevention must begin. This has been demonstrated by Dr. David Forsyth at the Westminster Pre School Clinic. At present we do practically nothing for children emerging from measles, whooping-cough, chicken-pox, mumps, or any other acute infection. Equally, we are doing practically nothing, except through a voluntary hospital or clinic here and there, for the chronic ailments of children from 1 to 5. Rickets is not always or merely a post-natal disease, and when present, it tends to disappear as age advances. But we are doing practically nothing towards the prevention of the condition. This is partly due to want of adequate

knowledge, but partly to inappreciation of the social gravity of the disease.

Now that the local authorities receive 50 per cent. of their outlay for the treatment of tuberculosis, it is expected that tuberculosis in children in a short time will be well provided for. But the conditions predisposing to tuberculosis are of even greater importance to children. The public health authorities have power to provide convalescent homes for those recovering from infectious disease and reception houses for those exposed to infection. One may reasonably look for an increased use of those great powers. If the health authorities developed their present resources to the full, we might be able to prevent much of the aftermath of the so-called "minor" infections, such as whooping-cough and measles. In those diseases notification has been largely dropped, because the results were not considered adequate. This was probably because the machinery of the Notification Act is not easily adapted to such diseases. A system of notification could be devised that would, at less expense, enable the health authority to do all that a health authority can fairly be expected to do. With the full application of such powers as exist, it is legitimate to look forward to an extension of open-air holiday homes, open-air convalescent homes, and similar institutions for children below physiological par. This brings the child forward to the compulsory school age, when he passes under the control of the school medical inspection system.

6. *General Measures.*—The whole environment of the young infant benefits by the general activities of the public health authority. Primarily, the need is for a pure milk supply. At present the municipalities have no power themselves to provide such a supply. It is worth discussing whether they ought not to have such power. For the present they must work through the rough approximation methods of regulation and inspection of private persons and limited companies. The conditions of milk preparation and production are certainly improving: but the pace of improvement is not conspicuously rapid. Milk will continue to be the chief element in the food environment of the child. The milk bills now before Parliament will help the local authorities materially in protecting this food environment; but, for my own part, after an intimate experience of dairy counties, I am not persuaded that the present systems of milk production in this country are compatible with the best application of known scientific methods. But where the problems are so great we are glad to see the steady advance that legislation is making.

The infantile environment is also seriously affected by bad housing, overcrowding, and bad sanitation generally. It goes without saying that any good results from baby clinics, maternity consultations, or inspection at the pre-school ages, are conditioned by the steady maintenance of good sanitation, the clearance of slum areas, and such provision of good houses as will make an uncongested life in towns physically possible. It is difficult to lay down standards, and it is easy to dogmatize. But it is not much to ask that a house should be big enough for any three persons in it to pass each other in any direction without touching. There are thousands of houses in this country that will not fulfil that test. No doctor doubts the deadly effects of overcrowding on the young child. Why, then, should the child have to die in order to show that he needs more room?

REFERENCE.
[1] Report of Proceedings, P. S. King and Son, Westminster.

II.—THOMAS DEWAR, M.D.Aberd., D.Sc.Edin.,

Inspector to the Scottish Local Government Board.

THE significance of a death-rate depends upon the average age of the population. The death-rate at any given age can only be known if the persons of that age in the community can be counted or their number estimated. This necessary number becomes increasingly difficult to obtain with each year of age, and is only readily found in the first year of life because of the compulsory registration of births. Thus it is accident, as it were, that has brought to knowledge and then into notoriety the deplorably high death-rate among infants in general and among those born in squalid and congested places especially. In many areas in Great Britain (particularly in the poorer parts of the large towns) this mortality is as high as 20 to 25 per cent. No other domesticated animal has such a high mortality among its young or proves so difficult to rear.

At the age of 5 in this country ordered public life commences. Not until that age are children gathered together otherwise than voluntarily, incidentally, and at long intervals. The beginning of school life, then, presents the first opportunity for systematic investigation by the State of the mechanical condition and well-being of the bodies of her future citizens. Within a year or two of the commencement of medical inspection of children at school the facts and figures that were revealed, especially as regards parasites, decay of the teeth, defective sight and poor nutrition, were so startling as to affect powerfully the public mind. The first-fruits of that stimulus are already becoming ripe. Soon it was found that the evils thus brought to light were by no means so very hard to alleviate. It was found that communal cleanliness and the diffusion of elementary knowledge of the body mechanism and requirements could reduce the death-rate among infants by 20 or 30 per cent. within a few years; that, as a result of a combination of appeal to pride and threat of exposure or punishment, parasitic conditions of schoolgirls' hair were no longer almost universal in the elementary schools, or regarded as inevitable by the mothers of the sufferers, and that the preservation of teeth and the correction of refractive defects of vision were merely matters of expenditure and some co-ordination of effort.

Thus during periods, on the one hand, limited by the duration of the earth's orbital revolution, and, on the other, determined by consideration of the age at which gregarious instruction can be begun with any hope of profit commensurate with its cost, the physical condition of the child was taken under the aegis of various beneficent departments of State. But it soon became evident that the facts that our planet's orbit was so relatively short and the progress of the young of our species to mental maturity so relatively slow were no reasons why the State should withhold her care of the child from his first to his fifth birthday. And it was clear that, alike from the point of view of health and education, this period of the four years after the first was second in importance only to that which preceded it. For it is the truth that, despite the slow progress of mankind to maturity, the bulk of our education is completed before we reach the age of 5. If we doubt this, we have but to bethink us that the greater part of our time is spent in doing what we had learnt—and learnt not without labour and application—before we ever thought of school, and that we went to assemblies of scholars to receive only the finishing touches—the graces, the three R's, and the S's and T's—that is to say, the sciences and technical proficiencies that follow. True, those later acquirements bulk most in our own and in our neighbours' eyes. But though it is the capital that defines the column, it is the shaft that bears the weight and gives proportion to the edifice.

The period preceding the years of school time is no less relatively important from the point of view of health. The danger of acquiring those grave diseases that lead to premature death and permanent disablement or impairment of function diminishes with each year of the first decade of life, so markedly so, indeed, that the child who attains his fifth birthday with a well-nourished body, with no manifestation of rickets, no chronic catarrh of mucous membrane, no active or evident tuberculosis, and no sequelae of measles or whooping-cough or scarlet fever may be held to have successfully run the gauntlet of the larger part of the ills that threaten youth. So the duty of the State towards the child between the age of infancy and that of school is to secure that education and physical welfare go hand in hand, neither being allowed to gain at the expense of the other. Were these two things in any way mutually antagonistic or incompatible, health must have first place, for ground once lost in the physical race can rarely be regained, while if education be retarded, leeway can often be marvellously made up. But they are not incompatible; on the contrary, unless the environment be the best for the body of the child, it will be the worst for his education.

In Scotland, it may be mentioned parenthetically, the school attendance of children under 5 years of age has never been so common as in England and Ireland. In England, ten years ago, half a million scholars under 5 years of age were in regular attendance at school as enrolled pupils—that is to say, two-fifths of all the children between the ages of 3 and 5 years. Though the number has fallen since 1906 as a result of new regula-

tions, it is still very considerable. Whether the age of school attendance should be reduced to 2 or 3 years or raised to 7 depends on what we mean by school. If we use the word in the common or conventional sense, then 7 years, as in Canada, is quite soon enough. During the last forty years there has been a steady and in the aggregate a vast improvement in school conditions. The rooms are brighter and more spacious, are kept more clean, and are better equipped than of yore. But there is still occasional need in winter of more warmth, frequently a deficiency of light, and in almost every case not nearly enough of aëration. (To use the word "ventilation" in the etymological sense were mere sarcasm; whenever the wind is felt to enter, the window—again despite its etymology—is partially or wholly closed!) If you doubt the truth of this, go into any elementary school at noon on any day when the school is open in this city of Aberdeen; and if you find an atmosphere that is notably close, and within a few minutes actually oppressive in the schools of this admirably administered city, how much worse may you expect to find it in areas where things are less well done!

But if by school you mean a place where free movement of the pupils is not only permitted, but encouraged, where means of complete rest are provided when Nature calls for it, where there is no "ventilation" in the modern and artificial sense of the word any more than there is on the common or by the shore, there the child should be, there the parent should be encouraged to send him for part of every day, from the age of 2 or 3. There he will have the company of others of his own age, which, above all other factors, will draw out his faculties; there he will learn countless joyful things about size and shape and colour and number, about sound and surface and smell, without knowing that he is learning, and without learning (what he must inevitably learn in later years) that high culture and full knowledge can only be attained by toil. By his absence for a few hours a day, his mother will be freed to do her housework and so make a healthier home to which he will return, knowing, as she will, that he is safe from harm—indeed, much safer than were he under her very eye.

Five years ago, when engaged in devising and elaborating a scheme of medical inspection of school children for one of the larger counties in Scotland, I was constantly told, "You are proposing to do what the father should do; you are undermining parental responsibility." So, I doubt not, I shall be told again. I do not care. If, under the present régime, the best is done for the physique of the growing body, the drawing out of the expanding mind, so be it; if it is possible to do better, let no time-honoured tradition stand in the way. There will be ample time left for home influence, although the child goes to a play place for several hours a day. But are these little children really at home? In bad weather they may be cooped up in close and cosy quarters. But on fine days they are in the streets. I am aware that in the New Jerusalem the children are to be found playing in the streets; however that may be in Eastern cities, it is not suited to our conditions—neither wholesome for the children nor convenient for the traffic. We can surely provide better playgrounds than those paved with granite causeway or laid with tar macadam.

I am thinking chiefly of children above the age of infancy. Crèches, provided for children under 2 or 3 years of age, are primarily meant to supply better food and adequate nursing to those babies whose mothers, from ignorance or industrial necessity, cannot themselves supply these things. I am thinking rather of communal or aggregated education, in the form of play—play organized and directed amidst the best attainable surroundings. The essential idea is precisely that of the boy scout movement. The restless, inquisitive, alert minded, but sadly desultory and fickle boy is taken, is given a purpose, a direction, an incentive. Then the curious, restless, purposeless activity that led him into all sorts of odd places now leads him straight; and, instead of wandering in a zigzag or at best in a circle, he goes towards some fixed point, and either gets there or goes far on the way. So with children 2 or 3 to 5 or 6 years of age. There is so much for them to learn. It is vitally important that they should so learn it that the acquisition is readily available for ever after. Can we afford to allow children at that susceptible and impressionable age to pick up what they can at random?

A by-product of this voluntary association of children for a few hours a day on the kindergarten principle—or something like it—would be the possibility of medical inspection from a much earlier age than at present. All workers upon this subject recognize the need for this. The child must have a dry and airy and clean and wholesome home, and this is being secured for him. Within the last five years there has been a great awakening of public activity and public interest on this subject of housing.

The child must be ensured clean and uninfected milk. The passage of a Milk and Dairies Bill, and, when it becomes an Act, the sound and general enforcement of its provisions, will go far to secure a pure, clean, and wholesome milk supply for every family. There are other requisites: The provision of open play places in our crowded towns; the removal of persons infected with chronic infectious maladies from the homes in which children live (a safeguard already tolerably well secured in the case of the acute infections); the provision of hospitals like that of the Sir William Treloar at Alton, where children affected with grave disease of bones and joints may be taken away from their fellows and treated with a minimum of surgery and a maximum of air and care, with consequent hope of ultimate restoration to a useful and uncrippled life—these things are in the way of attainment. It is, therefore, to the infant school (English will suffice to describe it) that we must next turn our minds; towards its provision in all populous places that the State must next turn its hand.

III.—Mrs. Ogilvie Gordon, D.Sc.Lond., D.Ph.Munich, F.L.S.

ENVIRONMENT OF THE CHILD.

I propose to direct attention to certain features in the relation of the State to children during the years of their attendance at the public elementary schools and in the subsequent years of adolescence. I would especially advocate greater insistence by the State on the practical training of girls in routine duties of home life and in the intelligent handling of babies and young children.

The causes that militate against efficient training of girls are varied and complex, but we cannot blind ourselves to a few obvious facts: (1) That for a large proportion of our girls there is no pretence of a complete or consecutive course of practical training, either in the schools or in the home; (2) that the State at present sanctions a correlation of industry and education for children between 10 and 14 years of age which is a serious blot upon the nation; (3) that even when girls remain at school until 14 years of age, and are given some specific training in the domestic arts, experience shows that it is too often inadequate for the actual needs and conditions, or that it is forgotten by the time the girls marry.

The school and health authorities, and voluntary bodies working in co-operation with them, are agreed in recognizing the need of more extended and detailed training, and none know better than the medical profession the enormous asset to the home that the capacity of the mother may be.

The pity is, that so little can be done through the schools under present conditions of child labour. In England and Wales 40,000 children from 11 or 12 to 14 years of age are attending school and employed in part-time labour: in Scotland 200; in Ireland 3,600. In England and Wales 240,000 children give full day attendance at schools and are also employed out of school hours, in Scotland 34,000, in Ireland 30,000. Approximately 1 in 10 elementary school children in England and Wales are daily wage earners, and in Scotland 1 in 11.5. This does not include those children under 14 years of age who hold exemption certificates from school, and are in full day employment. Can we say to ourselves that we are giving those children a fair chance in life or that we are doing our best for the future parentage of the nation in allowing the continuance of child labour?

The premature wage earning of the child is excused on the plea of extreme poverty in the home, and it is true that we touch here on the deepest roots of the whole

problem, namely, the insufficient recompense for the labour of the parent, or the incapacity of the parent to render marketable service in the open field of industry. This factor has to be reckoned with in any legislative efforts and some way devised that shall save the energies of the children without inflicting undue hardship on individual families. It is becoming clearer, year by year, that the State, as the "ultimate parent of the child," exercises its influence naturally and inevitably through the schools, and that it is *this* influence which will have to be enforced as the chief plank in the improvement of the home and the early environment of the children of the nation.

It is matter of surprise and regret that Mr. Denman's bill before Parliament for the better regulation of child labour and the extension of the period of school influences should have received such a poor reception in the House. I would beg the members of the British Medical Association to throw their weight and influence into the work of arousing public sentiment, both upon the general question of abolishing child labour and upon the real need of affording to every girl an ample, carefully-considered training in household knowledge and the rearing of infants.

The only satisfactory remedy at hand for bridging the gap between the school-leaving and marrying ages is by enforcing compulsory attendance at day continuation classes for several hours weekly, say to the age of 16 years. The interest and discipline of such attendance could be rendered a help to the girl in many ways. What is of the utmost importance is that the methods and courses of instruction should be kept thoroughly pertinent to the intimate affairs of the home—how to clean, cook, and nurse, to take care of infants, and safeguard the health of the home. The Italians have a delightful name for such training—they call it "puericulture." We are beginning to call it "home-craft" and "mother-craft." In the new schools of puericulture that are rapidly being established in Italy, the doctors are the lecturers and practical teachers in the care of the infant and the first principles of help. What we aim at is the joy of the mother, the joy of the child, something still more precious than the capacity of the mother and the weight and proper feeding of the child. When the workman knows his craft he rejoices in it. There is little unhappiness in homes where the mother knows her craft, and the children are likely to be turned out neat and clean, well fed, and joyous.

Probably the rush into popularity of the cinematograph entertainments has served to open the eyes of large sections of the public to the present unsatisfied demand of youth for recreative interests and enjoyments. It has certainly shown to the country the grave moral dangers to youth that may be associated with unrestricted amusements, and has stimulated a few of the local authorities into making by-laws to disallow the presence of children after 7 or 8 o'clock unless accompanied by guardians. The difficulty is that there is no national enactment to standardize our protection of youth in this respect. Our legislators devolve this important responsibility, like many others, upon the local authorities without taking measures to make sure that these authorities deal with them.

The only Board of Film Censors that exists in this country is entirely voluntary, but surely the State should hold itself responsible for the moral tone of public places of amusement open to children. There is no point on which women feel more strongly than this. A mother may keep a pure home, the schools may teach what they like, it will be so much wasted energy and money unless some control is kept over public catering for children and young persons and means taken to prevent the vile and prurient, either in places of entertainment or in cheap literature and in picture postcards.

In Sweden sex hygiene is taught to girls in all the secondary schools for girls and in all the elementary schools, with the exception of a few in rural districts. Instruction is given usually by women doctors, occasionally by the teacher of biology or hygiene. It is treated as a special part in the course of instruction on temperance and health. In the public schools for boys the subject does not, as a rule, form part of the curriculum, but separate lectures are delivered to the boys by medical men, and in connexion with these lectures facts about venereal diseases are stated. From conversation I have had with some of the leading women teachers in Stockholm it is clear that they confidently expect the same success in raising the moral standards of the people as they have in recent years achieved in such remarkable degree for the cause of temperance.

The comparative freedom of public life and manners customary to girls in the northern countries of Europe is in a sense their pride, but all the more it appears to me desirable that we should give our girls, ere they leave school, clearly to understand the disadvantage and consequences to motherhood of personal strain, negligence, or excesses in early life. The teaching, if conducted on rational scientific lines, would be in a sense supplementary to the more personal tone of what is taught by parents. I take it to be the duty of the State to present in the schoolroom the standard of morality that is required of good citizens and to implant in the minds of youth an equal moral standard for boy and girl, man and woman.

The recent action of the State in establishing the Commission on Venereal Diseases is an acknowledgement on its part that social purity has an economic as well as an ethical value to the nation, and that social impurity is a source of decay and degeneration of the race and an economic loss to the nation. If this position is consistently and courageously followed up by statutory measures and purposeful administration through all the organs of public work, it is bound to be in course of time productive of highly beneficial results in the early environment of the child.

Progress might be more easily attained in matters relating to children and adolescents if the administrative machinery of the State were simpler. At present, all the great administrative departments of the State—the Boards of Education, the Home Office, the Board of Trade, and the Local Government Board—have some concern with the child, and there is no centralizing body to co-ordinate the work with a view to the best interests of the child and no unnecessary expenditure to the State. In the United States the Federal Government in 1912 established a Federal Children's Bureau as a permanent statutory authority to carry on a nation-wide study and control of the whole problem of child welfare. A woman has been placed at the head of this bureau, Miss Julia Lathrop.

There is no doubt that we suffer considerably from the lack of some central *ad hoc* authority to act as a clearing house to the efforts of State and local authorities on behalf of children. Take the want of continuity in the matter of medical inspection. In the pre-school period the children are not medically examined by any public authority; during the school period they are examined by the school medical officer, under the local authority and the Education Department, but the half-timers and the exempted children employed in factories or mines also come under the certifying factory surgeons of the Home Office system. After school age, the examination by the certifying factory surgeon is the only statutory examination for young persons, and covers but a small proportion. At 16 years of age the panel system of the National Insurance Act again picks up the great stream of the employed youth of the nation. It will be noted that at present serious gaps exist just in the susceptible years of early childhood, and again, in the most critical years of adolescence, between 14 and 16 years, and that there is overlapping in the case of a certain proportion of the school-going children.

The chief advantage of a central State authority would be to unify and standardize the methods of treatment of all aspects of child welfare throughout the whole country. We have seen the unsatisfactory results of permissive legislation, applied and enforced by a few local authorities and left a dead letter by others. There is in the womanhood of the nation a great force that has only begun to be tapped by voluntary work. The women who do not happen to be mothers are penetrated none the less with deep instinctive love for childhood. To these women as workers outside the homes, no less than to the mothers within the homes, the State may turn, secure of a hearty response and willing service among children in carrying out wise enactments for the betterment of the race and the upbuilding of character. But women are supreme in their care of detail, and we shall not be satisfied except with properly-planned, complete systems of legislation, that leave the least possible opportunities for leakage.

IV.—A. Rudolf Galloway, M.B., C.M., M.A.,
Ophthalmic Surgeon, Aberdeen Eye Institution; Lecturer on Ophthalmology, Aberdeen University.

THE EYES AND EYESIGHT OF CHILDREN.

Consideration of the care of the eyes of children may conveniently be divided into two parts—the first dealing with the pre-school period from birth to the age of 6 years, the second with the school period up to the time of selection of an occupation or profession. While certain diseases or other abnormal conditions affect both periods, such as conjunctivitis and errors of refraction, it is the case that their incidence, nature, and treatment differ with the periods in question, and they should be considered separately.

I. *Pre-School Period.*

(*a*) *Ophthalmia Neonatorum.*—With regard to this disease, which in its typical form occurs about the third day of life, it is gratifying to be able to state that the prophylactic measures which have been in fairly general use for a number of years have resulted in a great diminution in the number of cases (in my eye institution practice about 50 per cent.) and that the recent adoption of compulsory notification by many public health authorities, including Aberdeen, will probably result, if not in the total abolition of the disease, at all events in the prevention of loss of sight therefrom. When it is remembered that ophthalmia neonatorum is held responsible for over one-tenth of all cases of blindness in Europe, the result of such action by the medical profession, seconded by the State, must be considered most satisfactory.

With regard to the treatment of the disease, on the early initiation of which so much depends, notification has resulted in cases being recognized and brought for treatment earlier than formerly. Every case in which treatment is begun not later than the commencement of the purulent stage may be cured with retention of undamaged vision. The treatment, apart from frequent cleansing of the eyes, should consist in the careful painting of the everted and dried mucous surfaces of the lids with 2 to 4 per cent. nitrate of silver, and in the instillation of ½ per cent. drops of the same solution thrice daily. I do not think that any of the more recent silver preparations are nearly so efficacious as the old nitrate salt.

(*b*) *Other inflammatory conditions* which affect the pre-school age, such as conjunctivitis and blepharitis, seldom assume the severe forms of the later period. While under treatment such children should be kept as far as possible from contact with other children, more especially if any discharge exists, and they should not use the same towels, basins or handkerchiefs.

(*c*) *Glioma Retinae.*—During this early period a yellowish appearance in the pupil is occasionally noticed by the mother, and careful attention should be given to such a complaint, for in most cases the eye will require to be enucleated on account of the presence of a gliomatous tumour.

(*d*) *Squint.*—The pre-school age is the period for the development of the visual centres and of the fusion faculty, and at this stage any defect in the relative direction of the visual axes is likely first to declare itself. In this affection also the increase in medical knowledge and skill has resulted in a great diminution in the number of disfiguring squints which used to be in evidence in later life. Still, the advice is frequently given that squint in a young child should be left severely alone, although punishment for squinting has disappeared. It should be made more widely known among parents and guardians that the cause of squint in children is, in nearly every case, an error of refraction, and that the proper treatment consists in spectacle treatment as early as possible, or, before the spectacle age, in the compulsory use of the squinting eye by various means, and in practice of the fusion faculty by stereoscopic pictures.

II. *School Period.*

(*a*) *Refraction.*—The ideal condition would be that every child should enter school with normal refraction, or eyes corrected to normal by glasses. Failing this, symptoms of blinking, frowning, headache, holding work too close to eyes, should call for a complete examination of the refraction under a cycloplegic, a suitable correction being ordered. It is unnecessary for this examination that the child should be able to read, for no child should be allowed to read under 6 years of age. Illiterate types or pictures on Snellen's principle may be used, and any case with visual acuity of less than ⅚ should be carefully examined. A skilled retinoscopist may rely on objective correction alone, and may dispense with the use of any type or other subjective test.

There is no doubt that modern demands of education are harmful to the eyesight of the nation, and that the school developmental stage of the eyes is the period of onset and increase of myopia. Attention is, however, being given in many schools to measures tending to counteract the undue strain, such as desks and seats to ensure an upright position and proper distance of work from the eyes, also sufficient illumination of the schoolroom coming from the proper direction.

The smallest amount of myopia occurring during school life should be a warning that the eye is feeling the strain and should not only be corrected by spectacles, but a certain limitation of the amount of near work should ensue. Should the myopia amount to 6 D. or over, then near work should be continued only under special conditions such as obtain in the myope classes of the London County Council schools. Up to −10 D. or −12 D. such errors should, as a rule, be fully corrected, for I have frequently seen increasing myopia arrested and all symptoms of strain disappear by such treatment. Over that amount it is often impossible to order a full correction for constant use, although occasionally a case may be greatly benefited by the constant use of a full correction of −15 D. to −20 D. I have found it a good plan in cases of high myopia that cannot be fully corrected to order for constant use a correction which gives a visual acuity of ⅚. The treatment of a refraction case should not, however, end with the ordering of spectacles. These require revision at least once a year, for breakages occur, and the interpupillary distance increases and necessitates a wider frame. Records of corrections should be kept, and teachers should be encouraged to hold a periodical examination of spectacles to ascertain that all are in order, and even to test the axes of cylinders by means of a Geneva lens measure, for it often happens that after a breakage, cylinders are wrongly inserted, causing great discomfort during their compulsory usage.

Attempts have been recently made to place the spectacle treatment of school children in the hands of opticians. It is perhaps unnecessary in a meeting such as this to indicate the very many serious objections to such a proposal, and I am glad to say that the various educational authorities have, so far, fully recognized the futility of such a proceeding.

The recently instituted schemes of the various educational authorities in Scotland for the medical treatment of school children have already done much good. Children with high refractive errors—two in my own experience with myopia of 10 D.—who otherwise would have received no treatment, have greatly benefited from the use of proper glasses.

(*b*) *Inflammatory Affections.*—It is during school life that the various external inflammations, and more especially those accompanied by discharge, assume epidemic form. It should be strongly emphasized that any case with eye discharge should be kept from contact with other children. Neglect of this rudimentary precaution before school medical inspection was instituted resulted in the outbreak of an epidemic of contagious ophthalmia, due to Koch-Weeks bacillus, in Aberdeen schools, during which 7,787 cases were treated at the eye institution. Such cases, of course, should be excluded from school; but as a precautionary measure during an epidemic no hand washing or use of towels should be allowed in any school, and disinfectants should be used for the interior of the schools and the stair rails. Of all external inflammatory conditions phlyctenular or strumous ophthalmia is the commonest. Even slight attacks of this disease are very distressing to the patients, while severe forms of perforating ulcer may cause serious damage to vision, attended with little discomfort or pain. Therefore, during such attacks, school attendance should be stopped and careful treatment initiated.

(*c*) *School Hygiene.*—In the general interests of cleanliness and freedom from infection, slates should not be allowed in school, pencil and paper being preferable. Under 9 years of age fairly large type double pica—

should be used. Over 9 years pica type is sufficient. While the general school hours are, perhaps, not too long, there is a fairly general feeling that too many home lessons are given. The total time spent on home lessons should never exceed one quarter of the school attendance hours.

(d) Pigmentation of Eyes.—We are often asked to state whether brown or blue, dark or light eyes are the stronger. Although it is impossible to give a definite answer to this query, it is undoubtedly the fact that eyes with a deficiency of pigment are weak and defective. In Aberdeenshire we have a large proportion of the fair or red haired, and light or blue eyed children. For such the amount of illumination of schoolroom and lessons, suitable for normally pigmented scholars, is often too great. Where possible some attention should be given to eye pigmentation in school children,[1] for the action of light entering a pupil seems to cause a stimulation of the pigment cells of the retinal epithelium of the iris, and a transference of such cells forward through the iris stroma to break up into granular pigment on the anterior aspect of the iris. Where the amount of pigment is small, discomfort arises, symptoms of dazzling and headache supervene, sometimes nystagmic movements occur, and it is likely that permanent changes may result in deteriorated vision.

(e) Colour Perception.—As approximately 4 per cent. of all boys are congenitally colour blind, no boy should be allowed to leave school and select an occupation until his colour perception has been tested. It often happens at present that several years of a defective boy's life are wasted from neglect of this precaution—an occupation in which normal colour perception is essential, such as the navy, mercantile marine, or railway service, having been chosen. For school children this modification of Dr. Edridge-Green's bead test which I show may be used, but preferably colour perception should be tested by the exhibition of coloured lights such as are used in the services mentioned. I have constructed a lamp* on the recent Board of Trade principle of pinhole lights, which represents the masthead and side lights of a ship one mile distant. One, two, or three lights can be shown in fourteen different positions and combinations, and are such that no normal person could possibly mistake them, while the colour-deficient individuals display their defect much more surely and unmistakably than by Holmgren or other wool tests. In addition, no person with an uncorrected myopia of 1 D. or over, or an uncompensated hypermetropia of a similar amount, could pass the test.

V.—J. SIM WALLACE, D.Sc., M.D., L.D.S.,

Formerly Lecturer on Dental Surgery and Pathology, London Hospital.

THE DENTAL POINT OF VIEW.

GENERALLY speaking, a healthy individual is an asset to the community, and an unhealthy individual a burden. It is recognized in civilized countries that the abandonment of unhealthy individuals to disease or death cannot be permitted by the State, and consequently the burden of supporting and curing the diseased falls upon the healthy worker. The burden thrown on the community through dental disease has hardly been recognized until recently, for dental treatment has been provided only to a slight extent for those unable to secure dental treatment for themselves. The indirect results of dental diseases, for the treatment of which the State has provided, have not been recognized until recent years (except in dental circles) to have had a dental origin.

The financial loss to the community resulting from dental diseases is now recognized to amount to fabulous sums. The amount paid by the wealthy for dental treatment, even though it may amount to two or three million pounds annually, is small compared with the loss entailed on those who are unable to pay for dental services. Lack of dental treatment gives rise to vastly more suffering than the actual treatment entails. It is beginning to be recognized that the mouth is not only the chief entrance portal of disease, but also that, in order to restore health, attention must primarily be directed to the eradication of the diseased conditions which are so generally present in the mouth. Thus we read that "the National Insurance Act was brought into being for the purpose of providing the industrial classes with, amongst other things, a medical service, at any rate for the ordinary ailments of life. No provision was made in the Act for dental service, but if it came to the question as to which was more needful—a medical or a dental service—we would unhesitatingly affirm the latter to be more urgent."[1] This, be it noted, is a quotation from a recent leading article in a medical journal, not from a dental journal.

The financial loss to the community is not represented fully by the amount spent or the amount which might be spent on the restoration of the teeth and mouth to a fairly healthy state. It is now known that one of the most fruitful sources of disease is what is misleadingly called "oral sepsis." Moreover, there are quite a large number of common diseases which are concomitant with dental disease in their origin. And further, several diseases are seriously aggravated in their course on account of diseased states of the mouth.

It is recognized that the State must do something. As regards dental diseases it may pursue one of two courses. It may provide dental clinics all over the country for the treatment of the diseases of the teeth of children, but if it did so there is no reason why it should not likewise provide for the dental treatment of adults; and for from fifty to a hundred million pounds per annum this method of procedure could no doubt be carried out without serious loss to the community as a whole, for the benefit resulting from such treatment might, *if it were continuous*, more than out-balance the money expended. Nevertheless such a course may not be at all justifiable. It may be that another method exists which is capable of bringing about far more excellent results and that practically without the expenditure of any money at all. Prevention is infinitely better than treatment, and the failure to prevent the diseases of the teeth simply means getting money from the public or from individuals and placing it in the pockets of doctors, dentists and thousands of others whom the State does not consider fit to be called dentists although they may be practising the art. Now the State already recognizes its duty to *prevent* disease. Thus we read *inter alia* that the duties of the medical officer of health are as follows: "He shall inform himself, as far as practicable, respecting all influences affecting or threatening to affect injuriously the public health within the district. (2) He shall inquire into and ascertain by such means as are at his disposal the causes, origin and distribution of diseases within the district, and ascertain to what extent the same have depended on conditions capable of removal or mitigation."[2]

The State dictates, therefore, that it is the duty of medical officers of health to ascertain the causes of the diseases of the teeth, and to indicate how they may be mitigated or done away with. When it was believed and authoritatively taught that dental diseases were of a hereditary nature, obviously little action could be expected; when, moreover, the diseases of the teeth were generally regarded as of trivial consequence, time and energy spent upon ascertaining their causes could not reasonably have been insisted upon. Now, however, it is authoritatively agreed that dental diseases are preventable, and moreover that they are serious in themselves, and still more serious in that they lead so frequently to other diseases. Consequently the attitude which was taken up towards those diseases in the past is now no longer permissible, and it is the duty of the State to exercise such pressure as may be required on those whose duty it is to ascertain the causes, and in how far the conditions which have brought the diseases of the teeth into existence are remediable.

For at least the last ten years we have known in a general way how the diseases of the teeth are caused, and how they may be prevented. Authoritative statements as to this may be found in the recent textbooks on dental surgery,[3] and in the last three annual reports of the Chief Medical Officer of the Board of Education they are tersely summarized. Sir George Newman says: "It cannot be too clearly emphasized that by far the most important factor in the production of dental caries in children is unsuitability in the character of the diet provided from infancy onwards. The immediate cause of the disease is the accumulation about the teeth, particularly in the interstices of the teeth and in the interdental spaces, of fermentable carbohydrate material."

* Shown at the Eye Institution.

In other words, dental caries results from errors in diet. There has been in the past no recognition of the fundamental principle of dietetics which claims that food should be of such a nature or the diet so arranged that the mouth will be left physiologically clean after the meal is eaten. How such physiological cleanliness may be attained in a simple and efficient way has been worked out some years ago, and—as I have repeatedly indicated and tried to bring forward prominently in my recent book on *Dental Diseases in Relation to Public Health*—when the physiology of oral hygiene is properly taught, dental caries and consequent and concomitant diseases will soon practically cease to exist in all families which are brought up with reasonable care and intelligence. Similarly, in Dr. James Wheatley's annual report for 1912 as County Medical Officer of Health for Shropshire, we find the following sentence italicized:

Intelligent parents with the requisite knowledge can with a fair amount of certainty bring up their children so that they will have good teeth free from decay.

In the same report Dr. Wheatley says: "The need for a campaign to prevent the conditions above described is most urgent. Each year of delay means another 1,200 children in the county who will have at the age of 5 ten or more decayed teeth and about 1,800 children who will have five to ten decayed teeth. It is quite impossible by treatment afterwards to remedy this most disastrous start in life." Think what this means. There is no good reason to believe that the teeth of the children in Shropshire are worse than the teeth of children in the other counties of Great Britain; consequently, we calculate that annually something like half a million children commence school life crippled for life by disease in that part of the body which is *par excellence* the entrance portal of disease, and it is quite impossible by treatment to remedy this completely in after-life, even by the expenditure of millions and millions of pounds. I have referred to the important work which Dr. Wheatley has done. But what have other medical officers of health been doing? With a few exceptions we may say with regard to this subject that they have done absolutely nothing. Surely, since the prevention of dental diseases depends upon the diffusion of knowledge with regard to the physiology of oral hygiene, every medical officer of health ought to urge upon physiologists the necessity for them to study this subject and to teach it to medical students, for as it has been through lack of teaching of this subject that dental diseases have assumed the prodigious proportions to which they have attained, so it should be through the diffusion of knowledge from medical men that dental and concomitant diseases will be more or less completely eradicated.

Considering the fact that dental diseases are more prevalent in all districts than any other disease, it is obvious that every report of every medical officer of health ought, if their duty as already prescribed by the State is appreciated, to contain a statement with regard to the diseases of the teeth, summarizing as fully as may be expedient the etiology of these diseases in so far as it has been worked out and authoritatively recognized; or, if the etiology of dental diseases as currently taught by those in authoritative positions be not considered correct or sufficient, that a reasoned statement should be made for the setting forth of opinions which are not authoritatively recognized. Another way in which the State might, could, and should bring pressure to bear in such a way as to decrease the amount of dental disease is by insisting on the introduction into the examination for a diploma of public health of questions dealing with the physiology of oral hygiene. It is now so fully appreciated that oral malhygiene is a far more common source of disease than insanitary slaughter-houses or faulty drains, that evading the subject of oral hygiene seems to be an absolutely unpardonable neglect of duty. And thus it is obvious that oral hygiene ought to be regarded as a vital part of the curriculum for a public health diploma, or for a diploma in State medicine. I do not intend to refer to any action which the State might take through the medium of the school medical officer; however, if we may judge from the reports of the Chief Medical Officer of the Board of Education, and from the reports of school medical officers, it is obvious that the prevention of dental disease is within their sphere, if not for the child before entering school, at least for children who are in attendance there. For several reasons it is highly desirable that through the influence of the school medical officer the early environment of the child should be ameliorated. Again, as dental diseases are preventable, and since they are recognized as being important factors in the causation of many other and more serious diseases, it would seem desirable that the State should require that all medical students should receive some instruction in the elements of oral hygiene, for lack of knowledge of this subject has in the past caused more disease and suffering than lack of knowledge of the physiology of any other organ in the body could possibly have caused.

I do not know whether school dental clinics should be regarded as part of the early environment of children which it might be supposed was part of the duty of the State to establish. One thing is certain, however, and the ratepayers will in time insist upon it—that whatever measures may be taken by the State, the most efficient and the least expensive measures shall be primarily undertaken. Those who have gone into the subject at all thoroughly recognize this. Thus Sir George Newman says:

> If permanent results are to be expected as the result of the appointment of school dentists, it should be clearly understood that the work must be undertaken on the lines of a well-organized plan, the first condition of which is that the scheme shall be laid on a *preventive* basis. In short, school dentistry must be conservative and constructive rather than palliative. It may not unnaturally seem to some authorities that the obvious course to take is to deal first with the children presenting the grossest amount of defect. On account, however, of the great volume of work to be done, such a policy will be found to be quite impracticable, and its cost would be prohibitive. Again, on such a plan no effective action would be taken to reduce the work of future years. The place of the children treated for advanced disease will be taken by others in whom the disease, though at first slight, has in turn become extensive. Further, if the time of the dentist be chiefly occupied with these cases of extensive disease, treatment can be given only to comparatively few children, very little being gained by applying partial treatment only. It is clear, therefore, that whilst palliative treatment of this kind appears to make, at first sight, a humanitarian claim upon us, it lacks constructive value and, indeed, may easily prove ineffective and wasteful.[4]

It may be urged that the school dental clinic is relatively inexpensive, considering the amount of good which it might do, but recognizing that even expensive treatment among the wealthy has done absolutely nothing in the past to decrease the amount of dental and consequent diseases from generation to generation, it may be questioned whether expenditure for school clinics is justified, more especially since through other channels the State could without expense decrease enormously the unparalleled prevalence of dental maladies, and so aid in the greatest triumph over disease that the history of preventive medicine will probably ever record.

Discussion.

Miss Barron, who is a teacher in the Aberdeen Deaf School, discussed the position of deaf children. In their case the hereditary method of teaching language—the mother's method, so good that now science could not better it—of teaching language to a child from its mother's lips, was of no use, and she was face to face with a problem as bewildering as it was to her inexplicable. How was the mother to be helped to guide the groping mind of the child to self-expression? It was the first few years of a child's life which made or marred its character. Little deaf children had an instinct for speech, and this natural instinct ought to be seized and made use of for good. It would be of great value if, when a child was found to be deaf, compulsory notification of the fact could be given to the educational authorities. If for certain purposes those authorities could combine with the medical, access could be had to better means of confirming and even making the diagnosis, and some kind of language training could be commenced as soon as the fact of deafness was discovered. Nursery schools, with voluntary attendance and short hours, with necessary intervals for rest, might be universally

established. Periodical visits to homes by visitors trained to the requirements of the deaf child, and helpful suggestions to parents as to treatment would be beneficial. The advantages which would come by linking up the child's environment from birth with its school environment were incalculable. The years of the deaf child's life from birth to school age in most cases were wasted; if he could be procured certain definite conditions whereby those years could be intelligently utilized and turned to account, the problem of his after-education and his consequent economic value would be simplified considerably.

Dr. HARRY CAMPBELL (London) described the condition of the teeth of the people of these islands as appalling. He estimated that there were in great Britain 200 millions of carious teeth, as many pyorrhoeic abscesses, and 30 millions or more of root abscesses—all preventable. He rarely saw any one in his out-patient department with healthy teeth, and when he saw, on rare occasions, a young woman with healthy teeth he read her a little sermon and told her she ought to regard the loss of one of them as a serious thing, that she ought to read the Burial Service over every tooth she lost. He was afraid the north of Britain was as much to blame in this respect as the south. The cause was, of course, diet. The only sugar the primitive man had was wild honey, and the only starch was from the vegetable kingdom, and in a raw state necessitated thorough chewing. Not only did modern man cook starch, but he greatly increased the proportion of it in his dietary. Masses of starch were poured into the stomach absolutely unmasticated, and that was the cause of the ill-developed jaws which were so common. He had very little sympathy with Scottish porridge; it was very nutritious, but it did not necessitate mastication. The same criticism applied to the delightful but pernicious Scottish cakes.

Dr. HAMILTON (Hawick) agreed with Mrs. Ogilvie Gordon as to the duplication of authorities dealing with children and the need for a central authority. He thought Dr. Campbell had been unfortunate in his experience of Scottish porridge; also it should be eaten with salt, not sugar; with sugar it formed a compound most delcterious to the teeth.

Dr. W. E. HENDERSON (School Medical Officer for Westmorland) spoke of the overwork of school children outside school hours. The fathers of the children were clamouring for an eight-hours day, but there was no word of an eight-hours day for the children. It was a poor and mean thing to filch from children their childhood. Dr. Henderson described a scheme for practical instruction of girls in domestic duties and care of children for which the approval of the Board of Education had been obtained in Kendal after some difficulty. Although one heard so much about teaching girls in preparation for motherhood, nothing was said as to teaching boys the duty of fatherhood. The only man who was doing that was a soldier—Sir R. Baden-Powell. He regarded the scout movement as a great educational factor. It was not only educational—it had recaptured for the boy his sense of wonder, and was developing the fine faculties which were being crushed out of boys by life in the slums.

Dr. DINGWALL FORDYCE (Edinburgh) criticized the Scottish Local Government Board as not being administered as efficiently and economically as was desirable. He thought Mrs. Ogilvie Gordon had touched the centre of the problem with her suggestion of a central authority for children's welfare, and he was surprised that the opening papers had contained no suggestion of this kind.

Dr. THOMAS RUSSELL (Glasgow) expressed the view that there was a want of confidence in the administration of the body responsible for Poor Law work in Scotland.

The discussion ended in the passage of the following resolution:

> Looking to the present confused conditions of State, municipal and voluntary methods of dealing with children, this Section unanimously requests the Council of the British Medical Association to press for the development of a central bureau to have control over all matters relating to child welfare.

DISCUSSION ON MEDICAL CERTIFICATION OTHER THAN UNDER LUNACY ACTS.

I.—Mr. CONDIE SANDEMAN, K.C.

UNLIKE doctors, lawyers have to give reasons for their beliefs, and I propose to tell you why it is I say that doctors who sign their certificates under the Insurance Act run no practical risk: some lunatic might raise an action, but it would not go far or cost much. When a patient consults a doctor it is not exactly a contract. A relationship is established between them. Out of that there springs first the duty of confidence. This duty of confidence is not respected by the law courts because, though lawyers are privileged by other lawyers, according to the laws of the country they are not privileged. Accordingly judges sometimes order doctors to reveal a confidence.

There is no breach of confidence in telling a man himself what you think of him. More particularly, when a man asks you "What do you think of me?" there is obviously no breach of confidence in giving a reply, and the certificate under the Insurance Act, which has been carefully thought out, is addressed to the person himself.

The next relationship which arises is the duty of treating the patient carefully. The medical practitioner must have that duty because he warrants his skill. Every professional man does that; it is all the goods he has to offer, and he has to warrant it. But the warranty only carries him to the point of due care, and if a doctor exercises due care to the best of his ability then he could not be held liable. One does occasionally see actions against doctors for malpraxis, but they are very few.

Another duty imposed by the Insurance Act is that of signing certificates. If a doctor were to sign reckless, wrong certificates, that, I think, would really be a fraud, and he would be liable for damages (leaving slander out for the moment): he would be liable for damages for having given a fraudulent certificate, either intending to hurt the patient or because he had made a careless examination. In the latter event he would be liable for malpraxis but not for slander.

Coming to the law of slander, the law of Scotland differs from that of England. In England you may address letters to a man, and he has no action, because he has no feelings, but in Scotland it is different. Scottish people have sensitive, delicate feelings, and if you hurt their feelings you have to pay a solatium; it is generally about a farthing, but it means the trouble of litigation.

Any publication of a certificate is made by the man himself, and he cannot recover damages for any loss caused by his publication; he need not use it unless he pleases. He is reduced to the minimum (in Scotland) of having a chance to sue for injury to personal feelings; but to get that he would have to aver that the doctor knowingly and from malice aforethought had constructed this certificate (which the plaintiff must say was false) against his sober judgement and to injure the plaintiff. Who is going to believe that? I have seen judges highly credulous, but not to the extent of swallowing a doctrine like that. That action would cost very little; the speculative lawyer will not take up cases like that. It would cost him something, and he would have no chance of success.

Therefore I think I have made good my proposition that no legal risks attach to the signing of the certificate. I can vouch my hypotheses from books, and you may sign these certificates with perfect ease of mind as far as questions of slander are concerned.

II.—A. C. FARQUHARSON, M.D., D.P.H.Camb., Durham.

PROBABLY no other administrative detail arising under the operation of the National Insurance Act has been regarded as of greater importance than that of medical certification because of its importance in regard to the financial solvency of approved societies. A relationship is too easily set up in the minds of some between the giving of certificates by medical practitioners and the depletion, no matter from what other causes this depletion may arise, of the funds of approved societies. In other words, it is suggested that many of the difficulties which approved societies are discovering in the administration of the Act are due mainly to causes which are partly, if not entirely, under the control of medical practitioners. A medical

certificate in this way is almost to be regarded as a cheque drawn upon the bank of an approved society or the State in the expectation that the cheque will be duly honoured. The doctor, therefore, is at once placed in a position of great delicacy and not a little difficulty, in virtue of what I may call his dual relationship to the patient and the State. He is on the one hand the confidential and possibly sympathetic agent of the patient, and on the other, at least in some degree, the trustee of the State, and the difficulties which beset the path of the doctor arise chiefly from this relationship. Those of us who have had for many years professional experience of the Workmen's Compensation Acts know quite well the existence and influences of this relationship, and how it in essence makes the doctor the arbiter on many occasions in a money claim in which he figures both as the paid servant of the appellant and also of the respondent. The person claiming compensation is his patient, and the company from whom compensation is claimed may have the same doctor retained at an annual salary for the sole purpose of certifying as to the honesty and legality of the claim. You will see how easily in a situation of this character, where one man is the agent of two interests, which for the time being are in conflict, difficulties arise, and I suggest that a similar situation has been created under the Insurance Act. It is in our interest to retain our patients, and it is equally in our interest not to destroy nor aid in destruction of the agency through which we are paid. In numerous cases the situation presents itself to the doctor in this way: A patient comes to him without any very definite physical signs of illness but complaining of symptoms which are not capable of proof beyond the patient's word. The doctor is at once faced with the problem of either refusing a certificate and inferentially telling the man he is a liar, or giving a certificate without thought or regard of the honesty or legality of the claim made upon the approved society.

My experience of many years' work in the coalfields of the county of Durham is that this particular problem has been almost universally regarded by the parties over whom the certificate was legally operative as one to be settled by the doctor invariably in favour of the patient or claimant. Colliery owners in the matter of compensation for accidents and miners' associations in the matter of sickness pay appeared at times to almost vie with each other in acts of altruism towards claimants, and the medical certificate came to be regarded very often as a document of such ethical value that it was beyond question, and further, that when any cognate point was in dispute the production of a doctor's certificate one way or the other was regarded as the final and acceptedly binding word on the matter. This is not a fanciful picture, and I know that one very large society in Durham was severely lectured by the English Commission upon the point indicated in the foregoing statement.

However much one may approve of the altruism displayed on these matters, one must realize that it encouraged a certain degree of freedom and flexibility in which the doctor could feel that any necessity for rigidity or strict interpretation of the rights of parties did not rest with him. With the coming of the Insurance Act and the inclusion of large numbers of workers under a scheme constructed upon a narrow and strictly financial basis, the flexibility which I suggest existed in the matter of giving and accepting certificates must of necessity disappear. It was a simple and unquestioned act on the part of the executive of a prosperous trade union to make good from its general fund a deficit of £20,000 or £30,000 at the end of a year upon the working of the sick fund of the union, but when a similar act is required of the State on behalf of approved societies it is evident that it cannot be performed with such ease, and causes have to be sought for with a view to remedies. The altruism of the administrators of the old sick funds and the looseness of procedure observed in the administration of these are in my opinion greatly responsible for the attitude displayed by many members of our profession towards certificate giving since the operation of the Insurance Act. However that may be, it is, I am sure, becoming recognized by the vast majority of the profession that it is not to the good of the profession nor to the State that this looseness or flexibility of procedure should continue.

A universal rigidity of procedure is essential to the safeguarding of the rights of all the parties which arise under the administration of the sickness benefits of the Insurance Act. I am convinced that defects disclosed in the procedure which has up to now been adopted under the Insurance Act are responsible for much of the financial difficulties which we hear of as existing at the present time, and I may be permitted here to indicate one or two points which are in my view paramount. It may be stated as a broad and general fact that the zones of opportunity for insured sick to obtain what we may call the illegal sustaining of claims are to be found, first, in the first week, and, secondly, in the later or prolonged weeks of convalescence. My suggestion is that by the procedure which has existed up to now many an insured person has obtained one or two weeks' sickness pay when, by a different system of procedure, it could have been quite justly shown that the incapacity for work was only of one or two days' duration. Regarding the group of first week claims, no opportunity has been given the approved societies by the procedure hitherto adopted to investigate these claims until, in fact, the claim has matured and the first week has passed. The first essential in a reformed procedure, therefore, is that the earliest notification of the existence of illness should be secured to the societies. Means should be devised whereby the societies are given the opportunity of reviewing or checking the claims of sick persons within the first period in which the claim becomes established—an initial certificate or note from the doctor merely stating the fact of illness, with some symptomatic indication where a full diagnosis cannot be given, signed and dated for the first day upon which the doctor saw the patient. This initial certificate need not be regarded as an element or legal factor in the final establishment of a claim, but simply as a notification of illness which sets in motion any supervisory machinery which the society may have at command. Where the illness is a bona fide one and genuine incapacity results, a second certificate should be given within the week, and only the giving of this second certificate should be regarded in so far as the doctor is a party to the proceedings as establishing the legality and honesty of the claim.

Difficulties are at present constantly arising from post-dating and ante-dating certificates both at the commencement and termination of sickness, and many doctors seek discretionary powers in this matter. I am strongly opposed to any such, and feel that in the proper administration of the Act the existence of any discretionary power vested in the units of the system is dangerous in the extreme. The discretion of the honest practitioner so easily becomes the indiscretion of the less scrupulous practitioner—an indiscretion so often used against the honest man—that we as a whole are entirely better without it. The doctor in my view, no matter how much he may feel personally justified in putting such date as he thinks proper on the certificate, must remember that he is part of a procedure which does not recognize his right to give evidence for any other day excepting that upon which he sees and certifies the patient. It is for the patient to satisfy the society, by such other means as are valid, that he was incapacitated on some day or days before the date of the certificate. The doctor should not, under any circumstances, be expected, or in my view even allowed, to certify to anything of which he has not personal knowledge.

In regard to the second group of cases, which may be subdivided into chronic and convalescent cases, I do not think that quite the same degree of responsibility should be attached to our profession as in the first group. For the first group I think we should unhesitatingly accept the fullest responsibility, but in the second group the societies may be expected to share with us the supervision of these cases. In many of these, the nature of the illness, questions of misconduct, treatment in hospitals or other institutions, and other points complicate the situation and tend in a way to diminish or modify the control of the case which the general practitioner has in the early stages. In this group the effort of the general practitioner must be supplemented by at least two officials, and the combined view of these persons and the doctor becomes the determining factor in the case. These officials are: (1) The professional referee; and (2) the sick visitor. The functions of the professional referee we ought to regard with approval.

THE SERUM DIAGNOSIS OF PREGNANCY AND OF CANCER:

A CRITICAL STUDY OF ABDERHALDEN'S METHOD.

BY

ARCHIBALD LEITCH, M.B.,

PATHOLOGIST TO THE CANCER HOSPITAL, LONDON.

II. THE PROTECTIVE FERMENTS IN CANCER: CRITICISM OF THE THEORY.

In the practical experiments on cancer, though I have had an unusual amount of operative material at my disposal, yet comparatively little seemed to me suitable, for reasons that will be explained later, and in the tests here recorded I have restricted myself to those in which good cellular tumours were available as "substrates." I have not used *post-mortem* material. The details of 100 cases examined to test the method in the serum diagnosis of cancer are as follows:

In the first set of experiments three different *substrates* were employed: (1) A large protuberant, non-ulcerated squamous-cell carcinoma of the scalp, extremely cellular, with fine supporting fibrous tissue trabeculae, the tumour being easily washed free of blood and being almost dead white; (2) a very cellular spheroidal-cell carcinoma of the breast with a minimal amount of stroma; (3) placenta.

In Nos. 2 and 13 the blood was withdrawn less than four hours after the last meal. In all the rest, with the exception of the last three in which I have no notes on the point, the blood was withdrawn at the time of the operation when the patient was in a fasting condition. In no cases was the serum haemoglobin-stained.

This set of experiments is the most favourable I have found to the claims of Abderhalden. The 9 cancer serums all gave positive results with the epitheliomatous tissue—if anything, more markedly in the case of squamous-cell than in the other carcinomata—whereas the 12 non-cancerous cases were negative with the exception of the case of lipoma, and one might quite easily, if dominated by the claims made on behalf of the method, have made excuses for this solitary lapse by blaming the technique. Unfortunately for this, the experiment was repeated in duplicate again with the same results. The mammary cancer was not such a good *substrate*. It did not give as good results with the mammary cancer cases as did the epithelioma. With it 5 cancer serums were tested; 3 gave positive reactions, 2 were absolutely negative: of 5 non-cancer cases, 4 were negative, 1 was positive. With placenta, 8 cancer serums were tested, 7 gave positive reactions, 1 was negative; of the 7 non-pregnant, non-malignant cases 1 was positive. In all cases the serums were used fresh.

In four cases an epitheliomatous tumour of the tongue was used as a *substrate*.

TABLE B.—*Epithelioma of Tongue.*

	Disease.	Serum alone, 1 c.cm.	Serum alone, 1.5 c.cm.	Epithelioma + 1 c.cm. Serum.	Epithelioma +1.5 c.cm. Serum.
22	Epithelioma of tonsil ...	0	+	+	++
23	Syphilitic glossitis	0	0	0	0
24	Normal male	0	0	0	0
25	? Lupus of face	0	0	+	+

None of the serums was haemoglobin-tinted. All were used fresh. In Nos. 23 and 24 the blood was withdrawn shortly after a meal (fifteen minutes after in the case of No. 24); in the first case it was withdrawn at time of operation; in the last case over four hours after the last meal.

The *substrate* behaved in the first three cases just as we hoped. The last case was the crux of the whole examination. There was what was supposed to be lupus of the face, and there was an ulcerated patch that was not healing under *x* rays; and the practical question arose whether or not epithelioma was developing. The reaction pointed to this being the case. As a matter of fact, it was not so. The patient gave a positive Wassermann reaction, and the ulceration healed under salvarsan.

In the following twenty-six cases a large, quickly-growing cellular carcinoma of the breast, with axillary

49	Normal male	0	0	0	0
50	,, ,, ...	0	0	+	+
51	Normal female	0	0	0	0

Only in Nos. 32 and 44 was the serum haemoglobin-stained. In Cases 34, 47, 48, 49, 50, 51, the blood was withdrawn less than four hours after a meal; in No. 34 it was withdrawn during a meal, and the serum was the most turbid I have ever seen, but it gave quite negative reactions. In all the other cases the blood was withdrawn at the time of operation.

masses was used as *substrate*. It was very thoroughly washed to free it of blood. It required twelve boilings before the water was free to ninhydrin.

Case 38 was clinically considered to be carcinoma of the intestine, and a portion of gut was removed under that belief; the reaction was positive; histological examination showed it to be tuberculosis. On the other hand, No. 39—a small ulcer on the lip—was thought to be epithelioma; the reaction was negative and the histological examination showed it to be tuberculous. No. 40—an abdominal mass—was diagnosed as cancer; the reaction was positive; operation showed it to be a case of old peritonitic adhesions. No. 35 was an interesting case; it was clinically considered to be malignant; the reaction was positive; histological examination showed it to be quite benign in nature.

A large epithelioma of the tongue with large glandular masses in the neck was used as *substrate* in the following 14 cases:

TABLE D.—*Epithelioma of Tongue.*

	Disease.	Serum alone, 1 c.cm.	Serum alone, 1.5 c.cm.	Epithelioma, + 1 c.cm. Serum.	Epithelioma, 1.5 c.cm. Serum.
52	Epithelioma of tongue ...	0	0	0	0
53	,, ,, ...	0	0	0	0
54	Epithelioma of lip ...	0	0	+	+
55	Epithelioma of palate ...	0	0	0	0
56	Epithelioma of oesophagus	0	0	0	0
57	Advanced carcinoma of rectum	0	0	+	+
58	Advanced carcinoma of rectum	0	0	0	0
59	Syphilitic glossitis ...	0	0	0	0
60	Normal male	0	0	0	0
61	Tertiary syphilis	0	0	0	0
62	,, ,, ...	0	0	0	0
63	Intestinal adhesions ...	0	0	0	0
64	Chronic constipation ...	0	0	0	0
65	Tuberculosis	0	0	+	+

In none was the serum haemoglobin-stained. In Cases 57, 58, 60, 61, 62, 64 the blood was withdrawn less than four hours after a meal; in the other cases it was removed at time of operation.

The reaction was positive in only 2 of the 7 cancer cases and negative in 7 non-malignant cases, but it was positive in a case of tuberculosis (histologically verified) which was thought clinically to have been lymphadenoma.

A carcinoma of the breast which contained much blood, no attempt being made to wash it free, was used as *substrate* in 8 cases:

TABLE E.—*Carcinoma Unwashed.*

	Disease.	Serum alone, 1 c.cm.	Serum alone, 1.5 c.cm.	Carcinoma, + 1 c.cm. Serum.	Carcinoma, + 1.5 c.cm. Serum.
66	Cancer of breast	0	+	0	+
67	,, ,, ...	0	+	+	+
68	Cancer of uterus	0	0	0	0
69	,, ,, ...	0	+	0	+
70	,, ,, ...	0	+	0	+
71	,, ,, ...	0	0	0	+
72	,, ,, ...	+	+	+	+
73	Epithelioma of palate ...	0	+	+	+

In none of these was the serum haemoglobin-stained.

All the cases were advanced far beyond operability. Two of the very grievous hypothetical fallacies were purposely committed—the *substrate* was not washed free of blood and the blood in all cases was withdrawn soon after a meal. Two controls of non-cancerous serum were employed, but as they gave reverse results—that is, reactions with the serum tubes and none with the tubes of serum *plus* cancer—they were rejected. Nos. 65, 67, 68, 69, 71 (that is, 5 out of the 8) would be considered negative according to any method of reading the results, whilst the remaining 3 could only be considered positive by rejecting the readings of the tubes with the larger quantities of serum. As far as these tests go, there is no support lent to the idea that the two purposely-made mistakes of technique had anything to do with the false reactions; instead of these reactions being negative, they ought to have been doubly positive.

A rodent ulcer was used as *substrate* in 4 cases:

TABLE F.—*Rodent Ulcer.*

	Disease.	Serum alone, 1 c.cm.	Serum alone, 1.5 c.cm.	Rodent Ulcer, + 1 c.cm. Serum.	Rodent Ulcer, + 1.5 c.cm. Serum.
74	Rodent ulcer	+	+	+	+
75	Carcinoma of rectum ...	0	0	0	+
76	Furunculosis...	0	0	+	+
77	Syphilitic glossitis	0	+	0	+

In none of these was the serum haemoglobin-stained.

In the first two cases the blood was removed at time of operation; in the last two cases probably less than four hours elapsed between a meal and the time of venipuncture. The reaction gave three false indications out of four. The blood serum of the rodent ulcer did not show evidence of any ferment activity against the protein of its own tumour.

A cellular carcinoma of the breast was used as *substrate* in the following 8 cases:

TABLE G.—*Cellular Carcinoma.*

	Disease.	Serum alone, 1 c.cm.	Serum alone, 1.5 c.cm.	Carcinoma, + 1 c.cm. Serum.	Carcinoma, + 1.5 c.cm. Serum.
78	Epithelioma of tongue ...	0	0	0	0
79	Carcinoma of rectum ...	0	0	0	0
80	Epithelioma of bladder ...	0	+	0	++
81	Locomotor ataxy	0	0	0	0
82	Sacro-iliac disease	0	0	0	+
83	Renal calculus	0	0	0	+
84	Papilloma of rectum ...	0	0	0	+
85	Cholecystitis	0	0	+	++

In none was the serum haemoglobin-stained. In No. 81 the blood was removed less than four hours after a meal; in the others, all operation cases, it was withdrawn at the time of operation.

In the 3 cancer cases the reaction was positive only in 1, but it was positive in 4 out of the 5 non-malignant cases.

In another series (Table H) the serums were tested simultaneously against four different cancers: (1) a carcinoma of the breast; (2) an epithelioma of the cervix which it was impossible to free from blood; (3) a protuberant epithelioma of the vulva; (4) an epithelioma of the tongue.

With the mammary carcinoma *substrate* only 4 cancer serums out of 12 gave positive results, and all 3 non-malignant cases were positive; with the uterine cancer *substrate* 9 cancer serums out of 12 gave positive results, and 1 of the 3 non-malignant cases was positive; with the vulvar cancer *substrate* 4 cancer serums out of 12 were positive, and of the non-malignant serums 1 was positive; with the lingual cancer *substrate* 2 of the 12 cancer serums gave positive results, and of the non-malignant cases 1 was positive. The mammary cancer *substrate* only succeeded in picking out 1 of the 6 cases of mammary carcinoma, the uterine cancer *substrate* picked out 2 of 3 cases of uterine cancer, and the vulvar cancer *substrate* picked out the case of vulvar cancer.

Of these 100 cases tested to prove the worth of the method in the serum diagnosis of cancer, 51 are cancer and 49 are non-malignant. In the 51 cancer cases positive results were obtained in 28, that is, 55 per cent.; and in the 49 non-cancerous controls positive results were

None of the serums was blood-stained.

obtained in 18, that is, 37 per cent. The method, therefore, is without diagnostic value.

COMMENT.

It is necessary, in view of the adverse results here obtained, that contrast so strikingly with those of the brilliant and deservedly honoured originator of the theory and with those of his numerous disciples in all parts of Europe and America, to search out the factors that led to the amazingly mistaken claims, as I consider them to be, and to show as well as I can, that my own results are not due to errors of technique or to biassed misunderstanding. It seems to me that the theory originated from the readings of some preliminary experiments. It may be that those readings unconsciously exaggerated the facts; the fundamental observations were not made sufficiently indubitable for a great structure to be reared upon them: and the observer, having satisfied himself that a certain result was to be expected, and knowing exactly what he had to deal with when identical experiments were repeated, could not avoid obtaining readings similar to the original. If the repetition of the experiments was entrusted to a disciple, as it probably was in a busy laboratory, there would be the greater chance of the original views being substantiated. Whether or not that be an ungenerous supposition, the fact remains that the fundamental experiments do not cover a sufficiently wide field, and it is obvious that a great jump was made from serum reactions to substances quite foreign to the animal body, to serum reactions to substances natural to the body. The experiments with the serum of pregnant women, viewed through the eyes of the impelling theory, would at first seem to justify this jump. The same phenomena were found, and these were rendered all the more plausible since the serum of many non-pregnant individuals failed to give them. False results would crop up, however, as the number of the latter cases increased. Surprised at these, an enthusiast would seek causes for rejecting them. If all biological laws were as dependable as the movements of the stars, then there would be little scope for the making of errors, and research would be unromantically monotonous. The unexpected false results would be associated with some accompanying phenomena, and a causal relationship between them would be assumed, so that on the recurrence of false results and their accidental association with such conditions one would feel in a position to reject them. In the course of time other phenomena would be found in association with untoward results and again means would be found to reject them. This seems to have been the history of the Abderhalden reaction. Now it bristles with hypothetical fallacies that have well-nigh obscured the reaction itself. Let us therefore consider the real as well as the fictitious fallacies.

The Substrate.

From the point of view of the theory of the reaction the proper preparation of the organ or tissue that is to serve as substrate for the "specific proteolytic ferment" is of the utmost importance. In the case of placenta, and similarly with other tissues, the fresh organ is washed free of blood until a "snow-white tissue is obtained." Let it be said at once that such a result is impossible. The method I have adopted has been to remove the adherent blood clot, connect the umbilical vein with the water tap, and let the water flow through it for about two hours. At the end of that time the placenta should be practically colourless. The membranes are now removed, the placental tissue is cut up into walnut sized portions, and these are kneaded in frequent changes of salt solution for another hour. Thereafter, the pieces having been cut up into smaller fragments are put in running water for a few hours. As these pieces lie in the bath they appear to be quite white, but if they are taken in bulk and the water expressed from them it will be found that they still preserve, no matter how long or how thorough the washing, a faint colour, which, in the case of the placenta, is a low-toned white or pale ivory. Every tissue that I have tried preserves a faint tint proper to the particular organ, and a "snow-white" condition cannot be produced. It is specially difficult to get cancers free from blood. I have used only fresh operation material and though there has been a large stock at my disposal it is seldom that we can get tumour material exactly suitable. It is very doubtful if the presence of small traces of blood—or even very large amounts, for that matter—has anything to do with the false reactions. Even supposing we admitted the possibility of some obscure ferment in the serum capable of acting on the very minute traces of blood still left in the washed tissue, so as to give sufficient amounts of diffusible substances detectable with ninhydrin (a rather large supposition)—that is to say, giving a positive reaction where a negative reaction is to be expected—the hypothesis would not account for negative reactions where positives are to be expected according to the theory. I have obtained such negative reactions even in pregnancy. The tissue that is to serve as substrate is boiled in distilled water, to which a few drops of acetic acid are added, then for several times in distilled water alone, being well rinsed between each boiling, until the boiled water, which ought to be about five times the volume of the tissue, ceases to give a reaction when 10 c.cm. of it are boiled with 1 c.cm. of 10 per cent. ninhydrin solution. Any one may easily satisfy himself that even then the boiled water may show a violet colour when stronger concentrations of ninhydrin are used, and I have always gone on with the boiling until the water was colourless to as much as 5 c.cm. of the ninhydrin solution. Placental and other tissues vary very much in the number of boilings they require before they are suitable. I have

often noticed the curious fact that the boiled water may give a colour with weak concentrations and none at all with stronger concentrations of ninhydrin. The explanation of that fact is a question for chemists, but it is a point to bear in mind that ninhydrin may fail to detect the presence of protein products simply because it is too strong, just as it may also fail to detect them because it is too weak. I have further observed that the water of the tenth boiling of a tissue, for example, may be colour-free to ninhydrin, whilst that of the twelfth may give the reaction. Once having got the water colour-free, if the tissue be allowed to stand, colour reactions may be obtained after varying periods of time, sometimes within a few hours. Some tissues seem to be very unstable in this respect. The ninhydrin reacting substances found in the boilings of tissues are diffusible through the dialysers, and even though we test the tissue immediately before use, as we always do, we may be sure that there is always a certain amount of diffusible substances from our substrate—apart from any other factor—capable of contributing to the result.

One of the hypothetical fallacies that Abderhalden has recently detected is that the connective tissue in the organ acting as substrate may itself be attacked and broken down by some intruding ferment: there may be some lesion of the connective tissues in the individual who furnishes the serum. This reduces the reaction to a farce, for there is no organ devoid of connective tissues and no organic disease incapable of implicating them. Besides, the latest method he adopts in the preparation of his substrates—the pounding of the tissues in a mortar—is calculated to get rid of as much parenchyma and to leave as much connective tissue as possible. The great difficulty in the preparation of cancerous material is to get rid of the blood and yet to leave the cancer cells in their connective tissue stroma. The more cellular the cancer the more easily are these cells removed by washing, and the fact that the connective tissue stroma renders the blood vessels of a malignant tumour so exceedingly tortuous militates against the freeing of the tissue from blood. In this case there are only two ways of getting suitable substrates—either to cut very thin slices of the tumour, running the risk of losing the epithelial cells, or to reject tumour after tumour until we light upon something suitable at last.

It has been imagined that in the case of a blood effusion a ferment will be elaborated against the corpuscles of that effusion, and consequently, if any tissue employed as substrate should contain some blood, then the serum of that case would in these circumstances be capable of giving a false reaction. I have already pointed out that I could find no evidence of this in experiments on rabbits. I have, however, used as substrate pure blood clot, boiled free of ninhydrin-reacting substances, and tested this with fifteen serums, one of these being from a case of cerebral apoplexy, and most of the others from cancer cases in which local haemorrhages were evident, with the result that in no single case was there the slightest suspicion of a positive reaction. Again, a piece of cancerous tissue—a mammary carcinoma—containing much blood was forthwith boiled without any preliminary washing, and tested with various serums; it neither picked out all the cancer serums nor gave reactions with all the non-cancerous; it merely behaved, or misbehaved, as other substrates scrupulously prepared according to the regulations.

But whatever theoretical objections be brought against the reliability of the substrates that I have used, whether it be that they were not absolutely snow-white, that they still held in spite of our care minute traces of blood, that they were too unstable, or that they contained connective tissue, the criticism quite loses its points if we can get false reactions with "substrates" that are beyond suspicion. I tried, therefore, as "substrates" pieces of sterilized sponge, kaolin, and glass wool. In this way 39 serums were tested; I obtained 7 well marked positive results. Recently Plant[1] has also obtained positive results where he used as "substrates" kaolin, barium sulphate, talc, and *Kieselguhr*. Like him I have also noted reverse effects (that is, reactions of the controls without substrate, and no reactions with the serum and substrate) in some cases, but the same thing has occurred several times in the ordinary procedures. It will hardly be argued by the most ardent believer in the *Abwehrfermente* theory that protective ferments are elaborated within the animal body capable of splitting up into peptones or amino-acids such substances as sponge, glass wool, and kaolin. Without for the moment denying the occurrence of specific protective ferments in the serum, I am convinced that the important point in the reaction is that the substrate, owing to its physical nature, splits up the serum, and not so much the serum that splits up the substrate.

The Serum.

In all cases I have withdrawn at least 20 c.cm. of blood from the median basilic or cephalic vein direct into sterile centrifuge tubes. The blood is allowed to clot spontaneously, and the serum removed after a few hours or immediately by centrifugalization; it does not matter which. Some serums, even from normal cases, are haemoglobin-tinted on each occasion on which we examine the blood; it seems to be a healthy abnormality. We do not know the reason of this. Abderhalden has insisted from the beginning that haemoglobin-stained serum should not be used, as the presence of haemoglobin indicates that the corpuscles have broken up and shed into the surrounding fluid their endocellular ferments, some of which are bound to be proteolytic. Either this is a purely hypothetical objection, capable of substantiation or otherwise, or it has been invoked to discount false positive reactions, and, as haemoglobin-tinted serum is not uncommon, a relationship between the two has been drawn. The mere presence of haemoglobin does not give rise to reactions in the dialysate. I have carefully noted the behaviour of haemoglobin-tinted serum in over 20 cases, but false positive reactions did not seem to be as frequent in these experiments as in the case of normally coloured serums.

Another point on which Abderhalden lays stress is that if the blood be withdrawn from a patient within four hours after a meal, the serum may produce false positive reactions. This, again, is a hypothetical objection, and by means of it one is enabled to explain away most of the adverse results. It may be said that the blood after a meal contains fugitive proteolytic ferments, or that there is a temporary accretion of free amino-acids. It is probable that the latter is true. Indeed, Costantino[2] has shown that the blood of fed animals contain more amino-acid (formol-titratable nitrogen) than the blood of starved animals, but he found that the excess was anchored to the corpuscles, and was not free in the plasma. Even supposing the presence of amino-acids in the serum had something to do with the production of colour reactions in the dialysate, yet a positive reaction is not reckoned by a mere presence of colour in a single dialysate, but by the comparison between the colours given by a test and by its controls; and the factor would be equal in both. I have always noted the relationship to time of last meal, and a consideration of the tables will show that the hypothesis does not hold good in practice. Still, whatever objection there be to the usage of serum taken from a patient who is not in a fasting condition, it must be admitted that it is well-nigh impossible to amass any large number of observations under such ideal circumstances. Our habits are such—and this applies to Germany at least quite as much as to this country—that seldom more than four hours elapse between meals of some sort, except when we are asleep, and any investigator would have little else to do who attempted to obviate the hypothetical fallacy. I have been fortunate in complying with the requirements in the great majority of my cases, for the blood was removed at the time of operation, when a minimum of six hours had intervened since the last meal. I have, on the other hand, examined blood taken actually during, or shortly after meals. It does not seem to make the slightest difference.

If a number of serums be tested, using dialysers of apparently equal permeability to peptone, it will be found not infrequently that the dialysates react to 0.2 c.cm. of ninhydrin solution—that is to say, they allow some constituent of serum to pass through in sufficient amount to be detected in the ordinary way. Other serums, again, do not give sufficient quantities to be detected with 0.2 c.cm., but if one tests the dialysates in these cases with slightly larger amounts of ninhydrin, it will be found that in practically every case some reacting substance has diffused through. This shows that serums, though varying in their content of diffusible ninhydrin-reacting substances, always furnish a certain

amount to the dialysate. If we dialyse against running water for several hours the serums which previously gave large amounts of reacting substances to the distilled water, and finally dialyse this again against distilled water, we shall find that this dialysis against running water has not succeeded in wholly removing, sometimes not in appreciably diminishing, the diffusible substances. This shows that the serum is not a stable material, but is splitting up progressively; it is partly an inherent characteristic of serum, and is partly due to the action of the distilled water.

The Dialysation Tubes.

Specially prepared dialysation tubes for the reaction are supplied by Schleicher and Schüll, No. 579A. These are supposed to be impermeable to protein, but permeable to peptones and other degradation products of proteins, and, though they are sold as having passed the tests, it is wise to satisfy oneself on the point. In the first consignments it was found that a fairly large percentage were permeable to protein, but in the more recent comparatively few failed to pass the tests that Abderhalden demands. They must be subjected frequently to these tests during the course of the experiments, and if the dialysers be numbered and at any time one is found faulty the cases in which it has been used since it last passed the examination will have to be rejected. In testing for the impermeability to protein, 2.5 c.cm. of a 5 per cent. suspension of fresh egg albumen are added to each tube, and this is dialysed against 20 c.cm. of distilled water for sixteen or more hours, and the dialysates are tested for the biuret reaction. If the reaction is positive the corresponding tube is rejected. It is very difficult, if not impossible, to be certain of detecting weak biuret reactions, and in every case I have repeated the test of the dialysate with ninhydrin. It is true that the two methods do not give strictly comparable results. It is considered by Leonor Michaelis and v. Lagermarck that the biuret reaction is not to be depended on, at least when performed in the way that Abderhalden recommends. They assert that they can in the same way obtain biuret reactions with distilled water, and they recommend the test of the dialysate with sulpho-salicylic acid.[3]

The second requisite is that they be permeable to peptones and all equally permeable. If we test a stock of dialysers with silk peptone, which is supposed to be a pure peptone, boiling the dialysates with 0.2 c.cm. of ninhydrin solution, we shall find that differences in depth of colour may be made out, showing that they are not uniformly permeable, and we must reject the extremes. The differences in permeability can be shown much better by using Witte's peptone, which is an impure peptone. The individual differences are very marked, and it is practically impossible to get a large series of absolutely comparable dialysers. At first sight it might be thought that by taking a large stock of dialysers, and by estimating the depth of colour in the corresponding dialysates by means of a colorimeter, we might arrange our dialysers in order of permeability. Unfortunately this is not satisfactory for the reason that the actual colours, as well as the tints, differ, and no strict comparison can be made. What is more important is that the permeability of any single dialyser is not constant; it decreases or increases by use; and what are to-day strictly uniform tubes exhibit in the course of time various differences. We may gain an idea of their variation by numbering them and observing the results they give with serum from time to time. The differences between them can be brought out, too, by testing a small batch with one serum and noting the depths of the colour reactions of their dialysates with increased quantities of ninhydrin. We have, therefore, to take into account two factors affecting the reaction, namely, that with uniform dialysers different serums vary in the amount of diffusible substances and that with a single serum dialysers vary in the amounts of ninhydrin-reacting substances they allow to pass. The only way, therefore, to be sure of obtaining reliable readings in practice is to manifold the tests and controls as far as the quantity of serum permits, and to strike a just average. I have never depended on single tests; they are worthless. It will sometimes be found that the dialyser containing substrate plus serum gives to the dialysate a less amount of ninhydrin-reacting substances than the dialyser containing serum alone. Such results and dialysers must in kindness be rejected before giving an opinion on the diagnostic value of the reaction, but must be borne in mind when considering the worth of a theory that relies for its substantiation on such fickle means.

The following is a typical experiment out of several that will show how positive reactions may come about:

The serum used was from a non-pregnant female. The placental tissue was boiled repeatedly until the water was colourless to 2.5 c.cm. of ninhydrin solution. The dialysation tubes were chosen as being as nearly uniform in their permeability to silk peptone as it was possible to judge from the depth of colour which their dialysates gave with ninhydrin. All the tubes were incubated for sixteen hours in the usual way, and thereafter each dialysate was boiled with 0.2 c.cm. of ninhydrin, the resulting colour was noted, then a further 0.2 c.cm. of ninhydrin was added, the test tubes again being boiled, and once again this procedure was repeated.

Tubes 1, 2, 3, 4, 5 contained equal amounts of placenta with 1.5 c.cm. of normal saline solution only. The dialysates remained quite colourless to as much as 3 c.cm. of ninhydrin solution, so that here apparently we may rule out of account any contributory factor from the placenta alone.

Tubes 6 and 7 contained 1.5 c.cm. of the unheated serum only. With 0.2 c.cm. of ninhydrin the dialysates were quite colourless; with 0.4 c.cm. both gave an equal faint golden colour; with 0.6 c.cm. both gave a light violet colour, more marked in No. 7 than in No. 6. Taking the weaker as an arbitrary standard for the colorimeter, and giving it the value of 1, the depth of colour of No. 7 would be represented as 1½.

Tube 8 contained 1.5 c.cm. of unheated serum along with placenta. With 0.2 c.cm. of ninhydrin the dialysate gave just the faintest grey tint; with 0.4 c.cm. a deep violet colour was produced; with 0.6 c.cm. the colour was very deep. The colorimetric value was represented as 9.

Tubes 9 and 10 contained 1.5 c.cm. of heated serum only. With 0.2 c.cm. of ninhydrin the dialysates were colourless; with 0.4 c.cm. a light violet colour was produced in No. 9, and a golden colour in No. 10; with 0.6 c.cm. No. 9 gave a marked violet colour—represented by the value 6—and No. 10 gave a light violet—represented by the value 1½ on our empirical scale.

Tube 11 contained 1.5 c.cm. of heated serum along with placenta. With 0.2 c.cm. of ninhydrin the dialysate was colourless; with 0.4 c.cm. it was a faint lilac; with 0.6 c.cm. the colour was violet and the colorimetric value was represented by 2½.

This experiment serves to illustrate the facts that apparently uniform dialysers vary very much in permeability when actually tested with serum, that all allow some ninhydrin-reacting constituent of serum to pass through; that the heating of the serum does not abolish, though it may diminish, the liability to spontaneous cleavage, and that the reaction is not a quantitative one. That dialysers are liable to allow a certain amount of diffusible substances from serum to pass is practically, though not actually, admitted by Abderhalden himself, seeing that he lays such stress on the equal boiling of the dialysates. We may gain an illuminating insight into the fallacies of the method by performing the following experiment suggested by certain observations of Frank, Rosenthal, and Biberstein.[4] Into one dialyser let us put the substrate alone, and into another the specific serum alone, and dialyse them in the usual way, and we shall probably find that the dialysates in both cases do not give reactions with ninhydrin in the usual concentration. But let us, at the same time, put *two* dialysers, one containing substrate only and the other the serum only, into the *same* container, and we may find that in this case the dialysate gives a good violet colour with the usual amount of ninhydrin. This excludes the possibility of the operation of a ferment, and shows that the result is due, in this case, to the summation of two effects which by themselves were not capable of detection.

The conclusions to which I have come after a careful investigation of Abderhalden's dialysation method are that the real fallacies of the technique are beyond control, and that the hypothetical fallacies which Abderhalden invokes to account for false reactions have no bases. Positive results are quite well accounted for by the facts that the "substrates" alone, and the serums alone, give diffusible substances reacting with ninhydrin; that the dialysers vary enormously in the quantities of such substances which they allow to pass in a given time; that serums, influenced by the distilled water and by the presence of a tissue acting in virtue of its physical state, are pro-

gressively cleaved; and that it is not the substrate which is split by the serum so much as the serum which is split by the substrate. These very real fallacies quite destroy the value of the method, and they cast grave doubts on the whole theory.

But it may pertinently be asked why we obtained such a large number of positive results in the serum of pregnancy in comparison to diseased conditions. As I said before, I may have been unconsciously generous to an attractive theory in my reading of the reactions, but I do not attach much weight to that explanation. It may be that pregnant serum more commonly possesses the property of being split up when some suitable physical accessory is added, such as placental tissue. But what seems more probable, and in saying this I do not detract from the general criticism nor give support to the theory of Abderhalden, is that there exists in serum, more frequently, though not exclusively, in pregnancy a *general* proteolytic and peptolytic power which we can demonstrate by adding a *suitable*, though not necessarily a *specific*, protein or peptone. The serum of the normal guinea-pig is generally credited with a fairly strong proteolytic power. I tested the action of several guinea-pig serums on egg albumen, coagulated cancer tissue, human blood clot, and human placenta, and it happened that only with the latter were strong reactions evident. That seems to show that placental protein is a suitable substrate for the demonstration of a general proteolytic power. Pincussohn and Petow, in the experiments previously cited, found that the normal serum of each species of animal had a peptolytic power against the muscle peptone of that species only, whereas the serum of the guinea-pig had a peptolytic power against the muscle peptones of all other species tested. We may thus even admit that more in pregnancy than in other states the human serum may have a proteolytic and peptolytic power against the proteins of human tissue more than against other proteins; even that certain proteins, owing to their physical configuration, are more suitable than others for a demonstration of these enhanced powers; and yet we may condemn Abderhalden's whole theory of specific guardian ferments.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

OXFORD AND READING BRANCH.

THE annual meeting of the Branch was held at Reading on July 23rd under the chairmanship of Sir WILLIAM OSLER, Bart., President.

Cases.

The following cases were shown in the out-patient department:—Dr. W. T. FREEMAN: Parasyphilis with nervous symptoms; fibroid phthisis, with skiagraph; a heart case with abdominal tumours. Dr. G. F. MURRELL: Two cases (brothers) of congenital absence of fingers and toes with marked family history. Drs. G. O. LAMBERT and G. S. ABRAM: Aneurysm of the aortic arch. Dr. E. P. CARMODY: A case suggesting pituitary disease. Dr. E. W. SQUIRE: Webbing of the second, third and fourth fingers of each hand. Dr. E. P. CARMODY: Enlargement of forearms and hands.

Specimens in the Pathological Laboratory.

Dr. R. DONALDSON showed chorion-epithelioma of testis, primary carcinoma of liver (child aged 3 years), epitheliomata of tongue and hand, sarcoma of calf's kidney, and various other interesting specimens. Dr. J. L. JOYCE showed a gall stone which caused intestinal obstruction in the small intestine. There were also a number of photographs of skin cases and skiagraphs of surgical cases.

Discussion on the Cases and Specimens Shown.

The cases aroused great interest. The case of abdominal tumour with a peculiar cardiac thrill and bruit was thought by some to be a primary abdominal tumour with deposits in the myocardium. The heart condition had developed quite recently. Dr. Collier had examined the blood there and then, and had excluded spleno-medullary leukaemia. The cases of absence of fingers and toes showed a marked family history. All the four children of the father were similarly affected; the father was affected and earned his living by mowing golf greens, and his mother was also affected. The case—a male, aged 40—showing bilateral enlargement of the hands and forearms, with wasting, especially of the deltoids, spinati and pectorales muscles, was thought to be probably of pituitary origin. It was agreed by several members that the cases were of unusual interest and well worth coming from Oxford to see. Dr. R. Donaldson, the pathologist, was heartily thanked for the series of specimens.

Organization of the Clinical Laboratory.

Sir WILLIAM OSLER addressed the meeting on the organization of the clinical laboratory. He pointed out the impossibility in many cases of arriving at a diagnosis without a laboratory. The great defect in the present state of medical practice was the lack of facilities for carrying out the clinical methods learnt before qualifying. He regretted that the curricula in the medical schools were so crowded, and thought that in the third, fourth, and fifth years each student of medicine should have his own desk in a laboratory, and be completely equipped with apparatus which he could use to investigate his own cases. This method was being followed in the United States. Again, although great advances had been made in the furnishing of large hospitals in populous centres during the last fifty years, the growth of facilities for laboratory work had not been commensurate. There were still many hospitals in Great Britain of two or three hundred beds in which a surgeon was unable to get a section of a tumour cut for examination. A large building was not necessary for this purpose, but a budget was quite essential. The staff should consist of a whole-time man specially trained in microscopy and bacteriology, and a whole-time chemist would be a great advantage. Then again a special man was required for the very important work of electro-cardiac investigation. Hospital committees must be taught that these things were costly, but worth paying for. Sir William Osler said that he realized how difficult it was to conduct a general practice and still keep in touch with advances in medicine. The general practitioner might do his work very well, but he had not the time nor the special training necessary for research work; a research worker was urgently required in every centre of moderate size. He thought no general practitioner should send a specimen of urine away for another to examine. The Government was seriously considering the establishment in each centre of a laboratory for use by the general practitioners. He thought it would be best placed in connexion with a hospital, and that its use and the right to obtain a second opinion should be free of charge. He thought the salaries of the research men should rise with experience, and that "blind alley" posts should be carefully avoided.

A discussion followed, in which Drs. J. B. HURRY, W. COLLIER, G. C. TAYLOR, G. F. MURRELL, H. A. WHITELOCKE, and W. L. WAINWRIGHT took part; Sir WILLIAM OSLER replied.

Carcinoma and Radium.

Dr. HOLDEN read some notes on a case of carcinoma of the œsophagus treated by radium under Mr. Pinch. The growth had diminished in size, so that more food of thicker consistency was being taken and the general condition of the patient had improved, whereas the patient would, apart from gastrostomy, have otherwise died. The cost was roughly £30.

Annual Dinner.

The meeting then closed, and members repaired to the Caversham Bridge Hotel for the annual dinner.

THE Dean of the Royal Dental Hospital of London of the School of Dental Surgery, Leicester Square, W.C., announces that the next award of the Storer-Bennett Scholarship will be made early in 1915, and theses should be in the hands of the Dean by December 31st, 1914.

British Medical Journal.

SATURDAY, AUGUST 15TH, 1914.

THE WAR.

THE response of the country to the great emergency has been worthy of our traditions. Men of all ranks and classes and occupations have come forward quietly and promptly to fill their places in the Royal Naval Volunteer Reserve and in the Territorial Force. We are proud to know that the members of the medical profession have been not less ready than the rest, and that the special responsibilities thrown upon the profession in every town and district have been met by prompt concerted action. Within the last week many hundred medical officers have left their civil practices to do military duty with the divisions of the Territorial Force, and many others are busily engaged in organizing, in all the great centres, the general hospitals of this force as provided by the scheme worked out when it was established. Our information from many of these centres indicates that the work is everywhere being done smoothly and quickly.

Meetings of the profession in most instances summoned by the officers of the Divisions of the British Medical Association—have been held in a large number of districts to arrange for the work of practitioners called to the colours. Similar meetings have been summoned in other districts, and we are confident that within a few days the necessary arrangements will have been made everywhere. Those who remain at ordinary civilian work are readily pledging themselves to act as substitutes for their brethren on military duty. The customary rule as to substitutes is in force, and in this way the financial interests and future prospects of the absent will suffer no more than is inevitable, and the public will receive the attendance it requires. At many of these meetings it has been resolved to undertake to give medical attendance free of charge to the necessitous wives and families of reservists and others called up for military duty. A reference to the question of the supply of drugs will be found on p. 341. The committees for the relief of distress now being established in all districts in accordance with the scheme of the special Advisory Committee sitting at the Local Government Board will find the medical profession organized to give any assistance in its power in all suitable cases.

In some few districts, chiefly the remoter rural, it is believed that there is some risk of the number of doctors being reduced below the proportion necessary to provide efficient medical service to the civilian population, but retired medical men have come forward with offers of assistance for districts from which a large number of doctors have been called up. In some instances, as at Exeter, these offers have been made direct to the Division or local committee appointed to organize the substitute medical service. Some offers from retired practitioners or others who are temporarily out of practice have been received by the central office of the British Medical Association (429, Strand), and the Medical Secretary will place the names on a list, and will give information as to the nature of the offers to the Honorary Secretary of any Division of the Association applying to him. We are informed by medical agents that there is, as might be expected, a certain shortage of ordinary locumtenents, and that in some instances very high rates have been asked. Adequate remuneration may of course fairly be expected, but terms which seem exorbitant ought not to be asked, and should not be paid. A Territorial medical officer who has joined or is joining his unit will be well advised to place his interests in the hands of the committee of the local Division of the British Medical Association, or, if no steps have yet been taken by the Division, to communicate with the Medical Secretary of the Association.

The response last week to the demand of the Navy and Army for volunteers for their medical services, to act as medical officers or dressers, was so prompt and ample that the Navy, as was indeed its right as the premier service, has had the pick of the young men of the schools to serve as temporary surgeons or probationer surgeons (dressers). Its immediate needs have been met, and the names of those now making application are being placed on a waiting list. They will be called upon if and when required. The needs of the army are larger, and when the recruits who have responded to Lord Kitchener's appeal have reached the training grounds of the six divisions in which the new force is organized additional medical officers will be required.

MEDICAL ATTENDANCE ON PATIENTS OF PRACTITIONERS ON MILITARY DUTY.

SOUTH-WESTERN BRANCH.

COLONEL H. MACKAY, Assistant Director of Medical Services, Wessex Division, with head quarters at Exeter, has invited the British Medical Association to communicate with the secretaries of all its Divisions in Devon, Cornwall, Somerset, Wiltshire, Hampshire, and Dorsetshire, asking them to furnish to him a complete list of medical men who would be available for service with the Wessex Division, Territorial Force, after the civil requirements of the locality in which they reside have been provided for. Colonel Mackay further asks that it should be stated what medical men have already agreed to serve in Voluntary Aid Detachments, and whether their services would be available for duties in other districts if not called upon for duty by their County Director of Voluntary Aid. It is asked that the return should include medical men who are not members of the British Medical Association.

Mr. Russell Coombe, Honorary Secretary of the Branch, has issued a circular to every medical practitioner in Devon and Cornwall whose address is known, enclosing a form asking for the particulars required by Colonel Mackay.

Country Districts.

The Honorary Secretary of the South-Western Branch reports that the Branch has arranged to place some retired practitioners, who have offered their services in certain areas denuded of medical men, and is using the

official lists of members and non-members supplied from the central office to get into communication with these gentlemen. Retired practitioners are indicated on these lists. He reports that the scarcity of petrol in that area is giving rise to a good deal of difficulty.

Exeter.

The special meeting of the Exeter Division, to which reference was made last week, was held on August 6th, when Dr. A. C. Roper, Chairman of the Division, was in the chair, and fifty-eight medical men, many of them from long distances, were present.

Dr. Roper, in opening the proceedings, said that the medical men who had not taken up military service could show patriotism not less well by undertaking to do the work which was left to be done at home. On the motion of Dr. W. Gordon, seconded by Dr. Davy, it was unanimously resolved:

> That this meeting is of opinion that work done for men on military duty should entail no expense to them except that of out-of-pocket expenses.

Dr. Gordon said that arrangements had already been made for carrying on the work of the Royal Devon and Exeter Hospital in Exeter. Dr. Davy had undertaken to go if and when required to the 4th Southern General Hospital of the Territorial Force at Plymouth, while he (Dr. Gordon) would remain in Exeter. Dr. Pethybridge was prepared to do all the pathological work at Plymouth; and Dr. Solly, who might have been summoned, would remain in Exeter. Dr. Frank Roper was already mobilized, but Mr. Harris would remain to do the x-ray work. A committee was appointed to organize and distribute the work of those in Exeter who might be absent on military duty, and the medical men on the insurance panel in Exeter were invited to nominate an additional member.

A communication was addressed to the British Medical Association with reference to the requisitioning of horses and cars and the supply of petrol. The Medical Secretary has addressed the War Office and the Board of Trade on these subjects with the result indicated at page 341.

The proceedings of the meeting throughout were perfectly unanimous. One gratifying result was that no fewer than seven retired medical men volunteered to give their services in districts where there might be a shortage of medical men, some of them offering to take distant work as locumtenents.

South Wales and Monmouthshire Branch.

Dr. Trevor Evans, Honorary Secretary of the Swansea Division, reports that the Swansea Division has made local arrangements for the emergency, and issued the following notice in the local papers:

> A considerable number of the medical men of Swansea have been mobilized, and it has been arranged by the Swansea Division of the British Medical Association that their patients will be attended by the doctors remaining in the town.
>
> In order to enable these doctors to overtake the increased work, the public are requested to co-operate in the following ways:
>
> 1. Ascertain which doctor or doctors are acting for their own medical man.
> 2. All patients who are able to do so, to consult the doctor at his house or surgery.
> 3. All messages, except in cases of emergency, to be sent before 10 a.m.
> 4. With each message, state clearly the name of their own doctor.

North Wales Branch.

Dr. J. R. Prytherch, who is Acting Honorary Secretary of the North Carnarvon and Anglesey Division for Dr. Corbett Owen, who has been called upon military service, informs us that a meeting, to which all the medical men resident within the area were invited, was held at the Carnarvonshire and Anglesey Infirmary, Bangor, on August 12th. It was resolved to take steps to safeguard the interests of medical men in the district who are called to leave their practices in the service of their country, and to provide medical treatment for the dependants of those insured persons who are on active service.

Surrey Branch.

Mr. E. H. Willock, Honorary Secretary of the Croydon Division, reports that the medical men in the Croydon borough have been asked by postcard whether they would be willing to assist in a scheme for providing free medical treatment of the immediate dependants of those men in the neighbourhood who may be serving during the war. The response has been unanimous, and the detailed arrangements will be settled immediately. Similar arrangements are being made as regards the outlying part of the Division.

Kent Branch.

Dr. E. A. Starling, Honorary Secretary of the Kent Branch, reports that the Tunbridge Wells Division has already taken steps to deal with the emergency, and that in conjunction with the secretaries of the other Kent Divisions he is arranging that within the next few days the whole of the county of Kent shall be dealt with.

Dr. T. F. Hugh Smith, Chairman of the Dartford Division, reports that the Division has undertaken to look after patients in the interests of their colleagues called away on public duty, and also to undertake gratuitously the treatment of all dependants of sailors or soldiers on active service.

Metropolitan Counties Branch.

The Secretary of the North Middlesex Division (Dr. M. Stewart Smith) reports that the wards of that Division will see to the work of those who are called away. On behalf of the Southgate Ward the local press has been notified that the medical men will attend free of charge the wives and families of needy Territorials and reservists.

The Secretary of the City Division (Dr. A. G. Southcombe) reports that that Division has circularized all the general practitioners in the area asking for co-operation on the lines of Exeter and Southampton. The executive will meet on Sunday to consider the replies.

Dr. B. W. Lacey, Honorary Secretary of the Woolwich Division, reports that the practitioners there have arranged for the work of any of their colleagues who have been called away on military duty.

The Executive Committee of the Greenwich Division met on August 10th to consider what arrangements were necessary in view of the war. It decided that it was unnecessary to call a general meeting of the Division, being convinced that all members of the profession in the Division would act loyally by those of their colleagues who were called away on military duties; and it was decided to issue a circular letter to all practitioners in the Division expressing this conviction. It was also decided to communicate with the Mayors of Greenwich and Deptford, and to assure them of the cordial support and assistance of the committee in any action they might be promoting for the treatment of sick and wounded.

The Executive Committee of the Tower Hamlets Division on August 10th decided that arrangements should be made to safeguard the interests of practitioners called away on military duties, and it expressed the hope that every member of the profession within the area of this Division would co-operate in refusing to accept any appointment held by such a practitioner, and in attending any of his private patients only on his behalf. The medical practitioners of the metropolitan boroughs of Poplar and Stepney were recommended to express their willingness to undertake, free of all charge, the treatment of the necessitous wives and children of all men engaged in the naval and military defence of the empire, and their readiness, when an organization for looking after the dependants of those thrown out of employment through the war shall have been formed, to assist such organization by treating gratuitously cases recommended to them.

Cambridge and Huntingdon Branch.

Dr. Harold Clapham, in the absence of the Secretary of the Isle of Ely Division, informs us that the members have unanimously pledged themselves to do their utmost to preserve intact the practices of members of this Division of the British Medical Association who volunteer for war service. A letter has been forwarded to the Administrative Medical Officer of the Eastern Command offering to place at his disposal temporary hospitals for men sufficiently recovered to leave the general hospitals.

East Anglian Branch.

The Honorary Secretary of the South Essex Division, Dr. J. F. Walker, reports that the Division has made arrangements for the local practitioners to conduct the practices of the three practitioners who have been called

away on service, and also to give gratuitous medical service to the wives and families of all non-commissioned officers and men on active service.

BIRMINGHAM BRANCH.

Dr. Smallwood Savage informs us that at a general meeting of medical practitioners in Birmingham on August 6th a strong committee was appointed, including the President of the Birmingham Branch, the Chairman of the Central Division, and the Representatives of the Branch on the Central Council of the Association. The committee was given powers to deal with the present emergency.

Dr. L. A. Taylor, Secretary of the Dudley Division, reports that the Division will take steps to organize any arrangements that may be necessary.

Dr. T. E. C. Cole, Honorary Secretary of the Warwick and Leamington Division, reports that at a meeting of the local practitioners held on August 11th the following resolution was carried:

> This meeting of the practitioners of Warwick and Leamington pledges itself: (1) To attend, if called upon, the patients of their colleagues who are called to the war, without remuneration to themselves, and not to retain them as patients after their return. (2) To give their services gratuitously to such of the wives and families of those engaged in the war as are recommended by any organized relief committee.

Dr. F. G. Layton, Honorary Secretary of the Walsall Division, reports that arrangements have been made in that area to deal with the emergency.

MIDLAND BRANCH.

Leicester.

The Committee of the Union of Medical Practitioners (Leicester Subdivision), feeling confident that every member would be willing and anxious to render all possible aid in attending the patients of their colleagues who may be engaged on military service, has sent forms to the residences of all doctors who have been, or may be, called out, for use when patients apply for treatment. A form will be filled in and handed to the patient, enabling him to go to any doctor of his choice during his own doctor's absence. There are separate forms for insured and private patients. The committee suggests that in the case of confinements the old-standing custom of halving the fee should be observed. All records are to be retained and handed to the doctor concerned on his return.

SOUTH MIDLAND BRANCH.

Dr. P. S. Hichens, Honorary Secretary of the Northampton Division, reports that arrangements have been made, as regards the County of Northampton, by the Panel Committee to carry on the work of those practitioners called away on active duty.

LANCASHIRE AND CHESHIRE BRANCH.

Mr. P. F. Braithwaite, one of the secretaries of the Bury Division, reports that arrangements have already been made in that area. Patients, either private or panel, of doctors serving with the colours will be attended by any doctor in the town during the emergency. It has also been agreed that no medical man shall accept as his patients the patients of any of those who are serving with the colours after their return. The following notice has been published in the local papers:

> *Bury Local Medical Committee.*—Notice is hereby given to all patients of Bury medical men serving with the colours that they may receive medical attendance from any medical man in Bury, and still retain their connexion with their own practitioners. This applies to both private and panel patients, and any one requiring attendance should state to the doctor chosen the name of his regular medical attendant. (Here follow the names of the doctors who have been called up.)

Dr. Malcolm Hutton, Secretary of the Oldham Division, states that arrangements have already been made by the Local Medical Committee, of which all the officers of the local Division are members.

Dr. J. Shearer, Honorary Secretary of the Blackburn Division, reports that the doctors at Darwen have made arrangements for the work of those doctors who are called from their practices to serve the Government. No transfer of panel patients from the absent doctors' lists will be permitted, and insured persons will be attended by any medical men in the town. Wives and families of reservists and others called upon to serve will be medically attended free of charge.

The Secretary of the Warrington Division, Dr. T. A. Murray, reports that the Division on August 11th passed resolutions undertaking to safeguard the interests of those of their colleagues called to leave their practices in the service of their country; the arrangements adopted are based on the Southampton resolutions.

Similar arrangements have been made by the Liverpool Division, which has also addressed a letter to the town clerks of Liverpool and Bootle and to the honorary secretaries of the Liverpool medical charities, stating that if the medical staffs of the various charities in the city or in Bootle should be seriously depleted owing to their members being called away on active service, the Executive Committee of the Division will be glad to help in any way it can to arrange for temporary help to be given by other members of the profession.

A special meeting of the Rochdale and District Medical Society was held on August 10th, 1914. Dr. Chadwick presided; eighteen members were present, and the following resolutions were passed:

1. That this meeting approves, and requests all medical men practising in Rochdale and district to sign this pledge: We, the undersigned members of the medical profession practising in Rochdale and the surrounding district, hereby pledge ourselves to safeguard the interests of those of our colleagues who are called to leave their practices in the service of their country, and to undertake any medical duties on their behalf.
2. That a committee be formed, with power to add to its numbers, to undertake the necessary work which may arise in connexion with the above resolution.
3. That the committee be instructed to co-operate with Government and local authorities, and with the Red Cross Society and other bodies undertaking the medical care and nursing of those wounded or invalided through the present war.

The Secretary was instructed to send the following notice to the lay press:

> At a meeting of the Rochdale and District Medical Society a committee was appointed and arrangements were made for the treatment and attendance of the patients of those local medical men who have been or may be called away on active service. The committee were also empowered to make arrangements for co-operating with the Government and Red Cross Society in arrangements for the treatment and nursing of those wounded or invalided during the present war.

NORTH LANCASHIRE AND SOUTH WESTMORLAND BRANCH.

Dr. A. E. Thompson, Secretary of the Furness Division, reports that meetings of medical men in that area have already been held and arrangements made to carry on the work of those medical practitioners who are called up for active service.

THE HOSPITALS AND MILITARY REQUIREMENTS.

ACCOMMODATION OFFERED BY MANY HUNDREDS OF INSTITUTIONS.

FROM London and all parts of the country the War Office has received several hundred offers of hospital accommodation for military purposes.

London.

The number of beds proposed to be placed at the disposal of the military authorities varies from 250 in the case of the London Hospital to 25 in the case of small country institutions. These smaller offers, however, are none the less welcome, for in many instances the buildings are in positions where accommodation is not only scanty, but likely to be very much in demand—for example, in the less densely populated areas near the coast line. It is not possible to accept all offers definitely at this stage; they are being tabulated, and the various hospital authorities will be communicated with as the needs of the situation become more clearly defined. Practically all the London hospitals have offered to provide beds, the numbers varying from about 50 to 150, with the exception of the London Hospital just mentioned. The offers include the provision of surgical and nursing attendance. In addition, many large country houses have been placed at the disposal of the War Office.

We are asked by the head quarters of the Army Medical Service to state that offers of comparatively small

numbers of beds in convalescent homes and similar institutions should be addressed to the British Red Cross Society, Devonshire House, Piccadilly, W., which is acting as a clearing-house in this matter. Proposals to place a considerable portion of a big hospital, in full working order, at the disposal of the military authorities may be sent direct to the Director-General, Army Medical Service, The War Office, S.W.

In addition to the established military hospitals, the War Office has taken over temporarily several orphanages and institutions of that kind and is adapting them for hospital purposes. One of these is the Patriotic Asylum for children of soldiers and sailors, situate near Clapham Junction. The expeditionary force will, of course, establish a base hospital at some suitable point. Those admitted there who do not recover sufficiently quickly to return to their units will be invalided home.

Under the Territorial Forces Act each of the two divisions into which London is divided is to have two general hospitals, each providing accommodation for 500 beds—that is to say, four general hospitals in all. A wing of King's College Hospital, Denmark Hill, Camberwell, forms the nucleus of one of these hospitals; 500 beds have not yet been provided there, but additional accommodation will be available in the hospital if required.

In another part of London a scheme wholly independent of existing hospitals is in progress. Preliminary arrangements were made many months ago to requisition a teachers' training college, which stands some distance from the road in its own grounds. A large London County Council secondary school adjoins one side of the site; the boundary wall will be broken through, and the school, which is a modern, airy, and well lighted building, will form the main hospital. On the other side of the college site is a large elementary school; this is separated by a lofty iron enclosure, and will be used to segregate infectious and venereal cases. The principal's house of the college will provide accommodation for the medical staff, and some of the college lecture rooms will also be used for hospital purposes, for which they are well suited, being floored with polished wood blocks, well lighted, and situate on one level on either side of a central corridor. Another part of the college is considerably older than the rest; a great deal of alteration to the windows will be needed there, and this portion will only be used if the pressure upon accommodation becomes acute. Lifts will be put in at various points of the buildings, and bathroom and lavatory accommodation will be added. The grounds provide ample space for convalescents or for the erection of temporary buildings, and a fives court in a corner of the grounds will serve as a *post-mortem* room and mortuary. The whole site adjoins a railway line, and a temporary platform will be erected to facilitate the reception and ready removal of patients.

In the rest of the country the details of the schemes for the General Hospitals outlined in the constitution of the Territorial Force are being rapidly filled in. The following notes do not pretend to be complete, but will give a general idea of what is being done to establish these General Hospitals at all the centres in which it was arranged they should be provided.

Portsmouth.

The 5th Southern General Hospital, Territorial Force, is being rapidly organized. Municipal school buildings in Portsmouth are being prepared for patients, and will be ready for hospital purposes in a few days. One large operating theatre provided with three tables is being fitted up. These hospitals will be staffed by practitioners who joined the Territorial Force in 1909, and will be under the command of Lieutenant-Colonel J. Kyffin, R.A.M.C. (T.F.). Military officers will be treated at the Military Families' Hospital, Portsmouth, which will be reserved for their use. Another school building is being prepared for a hospital under the British Red Cross Society. It has not yet been decided what arrangements will be made at the Royal Portsmouth Hospital for the reception of war patients. Portsmouth is well organized in making provision for the wives and families of those who may suffer because their breadwinners have either gone to the war or are called up to assist in coast defence. Over £1,200 has been subscribed to the relief fund, and 400 cases have already been dealt with. At a meeting of the Local Medical Committees, held on August 11th, it was resolved to recommend that insurance patients on the lists of doctors who are serving in the present emergency should be attended gratuitously by the remaining insurance doctors, and that these should refuse to accept "transfers" from the lists of those serving, except in very special cases, up to the end of the war.

Bristol.

Bristol provides two units for the Territorial Force, the 3rd South Midland Field Ambulance and the 2nd Southern General Hospital, besides the medical officers for the combatant units. The former is one of the three field ambulances of the South Midland Division (the other two coming from Birmingham) and the latter is counted in the army troops.

The Field Ambulance was in the fortunate position of being up to full strength when war was declared—in fact, it has been so for the last three years. In addition to having its ranks full it has supplied thirty-four men to the Special Reserve, Royal Army Medical Corps, and these have now joined at their war station for foreign service. It also was able to fit up the various units with their complement of "water duty men" and supply clerks for the head quarters staff, Royal Army Medical Corps Territorials, and the dépôt at Birmingham. Since the mobilization order came the field ambulance officers have been busy fitting the men out, paying the bounty and packing the large amount of stores that field ambulances carry. At the time of writing this unit is ready to start with everything fully equipped for service. The officers are Lieutenant-Colonel J. Young, commanding officer, Major B. M. H. Rogers, Captain J. S. Mather, Captain T. A. Green, Captain P. Moxey, Lieutenants C. E. K. Herapath, J. Scott Williamson, J. Harty, G. Smyth and Quartermaster H. Lambert. The unit moved on Tuesday night to its war station.

The Second Southern Hospital is commanded by Lieutenant-Colonel J. Paul Bush, C.M.G., and has for its Quartermaster Lieutenant Nicholls. The accommodation for this unit is the Royal Infirmary, which was promised for the hospital when the unit was raised, and Colonel Bush has taken over the command. This unit is also up to its full strength both for hospital orderlies and nurses.

Lincoln.

The Fourth Northern General Hospital, which was mobilized on August 5th, took over the Lincoln Grammar School, with its field of about 10 acres, and construction was started on August 6th. The hospital is under Lieutenant-Colonel W. H. B. Brook, administrator, with Major Lambert as registrar. The medical officers of the hospital consists of 2 lieutenant-colonels, 6 majors, and 10 captains. The nursing staff number 91.

In the building are the administrative quarters, operation room, dispensary, *x* rays and pathological rooms—all well forward towards completion, and 72 beds for patients are already fitted up and ready for occupation. Two hundred men are at work in construction: 22 huts are being erected in the field, each to contain 20 beds; of these 10 are practically finished. Electric light and water are being laid on as erection proceeds, as well as necessary drains. Huts for the units are being built, and are nearly complete. The new nurses' home at the Lincoln Hospital, which was just ready for furnishing, has been taken over for the nurses.

Leicester.

The old County Asylum—where the British Medical Association had a garden party during the 1905 meeting—is now vacant and has been taken over. In it the Fifth Northern General Hospital for the Territorial Force will be established, with 500 beds. The alterations are being pushed forward with extreme rapidity under the Commanding Officer, Major L. K. Harrison, and Mr. Pick, the architect. The nursing arrangements for this hospital and for the Fifth Northern (Lincoln) were made in peace, some 120 fully trained nurses being enrolled, of whom up to 90 will be called up. Interpreters are arranged for, and everything possible for the welfare of the patients has been considered. The mobilization of these hospitals has proceeded with remarkable smoothness, far exceeding any expectation.

Newcastle-upon-Tyne.

More than a week ago the medical staff cleared several of the wards of the Royal Victoria Infirmary, and at once placed 200 beds at the disposal of the military authorities. Members of the honorary medical and surgical staff have had military rank assigned to them according to their infirmary position. The Armstrong College, which closely adjoins the infirmary, has been taken over and several of the large class and exhibit rooms have been transformed into hospital wards, and excellent wards they make. One contains 40 beds. In the building there are already nearly 300 beds. There is a full staff of nurses, so that all is ready.

It is proposed to treat the surgical cases in the Royal Victoria Infirmary and the medical cases in Armstrong College, where also minor surgical cases will be dealt with. The two buildings at present form the Base Hospital, and from an administrative point of view are under the charge of Major Gowans. The out-patient department at the infirmary is, practically speaking, closed. To relieve the strain upon the infirmary, Lord and Lady Ridley have most generously placed their home, Blagdon, eight miles north of Newcastle, at the disposal of the committee. Already nine patients are there. Lady Ridley has the assistance of trained nurses. Five beds of the Convalescent Home, Whitley Bay, are in the occupation of the military. So far it has not been thought necessary to occupy the schools of the city.

Edinburgh.

Hospitals, nursing homes, and private houses, public schools, etc., are readily being lent and fitted up for all emergencies. The Royal Maternity Hospital has begun to take the wives of Reservists and Territorials for a little while before as well as at confinement. The Parish Council has granted the Craigleith Poorhouse and the Children's Home for the use of the 2nd Scottish General Hospital.

Mr. Alfred Moseley, C.M.G., who served with the Princess Christian Hospital in South Africa, has undertaken to organize a hospital at South Queensferry for the reception of sick and wounded naval officers.

SCOTLAND.

SCOTTISH COMMITTEE OF THE BRITISH MEDICAL ASSOCIATION.

AT the invitation of the Scottish Committee representatives of the medical faculties of the Universities and Royal Colleges met it in conference in Edinburgh, on August 12th, to consider what steps should be taken to meet the emergency arising owing to so many medical practitioners having been called up for active service. A Committee, consisting of the Deans of Medical Faculties, the Presidents of the Royal Colleges, and eight other members, was appointed to concert the necessary steps.

NORTHERN COUNTIES OF SCOTLAND BRANCH.

Dr. Munro Moir, Honorary Secretary of the Northern Counties of Scotland Branch, reports that the following resolution was passed unanimously at a meeting of medical men held in Inverness, and a copy sent to the Insurance Committees of the town and county of Inverness:

> That this meeting loyally undertakes to safeguard the interests of those medical men who are called upon to perform military duties in connexion with the present crisis, and also to undertake any work either of a public or private nature falling to be done by those who may be called upon to do duty away from their practice, and that each doctor so called away should endeavour to arrange with his colleagues in the neighbourhood to do his work.
>
> Panel patients who are on the lists of those doctors who are away to be allowed free choice of any doctor in town, the doctor attending those patients to endeavour to keep the usual records.

DUNDEE.

Dr. R. C. Buist informs us that the following draft scheme of an emergency medical service was decided at a large and unanimous meeting of the practitioners to establish in Dundee for the duration of the war. The central office is to be at the Royal Infirmary, and it has its own clerical staff and its own telephone. Mandates have been signed by the doctors who are away to enable the scheme to be financed on the basis of advance insurance credits, 50 per cent. being paid to the committee. This leaves the other 50 per cent. meantime for the expenses of the doctors' households, and any further adjustments may be made on their return. The scheme has the advantage of making it possible to undertake at a day's notice the work of any practitioner who from illness or other cause may have to leave his practice. The population already involved by the absence of practitioners is about 50,000.

Draft Scheme.

1. Establishment of a central office.
2. Establishment of a central dispensary. For this purpose the out-patient department of the infirmary has been kindly placed at the disposal of the committee by the directors.
3. Any individual patient may, by arrangement between the representative of the absent doctor and another practitioner, be referred directly to that other practitioner. Such arrangement to be considered outside the scheme.
4. All messages from the patients of absent doctors to be sent to the central office.
5. It is proposed to distribute visits by locality and by rota amongst the doctors willing to participate in the scheme.
6. Consultations for patients who are able to attend at the dispensary to be conducted there. Consultation work at the infirmary it is proposed to perform by rota amongst those doctors who are to participate, each giving two hours, which may be from 5 to 7 or 7 to 9 on stated nights.
7. The doctors who have been called up have agreed to contribute for the expenses of the committee.
8. The Local Medical Committee will engage the clerical assistance for keeping the necessary records, and the rest of the fund will be distributed amongst the doctors sharing in the work.
9. With regard to midwifery work, it is proposed to ask the maternity service of the infirmary to undertake this with the supervision of a medical staff. It is proposed to charge £1 1s. for each case, and to use this further remuneration for discharging the financial responsibility involved.
10. The Local Medical Committee has appointed the following as a Committee of Management:—Dr. Charles S. Young, Dr. R. C. Buist, Dr. J. K. Tulloch, Dr. Emily Thomson, Dr. J. H. W. Laing.

IRELAND.

Temporary Surgeons.

EARLY last week notices were published in the public press by Trinity College, the College of Surgeons, and the Apothecaries' Hall of Ireland requesting recently qualified medical practitioners who were not in permanent employment or who were desirous of temporary employment as surgeons in the army and navy, to apply to the registrars of the several institutions; there was a large and immediate response; sixty names were sent in on the first day. In the case of several of the hospitals in Dublin large numbers of the resident staff, both students and nurses, have left or are leaving. In the case of one of the large city hospitals, one of the visiting surgeons, three of the assistant staff, the resident medical officer, and a resident pupil have already left. The result is that those who are left behind have much extra work thrown upon them, and in most hospitals the visiting staffs are under an agreement with the Government to undertake local military medical duties if required.

St. John Ambulance Brigade.

The Dublin members of the St. John Ambulance Brigade have responded enthusiastically to a call for the mobilization of the Royal Naval Auxiliary Sick Berth Reserves. Service in this corps is voluntary for members of the St. John Brigade. No fewer than fifty-six men from the St. James's Gate, the City of Dublin, and the Fairview Divisions volunteered, and many of them consented to go abroad if they were so required. They were mobilized under the direction of Assistant Commissioner Dr. Lumsden, assisted by two superintendents, and left in two contingents for the Chatham Naval Barracks. A certain number of members of the St. John Ambulance Brigade have been invited to enlist for a period in the Royal Army Medical Corps.

REQUISITIONING OF CARS AND HORSES AND THE SUPPLY OF PETROL.

At the suggestion of the South-Western Branch, the Association made representations to the War Office urging that the horses and motor cars of country practitioners, save in the last resort, should not be taken by the military authorities, and also urging on the War Office or other authority the necessity for making arrangements for securing that country practitioners should be able to get petrol in the necessary quantities at a price not unduly inflated.

The Medical Secretary has been informed that the Army Council has given instructions that where possible the horses, and in all cases the motor cars, of country medical practitioners should be spared from being impressed.

As regards the question of petrol, replies have been received both from the War Office and from the Board of Trade to the effect that the great importing agencies have assured them that there is no reason for any undue inflation of prices, and sympathetic consideration has been promised to the question of securing a supply of petrol for doctors in remote country districts.

DOCTORS' CARS: THE PRICE OF PETROL.

By H. Massac Buist.

Why there is no Need to Requisition Doctors' Cars.

The steps taken by the British Medical Association to draw the attention of the War Office to the inadvisability of commandeering the cars of medical men in a war which it has already been recognized will be largely a motor campaign, are timely. A great deal of inconvenience will be saved by the avoidance of a step which is quite unnecessary. Such vehicles as doctors use are possessed in this country in vaster numbers than can actually be used until the moment these shores are invaded. It is questionable if even then we should have enough fuel to use them. There are well over 100,000 pleasure cars in the country. Cars, of course, will be needed only for the transport of troops in rapid fashion, in that the average touring vehicle and town carriage is of little or no use for goods haulage. For messenger work the motor cycle is fully as rapid, and vastly cheaper to run, particularly in regard to fuel, which it is so essential to save until the issue on the high seas shall have been determined so that the sources of supplying fuel shall be thrown open to us again. Consequently, till every private owner's car, other than those of medical and military men, shall have been requisitioned by the authorities, there can be no adequate reason for requisitioning doctors' cars. Further, before it comes to using the medical man's vehicle, we should make use of all the second-hand cars that are crowding up dépôts, and for which there is no demand in the marts where such things are dealt in: as well as all pleasure cars that have been manufactured this year and which have not yet been sold. The last-named course has been taken already.

The Fuel Problem Explained.

In regard to the price of fuel, which was put up by retailers to as much as 2s. 6d. a gallon before war was declared, and which in many parts of the country is 5s. a gallon and even more to-day, despite the fact that the importing companies are not charging their retailers any more for it, the causes for this are various. First and foremost is the rapacity of the private dealer, striving to snatch a quick profit at a time when he does not know how much longer his business will continue, but when he foresees quite clearly that there must be an enormous curtailment of his ordinary trade. A second cause is that greedy folk suddenly ordered large quantities of petrol to store, with the result that one of the big difficulties of the fuel trade in this country has been emphasized—a high proportion of tins have gone out of "circulation." Therefore the wholesale firms have been unable to distribute the normal proportions of fuel merely through shortage of cans. All empty cans should be returned as promptly as possible.

The authorities, further, should take prompt measures to prevent individuals about the country storing petrol in appreciable quantities. Indeed, as promptly as possible they should take charge of the whole of the fuel. It must be had in mind that our supplies are derived from two chief sources, one from the United States of America and the other from British and other traders operating in other parts of the world. From the moment war was declared the United States ceased shipping liquid fuel of any sort to Europe. Therefore, though at the outbreak of hostilities we had certainly enough fuel in this country for four months, nevertheless we have to remember that those stores will run low rapidly, in that from now onwards at most we are only receiving half our normal supplies.

Official Control and the Prevention of Waste.

In regard to our other sources of supply of petrol, as long as the enemy's ships are rushing about the waters of the world, like de Wets of the sea, so long are our fuel transports in danger; therefore, that other half of our supplies is likely to be held up. Accordingly, it behoves everybody to go as cautiously as possible. In the course of mingling with their fellow citizens at this juncture medical men would be well advised to speak to all whom they discover to be using petrol unnecessarily. By "unnecessarily" I mean for idle pleasure, as we see so many youths doing on motor cycles in this holiday season—a perfectly natural procedure, in that they do not understand the situation yet. The moment they do so we may be sure they will appreciate the doctrine that should be preached far and wide: every unnecessary mile traversed by a motor vehicle is contributing to cause possible future embarrassments in this country.

It must be had in mind that the seas of the world cannot be open to trade under free and normal conditions for many weeks yet. As long as any one of the enemy's warships rush about so long are all craft bringing goods to these shores in grave peril. Ultimately, of course, they will come here in the ordinary way.

In the meantime, medical men should insist on the local garages with which they deal regularly supplying them with fuel on the ordinary terms. They should report cases of extortion to the police, as coming under the Government scheme for preventing excessive rise in prices. The local vendor so reported would then have to prove to the authorities that he has actually been charged more by the wholesale firms for the fuel. That, of course, cannot be proved at the moment. But the local vendor charging more will say he does not know when he is going to get his supplies replenished. That is probably quite true in many cases. Even so, however, the fact does not justify him in making extra individual profit at the expense of the community, though in cases where fuel is being used merely for the purpose of running cars and motor bicycles on purely pleasure errands the local vendor is justified in charging any sum he can extort. The case of the medical man, however, is one which it is absolutely necessary should be brought to the notice of the authorities in the way that has been done officially by the British Medical Association. The matter should receive widespread attention that effective measures may be taken promptly.

DRUG STOCKS.

The Government, in the course of its inquiry into the supply of food and other necessaries of the country, has made certain preliminary investigations with regard to the supply of drugs. It is found that there is at present a shortage of certain drugs owing to the stoppage of some foreign supplies and the general dislocation of commerce. To one of the most serious of these the President of the Pharmaceutical Society calls attention in a letter published at the end of this note, in which he points out that the main source of potassium salts is Germany, and advises that, as far as possible, sodium salts should be substituted in prescriptions.

We understand that among the drugs of which the British market is at present short, in addition to potassium salts, are salicylates, bromide salts, preparations of mercury, and permanganates. We understand that there is not at present any serious shortage of quinine and cinchona preparations, or of iodine, though the prices of both have been put up. Dr. B. A. Richmond, Secretary of the London Panel Committee, states that he has made special inquiry, and that among drugs which should be added to the above list are syrups, phenacetin, phenazone (antipyrin), and

acetanilide (antifebrin). The British Medical Association has received an invitation to a conference, to be held at an early date, to assist the Government in considering how the medical profession can best co-operate in dealing with the situation. It is hoped that this shortage will be only temporary, and that soon alternative sources will be opened up. Meanwhile practitioners are invited as far as possible to replace the preparations indicated above by others having similar therapeutic effects. It is probable that in an early issue we shall be able to add to this preliminary notice.

The following is the letter referred to:

SIR,—In connexion with the threatened shortage of supplies of medicinal substances, I should like to draw the attention of physicians and pharmacists to the desirability of employing sodium salts wherever possible instead of potassium salts. In England we have an unlimited supply of sodium carbonate, but we depend for potassium carbonate almost entirely upon the mineral deposits of Germany, which are now closed to us. Such salts, for example, as the acetate, benzoate, bicarbonate, bromide, carbonate, chlorate, citrate, formate, hydroxide, iodide, nitrate, nitrite, phosphate and tartrate can be used in most cases either as the potassium or sodium salts. At the present rate of consumption the available supplies of potassium compounds will soon be exhausted, but if the sodium salts are used in every possible case, the supply of potassium salts, where such have any medicinal properties not possessed by the corresponding sodium salts, will last very much longer.

I shall be much obliged if you will give these facts the fullest publicity.—I am, etc.,

EDMUND WHITE,
President of the Pharmaceutical Society of Great Britain.

London, Aug. 12th.

THE WIVES AND CHILDREN OF COMBATANTS.

As will be seen from our reports, there seems to be a universal movement in the profession to undertake to attend the necessitous wives and children of men engaged in the naval and military defence of the country.

The profession desires to assist the local distress committees in every way, and as soon as these bodies get to work medical practitioners will be disposed to accept all cases referred by such committees. The question, however, arises how the cost of drugs and accessories for the treatment of such cases can be met; in certain areas arrangements have already been suggested by which this should be done through the machinery of the distress committees.

MEDICAL ASSISTANCE FOR RURAL DISTRICTS.

THE embodiment of the Royal Navy and Volunteer Reserve and of the Territorial Forces has called a large number of civil medical practitioners from their practice, and although, as will be seen, prompt measures are being taken, through the Divisions of the British Medical Association and by meetings of the profession in many localities, to do the work of these officers for them, and to minimize the inconvenience to the public, it is feared that some few districts may be almost denuded of doctors. At the meeting of the Exeter Division seven retired practitioners offered their services to the special committee appointed by the meeting, expressing their readiness to act as locumtenents. Dr. Cox, the Medical Secretary of the British Medical Association, invites the Secretaries of the Divisions or Branches in the United Kingdom to inform him of any districts in which assistance may be needed by the civil profession, and has opened a list of names of retired practitioners willing to give their services at the request of the Division or special committee of the medical profession in any district in which there is, or may shortly be, a serious shortage of civil practitioners to do ordinary medical work.

Some names have already been received by him, including Dr. W. A. Chapple, M.P., Dr. F. Harrison Tetley, Dr. James M. Heron, J.P., Major C. L. Williams, I.M.S. (ret.).

INSURED MEN IN THE ARMY AND NAVY RESERVES AND TERRITORIALS.

THE Insurance Commission for Scotland has issued a circular to approved societies pointing out that the calling up of members of approved societies who are in the Army or Navy Reserves or Territorials will materially affect their position as regards insurance. From the moment they are called up they will be treated, not as employed contributors, but in the same way as serving soldiers and sailors; that is, the only benefit to which they will be entitled is maternity benefit. Societies will continue to deal with any claims for maternity benefit exactly as if the members had remained ordinary employed contributors. The weekly contributions will be at the reduced rate of 3d.

Men of the Army Reserves will be required to hand in their current "A" Cards at their dépôts, but Territorials will be in a position to send cards to societies themselves. Contributions will be paid to the societies in the same way as those of regular soldiers and sailors—that is, "B" cards in the case of soldiers, and directly by the Admiralty in the case of sailors. Arrears cannot in any circumstances affect the payment of any benefit during the period of service. It will not, therefore, be necessary for societies to send the usual arrears notices in such cases, and any member's wife who has received an arrears notice may be informed, if she inquires, that her husband will have a special opportunity of paying any arrears after he comes back from service before any reduction of benefit. Societies will be informed in due course of the members of their society who have been called up.

FAMILIES OF TERRITORIALS AND RESERVISTS.

THE Under-Secretary of State for War, in the debate on the adjournment, said that a large number of employers had already announced their intention to pay one-half of the wages of the men who are going to the front, and he believed that most good employers, after demobilization, would do everything in their power to reinstate men returned from the war.

It may be useful to reproduce as a guide the regulations which have been approved with respect to civil servants who have been called up for service in any rank as Royal Naval Reservists, Royal Fleet Reservists, Royal Naval Volunteer Reservists, or as Army Reservists, Special Reservists (other than the Royal Engineer Special Reservists of the Postal and Signal Sections, and Special Telegraph Reserve), or as members of the Territorial Force:

1. Their civil posts will be kept open until their return from naval or military service, and such service will count for civil pension and for increment of civil salary.
2. All ranks will receive their civil pay, from which navy or army pay and allowances, including army separation allowance, will be deducted. No distinction will be made between married and unmarried men.
3. Departments may pay civil salary so reduced to any person designated in writing by the civil servant to receive his civil pay on his behalf, obtaining the usual receipt from the payee.

The above regulations will also apply to any civil servant who joins His Majesty's forces after August 4th, 1914, with the permission of the head of his department. Such permission will not be given if the head of the department in the exercise of his discretion considers that serious detriment to the public service is thereby involved. The above Regulations will also apply to persons holding whole-time unestablished and temporary situations, provided that their service is not intermittent, but quasi-permanent and regular.

The Prime Minister stated, further, that during this war separation allowances will be made, and widows' and children's pensions will be granted to non-commissioned officers and men married off the strength in the army as if they were married on the strength. Such provision is already made for all married men joining from the National Reserve, but this is the first time such allowance has been made to men married off the strength.

Later, on the motion for adjournment, the Under-Secretary of State for War stated that the regulations with regard to separation allowances were as follows:

1. Separation allowances are granted from army funds to the families who are not in public quarters at the following daily rates according to the rank of the soldiers—namely, warrant

officers 2s. 3d.. quartermaster sergeants and equivalent ranks 2s. 1d., colour-sergeants and equivalent ranks 1s. 4d.; sergeants, corporals, and privates and all equivalent ranks 1s. 1d. The above rates are increased by sixpence per day for families who were residing in the London postal area on the date of mobilization, and continue to reside there. Children of any of the above—that is. boys under 14 and girls under 16—2d.

2. When the family is in occupation of public quarters and is provided with fuel and light, the wife will receive separation allowance while her husband is separated from her by the exigencies of the service at the reduced rate of fourpence a day. The allowance is twopence a day for each child subject to the above.

3. When the soldier's child or children are motherless the rate of separation allowance is fourpence a day for each child.

4. Payment of separation allowance is made monthly in advance by means of army money orders payable at the post offices. Families of reservists are paid by the army paymaster from whom the men receive their reserve pay prior to their being called up for service. And the families of soldiers of the Territorial Force are paid by the secretary of the county association by which the Territorial Force unit is administered.

5. The first payment to families is made as soon as possible after the men rejoin for service, and covers the period between the date of rejoining and the end of the month; later payments are made on the first of each month in advance.

6. These issues are irrespective of any allotment of pay which the soldier may make.

THE SANITARY SERVICE OF THE TERRITORIAL FORCE.

The Local Government Board in England has issued a circular to county councils and sanitary authorities pointing out that in many areas the medical officers of health and other officers engaged in public health work will be giving their services to the navy or army, so that it will be necessary for the local authority to make other arrangements for carrying on their work. It is suggested that in many areas adequate temporary arrangements may be made by co-operation between the county and district authorities or between neighbouring district authorities. The Board adds that it is essential that there should be no relaxation of the activities of local authorities in the prevention and control of epidemic diseases, the protection of water supplies from contamination, and the promotion of child welfare, and in securing the wholesomeness of food supplies and the general sanitary condition of each area. On this account it is important that all vacancies in the minor sanitary staff should be filled up.

At the time of writing, those medical officers of health who are sanitary officers of the medical service of the Territorial Force have not had their services requisitioned. This service was formed about six years ago, and includes the principal medical officers of health in Great Britain. In 1909 six of them were given commissions of Lieutenant-Colonel, 40 of Major, and 80 of Captain. It was understood that their services would be available on mobilization, and that they would be asked to assist with their advice in time of war should troops be massed in the vicinity of their own spheres of work. Many of them have taken pains to make themselves familiar with the details of military hygiene, at their own cost have provided themselves with uniform, and in other ways have ensured that their services should be instantly available. In London there are two special Sanitary Companies, the 1st London (City) and the 2nd London.

VOLUNTEERS FOR MEDICAL SERVICE WITH THE ARMY.

Several inquiries have been received at the offices of the British Medical Association from practitioners who are anxious to make themselves useful, but do not know where to apply; or who, having applied to the War Office, have not yet received an answer. Inquiries have been made at the War Office, and we are told that the immediate need of the army is the younger men who will be prepared to enter the service and go anywhere they are sent. These applications have been coming in so freely as to tax to the uttermost the clerical staff of the War Office, so that those received from older men or from men who are only able to offer their services in certain conditions of time and place have either not yet received a reply or merely a formal one. We are asked to assure all such applicants that their offers have by no means been overlooked, and are, on the contrary, being carefully filed for future use. We are further asked to request all applicants who offer their services not to make merely general statements of their willingness to make themselves useful, but to give their age, qualifications and experience, and state what they are prepared to do; that is, whether they can only accept service locally or in this country, or are prepared, if ordered, to go abroad. Intending applicants must further understand that though their special qualifications may be of a surgical nature they must be prepared, until such special experience is required, to do ordinary general medical work. The War Office is anxious to have this made clear, because a small number of those applying, whose work has recently been purely surgical, have stipulated that they should only be used in this way. Such a stipulation tends to make their offer less useful than it is doubtless intended to be. There is no fear that if and when the time comes their surgical abilities will not be utilized to the full.

ANTITYPHOID INOCULATION.

The following memorandum on the importance of early resort to antityphoid inoculation has been issued by the War Office:

1. There is no need to remind officers of the Royal Army Medical Corps of the disastrous effects of typhoid in recent campaigns.

2. It can hardly be hoped that improved sanitary precautions will succeed completely in safeguarding the force from infection, since it will certainly be exposed to three sources of infection, difficult or impossible to control—namely:

(*a*) Men in the incubation stage of typhoid who have accompanied or joined the force.
(*b*) Unsuspected typhoid carriers.
(*c*) Contact with the inhabitants of the country in which typhoid may be present.

3. The preventive value of antityphoid inoculation is now universally recognized, and is well known to all who have served in India.

4. As it was not found possible to inoculate the force on mobilization, only a small percentage of the men will have been protected, but it should be practicable, by seizing every opportunity, to raise the number of inoculated men very considerably. If a unit is likely to be stationary for a short time, advantage might be taken of this, with the consent of the general staff, to inoculate a certain number of men—for example, a company or half a company, and in this way a whole regiment or other unit might be protected, without any serious interference with its duties.

In the same way individual men temporarily disabled by minor ailments, or otherwise available, might be inoculated.

It is strongly urged that medical officers lose no opportunity of introducing and carrying through some such system.

5. Antityphoid vaccine has been sent to the base dépôt of medical stores, and will be issued, as required, on requisition.

6. *Dosage.*—Where time permits, the usual system of two doses, at an interval of 10 days, should be adhered to (that is, ½ and 1 c.cm. respectively) but if this is *not* possible a single dose of 1 c.cm. 17 minims) will suffice. It has been found by experiment that, after the single dose—

About 60 per cent. of the men were fit for duty after 36 hours.
About 90 per cent. of the men were fit for duty after 48 hours.
And that 2 to 5 per cent. might still be unfit for hard work on the third day.

7. Simple surgical asepsis should be observed as to the syringe and needles, and the arm prepared by a dab of iodine solution.

8. Should typhoid make its appearance in a unit especial efforts should be made to inoculate all exposed to infection. Inoculation, in the opinion of Colonel Sir William Leishman, does not cause any increased susceptibility to infection, and anyone inoculated in the incubation stage will probably have but a mild attack.

A CHEAP DISINFECTANT.

Dr. F. W. Alexander, Medical Officer of Health for Poplar, where the system has been in use for eight years, writes to suggest that in camps and emergency hospitals near the sea where electricity is available, electrolysed sea water would be found an efficient and inexpensive disinfectant. A plant can now, he says, quickly be set up, as a cell has recently been invented allowing the current in some instances to be taken directly from the mains without a converter.

The fluid is a powerful deodorant and germicide and can be freshly made by simply switching on the current and permitting sea water to run through the electrolysers. If necessary the fluid can be so made as to remain stable almost indefinitely.

The War Office (at Netley), and the Admiralty (at Osborne) have the system in use for dealing with sewage, and the Portsmouth Corporation has installed a plant for making the fluid from sea water for municipal purposes, and the sewage of Worthing, Ipswich, and Lytham has been treated in this way. The system is also in use at Havre and Rouen for dealing with sewage.

In time of war commercial disinfectants may become costly, but where sea water is at hand and electricity available, electrolysed sea water for crude disinfecting purposes can be manufactured more readily and more cheaply than in Poplar, where artifical sea water has to be made; the cost there is over a ½d. a gallon, including electricity.

To appreciate the simplicity of its manufacture and its utility a visit to a place such as Poplar, where 313,000 gallons have been made (from artificial sea water) and used for every purpose in eight years (67,000 gallons during 1913), will explain more than any written description.

Dr. Alexander states that by the use of electrolysed sea water latrines, pails, and urinals could be quickly purified, and that, as was proved by the experience at Riker's Island, Sea River, New York, large masses of garbage could be rendered inoffensive by spraying. Dr. Alexander suggests also that the fluid could be used for disinfecting foul bandages and even for douching contaminated wounds.

RELIEF AND RED CROSS ORGANIZATION.

CENTRAL ADVISORY COMMITTEE FOR THE PREVENTION AND RELIEF OF DISTRESS.

This Committee has been constituted, with Mr. J. A. Pease as Chairman, to advise on the measures necessary to deal with distress that may arise in consequence of the war. It is sitting at the offices of the Local Government Board, Whitehall. Representative Local Committees are being formed in each county and in each borough and urban district. The function of these District Relief Committees will be to consider the needs of the localities, to co-ordinate the distribution of such relief as may be required, and to co-operate with the Poor Law authorities. It is hoped that these committees will first enlist the help of all agencies and voluntary workers in their area with a view to the provision of economic and remunerative employment before attempting to meet the emergency by the distribution of money or food. The committees will contain representatives of the Soldiers' Families Association. All those who wish to assist in the work of prevention and relief of distress should communicate with the mayors and chairmen of local committees, where help is most needed.

The Medical Secretary, acting on instructions from the Chairman of Council, wrote to the Right Hon. J. A. Pease, who is Chairman of the Central Committee for the Prevention and Relief of Distress, placing his services and the machinery of the Association at the disposal of the Government if required. Mr. Pease has cordially acknowledged the offer, adding that he is very glad to be able to add the name of the British Medical Association and that of the Medical Secretary to the list of persons whose services are available for the use of the Central Committee.

THE PRINCE OF WALES'S FUND.

The Prince of Wales's Fund for the relief of distress caused by the war met with a response so prompt and overwhelming that the clerical assistance provided was found to be quite unequal to the task of doing the work with the desired celerity. An offer from the British Medical Association to lend the services of some members of its staff to cope with the urgency was gratefully accepted, and four shorthand typists with their machines have been at work and have proved of the utmost value to the officers of the Fund at York House, St. James's Palace, S.W.

THE BRITISH RED CROSS SOCIETY.

The British Red Cross Society is very busily engaged, and has made many preliminary arrangements. A very large number of offers of assistance have been received from hospitals, and the accommodation has been inspected for the committee by Surgeon-General Lloyd, V.C., Surgeon-General Kenny, and Colonel Bateson. The selection committee has been busily employed in examining the offers, and those selected have been notified to the War Office. Many people have offered their houses to be used as hospitals and convalescent homes, and all these offers are being examined. Among the large country houses offered are Chatsworth (Duke of Devonshire), Eaton Hall (Duke of Westminster), Arundel Castle (Duke of Norfolk), Cliveden (Mr. W. Astor, M.P.), and, if need be, Welbeck (Duke of Portland).

The committee on August 12th appointed Surgeon-General Sir Alfred Keogh, K.C.B., as its representative at the seat of war.

The following Committees have been appointed. The member whose name stands first has made himself or herself responsible for that particular work:

Personnel.—Sir Frederick Treves, Bart., G.C.V.O., C.B.

Convalescent Homes (Joint Committee with the Soldiers' and Sailors' Help Society).—Her Royal Highness the Princess Christian; Sir Rowland Bailey, C.B., M.V.O.; The Lady Northcote, C.I.; Major-General Lord Cheylesmore, K.C.V.O.; Major Tudor Craig; Field-Marshal the Right Hon. Lord Grenfell, K.C.V.O.; Georgina Countess of Dudley, R.R.C.

Medical Comforts and General Gifts of Stores.—The Hon. A. Stanley, M.V.O., M.P.; The Lady Amptihll, C.I.; The Lady Wolverton.

Hospitals and Red Cross Assistance Abroad (Stores, Equipment, Staff).—Sir A. Bowlby, C.M.G.; Lady Perrott.

Arrangements Necessary for the Transport of Red Cross Assistance Overseas to the British Army.—Sir William Garstin; Captain W. G. Lyons.

Arrangements Necessary for the Transport of Red Cross Assistance to Our Allies. Major the Hon. R. White, 16, Stratton Street (7775 Gerrard).

Auxiliary Home Hospitals.—George Henry Makins, Esq., C.B.; Dr. Edward Stewart.

Hospital and Ambulance Ships.—Sir Frederick Treves, G.C.V.O., C.B.; Dr. Edward Stewart.

Motor and Ambulance Transport.—Sir Frederick Treves, G.C.V.O., C.B.

Finance.—The Hon. N. Charles Rothschild; Mr. E. A. Ridsdale.

The Distribution of Medical and General Comforts to Home Hospitals.—Mr. Horace Folker; Mr. H. W. Laurie, 27, Harrington Gardens, S.W.

Office.—Sir Walter Lawrence.

The society has recently received about £15,000, but this is wholly insufficient for the work ahead of it, and it is to be hoped that further subscriptions may be received shortly. Overwhelming applications for patterns for under garments have been received. These, together with a book of instructions, can be obtained from the society, price Is. 8d. The British Medical Association has been able to give clerical assistance to this society also in dealing with the great mass of correspondence received daily.

The Duke of Devonshire has placed the whole of the ground floor of Devonshire House, Piccadilly, at the disposal of the society, and he takes great daily interest in seeing that the comfort of the large staff engaged is attended to.

THE SUPPLY OF LOCUMTENENTS.

Sir,—As usual at this time of year the demand for locumtenents is in excess of the supply, and consequently in some cases demands are being made for fees which many, whose practices are small, cannot possibly pay.

Now that we are at war many retired army and navy men who have taken up general practice, and others who have duties in connexion with territorial work, have to leave their practices at short notice in order to serve their king and country, and their practices must suffer unless they can get reliable help at reasonable prices.

May I therefore appeal, with your permission, to the

patriotism and loyalty of all medical men willing to accept temperary work during war time to be satisfied with as low a fee as possible consistent with the duties required of them? Constant employment can be guaranteed at the rate of 4 to 6 guineas a week.—I am, etc.,

4, Adam Street, Adelphi, London, W.C., Aug. 11th. PERCIVAL TURNER.

*** We have received a letter on the same subject from Messrs. Blundell and Rigby (418, Strand), who express the opinion that excessive demands by locumtenents "mean cornering the income of the wives and families of professional colleagues, many of whom will be in the firing line."

SALARIES OF ASSISTANT MEDICAL AND TUBERCULOSIS OFFICERS.

THE attention of members of the Association, and especially those who may be thinking of applying for posts as assistant school medical officers or assistant tuberculosis officers, is drawn to the fact that at the recent Representative Meeting alterations were made in the minimum salaries which the Association is prepared to approve for these appointments. The minimum recognized salary for whole-time assistant tuberculosis officers is now £350 per annum, or £250 if resident, while the minimum for whole-time assistant school medical officers has been raised from £250 per annum to £300. The salaries in each case are net salaries, exclusive of travelling expenses, clerical assistance, postage, etc. In settling these increases the Representative Meeting was guided not only by the responsible nature of the work expected of the officers in question, but by the fact that many local authorities have recently found it necessary to offer such increased salaries on account of the difficulty of securing suitable officers at the salaries formally recognized as a suitable minimum. It should be specially noted in connexion with these appointments that the Representative Body has declared that the salaries paid to medical women shall not be less than those paid to medical men in respect of the same work. In future the JOURNAL will not be able to accept advertisements of appointments offered at salaries lower than those above mentioned, and it is hoped that medical officers of health and tuberculosis officers who are called upon to advise local authorities in regard to these appointments will note the new conditions.

THE General Medical Council announces that the publication of the new *British Pharmacopœia* has been indefinitely postponed owing to the outbreak of war, and that the review copies, which it had intended to supply last Monday, will not now be issued.

Medical Notes in Parliament.

The Milk and Dairies Bills passed through the Report and Third Reading stages with small amendment.

The Housing Bill in Committee was cut down to the clauses dealing only with the housing required at Rosyth, and was passed in that form.

Territorial Forces' Kit Allowance.—The Under-Secretary of State for War stated that officers formerly members of the Territorial Force whose period of service had expired and who had now volunteered would draw the camp kit allowance of £5 15s. on being gazetted and a special outfit allowance of £20. Kits were supplied by the Government to men. The embodiment gratuity of £5 was not issuable to men who enlisted now, but was confined to Territorials called out.

MESSRS. THACKER AND CO. have postponed the publication of the *History of the Indian Medical Service*, by Lieutenant Colonel D. G. Crawford, I.M.S., retired.

Medical News.

IT is again necessary materially to curtail the size of the JOURNAL, and it is impossible to say when it may be possible to resume publication of the usual number of pages. This must interfere with the customary rapidity of publication of the proceedings of the Sections of the Annual Meeting. The main reason for this curtailment is the shortage of paper, which has become a very serious difficulty for the periodical press. The consumption is greater owing to the enormous demand for the many editions of the newspapers, and the supply has greatly diminished owing to the stoppage of exports of paper and material from the Continent and the other side of the Atlantic. The supplies from the latter source will, it is hoped, shortly increase, but with regard to the former it is not safe to hazard any conjecture. No German or Austrian medical periodicals have been received for the last two weeks, and very few from France. In these circumstances the regular publication of the Epitome of Current Medical Literature has been suspended.

DURING the absence of Dr. Bertram Rogers as a major in the 3rd South Midland Field Ambulance (T.F.) Dr. Alexander Smith will act as medical adviser to the Bristol Insurance Committee as locumtenent for Dr. Rogers.

AT the annual meeting of the board of directors and members of the Apothecaries' Hall, Dublin, on August 1st, Dr. Edward Magennis, J.P., was elected its representative on the General Medical Council.

A FRENCH anti-opium league has been formed, of which the presidents are M. le Myre de Vilers, formerly Governor of Cochin-China, and Professor C. Richet. The object of the league will be to use every endeavour, by enlightening public opinion and by securing the infliction of heavy penalties on offenders, to stop the opium traffic. It will include within the sphere of its operations an active campaign against the sale of cocaine, haschich, and other narcotics.

UNTIL further notice, the head office of the Automobile Association, Fanum House, Whitcomb Street, London, W., will be open day and night, including Sunday, for any urgent messages, telegrams (Fanum, London), or telephone calls (300 Regent). The same will apply to the principal provincial branch offices at Manchester (5489 City), Leeds (2027 Central), Birmingham (973 Central), Exeter (1000 Exeter), and Glasgow (7199 Central).

A THREE months' course of lectures and demonstrations in hospital administration for the diploma in public health will be given on Mondays and Thursdays at 5 p.m., beginning Monday, October 5th, at the North-Western Hospital, Hampstead, N.W., by Dr. J. MacCombie, medical superintendent, and at the Grove Hospital, Tooting, S.W., by Dr. J. E. Beggs, medical superintendent. The fee for the course is £3 3s. Further particulars can be obtained on application to the clerk to the Metropolitan Asylums Board, Embankment, E.C.

A LEAFLET entitled "The Best Foods to Buy During the War: The Highest Nutritive Value at the Lowest Cost," intended to be issued by Public Health authorities, has been compiled mainly from material supplied by the Croydon borough health department, and is printed by the *Medical Officer*, 36-38, Whitefriars Street, London, E.C. It points out how money may best be expended, that the real value of foods does not correspond with their cost, and that by sensible buying and cooking it is easy to prepare a meal which is pleasing and palatable and of high food value at a much smaller cost than if no care and intelligence be exercised in choosing. A few simple recipes are added. Copies will be supplied, with the name of the borough inserted, at 7s. 6d. per 100, or 30s. per 1,000.

IN view of the fact that fire brigade and fire patrol work may shortly be required on a more extensive scale than heretofore for our fortified and defended places, for our arsenals and national stores, and for certain Government establishments requiring special protection, the British Fire Prevention Committee is preparing a roll of retired fire brigade officers and firemen (both professional, volunteer, and private) who are ready to join an emergency fire service force or forces. It desires also to form a supplementary roll of young engineers (used to steam engines or motor cars) and young surveyors or architects (used to building, survey, or dangerous structure work) who, although not having actual fire experience, would be valuable in an emergency fire service force. Applications to be entered on the roll should be addressed to the British Fire Prevention Committee, 8, Waterloo Place, London, S.W.

The Services.

ROYAL ARMY MEDICAL CORPS.

THE following is a list of the successful candidates at the July competition for commissions. There were 22 candidates:

Name.	Degrees, etc.	Medical School.	Marks.
*D. C. G. Ballingall	B.A., M.R.Cantab., M.R.C.S.Eng., L.R.C.P.Lond.	Cambridge University, St. Bartholomew's Hospital	560
H. G. Winter ...	M.R.C.S.Eng., L.R.C.P.Lond.	London Hospital	552
*J. M. Evatt ...	B.A.Cantab., M.R.C.S.Eng., L.R.C.P.Lond.	Cambridge University, University College Hospital	546
*F. G. Thatcher...	M.B., Ch.B.Univ. of Edinburgh	Edinburgh University	538
*W. P. Mulligan...	M.B., Ch.B.Univ. of Aberdeen	Aberdeen University	534
*G. P. Selby ...	B.A., M.B., B.Ch. Oxon., M.R.C.S. Eng., L.R.C.P.Lond.	Oxford University, St. Bartholomew's Hospital	525
*J. G. Butt ...	B.A., M.B., B.Ch., B.A.O.Univ. of Dublin	Trinity College, Dublin	507
*N. Cantlie ...	M.B., Ch.B.Univ. of Aberdeen	Aberdeen University, Charing Cross Hospital	497
*E. A. P. Brook ...	M.R.C.S.Eng., L.R.C.P.Lond.	St. Bartholomew's Hospital	489
*P. T. Priestley ...	M.B., Ch.B.Univ. of Birmingham, M.R.C.S.Eng., L.R.C.P.Lond.	Birmingham University	479
E. Phillips ...	M.B., Ch.B.Univ. of Durham; M.R.C.S. Eng., L.R.C.P.Lond.	Durham University, London Hospital	476
S. D. Reid ...	M.B., Ch.B.Univ. of Edinburgh	Edinburgh University	453
P. J. Ryan ...	B.A., M.B., Ch.B., B.A.O.National University of Ireland	National University, Ireland	441
B. J. L. Fayle ...	B.A.Cantab., M.R.C.S.Eng., L.R.C.P.Lond.	Cambridge University, Bristol University	437
E. A. Sutton ...	M.R.C.S.Eng., L.R.C.P.Lond.	Charing Cross Hospital	402

* Received an allowance of marks as holder of an Officers' Training Corps certificate.

INDIAN MEDICAL SERVICE.

AT the July examination there were 28 candidates, the first 15 being admitted as lieutenants on probation. The names of the successful candidates with the marks obtained by each out of a possible total of 5,100 are given below:

Name.	Degrees, etc.	Medical School.	Marks.
J. W. Pigeon ...	M.R.C.S., L.R.C.P., B.C.Cantab., B.A.	Cambridge University, St. Bartholomew's Hospital	3,304
M. L. Treston ...	M.R.C.S., L.R.C.P.	London Hospital	3,173
P. Vieyra	M.B., Ch.B.Edin.	Edinburgh University, Rotunda, Dublin	3,141
B. M. Mitra ...	M.R.C.S., L.R.C.P.	Calcutta Medical College, Middlesex Hospital, Coombe Hospital, Dublin	3,101
P. Savage	M.R.C.S., L.R.C.P.	Guy's Hospital, Durham University	3,071
T. B. Paul... ...	L.M.S.S.A.	Middlesex Hospital	3,049
A. Chand	M.B., B.S. Punjab	Lahore Medical College, University College Hospital	3,046
R. Lee	M.B., Ch.B.Liverp.	Liverpool University	3,040
N. S. Jatar ...	M.R.C.S., L.R.C.P., L.M. and S.Bombay	Grant Medical College, Bombay, University College Hospital	2,972
T. S. Sastry ...	M.B., C.M.Madras	Madras Medical College, St. Bartholomew's Hospital, Middlesex Hospital	2,891
Jamal-ud-din ...	M.B., Ch.B.Edin.	Edinburgh University	2,810
T. B. Chenoy ...	M.R.C.S., L.R.C.P., L.M. and S.Bombay	Grant Medical College, Bombay, London Hospital	2,709
S. B. Venugopal...	M.R.C.S., L.R.C.P., L.M. and S.Madras	Madras Medical College, University College, Guy's Hospital	2,697
C. de C. Martin ...	M.B., Ch.B.Edin.	Edinburgh University	2,636
J. H. Smith ...	M.B., Ch.B.Edin.	Edinburgh University	2,687

THE Governor of Hong Kong has informed the Secretary of State for the Colonies that six cases of plague were reported during the week ending August 8th, and that six deaths occurred.

Universities and Colleges.

UNIVERSITY OF LONDON.

MEETING OF THE SENATE.

A MEETING of the Senate was held on July 15th under the chairmanship of the Vice-Chancellor, Sir Wilmot Herringham.

Recognition of Teachers.

The following were recognized as teachers of the University in the subjects and in the institutions indicated:

King's College.—Dr. Reginald J. Gladstone (Embryology).
Guy's Hospital Medical School.—Mr. T. J. Evans (Biology and Zoology).
Middlesex Hospital Medical School.—Dr. E. A. Cockayne (Pharmacology), Mr. R. A. Greeves (Ophthalmology).
Charing Cross Hospital Medical School.—Dr. R. C. Jewesbury (Medicine), Dr. E. D. Macnamara (Mental Diseases).
London School of Medicine for Women.—Dr. M. L. Hepburn (Ophthalmology), Mr. Charles A. Pannett (Surgery).
St. Mary's Hospital Medical School.—Mr. R. W. Collum (Anæsthetics), Dr. Paul Haas (Chemistry), Dr. F. S. Langmead (Medicine).

Emeritus Professor of Chemistry.

The title of Emeritus Professor of Chemistry was conferred upon Professor J. M. Thomson, LL.D., F.R.S., who has occupied the Chair of Chemistry at King's College since 1887.

Lecturers in Physiology.

The following were added to the panel of lecturers in physiology: Dr. C. J. Douglas, Dr. F. L. Golla, Dr. H. J. Page.

Mental Disease Research.

It was resolved, in response to a request from the Board of Control, to suggest the following conditions in connexion with the grants placed at the disposal of the Board by the Treasury for the purpose of aiding and encouraging scientific research into the causes and treatment of mental diseases and mental defect:

1. Individual grants to be made to a few observers who have been thoroughly trained, and who are capable of carrying out scientific investigation.
2. No grant under the scheme to be made merely to maintain or assist pathological laboratories, or to be given to persons for the purpose of routine work.
3. Grants to be given only to advance the study of fundamental problems connected with insanity and mental deficiency.

It was also decided to inform the Board that the Senate would be pleased to advise as to the objects towards which investigations aided by the Board might with advantage be directed.

Grant from London County Council.

The thanks of the Senate were voted to the London County Council for a building and equipment grant of £30,000 for the promotion of higher education at University College.

Amendment of Regulations.

It was resolved that the regulations for the examination in anatomy at the second examination for medical degrees, Part II, be amended as follows: By the substitution for the word "dissection" of the words "A practical examination consisting of an examination of freshly dissected parts," in line 12, on page 173 of the Red Book for 1913-14, and in the fourth line from the bottom of page 225 of the Blue Book, September, 1913.

Boards of Studies.

Dr. R. J. Gladstone (King's College) has been appointed to the Board of Studies in Human Anatomy and Morphology.

Chairman of Committee.

Dr. S. Russell Wells has been elected Chairman of the Council for External Students for 1914-15.

Rogers Prize.

The Rogers Prize, not having been awarded this year, will be offered for award in 1915, the subject of the essay or dissertation again being "The nature of pyrexia and its relation to micro-organisms."

Examinations.

The following candidates have been approved at the examinations indicated:

FIRST M.B.—Lena C. Adam, W. M. Anthony, N. D. Bali, L. S. Banes, Annie H. Banks, M. Baranov, L. H. Bartram, H. E. Beasley, E. A. Beaulah, H. S. Bell, Enid M. M. Bevan, J. Brodetsky, J. D. M. Cardell, C. E. Cobb, H. N. F. Cook, R. V. Cookes, G. E. Cornaby, A. B. Cowley, Nora A. Crow, G. P. Crowden, D. S. Davies, Idris Davies, Mary Day, F. P. de Caux, W. S. Dickson, G. W. R. W. Dreincller, A. Eidinow, Sylvia Y. Elman, F. A. Evans, D. C. Fairhairn, Lilian M. Fisher, G. W. T. H. Fleming, A. Foner, W. F. Francis, F. A. Gaydon, E. J. G. Gibb, A. L. Goff, W. H. Grace, St. G. R. D. Gray, Gwenvron M. Griffiths, A. S. Hands, N. G. Hill, O. S. Hillman, J. W. Hirst, A. W. Holgate, H. N. Hornibrook, M. Jackson, S. W. Jeger, R. D. Jones, V. R. Khanolkar, Muriel E. Landau, Mary K. F. Lander, E. H. L. Leclézio, C. G. Lewis, S. S. Liebermann, C. A. Lindup, A. B. McBride, E. K. Macdonald, D. McDonald-Taylor, *Janet M. McGill, N. O. C. Mackenzie, G. J. W. McMichael, Vida S. Maxwell, A. Mitchell, G. S. Morgan, Edith M. P. Morris, J. E. Nicole, Norah D. O'Flyn, R. E. Overton, Marguerite H. Pam, M. J. Panthaky, C. F. Parry, T. Parry, R. J. Perkins, G. F. Pefers, G. S. B. Philip, F. C. Player, L. D. Porteous, J. N. J. Powlesland, Dorothy P. Priestley, Mary M. Prior, W. E. K. A. Quitmann, E. F. Rabey, R. S. Ralph, E. D. T. Roberts, H. S. Robinson, G. R. Rolston.

E. S. Rose, B. Rosenstein, D. J. L. Routh, C. C. Rowland, A. E. Sawday, J. R. O'D. Scroggie, S. N. Senitzky, B. B. Sharp, S. A. Sharpe, J. H. Shaw, *J. H. Sheldon, A. H. Shelswell, R. D. Shirvalkar, W. H. Simmons, W. Skelly, B. L. Slater, G. J. Sophianopoulos, Frances M. Spickett, G. P. Staunton, Mary S. Stocks, H. E. Suter, K. S. Tan, S. R. Tattersall, J. A. Tennyson-Smith, C. J. Thomas, H. M. Toop, R. L. Walker, A. D. Wall, Hygeia L. J. Wallace, A. E. Ward, R. W. Warrick, E. R. Webb.

SECOND M.B. (*Part I.*—C. H. Atkinson, G. A. L. Barnes, K. C. Beatty, E. J. Bilcliffe, A. O. Bolton, J. W. Brash, I. Braun, C. H. Brew, Margaret H. Bridge, D. Cameron, H. Carpenter, J. D. Carpenter, B. R. Chandhri, H. J. C. Churchill, D. C. Clark, C. S. Cloake, H. Das, O. G. Davies, A. H. Douthwaite, *R. W. L. Edginton, W. Eidinow, V. F. Farr, W. A. Flynn, Beatrice Ford, J. C. Gie, L. C. Gomment, Dorothy W. Gowers, A. S. Green, R. B. Green, W. A. Hawes, C. G. Haynes, N. R. Jenkins, T. Johnston, Constance A. Jones, D. M. Jones, M. E. Jones, N. Kamchorn, D. M. Lala, D. A. C. Layman, W. A. Low, J. G. McCann, Lily O. G. McGregor, Kathleen M. McKeown, T. H. McLeod, B. G. Marshall, C. L. Mason, G. G. Michell, Arnie S. Miles, H. W. L. Nichols, D. R. Owen, A. E. B. Paul, S. L. S. Pearson, M. C. Polhill, Jean S. Pope, W. R. Ranson, A. Rathouse, Frances E. Rendel, G. H. Roberts, J. S. L. Roberts, Gwendolen M. Rolfe, H. Rowan, W. H. Royal, J. F. Ryan, S. Sacks, E. J. Samuel, G. S. Sansom, C. K. Scales, H. Schaal, Charlotte A. Shields, R. D. Shirvalkar, K. L. Singer, Muriel Starling, V. R. Stewart, M. B. R. Swann, R. Theron, A. J. Usborne, J. A. Van Heerden, Kathleen S. Vine, Elsie M. Visick, A. C. S. Whiteway-Wilkinson, I. G. Williams, E. B. Woolf.

* Passed with distinction in one or more subjects.

CONJOINT BOARD IN ENGLAND.

SPECIAL FINAL EXAMINATION.

A SPECIAL final examination in medicine, surgery, and midwifery for the diplomas of L.R.C.P. and M.R.C.S. will be held by the Conjoint Examining Board of the Royal College of Physicians of London and the Royal College of Surgeons of England, commencing on Tuesday, September 8th. Applications from intending candidates should be sent to the Secretary, Examination Hall, 8-11, Queen Square, Bloomsbury, W.C., by August 27th.

Diplomas and Examinations.

The following candidates have received the diplomas indicated from the Royal College of Physicians and the Royal College of Surgeons respectively:

M.R.C.S., L.R.C.P.—W. H. Alderton, C. P. S. Allingham, C. F. Anthonisz, A. L. Anthony, A. B. Appleton, W. D. Arthur, J. E. Ashby, L. B. Baird, F. A. Beattie, M. W. K. Bird, N. Briggs, I. M. Brown, N. H. M. Burke, A. J. Chillingworth, E. R. T. Clarkson, M. T. G. Clegg, *J. R. M. Collie, B. K. T. Collins, S. H. Cooke, D. L. Davies, D. C. de Fonseka, J. B. G. Dotto, G. E. Elkington, H. L. G. Foxell, W. D. Galloway, G. A. Gassmann, E. Gray, E. W. Griffith, B. G. Gutteridge, A. R. Hacker, O. Hairsine, C. S. P. Hamilton, A. H. Harkness, A. H. Harty, B. W. Hay, H. S. C. Hooper, G. B. Horrocks, A. M. Hughes, J. B. Hunter, R. N. Hunter, B. L. Hutchence, R. T. Jones, T. C. Kidner, S. D. Kilner, G. C. King, C. Lambriundi, J. Lloyd, C. E. Lowe, D. M. MacManus, F. Mahabir, R. Mallet, J. B. Matthews, J. L. Meynell, J. D. Milne, B. M. Mitra, F. J. Nattrass, D. W. Pailthorpe, C. E. Petley, K. B. Pinson, D. J. Platts, D. A. Power, A. B. Preston, W. B. Purchase, J. B. Rawlins, G. F. Rowcroft, H. C. Samuel, F. H. A. Saved, F. G. L. Scott, P. D. Scott, E. J. Selby, A. el K. Selim, J. Sen, G. D. Shann, W. H. Shephard, A. G. Simmins, J. R. Smith, K. V. Smith, G. J. G. Smyth, L. C. Somervell, F. L. Spalding, C. W. Sparks, C. J. Stewart, G. Stiell, E. A. Sutton, C. H. Thomas, T. A. Townsend, D. C. L. Vey, E. H. Walker, J. F. West, C. L. Williams, F. A. Williamson, J. St. G. Wilson, F. B. Winfield, W. P. Wippell, T. M. Wood-Robinson, M. S. Woolf, E. J. Wright.

D.P.H.—Estelle I. E. Atkinson, W. J. Bannister, L. M. Biswas, A. Bloom, S. Bradbury, (Surgeon R.N.), H. Chand, A. D. Child, R. E. Collins, N. E. Dunkerton, W. Egan (Captain R.A.M.C.), H. H. A. Emerson (Captain R.A.M.C.), J. Erlank, K. Ghosh, S. M. Ghosh, D. H. C. Given (Surgeon R.N.), J. Griffiths, S. H. Griffiths, D. G. Howell (Captain R.A.M.C.), W. W. Jameson, T. S. McIntosh, W. H. McKinstry, H. B. W. Morgan, B. P. Mozoomdar, V. P. Norman (Captain I.M.S.), G. S. Parkinson (Captain R.A.M.C.), A. Z. Philips, R. B. Price (Lieutenant R.A.M.C.), K. A. Rahman, R. C. Roy, K. S. Sethna, J. V. Shirgaokar, F. Standish, W. S. D. Henderson (Captain I.M.S.), S. N. Sur, A. L. Urquhart (Lieutenant R.A.M.C.), F. W. Waterworth, J. S. Webster, J. I. P. Wilson, and W. B. Winston.

The following candidates have been approved at the examination indicated:

FIRST COLLEGE, *Part I (Chemistry), Part II (Physics).*—*G. W. Almeyda, R. W. C. Ball, Margarita S. Barfield, †F. J. Biddle, E. J. S. Bonnett, M. V. Boucaud, O. H. Brown, †J. F. E. Burns, *A. A. Casalis, *A. J. Chiappa, †A. E. Collie, A. J. M. Davies, *T. H. R. Davies, †F. E. Edwards, T. G. Evans, †Ahmed Faig, D. C. MacDonnell, C. Moffatt, R. B. Munday, A. R. Neckle, Farquharson, A. J. Fenn, Blanche S. Gardner, *Malik Girgis, W. R. G. Harris, R. Hilliard, †R. V. Hudson, A. B. Isaacs, Mahmoud F. Ismail, F. W. Lemarchand, A. V. Lopes, J. J. M. †C. Nicory, †A. A. Osman, E. J. Papenfus, J. C. Pauw, E. A. Pearson, M. L. Quinlivan-Bulger, †Hussein Ramzy, D. H. Richards, J. S. Rogers, *Khurshedjee J. Rustomjee, †M. C. Sarkies, †O. L. C. Sibley, W. R. B. Smyth, E. A. Sparks, †E. A. L. Sturridge, *Ina V. Vincent, *P. H. Williams, †S. Wolff, †H. W. Woollett, Fuad W. Zagiama. *Part III (Elementary Biology).*—F. J. Biddle, L. Birtles, A. J. M. Davies, B. O. Dewes, L. Dinerstein, G. H. Duffield, A. P. H. Egerton, Malik Girgis, E. S. Goodwin, V. A. F. Greenish, G. R. Hubbard, E. L. Hunter, Mahmoud F. Ismail, H. S. Jackson, E. Kopelowitz, W. Lambert, B. L. Laver, J. C. W. MacBryan, G. Meadows, N. F. Meldrum, R. B. Munday, J. C. Pauw, A. Peine, J. Peter, D. H. Richards, O. L. C. Sibley, Mohamed Sidky, R. E. Williams, I. H. Zortman.

* Passed in Part I. only. † Passed in Part II. only.

CONJOINT BOARD IN SCOTLAND.

THE following candidates have been approved at the examinations indicated:

FIRST COLLEGE.—W. H. Duff, T. L. Edwards, R. L. Goodall, J. Hughes, A. P. Robb.

SECOND COLLEGE.—W. C. Borrie, N. S. Bruce, J. T. Dier, J. V. Griffith, L. W. Hughes, J. G. M'K. Macaulay, *J. W. Morris, D. R. Nicol, R. J. Patchett, R. Pollok.

THIRD COLLEGE.—G. Beveridge, J. T. Brady, A. Gaston, A. L. Gibbon, G. M. Harley, J. P. Mathie, C. Read, P. M. Saptarshi, G. Thomson.

FINAL.—L. Fraser, R. B. Lilly, G. L. Neil, Rona Lockhart, Sengarapillai Ponniah, A. Crawford, J. W. Cowie, J. Gilchrist, G. F. Walker, J. R. C. Gordon, A. W. Cochrane, A. I. Clarke, Babu S. Thakur, C. A. Bernard, C. Gray, D. W. Woodruff.

* With distinction.

APOTHECARIES' HALL OF IRELAND.

THE Apothecaries' Hall of Ireland has decided to hold a special qualifying examination on August 19th. Intending candidates should communicate at once with the Registrar, Apothecaries' Hall, 40, Mary Street, Dublin.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have been approved in the subjects indicated:

SURGERY.—*†J. C. P. Bayley, †C. D. Day, *†G. B. Holroyde.
MEDICINE.—†L. B. Clarke, †G. W. Maw.
FORENSIC MEDICINE.—C. D. Day, A. Glen.
MIDWIFERY.—A. Glen, S. B. King, N. W. Rawlings, E. M. Townsend.
Section I. Section II.

The diploma of the Society has been granted to Mr. G. B. Holroyde.

Obituary.

SURGEON-GENERAL SIR ANTHONY HOME, V.C., K.C.B.

SURGEON-GENERAL SIR ANTHONY DICKSON HOME, V.C., K.C.B., the most distinguished officer on the retired list of the Medical Department of the British Army, died in London, aged 87, on August 9th. He was born at Dunbar in 1826, took the diploma of M.R.C.S. and the degree of M.D. of St. Andrews in 1847, and entered the army as assistant surgeon on March 17th, 1848. During the first six years he served in the West Indies, Nova Scotia, Guernsey, Ireland, and Gibraltar successively. In August, 1854, he went to the Crimea with the 8th Hussars, and served there till the end of the war. On the outbreak of the Indian Mutiny he went to India as surgeon of the 90th Foot, having been promoted to that rank from February 9th, 1855. At Lucknow he won the Victoria Cross by his heroic defence of the wounded left behind by the relieving column when Havelock forced his way to the Residency during the first relief. He was thus one of the first medical officers to gain this most coveted honour (three A.M.D. officers gained the V.C. in the Crimea, and three in the Mutiny). At the time of his death he was the senior medical officer, both in date and in rank, who held it. It was conferred upon him from June 18th, 1858. On March 31st, 1858, he was appointed a staff-surgeon. From India he went to China, and served through the China war of 1860, on the staff of the Commander, Lieutenant-General Sir James Hope Grant. On his return to England he was sent to Canada, war being threatened between Britain and the United States—a war which was happily averted. Soon after he returned to India, and thence was sent to New Zealand, where he served in the Maori war of 1864–5, being decorated with the C.B. from July 5th, 1865, and specially promoted to surgeon-major. In 1873–74 he served as principal medical officer of the force under Sir Garnet Wolseley in Ashantee, being promoted to K.C.B. from March 31st, 1874. On April 4th, 1880, he reached the rank of Surgeon-General, and was appointed P.M.O. of Her Majesty's Forces in India. Many retired officers and a few still serving will remember him when holding this post. He retired, with thirty-eight years' service, on November 30th, 1886.

The list of Sir Anthony's war services is long. It comprises the Crimean campaign of 1854–5, when he was present at the battles of Balaklava and Tchernaya, the siege of Sebastopol, and the operations near Eupatoria, receiving the medal with two clasps and the Turkish medal; the Indian Mutiny of 1857–8, when he took part in the first relief of Lucknow, was in the Residency during

the second siege, and with the force left at Alumbagh, and served in the final capture of Lucknow, gaining the medal with clasp and one year's service for Lucknow, as well as the V.C.; the China war of 1860, at the capture of the Taku Forts, and the action near Palichoo on the road to Pekin, medal; the New Zealand war of 1863–5, in the campaigns in Waikato Valley, Tauranga, and Wanganui, where he got the medal, the C.B., and was specially promoted to surgeon-major; and the Ashanti war of 1873–4, when he was principal medical officer of the force, and was present at the action of Essaman, was mentioned in dispatches in the *London Gazette* of November 18th, 1873, and March 7th, 1874, receiving the medal and being advanced to K.C.B. Besides the distinctions mentioned above, he received one of the pensions awarded for distinguished and meritorious service from November 15th, 1894. In 1912 his autobiography, *Service Memories*, containing rough notes of his service and experiences to the end of the Maori war, edited by Lieutenant-Colonel C. H. Melville, R.A.M.C., was published by Edward Arnold.

WHILE Europe is arming for the coming struggle, another of the few remaining survivors of the surgeons of the Crimean war has quietly passed away. Dr. WALTER ACTON was born at Ludlow in 1826, was educated at University College, London, and took the diploma of M.R.C.S. and L.S.A. in 1850. He volunteered for service in the Crimea, and was Staff Surgeon to the Osmanli Cavalry for two years. After the war he practised for a few years at Stilton, and afterwards at Newcastle-under-Lyme. He retired in 1887, and since 1893 had resided at West End, near Southampton, where for some years he took a very active interest in the church and in parochial matters generally, serving as churchwarden and also guardian of the poor. Of his Crimean experiences he spoke but little, except to his most intimate friends, though from manuscript notes and paragraphs in published works it is evident that he held responsible positions, and was well known among his colleagues and the suffering troops. For the last five years failing health confined him for the most part to the house, but he never ceased to take a keen interest in the affairs of the day. During his declining years he was deservedly beloved by all whose privilege it was to know him, and all admired the truly Christian faith and patience with which he awaited the end. It came quietly and suddenly on August 8th.

Dr. JAMES MONTAGUE BRAUND, of Stratton, North Cornwall, died on July 23rd, at the residence of his son-in-law in London. He was born on October 25th, 1830, at Hatherleigh, North Devon, and was the son of the Rev. William Hoskin Braund. He received his medical education at the Middlesex Hospital, and took the diplomas of M.R.C.S.Eng. and L.S.A. in 1855. After practising for a short time at Grantham, where he married the daughter of Dr. Mather, he moved in 1857 to Stratton in North Cornwall, where he lived until he retired from practice a few years ago. He was over forty years Poor Law medical officer and public vaccinator for the north district of the Stratton Union and to the Stratton Workhouse, and was M.O.H. to the Stratton Rural District Council. On retiring he received his well-earned pension. He was greatly respected by the whole district and much beloved by his patients; he was assiduous in his attention to his poorer patients, and many stories are told by them of his devotion and kindliness of heart. In his time in the Stratton district it was no sinecure to be parish medical officer, as the people were very poor and the distances great; but to turn out at night to go perhaps ten miles to the call of one of his parish patients was to him a labour of love. He was, on retiring, succeeded in his appointments by his son, who had been in partnership with him for some years previously. He was a good sportsman, being particularly fond of shooting and coursing. He contributed original articles on two occasions to the *Lancet*. He married his second wife, the eldest daughter of Mr. B. Smyth, of Calcutta, in 1879. She predeceased him by two years. His body was brought from London and buried at Stratton Churchyard on July 27th; the funeral was attended by a large number of his old friends and patients.

LETTERS, NOTES, ETC.

TREATMENT OF PRURITUS ANI.

MR. CHARLES J. LYONS, F.R.C.S.I. (Johannesburg), writes: I have read various letters on this ailment lately, but no one has suggested the treatment I have recommended for many years—namely, bathing the part with alcohol before going to bed, and in fact any time the itching occurs. The treatment is clean and effectual. Of course, the bowels should be kept regular and any local causes rectified.

W. L. notes how successful Dr. J. Cropper Chepstow has been with tinct. iodi and tinct. benzoini co., and would be glad to learn details of treatment.

THE CAUSE OF CANCER.

DR. ARTHUR TODD-WHITE (Leytonstone, E.) writes: The Registrar-General, in his annual report, again records an increase in the number of deaths from cancer. This obviously points to one thing—that there must be some cause in modern life, in the conditions under which we live, or in the food we take, which causes the increase, and it is the duty of our profession to consider every possible cause, and therefore I bring the following forward. I have not seen this theory mooted before. In the course of an interesting conversation with Mr. Alfred E. Moore, the energetic and enthusiastic secretary of the Pure Food and Drug Society, he suggested that "we are constantly taking food which is adulterated or faked, and often contains minute portions of drugs for preservative purposes. Now, the constant taking of these preservatives must interfere with natural metabolism. Their presence in the body must tend to cause cell growth to vary and to upset the proper development of the various organs, and in so doing either predispose to cancer or actually affect cells in such a way—in, say, a damaged part of the body—that instead of the tissues being able to recover their original condition they become cancerous." Now, Sir, those of us who are gardeners know how enormously plants vary according to their food (for example, the colours of the iris can be changed by transferring it from a gravel soil to a chalky soil), and it is perfectly obvious that abnormalities must occur in the same way in the human race if their food varies; this, of course, is well known. Cancer is more prevalent in some places than others. This is due not to humidity and atmospheric changes probably, but to the water of the district as regards water, we have the abnormal growth of the cells in the thyroid, which has led to the term "Derbyshire neck", or possibly to the fact that in some districts food of a special sort is taken more than in another. It is, of course, common knowledge that even now in England in different parts special dishes peculiar to each district are taken. For example, in Somerset and Devonshire people eat a lot of cream. Who has not tried a "Devonshire tea"? Probably more cider is drunk in these counties, and the bacon derived from pigs fed on apples is totally different from bacon from other parts of the country. Going north, people go in for girdle cake, hot rolls for breakfast, oatcakes, etc., more than in the south. The butter of South Wales is totally different from the butter we get from Brittany and eat in London. It seems to me that an investigation based on Mr. Moore's theory might lead to very important results, and there are two things which the medical profession ought to find a cure for, and which any medical man ought to devote his time to, and they are phthisis and cancer. Of course there is the question of heredity, and I have never seen a case of cancer without some family history; but still, this cannot be all, and I consider Mr. Moore's theory of the utmost importance.

EIGHTY-SECOND ANNUAL MEETING
OF THE

British Medical Association.

Held in Aberdeen on July 29th, 30th, and 31st.

PROCEEDINGS OF SECTIONS.

SECTION OF SURGERY.

J. SCOTT RIDDELL, M.V.O., M.B., C.M., President.

DISCUSSION ON THE EVOLUTION OF THE SHOCKLESS OPERATION (ANOCI-ASSOCIATION).

OPENING PAPER.

By H. M. W. GRAY, M.B., C.M.Aberd., F.R.C.S.Edin.,
Surgeon to the Royal Infirmary and Sick Children's Hospital, Aberdeen.

I PROPOSE to consider the subject of this discussion from a purely clinical point of view.

After an experience of nearly twenty years in the use of local anaesthesia, I have come to regard it as *the* chief, *the* most important factor of any of those at our disposal in the prevention of pain and therefore of shock. I look upon general anaesthetics, narcotics, and other precautionary measures merely as adjuvants to the local anaesthetic.

Novocain, at all events in weak solutions of ¼ to ½ per cent., may be regarded as non-poisonous, having no deleterious action either at the site of application or on distant organs. This cannot be said regarding either general anaesthetics or narcotics. They may be considered at present as unavoidable evils. Following the method in which I use novocain, they play a subordinate part. According to the nature of the case, sometimes one, sometimes the other, is brought into more prominent action. Because ether, and to a greater extent chloroform, exert, by their chemical action, an undesirable effect on the brain cells, and thereby probably predispose to shock, and because morphine and omnopon not only do not have this baneful influence, but actually prevent cerebral irritation, I make use of these narcotics in preference to general anaesthetics in doses which tend to render the patient more or less regardless of what is going on. The method reduces the amount of general anaesthetic, for even extensive operations, to practically a negligible quantity.

Prevention of mental excitement or irritation is nearly as important as the prevention of pain. It is almost superfluous to say how necessary it is that the patient should have complete confidence in his surgeon. The medical attendant as well as the surgeon and his assistants—in fact, every one who comes in contact with the patient—can do much to engender this confidence. Thus is attained, in great measure, the elimination of apprehension, that great predisposing factor of shock. Apprehension can be allayed or entirely removed by the use of sedatives. Directly the operation is past, the anxiety usually at once disappears.

Few workers have succeeded in arousing such a fresh, practical interest in this subject as Dr. Crile of Cleveland.[1] I venture to think, however, that appreciation of what is necessary is still inadequate. From what one has seen and read, operation by what is called "Crile's method" entails, in too many cases, merely a haphazard infiltration of the area of incision, and too little regard to the other procedures which he advocates. It has appeared to me that many operators have had only scanty experience of what is required to produce local anaesthesia. I recommend these operators to attempt to perform intricate operations under local anaesthesia without the aid of any adjuvant. If the solutions be injected in a perfunctory or unskilled way, it is extraordinary how many failures will be experienced. The use of a general anaesthetic prevents a proper appreciation of the value of even the modified "Crile's method." If the injections are not carefully and adequately performed, they may almost as well not have been made.

I propose to give a very plain statement, couched in very plain language, of what I believe is essential in the prevention of shock. My efforts to attain this may be summed up as consisting chiefly in the efficient use of local anaesthesia combined, when necessary, with the administration of a suitable dose of a narcotic and of ether. There are, further, the very important factors of the preparation of the patient and of the technique of the operation, and these I shall discuss first.

Preparation of the Patient.

I believe that usually too much time is occupied in the preparation of the patient. It is, especially, unnecessary and undesirable to keep a patient entirely confined to bed before most operations. We should learn lessons from emergency patients of all kinds in whom "preparation" is of the worst possible type, yet 70 to 90 per cent. of such cases recover with very little manifestation of shock. The anticipation period should be cut as short as possible. Unless there be good reason to look for improvement from preparatory treatment—as, for example, when the cardiac or general condition of the patient is bad, when medical treatment, transfusion of blood, etc., may be invaluable—the operation should be carried out as soon as possible after the decision to operate has been made. Long preparation is bad, especially if the patient is kept in bed: the patients lose vasomotor tone, so that, under strain, they tend to have cerebral anaemia. We find constantly that patients who have been kept under observation for some time in medical wards not only give greater cause for anxiety during operation, but also occupy a longer time in convalescence. Other considerations I need not touch upon. As far as possible we should avoid disturbing the patient with elaborate preparations, and try to prevent undue deviation from ordinary habits and diet to within a reasonable time of the operation.

In order to exclude external impressions as much as possible during the immediate preparation and actual operation, after receiving an injection of omnopon, the patient's eyes are covered by lint or cotton-wool pads, and the ears are stopped with moist cotton-wool.

Technique of the Operation.

What is known nowadays as "carnivorous surgery" must be avoided. Cutting instruments must be sharp. Seizing large masses of tissue in pressure forceps, rough, sudden, or irregular retraction of wound surfaces, rough handling, tearing or pulling of tissues, especially of the parietal peritoneum or pleura, mesentery, and so forth, must be avoided as far as possible. In an abdominal operation conducted under local anaesthesia alone, it is easy to appreciate that severe shock is readily produced by unskilled handling. It is also very appreciable how far shock may be completely avoided by well placed injections of local anaesthetic in the abdominal parietes, mesentery, broad ligaments, etc., coupled with gentle treatment of the tissues. The use of local anaesthesia demands that desirable delicacy of manipulation.

The proper temperature and non-irritating nature of fluids used in a wound, especially if used inside the abdomen, are important in preventing shock. Too hot or too cold solutions, or too strong and irritating antiseptics will readily produce shock. Normal saline solution, at the temperature of 100° to 103° F., is all that is usually required for purposes of irrigation or cleansing.

I need not do more than mention the importance of conserving heat and obviating irritation by the avoidance of undue exposure of abdominal viscera, raw surfaces, or even of large areas of skin. Proper clothing and other coverings, preferably sterilized, and a proper regulation of the temperature of the theatre, are not unimportant factors in the prevention of shock.

Accurate and immediate haemostasis is more than desirable. Loss of even small quantities of blood may turn the scale in some patients. It is still necessary to point out that it is impossible to work with desirable accuracy in a wound whose surface is obscured by the presence of blood.

The avoidance of tight suturing and the application of a

proper dressing may appear insignificant, but even such details are of importance in the prevention of shock. The pain, occasioned by tight sutures or dragging of an unsuitable dressing, which is felt as soon as the patient becomes conscious, cannot be disregarded at a time when the nervous system is still under the deleterious influence of a general anaesthetic. This is especially of importance in neurotic patients. Proper technique, proper dressings, and local injection of anaesthetic solution obviate shock from this cause. Firm compression of the wound for twenty-four hours prevents effusion and consequent tension on the sutures.

In abdominal cases I believe that a firm binder has a beneficial effect during the first, possibly precarious, hour or two. Clinical impressions receive confirmation from Hill and Barnard's observations on the effects of anaesthesia on the abdominal vasomotor system. Such compression combats the tendency of the patient to bleed into his own abdominal vessels, and thus bring about harmful anaemia of the brain. Further, it permits of the patient being placed immediately after operation in the Fowler position, a proceeding which is beneficial in preventing various complications. I remove the binder usually after twenty-four hours.

The Use of a General Anaesthetic.

In view of numerous observations regarding changes produced by anaesthetics in brain cells and their immediate and remote effects on the heart and other important organs and tissues, surely it is right to dispense with them as much as possible. This toxicity is greatest in the case of chloroform, ether stands next, while nitrous oxide has little deleterious effect when skilfully administered.

Chloroform in surgical practice is fast becoming almost obsolete. Nitrous oxide and oxygen involve much expense, complicated apparatus, and a highly skilled administrator in cases of prolonged operations. "Open ether" is safer than nitrous oxide when a skilled administrator is not available; it is incomparably cheaper and no elaborate apparatus is required. These considerations have inclined me to develop the use of ether along special lines. By the combination of local anaesthesia and narcotics the amount of ether (if any) which may be required is negligible. Ether is given only if patients, in spite of the narcotic, remain too sensitive and apprehensive, or where it is apparent that they are suffering pain. Sometimes in excitable patients literally only a few drops of ether are required to distract their attention and produce an immediate reduction in the pulse-rate. In other cases it suffices to induce only the primary anaesthetic stage of ether.

I venture to recall that a primary anaesthesia, lasting for about a minute, is produced when ½ oz. to 1 oz. of ether alone has been given, but when a narcotic has been given beforehand usually only a drachm or two of ether is required to produce this condition. If careful and gentle manipulations are thereafter observed, the patient may continue to sleep even as long as three-quarters of an hour. The advent of this stage may be indicated by instructing the patient to hold his arm erect as long as he can. When the arm drops short operations may be effected without pain. If etherization is continued the patient may wake up again, even speak and struggle. It is desirable, therefore, when ether is combined with local anaesthetics and narcotics, to discontinue the general anaesthetic entirely at this stage. Perfectly satisfactory examination of deep parts, short, deep manipulations, injection of anaesthetics into the mesentery, etc., can be made at once. The ether mask should be removed so that the patient may breathe air as pure as possible. I cannot say that I have found that patients have benefited from respiring their own or other carbon dioxide.

The evil effect of prolonged ether anaesthesia on the brain cells and other tissues is obviated by this method. Only in very rare cases where prolonged, deep, and very difficult manipulation has to be done, is it necessary to give ether in the usual manner or amount.

The Preliminary Use of Narcotics.

In my experience the combination of omnopon and scopolamine is the best. The average dose is ⅔ grain omnopon, $\frac{1}{150}$ grain scopolamine, in 17 minims of water, given an hour and a half before operation. A little experience, coupled with the indications given in my paper of 1911, enables one to modify this dose to suit individual cases. I have practically nothing of importance to add to what I wrote in 1911 except to say that now I enhance their action by giving veronal, to certain patients, on the evening before operation (5 grains at 5 or 6 p.m., and 5 between 9 and 10 p.m.). This ensures almost always a good night's rest for the patient, a matter of considerable importance. Apparently no change in the brain cells is produced by omnopon and scopolamine and the changes in these cells consequent on peripheral trauma, as by operation, are materially lessened by their use, as has been shown by Crile's experiments. They prevent the acute metabolic waste which accompanies serious operations as ordinarily conducted. They prevent psychic shock. They usually produce an agreeable indifference to what may be taking place. They usually remove any apprehension, which in ordinary cases is at its height during the hour or two immediately preceding operation. The local "atmosphere" surrounding British patients too often aggravates this apprehension if local anaesthetics are to be used, for there is still an unjustifiable distrust on the part of the large majority of medical men in this country as to the efficacy of these, especially for major operations, and this distrust is reflected in the minds of nurses, friends, and relatives, who are in more or less constant association with the patient previous to operation. This feeling is transmitted directly or subconsciously to the mind of the patient. This unfortunate attitude is engendered by the fact that most operators have not taken the time and trouble to master the technique which is essential for success.

Local Anaesthesia.

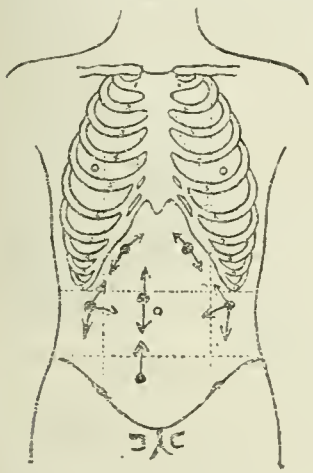
This brings up the question of whether this time and trouble are worth while. For my own part, I think it is almost criminal to neglect the development of this technique. Many life-saving operations in cardiac, pulmonary, diabetic, renal, and other cases are rendered comparatively safe, instead of being, on account of the use of a general anaesthetic, a direct cause of death in too many instances. Surely, therefore, local anaesthesia practically removes risk in ordinary cases. When I say that I have succeeded in performing painlessly all the ordinary operations which fall to be done by a general surgeon with local anaesthesia, aided merely by omnopon or omnopon-scopolamine, I am not guilty of any exaggeration. As indicated already, for various reasons, insignificant amounts of ether may have occasionally to be given. It seems absurd to speak of etherization when the quantity of ether used by the open method, even for such extensive proceedings as Albee's operation for spinal caries or abdomino-perineal excision of the rectum, amounts to no more than 2 to 4 drachms.

I have long ago given up spinal anaesthesia. I rely entirely on ordinary nerve blocking and local infiltration. I claim that, with the method I use, equally good anaesthesia can be obtained without that percentage of danger which is incurred when anaesthetics are injected inside the dura mater.

The technique I carry out in an abdominal case involving a long paracentral incision is as follows: Unlike Crile and his followers, I block the intercostal and lumbar nerves as near the costal margins (or in the subcostal grooves) and as far back in the loin as convenient. I find that I can anaesthetize practically the whole of the anterior abdominal parietes, including the sensitive subperitoneal tissue. I have not yet tried paravertebral injection. To save time and prevent post-operative pain more certainly I infiltrate also the skin and subcutaneous tissue along the line of incision. I began many years ago to infiltrate the area of the incision at the end of an operation, in order that the patient might be saved the first severe pain felt on recovering consciousness. Very soon I found that my patients did not suffer so much from shock and other discomforts. I began then to make the infiltration before the skin was incised. Long before Crile's paper appeared I had been infiltrating the line of incision *percutaneously*, not injecting each layer before it is divided as Crile advises. I found that with practice it is possible to be quite certain of the position of the point of a needle in the abdominal wall. In order to obtain this precision I recommend beginners to control their efforts to inject solutions at varying depths by making these injections

only in the line of incision, so that, when this is made, the solution is found in the tissues aimed at. When perfection is attained, they can go on to the method I now advocate, which saves much time, allows far greater freedom of intra-abdominal manipulation because a larger area of subperitoneal tissue is anaesthetized, and gives as perfect relaxation of the muscles as one can wish. With the help of a trained assistant, a series of operations can be carried out just as quickly as when general anaesthetics are used. The assistant prepares the next patient at the proper time.

The anaesthetic is injected as follows: Five or six skin blebs are made with a fine needle in the situations indicated in the diagram. Through the blebs I infiltrate with a thicker, longer needle, first the line of incision and then the lateral abdominal parietes, down to the peritoneum. If pain is made much of at this stage, the patient is given a small amount of ether, and if the operation is likely to entail difficult manipulation, he is given ¼ to ½ grain more omnopon. According to the length of the incision and the thickness of the abdominal wall, 100 to 200 c.cm. may be used. After 10 to 15 minutes the operation may be begun. If pain is felt in the deeper layers, either a little more solution is injected locally or else I wait for a few minutes longer. Further injections may have to be made into the peritoneal attachments of the organs which are to be operated on. As already stated, a small amount of ether may have to be given at this stage, but need not usually be continued.



When infiltrating the abdominal wall the solution should be injected as the needle is being pushed onwards, so that vessels and nerves, unless fixed in fibrous tissue, are floated aside. This will also cause the peritoneum and the fairly dense subperitoneal tissue immediately lining it to be carried in front of the solution, so that the looser part of the sub-peritoneal tissue is flooded with the solution. Diffusion of the fluid joins up the lines of punctures. Frequently, in cases of appendicectomy, for example, I deliberately push the needle through the peritoneum, at the same time forcing out the anaesthetic solution at greater speed, so that the bowel may be floated away from the point of the needle.

I do not believe much in statistics, but the table shows the average pulse-rate of two unselected series of abdominal cases. The cases range in severity from, for example, interval appendicectomies to extensive colectomies and cases of diffuse peritonitis. The latter probably account for the high pulse-rate at the beginning of the operation. I believe that the pulse-rate gives a fair indication of the amount of shock present, but one cannot imagine that any real shock or even predisposition to it is present in a case where a drachm or two of ether, given by the "open method," completely quietens an excited patient and reduces the pulse-rate by twenty to thirty beats within a very few minutes.

The first series is taken from patients in whom the area of incision only was infiltrated percutaneously with anaesthetic solution, the second series from patients who were injected by the method I use now. The evidence, it will be seen, is strongly in favour of using my later method.

Table showing Pulse-rate during and after Operation (60 Patients).

	Before Incision.	Abdomen opened. Retraction.	Skin Sutured.	Evening.
With infiltration of line of incision only	89	95	94	95
With blocking of abdominal parietal nerves	94	87	89	85

I wish to emphasize the feeling of well-being which patients thus treated have immediately after operation. In young adults, when the dose of omnopon is not sufficient to make them sleep, the patients frequently have a meal when they return to bed, and in an hour may be found reading a newspaper. In more severe cases, when larger doses of omnopon and possibly ether also have been given, the patients often sleep for four to six hours, and may then wake up without any knowledge that an operation has been done. In a large majority of cases little or no pain in the wound is complained of, except when the patient coughs, sneezes, or retches. This is important, because there is not much doubt that the shock which used to appear within an hour or two after operation was precipitated by the pain felt as consciousness returned. In my cases such experiences never occur nowadays. I believe that these results are due chiefly to the kind of anaesthetic solution which I have used for nearly a year. It was introduced by Hoffmann and Kochmann.[2] It consists of novocain ¼ per cent., potassium sulphate 0.4 per cent., and 12 drops of (synthetic) adrenalin to each 100 c.cm. The potassium salt enhances and prolongs the effect of the novocain. It seems to me that this solution acts almost as well as urea and quinine. After its use there has been no interference with healing, no oedema, and no sloughing, as has been stated to occur after the use of urea and quinine, and in expense it compares favourably. While 5 c.cm. of the latter costs 4½d., one litre of "N.P.A. solution" costs not more than 2s. 4d., or one seventh of a penny per 5 c.cm. My house-surgeons call it N.P.A. for short. This indicates both its composition and its action. Novocain - Potassium-Adrenalin! No Pain After! Although Claude Bernard asserted that potassium salts have a poisonous effect when injected into the blood stream, I have never seen any bad effects attributable to this. I use a special syringe for this work.* It has a capacity of 40 c.cm. It has interchangeable needles and nozzles; a fine Schimmel's needle in the straight nozzle is used for making the skin blebs; a strong long needle in the bent nozzle is used for the deeper injections. For rapid working two or more syringes may be used—one being filled while the other is in use.

During a severe operation, if the pulse tends to flag—especially if severe haemorrhage or previous sepsis has occurred—I believe that an intravenous or subcutaneous infusion of saline solution is the best restorative, unless direct transfusion of blood cannot be made, but this unfortunately is rarely possible. Transfusion should certainly be resorted to if shock threatens after operation.

In my operative cases shock is now an occurrence of the greatest rarity. In well over 2,000 abdominal sections performed during the last three years, I have records of only two which suffered from post-operative shock. In both cases dread of operation had dominated the patient's mind for weeks.

My experiences support Crile's assertions in a very ample way, and I am ashamed to say that until a week or two ago I had not read more than a short epitome of his paper. It was all the more pleasant to find that I had been working in the right direction. Crile has shown experimentally the evil effects of fear, trauma, insomnia, and other causes of vital depression. For years one has felt that too little attention has been directed to the elimination of these noxious influences. In the prevention of shock Crile demonstrates that, apart from raising the threshold of resistance and avoiding physical exhaustion in various ways, one must aim at preventing traumatic and deleterious psychic stimuli from taking effect on the brain. In this effort I believe that efficient local anaesthesia must be given first place, narcosis second place, and general anaesthesia third place—the last to be used only in exceptional circumstances. In this connexion I beg to refer to my paper published three years ago.[3]

In conclusion, I wish to remark that I have endeavoured to combine efficiency, safety, and cheapness in my operative work, and I feel that I have succeeded fairly well. As an instance, for a dozen abdominal cases of moderate severity operated on in hospital on July 9th and 10th, and in which the principles I have enunciated

* Made by Down Brothers, Ltd., London.

were carried out, the cost for local anaesthetic solution amounted, at a generous estimate, to the sum of Is. 7d. If nitrous oxide and oxygen had been used, according to Mr. G. H. Colt's investigations made a few years ago, the cost would have been approximately £5 (five pounds). I do not venture to think that the method I advocate is at present perfect. I hope, as time goes on, that it will become more nearly so. Before becoming proficient in a new procedure one must, almost necessarily, encounter occasional failures. In spite of this an increasing number of patients in the North here are actually requesting that their operations shall be done under these new conditions. When the present prejudice in the general professional mind has yielded—and this change is occurring much more rapidly in other countries than in Great Britain—it seems to me that the public will quickly appreciate what is best for it, and demand that the principles of anoci-association shall be those which regulate surgeons everywhere in their operative procedures.

DISCUSSION.

Mr. CUTHBERT (Gloucester) said that for the past year he had carried out the Crile method of anoci-association in a considerable number of cases. The main objections made to it were that it was troublesome, took time, and involved an extra risk of sepsis. It involved, however, very little trouble when everything was ready on a separate table and looked after by a nurse well up to such work. The time taken was certainly not more than five minutes during the operation, and this was not to be considered. The infiltration of skin and muscles by novocain could be carried out three-quarters of an hour before the patient was brought into the theatre. This allowed time for it to take good effect and got rid of the oedematous condition of the tissues; more novocain could be injected into the deep muscles and structures previous to cutting them. The peritoneum as it was cut was infiltrated with urea-quinine hydrochloride solution (½ per cent.). There ought to be no extra risk of sepsis if the syringes and fluid were properly sterilized. It was very necessary to use the proper needles bent at the proper angles, as used by Crile, Mr. Gray, and others. He had had the privilege of seeing Mr. Gray's work, and no one could help admiring the complete analgesia he obtained in the entire absence of general anaesthesia. The advantage of this seemed to be that if the patient gave any response to pain, more of the solution could be injected as the operation proceeded. Mr. Cuthbert said that hitherto he had avoided the urea-quinine method of infiltration in septic cases, and asked Mr. Gray what course he pursued in such cases, and what were the real objections to the method in septic cases. The entire absence of rigidity, and the absolute flaccidity of the muscles and hollow organs after being injected, added enormously to the ease of manipulations and in sewing up the peritoneum. In so-called fulminating appendicitis the Murphy method of rectal irrigation, with the addition of adrenalin before, during, and after the operation, was, in Mr. Cuthbert's opinion, of enormous benefit, and it seemed reasonable to suppose that adrenalin injected into the peritoneum in conjunction with urea-quinine could have no other than a good effect in shutting off nerve transference of shock. While regarding Mr. Gray's work with admiration, he still thought that light general anaesthesia, enough, as it were, to blind the patient during his removal to the theatre and at the commencement of the operation, was advantageous.

Mr. ALEX. DON (Aberdeen) said that, like most surgeons, he had had recourse to most of the newer methods of anaesthetizing patients, and had had this advantage over many hospital operators, that he was responsible for the anaesthesia as well as for the operation. Some of the intravenous and rectal methods he had not tried, but long before Crile's paper on the shockless method appeared he had formulated certain conclusions from practical experience and observations that a general anaesthetic did not prevent stimuli from the field of operation reaching the cord and brain cells, but merely dulled their effects by making the patient unconscious of the injuries and preventing motor responses. He then related a personal experience:

I have suffered from dental caries ever since I can remember; my teeth are difficult to extract and cannot be completely anaesthetized locally. I took a good dose of omnopon and scopolamine an hour before my appointment with a dentist. It certainly braced up my courage. I got a big dose of novocain and adrenalin into the neighbourhood of the offender. I did not feel the application of the forceps very much, but the wrench severely. I walked home. The whole side of my head was by then quite wooden, but touch sensation was unaltered, except that the part touched seemed a foot or so away from my face. I had got about half-way home when the calves of my legs got first creepy and then weak and shaky. In a couple of hours I was sick and the anaesthesia had almost left the side of the head. I became completely apathetic. Two hours later the telephone bell rang and I got up to answer it. I found I had to plant my feet far apart to steady my staggering gait, and then I seemed to have forgotten why I rose. I answered the 'phone, I suppose correctly, and immediately forgot all about it. It was four or five hours later before I became a normal sentient being, and had forgotten that I had been at the telephone at all. I had been perfectly conscious all the time and, except for the sickness, had felt quite well, had spoken when addressed, and had remained sitting the whole time without feeling hungry or out of sorts. But for fully a week after I felt unable for any effort, mental or physical, was yellow in colour, and had no desire for food. I do not pretend to be able to analyse the effects, nor to single out the drug that caused the symptoms, but I am sure that it was neither the mental nor physical shock of the extraction that caused the condition. I had noted similar effects on some of my patients before, and I have no doubt that had I undergone a serious operation, the effects of this combined drugging would have jeopardized my chances of recovery considerably.

Omnopon, he said, was a very crude extract of a very uncertain compound, opium. It was not known whether the alkaloids were extracted by the acid in their relative proportions, but opium itself was a very indefinite compound, and so, therefore, must be omnopon. Even were it of definite composition, it contained too many substances, the effects of which could not be judged even singly, and he considered that its use was a distinctly retrograde step in therapeutics. To compare it with morphine or with morphine and atropine or scopolamine was like comparing a blunderbuss loaded with small stones to a modern rifle. In the hands of experts, a combination of morphine with either hyoscine or atropine some time before the operation, and open ether in the theatre, seemed quite satisfactory, and there was very little shock with surgeons who cut cleanly with anatomical precision, used brutal retractors sparingly, not tearing the tissues by force or licking them back off tender structures with a coarse gauze sponge. Even if, by blocking, the impulses were prevented from reaching the brain at the time, these or similar impulses would reach the brain later from the field of operation after the local effects of the anaesthetic had worn off, and when the anaesthetic had itself reached the brain cells, and was there producing its numbing effects, as in his own case. Coarse surgery could not be indulged in under local anaesthesia. He had tried quinine-urea hydrochloride, though not on account of complaints by patients of post-operative pain. There was seldom any complaint unless vomiting was severe, and that was not so common with preliminary morphine and hyoscine. The effect of quinine-urea was said to last a day or more, but this, he thought, was surely exceptional. He had injected an ampoule subcutaneously into himself, and the effect had altogether disappeared in some eight hours, a painful spot remaining. With morphine and hyoscine there was seldom any complaint about operation pain till after eight hours, for vomiting was usually delayed after morphine. Injections into the tissues anywhere caused a certain amount of damage, even if the fluid injected was normal saline, and this damage must delay healing. He believed that there was a field for this combined anaesthesia, though the necessity for the morphine in some cases might be doubted, where there were objections to a general anaesthetic or the services of an anaesthetist could not be obtained. The field for the method of Crile was not unlimited; besides the objections already indicated, there were the element of time, the handling of many extra instruments, the diversion of the surgeon's mind from his main purpose every now and then to attend to the anaesthesia. This method produced greater risks of sepsis, and had a greater morbidity, and also, he thought, a greater mortality. Anoci-association must at present be held to be on its trial.

Mr. C. A. Pannett (Plymouth) said that in a recent experimental investigation he had attempted to measure the efficiency of Crile's technique by determining whether, when it was employed, impulses set up by abdominal operations were prevented from reaching the medullary centres. The criterion of such interference relied upon was the disappearance of vasomotor and respiratory reflexes normally observed during such manipulations. The experiments led to the following conclusions:

1. More powerful impulses proceed towards the medulla as the result of manipulation of the viscera than result from the incision of the abdominal wall necessary to reach the viscera. Presumably they have a greater influence in the production of shock.
2. It is, therefore, more essential to block impulses coming from the viscera than those coming from the abdominal wall.
3. In animals (cats, rabbits) it is possible to block impulses coming from the stomach by local anaesthetization of the attachments of this viscus with ¼ per cent. novocain.
4. It is possible, in animals, to block impulses coming from the intestine by similarly anaesthetizing the attached mesentery.
5. When the incision is in the middle line, Crile's technique for opening the abdomen effectually prevents afferent impulses, the outcome of this procedure, from passing up to the medulla.

Manipulation of the intestines and stomach led to the dispatch of shock-producing nerve currents to the medulla, and to a disturbance in the centres much greater than occurred on injuring the abdominal wall. This was directly opposed to Crile's findings. He says on page 41 of his book:[1]

The only shock-producing factors in operations on the intestines are traction of the mesentery and traumatization of the peritoneum. Suturing, cutting, burning, and even crushing the intestines, independently of other factors, cannot produce shock, as no noci-ceptors have been evolved against these types of trauma.

But electrical stimulation and pinching of the gut produced marked changes in blood pressure and respiration. Braun[2] admitted that when the abdomen had been opened under local anaesthesia division of the mesentery might sometimes be very painful, and Hirschel[3] stated that this was usual. Moreover, Crile, on page 87, makes a statement contradictory of his fundamental views when he says: "Ligation of the stump of the appendix causes sharp cramp-like pain." Such beliefs led to the cessation of efforts to intercept a very important set of impulses. The establishment of the fact that noci-ceptors for the viscera existed rendered necessary some measures to prevent them from being the means of recording in the central nervous system the injuries which operative procedures produced. In man, at present, this could not be successfully accomplished. It was not possible to infiltrate the attachments of the stomach without so much manipulation that the advantage gained during the performance of such an operation as a gastro-jejunostomy would probably be counterbalanced by the ill effects of the increased handling. It was, however, a simple procedure to infiltrate the mesentery of a length of small intestine. The same measure could be taken when the transverse or the sigmoid colon was involved, but some research would be necessary to devise methods for blocking impulses from the caecum, ascending or descending colon. The technique recommended by Crile for the abdominal wall was only efficient when the opening was made in the middle line, where nerve endings alone were encountered, and their anaesthetization with ¼ per cent. novocain easy. Away from the middle line it was not such a simple matter to block afferent impulses. When making a Battle incision the nerve trunks running behind the rectus must be found, and their conductive power destroyed by a perineural injection of 1 per cent. novocain (or an endoneural injection of ¼ per cent. novocain), before the procedure became painless. In the McBurney incision, infiltration of the different layers with ½ per cent. novocain was necessary, and long intervals (10 to 15 minutes) must elapse between the infiltration of each layer of the abdominal wall, and its severance. Only in this way could efficient local analgesia be produced, and the method was therefore contraindicated in combination with a general anaesthetic because of the great prolongation of narcosis which it necessitated. One aspect of shock in abdominal operations, the inhibition of peristalsis which followed every laparotomy and caused so much distress to the patient, had not received the attention it deserved. This was part of a general suspension of function of the alimentary organs which Meltzer and Auer[4] and Cannon and Murphy[5] had found depended upon (1) a reflex inhibition, the centre being in the spinal cord, the afferent paths being the sensory nerves in the abdominal wall, and the efferent path the splanchnics; (2) a local reflex inhibition, the centre being Auerbach's plexus (or possibly the coeliac plexus) the afferent nerves coming from the visceral wall. The cessation of peristalsis, due to a local reflex, might be regarded as a manifestation of peripheral shock. By infiltrating the abdominal wall as indicated above the first reflex stoppage could be prevented, but there was no way of hindering the local reflex; all that could be done was to handle the viscera as gently as possible. It was claimed that local novocainization of the abdominal wall lessened muscular rigidity. The tone of the abdominal muscles was increased by injury to the abdominal wall, and especially to the parietal peritoneum, or by manipulation of the viscera. He had shown experimentally that the increased tone of the abdominal muscles resulting from injury to the small intestine could be abolished by infiltration of the mesentery, and that due to irritation of the parietal peritoneum by infiltrating it. This proved to be true in man, for the abdominal rigidity which was so often experienced when dragging on the parietal peritoneum to suture it disappeared if it were infiltrated with novocain from its abdominal surface. Suturing was thereby rendered much easier. Local infiltration of a middle line incision with ¼ per cent. novocain diminished shock by eliminating painful and other afferent impulses; it abolished the reflex inhibition of peristalsis, the centre for which was in the spinal cord; and it prevented the reflex rigidity of the abdominal muscles dependent upon injury to the parietal peritoneum. When the incision was not in the middle line this reflex rigidity could be eliminated by infiltrating the peritoneum on either side of the incision with ¼ per cent. novocain, though a similar injection of the other layers of the abdominal wall was useless as a shock-preventive procedure. In the presence of sepsis it was not permissible to risk the dissemination of organisms by thrusting the needle through infected tissues. The method, therefore, could not be employed in many serious intra-abdominal conditions in which it would be a distinct help.

Mr. Miles (Edinburgh) found himself unable to go the whole length with Mr. Gray in the method described. There was a danger of becoming too enthusiastic, and surgeons must not permit themselves to be carried away by a phrase—though there was little that was attractive in the phrase "anoci-association." No hard and fast lines could be laid down. It was necessary clearly to define the "noci" to be met and what association of noci occurred. He was not prepared to abandon chloroform, which he thought a very safe anaesthetic. Two great factors in diminishing shock were crispness and rapidity in operating. The elaborate infiltration method described demanded a large expenditure of time, no matter how expert the surgeon might be. The time element seemed to him to bulk largely in the question. Operators of past generations were much more rapid than those of the present, and he thought that in their descriptions of big operations the absence of mention of shock was due to the time factor.

Dr. Manson Fergusson (Banff) said that he had used Mr. Gray's technique for three years, and his improved method of infiltrating the abdominal wall for four or five months. Prior to using the latter method, 1 per cent. and sometimes 2 per cent. novocain was necessary, but he found that a perfectly satisfactory anaesthesia could be obtained with the "N.P.A. solution." The operations during the latter period included appendicectomies, both acute and interval, gastro-enterostomies, prostatectomies and laparotomies for perforated duodenal and gastric ulcers. He used "N.P.A." also for major amputations, thyroidectomy, and excision of neck glands. The pulse had been taken regularly before, during, immediately after, and a few hours subsequently, and the variation in rate and character was very slight compared to that

observed with morphine-scopolamine open ether anaesthesia. He had visited his last twenty abdominal sections every four hours during the first twenty-four hours, and had not seen the slightest appearance of shock—in fact, the feeling of well-being had been remarkable. In addition to this there were the additional advantages of a very complete relaxation of the abdominal muscles, the absence of anaesthetic sickness, and the reduction of work for the nursing staff. The sister in charge of his patients stated that the work had diminished to a quarter or less. Among the disadvantages said to attend this method was haematoma in the wound. He had had one such case, due to the fact that there was too much adrenalin in the solution and some bleeding point was missed. He had not had any case of sepsis following with this method, and thought Mr. Gray's method of percutaneous infiltration as compared with the layer by layer infiltration advocated by Crile obviated this. The amount of ether given by the open method was practically negligible and never exceeded a few drachms; it was necessary only if any great traction had to be made in the course of intra-abdominal manipulation.

Mr. McADAM ECCLES (London) observed that the simple incision by a sharp knife gave far less pain and shock than the dragging upon tissues. To prevent pain and to lessen or abolish shock in severe operations a narcotic shortly previous to the operation should be combined with skilled administration of a general anaesthetic, the blocking during the operation of the associated nerve areas, rapidity and skill, with as little dragging as possible, and care and encouragement by a trained nurse after the operation. Shock was not so frequent as seemed to be implied, but he asked whether "anoci-association" methods lessened or got rid of such common minor post-operative trials as vomiting, meteorism, and retention of urine.

Mr. HEY GROVES (Bristol) asked if it was possible to regulate the dosage of the alkaloids administered as a preliminary injection, or whether the dosage was practically unlimited. The preliminary injections of themselves might give rise to post-operative trouble. He was anxious to know also if this was to be a routine method.

Professor J. T. J. MORRISON (Birmingham) thought that there was a province for each of the new methods of anaesthesia. He regretted absence of reference to spinal anaesthesia, which seemed to him to occupy a position of importance at least equal to local anaesthesia in contrast to general anaesthesia. Broadly speaking, from the patient's point of view and in many respects from the surgeon's, spinal and local anaesthesia were superior to general anaesthesia. He indicated three points in which spinal anaesthesia held the advantage: (1) As to time: spinal anaesthesia was induced by a single puncture and the injection of 20 drops of fluid; anaesthesia was almost immediate, certainly within three minutes amputation through the thigh or laparotomy could be proceeded with. (2) When operating over a septic area the spinal method was safest, as the puncture was distant from the operation field. (3) The after-effects of spinal anaesthesia were of no importance at all in contrast to those of general anaesthesia.

Mr. DE C. WHEELER (Dublin) prophesied the disappearance of general anaesthetics in other than exceptional cases. He had been scouting along the lines of anoci-association for ten years, following the technique of Kocher. Lately his experience had been limited to Crile's method. He joined issue with the teaching of Crile as regards the prevention of psychical and emotional phenomena by a general anaesthetic, whether ether or gas. Brain cell changes from emotional noxious stimuli could be better prevented by previous administration of some drug like omnopon. With local anaesthesia the surgeon desisted when the patient complained of pain; the operator was thus warned that he was sending harmful impulses to the brain. This was only possible in theory under general anaesthesia. He found that after major abdominal operations shock, whether Crile's method was used or not, depended more on whether the operation was "carnivorous" or was carried out methodically and gently. Nevertheless, it was obvious in most cases that breathing vomiting, coughing, and the opening of the bowels after operation were rendered easy to the patient when Crile's method was used. In some cases, even in major cases—pylorectomy and gastro-enterostomy—no sensation of operation was experienced by the patients the day of and following operation.

Dr. OGILVIE WILL (Aberdeen) desired to testify to the excellence of the results obtained by Mr. Gray in cases under his own observation, especially in regard to the comfort of the patients and the absence of anxiety.

Mr. GRAY, in reply, said that by his method he was practically independent of the anaesthetist. He admitted that a considerable amount of training was necessary for the correct carrying out of the method, but training was also necessary for administration of general anaesthetics, and no longer time was required for the former than for the latter. If a man had a knowledge of anatomy and delicacy of touch he could do this work sufficiently well. If sepsis were present he would not inject in the line of incision; for example, in an abdominal case the nerve blocking method only was used. Within the abdominal cavity he tried to inject the mesentery, the broad ligaments, the peritoneum alongside the gall bladder, and so on, so that the shock, so far as these organs were concerned, was eliminated. He did not think that the time factor was of such paramount importance, nor that the total expenditure of time was increased. He thought omnopon was less prone to cause meteorism in abdominal cases than morphine; he had found patients pass flatus on the night of the operation even after a colectomy. If meteorism persisted the best treatment was injection of pituitary extract.

OPIUM AND OMNOPON.

BY

PROFESSOR DR. H. SAHLI,

DIRECTOR OF THE MEDICAL CLINIC OF THE UNIVERSITY OF BERN.

WHEN at the International Congress of Medicine held in London I had occasion to note that several of my colleagues were conversant with my work on the opium question. It may therefore be of interest to place before a wider circle the various phases of the further development of this problem which have led to results relatively important for general practice.

I started with the observation, confirmed by those of many observers, that the action of opium does not coincide in every respect with that of morphine, its most important and active constituent.

For many years I used tincture of opium (laudanum) as a substitute for morphine where a sedative and hypnotic effect was desired, as I had the impression that its action was frequently far more powerful than that of the amount of morphine it contained. This fact has been known for a long time, for, among many others, Bernatzik-Vogel[1] states that, although opium contains 10 to 12 per cent. of morphine, its action is not ten times, but only five or six times, less powerful than that of morphine. There are some patients upon whom a dose of even 10 drops of the tr. opii (Pharmac. Helvet.) has a marked soporific effect, yet the amount of opium in this dose does not contain quite 2 mg. of morphine. As a cough sedative and to alleviate colicky pains, opium is markedly more efficacious than morphine. The fact that Dover's powder has maintained its place in the treatment of patients suffering from cough, despite the ubiquitous introduction of morphine, shows that the practitioner has appreciated the difference between the action of opium and that of morphine. At the same time I noticed that, in many cases in which opium was administered in place of morphine, it was well tolerated even by those patients who cannot take morphine on account of digestive disturbances, nausea, vomiting, and headache. These considerations, as well as the desire to make the total active constituents of opium therapeutically applicable by subcutaneous injection, and therefore in a more powerfully active form enabling possibly a smaller dose with a lesser proportion of morphine to have an equally marked effect, determined me to approach Messrs. Hoffmann-La Roche

in Basle and to suggest to them to extract the total alkaloids from opium, preserving the same proportions in which they occur in the drug, thereby preparing a product which would present the total activity of all the opium alkaloids and could be injected subcutaneously. The preparation which this company succeeded in obtaining, representing the sum total of all the different alkaloids isolated in the form of their chlorides, has been called omnopon* in order to express the fact that the preparation represents the total action of opium—that is, of poppy juice. In opium the alkaloids occur as only slightly soluble meconates, whereas in omnopon they are present as easily soluble and rapidly absorbable chlorides. Opium contains besides these about 75 to 80 per cent. of inert and indifferent ballast material, such as waxes, fats, resins, and gum, in which the alkaloids are enveloped. Omnopon, on the other hand, is a preparation in which the alkaloids have been totally freed from these disturbing substances. Omnopon is a stable, yellowish-brown powder. The preparation dissolves readily in cold water (about twelve parts), and is very soluble in hot water; the resulting solution shows a slightly acid reaction to litmus.

It is far less soluble in alcohol. Other solvents, such as acetone, chloroform, and ether, only dissolve certain of the alkaloids, some remaining undissolved. When dissolved with Froehde's reagent (ammonium molybdate with sulphuric acid) omnopon shows a beautiful transitory violet colour (morphine reaction); with concentrated sulphuric acid the solution is of a blood red colour (thebain). When burned omnopon leaves only an unweighable residue.

Omnopon is put on the market as a powder, in tablet form (each tablet contains 0.01 or 0.02 gram), and in ampoules for hypodermic injection, containing each 0.02 gram. In order to prepare concentrated solutions it is advisable to use a mixture of 75 per cent. of distilled water with 25 per cent. of glycerine. With this it is easy to prepare a 2 per cent. solution which can be used for internal administration or for hypodermic injection should the ampoules not be available. The glycerine acts as a preservative, and solutions prepared in this manner keep indefinitely. It is advisable to fill this solution into bottles which are of glass of very low alkalinity (Jena glass), since some inferior forms of glass give up so much alkali that solutions kept in them become turbid owing to the deposit of alkaloids. The dosage of omnopon is about double that of morphine. The 2 per cent. solution mentioned above is given in similar doses to tr. opii. With opium itself the full opium action is incomplete, owing to the contained resinous and gummy substances, which hinder solubility, make the alkaloids difficultly soluble and materially interfere with their absorption. This is the reason why the pharmacopoeias have in general adopted an aqueous extract of opium. But that even this is only an incompletely purified opium product is shown by the fact that its maximum dose is but one and a half times lower than that of opium. Owing to this incomplete purification the solution is turbid and not suitable for injection. Further, the aqueous extract of opium does not contain the total opium alkaloids, since a part remains behind undissolved. Tincture of opium does not correspond to what has been achieved in omnopon, since it neither contains the total alkaloids of opium, nor is it free from gummy material; moreover, the alcohol used seriously militates against subcutaneous injection.

Taking these circumstances into consideration it was hoped that the use of omnopon would not only show advantages when injected subcutaneously, but that when taken internally the general opium action would also be enhanced. This hope rested mainly on the greater content of active constituents, compared to the older preparation, as well as on the more ready solubility and consequent rapidity of absorption.

Opium contains, besides its predominating content of morphine, not less than nineteen other alkaloids, which belong partly to the Phenanthrene group, partly to the Isoquinolin group. With such a complicated composition it can easily be understood that the therapeutic action of the morphine contained in the opium or omnopon is modified owing to this association with other substances. This fact has been empirically proved in the case of opium for some considerable time, and is confirmed by the use of omnopon. This altered and qualitatively modified action of drug mixtures, in contradistinction to simple chemical substances, can be aptly compared to the taste of flavours. The sensation of flavours is the reaction to a nerve stimulus. It is quite conceivable that the action of drugs, especially narcotic ones, should be subjected, by combinations, to similar fine gradations in their action on the central nervous system as that of combined flavours and scents, since the olfactory and gustatory apparatus is only a part of the central nervous system, and in man not the most highly developed part.

The most important modification of the action of morphine by the presence of by-alkaloids is seen in the lesser action of omnopon upon the respiratory centre. This was first recognized by Burgi and his pupils by experiments upon animals. The fact that this holds good in the case of the human subject was confirmed later on by other observers. The importance of this fact lies in the use of omnopon for omnopon-scopolamine narcosis in severe cardiac diseases and diseases of the respiratory tract; it constitutes a very tangible advantage over morphine. Popper has shown that these by-alkaloids of opium have, even if present in exceedingly minute quantities, a demonstrable action. In a series of experiments with mixtures of morphine and papaverine, Popper found that a mixture which contained the two in the same proportion as opium and omnopon produced the maximum depressor effect upon the longitudinal muscles of the intestine. This experiment, according to Popper, explains the constipating action of omnopon and opium. Recently, Pal has shown that papaverine possesses a peculiar anaesthetizing action locally and has a distinct action upon the blood vessels.

In omnopon we have a drug with a constant opium action. Mannich and Schwedes, by investigations in the Göttingen Pharmacological Institute, ascertained that the content of morphine and by-alkaloids in pantopon (omnopon) corresponds to the statements made. The literature about omnopon is extraordinarily voluminous. I have seen not less than 378 articles and references in twelve different languages, the majority in German. The bulk of these communications are very favourable to the drug, and have fully substantiated my remarks in my earlier writings upon the subject.

It is impossible to cite all the numerous indications for which omnopon has proved itself efficacious, and I shall first mention my own experiences.

Omnopon has been used daily for a number of years in the Medical Clinic at Bern. We use it internally as well as subcutaneously. The 2 per cent. solution mentioned above can be used equally well for both purposes. Besides this we use it in the form of mixtures, powders, pills, and suppositories. The dose is, roughly proportionate to the morphine content (50 per cent.), about double that of morphine.

The drug is given subcutaneously with excellent results as an analgesic and hypnotic in painful conditions, also in insomnia as a result of psychic conditions of excitation and fear, and for dyspnoea.

The injections have proved of value in dyspnoea of cardiac or pulmonary origin, and act excellently in bronchial asthma. In tabetic crises this preparation acts especially well. In facial neuralgia and sciatica its action frequently surpasses all others, even that of morphine. Haemoptysis in phthisical patients is frequently quickly stopped by one injection of omnopon, after which the patient falls into a long deep sleep. Is it not possible that the action on blood vessels of papaverine mentioned by Pal may play a part here? Pal has also achieved good results by administering papaverine alone in haemoptysis.

In all serious conditions affecting the breathing of the patient omnopon is to be preferred to morphine, owing to the fact, established by Bürgi and others, that the former has far less effect upon the respiratory centre. In view of this, one need not be so anxious about the dosage of omnopon in dyspnoea of cardiac and pulmonary origin. Omnopon gave excellent results in a case of diabetic pruritus in which the irritation prevented the patient from sleeping. Lastly, this drug is used as an agent to produce euphoria in incurable cancer and tuberculosis.

I see an especial advantage in the fact that we are now able to attain the rapid and full therapeutic action of opium by hypodermic injection of omnopon in cases of peritonitis, appendicitis, and ileus. Opium, when administered

* From *omnis*=all, and *opos*=juice.

internally in these cases, frequently acts only to a slight extent on account of the vomiting, and the fact that intestinal absorption is markedly impaired. This statement also holds good for severe cases of diarrhœa, which frequently react in a far more satisfactory manner to subcutaneous injections of omnopon than to internal administration.

Omnopon is also efficacious when injected hypodermically in cases of gall-stone colic, renal colic, intestinal colic, and tenesmus vesicae. Its action suggests that here also the by-alkaloids are of importance. Intractable hiccough will often yield to an injection of omnopon.

I have repeatedly used injections of omnopon for severe headaches due to cerebral compression, and it is a great advantage in this instance, again, that the dose of omnopon need not be so small, since there is less fear of a depressing action upon the respiratory centres with it than with morphine.

An average dose for injection would be 1 c.cm. of the 2 per cent. solution mentioned before; for delicate and weak patients half this dose is quite sufficient. In severe cases in which a certain degree of habituation has taken place larger doses will have to be given, each dose will have to be increased (rarely more than 3 cg.), and the diurnal dose will also have to be augmented by more frequent injections.

In severe cases the daily dose may be rather large without any inconvenient symptoms arising. One patient who was suffering from severe neuralgia of the trigeminal, who had become accustomed to the drug, received eight injections of 2 cg. each daily over a lengthy period without any untoward symptoms developing, and was easily broken of the habit when her condition improved.

The injections rarely occasion any local irritation. Now and then hypersensitive patients complain of a slight transient burning pain at the seat of injection, as noticed fairly frequently after hypodermic injections of morphine. Occasionally ecchymoses are seen at the point of injection, which, now that our attention has been drawn to the fact, we have noticed occur also after morphine injections. Other symptoms, such as nausea, vomiting, constipation, anorexia, or excitable conditions after injection, occur only very occasionally, and are certainly much rarer than with morphine. Retention of urine, so frequently seen after hypodermic injections of morphine, I have very rarely noticed after injections of omnopon. Many patients who have previously had morphine injections prefer omnopon. The sedative as well as the analgesic action of an injection of 2 cg. of omnopon is frequently more marked than after one of 1 or 1½ cg. of morphine. I have been able to satisfy myself on this point chiefly in the case of the pains of tabetic patients. In alcoholic delirium a combined injection of 2 cg. of omnopon and $\frac{1}{10}$ mg. of hyoscine acts excellently.

We make extensive use of omnopon as an addition to cough mixtures and to powder or pills destined for anti-catarrhal medication; 0.03 to 0.06 of omnopon can be added to 200 c.cm. of infusion of ipecacuanha or to a mixture containing ammonium chloride, or omnopon can be given by itself or with the desired anti-catarrhal additions as a pill or a powder, three to four times a day, 0.005 gram of omnopon to a dose. Dover's powder after the formula of the pulvis ipecacuanhae opiatus, containing instead of extract of opium 0.005 of omnopon, has shown itself valuable in coughs. When administering omnopon to calm an irritable cough, one can see that the drug has a more powerful narcotic effect than is warranted by its content of morphine. I shall always remember a case in my private practice. A patient suffering from acute laryngitis accompanied by severe irritation and cough, and in a nervous irritable condition, was given 5 mg. of omnopon three times a day. The cough and irritation were immediately alleviated and after two doses she fell into a peaceful sleep. This patient habitually suffered from insomnia and had tried many hypnotics without avail, among them morphine, which she could not tolerate, since it threw her into an excited and nervous condition. The action of this small dose of omnopon (each dose was only equivalent to 0.0025 of morphine) was exceedingly remarkable, and I should hardly have thought that such small doses could procure sleep so promptly. This patient experienced no troublesome effects from the omnopon. Whooping-cough is another condition in which this drug has proved of value.

Internally omnopon, either alone or in conjunction with astringents, has a marked sedative effect upon peristalsis and in checking diarrhœa, in doses of 5, 10, or 15 drops of the 2 per cent. solution, the dose to be repeated until the effect has been produced. Decoction of rhatany root, 10 to 20 grams in 200 c.cm. of water with the addition of 0.1 of omnopon, acts very well, especially in the diarrhœa of phthisis. It is no disadvantage that the alkaloids are precipitated by the action of the tannin if the mixture be well shaken. On the contrary, the formation of these insoluble tannates of the alkaloids, adhering as they do to the mucous membrane, may in this special case be of advantage.

It appears almost paradoxical that on the one hand omnopon exerts a powerful calming action upon peristalsis and is an efficient agent in the symptomatic treatment of diarrhœa, whereas on the other hand, when fulfilling its office as an analgesic, hypnotic, and a reliever of troublesome cough, the constipating action should be only so slightly marked as to be almost negligible, certainly far less than that of morphine. This noteworthy point is closely related to the technique of administering this preparation according to the different indications. In order to get the full action upon peristalsis, the preparation must be given on an empty stomach; this is usually all the easier since the administration is usually to fasting patients or to those to whom a fast has been ordered for therapeutic reasons. In this method the alkaloids of opium come into intimate contact locally in relatively high concentration, and the action upon peristalsis is therefore decidedly enhanced. When given by the mouth to allay a troublesome cough it happens that the frequently repeated doses of the preparation do not enter a quite empty stomach, and as the individual doses are small the concentration reached in the gastro-intestinal tract is rarely high. Constipation can be obviated by suitable distribution of small doses and avoiding giving them on an empty stomach. By this means the action of the preparation upon the intestinal wall is very much weakened. This is especially the case when giving omnopon in the form of a mixture in two-hourly doses for cough, since here the daily dose is widely distributed.

Paradoxical conditions with regard to the constipating effect appear to obtain also when the drug is administered subcutaneously. If the injections are made with the object of inducing sleep or for their analgesic effect, the constipating action is not in evidence or may be absent altogether. The cause of this is that, in contradistinction to internal administration, the local action upon the intestine takes place only through the excretion of the alkaloids through the mucous membrane, as has been proved with morphine, and therefore in a mitigated form. Notwithstanding this, diarrhœa can be controlled with ease by subcutaneous injections of omnopon, and this can be explained by the well known pharmacological rule, which has its analogy in the laws of irritability of the central nervous system, that an irritated function can be more easily checked than one not pathologically excited, and that generally pathologically altered functions can be more easily acted upon pharmacologically than normal functions. This is well known in the case of digitalis.

Omnopon administered internally acts as a more powerful antidiarrhœic than opium given in a similar way, either as opium, tr. opii, or as extr. opii. This does not quite agree with the usual assumption that the insolubility and difficulty of absorption of the older opium preparations and their consequent adhesion to the intestinal mucous membrane gives them their more constipating qualities in comparison with that of morphine. I am inclined to the view that this more powerful constipating action of omnopon, noted when larger single doses are given on an empty stomach, is caused by the greater intensity of the local action.

Unpleasant symptoms I have rarely noticed when administering omnopon either by the mouth or subcutaneously. Statistics compiled by F. Kikodze of 72 patients treated with omnopon at my clinic showed nausea or vomiting in only 4 and constipation in only 2 cases.

[Professor Sahli concluded his paper by enumerating a number of indications for which this preparation has been recommended in the literature up to the present.]

SECTION OF NAVAL AND MILITARY MEDICINE AND SURGERY.

THE TREATMENT OF WOUNDED IN NAVAL WARFARE.

By Fleet-Surgeon D. Walker Hewitt, M.B., F.R.C.S., R.N.

This subject is one of vital interest and importance to naval medical officers, and not only for our own credit, but also in the interests of the service to which we have the honour to belong, it should be constantly before our eyes. As a nation we have never had an opportunity of testing our methods under actual conditions of modern naval warfare, and it therefore behoves us all the more to be on our guard. Our brothers in the Royal Army Medical Corps have had in recent years a vast amount of experience, which after all is the foundation of knowledge. Although we can learn many lessons from them, the conditions of naval warfare are so different that we must map out a line of action for ourselves. Not only are the obstacles we have to contend with very different from theirs, but also the nature of the wounds we shall have to treat, and to a certain extent even the methods of treatment must be different and adapted to our special conditions. Various matters of hygiene and sanitation incidental to fighting on land, epidemics and a doubtful if not dangerous water supply, and diseases peculiar to the country fought in have to be met by them and battled with. On the other hand, although none of the above affect us to the same extent since we fight on board our own ships and therefore in our own country so to speak, yet we have other very serious obstacles in our way, the most important of which are want of space, overcrowding, difficulties of transport from inaccessible positions, absence of Nature's germicides, sunshine and to a certain extent fresh air, and the desire not to interfere with or hamper the fighting machine. We are constantly in the fighting line, so to speak, during the action.

First and foremost we must recognize that a man-of-war is a fighting machine, and that no amount of zeal and ingenuity on our part can convert it into a floating hospital. Our arrangements, therefore, must and should be subservient to fighting efficiency, and we should endeavour to assist this to the best of our ability. In dealing with our subject, therefore, we should not forget this, while at the same time endeavouring to do our best for our sick and wounded.

Having recognized our difficulties we proceed to the most important consideration—namely, how to contend with them. This can only be done by a thorough preparation by each of us individually, taking in all the details, and of these I consider the most essential is to have an efficient first aid party—a party which has been thoroughly instructed in what to do and how to do it. Each individual should have a correct knowledge of how to carry a wounded comrade and where to carry him to. This is, in my opinion, of far greater importance than the administration of first aid properly so called. The first aid during action should be carried out in the dressing stations under the eye of the surgeon except in unusual circumstances. If we allow it to be done by the first aid party (ambulance), where the men fall at their guns, we shall, I am convinced, be running grave dangers. Our dressing stations are so near at hand to all parts of the ship that it is a waste of time for the bearers to attempt it; not only so, but the handling of wounds by men whose intentions may be of the best but whose hands cannot possibly be surgically clean, can only lead to bad results. Furthermore, in the heat and hurry of an action, how can we expect unskilled men to do the right thing? They may lose their presence of mind and forget ordinary details.

The greatest danger naval surgeons had to contend with in the old days of the cockpit was sepsis, its accompaniments and sequelae. Lacerated wounds, burns, and scalds, we know, are especially prone to sepsis, and everything will depend on the primary treatment of these cases. Thorough attempts at asepsis should be our motto, and we cannot reasonably expect these from an ambulance party. On a battlefield, where wounded men are scattered over wide areas, first aid where they fall is a necessity, and from the nature of the majority of the wounds—bullet wounds, bayonet or spear wounds—haemorrhage is common, and therefore immediate action and the use of the tourniquet a *sine quâ non*. On the other hand, the character of the wounds and injuries in a naval engagement are so different that cases of haemorrhage (by this, of course, I mean primary haemorrhage) are rare. Shell wounds which lacerate and contuse the tissue are not accompanied by bleeding, and this has been borne out by the experience of the Japanese in their recent naval fights and by ourselves in accidents from big guns on board our own ships. First aid has always up to the present time been so bound up with the stopping of bleeding and the cult of the tourniquet (we have only to take up any of the first aid books to see this) that I consider it is primarily responsible for the idea that our first aid party should treat men on the spot where they fall in preference to that which I am advocating—namely, rapid transit to the surgeon and the dressing station of the wounded just as they are. In other words, if we admit, as I think we must, that the dangers of primary haemorrhage in naval warfare are slight, we, *ipso facto*, do away with one of the most important arguments in favour of treatment by the unskilled bearers. It should only be a matter of a few minutes to convey a wounded man to the dressing station, and here he will be able to have his injuries treated in a scientific manner by his medical officer. There are no surgical conditions so far as I am aware under which a delay of this kind—if we set aside the question of haemorrhage which I have already dealt with—will deleteriously affect a wounded man. Again, as I shall point out later, the most important duty of the medical officers is not to do major operations but to administer first aid, and not to stand idly by in the dressing stations till the action is over or a lull occurs, whilst unqualified bearers attempt what they are not fitted to do. In the interests of the *morale* of the rest of the crew the speedy removal of the wounded from the actual area of fighting is essential. I cannot do better than quote the words of the medical officer of the Japanese ship *Fuji*, who, from his experience in the Russo-Japanese war, says:

> It would be utterly impossible for bearers to examine the nature of wounds whilst the fight is going on briskly around them, and indeed they often fail in their hurry to make use of the simplest supplementary appliances, such as the four-tailed bandage.

It may be argued that ships, especially large battleships, have altered in construction greatly since that war, and that, owing to the numerous bulkheads and armoured hatches, transport will be more difficult nowadays. With this I agree, but at the same time it is only reasonable to expect that this compartment system will diminish the casualties under armour and that the great bulk of the wounded will be in the exposed or semi-exposed parts, from which access to the dressing stations is still easy.

I should only permit dressings by the bearers therefore:

(*a*) When the casualties are heavy and the dressing stations are filled.

(*b*) When wounded are in positions difficult of speedy removal, such as the engine room or tops.

A well-organized company trained to carry the wounded properly will be the best asset to the medical officers of a ship in action. Its numbers should be in two or more divisions corresponding to the number of the dressing stations, and one individual in each division should be stationed near the dressing station, and take as his sole duty the organization and direction of his company, especially as to the disposal of the wounded as they arrive in and around the station, thus preventing disorder, and leaving the medical officers with the sick berth staff free to look after and investigate the actual wounds and apply the first aid dressings. Another should be told off, also in the area of the dressing stations, to distribute water and medical comforts to the wounded as they arrive.

As regards the actual means of transport, I desire specially to bring to consideration the method which I believe is the only feasible one for the moving of the

wounded to the dressing stations during action or during a lull in the action, and that is the hand method. Stretchers of various descriptions are valuable and necessary after action, but their use will be very limited during actual fighting. Lack of space is the greatest difficulty we have to contend with, and it is impossible to think that stretcher parties will be able to move about interfering with working and ammunition parties during the hurry and bustle of an action; besides we cannot have mechanical contrivances for transport everywhere just when they are wanted. We will have to depend on the human element alone. I do not consider that any mechanical contrivance, no matter how simple, can take the place of the latter. One or two men unencumbered with a stretcher and properly trained can carry a wounded comrade with rapidity up or down ladders and through narrow spaces where stretchers or other mechanical contrivances would be impossible. The dressing stations are so close at hand that it is a waste of time to put a man on a stretcher.

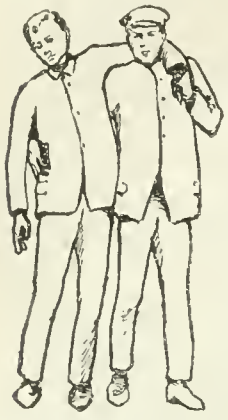

Fig. 1.—The bearer and patient side by side, one arm of the patient around the bearer's neck, and one of the latter's arms around the patient's waist.

The simple methods shown in the accompanying sketches were used in the Russo-Japanese war.

The necessary dexterity and manipulative skill in these methods of "manhandling" as it is called, so as to act with a minimum of suffering to the wounded and non-interference with others, can only be acquired by practice, and in my opinion is of more importance than niceties of bandaging and other surgical details which the bearers will probably forget in the heat of an action. They should be practised seriously as a routine drill, and include the carrying up and down ladders of men by their comrades. The first aid party should be trained in such a way that they can act automatically. I think the greater part of the crew should be trained in these methods as well as the actual bearers.

Fig. 2.—The pick-a-back.

Fig. 3.—Two bearers, one in front of the other, both facing in the same direction. The legs of the patient resting astride the foremost bearer's waist and the rearmost bearer grasping the patient round the axilla and clasping his (the bearer's) hands in front of the patient's chest.

I wish it to be understood that I am not deprecating the usefulness of a training in first aid, but am trying to prove that it is rarely necessary under the special conditions of naval warfare for the first aid party to concentrate their ideas on surgical methods, but rather to consider their sphere of usefulness to be the rapid and painless transport of the wounded to the care of the surgeons in the dressing stations.

Time will not permit me to do more than mention a few of the various preliminaries before going into action. Suffice it to say that all the crew should, if possible, scrub their bodies well with soap and water and wear clean or sterilized clothing. The dressing stations should be scrubbed down with soap and water and afterwards disinfected with carbolic acid. Dressings and instruments should be sterilized, and in this connexion I may mention that no difficulty should be experienced in rendering these sterile, and also, to a large extent, the clothing to be worn in action, thanks to the very efficient disinfectors now supplied to a large number of ships. Ice, if possible, should be made and kept ready, as also a plentiful supply of boiled water. Candles or accumulators should be at hand in case of breakdown of the electric apparatus.

Experience has shown that rupture of the tympanum is very common in action, and can be prevented by plugging the external auditory meatus with cotton-wool or other material. The medical officer should himself see that this is properly done.

As regards the positions of the first aid stations, ships differ so much in their structural arrangements that it is impossible to do more than generalize in their selection. Two or more are fitted up in our larger ships with as careful consideration as possible, and although we are met here with many difficulties, including easy mode of access, a position protected by armour, and not too hot, yet these are greatly intensified when we come to the smaller craft. To obtain the proper amount of space and protection in an already cramped and overcrowded light cruiser, not to speak of a necessary supply of fresh air, is often exceedingly difficult. I am inclined to think that in these circumstances we should select and distribute our wounded over a larger number of first aid stations than in those big ships where we can have ample protection. I appreciate the objections—and there are objections to this—but, on the other hand, the danger of a single shell to all our wounded and the medical staff when they are huddled together in an unprotected space, as actually happened in the Japanese ship *Hiyei* at the battle of Yalu, must be seriously reckoned with. I should feel inclined, therefore, to select four or more separate positions and decentralize. The whole question of the treatment and disposal of the wounded in these smaller ships is fraught with the greatest difficulty. Much must be left to the discretion and individuality of the officers concerned to make the best selection they can. One thing is certain, however, that the sooner the wounded are removed from the fighting ship the better for all concerned. If this question is difficult in ships with medical officers and their hospital-trained assistants, how much more is it so in the large number of small craft which carry neither! The present system is to give first aid lectures to the crews. I do not question the advisability of this; it is excellent in its way, but I think we should go further. I consider the best way to deal with this serious problem would be to train three or four of the crew in each small craft in practical first aid. By this I do not mean only attendance at lectures, but giving them in addition at least a week or a fortnight in the surgical wards of a naval hospital, where they could learn by practical experience something they could retain as to the actual treatment of wounds, and where they could become accustomed to surgical sights. A man cannot become a qualified gunner or torpedo man by means of lectures only, neither can he become proficient in first aid. Personally I think that the small amount of time thus spent would be worth dozens of lectures, and if there were some inducement given for qualifying the results would be well worth it. It might be arranged for the selected men to attend for a few hours daily at the hospitals when in their vicinity. One great objection, of course, to the above is that the crews change so often. I am not bringing forward this as a cut and dry scheme, but for consideration and for suggestions.

Here we are met with the question of a fresh air supply to our dressing stations. We have our supply fans it is true, but what about the source of supply? When our own guns are at work, and the enemy's shell bursting around us on our decks and possibly between decks, are we below safe from suffocating vapours and fumes pumped down to us? I suggest as a remedy here a supply of oxygen which could be carried in time of war. This may appear fantastic, but the danger is a real one, and appreciated by any one who has been on board a battleship during big gun practice, and has experienced the suffocating

effects of lyddite; when we add to all this the results of the enemy's shell, and charred and burning paint, I think we should be prepared.

Coming now to the actual surgical treatment of the wounded during an action, I shall be very brief. Aseptic or antiseptic methods, or a combination of both, must be adopted as considered necessary. Experience has shown that lacerations from shell wounds, burns and scalds, will form the great bulk of our serious cases, and the primary danger of all three can be summed up in the one word "shock." Sepsis and secondary haemorrhage are the sequelae, but our own patients should be on shore in hospitals or in hospital ships and from under our care when these supervene, so that they only indirectly concern us. For "shock," however, we must be prepared and have at our hands the necessary measures for treating it. When we consider the modern conditions of naval warfare—the exposure, want of rest, the highly strung nervous system, and the nerve racking strain of watching for an enemy concealed beneath the sea or in the air—and combine the above with the nature of the wounds, we have all the factors for the incidence of severe shock. I commend for attention the excellent work of Crile and his school on this condition and its treatment, and also the remarks of Lieutenant-Colonel Stevenson, C.B., in his *Wounds in War*.

The performance of anything approaching a major operation during the action will, I think we all agree, be out of the question. All the attention of the surgeon and his assistants is necessary for work of this description, and when the wounded are being brought down, or even when we are in a state of doubt as to what is going to happen, we cannot conscientiously attempt it.

It is our duty to assist to the utmost the fighting efficiency of our ship, and therefore to get men temporarily disabled back to their work as quickly as possible. Numbers of men with minor injuries will come for first aid, and these will have to be temporarily fixed up, and this would be impossible if all our attention is to be riveted on serious work. When the engagement is over we must be guided by circumstances; looking only at one side of the question, and, to put the matter briefly, here we should remember that these are the days of conservative surgery, and that an expectant policy, if we perhaps exclude head injuries, is oftener than not the best. Our motto should therefore be first aid, and our duty to do the best for the majority and assist the fighting force by attending to the slightly as well as severely wounded. It is not my duty, nor have I time in this paper, to go into details of surgical treatment and technique; these must be left to the individual surgeons.

When the action is over, the sooner we get rid of our wounded the better, not only for their sake but for that of the fighting efficiency of the ship. If we have to keep them with us for any length of time our mortality in spite of all our efforts will be high. In the battle of the Yalu the occurrence of sepsis was directly proportionate to the time the wounded were kept on board the fighting ships. One can picture the nightmare of a naval surgeon whose ship is going into action with a number of wounded on his hands who has to prepare for further casualties. Well equipped hospital ships are a necessity.

Now is the time when our stretchers of various descriptions and other improvised means become essential. Rapidity in clearing out our unfit will undoubtedly help our fighting force. For a ship to be kept waiting whilst the wounded are being slowly transferred to a hospital ship and thus prevented from joining the fighting line might be disastrous. Drills carried out with a view to celerity of transport should be regularly practised in all fleets. After some of these drills a conference could be held including the executive officers and the senior medical officers of the squadron, and the difficulties existing could then be attended to and opportunities obtained for further experimenting and perfecting our system.

Lastly, I should like to pay a tribute to our friends the Medical Director-General and other medical officers of the imperial Japanese navy for the detailed surgical history they have published on the Russo-Japanese war with their usual thoroughness; it has been a great help to me in writing this paper.

Sir James Porter, K.C.B. (late Medical Director-General, R.N.), said that the problem was very large, for it embraced everything that had to be done from the minute the man fell wounded till he was in the base hospital. This would involve first aid on board, transfer as soon as possible to the hospital ship, and thence to the base hospital. If all this was to be carried out smoothly in action, it should be a frequent routine drill in peace. At inspections, for example, a proportion of the fighting force should be labelled with the particular injuries they were supposed to have sustained, and so put through routine arrangements on board individual ships; not only so, but frequently, as suitable occasion arose, they should be landed in numbers and conveyed to hospitals. All the arrangements, from start to finish, should be tested.

SECTION OF OPHTHALMOLOGY.

C. H. Usher, B.A., M.B.Cantab., F.R.C.S.Edin., President.

DISCUSSION ON THE HYGIENE OF READING AND NEAR VISION.

OPENING PAPER.

By J. Herbert Parsons, D.Sc., F.R.C.S.,
Ophthalmic Surgeon, University College Hospital; Surgeon, Royal London Ophthalmic Hospital.

The subject for discussion is very wide, but certain parts of it have long occupied a prominent place in ophthalmology and have been worn well-nigh threadbare. I refer to such matters as asthenopia due to errors of refraction and muscular imbalance, the effect of near work in the production of myopia, and so on. These I do not propose to deal with. Other points of the subject have received the scantiest attention from ophthalmologists, though they are astonishingly interesting and not less important than the well-worn topics. I refer particularly to the physics and physiology of the various types of near work—reading, writing, sewing, and the details of innumerable handicrafts. These occupations have gradually evolved as civilization progressed, and have now attained a complexity which demands highly developed faculties and a minute correlation of physiological functions to environmental conditions. This correlation has progressed empirically with the ever-increasing demands, but it is only recently that the attempt has been made to analyse the conditions scientifically and replace empiricism by sound logic.

Let us, first, consider reading. Anthropology teaches us that it began with the use of picture-signs to convey thoughts. The transition from pictures to alphabets is obscure, but the Egyptian and other hieroglyphics afford some inkling as to the course of development. The fully established alphabets and signs were determined with little consideration of physiological requirements, but largely by the mechanics of their production. Writings were in the early days literally upon the wall or upon clay, and the signs were such as could easily be impressed upon clay or chiselled in stone. The monotony of a cuneiform inscription was ill adapted to rapid or even accurate reading, but it sufficed. With the introduction of writing upon papyrus, parchment, and pith the result was again primarily conditioned by the implements used. Economy of effort in production rules supreme; little heed is paid to economy of effort in interpretation. Thus, the Hebrew penman and the Persian calligraphist leaves out all but the most important vowels, and, indeed, the latter in time comes to pay more attention to the aesthetic beauty of his handiwork than to utility. The result is a charming puzzle, decipherable only by the expert.

The development of writing of the Western scripts must not detain us, interesting though it be. The influence of the implements and the aesthetic taste are again prominent. Fortunately for us, the introduction of printing set a curb upon calligraphic enthusiasm. The new implements demanded a restriction in the diversity of forms of

individual letters. Gradually they became crystallized upon the basis of the written signs, until eventually their diversity became reduced to a minimum.

Thus it came about that by purely empirical processes printing became what it is. The aesthetic element was by no means lost sight of, nor is it even at the present day. The master printer, then and now, thinks more of the beauty of his printed page—the sharpness of his letters, the orderliness of his lines, the accuracy of his spacing and leading, and the width of the ample margins—than of the legibility of his handiwork. From the physiologist's point of view, he is the worst type of bibliophile; but it is not wholly his fault, but rather that of the physiologist, who has given him little or no help.

With advancing years and the increased utilitarianism of printing legibility has gradually gained in importance, but, even so, the physiological requirements have been met, in so far as they have been met at all, by empirical and tentative methods. The separation of words and sentences, the use of capitals and stops, and so on, are results of development along these lines.

It is only within the last thirty years that the *science* of reading can be said to have been studied at all. It is true that much work had been done before that time on visual acuity, in which printed letters were often the test objects. They were found, however, to introduce psychological elements which vitiated the accuracy of the results; and, though the basis of reading is doubtless visual acuity in the ordinary sense of that term, the science of reading is a complex subject which involves the most difficult problems of physics, physiology, and psychology. Nevertheless, it is well worthy of more study than has been devoted to it by ophthalmologists.

We owe almost all the knowledge we possess on the subject to the researches of Cattell (1885), Erdmann and Dodge (1898), Huey and Delabarre (1898), and Lamare and Javal.

If we consider ordinary Roman printed characters we find that all capital letters extend above the line. Of the small letters thirteen are short, eight extend above the line (ascending letters), and four below the line (descending letters). There are thus twice as many ascending as descending letters, and in an ordinary page of print it will be found that of the long letters about 85 per cent. are ascending and only 15 per cent. descending. Examination of the short letters shows that their most characteristic features are in the upper parts. Hence in reading, attention is specially directed to the upper parts of the letters, as is strikingly demonstrated by covering the lower parts of a line of print with a card. The print is almost as legible as if it were uncovered. If, however, the upper halves of the letters are covered, it is almost, if not quite, impossible to read the print.

The ends of the lines of which letters are composed are commonly emphasized by means of serifs. These were doubtless introduced empirically, but the advantage in sharpness of definition has a physiological basis. They counteract irradiation, and hence the visibility of letters is improved if the serifs are triangular.

The tendency of typefounders has been to minimize the differences between letters, probably with a view to greater regularity of line and uniformity in appearance. For example, round letters have been flattened laterally and square letters rounded. The loops of *b*, *d*, *p*, and *q*, have been equalized to *o*. If the lower parts of short letters are covered, the similarity in the topmost curves of *a*, *c*, *e*, *o*, *s*, of *n* and *r*, of *h* and *b*, or of *n* and *p*, is much greater in modern print than in some early samples.

Legibility is not determined solely by visibility in the physiological sense of the term. Thus, the emphasis of some lines in letters, which originated in the use of reeds and pens for writing, increases legibility whilst diminishing visibility. A child learning to read depends upon physiological visibility; hence there should be little difference between the breadth of the thick and slender strokes. As facility in reading is acquired legibility is increased by diminishing the breadth of the slender strokes, and as smaller letters are used the diminution must be more rapid than that of the heavy strokes, so that the interspaces may not be unduly contracted. At the same time, the slender strokes must not transgress the limits of visibility at reading distance, and their distribution should be emphasized by suitably formed serifs. Hence, Jaeger small types are more legible than Snellen's.

The spacing of the letters and words has a considerable effect upon legibility. Irradiation plays an important part here. Roughly speaking, the interspace between letters should be at least as broad as the blanks in *m* or *n*, but round letters like *o* and *e* should have slightly less interspace than square letters. Owing to irradiation the interspaces in general look larger than they really are, and two *o*'s separated by a space look farther apart than two *n*'s separated by the same space. Javal attributes a large part of the "remarkable legibility of English books" to the shortness of most English words and the consequent multiplication of blank interspaces. Of course, the spacing of words, and to a less degree of letters, in ordinary printing is very largely haphazard as far as legibility is concerned, the main object of the printer being to obtain general uniformity of appearance with rigid equality in the lengths of the lines. There is some difference of opinion as to whether "leading" or interlinear spacing is beneficial. Owing to the design of the blocks of type there is always a small space between the lower limits of descending and the upper limits of ascending letters, even without leading.

A line of print is read in a series of small jumps. At each pause a group of about ten letters is more or less accurately visualized; the movements are too rapid to permit of visualization whilst they are occurring. The number of leaps taken by the eye remains the same irrespective of the distance of the book, so long as this is consistent with legibility. A child reading makes more jumps in a line than the average, and the same applies to people reading a foreign language or correcting proofs. Attention is directed chiefly to the commencements of words, and words are not read by letters but by their general configuration. There is therefore a very important psychological factor involved in the act of reading, quite apart from the interpretation of the meaning of the words.

As long ago as 1746, in the days of Francis I, an imperial patent was issued concerning "the books in the Holy Roman Empire and the Commission by Royal Grace thereover appointed," which stated that "every publisher and printer shall henceforth use good white paper and legible type." In 1798 Immanuel Kant wrote on the precautions to be observed for the eyes with regard to the printing and paper of books, and the subject also claimed the attention of Hufeland (1825), Beer (1800), and von Arlt (1846).

Cohn takes the letter *n* as a convenient standard of size of type. A letter measuring 0.7 mm. in height subtends an angle of 5 minutes at the nodal point of the eye when it is about 30 cm., or 1 ft., away. It should therefore be clearly visible at that distance, and the amount of convergence required will be only 11 degrees. It will be found, however, that prolonged reading of print of this size is extremely trying to the eyes. Adolf Weber investigated the rapidity of reading with type of different sizes. He found that the rate diminished if the letters were more than 2 mm. in height, and that the best mean height was about 1.5 mm., which has been adopted by Cohn as a standard. Weber found that as a mean 1,464 letters could be read out loud in one minute, 1,900 if not pronounced out loud. The perception of a letter takes, therefore, three hundredths of a second, its perception and pronunciation four hundredths. It is obvious that these results are only very approximate.

Griffing and Franz in New York showed in 1896 that print 1.8 mm. in height can be read quicker than when it is only half that height. The same number of words were read in about nine-tenths the time taken for the smaller letters. The rapidity diminishes with very large print because fewer letters are seen at one glance. If short sentences are exposed to the eyes for $\frac{1}{20}$ second only, about half the number of words are read correctly with 0.9 mm. type as compared with 1.8 mm. The intensity of light necessary for reading increases rapidly in passing from 1.5 mm. type to smaller sizes. The thickness of the strokes of letters can be measured with a magnifying glass and a vernier. As a rule, the thicker strokes are barely $\frac{1}{4}$ mm. broad in type 1.5 mm. high, and Cohn advocates this thickness as minimum. Fick and Stettler found by experiment that a thickness equal to one-fifth the height gave the best visibility, thus confirming Snellen's deduc-

tions and the forms adopted in his test types. Greater thickness afforded no improvement, and diminution reduced the visibility. Fick recommends a square shape for letters, so that they are nearly as broad as long, but Javal has adduced potent arguments against adopting this style in ordinary books. Schneller recommends 0.3 mm. thickness, and the same distance between the strokes, so that his would measure 0.9 mm. in breadth.

Cohn does not agree with Javal as to the relative insignificance of interlineation; he seems to attach too little importance to the favourable effect of the ascending and descending letters in necessitating large blank areas which may be considered sufficient for practical purposes. Weber advocates a 2 mm. interspace for 1.5 mm. type, but Cohn requires 3 mm. Fick rightly points out that the interlining should be broader when the lines are long, so that in passing from line to line less difficulty will be experienced. He recommends the proportion 40 to 1 between the length of line and the breadth of interlineation. For a line 100 mm. long the interspace would be 2.5 mm., which accords with Cohn's irreducible minimum.

As regards the distance between letters and words, Weber found that an average of sixty letters in 100 mm. gave the best results. Too great dispersion of the letters diminishes legibility, forty letters in 100 mm. being, according to Weber, the minimum allowable. At least 0.5 mm. should be allowed between each letter. Cohn permits 1 mm. between the letters, 3 mm. between the words, and forty-four to forty-six letters in a line 94 mm. long; with letters 1.5 mm. high this arrangement gives a very pleasing and legible print.

The tendency in modern books has been to reduce the length of the lines, partly, perhaps, owing to the loss of favour for quarto volumes. Cohn gives 90 mm. as the ideal length, 100 mm. as the maximum, and 30 mm. as the minimum. Longer lines than the maximum throw an undue strain upon the accommodation, render it difficult to pick up each succeeding line, and involve greater range of movement and expenditure of muscular energy. Shorter lines interfere with the proper grouping of the words as the eyes pass from one group to the next, and increase the number of long jumps from line to line. At the same time it must be observed that the golden mean advocated applies only to type of fair size, such as that of 1.5 mm. in height, and that no absolute rules can yet be devised for the best proportions to be adopted under the very various conditions which can be contemplated.

Schubert in 1892 devised a method for judging the quality of printing from the hygienic point of view. He counts the letters in four lines of 10 cm. length, and takes the mean—for example, 60. He then counts the number of lines in 10 cm.—for example, 24. These numbers are multiplied together, and divided by 100—in the example given 14.4—which gives the average number of letters in one square centimetre. The number should not exceed 15 in good print. Cohn has simplified the method by cutting a square centimetre hole in a card, and counting the number of letters which can be seen through it when it is applied to the page. As a rough guide, he finds it sufficient simply to count the lines visible. Only when there is no trace of more than two lines visible in the aperture can the print be considered suitable in size and interlineation from the hygienic point of view.

Dr. R. T. Williamson of Manchester has submitted 250 school books and college textbooks to Cohn's test. The type was equal to or larger than Cohn's minimum in 109 books. In thirty other books there were in some paragraphs two lines, in other paragraphs three lines in the centimetre square. In 111 books, or 44 per cent., the type was decidedly too small, namely, three lines or more.

An admirable piece of work has recently (1912) been carried out by a committee of the British Association which included Messrs. Priestley Smith, H. Eason and N. Bishop Harman. It resulted in a report on the influence of school books upon eyesight, which contains many excellent suggestions.

Another subject to which I wish to draw your attention and elicit your opinions is the relationship of illumination to near work. Here again empiricism has reigned supreme. The effect of illumination on visual acuity and legibility has been studied by many people. I cannot enter into the complicated physical, physiological and psychological questions which are involved in this study. Roughly speaking, various observers have shown that the minimum illumination of the types which permits of normal visual acuity with Snellen's test is 2–3 metre-candles. Vision improves as the illumination is increased up to 10 metre-candles, after which it remains almost constant up to 30 metre-candles and over.

A glaring light in the field of vision has less effect in diminishing visual acuity at ordinary illuminations than might be thought, but there is no doubt that it is distressing and should be avoided. The artificial and daylight illumination of schools has formed the subject of investigation of a committee of the Illuminating Engineering Society. Two interim reports have been issued and contain much that is worthy of consideration. It is suggested that (*a*) for ordinary clerical work (reading and writing, etc.), the minimum illumination measured at any desk where the light is required, should not fall below 2 foot-candles; (*b*) for special work (art classes, drawing offices, workshops, and stitching with dark materials, etc.), a minimum of 4 foot-candles is desirable: (*c*) for assembly rooms, etc., and for general illumination a minimum of 1 foot-candle measured on a horizontal plane 3 ft. 3 in. from the ground.

DISCUSSION.

Dr. Angus MacGillivray (Dundee) said he was glad to know that the subject of school hygiene was in such practical hands as those of Mr. Parsons and Mr. Bishop Harman. He felt, however, that there was a tendency at the present time to run riot in connexion with this subject. He had never seen any organic trouble produced by the wearing of improper glasses.

Dr. F. W. Edridge-Green (London) said that some simple physiological facts had an important bearing on the subject; the explanation of these facts was that the centre of the retina was sensitized from the peripheral parts, and it was necessary, therefore, that the whole retina should be illuminated. Many persons who suffered from headaches after reading with a reading lamp in an otherwise dark room, or playing cards with a light over the table, lost their headaches when the whole room was lighted up.

Dr. L. A. Parry (Hove) called attention to the large number of rooms in elementary schools which were improperly lighted. All authorities were agreed that the only proper and scientific method of lighting rooms was that in which the whole or main source of light should come from the left. He wished more pressure could be brought to bear on education authorities to induce them to alter the lighting of their improperly illuminated schoolrooms. He was glad to be able to say that in most schools badly printed books had been abolished, and also fine sewing by small children. He thought that as the law compelled children to attend school at a period of great importance—the age of 5 to 14, during which their eyes were under considerable strain—the least that education authorities could do would be to see that they were educated under the best hygienic conditions.

Dr. A. J. Ballantyne (Glasgow) said that some speakers had expressed the opinion that the discussion of the hygiene of vision had been rather overdone. There was one direction in which the discussion of the subject might come to be of great importance. The impression was becoming more widespread that the eyes might suffer actual injury through "glare" and through badly arranged illumination in schoolrooms, to give two examples. They were all aware of the distressing symptoms which were caused by the presence of bright points of light in the visual field. He personally believed that the phenomena were psychological and not ophthalmological, but they might find, in the course of the next few years, the claim being made that compensation ought to be given to workmen on account of eye injury alleged to be due to glare in their workshops. Again, as Mr. Parsons had said, indirect illumination was inferior to direct illumination for certain occupations such as screw-cutting, yet they might find employers installing indirect illumination in their workshops to avoid claims in respect of damage from glare. With the possibility of legislation embodying popular views of the injury due to glare and faulty illumination generally, now was the time to try and arrive at a sound scientific

knowledge of the phenomena with which they were dealing in this discussion.

Dr. JAMES A. WILSON (Glasgow) thought that the whole subject was much overdrawn, and that all that was possible to say about it had already been considered.

Dr. R. A. REEVE (Toronto) spoke of the trying effect of over-glazed paper, especially when used for children's books.

Dr. CASEY A. WOOD (Chicago) spoke of various papers suitable or unsuitable for illustrations; glazed papers were essential for certain illustrative work.

Dr. MARION GILCHRIST (Glasgow) said that the eyes of children were much better looked after than was formerly the case. She considered that badly fitting spectacles were productive of great harm.

Dr. MONTAGU HARSTON (Hong Kong) said that the more this subject was ventilated the better. It was most important in the tropics, where it was necessary to keep blinds tightly drawn on account of the heat, and then artificial light had to be used. He was greatly interested in the remarks of Dr. Edridge-Green. He had noticed the same thing, and the facts mentioned by him (Dr. Edridge-Green) explained them.

Mr. PARSONS, in reply, strongly deprecated the idea that the subject was overdone. He thought that Dr. Edridge-Green had opened up a most interesting subject. Electric light he considered responsible for a good deal of discomfort in the eyes. It was a fact that all improvements made of late in illuminants made use of the violet end of the spectrum rather than the red end, such as metal filament lamps and incandescent gas mantles.

THE TEACHING OF OPHTHALMOLOGY.

By A. MAITLAND RAMSAY, M.D.Glasg.,

Ophthalmic Surgeon, Royal Infirmary, Glasgow, and Lecturer on the Eye, University of Glasgow.

To an audience of ophthalmic surgeons it is needless to emphasize the importance of ophthalmology as a branch of the medical curriculum, for we are all agreed that medical education is incomplete if it does not include a fair working knowledge of the diagnosis and treatment of diseases and injuries of the eye.

The eye is a small organ, but ever since the introduction of the ophthalmoscope able men all over the civilized world have found its study sufficient for their life's work; and some idea of the magnitude of ophthalmic specialism may be gained from the fact that its current literature as synopsized in the *Jahresbericht* for 1913 runs to over 4,000 articles by 1,884 authors. It is true that in ophthalmology, as in every other department of medicine, much is written that is of no permanent value, yet the very fact that year after year brings such a large and increasing output of literature gives some indication of the earnestness and enthusiasm of those who devote their lives to this branch of knowledge. No more epoch-making book has ever been published than Donders's *Accommodation and Refraction of the Eye*, and the Graefe *Saemisch Handbuch* ranks in importance with any cyclopaedia of medicine and surgery.

For the purpose of to-day's discussion, however, it is probably most important to emphasize the close relation of ophthalmology to general medicine. Dr. C. O. Hawthorne, in a paper read at the Oxford Ophthalmological Congress of 1913, says:

> The routine clinical examination of the patient demands an inspection of the fundus and other parts of the eyeball, just as much as it demands the use of the stethoscope and the application of chemical tests to the urine.

This close and natural relationship is, however, rarely recognized, indeed it seems to be often completely disregarded. The eye is not only in the body, but it is also of the body, and many of its diseases are simply an expression of a general pathological state, and can be properly understood only when considered in their true perspective. Moreover, it is in an eye clinic, better probably than in any other medical clinic, that the student can observe at first hand the practical application of every-day practice towards the solution of many of the most interesting problems of modern pathology.

Such being the case, it is important to ask, What is the attitude of our Scottish medical schools to the teaching of ophthalmology to medical students? Under the new ordinance the subject is compulsory, but the number of hours prescribed for its study are so few as to be quite inadequate, and, except at the University of St. Andrews, students are not required to take ophthalmology as part of the final examination. It is true that very occasionally a question on the eye appears in the paper on medicine or surgery, and that a student may in the course of the clinical examination be asked to use the ophthalmoscope or to examine a patient suffering from an ocular affection, but the university lecturer on ophthalmology does not take part in the examination. If we are agreed that ophthalmology is a subject of major importance, such a state of matters is surely far from satisfactory. It contrasts badly with the arrangements in the medical schools in Ireland, in Continental Europe, and also in many universities and colleges in America, where the study of eye diseases is not only compulsory, but the subject forms an integral and important part of the final examination. Some may regard an examination on ophthalmology as unnecessary, and argue that examinations are a hindrance rather than a help in the acquisition of knowledge, but, as we all know, the average student pays most attention to those subjects in the curriculum on which he is required to pass a professional examination.

That brings us, then, to the crux of the whole matter. The present medical curriculum is already so overcrowded, relative to the time in which the studies are expected to be completed, that the average student does not willingly add to his heavy burden, but naturally devotes himself only to the subjects on which his knowledge is to be tested, quite content with an attendance certificate for those which, although compulsory, are not required for the purposes of examination. He speaks of such subjects as the "small classes," and his chief concern connected with them is to find a spare hour during which he can conveniently fit one or other into his scheme of work. That is the situation; and, in the circumstances, it would simply be a counsel of perfection to advocate a complete course of instruction in ophthalmology for every medical undergraduate.

Our teaching should instead follow two distinct lines—for the mass of ordinary students it should necessarily be something much less ambitious, and for those who require more special knowledge there should be a post-graduate course just as there is in public health. With regard, first, to the undergraduates, there are three important factors—the point of view of the general student, his future professional aim, and the time he can reasonably be expected to give to the subject. As to the first of these the attitude of the student must be completely transformed. He must be discouraged from looking on ophthalmology as a speciality that he can afford to disregard, and must be made to realize instead that it is one of the most important branches of medicine and surgery and worthy of as much attention as the major clinics. In dealing with the student's future aim and the time at his disposal, it must at once be admitted that want of time is a very serious obstacle to the carrying out of any radical change in the teaching of ophthalmology, and one must besides always bear in mind that the majority of the students are ultimately destined to engage in general practice. In this last connexion it is sometimes said that there is no need for the general practitioners to study ophthalmology, for the public has become so much accustomed to specialists that it demands expert advice in all diseases of the eye. In a measure that is true, but the public would be better served if the general practitioner knew more rather than less of ocular affections than he does at present. Indeed the public has a right to expect the family doctor to be able to recognize the more important diseases of the eye, and to know when he can safely treat them himself, and when he should summon the assistance of a specialist.

In addition, the general practitioner never knows when he will be face to face with a serious emergency—an

injury to the eye, acute glaucoma, etc., in which prompt and immediate action may be the only means of avoiding disastrous results.

If, then, it be necessary for the general practitioner to be familiar with ophthalmology, what amount of time ought every medical student to give to the subject, and what should be the scope and method of the teaching—in short, what place ought ophthalmology to occupy in the regular medical curriculum? In present circumstances the majority of teachers will probably agree that fifty hours during one of the three terms of a session are necessary, and that the students should take the class during the fourth or fifth year of their studies. The amount of work which can be satisfactorily accomplished will depend a good deal upon the teacher, but in every case the aim will be not to train ophthalmologists, but to contribute to the efficient all round education of the family doctor. It is the country doctor who requires most of all to be trained on broad and thorough lines, for he has to meet emergencies single-handed, and to deal alone with situations that his medical brother in a city would never think of approaching without the aid of the experts who are always within immediate reach.

The aim of the teaching must therefore be not simply to put the student in possession of facts as they are known at the moment, but rather to instruct him in due scientific method. The student must accordingly be taught first of all how to examine an eye properly, and at the same time thoroughly trained in the broad principles underlying diagnosis and treatment. By individual attention and instruction he must be drilled in the use of the ophthalmoscope, and encouraged to employ it in his examination of medical and surgical patients as readily as he would a stethoscope or a clinical thermometer. He ought to be shown typical cases and made to study them well in order that he may be able to treat the commoner superficial diseases of the eye; to render first aid in cases of injury or of other emergencies which may arise in ophthalmic practice; to recognize promptly those serious diseases which may lead to blindness; and to know when he is competent to treat the patient himself and when he ought to ask for the help of a consultant. That, in my opinion, is about all that can be accomplished in the time available, and if such a range of study were agreed upon it would be no great hardship if the licensing boards insisted that every student be examined in ophthalmology before he could get a qualification to practise.

I have purposely said nothing about refraction, because if a student can examine an eye properly he will be able at once to determine the presence of hypermetropia, myopia, or astigmatism, and a working knowledge of the treatment of anomalies of refraction can be acquired only after much study and practice. What the general practitioner wants to know is, how far an error of refraction is responsible for the occurrence of headache or other departure from health, and as a rule he is wiser to leave the prescription of suitable spectacles to a specialist rather than to try to adjust them himself.

An important part of the scheme of instruction, too, ought always to be to encourage the student to look for a relation between ocular and general diseases, and, consequently, it would be a great gain if the teaching of the eye could be correlated with the teaching of medicine and surgery. Professor de Schweinitz has elaborated a method of correlation of the medical classes in the University of Pennsylvania, and in a letter which I received from him recently he says:

> I have an arrangement at the present time with the chair of medicine and the chair of surgery and, to a certain extent, with the chair of neurology, by which, at certain periods in the course of instruction proceeding from these chairs, I am permitted to take part. Thus, when the professor of medicine is engaged on the subjects of cardio-vascular disease and renal disease, I take one or two lecture demonstrations, in order to make the students realize just how closely ophthalmology and general medicine are associated. The same is true in surgery; when, for example, the surgery of the brain is under discussion, the surgery of the pituitary body, etc. We have found this blending of the courses very advantageous. You understand that this in no way alters the regular course in ophthalmology, but simply tries to impress upon the students that the eye is not a separate entity but a very distinct organ of the body, subject to all the laws that all other organs are subject to. It has really served to fix the attention of the students on their ophthalmic work in a very remarkable way.

Teaching on these lines is essentially clinical and practical, but that need not prevent it from being inspired by scientific ideals, for the clinician should work in his ward just as the physiologist or the chemist works in his laboratory or the litterateur in his library. It is essential that the student be brought face to face with the patient, and in order that each may receive the individual attention that he requires the numbers attending the classes should be limited. The lecture demonstration is of great value in training the student to observe accurately by instructing him as to what he ought to look for; and when it is illustrated by colour photographs, and by normal and pathological specimens and microscopic sections projected on a screen, it enables the teacher, speaking from the history of an individual case, to classify and generalize, and to thoroughly discuss symptoms and signs, etiology, pathology, and treatment. In all this the two most important factors of satisfactory teaching in face of the many difficulties are, to my mind, small classes and careful methodical arrangement of the work of the clinic.

Looking to the severe limitations imposed by the short space of time available and the great congestion of the curriculum, we may perhaps regard such a course as has been outlined as sufficient for the wants of the average student. It must not, however, be taken as worthy of the subject, and when we come to consider the case of those who require wider and more definite knowledge of the eye it must be held to be quite inadequate. To the profession there nowadays lie open many public posts with duties attached to them demanding special acquirements—those of county and burgh medical officers; doctors appointed under education authorities for the medical examination and treatment of school children; doctors holding other appointments under local government authorities, more especially those in remote districts difficult of access; and to these, for our present purpose, there must be added missionaries and doctors in certain industrial districts with large populations liable to accidents to the eye or to troubles that affect the sight. For all who aspire to occupy such positions or are called on to deal frequently with ophthalmic work, much greater specialized eye knowledge is requisite; and yet for this large and increasing class, so far as ophthalmology is concerned, the teaching bodies at present do nothing or next to nothing. For them there should be organized a course of instruction suited to their needs and worthy of the claims of ophthalmology to form an integral part of advanced university teaching. Such a scheme ought not to present any great inherent difficulties, other than finding the money required. What is wanted is the founding of a chair of ophthalmology in each university, the professor to have control of a complete hospital unit for treatment of patients, training of students, and prosecution of original research. The hospital unit should be on the lines suggested by Sir William Osler and advocated in Flexner's account of the medical schools of Europe and in the final report of the Royal Commission on University Education in London. It ought to include accommodation for the treatment of both indoor and outdoor patients, clinical and research laboratories, and a well equipped classroom. Teaching cannot reach its highest level and be a truly living force unless it be nurtured and invigorated by the scientific atmosphere which pervades the research laboratory. I do not mean that every investigation pertaining to the eye and connected with the eye wards should be conducted in special laboratories. On the contrary, if the larger questions which are constantly arising are to be satisfactorily solved, there must be co-operation with the laboratories devoted to general pathology and to clinical research; but provision should be made in the ophthalmic unit for the investigation of special problems and the preparation of sections and specimens to be used in the lecture demonstrations.

If a university department for the study of ophthalmology were founded on these lines adequate instruction could be offered to both medical students and practitioners. There would then be a senior class as well as a junior, and the members of the former could have ample opportunity of examining and treating out-patients under supervision, of practising refraction, of acting as clinical clerks in the wards, and of seeing operations, and to any who were specially interested facilities could be given for original research.

Lastly, the final and complete recognition of the value

of ophthalmology would be the granting of a diploma, as is done now in the universities of Oxford and Liverpool, and for that purpose the work of the eye department would be linked up with that of the physical, physiological, pathological, and probably also the psychological laboratories. Such a qualification would encourage the taking of a complete post-graduate course in the subject, and would thus necessarily give a great impetus to advanced study, and create an atmosphere in which the young ophthalmic specialist could train and develop.

DISCUSSION.

Mr. MALCOLM L. HEPBURN (London) said that the teaching of ophthalmology to medical students must of necessity fall under two headings. (1) The teaching of students who intended to become general practitioners, and (2) the teaching of those who proposed to practise ophthalmic medicine and surgery. In regard to the first, since the time at the disposal of the students in question was unavoidably short, it should be expended in accumulating knowledge of those parts of ophthalmology which were most likely to concern the general practitioner; consequently the teaching should be centred round methods of diagnosis, special attention being paid to external diseases and external manifestations of intraocular disease, with a minimum amount of ophthalmoscopic work, operative surgery, and book reading. Ophthalmoscopic work should be limited to a knowledge of the appearance of the disc and the diagnosis of opacities in the media. The teaching should be mainly clinical and practical; refraction work should be taught and learnt as accurately as possible in the time, not with a view to the prescribing of glasses, but chiefly for diagnostic purposes, owing to the importance of being able to exclude refractive error in any given case. The course should be taken near the end of the medical curriculum, and the board of examiners should always include an ophthalmic surgeon, who should examine candidates on the lines indicated. As for the education of future ophthalmic surgeons—including those who wished to do ophthalmic work under school boards, county councils, etc.—let the teaching be of the highest order in all branches of ophthalmology; let it include a thorough grounding in the preliminary subjects of optics and physiology conducted by special teachers, and let the students be required to hold a degree (by examination) in ophthalmology. The difficulty of carrying out ophthalmological teaching on a large scale lay partly in the fact that so many different branches of a subject had not so far been conducted in one central institution, and students were therefore forced to spend a good deal of time, trouble, and money in going from one place to another. At present post-graduate centres had attempted to cope with this difficulty by establishing special lectures, papers, and clinical evenings, etc., but the really practical and clinical side must in any case be neglected, owing to the absence of sufficient clinical material, the inconvenience of collecting cases belonging to different hospitals, and to the fact that disproportion between the number of students and patients often interfered with satisfactory individual examination. In addition to the subjects already mentioned, there should be facilities for the study of both medical and surgical ophthalmology, operative surgery, pathology, bacteriology, clinical work, and neurology; but the difficulty of carrying on instruction in ophthalmology on these lines was obvious. At Moorfields they endeavoured to approach this ideal by distributing the teaching amongst the thirteen members of the staff, but medical ophthalmology must necessarily be neglected at such a hospital. Cases of this order were, and should be, transferred to some general hospital, or remained under the care of the physician. Three times a year they had scheduled lectures, which lasted two months, and dealt with the examination of the eye, refraction, ophthalmoscope, motor anomalies, surgical anatomy, operative surgery, pathology, bacteriology, and medical ophthalmology, while clinical demonstration went on daily all the year round. The advantages of a surgical hospital such as Moorfields were very great, owing to the large amount of clinical material and the variety of methods employed by different members of the staff, whose results could be carefully watched and compared; but it did not represent all that was desired, and the preliminary subjects—medical ophthalmology and neurology—received only a very small place in the teaching. From the students' point of view, plenty of clinical material was essential, and some of the large general hospitals, with a correspondingly large ophthalmic department, suggested themselves as possible centres to combine all the teaching required; but there were few such hospitals, even in London, and many of the ophthalmic departments were inadequate even for the proper teaching of ophthalmology for the general practitioner. The teachers should be men engaged in ophthalmic practice, not those who had gained their experience solely in hospital work.

Dr. A. F. MACCALLAN (Cairo) said that the importance of the teaching of ophthalmology was recognized in Egypt. The students had to acquit themselves sufficiently well in a special paper in ophthalmology in the final examination for the diploma in medicine and surgery at the Government medical school. Those post-graduates who desired to take up the speciality of ophthalmic surgery were drafted to the ophthalmic hospitals, which were now sixteen in number. Here there was unlimited practical work to be done, while once a year a course of six weeks of clinical and pathological teaching was given, which included laboratory work.

Dr. MACGILLIVRAY (Dundee) detailed the method adopted in the teaching of ophthalmology in the University of St. Andrews, and in examining candidates in their final examinations. He advocated the importance of every student knowing how to correct refractive errors, showing that it was easier to teach a student how to prescribe spectacles than to prescribe rationally for dyspepsia. If adopted generally, it would stop the wholesale spectacle mending at present in vogue.

Dr. R. A. REEVE, Dr. CASEY A. WOOD, Mr. T. H. BICKERTON, and Dr. A. HILL GRIFFITH, having described the methods of teaching adopted in the universities and colleges with which they were respectively connected, Dr. RAMSAY, in reply, said he thought that during the limited time at the disposal of the medical student, he should be taught the most important subjects, and it was impossible to turn them out skilled refractionists. The aim should be to improve the general teaching as much as possible rather than to devote much time to special subjects.

A CASE OF DISSEMINATED SCLEROSIS TREATED BY INOCULATION.

BY

H. LYON SMITH, M.D.DURH.

With Clinical Report

BY T. GRAINGER STEWART, M.D., F.R.C.P.,

PHYSICIAN TO OUT-PATIENTS AT THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, AND ASSISTANT PHYSICIAN TO THE WEST LONDON HOSPITAL.

THE reason for reporting this case of disseminated sclerosis at such an early date is that it presents some features of unusual interest, and that the line of treatment has apparently been sufficiently successful to justify others, who may have to deal with similar cases at their onset, in testing its value. It is in the initial stages of an infection that one can expect to intervene most effectively.

A girl, aged 19, a probationer in a sanatorium for tuberculous children, was in good health until the beginning of March, 1914, when she was invalided home with obscure symptoms of muscular weakness, and came under the care of Dr. Robert Grant of Cromer. Involvement of motor areas progressed very rapidly. Disseminated sclerosis was diagnosed; a Norwich specialist was called in consultation, and a very grave prognosis was given. On May 24th Dr. Grant sent her up to London in an ambulance for bacteriological investigation, with a view to experimental treatment if any clues were forthcoming. On admission to the Duchess Nursing Home the patient was unable to stand, to feed herself, or even to move her arms and legs without involuntary jerks. Dr. Grainger Stewart pronounced her condition to be typical of disseminated sclerosis.

Clinical Report by T. GRAINGER STEWART, M.D.

The patient, a young unmarried woman aged 19, came of a healthy stock and had always enjoyed the best of health except that between the ages of 5 and 9 she had suffered from "glands" in the neck. These quite disappeared and she has never had any sign of them since. Before Christmas, 1913, she cut the middle finger of her right hand, and the wound suppurated and did not heal up for about three weeks.

Present Illness.

Early in March, 1914, she had a slight bilious attack which lasted for two days. It was not accompanied by any febrile disturbance, and she apparently recovered completely and was quite well for a week.

About the middle of March, 1914, she suddenly lost the use of her legs, the right leg became almost powerless and the left was weak and shaky and at the same time she lost control over her water. The onset was sudden, without any noticeable febrile disturbance, and she suffered no pain and did not lose the feeling in the legs (tested with pin and cotton-wool). She was confined to bed and three days later the right hand and arm became "numb," weak, and very shaky so that she could not feed herself well or write or use the right hand at all. At the same time she saw double and a "squint" was noticed. She had no pain, headache or vomiting, and felt quite well in herself. During the next three weeks she slowly improved, the diplopia became less and the legs stronger, but the right leg was very unsteady and shaky and she was still unable to stand or walk even with help, and could not use her right hand. She then had another sudden attack in which her left hand become numb and shaky, and the right leg again became weak. Since then she has slowly improved and has not had any further relapse. At no time did she suffer from any headache, pain, or loss of vision apart from that due to the diplopia.

State on Examination, May 25th, 1914.

The patient was bright and cheerful, and her memory and attention were good. Her complexion was rather muddy, and the skin over the lower extremities dry and scaly; the skin on the soles of her feet was peeling. Her general health was good, and there was no evidence of any organic disease of the heart, lungs, or abdominal viscera. There was no glandular enlargement. The urine was normal. There was no history of any previous trouble in the nose, ears, or throat, and the mouth was healthy except for a slight degree of gingivitis. Her periods were regular.

Cranial Nerves.—Smell, taste, hearing normal. Vision good; no impairment of visual fields. Optic discs normal. 3.46. Pupils equal; reacted normally to light and on convergence. Ocular movements: no obvious paralysis, but the patient complained of slight diplopia on looking down and to the right. Coarse nystagmus was present on conjugate lateral movement of the eyes to the right and to a less degree to the left. Slight nystagmical jerkings were present on looking upwards and downwards.

Motor System.—General musculature good.

Upper Extremities.—Muscles well developed; no wasting. There was slight spasticity in the right arm; none in the left. Power was diminished in both arms, especially in the right. On getting the patient to hold out her hands or to touch the point of her nose there was a well marked coarse tremor, more on the right than on the left. At rest no tremor was visible. The patient was unable to write or to hold a cup of tea in either hand without spilling it.

Head, Neck, and Trunk.—She could not raise herself in bed without using her arms. When sitting up there was a distinct unsteadiness noticed, the movement being in the antero-posterior axis.

Lower Extremities.—The right leg was slightly spastic and very weak in all movements. The patient could move it in bed, but was unable to raise the extended leg from the bed: all movements were accompanied by intention tremor. The left leg was not spastic, but was slightly weak and ataxic.

Gait.—She could not stand alone, and was unable to walk even with support.

Sensory System.—There was a feeling of numbness in both hands, but there was no pain or tenderness. On examination there was definite loss of sense of position in the thumb and fingers of the right hand and in the two ulnar fingers of the left.

Reflexes.

	Right.	Left.
DEEP.		
Arm—		
Biceps	++	+
Triceps	++	+
Supinator	++	+
Leg—		
Knee	++	+
Ankle.....	++	+
	Clonus	Slight clonus.
SUPERFICIAL.		
Epigastric	Absent	Absent.
Abdominal	Absent	Absent.
Plantar	Extensor	Extensor.
SPHINCTERS.		
No loss of rectal control.	—	—
Some loss of control over bladder. No distension.	—	—

There was no loss of discrimination of two points, of vibratory sense, or of tactile, painful or thermal sensibility. Elsewhere, sensation was normal. The patient was unable to distinguish differences in the weight of coins placed on the fingers, but there was no asteriognosis.

Further Progress.

May 30th, 1914.—No diplopia, no nystagmus. Intention tremor less in arms; still loss of sense of position in hands and fingers. Right leg stronger and less shaky, but the patient cannot stand alone or walk without support. Abdominal and epigastric reflexes absent. Plantars extensor. Micturition normal. Complexion clear, and the patient looks more healthy.

June 3rd.—No diplopia, no nystagmus. Upper extremities: Power good, intention tremor only present in slight degree in right hand. Can write slowly and unsteadily with right hand; can feed herself quite well. Legs: Power of right much improved; can stand alone and walk with help. Plantars: Right, extensor; left, flexor.

June 9th.—No diplopia, no nystagmus. No loss of sense of position in the hands or fingers; can write, sew, and crochet. Can stand alone on both legs and on the left foot, and can walk without support, though still unsteady. Plantars: Right, indefinite flexor; left, flexor. Abdominal and epigastric reflexes present on both sides.

July 1st, 1914.—Cranial nerves: Normal, no nystagmus. Motor system: Arms normal, no tremor, no weakness. Head, neck, and trunk: Normal, no tremor. Lower extremities: Slight weakness of right leg and slight ataxia, but the patient can walk alone quite well; can walk along a straight line, and can stand alone on either leg. Sensory system: No defect can be detected. Sense of position perfect in all fingers. Reflexes: Deep, are all brisk, and there is now only a tendency to clonus at the right ankle. The epigastric and abdominal reflexes are normal, and both plantars are flexor, though the right is more difficult to obtain than the left. Sphincters normal.

Treatment.

In addition to the vaccine therapy, the patient was put upon Frankel's exercises for the hands and legs, and was practised in sitting up, later in standing, and finally in walking with foot step exercises.

Remarks by Dr. GRAINGER STEWART.

The symptoms and physical signs present in this case conclusively prove it to be organic, and the history and the mode of onset and nature of the symptoms are characteristic of disseminated sclerosis. The absence of any noticeable febrile disturbance, pain, or severe sensory loss contraindicate a diagnosis of disseminated myelitis, and the absence of any evidence of specific infection negatives a diagnosis of cerebro-spinal syphilis.

It is unfortunate that the Wassermann reaction was not tested in this case, although there was not the slightest indication of any specific disease, and also that a further examination of the cerebro-spinal fluid was not possible.

The improvement which has taken place both as regards its extent and rapidity is also characteristic of the clinical course of the early stages of disseminated sclerosis, and this, taken into consideration with the fact that it had already started before the commencement of the vaccine treatment, must make any one who is acquainted with the disease very cautious before attributing the subsequent recovery to the vaccine treatment employed.

The onset of disseminated sclerosis is usually sudden and the initial symptoms may be severe or relatively slight, but in many cases complete recovery takes place, and the patient may remain apparently healthy for months or even years before the onset of the second attack. The occurrence of such remissions has led on many occasions to a mistaken diagnosis of hysteria. On the other hand, the popular conception of disseminated sclerosis as being an absolutely hopeless and incurable condition is too extreme, for although the great majority of cases eventually become chronic, yet the remissions and degree of recovery in the earlier stages should caution one against giving too gloomy a prognosis.

This tendency towards remission and recovery in the early stages makes it well-nigh impossible to attribute temporary recovery or improvement to any special form of treatment, although some apparently have a beneficial effect.

In the present case a certain degree of recovery would, I think, have been expected apart from any treatment, as it was the initial attack. As some improvement had already taken place before vaccine treatment was adopted, it might be urged that the ultimate recovery which took place was merely coincident with the treatment and not due to it; at the same time it was remarkable to note the extreme rapidity with which the symptoms and physical signs disappeared after the commencement of the vaccine treatment.

There appeared to be two possible portals of entry of infection. At the end of December, 1913, she had cut the tip of the middle finger of her right hand with broken glass, and the wound took a month to heal. It seemed possible that some pathogenic microbe might have found its way along a nerve trunk. The second possibility was infection from her gums, which were distinctly septic.

There was marginal gingivitis, and at several points the spongy gums bled at the slightest touch.

On May 25th 10 c.cm. of blood were withdrawn from a vein, and proved to be sterile. On the same day Dr. Grainger Stewart made a lumbar puncture and 25 c.cm. of cerebro-spinal fluid were withdrawn. Through the cannula 6 c.cm. of normal saline finid, prepared with triply-sterilized distilled water, were injected with the double purpose of replacing some of the cerebro-spinal fluid and of stimulating lymph lavage. 1 c.cm. of the cerebro-spinal fluid was injected hypodermically immediately after its withdrawal, on the assumption that it might contain specific toxin in solution, or even the living virus, if such was present. The latter proved to be the case, as an examination of the fluid almost immediately after its withdrawal showed the presence of about 50 small lymphocytes in 1 c.mm. and a number of living cocci, which were roughly estimated at 2 million in 1 c.cm. The Wassermann reaction of the fluid was not tested.

Tubes of serum agar, blood broth, and ordinary agar were inoculated with the cerebro-spinal fluid, and a growth of *Staphylococcus aureus pallidus* developed quickly. A vaccine was prepared from this, and was used on May 27th. Doses of 50 million, 100 million, and 200 million were given on three successive days; 300 million were given at intervals of forty-eight hours for three doses, and then 400 million every third day. For a few hours after the lumbar punctnre, the patient suffered from severe headache and vomiting. The injection of the cerebro-spinal fluid caused little local pain or discomfort, and no swelling or tenderness could be discovered over the area when examined next day.

The patient was obviously improved thirty-six hours after the first inoculation, and on June 3rd, when she had received four doses of the sterile vaccine, the general improvement was manifest. Her movements were less jerky, she was able to stand alone for a few seconds, and even to write a little. Her colour had improved, and the gums were in a much healthier state. At the end of a fortnight she was able to feed herself, to stand and walk with a fair amount of confidence, could write quite well, and each day seemed to mark some recovery of strength.

On June 21st, as the temperature still showed an afternoon rise of 1° F., daily injections of 400 million of her vaccine were given in the hope of inducing a normal temperature. She was unwilling to submit to another lumbar puncture unless further symptoms developed, therefore we were unable to complete our investigations by a Wassermann reaction or a repetition of bacteriological tests. The chart showed an improvement at the end of the week, and it was decided to reduce the inoculations to one in seven days, until absence of the slightest febrile symptoms indicated that the infection was quite dormant. On July 4th she returned to Cromer to spend a couple of months quietly convalescing, all traces of the paralysis having entirely disappeared.

Some points of interest in this case are: (1) Infection of the cerebro-spinal area, whilst blood cultures showed no indication of infection in the general systemic circulation. (2) Workers in the field of general paralysis and locomotor ataxy tell us that there is no exchange between the cerebro-spinal system and the general circulation—by which they explain the failure of salvarsan injections—but it would appear from this case that antibodies developed in the blood can reach the tissues of the cerebro-spinal system. (3) The first inoculation contained some 2 million of living cocci. Eighteen months ago Besredka urged me to use living sensitized bacteria for immunizing purposes, but this is the first time I have ventured, in spite of the brilliant results obtained by Broughton-Alcock, some of which he was good enough to show me when I was in Paris. To what extent the cocci were sensitized in the present case is an unknown quantity, but some may be inferred from the fact that there was no perceptible reaction at the site of the inoculation. (4) It is difficult to judge whether the marked constitutional disturbance which immediately followed was due to (*a*) the lumbar puncture, (*b*) the withdrawal of too much cerebro-spinal fluid (25 c.cm.), (*c*) its partial replacement by normal saline, or (*d*) systemic reaction to the living vaccine.

Reviews.

ISOLATION HOSPITALS.

In public health literature it is remarkable that so few books have been written referring exclusively to hospitals for infectious diseases. This may possibly be due to the fact that as long ago as 1882 Sir (then Dr.) Richard Thorne Thorne presented to the Local Government Board a most exhaustive report on the whole subject. This was so elaborate and authoritative that for many years there seemed little need for anything more to be said on the question. It is a tribute to Sir Richard Thorne's prescience that this report was reissued in 1901. At that date and for some time before and afterwards Dr. H. FRANKLIN PARSONS, First Assistant Medical Officer of the Local Government Board, was concerned very intimately with all the hospital schemes which came before the Board, and it was therefore quite appropriate that in 1912 he should have made a further report on the question. The document which he produced, though not so elaborate as that of 1882, has already, like its predecessor, become a classic. Upon his retirement from the Board Dr. Parsons set himself the task of producing a work in which, though basing himself upon his official report, he was able to write with greater freedom than when trammelled with official responsibilities. This work, entitled *Isolation Hospitals*,[1] was completed shortly before his death and has been included in the Cambridge Public Health Series, edited by Dr. G. S. GRAHAM-SMITH and Mr. J. E. PURVIS. It will now become a standard work of reference for all those who have to concern themselves with these institutions. He expresses the opinion that the uses of a hospital for infectious diseases are the cure or relief of persons suffering from such diseases; the separation of such persons from the rest of the community with a view to prevent the spread of disease, and to obviate the disabilities, inconveniences, and pecuniary losses which the presence of infectious sickness might entail. The very definite statement is made that scarlet fever, contrary to former belief, is infectious from the very commencement of the symptoms, and this is given as one reason for the non-success of hospital isolation of scarlet fever cases, another being that the patient may apparently in some cases continue capable of conveying infections even when no pathological condition can be discovered, for it is now believed that the contagion that was formerly, and is still popularly, supposed to have its seat in the desquamation from the skin resides in secretions from the mucous membranes of the nose, throat, and ears, and possibly also in the urine. On a review of the whole question of the advisability of the hospital treatment of scarlet fever, it is pointed out that there are instances in which the patient has not the proper lodging and accommodation required for his own well-being, nor for the prevention of grave risk of spread to other persons in the same building, such as in a common lodging-house or in the crowded houses of people of the poorer class. Then there are severe or complicated cases in which the patient requires treatment and nursing which he can obtain much better in a hospital than in his own home. Cases also occur in circumstances where non-removal might involve serious pecuniary loss, as at a hotel or a boarding-house. On the other hand, the author considers that it is doubtful whether the removal to hospital as a routine practice of every case of scarlet fever is advisable on grounds of health, or is worth the expenditure which it involves.

Referring to the isolation of cases of tubercle, it is asserted that the objects which may be had in view in the reception of phthisical patients into hospitals are the cure or arrest of the disease and restoration of the patient to health, or at least the amelioration for the time being of his condition; the isolation of the patient with the view to prevent his infecting other persons; the educative treatment of the patient with the view to teaching him good habits—as of living in fresh air and the proper disposal of sputum, which may conduce to his own benefit and to the safety of other people after he has left the hospital; and the keeping of the patient under observation for a short

[1] *Isolation Hospitals.* By H. Franklin Parsons, M.D.Lond., D.P.H. Camb. Cambridge Public Health Series, under the Editorship of G. S. Graham-Smith, M.D., and J. E. Purvis, M.A. Cambridge: The University Press. 1914. (Demy 8vo, pp. 289; 55 figures. 12s. 6d. net.)

time with a view to ascertaining whether he is likely to be benefited by sanatorium, tuberculin, or other treatment.

A very valuable, if not the most useful, portion of this work is that dealing with the designs of isolation hospitals, and it is interesting to find that the author appears inclined to prefer smaller wards than those usually designed. One of the great advantages of single bed wards appears to be that a much smaller amount of cubic space is necessary than is the case in larger wards. In the latter the Local Government Board requires 2,000 cubic feet of air space for each patient, but in the former 1,440 cubic feet is said to be sufficient. The value of the work is very considerably increased by the inclusion of a large number of plans of existing hospitals and of a very exhaustive bibliography.

NUTRITION.

The admirable lecture delivered by Professor Graham Lusk two years ago as the anniversary address of the New York Academy of Medicine has been published in a volume with the title, *The Fundamental Basis of Nutrition*.[2] It is written in a language quite suited for non-professional readers. After a short historical review in which the author leads up to the modern conception of food as fuel, he explains the method by which the heat value of different articles of food has been determined, and the production of heat in the human body under varying circumstances of rest, slight exertion, and moderate exertion fixed. These data being accepted, he shows how it is possible to arrive theoretically at the exact amount of food required by individuals under any given condition, and he demonstrates how actual experiment has justified the theoretical deductions. From these considerations, which after all have been pretty well known for a good many years, he passes to the more interesting, because comparatively novel, views of the mode in which the tissues are built up from the constituents of food. While carbohydrates and fat, however derived, possess a similar efficiency, the various proteins have been shown to be by no means equivalent to one another. Gelatine, for example, is not capable of repairing the loss of body protein, apparently because it contains no tyrosin, cystin, or tryptophan. Vegetable proteins, especially those of bread, beans, and Indian corn, are inferior in body building power to the proteins of meat, fish, egg, and milk. Of the proteins of wheat, gliadin is much inferior to glutinine, and zein, which constitutes half of the protein in Indian corn, is also inferior to it. Rats fed on zein lose in weight and die unless a change in diet affords them relief. This defect in vegetable proteins cannot be made up in the body, as is possible with casein, which, although deficient in glycocoll, yields this substance within the animal organism. Besides these differences in the chemical formation of proteins, which influence so greatly the food value of many articles, there is also the question of vitamines, the existence of which modifies what has been already said regarding the universal efficiency of carbohydrates and fats. Thus it has been shown by experiments on young rats that their growth comes to a standstill when the fat in their diet consists of lard, but proceeds rapidly if butter fat be substituted, so that butter fat contains something essential to growth in which lard is deficient. The relation of polished rice to the production of beri-beri is well known, but a chemically pure mixture of salts, fats, carbohydrates, and protein is not sufficient to maintain life. In discussing the monetary value of foods, Professor Lusk gives tables showing the cost of a thousand calories afforded by different articles, and shows how wastefully extravagant are many foods in common use. He quotes from Miss Dorothy Lindsay's report on the diet of the working classes in Glasgow, which states that "one of the main contributing factors of malnutrition among the poor is bad marketing." He suggests that all food sold in packages should bear a Government label certifying not only to its purity but to its food value. "Pure food is necessary; foul food should be strangled at its source, but besides this a widespread knowledge of what food really is would be of great value and would blast out of existence some commercial dietary impostures of the meanest description." We commend this little book as containing information by no means universally possessed, if we may judge by the kind of foods seen so often in the sick room, where money is commonly wasted upon proprietary and other articles of little worth.

Of a different type is the larger book on *Nutrition*[3] by Mr. Charles E. Sohn. In spite of its title, the greater part deals with food rather than with the problems of metabolism, which is as it should be in a work written by a chemist and not by a physiologist or a physician. The author describes and explains the chemical processes of nutrition and the composition of food, supplying an abundance of diagrams and tables which would be found useful in the preparation of popular lectures on this subject, but the drawing of some of the diagrams might be improved. The author points out the exaggerated claims too often put forward for proprietary articles of food and their comparatively uneconomic character; he makes an effective criticism of the puff of a certain meat extract by pointing out that the gain of weight shown by the dogs who had this extract added to their ration of biscuit might be explained by the fact that this meat extract contains a considerable amount of salt, which would conduce to the retention of water and thus account for the moderate increases of weight in the animals observed.

NOTES ON BOOKS.

Mr. J. Henry Lloyd has compiled a handbook[4] containing all the legal and administrative orders and memorandums with regard to medical and sanatorium benefits which have been issued by the Commissioners up to the date of publication, including the full text of the clauses of the Acts and regulations concerning these benefits. It is arranged in a convenient form, with coloured tabs projecting from the margins of the pages to facilitate reference. There is a full and detailed account of the medical card system, and all the documents concerning the constitution of insurance, local medical, panel, and pharmaceutical committees are quoted in full. The provisions of the Acts and of the Commissioners for maintaining the efficiency of the medical service are given, and the procedure in disputes fully explained. The regulations, orders, and memorandums concerning the financial arrangements with doctors and chemists and the finance of sanatorium benefit are quoted. Perhaps the fullest chapter is that on the panel arrangements for medical service, and the special arrangements for persons required or allowed to make their own arrangements, and for old and disabled members of societies and seamen. In all cases the original documents are quoted, mostly in full, with no attempt to express any opinion, the object being to collect for reference all the official information needed with regard to medical and sanatorium benefits by medical men, chemists, or members and officials of insurance committees. In an appendix is a list of the sanatoriums approved by the Local Government Board under the National Insurance Acts for England and Wales. The book cannot fail to be of the greatest value to all who are in any way connected with the working of medical and sanatorium benefits.

We can strongly recommend to all who are interested in dietetics and cookery for invalids the *Apsley Cookery Book*[5] by Mrs. John J. Webster and Mrs. H. Llewellyn, for although the primary object of the authors is to assist those who desire to live on a uric-acid-free diet, or as it is now called, a purin-free diet, the general hints on cooking may be read with advantage by every one, and the recipes are so practical and useful that they would be an addition to the resources of all housewives. The success of this little book is already assured, and it really needs no commendation from us. It is in its tenth thousand, and the new edition contains fifty additional recipes. Of special interest in the dieting of invalids are dishes which are sweet without containing sugar or saccharine, and drinks which are a substitute for tea and coffee, but this by no means exhausts the useful hints which the book affords.

SATURDAY, AUGUST 22ND, 1914.

THE WAR.

THE MEDICAL PROFESSION AT HOME.

From all over the kingdom news has been received that the local medical profession is taking steps to safeguard the interests of practitioners who are called in the service of their country to leave their practices. This means that those who remain at home will undertake between them to act in every respect as substitutes for the absentee, keeping a separate account of all attendances on his patients, and refusing to continue attendance on them when he is able to take up his practice once again. This does not necessarily mean that any practitioner who has a distinct objection to working under the Insurance Act should undertake any such work for the absentee panel doctor, as it will in almost all districts be possible to find insurance doctors to do it. At the same time, there may be districts where a large number of panel doctors are away on service, and we can hardly imagine that any Insurance Committee will keep to the strict letter of the regulations about substitutes, even though the absentees may be away on service for a year or more. As a mere act of justice to those who are risking their lives for the country, the Insurance Commissioners should make special regulations to meet such cases. What the Commissioners on their side may demand is simply that the insured should receive proper medical attendance, and if the local panel voluntarily undertakes to provide this by attending the patients of those who are away in the field and allowing them to receive the fees on their return, the Commissioners and Insurance Committees should do everything to facilitate such arrangements.

The vast majority of the Territorials and reservists who have been called up are insured persons on the list of some panel doctor. While they are away the navy or army will, of course, provide them with medical or surgical treatment, and to that extent the work of the panel doctors remaining at home will be lessened. But, unfortunately, it is only too certain that the wives and families of the non-commissioned officers and men on active service must suffer through the absence of the breadwinners. In addition to this, the partial or complete closing of mills, warehouses, and works of all kinds, even though this should prove to be only temporary, cannot fail to cause a great amount of distress among the workers thrown out of employment, as well as among the dependants left at home of men on military service.

We have therefore two classes to consider—the necessitous wives and children and other dependants of men who are on military duty in this emergency, and the similar necessitous dependants of workers who will be thrown out of employment should the dislocation of industry and trade produced by the outbreak of war long continue. The offer of the profession—the very generous offer—which has been made in all parts of the country is to give free attendance to the first class. The care of the other class must be provided for if and when the necessity arises. When trying to estimate the effect of the war on the position of medical men, it is necessary also to recognize that acute pecuniary embarrassment has been produced among a class in receipt of incomes above the wage limit of the Insurance Act who have always been in the habit of employing private practitioners and paying their fees. It is to be feared that many so affected will hardly be in a position to pay medical accounts unless the renewal of trade for which the Colonial Secretary is working, by getting the command of markets hitherto controlled by German traders, is achieved. The medical profession will undoubtedly be hard hit by the war from all these directions.

The desire of the profession to give its services to men on military service seems to be general throughout the country, but it is essential that the work should be properly organized to ensure smooth and uniform working and to prevent abuse. The Chairman of Council and Medical Secretary of the British Medical Association, acting in consultation with the President and Parliamentary Secretary of the Pharmaceutical Society, have made suggestions on this head which are now under the consideration of the Cabinet Committee. As has been recognized at the majority of the local meetings of the medical profession throughout the country, the scheme for medical attendance should be worked through, or in co-operation with, the local Distress Committees, and should make provision for defraying the cost of drugs and appliances from the funds available to those committees.

The question has arisen as to the position of the medical and sanatorium benefit funds under the Insurance Act. The Government will, of course, be responsible for providing all medical attendance for insured persons now called up to the services, at any rate so long as they remain on service. Their insurance contributions will be at the reduced rate of 3d. per week instead of the usual 7d., and they will not, so long as they remain in service, be entitled to medical, sanatorium, sickness, or disablement benefits, the only benefit payable being maternity benefit, which will go to their wives. The question then arises, supposing the war lasts, say, at least to the end of the year—that is, roughly, five months—Will the Government or, what is for practical purposes the same thing, will the Navy and Army Insurance Fund claim to receive five-twelfths of the 9s. available for the year for the medical attendance on these persons, or will there be some method of transfer of case values? Either alternative would involve a serious lessening of the panel and drug funds of

Insurance Committees, which would entail a further hardship on the panel doctors, who will have so much unavoidable gratuitous work to do for the wives and families of their former panel patients. The least that could be done to lessen this hardship would be that part at least of the money in question should in some way be devoted to the medical and sanatorium treatment of the wives and families of the men away on service. It may be assumed that the men themselves would welcome some such arrangement. The total amount would of course fall far short of the cost at the very lowest estimate, but it might help, with what assistance the Distress Committees can give, to tide over the difficulties ahead.

A further question will arise later as to the treatment of men invalided out of the Reserves or Territorials for wounds or disease.

THE VALUE OF ANTITYPHOID VACCINATION.

AN APPEAL BY THE WAR OFFICE TO THE PROFESSION.

WE have received the following letter from Colonel Sir W. B. Leishman:

Sir,—With the permission of Sir Arthur Sloggett, Director-General of the Army Medical Department, I beg to ask the hospitality of your columns in the following matter.

Antityphoid inoculation remains, unfortunately, on a voluntary basis in our army, and it is only possible to secure the benefit of its protection to our troops by persuading the officers and men, first, of the reality of the danger of typhoid fever; and, secondly, of the protective value of the vaccine.

Needless to say, no efforts are being spared by the Medical Department of the Army to give effect to Lord Kitchener's strongly expressed wish that as many men as possible should be inoculated, with due regard, naturally, to the exigencies of the military situation. Steps have already been taken to impress this upon all concerned with the medical care of the Home Forces, as had already been done in the case of the Expeditionary Force.

Many, however, of the medical officers of the Territorial Force, as well as the newly-enrolled civil surgeons, are less familiar than Royal Army Medical Corps officers either with the danger of typhoid in epidemic form, to which the Home Forces will most certainly be exposed, or with the high protective value of antityphoid inoculation. I have no doubt that these officers, and also members of the profession outside the ranks of the army, will be consulted on the subject by many who are in doubt as to the value or the necessity of the process. In such cases I venture to appeal for the strong support which it will be in their power to give to the efforts we are making to secure the protection of the Territorial Force.

The facts relating to inoculation and its results have been widely published in recent years and the pronounced benefits and harmless nature of the procedure are admitted by all who have had experience of it. I may, however, refer to a few points which, although well known to army surgeons, are less familiar to others.

1. No army in recent wars has escaped typhoid fever, which, in several campaigns, has killed more men than the enemy. In the South African war, for instance, there were 57,684 cases of typhoid, of which 19,454 (33 per cent.) were invalided and 8,022 (13.9 per cent.) died. The deaths from typhoid exceeded the total number of men killed in action.

2. It would be most rash, in the opinion of those who have studied the question, to assume that the forces serving at home will not be exposed to the dangers of typhoid in epidemic form.

3. The benefits of inoculation are so well recognized in the regular forces that we find little difficulty, in foreign stations, in securing volunteers for inoculation; for instance, about 93 per cent. of the British garrison of India have been protected by inoculation, and typhoid fever, which used to cost us from 300 to 600 deaths annually, was last year responsible for less than 20 deaths.

4. Inoculation was made compulsory in the American army in 1911 and has practically abolished the disease; in 1913 there were only 3 cases and no deaths in the entire army of over 90,000 men.

The organization for the preparation and distribution of the vaccine should be equal to all the demands made upon it. In view of the possibility of such an emergency as has now arisen, arrangements were made some years ago at the R.A.M. College to prepare and maintain a very large reserve of the vaccine, and from this reserve we have been able to issue, since mobilization, more than 170,000 doses for the use of the troops. The Vaccine Department at the R.A.M. College, under Major D. Harvey, will continue, for the present, the preparation of the vaccine, and we are also fortunate in receiving most generous and valuable assistance from the staff of the Lister Institute and from Sir Almroth Wright.

The ideal of universal protection is, I fear, too much to hope for, but, with the support of the profession, on which I feel sure we may count, we may hope to save many valuable lives and to minimize one of the gravest causes of depletion of the fighting force.—I am, Sir, yours obediently,

W. B. LEISHMAN,
Colonel, R.A.M.C.

War Office, Aug. 16th.

MEDICAL ATTENDANCE ON PATIENTS OF PRACTITIONERS ON MILITARY DUTY.

THE information printed below, taken with that published last week, shows that the profession generally in all parts of the country is prepared to undertake to attend gratuitously the necessitous wives and dependants of men absent on military duty. As mentioned on the preceding page, a scheme prepared by the officers of the British Medical Association and the Pharmaceutical Society for the organization of the work and the provision of drugs and appliances is now under the consideration of the Cabinet Committee. The scheme would be worked in co-operation with the local Distress Committees, through which the Prince of Wales's Fund is to be administered. Dr. E. R. Fothergill writes to express the opinion that it would be wiser for the profession to subscribe to the Prince of Wales's Fund for the Relief of Distress than to offer to give medical attendance gratuitously to the wives and children of the men now serving. Whatever opinion some hold on this point, all will agree on the necessity for an organized scheme, under which all the members of the profession in each locality shall act together. It is eminently undesirable that any individual practitioner should, from whatever motive, make a personal announcement of his willingness to give those services which all his colleagues are equally ready to render.

The *National Insurance Gazette* is publishing this week a leading article in which it again refers to "the most handsome and patriotic action of the doctors in offering free treatment to the necessitous dependants of their panel patients called to the front. This action," it adds, "has already been much admired by Insurance Committee men and representatives of approved societies. . . . We should gain enormously if the doctors looked on us as friends. . . . They, too, would gain in various ways from

the better spirit. Unfriendly relations have as their outcome suspicion, complaints, demands for a State medical service." We are glad to read and to reciprocate such views, and to believe that what is now happening is leading to a more generous appreciation of the spirit by which the medical profession is actuated. Antagonism between the individual doctor and the individual sick man is unthinkable, and there is really no sound reason why there should be antagonism between the organized bodies representing the one and the other. We are all in the same boat.

London.

Hospital for Officers.

Jeanne Lady Coats has placed her house in Hill Street, Berkeley Square, London, at the disposal of Princess Henry of Battenberg for use as a hospital for sick and wounded officers of the Navy and Army, including the Territorial Forces. It is now being fitted up to fulfil the purpose, and will, it is hoped, very shortly be available. Dr. Rice-Oxley, Physician-in-Ordinary to Princess Henry, has been appointed medical superintendent of the hospital, and Sir Frederic Eve has accepted the post of surgeon.

Metropolitan Counties.

Dr. C. M. Pennefather, Honorary Secretary of the Harrow Division, reports that a circular has been sent to all medical men engaged in general practice within the area of the Division, asking them to give gratuitous medical attendance to the wives and dependants of soldiers and sailors, including Territorials, Reservists, and ambulance men engaged on active service where these dependants are necessitous. Notices have been inserted in the local press calling the attention of persons entitled to avail themselves of this offer, and the local secretaries of the Sailors' and Soldiers' Association have been notified of the willingness of the profession to give their services gratuitously.

Dr. Arthur Todd-White, Honorary Secretary, South-West Essex Division, reports that at a meeting of medical men of the district held at Leyton, it was unanimously resolved that members of the profession should look after the interests and practices of the members who had been called up for service with the colours, and should attend free of charge the dependants of men called up to the army, subject to arrangements being made by the ward committees. It was also resolved to attend without fee wounded soldiers of all nations drafted into the district from base hospitals, and to prepare a list of doctors willing to extend hospitality to wounded soldiers and receive them in their houses. A large committee was elected to deal with local medical matters during the war, of which Dr. Pottinger Eldred was appointed Chairman, and Dr. A. Todd-White, Honorary Secretary. The committee has printed its resolutions in the form of a bill, which has been sent round to all medical practitioners for placing in their surgeries.

At a meeting on August 13th of members of the medical profession practising locally in the borough of Hampstead the following resolutions were unanimously carried:

1. That this meeting of the profession loyally undertakes to safeguard the interests of those colleagues who are called in the service of their country to leave their practices; and that any medical duties for the absentees shall be performed under arrangements favourable to the latter.
2. That the ordinary custom obtaining in the neighbourhood shall be the basis upon which arrangements shall be made.

A copy of these resolutions has been sent to every member of the local profession, and members who might be called up have been informed that in cases where no private arrangement had been made with regard to their practices, every assistance for the safe conduct of such practices will be given on application to the Honorary Secretary, Dr. Adam Oakley, 19, Hollycroft Avenue, Hampstead.

The Middlesex Panel Committee has issued a circular letter recommending the practitioners on the Middlesex Panel to attend gratuitously the dependants of all insured persons who are away from home in their country's service.

Kent.

Dr. Chisholm Will, Honorary Secretary of the Bromley Division, reports that the profession in that area has agreed to safeguard the interests of their colleagues called away in the service of their country, and that the Executive Committee of the Division, with power to add to its number, has been empowered to take any action which may be necessary. In case a doctor called away is unable to make personal arrangements with doctors in his neighbourhood, he is asked to notify the Secretaries, Dr. Tennyson Smith or Dr. Chisholm Will, who will attend to the matter.

The meeting resolved to provide free of charge attendance and prescriptions for the necessitous dependants of those who were on military duty, provided that the cases are vouched for by a properly constituted local relief committee. All the practitioners in the area and also the Clerk of the Kent Insurance Committee have been notified of the arrangements.

Surrey.

Dr. T. W. Letchworth, Honorary Secretary of the Kingston-on-Thames Division, reports that a meeting of medical practitioners in that area was held on August 11th, when the following resolutions were unanimously passed:

1. That any doctor called away on duty in connexion with the war be invited in the first instance to make his own arrangements for carrying on his practice.
2. That if he be unable to make such private arrangement he shall notify same to the honorary secretary of the local Division.
3. That in cases so notified the arrangements for the carrying on of the absent practitioner's practice shall be left in the hands of trustees.
4. That the local practitioners bind themselves to attend any patient belonging to the absent practitioner, and decline to continue to attend them after his return unless released by the practitioner, and to protect his practice under all eventualities.

The following were elected trustees of absent practitioners: Dr. Cooper, Dr. Goodman, and Dr. A. E. Evans.

It was also carried, *nemine contradicente*, that gratuitous attendance, advice, and treatment be given to the direct dependants of soldiers and sailors recommended as necessitous by the relief committees in the area. A copy of this last resolution was sent to the relief committee.

Mr. E. H. Willock, Honorary Secretary of the Croydon Division, reports that the Division has appointed a Provisional Committee to deal with the present emergency, and has co-opted certain non-members of the Association. A circular has been sent to all practitioners, which states that at a meeting of Croydon doctors it was agreed that gratuitous medical attendance should be given to those cases which are really necessitous, and dependent for their support upon one serving in the war. It was recommended that each patient should be supplied with a voucher, to be obtained from the local relief committee, but that urgent cases would be treated without a voucher, a voucher being obtained before further attendance is given, and that midwifery cases would be attended at a reduced fee on the production of a voucher—the amount of reduction to be agreed upon between the doctor and patient.

The chemists in Croydon are co-operating, and will dispense medicine at cost price without any charge for dispensing. Forms have already been drafted (1) for requesting the doctor to attend a person who is vouched for by the Mayor's Medical Relief Committee, and (2) for the prescriptions ordering medicines for any of these persons.

Mr. Willock reports that similar arrangements have been made in the Sutton, Epsom, and Leatherhead areas of the Division.

Sussex.

A conjoint committee, representative of the Brighton Division of the British Medical Association, the Panel Committee for the Borough of Brighton, and the Panel Committee for East Sussex, has been formed for the purpose of dealing with questions which will arise in consequence of the absence of practitioners who are called upon to render military service (medical or otherwise) during the war. It held its first meeting on August 12th, when the following resolutions were passed:

1. That every practitioner who is not mobilized should be willing to assist in carrying on the practice of those practitioners who have been.
2. In view of the fact that practitioners who are mobilized will receive payment from the Government for their services, this Committee considers that those doing the work of the absent practitioners should not be wholly unremunerated by them.

3. That every practitioner called to attend a patient of another practitioner who has been mobilized should do all in his power to safeguard the interests of the absent practitioner.
4. That if it should be considered necessary to provide for the medical attendance of the dependants of soldiers and sailors (regular, territorial, reserve, or otherwise), this Committee is of opinion that the local committee of the National Relief Fund should enter into arrangements with the existing organizations in the district, such as the Brighton Public Medical Service and the Provident Dispensary.

An offer by the Executive of the Division to nominate members to serve on the local relief committee has been cordially accepted.

South-Western.

Dr. E. J. Donbavand, Honorary Secretary of the Plymouth Division, reports that at a largely attended meeting of members of the profession in Plymouth, held on August 12th, the opinion was expressed that a register should be compiled of all qualified medical men willing to give all or any part of their time to doing the work of practitioners who are serving on military duty. Dr. Donbavand has undertaken to keep this register.

East Anglian.

At a meeting of the East Norfolk Division of the British Medical Association held in Norwich on August 12th, 1914, the following resolutions were passed unanimously, and it was requested that, unless locumtenents, partners, or others are definitely engaged to act for practitioners absent on war service, the resolutions will be complied with by practitioners in the area:

1. That the members of the Division pledge themselves to help all those practitioners in the area called away on national service in their practices.
2. As regards Poor Law practice, that any substitute or substitutes doing Poor Law work for a practitioner absent on national service should be paid one-third of the salary arising from the appointment during the absence of the principal.
3. As regards private practice, uninsured members of friendly societies, and other public appointments, that any substitute attending the private patients of a practitioner absent on national service should send in his record of the work done to the absent practitioner; this latter will send in his accounts and pay to the substitute one-third of the amount received in payment of these accounts.
4. Insurance Acts practice: That the practitioners on the panel in this area agree to attend free of charge to the absent practitioner any insurance patients on his list, the patient being requested to go to the nearest practitioner.
5. That the families of Reservists and Territorials absent on national service not otherwise provided for, and who may be in poor circumstances, be attended free.

N.B. Resolution 4 was approved and adopted at a meeting of the Norfolk Panel Committee held subsequently to the British Medical Association Division meeting.

Dr. J. L. Forrest, Honorary Secretary, West Norfolk Division, reports that at a special meeting of the Division held on August 12th, it was resolved that the members should assist in every way possible to safeguard the interests of their colleagues absent on national service, and should undertake gratuitously the treatment of all dependants of Reservists and Territorials on active service.

Midlands.

Dr. A. M. Pilcher, Honorary Secretary of the Chesterfield Division, reports that at a meeting held on August 13th it was decided to adopt the Southampton scheme, and that all work done (private and panel) should simply be entered into a day book (no insurance records to be kept). It was resolved also to recommend that practitioners should treat the wives and necessitous dependants of all those called to the colours (midwifery excluded), and that the fees for ambulance and Red Cross lectures should be suspended during the war.

Mr. Alfred Linnell, Secretary of the Northamptonshire Panel Committee, informs us that at a meeting of that Committee held on August 12th at Northampton the following resolutions were passed:

That 25 per cent. of receipts be paid by absentee practitioners to their deputies (to cover expenses) for panel patients (payment to be made on a basis of number of record cards) and 50 per cent. for all others whether club, private or confinement.

That these proposals be put before practitioners in the areas affected, and if accepted by them be notified by circular to all the panel practitioners in the county and if no disapproval be expressed within four days approval will be taken for granted.

Drs. Baxter and Robb were appointed a deputation to visit the areas affected and interview the local medical men. It was decided that no panel practitioner should accept a transfer of any panel patient from the list of a panel practitioner on active service.

The Committee also resolved to recommend that dependants of men on active service be attended free of charge, and the Secretary was asked to write to the Pharmaceutical Committee and inquire if the chemists would co-operate.

Birmingham.

At a meeting of the whole profession in this district a Committee was elected to care for the practices of medical men called out, and to organize gratuitous attendance on dependants of men on active service. The Chairman of the Committee is Mr. W. F. Haslam, and the Honorary Secretary, Dr. A. G. C. Irvine (Bonshaw House, Selly Oak).

The case of the practices of specialists and consultants was referred to the Birmingham Consultants' Committee.

It was arranged that the ward secretaries of the Birmingham and District General Medical Practitioners' Union should summon meetings, to which all practitioners in the ward area should be invited, to arrange that as far as practicable the work of the absentees should be divided and undertaken.

A subcommittee has met a subcommittee of the Medical Benefit Subcommittee and arrangements have been made, it is hoped of a permanent order, to deal with Insurance practices. In one or two instances of very large panel practices it has been necessary to engage a locumtenent.

A circular letter to patients of absent doctors was drawn up, and copies will be supplied to their representatives. The letter was in the following terms:

Your medical attendant has been called away from his practice to serve his country.

This Committee is formed to ensure, as far as possible, that he shall not by so acting lose his practice, which is his livelihood.

Any of your doctor's medical brethren are now willing to attend you *for him*, and at the end of the attendance will send in an account payable to him.

This is all we are able to do, but it is in your power to do still more—by keeping faithfully to your own doctor on his return, at however long an interval, to his practice.

We feel confident that this appeal to your patriotism will not be in vain.

Staffordshire.

Dr. H. C. Mactier, Honorary Secretary of the South Staffordshire Division, reports that the Wolverhampton Panel Committee (of which he is also honorary secretary) has arranged for the attendance upon insured persons on the lists of those panel practitioners who are called away on military duty.

The Division has asked practitioners generally: (1) To undertake to treat the patients and safeguard the interests of those members serving with the forces; (2) to regard themselves as deputies for those on active service, the remuneration being a matter of arrangement between the two practitioners, and has urged that after the return of a practitioner from service the deputy shall refuse on any consideration except that of urgency to treat any of the returned practitioner's patients, whom he has seen as deputy, for a period of twelve months; and (3) to undertake the gratuitous treatment of the dependants of the non-commissioned officers and men called to the colours during the war.

Dr. Mactier reports that the response to these requests has in both cases been excellent.

Lancashire and Cheshire.

Dr. J. Shearer, Honorary Secretary of the Blackburn Division, reports that the Chairman of the Blackburn Local Medical Committee has issued a letter to the medical men of the town who are not called away suggesting that they should voluntarily undertake to attend the patients of absent doctors, "and preserve intact their practices and emoluments." It will be arranged that patients will have a free choice among the doctors nearest their residences. Already 48 out of 64 medical men in the town have intimated that they are ready to do the work in

accordance with the terms of the letter, and it is believed that the others, some of whom are at present away, will do the same.

Dr. C. Jephcott, Honorary Secretary of the Chester Division, reports that at a meeting of the profession held on August 12th, the following resolution was passed and sent to all practitioners in the Division area:

> That this meeting of the medical profession loyally undertakes to safeguard the interests of those of their colleagues who are called to leave their practices in the service of their country, and also undertakes any medical duties for the sole benefit of the absentees.

Dr. Robert Harris, acting as Honorary Secretary of the Southport Division in the temporary absence of Dr. Harker, reports that at a meeting of the profession called by the Division, held on August 15th, it was resolved to safeguard the interests of those called to leave their practices in the service of their country, and to undertake any medical duties for the sole benefit of the absentees. The opinion was expressed that the interest of those whose services had been accepted would be best consulted by their making their own arrangements. The Executive Committee of the Division was appointed a committee to look after the interests of any for whom private arrangements have not been made, and the meeting also resolved:

> That the medical profession would be willing to attend gratuitously necessitous dependants of reservists who may be recommended to them by the Case Committee of the local National Relief Committee, and that the Case Committee should be informed of this decision.

Dr. F. J. Knowles, Honorary Secretary of the St. Helens Division, reports that at a well-attended meeting of the Division, held on August 17th, it was unanimously resolved: (*a*) That practitioners in the neighbourhood should pledge themselves to safeguard the interests of those colleagues called away on active service, and to undertake any medical duties on their behalf; (*b*) to give their gratuitous services to the wives and children (up to the age of 16) of all those men engaged in the present war—including the provision of necessary medicines; and (*c*) to call the attention of the profession to the scarcity and high price of certain drugs and to the necessity of economy.

NORTH OF ENGLAND.

Dr. James Don, Honorary Secretary of the North of England Branch, reports that a circular letter has been sent to all the members of the Newcastle Division stating that at an emergency meeting representing all branches of the profession in Newcastle it was unanimously decided that it is the duty of those who remain at home to safeguard the practices of those who are serving their country, and that all members of the profession should be asked to attend without remuneration any patients, whether private or panel, belonging to practitioners called to active service. It was suggested that the detailed arrangements should be dealt with by the practitioners in the various areas of the city. The circular made the following suggestions:

> As regards private patients, records of visits and consultations to be kept; medicine to be supplied by the practitioner or a prescription given signed by the practitioner giving the prescription, and stating the name of the practitioner for whom he is acting.
>
> As regards panel patients, records to be kept in such a way as to satisfy statutory obligations. Patients calling at the surgery of any of the doctors called away will be given the visiting card of their own doctor as evidence of their bona fides.

Dr. Rutter, Chairman of the Panel Committee, is prepared to make arrangements for any practitioner who is suddenly called on active service. The chemists have arranged that they will dispense medicine for private patients on panel terms.

Dr. Don reports that similar arrangements are being made in neighbouring Divisions.

YORKSHIRE.

Dr. R. F. Castle, Representative of the Barnsley Division, acting in the absence of Dr. Harold Horne called away on service, has circularized all the practitioners in the area of the Division, suggesting that they should follow the example set by Southampton, by each medical man undertaking (1) to do his best to safeguard the interests of any of his colleagues who may be called upon to serve his country, so that the absentee may suffer as little loss as possible; and (2) to attend gratis the families of any men called away on duty connected with the war.

Dr. Castle has intimated in his circular that he will take no reply as meaning an assent to the proposition, and does not anticipate any refusals.

LOCAL HOSPITAL AND OTHER MEDICAL ARRANGEMENTS.

BRIGHTON.

The Mobilization of a Territorial Hospital.

THE mobilization at Brighton of the 2nd Eastern General Hospital, which is one of twenty-three similar hospitals of the Territorial Forces in the United Kingdom, is, perhaps, a good example of the readiness with which the force can act in an emergency and a proof of the ability and soundness of the organization now prevailing at the War Office.

The Royal Proclamation which ordered a general mobilization of the Territorial Forces was promulgated on Tuesday, August 4th. The administrative officers of the 2nd Eastern General Hospital at once took measures to ensure that their hospital should be ready at the earliest possible moment for the reception of sick and wounded men. The peace strength of the company consists of three administrative officers and 43 non-commissioned officers and men, together with a staff of 31 medical officers, whose services became available on mobilization. At war strength the number of non-commissioned officers and men is increased to 110. The necessary additional men were obtained with the greatest ease in a few days; in fact, so many were the applications that a very careful selection was made from those who were anxious to enlist. All the men were at once provided with uniforms.

After the numerous preliminary arrangements had been made, the first and great essential was to secure an appropriate building. The new Grammar School, situated in a particularly healthy, elevated, and open part of the town, in the upper part of the Dyke Road, was requisitioned. The building is a handsome new structure of red brick, standing in its own grounds, and consisting of two main blocks, the school itself, and the boarding house, both eminently suitable for use as hospital buildings. The head master and governors showed a truly patriotic spirit, although to them the seizure of the school was a very serious matter, for it meant the closing of the school certainly for next term, possibly for longer. They made no difficulties, but at once set about finding a fresh building to which their boys might return in September.

The school was occupied on Friday, August 7th. On Thursday, August 13th, the hospital was ready in all respects to receive 150 patients, or even on an emergency 260. The total number to be provided for eventually is 520. The buildings have now quite a military appearance with the large Red Cross flag flying, and the gates closely guarded by uniformed men. A few patients are under treatment in the hospital at the present time, territorials who have been seized with illness on duty.

In addition to the Grammar School, the authorities have occupied Stanford Road Council School, not very far distant. At the present time it is being used as a barracks for the men of the unit, but later it is intended to provide hospital beds there. The school is now being cleaned down thoroughly, and all arrangements made for the opening of the wards, etc. The men are at present messing at the Grammar School, where the cooking arrangements by men of the unit, who with only one range and one gas stove are providing good meals for over one hundred men, deserve every praise.

As to the details of organization, a few words will be appropriate. The beds and bedding have been obtained largely from private sources. Thus the head mistress of Roedean Girl's School, Miss Lawrence, sent 80, 100 were already in the Grammar School Boarding House, 50 were procured from the guardians of the Brighton parish, private inhabitants have given some, others are being purchased from local dealers, and some are on order from Birmingham. Drugs, dressings, stores and instruments have been purchased locally, in addition to those sent down by the Army Medical Department. All provisions, meat, groceries, vegetables, bread and milk are being procured from tradesmen in the town, and no attempt is being made by them to run up the prices. Stores of all

kinds have been laid in—in the way of provisions, jam, marmalade, rice, tapioca, lentils, bovril, cocoa, corn flour, lemonade, etc.; in the linen department, sheets, towels, bedspreads, and socks. Several gas stoves have been fitted by the Brighton and Hove Gas Company, and some new hot and cold baths have been installed. Every facility and encouragement is given to the men to have baths on the premises, and the registrar takes the whole unit when possible down to the sea in the early morning to bathe.

In four days the laundry was successfully converted into a really excellent operating theatre. All the requisites of a modern operating room are present, and any operation, major or minor, can be undertaken there.

An *x*-ray department, quite up to date, is in process of equipment, and rooms for the proper treatment of dental cases, and for the examination of nose, throat, eye, and ear cases are being arranged.

There is a fully equipped consulting room, where the orderly medical officer sees casualties, men reported unfit for duty, etc. This has been in use for some days. A mortuary has also been provided. The administrator's and registrar's offices are complete, and rooms have been, or are being, fully prepared for the matron, theatre sister, and various other officials, medical, administrative, and nursing.

The administrative staff consists of a major as administrator, a lieutenant as registrar, and a quartermaster. The medical staff is made up as follows: Two lieutenant-colonels, four majors, and twelve captains, most of them drawn from the staffs of the various local hospitals, all with special experience of surgery, medicine, or with some specialist knowledge. There are also thirteen other officers whose services may be utilized if necessary. Their duties so far have been to examine recruits, not only for their own corps, but for various other units, such as the Army Service Corps, the Artillery, the Cyclist Corps, etc. In addition they have been treating sick and injured men, and performing various sanitary and administrative duties. In the future their work will mainly consist in the medical and surgical treatment of the sick and wounded sent to the hospital by the army authorities, including the performance of any necessary operations.

The nursing arrangements are well forward. A principal matron, a matron, about thirty sisters, and ninety nurses is the full staff, all of whom have been recruited, although they have not, so far, all been sent for. Many come from the Sussex County Hospital, and others from all parts of the county. They are at present all billeted at the Convent of the Sacred Heart in the Upper Drive, where they have received a hearty welcome from the nuns, most of them French, who are most anxious to be of assistance to the allies of their country.

The dispensary is well equipped with drugs, dressings, splints, and crutches. All arrangements are made for properly dispensing the medicines ordered.

The routine day of the men is at present as follows:

Reveillé	5.0 a.m.	Dinner	1.0 p.m.
Bathing parade ...	6.0 ,,	Parade	2.15 ,,
Drill	7.30 ,,	Tea	5.0 ,,
Breakfast	8.0 ,,	Bed	9.30 ,,
Commence duties	9.0 ,,	Lights out ...	10.0 ,,

Every credit must be given to those concerned in mobilizing this 2nd Eastern General Hospital, from the administrator, registrar, and quartermaster down to every single private. All have worked magnificently, and this fully equipped hospital, ready in so short a time after the order from the War Office, for the treatment of our sick and wounded soldiers and sailors does them the very greatest credit.

Sheffield.

The 3rd Northern General Hospital (T.F.).

Sheffield is the head quarters of the 3rd Northern General Hospital, with Lieutenant-Colonel A. M. Connell as commandant and Captain G. H. Pooley as registrar.

Lieutenant-Colonel Duncan Burgess has been appointed officer in command of the medical section and Lieutenant-Colonel Sinclair White officer in command for the surgical section. A full complement of medical officers whose names appear in the *Army List* as "available on mobilization" have signed on for service, and Lieutenant-Colonel Burgess and Lieutenant-Colonel Sinclair White are already in active work. An ever-increasing number of patients is being received from the Territorial camps in the neighbourhood of Doncaster and elsewhere. The revised scheme for a military hospital has been adopted. The King Edward VII Grammar School, the hostels for male and female teachers, and the Teachers' Training College have been taken over. The hostels are new buildings, and the King Edward VII Grammar School and Training College have been quite recently renovated. All four buildings are of stone, situated in a healthy locality, with plenty of surrounding open spaces. They are well drained, suitably heated, excellently lighted and ventilated, and have water, gas, and electric supplies. The two hostels and the Grammar School are provided with good kitchens and a large supply of kitchen utensils. The whole scheme provides accommodation for 20 sick officers and up to 606 beds for soldiers. It provides also for housing 91 female nurses and the 43 men forming the hospital male unit. At the end of last week 200 beds were available, and within a few days the rest of the accommodation will be ready. The authorities of the city of Sheffield have set aside 150 beds in the municipal hospitals for the treatment of soldiers suffering from typhoid fever and other infectious diseases. The Royal Infirmary and the Royal Hospital will, if required, provide over 200 additional beds. The Woofindin Convalescent Home, containing 70 beds, has been offered by the trustees and will form a valuable asset.

The male unit staff of the hospital is full to overflowing, and the men are in a high state of efficiency. They will be supplemented by two county companies of the Red Cross Society. The female nursing unit—120 strong, all fully-trained hospital nurses—is mobilized and ready for work at an instant's notice.

Field Ambulance.

Sheffield is also the head quarters of the 3rd West Riding Field Ambulance under the command of Major J. W. Stokes. The unit, with its full complement of 240 men, was mobilized a week ago and has left Sheffield to take up its allotted station. Numerous offers from private citizens to provide additional hospital accommodation are pouring in, and everybody is desirous to help.

Ordinary Work of the Hospitals.

The many gaps in the hospital staffs owing to the withdrawal of doctors by the Territorial regiments have rendered the work of those remaining very heavy, but all are working with zeal and determination to see the thing through.

Manchester.

The Red Cross flag is now flying over the Manchester Royal Infirmary and the Central Receiving Branch on the old infirmary site in Piccadilly. The East Lancashire Branch of the British Red Cross Society was formed about four years ago and under the energetic direction of Colonel Coates, the County Director, is now rapidly perfecting its organization. The chief object is to make good the gap existing between the fighting line and the base hospitals, and the East Lancashire area has been divided into twenty-eight divisions often with some further subdivisions. At least two detachments, one of men and one of women, are to be raised in each division, the men's detachment consisting of a commandant, preferably a retired officer, a medical officer, a quartermaster, a pharmacist, four section leaders, and forty-eight men, most of whom are required to have a certificate for first aid. The women's detachment is to consist of a commandant or medical officer, a lady superintendent who must be a trained nurse, a quartermaster, and twenty women, all of whom except the cooks are to hold a first aid and home nursing certificate. Offers of assistance have been pouring in from all sides, and among them are offers of houses and buildings for hospitals and convalescent homes, all free of charge. Worsley Hall and Park has been offered by the Earl of Ellesmere, Haigh Hall and the Woodlands by the Earl of Crawford, Stubbins Vale House, near Ramsbottom, by Mr. Porritt, and the large house and grounds called Summerville, at Irlams o' th' Height, by Sir Lees Knowles. The Convent of the Cenacle near Alexandra Park has also been offered, and numerous other residences.

It was at first proposed to take the Manchester School of Technology and fit it up with about 1,200 beds, but it was not found to be altogether suitable, and at present the

Manchester Secondary Schools in Whitworth Street are being rapidly converted into a general base hospital. If necessary, room could be found for over 1,000 beds, but it is proposed to provide at the outset 520 beds. The nurses are at present housed in Dalton Hall and Hulme Hall, the residential halls of university students. School buildings at Rusholme, Fallowfield, Whalley Range, Stretford and Old Trafford are also to be used for hospital purposes, arrangements having been made for the pupils at other schools.

It is the wish of the East Lancashire Branch to send to the front a Red Cross Hospital fully equipped and staffed in every way, and an appeal is now being made for funds for that purpose. The central office of the Branch is now at the Y.M.C.A., Peter Street, Manchester. Messrs. Tootal, Broadhurst and Co., of Manchester, have undertaken to receive and pack and send to their destination all comforts intended for soldiers and sailors, or for the various military hospitals, and several typewriting institutions have placed their shorthand and typist clerks at the disposal of the branch. It is believed that the organization is so ready that it could at twenty-four hours' notice from the military authorities accommodate 3,000 to 4,000 casualties.

The 18th Field Ambulance of the R.A.M.C., Manchester, under the command of Colonel Watson, has definitely taken over the responsibility of joining the expeditionary army on foreign service. The unit is complete in both personnel and equipment, and though a part of the R.A.M.C., Manchester Territorials, is known as the Special Reserve, as the men have received a retaining fee from the Government to seal their contract for foreign service. The 2nd Field Ambulance, under the command of Lieutenant-Colonel W. B. Pritchard, has also been invited to volunteer for foreign service, and the response has been most gratifying to the military authorities.

BIRMINGHAM.

1st Southern General Hospital.

The university buildings at Bournbrook have been taken over for the 1st Southern General Hospital, and at the end of the period allowed for organization Lieutenant-Colonel F. Marsh was able to announce that the hospital was prepared to receive 520 patients, and that the staff consists of 21 officers, 109 non-coms. and men, matron, 22 sisters, and 63 staff nurses.

Accommodation for the nurses is provided in the Women's Hostel, and for the men in the physics laboratory. The university authorities have co-operated wholeheartedly with the unit in their efforts; some of the staff returned from their holidays in order to assist in supplying light and electricity.

LEEDS.

2nd Northern General Hospital (T.F.).

The large new training college for teachers, situated in Beckett's Park, Far Headingley, which is the finest equipped centre of its kind in the country, has been requisitioned for the purposes of the base hospital for the reception of the sick or wounded. This will be staffed by those members of the honorary staff of the Leeds General Infirmary who hold commissions in the R.A.M.C.(T.), and whose services were made available on mobilization. A staff of dressers and clerks has also been secured, and it is believed that the arrangements will work smoothly through the period of stress which is impending. Mr. J. F. Dobson is the officer in charge of the arrangements. In the main building 200 beds have already been prepared, and this number can be increased to 500. Additional beds, bringing the total up to 2,000, can be secured by the erection of marquees in the grounds. There is good tramway communication between the base hospital and the centre of the city, and the members of the staff have been ordered to hold themselves in readiness for instant service when required.

The General Infirmary.

In addition, the authorities of the General Infirmary have converted their large out-patient waiting hall into an emergency ward with some 50 beds, and arrangements have been made with the Leeds Public Dispensary for taking over the ordinary out-patient work of the institution during the time that this may be required.

Nursing.

The Lady Superintendent of Nurses at the General Infirmary, Miss Innes, will be in charge of the base hospital, and will have under her one of the former sisters of the Infirmary, Miss Hill, who is now Matron of the Halifax Infirmary, and a certain number of the sisters and nurses who have been working under her at the Infirmary, whose places will be filled by the appointment of new probationers.

Voluntary Aid Detachments.

The Territorial Branch of the St. John Ambulance Association is developing its Voluntary Aid Detachments, and will render valuable assistance.

WALES.

The organization of voluntary work in Wales to supplement the Army Medical Service during this titanic war has been taken up with quiet determination and much vigour.

Field Ambulance.

The 2nd Welsh Field Ambulance, under Colonel Tenison Collins, R.A.M.C.(T.), has had the distinction of being accepted for foreign service, and is ready to start at a moment's notice. Mr. Tenison Collins is the well-known gynaecologist to King Edward VII Hospital, Cardiff.

Hospitals.

The only base hospital in Wales (the 3rd Western General Hospital, T. F.) is under the command of Colonel Hepburn, V.D., who for many years has been a most keen volunteer, and has at last had an opportunity of displaying his great power of organization; this has already been shown in civil life in connexion with the organization of the National Medical School of the University of Wales, which for the moment must rest until war preparations are completed.

At King Edward VII Hospital 150 beds have been placed at the disposal of Colonel Hepburn by the Board of Management, and schools are converted into wards to bring the total to the establishment number, 520.

Mr. James Howell, J.P., has, on behalf of the family of the late Mr. James Howell, given the old Mansion House for fifty beds for Red Cross work; and Bedford House, the private nursing home of Mr. Lynn Thomas, is also at the disposal of the Army Medical Service.

Roughly, there are 2,000 beds in Glamorgan available in case of need.

Red Cross Organization.

Lord and Lady Plymouth have been busy in completing the Red Cross organization in Glamorgan. There are sixty voluntary aid detachments in Glamorgan, with a personnel of 1,901, and an appeal has been made for £6,000 equipment fund (£100 for each detachment). The Lady Mayoress of Cardiff convened a public meeting for the appeal at the City Hall, and, considering the short notice, it was one of the most remarkable meetings ever held in Wales for Red Cross work.

Great activity has been shown in Cardiganshire under the President of the Red Cross, Lady Webley-Parry-Pryse, and Sir Edward Pryse has been indefatigable in his exertions to assist. He belongs to an old fighting stock, and was in the Zulu war and in the Boer war, where he received serious injuries. Lady St. Davids is actively at work in Pembrokeshire, and Carmarthenshire's Voluntary Aid Detachments are being got ready by that gallant veteran, Sir James Hills-Johnes, V.C.

SCOTLAND.

MEDICAL SERVICE EMERGENCY COMMITTEE.

The Chairman of the Scottish Committee of the British Medical Association, Dr. J. R. Hamilton, reports that the Medical Service Emergency Committee appointed jointly by the Scottish Committee and Representatives of the Universities and Colleges in Scotland has elected Dr. Norman Walker to be Convener.

The Committee has been constituted for the purpose of assisting to meet the immediate difficulties, in regard to medical practice among the civil population, which have arisen or may arise owing to the departure of practitioners summoned to take up military duty.

It is understood that some 300 Scottish practitioners have been thus called away from their practices, and more are liable to be called for at short notice.

In large towns these difficulties are little felt, for the practitioners remaining have willingly undertaken to attend to the work and to safeguard the interests of their absent colleagues. But in smaller places and in rural districts such friendly arrangements are less easily made. Locumtenents are not numerous and the rate of remuneration they expect tends to become prohibitive.

To cope with the emergency the Committee suggests that the following steps should be taken:

1. That it should be generally agreed that the fee offered to a locumtenent taking the work of a practitioner engaged in military duty should not exceed 5 guineas a week.
2. That retired practitioners willing to relieve their professional brethren, and so to enable them to serve their country in the field, should send their names to the Emergency Committee forthwith for registration and ultimate allocation to temporarily vacant practices.
3. That it be suggested to the educational authorities that school medical officers should be permitted to give at least part of their time to general work.
4. That the visiting staffs of large hospitals, infirmaries, and asylums should consent to a reduction of the numbers of their medical residents and clinical assistants, and should themselves undertake a proportion of the work usually assigned to these junior officers.
5. That in the larger towns young practitioners, whose practices are not yet extensive, should in pairs make an arrangement whereby one undertakes the whole town practice for, say, two months, while the other acts temporarily in the country for a third colleague absent on duty; and so alternatively for successive periods.

In these and other ways the Committee has reason to believe that a sufficient supply of practitioners for the present need could be provided; what is still required is to bring the workers and the work together.

The Committee is convinced that the profession generally will recognize that the needs of the civilian population must continue to be met, even in the presence of an imperative call for an adequate service in the field, and that whoever relieves a colleague summoned to military duty *ipso facto* is also serving his country in this time of stress.

The ordinary agencies for the supply of qualified assistants and locumtenents are in active operation, and they should in the first place be resorted to by practitioners requiring such assistance. The Committee does not propose to assume the functions of such agencies; but by furnishing a bureau or "clearing house" for the collection and dissemination of information, on the one hand regarding districts or practices deprived of qualified practitioners to work them, and on the other hand regarding practitioners prepared to undertake the duty of supplying such vacancies for a time, the Committee is satisfied that a valuable service may be rendered to the profession and the public.

The Committee is now ready to receive communications from medical practitioners in Scotland who are desirous either of obtaining or of affording professional help in the circumstances above indicated. All such communications should be addressed to The Convener, Medical Emergency Committee, Royal College of Physicians, Edinburgh.

EDINBURGH.

If one may judge from the numerous offers of hospitals, nursing homes, convalescent homes, and private mansions recorded daily in the local newspapers, the military authorities in and around Edinburgh should have no difficulty in providing beds enough for their needs.

The 2nd Scottish General Hospital.

An instance of the rapidity and smoothness with which a big change can be made is found in the transformation of the Craigleith Poorhouse into the 2nd Scottish General Hospital in connexion with the Territorial system. It is said that at a day's notice the inmates of Craigleith were transferred to the Craiglockhart institution and the former building converted into a hospital; hardly anything required to be done to the institution itself, save the addition of an *x*-ray department and the enlargement of the operating theatre.

The full working staff of the hospital numbers 220, consisting of members of the Royal Army Medical Corps (T.F.), Territorial Nursing Association, and Red Cross Society, etc. The Commanding Officer and Administrator is Lieutenant-Colonel Sir Joseph Fayrer, Bart., Superintendent of the Royal Infirmary of Edinburgh; Captain D. J. Graham is Registrar, and Hon. Lieutenant C. W. Baker is Quartermaster—these constitute the permanent staff of the hospital. The medical and surgical staff now mobilized consists of the following: Lieutenant-Colonels J. M. Cotterill, C. W. Cathcart, R. W. Philip, and F. M. Caird; Majors W. Russell, G. A. Berry, J. J. Graham Brown, J. W. Hodsdon, G. L. Gulland, D. Wallace, C.M.G.; F. D. Boyd, C.M.G.; and J. D. Comrie; Captains H. J. Stiles, R. A. Fleming, H. A. Thomson, H. G. Langwill, A. Miles, H. Rainy, A. Logan Turner, D. C. Watson, W. Guy, W. T. Ritchie, J. W. Dowden, E. Bramwell, A. S. Skirving, C.M.G.; J. G. Cattanach, G. L. Chiene, E. Matthew, W. J. Stewart, J. Eason, E. W. S. Carmichael, and J. W. Simpson. In the event of wounded being landed, a staff of nearly 100 nurses will be called upon; they will be accommodated in the new Children's Home; at present the number of nurses in residence is limited.

It is understood that a hospital in Edinburgh which had just received from the makers an expensive and up-to-date sterilizer handed it over at once for the use of the Craigleith Hospital, so that there might be no delay in the acquirement of this essential part of the surgical armamentarium; the hospital will in all probability be able to replace the sterilizer in a few days.

Convalescent Hospitals.

Among many similar presentations of buildings for use as hospitals or convalescent homes special mention may be made of Lord Rosebery's offer of Dalmeny House, the Duke of Buccleuch's of Bowhill House, Mr. A. M. T. Fletcher's of Saltounhall, and Lady Ninian Crichton-Stuart's of the House of Falkland. The Edinburgh Branch of the British Red Cross Society has shown great activity during the past few days; the Duchess of Abercorn has agreed to act as Convener of the Work Parties Committee: Professor Caird, Professor Harvey Littlejohn, and Mr. J. L. Ewing are on the Hospital Accommodation Committee; and Mr. Harold J. Stiles is on that dealing with equipment. It is also reported that Dr. John Fraser, F.R.C.S.E., has been appointed specialist in operative surgery at the Military Hospital, Edinburgh; and that Civil Surgeon C. Price has assumed medical charge of staff and departments.

Abandonment of Post-Graduate Courses.

On account of many of the teachers being needed for the 2nd Scottish General Hospital, and because several of the medical men attending the August post-graduate classes in internal medicine had to return to their own countries on the outbreak of war, this course has been stopped for the present year. The September general course and surgical course have also been cancelled for the present season.

IRELAND.

RED CROSS WORK.

A crowded meeting in connexion with the organization of Red Cross work in Ireland was held last week in the Royal Dublin Society's Lecture Theatre. The Countess of Aberdeen, who presided, expressed great gratification at the splendid response to the invitation to the meeting. The first thing to do was to provide means whereby as large a number as possible could be trained to care for the wounded and look after the health of the general community, who were bound to suffer many trials. Mr. George Fletcher, of the Department of Agriculture and Technical Instruction, said that it had drawn up a syllabus under which a course of instruction in Red Cross work could be provided under three groups: (1) First aid to the injured, (2) hygiene and emergency nursing, (3) ambulance work. Grants would be paid on account of each of these parts of the syllabus. A resolution calling upon the women of Ireland and men who were not serving with the army or volunteers to qualify themselves for Red Cross work was carried amidst applause, and already numerous classes have been started in Dublin and throughout the whole of Ireland.

TEMPORARY PROBATIONERS IN THE DUBLIN HOSPITALS.

At a conjoint meeting of the Visiting and Nursing Committees of the Richmond, Whitworth, and Hardwicke Hospitals it was resolved, in view of the present

emergency, to admit, for limited periods of hospital training, ladies anxious to qualify themselves in preliminary hospital work. It is hoped by this means to increase the nursing resources of the country, which at the present moment are being depleted for foreign service. Other hospitals in the city are making similar arrangements.

THE BRITISH RED CROSS SOCIETY.

Organization and Equipment of Detachments.

The first British Red Cross Detachment started for Belgium on August 16th. It was sent at the request of the Belgian Government, for general service with the allied troops, and consisted of 10 surgeons, 10 dressers, and 20 nurses. The surgeons, who were carefully selected for the work, are Messrs. Elliott, Taylor, and Austin, of the London Hospital; Bloom and Erland, of Edinburgh; Wyatt, of St. Thomas's Hospital; and Attlee, Kemp, Neve, and Pascall, of St. Bartholomew's Hospital. Some of the dressers have already had experience in the Balkan war. The nurses are fully trained hospital nurses of not less than three years' training. The members of the detachment took light equipment, and on arrival their services were placed at the disposal of the war authorities. This unit is establishing a hospital at the offices of the Sleeping Car Company at Brussels. Two of the surgeons have gone forward with the Belgian troops.

The rates of payment are: Surgeons, £1 a day, with uniform and rations; dressers, £2 a week, with outfit, uniform, and rations; and nurses, £2 2s. a week, with uniform, rations, etc., and an allowance for outfit.

The Chief Commissioner of the British Red Cross Society in charge at the seat of war is Sir Alfred Keogh, K.C.B., formerly Director-General of the Army Medical Department. Sir Frederick Treves is responsible for the selection of the personnel. No one will be sent out unless seen personally, and so far no medical man over 40 has been accepted.

The British Red Cross Society will continue to send out parties of forty constituted as above unless otherwise advised. Each party takes out stores. To the first party is attached Major Richardson with his ambulance dogs; his assistant is Mr. Cherry-Garrard, who was with Captain Scott in the Antarctic, where he had charge of the dogs.

With regard to dressers, Sir Frederick Treves would prefer to take a body of ten men (picked by a responsible person) from one hospital rather than ten independent individuals. It is hoped that the hospitals will note this request.

So far the society has sent out no orderlies, none having been applied for, but they are certain to be required, and the society is working in close touch with the St. John Ambulance Association; at present all orderlies applying to the society are referred to the association.

Up to midday on August 20th the society had received £34,000 in subscriptions.

Nursing Department.

The nursing department is under Lady Gifford (who nursed for two years in South Africa during the Boer war), assisted by Mrs. Ludlow, R.R.C., late matron of the Royal Free Hospital, who served in Ladysmith during the siege. Queen Amelie of Portugal is acting as registering and checking clerk in the nursing department.

All the nurses sent out are hospital nurses with full training, but as the supply of fully trained nurses fails the society will be compelled to send out with every party of fully trained nurses a small proportion who are not so fully trained. This it is impossible to avoid, as the demand for fully trained nurses is beginning to exceed the supply. So long, however, as the fully trained nurse can be obtained, no nurse will be employed who has not completed her training. It is, perhaps, needless to add that no nurse can be accepted who has not had hospital training, and no application from amateurs can be for a moment considered.

Convalescent Homes and Hospitals.

The society has a very complete and detailed register of beds available in hospitals, or convalescent homes, and in private houses and non-medical institutions. The number of beds on the register is about 50,000. When the War Office needs beds in any particular area the society will have all the particulars ready. Several hospitals in private houses (with 100 beds) are nearly ready, operating theatre and all complete. Cardinal Bourne, Archbishop of Westminster, who was one of the first to offer accommodation for wounded soldiers and sailors, has placed Dollis Hill, Willesden, a large, fully equipped hospital, at the disposal of the society. Mr. G. H. Makins, C.B., and Sir Rowland Bailey have this in hand.

Motor Ambulances and Cars; Ships.

Lord Norreys is compiling, with Sir Frederick Treves, a register of motor ambulances, touring motor cars to be transformed into ambulances, and tractors for fitted carts. When the War Office wants such help in any district full and detailed information can be at once supplied.

No hospital ships have as yet been asked for, but it is thought probable that there will be a demand for boats of shallow draught to convey sick and wounded up shallow estuaries and rivers.

Head Quarters and Store Dépôt.

The head quarters of the British Red Cross Society are at Devonshire House, Piccadilly, W. The premises are so extensive that they afford ample space for coping with the work. The forecourt is being covered with temporary buildings for stores, and the coach houses and garage are being used for offices. A stores department has been established at 83, Pall Mall.

The Hon. Arthur Stanley, M.P., is doing splendid work in the department of stores. Lord Onslow and Major the Hon. R. White look after communications and foreign transport.

Garments for Sick and Wounded.

The British Red Cross Society has issued a pamphlet and a set of patterns for making the following:

Bed Jacket.	Hot Water Bottle Covers.
Helpless Case Shirt.	Helmet.
Man's Dressing Gown.	Jersey (medium size).
Man's Night Shirt.	Knee-cap.
Nurse's Apron.	Men's Socks.
Pyjamas.	Invalid's Slippers.
Surgeon or Male Assistant's Coat.	

The pamphlet has been prepared by Miss Emily Peek, teacher of the dressmaking classes at the Polytechnic, Regent Street, London, and has been made as simple as possible. Particular attention is drawn to the necessity of accurate cutting out, care in fixing and sewing, and evenness in machine stitching. As invalid garments require careful and quick manipulation when being changed, and frequent washing to ensure the comfort of the patient, it will be readily understood that there must be no bulky corners, no puckered seams, no badly worked buttonholes cut too near the edge, and no careless sewing on of tapes and buttons. Attention is also called to the fact that any stitches dropped in a knitted article will spoil it quicker than ordinary wear. The patterns and pamphlet can be obtained from the Red Cross Society (Garments Department), 83, Pall Mall, London, S.W., post free 1s. 8d.

ST. JOHN AMBULANCE.

The Ambulance Department of the Order of St. John of Jerusalem forms part of the Red Cross organization of Great Britain, with the British Red Cross Society and the St. Andrew's Ambulance Association (Scotland), and is recognized by the British Government under Article 10 of the Geneva Convention as a society to assist the medical services in time of war. Funds are urgently needed, as already over 4,000 men of the St. John Ambulance Brigade have been mobilized as hospital orderlies with the navy and army; several thousands more are held in reserve. Surgeons and a large number of fully certified hospital nurses have been dispatched by the Ambulance Department to Belgium at the request of the Belgium Red Cross Society.

THE LEAGUE OF MERCY.

At a meeting of the Executive Council of the League of Mercy on August 18th, under the presidency of Prince Alexander of Teck, it was resolved to utilize the machinery of the League of Mercy as a collecting agency to aid the supply of hospital treatment for the sick and injured from the war. The intention, we understand, is by this special effort, not only to secure for hos-

pitals which are preparing to admit sick and injured soldiers and sailors from the war the accustomed support afforded by the league, but also to meet the additional strain thus thrown on their resources and accommodation by more generous support from the League of Mercy. As an organization the league is well known and its machinery understood, and, without overlapping the valuable work of other agencies, it is well qualified to render in time of war yet greater assistance to the sick and suffering than it has already rendered successfully for fifteen years in times of peace. The British Red Cross Society, which received its Royal Charter nine years after the League of Mercy, is primarily devoted to "furnishing aid to the sick and wounded in time of war," and it is specially empowered "to make and carry out any arrangement for joint working or co-operation with any other association or body, whether incorporated or not, carrying on work similar to any work carried on for the time being by the society." Due care and self-restraint will be needed on the part of such central agencies, and still more on the part of less authoritative bodies and well meaning though sometimes ill-advised philanthropists, in order to co-ordinate these beneficent efforts and avoid overlapping with the resultant conflict and futility.

THE CARE OF CONVALESCENTS.

DR. W. S. GREENFIELD, late Professor of Pathology and Clinical Medicine in the University of Edinburgh, has published in the *Scotsman* a valuable letter, the following extracts from which will be read with interest:

Even in normal conditions during peace there is great difficulty in providing for the after-care of those who have been under treatment in hospitals. This is the case both with medical and surgical patients, but especially so with surgical. . . . It is clear that the immediate or early treatment of the seriously wounded should, as far as possible, be carried out in thoroughly equipped surgical hospitals, provided with a complete staff and all modern appliances. But it would be an enormous advantage if there were also hospitals to which patients could be readily sent by sea or land as soon as they could be moved with safety, where any necessary dressing and nursing could be given. And it would be especially valuable if these hospitals were in healthy suburban or country districts. There will, further, be great need for accommodation for those who only require good food, fresh air, and cheerful surroundings until they recover completely and are fit for work.

To put it briefly, there should be:

(*a*) Thoroughly equipped and staffed central hospitals.
(*b*) Hospitals where only a certain amount of after-dressing and nursing are required; in other words, relief hospitals.
(*c*) Provision for slighter cases, and for complete convalescence. This is especially important, seeing that a large number of men in the navy will be far distant from their homes, and will be unfit to travel far for some time, even after fairly complete recovery from their injuries.

In any provision which is made for (*b*) and (*c*) it should be borne in mind that the places provided may be needed for some months, even if the war be short. Probably three months after the close of the war would not be too long to arrange for. Hence, any buildings which are erected or utilized for the purpose should be such as can be retained for some time, and those responsible should lay their reckoning for a prolonged occupation, which must extend into the winter months.

It is therefore desirable that the buildings selected should not only be suitable for occupation in winter, but that such places as school houses should not be used. Unless in case of actual invasion, school work should be carried on, and the regular life of the people should be as little interfered with as possible. I may add that most school buildings are ill adapted for the purpose; factory sheds and farm buildings would often be preferable. Their use as temporary shelters in emergency is another matter, and they might be reserved for this purpose, if required. There are many hydropathics and hotels or boarding-houses at summer resorts which would be admirably adapted for the purpose. Many of them are practically empty for a great part of the winter and spring, and their use would cost little loss to the proprietors. For such loss they could, if necessary, be compensated on the basis of their average receipts during the corresponding period.

I feel sure that these suggestions will be fully endorsed by all hospital surgeons, and more especially by those who have seen anything of hospitals during and after war. In my own hospital experience of over forty years there is no more painful memory than that of the hospital wards immediately after the suppression of the Commune in Paris in August, 1871, when the beds and the wounded were so crowded together that it was difficult to move between them.

Anything which will tend to diminish the congestion of the central or base hospitals, and which will relieve surgeons from anxiety as to the after-care of cases recovering from serious operations, will be an enormous boon.

Overcrowding of wards is one of the most dangerous factors in the production of epidemic and infectious disease.

Open-air Hospitals.

Dr. W. H. Parkinson, Assistant Medical Officer for Warwickshire, writes to us to express the opinion that a mistake is being made in converting buildings of various descriptions into temporary hospitals. What seems to him more important is the establishment of open-air hospitals, since there is abundant evidence that almost all kinds of cases, but surgical cases in particular, do better in the open air than in buildings of any kind.

Professor Saundby published a letter on the subject in the *Times* last week in the course of which he wrote:

We have learnt, especially in connexion with sanatoriums for consumption, but not alone in that disease, how much better more or less open buildings with abundance of light and fresh air are for the treatment of the sick and wounded. Even so long ago as the Civil War in America in was noticed how much better the sick did in open tents than in the hospitals, and in the *Life of Florence Nightingale* there is an instructive letter from the then Crown Princess of Prussia telling how certain wounded men whose wounds had been doing badly in hospital improved rapidly and recovered after removal to a shed in the garden whose walls did not reach to the roof and on one side was open. The success obtained in the large wards of the Liverpool Country Hospital for Children under the care of Mr. Robert Jones sufficiently demonstrates the value of such open-air treatment for a class of cases that notoriously recover slowly if at all in ordinary hospitals. In Birmingham the Queen's Hospital opened a roof ward some years ago in which medical cases have been treated summer and winter, and at the General Hospital we have enlarged our balconies, and have treated as many medical and surgical patients there as we have room for. It would not only be more efficient but cheaper to put up suitable sheds in the parks and pleasure grounds surrounding the buildings it is proposed to appropriate, which latter may well serve the useful purpose of administration blocks. The patients could then be kept on one floor and more or less in the open air, while it would not be difficult to arrange that in these improvised buildings all the wards should be open to the south.

The suggestion seems worthy of note, especially by those who are seeking to provide for the second and third categories enumerated by Professor Greenfield.

DENTAL TREATMENT FOR SOLDIERS.

IF it be true that an army fights upon its stomach, then it would seem well that this organ should be protected by good teeth. The remembrance of what happened through dental inefficiency in the South African war is still with us; the economic aspect alone can only be represented by many thousands of pounds. Something, no doubt, has been done since then to remedy matters, but at the present time of expeditions and recruiting there is reason to believe that good work may be done in order to raise general efficiency.

The Executive Committee of the British Dental Association on August 6th addressed letters to the Admiralty and War Office offering to assist in arranging to provide dental surgeons to supplement the civilian dental surgeons employed by the Navy and to serve with the Army (Regular and Territorial).

At the same time, members of the association were informed of the action through the honorary secretaries of its branches and asked to offer their services. In response, a great many offers of assistance were received, and in many parts of the country recruits are already being seen and treated.

The Director-General of the Army Medical Service has gratefully accepted the offer, and has asked that recruits otherwise suitable who are rejected on account of defective teeth may be treated. He is sending out notices to all recruiting stations, suggesting to the medical officers that suitable men rejected on account of defective teeth should be given a form of application for dental treatment on the understanding that they submit themselves to medical examination afterwards. The treatment will be limited to fillings and extractions, and no dentures will be fitted.

The form of application will be presented either at some dental hospital or institution where dental treatment of a conservative nature is carried out, or, where there is no such institution, at the surgeries of members of the British Dental Association and others who have offered their services. After dental treatment recruits will be referred to the medical officers for re-examination.

It is also hoped that it will be possible for the authorities to arrange for the treatment of recruits who are accepted, of whom a great number require dental treatment, either at the dépôts to which they will at first be attached or later at their training centres. This scheme will, however, probably be distinct from the first, which is gratuitous, as it will probably require the services of whole-time dentists.

What the association is at present trying to do is to ensure that recruits, who are otherwise suitable, should not be refused simply on account of defective teeth.

Later it is hoped to arrange for dentists to be attached to base hospitals and hospital ships, both at home and abroad.

The National Dental Hospital in Great Portland Street —which has recently become the dental department of University College Hospital—has been able within a week to organize a staff of 40 volunteers amongst its former students now practising in the metropolitan area to attend in relays every morning.

Men in uniform, reservists called up, and would-be recruits who have been referred on account of defective teeth are admitted for free treatment by stoppings or extractions. It has been thought advisable not to worry the War Office at this time of stress for any official sanction or financial help, but it is hoped that by making the scheme known at barracks and recruiting stations men may learn of the opportunity offered. The medical officers at some of the barracks appear to recognize the advantage of such a scheme, and, although in working order for only a few days as yet, the attendance is increasing. A donation by a private benefactor has provided filling materials, the volunteer dental surgeons bring their own hand instruments, and the dental engines belonging to students (now in vacation) are being utilized.

ROYAL NAVY.

Appointment of Consultants.

The following consultants have been appointed by the Medical Department, Royal Navy, and in most instances have been detailed for special duties:

Sir Watson Cheyne.
Sir William Macewen.
Sir Alfred Fripp.
Mr. G. R. Turner.
Dr. H. D. Rolleston.
Mr. G. L. Cheatle.
Mr. Raymond Johnson.

The Royal Naval Hospitals are, of course, on a war footing and ready at any moment to receive sick and wounded from the fleet. The scale on which they are constructed and equipped may be gathered from the account given recently[1] of the Royal Naval Hospital, Chatham, which has accommodation for 926 patients. Should any serious pressure on these Royal Naval Hospitals arise the aim will be to send convalescents and less severe cases to the hospitals, convalescent homes, or other private institutions which have been placed at the disposal of the Medical Department of the Admiralty. The number of such beds now registered is large and more than sufficient to meet any probable requirements, at least in the near future.

[1] BRITISH MEDICAL JOURNAL, July 18th, p. 125.

WAR RISKS.

Insurance of Men with the Expeditionary Force.

Dr. John Livingston (Honorary Secretary, North Lancashire and South Westmorland Branch), writes: I have communicated with two insurance companies asking the position of men with the expeditionary army. I am told that the extra premium on policies already in existence is 3 per cent. for non-combatants and 5 per cent. for combatants.

Taking into account the expenses incurred in providing locums, in addition to the shrinkage of practice when away, I am afraid a number of men will not be able to afford this extra war tax—£15 additional premium for a policy worth £500. Can anything be done in the matter? The Government safeguard shipping extra risks, why should they not do the same for medical men called away from their practices?

*** Dr. Livingston's letter draws attention to the fact that certain life offices are charging extra premiums to members joining the expeditionary force. It may be of some assistance to our readers if we briefly give in general terms the results of inquiries we have made on the subject. The statements, we believe, apply to most, if not all, first-class offices, but it will be necessary for the individual by examining the terms of his policy to satisfy himself as to whether it belongs to Class 1 or Class 2, and to ascertain from the office in writing its attitude in the matter. We will divide the policies into four classes:

1. *World-wide and Unconditional Existing Policies.*—Those who, by reasonable precaution in the first instance, have secured "world-wide and unconditional" policies are not liable for extra premium under any circumstances.

2. *Existing Restricted Policies*, under which members joining the expeditionary army will have to pay an extra premium of 5 guineas for one year per £100 sum assured as combatants, or 3 guineas as non-combatants. For home service ashore no extra premium will be charged, and for service in the navy 5 guineas extra will be charged for combatants and non-combatants.

3. *All New Policies.*—At present no charge is being made under any new policy in respect of home service ashore, but all new policies contain a clause throwing the onus on the assured of applying for a licence in the event of his engaging in *foreign or war service*, and paying such extra premiums as may be required. At the present time most of the offices are charging 7 guineas for combatants and 5 guineas for non-combatants for the expeditionary army, and 7 guineas for both classes in the navy.

4. *Medical Insurance Agency Policies.*—We are informed that all policies effected through the Medical Insurance Agency, with certain exceptions made for special reasons, are entirely world-wide and unconditional, and that the holders thereof may go anywhere and do anything without extra charge.

Members who have effected policies with other companies, but not through the Medical Insurance Agency, who have any intention of volunteering for service should now carefully examine their policies, and unless such policies are found to be free from restriction or special condition, they should ask for a statement in writing as to what extra premium the company will require to cover any extra risk to be incurred. In this connexion the Medical Insurance Agency will render any assistance in its power. Inquiries addressed to the Agency at 429, Strand, will receive early attention.

Grants and Pensions for Officers and their Dependants.

In respect of compensations for injuries, illnesses, or death, civilian medical men doing duty with His Majesty's forces in any capacity whatever, as also their dependants, enjoy precisely the same advantages as regular officers of equivalent rank and their dependants.

The rank of a civil surgeon is that of a lieutenant; that of a temporary surgeon in the navy, that of surgeon; and that of a Territorial officer, that which is shown on his commission or to which he is promoted by gazette.

The right of an army officer to a gratuity and a special wound pension is absolute if he receives in action a wound which occasions the loss of an eye, or of a limb, or the use of a limb; or an injury certified by the regulated medical

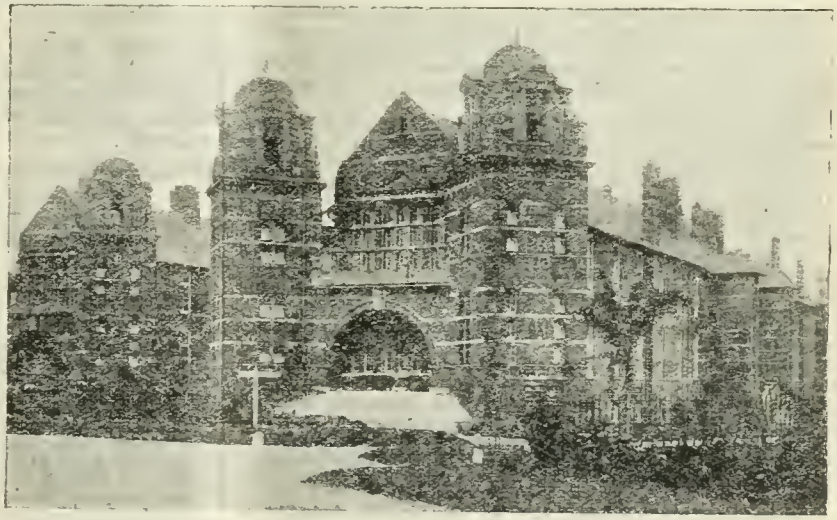
authority to be equivalent to such loss; and it is open to the Army Council to grant a lesser amount in respect of an injury which, though not equivalent to the loss of a limb, is nevertheless certified to be very severe. In regard to injuries received not in action, but due to the performance of military duty, the Army Council may grant a pension if the injury is permanent and serious, or a gratuity if the injury, though severe, does not justify the grant of a pension. The pensions for wounds received in action range from £300 per annum in the case of a colonel or lieutenant-colonel, to £70 per annum in the case of a first or second lieutenant. The corresponding gratuities range from £600 in the case of a colonel, to £100 in the case of a second lieutenant. The pensions for injuries received during the performance of military duty, but not in action, range from £250 per annum in the case of a colonel or lieutenant-colonel to £50 per annum in the case of a lieutenant or second lieutenant. In regard to the dependants of deceased officers, there are three classes of grants—highest, intermediate, and ordinary. Grants of the first class are made to the dependants of officers who are either killed in action, or die—within seven years—in consequence of a wound received in action; those of the second class, to the dependants of officers who die from injuries received during the performance of military duty, but not in action, or from illnesses which can be directly traced to fatigue, privation, or exposure incident to active operations in the field, provided that in either case the death takes place within seven years of such illness or injury. The lowest, or ordinary class of grant, may be made to the dependants of any officer, whatever the cause or date of his death, subject to certain stipulations in regard to the length of his service and other matters, which are of such a character as to exclude officers who do not hold a permanent commission. If a deceased officer leaves neither wife nor children, but has a mother or sister dependent on him, corresponding grants may be made to these. In the case of the dependants of a major, the "highest" pension is £140 per annum for the widow and an allowance of £21 per annum for each child; "intermediate," £135 per annum for the widow and £20 per annum for each child; and "ordinary," £90 per annum for the widow and £16 per annum for each child. In the case of the dependants of a lieutenant or second lieutenant the corresponding pensions and allowances are £80 and £15, £60 and £12 10s., £40 and £10.

Royal Naval Hospital, Chatham: Administrative Block.
(Photograph by Vernon E. Hancock, Gillingham.)

Medical officers in the navy do not ordinarily receive any special pension for wounds received in action or during the performance of their ordinary duties, but they are exempted by such a wound from the rules respecting the length of service entitling them to a pension or gratuity. Their widows and children, however, receive grants of the same kind as those already described. Thus the wife of a medical man temporarily employed in the navy as a surgeon would be entitled to a pension of £80 per annum if he were killed in action, and to an allowance of from £12 to £16 for each of her children up to the age of 18 in the case of boys and 21 in the case of girls; while, if her husband lost his life through the act of the enemy in any other fashion, her pension would be £65 per annum, and the grants for each of her children from £10 to £14. In addition to her pension, the widow of such a medical man would also be entitled to a gratuity equal to the pay which her husband would have received for one year and to one-third of that amount in addition in respect of each child under the age of 21.

DRUG STOCKS AND THE DRUG TRADE.

As was stated last week, and as the profession has been informed from other sources, it is desirable to practise economy in prescribing certain classes of drugs until the drug market has adapted itself to the new conditions brought about by the arrest of exports from Germany. At present the arrest is complete, and during the continuance of the war supplies of the potassium salts, including bromide, and of synthetic preparations hitherto obtained from Germany are not likely to reach this country except by some indirect route.



Royal Naval Hospital, Chatham: One of the ward pavilions.
(Photograph by Thornton Bros., New Brompton.)

Existing conditions offer a great opportunity to the British drug manufacturing trade; it would be not only profitable but patriotic to take advantage of it. There is no reason why the majority at least of the synthetic drugs most generally used should not be manufactured in this country if the necessary enterprise and capital be forthcoming. The home demand would at once be very considerable, and there is a good opportunity to secure new markets, for, as the French Minister of the Marine has pointed out to French shipowners, the sea commerce of the allies is now free, and there is good reason to hope that

it will so continue. The relief to overseas commerce which the silent work of the British navy and its allies has brought about in the last week or ten days, is shown in a very practical way by the reduction of the premium of insurance on cargoes in steamers. It was at first £5, it was soon reduced to £4, and on August 18th to £3 3s. per cent.

The Government has appointed a professional committee to consider questions arising in connexion with the supply of drugs in the United Kingdom. The committee has already held one meeting, and further meetings will be held as circumstances may require.

The committee is constituted as follows:

Dr. J. Smith Whitaker, of the National Health Insurance Commission, chairman; Sir Thomas Barlow, Bart., Sir T. Lauder Brunton, Bart., Dr. A. Cox, Medical Secretary of the British Medical Association; Dr. A. R. Cushny, F.R.S., Professor of Pharmacology, University College, London; Dr. E. Rowland Fothergill, Member of Council of the British Medical Association; Dr. B. A. Richmond, secretary of the London Panel Committee; Dr. F. J. Smith, Dr. W. Hale White, with Dr. E. W. Adams, medical officer of the National Health Insurance Commission, as secretary.

WIVES AND OTHER DEPENDANTS OF SAILORS AND SOLDIERS.

ON August 19th the Local Government Board, Whitehall, S.W., issued to boards of guardians a memorandum with regard to the assistance available for the wives and other relatives of soldiers and sailors (including Territorials) stating that allowances of various kinds are payable to the dependants of men who have joined the colours, and that where for some cause or another the sums thus payable to the dependants of a soldier or sailor have not reached his family, or the amount is inadequate for their necessities, assistance may be obtained either from the local branches of the Soldiers and Sailors' Families Association or from the local committees which have been constituted for the purpose of dealing with the prevention and relief of distress consequent upon the war. The Board assumes that the guardians will agree that it is not desirable that the wives and other relatives of soldiers and sailors should have recourse to poor relief.

MEMORANDUM.

1. Advances of various kinds are payable to the wives or other dependants of sailors and soldiers of the mobilized forces of the Crown by the Admiralty and the War Office respectively.

2. All sailors, including marines, are entitled to make allotments and remittances through the Admiralty to their relatives or other friends ashore.

3. The wives and children of soldiers are entitled to separation allowances on a fixed scale according to rank, paid monthly in advance through the ordinary army channels, except that in the case of Territorials serving in the United Kingdom payment is made through the county associations.

4. Soldiers serving at home should make their own arrangements as to sending money to their families out of their pay.

5. In the case of soldiers serving abroad, the army authorities compel the allotment of a minimum amount according to rank for the benefit of the wives and families of the men and issue the money.

6. On embodiment, a soldier in the Territorial Force receives a bounty of £5.

7. It is also understood that in many cases public bodies and other employers of labour whose men have been called up or have volunteered for service are making provision for the wives and families of the men.

8. Where, however, for some cause or another the sums payable to the dependants of a soldier or sailor have not reached his family, or the amount is inadequate for their necessities, assistance may be obtained in the following way:

The Soldiers and Sailors' Families Association, founded in 1885, of which Her Majesty Queen Alexandra is the president, is a body organized for the express purpose of seeing that adequate aid is given in such cases. In places where the association has branches in full working order assistance to the dependants should be granted through their agency. Wherever the local branch of the association is not in full working order steps are being taken to strengthen it.

In the meantime, any assistance required by the dependants should be given by the local committee which is being constituted for the purpose of dealing with the prevention and relief of distress consequent upon the war. Committees are receiving grants for this purpose on application to the Prince of Wales's National Relief Fund.

It is suggested that the representatives of the association on the committee might for this purpose—with the addition, if necessary, of other persons—serve as a subcommittee specially entrusted with the duty of dealing with the cases of dependants of soldiers and sailors.

9. In any necessitous case in which an advance is made for the relief of a soldier's family (whether of the Regular Army, Special Reserve, or Territorial Force) pending the issue of separation allowance, and it is intended to reclaim the same or any portion thereof from army funds:

(1) Women should be warned that the money given to them is an advance to be recovered from their separation allowance.
(2) Sufficient particulars should be taken of the soldier to secure his identification—rank, regiment, etc. In particular it is desirable to have his number, so as to be able to distinguish men of the same name.

10. The town or county committees will be advised as to keeping a general register of all persons desiring assistance in their areas and the wives and dependants of soldiers and sailors will be included upon the register, but it will be suggested that these cases should be separately distinguished.

THE SUPPLY OF "LOCUMTENENTS."

WE have received several letters on this subject, from which we make the following extracts:

APIBUS SUAM MELLEM considers that limitation of the locumtenent's fee to a maximum would be against the principle of the open market and the spirit of modern democracy. Since medicine has been "democratized" the locum will demand his reasonable share. What that should be could be easily got at by the size of the particular principal's panel and private work (1,000 panel patients equals £300 gross). Whether the actual work done is heavy or light is beside the mark; the amount contracted for is the point, and on this the principle of proper remuneration or "sweating" hinges.

D. is of opinion that Mr. Percival Turner is scarcely equitable. He must consider that retired army and naval men enjoy pensions and gratuities from the Government already. All surgeons engaged in the present trouble will, according to their rank, receive pay at a minimum of 22s. a day. All surgeons in practice will receive their quarterly cheques from their Insurance Committees, which averages another £1 a day. The emoluments from their private practice will go on as usual and also from other appointments which established practitioners have so successfully contracted for. If the law of supply and demand favours for a few months the reliable locumtenent, then why should it be altered?

LOCUM, while appreciating Mr. Percival Turner's appeal to the patriotism of locumtenents not to demand exorbitant fees, suggests that medical agents should also reduce their fees, so as to meet the smaller fees of locumtenents.

The Services.

DECENTRALIZATION OF OFFICE OF THE DIRECTOR-GENERAL ARMY MEDICAL SERVICES.

SURGEON-GENERAL GEORGE J. H. EVATT, C.B., writes: I recommend that the Director-General Army Medical Service be in future called Director-General-*in-Chief* Army Medical Services.

I further strongly advise that a new officer be appointed with an office *outside the War Office* to be called Director-General Medical Service Home Army. To him much of the routine work as to movements and duties in England, Ireland and Scotland should be devolnted. This official should have in his office a Deputy Director-General Home Army *dealing entirely with the Territorial Forces.*

It is absurd to have to trouble the Central War Office Medical Staff with routine questions that could be settled outside the War Office building.

They have ample duty in thinking ahead and dealing with great principles. I cannot imagine individual officers and nurses going into the War Office to see the high officials of the medical service about subordinate personal matters at the present crisis.

The Territorial Medical Services should at once have a separate section in the new office I suggest. I regard this latter matter as vital to effective working.

FIVE cases of plague were reported in Hong Kong during the week ended August 15th; the number of deaths was five.

BRITISH SPAS.

THE number of British subjects under treatment at German and Austrian spas when war broke out is not known, but it must have been large, though not so large as would probably have been the case had peace been maintained for another fortnight or three weeks. It is reported that some three hundred English-speaking visitors are finding their way home by way of Italy from Carlsbad alone. Their experiences are likely to have been much less distressing than those of visitors to German spas, but nevertheless they must have been involved in considerable worry, discomfort, and expense. Consequently the occurrence again raises the question why so many well-to-do inhabitants of these isles have got into the habit of going to German and Austrian spas when there are so many well managed places with efficacious mineral waters available at home. Are there not Harrogate and Buxton, Llandrindod and Strathpeffer, Woodhall, Droitwich and Leamington, Bath, and the very remarkable iron spring of Trefriw in the romantic Vale of Conway? Whatever the cause for the comparative neglect of British spas by the British in the past, it may in present circumstances be pointed out that there is no indication for treatment hitherto fulfilled by German and Austrian spas which cannot be equally well or better met by the waters of our own country.

THE PROVISION OF MEALS FOR CHILDREN.

AMID the cares which oppress the public mind in these anxious days not the least is the prospect of suffering among the children of the working classes, and the Board of Education has done well to issue a Memorandum on methods of providing meals for children in connexion with public elementary schools.[1] The Board points out that the Local Education Authorities are now competent to take such steps as they think fit for the provision of meals for children in attendance at Public Elementary Schools, and that it is intended to furnish grants in aid up to 50 per cent. of the expenditure actually incurred out of the rates. The Board further remarks that in areas where acute distress prevails it may be expedient to utilize the same machinery and organization to provide meals for children too young to have been enrolled on the school books, and suggests that, in that event, it would be convenient to supply special tickets for meals to children who are not on the school register. Since it will clearly be necessary to supplement the available funds by voluntary contributions, it is recommended that the collection of the latter should be undertaken by the local committees. With respect to machinery, the Board points out that it is desirable to enlist the services of teachers wherever possible, and thinks that in most cases it will be convenient to arrange for the meals to be given in the school buildings. The Memorandum concludes with a discussion of dietaries from the physiological and economic standpoint. The physiological information imparted seems eminently practical, even if valetudinarians dissent from the assertion that Welsh rarebit is a "usually digestible article of diet." The approximate cost per 100 children, based on estimated contract prices for food supplied in large quantities, for one course dinners varies from 7s. 2d. in the case of a soup dinner, consisting of vegetable soup with dumplings, to 11s. when stewed meat, suet pudding, dried peas, and gravy are provided. The cost of a dinner consisting of cheese pudding and meat gravy is estimated as 8s. 3d. This Memorandum ought to be closely studied by all members of Local Education Authorities and Care Committees, not to speak of others interested in charitable work. To some of those who are now imploring the authorities to assist the country in her hour of need, serving meals and washing plates may not appear very dramatic. We should do well, however, to consider whether the mitigation of children's sufferings is not a work second in importance to no other. It is, of course, obvious that the co-operation and advice of the medical profession will be required, particularly if, as is probable, provision has to be made for feeding infants, and there is no doubt that such co-operation will be readily afforded.

[1] Memorandum on Methods of Providing Meals for Children in Connexion with Public Elementary Schools and on Dietaries suitable for the Present Circumstances. Board of Education, Circular 856, August 15th, 1914.

DR. CHRISTOPHER ADDISON.

DR. CHRISTOPHER ADDISON, M.P., has been appointed Parliamentary Secretary to the Board of Education. Dr. Addison, who graduated M.D. in the University of London in 1893, and became F.R.C.S.Eng. in 1895, held successively the posts of Lecturer on Anatomy at the medical school of Charing Cross Hospital, Professor of Anatomy in the University of Sheffield, and Lecturer on Anatomy in the medical school of St. Bartholomew's Hospital. He only resigned the last named post about a year ago. He was elected M.P. for the Hoxton Division of Shoreditch in 1910. He has rapidly won his way to a position of much influence in the House of Commons, for, while always loyal to his party obligations, his political opponents recognize his knowledge of social questions, his soundness of judgement, and honesty of purpose. He served on the Departmental Committee on Tuberculosis, of which Mr. W. Astor, M.P., was chairman, and is a member of the Medical Research Committee entrusted with the duty of directing the allocation of "the research penny" accruing under the sanatorium clauses of the Insurance Act. The duties of the Parliamentary Secretary of the Board of Education are, at the present moment, onerous and important: great developments are taking place in secondary, technical, and university education, and difficult questions will arise during the coming winter in respect to elementary education, in relation especially to the feeding of school children. If wisely administered, the large grants made this year may go a long way to relieving the bitterness of the distress which seems to be inevitable. Dr. Addison's appointment is a valuable accession of strength to the Board at a time of stress. He is, we believe, only the second medical man who, during recent years at least, has become a member of the Government. The other was the late Sir Walter Foster, afterwards Lord Ilkeston, who was Parliamentary Secretary to the Local Government Board from 1892 to 1895.

THE CHAIR OF PATHOLOGY IN THE UNIVERSITY OF ABERDEEN.

THE King has been pleased, on the recommendation of the Secretary for Scotland, to approve the appointment of Theodore Shennan, M.D., F.R.C.S.Edin., at present pathologist to the Royal Infirmary of Edinburgh, to be Regius Professor of Pathology (Sir Erasmus Wilson Chair) in the University of Aberdeen, in the place of Professor George Dean, deceased. It is now some thirty-two years since David J. Hamilton, who then also was holding the post of pathologist to the Royal Infirmary of Edinburgh, was appointed to be the first occupant of the Sir Erasmus Wilson Chair of Pathology, and he acted with high distinction as professor until failing health compelled him in 1908 to relinquish his duties. Dr. George Dean, a former assistant of Hamilton's, succeeded him in the same year, but he was only able to occupy the chair for a few years; bad health, which had already begun in London, was not checked by a residence in the northern university town. Dr. Shennan, who succeeds him as the third occupant of the chair, graduated M.B. and C.M. in the University of Edinburgh in 1890, and proceeded to the doctorate in 1895. He became a Fellow of the Royal College of Surgeons in 1893, and one of his published works is the third volume of the *Catalogue* of the rich museum of pathological specimens belonging to the college. Until

about a year ago Dr. Shennan was a popular lecturer on pathology in the Extra-mural School of Medicine in Edinburgh; then he was appointed to the newly instituted lectureship on morbid anatomy in the university. For several years he has been senior pathologist to the Royal Infirmary, and he was formerly pathologist to the Royal Edinburgh Hospital for Sick Children. Professor Shennan has made many contributions of note to the literature of pathology, and the good wishes of his colleagues in Edinburgh will follow him to Aberdeen.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

Provision of Meals for School Children.—Among the votes in Supply is the grant for the provision of meals for the portion of the present financial year. It represents an increase of £77,000 on the original estimate, the total now being £252,000. It is estimated that some 40,000 children are receiving meals at the present time, but it is anticipated that this number may shortly be very greatly exceeded. The Board of Education issued a circular to the local education authorities pointing out that the Elementary Education (Provision of Meals) Act, 1914, which has now become law, alters the existing law, as embodied in the Education (Provision of Meals) Act, 1906, in three respects: (*a*) It legalizes the provision of meals during holidays and on other days when the school is not open. (*b*) It repeals the limit imposed by Section 3 of the Education (Provision of Meals) Act, 1906, under which the expenditure of the local education authority on the provision of food was limited to the produce of a halfpenny rate. (*c*) It abolishes the necessity of obtaining the sanction of the Board of Education to expenditure out of the rates on the provision of food, but it will still be necessary for a local education authority which desires to provide food at the cost of the rates, to resolve that there are children who are unable by reason of lack of food to take full advantage of the education provided for them and to ascertain that funds other than public funds are not available or are insufficient in amount to defray the cost, as it is probable that dislocation of trade and other circumstances will occasion an exceptional amount of distress in the industrial population whose children attend public elementary schools. The Board considers it very important that local education authorities should in good time make preparations to deal with such distress. Grants will be made in the current financial year in respect of the expenditure incurred by local education authorities in the financial year ending March 31st, 1914, to an extent not exceeding 50 per cent. of that expenditure, and grants on as favourable a basis will in any case be available in respect of expenditure incurred in the current financial year. A great amount of voluntary service will undoubtedly be forthcoming, but it is essential that the organization of the work should be thought out beforehand and that preparation for the provision of the necessary equipment should be made in good time. To avoid overlapping and waste of effort local education authorities should work in close co-operation with the committees which will probably be established at an early date and called together by the lord mayors, mayors, chairmen of county councils, and chairmen of the larger urban district councils to deal systematically with any distress which may arise in their respective areas.

Maternity and Child Welfare.—A grant of £12,000 is made in the Supplementary Estimate to the Local Government Board for the administration of maternity and child welfare centres and the purpose of the grant is shown in the following synopsis:

MATERNITY AND CHILD WELFARE.

A complete scheme would comprise the following elements, each of which will, in this connexion, be organized in its direct bearing on infantile health.

1. Arrangements for the local supervision of midwives.
2. Arrangements for—

Ante-Natal.—(1) An ante-natal clinic for expectant mothers. (2) The home visiting of expectant mothers. (3) A maternity hospital or beds at a hospital, in which complicated cases of pregnancy can receive treatment.

Natal.—(1) Such assistance as may be needed to ensure the mother having skilled and prompt attendance during confinement at home. (2) The confinement of sick women, including women having contracted pelves or suffering from any other condition involving danger to the mother or infant, at a hospital.

Post-Natal.—(1) The treatment in a hospital of complications arising after parturition, whether in the mother or in the infant. (2) The provision of systematic advice and treatment for infants at a baby clinic or infant dispensary. (3) The continuance of these clinics and dispensaries, so as to be available for children up to the age when they are entered on a school register—that is, the register of a public elementary school, nursery school, crèche, day nursery, school for mothers or other school. (4) The systematic home visitation of infants and of children not on a school register as above defined.

The additional grant to the Board of Education for schools for mothers has also been adopted, and a memorandum has been issued by the Board describing the objects and mode of conduct of them. Regulations also have been issued setting out the conditions under which grants may be given by the Board.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

WATER SUPPLY OF DUBLIN.

In spite of the heavy rains which have fallen during the last fortnight or three weeks, the water in the reservoir at Roundwood continues to decrease. It is now 10½ ft. below the sill, being a foot lower than it was eight days ago. The daily consumption for the past week averaged almost 13½ million gallons. Owing to the seriousness of the situation the Waterworks Committee of the Dublin Corporation has decided that no Vartry water should be used to water the streets in the city or townships, and other precautionary measures were adopted.

MEALS FOR SCHOOL CHILDREN.

The Education (Provision of Meals) (Ireland) Act which has received the Royal Assent, does not go nearly so far as its promoters intended, but limited as is its scope it cannot but prove a great boon during the winter months, for great as is the poverty in Dublin at any time it must prove particularly severe this year on account of the European war.

NON-PAUPER PATIENTS IN WORKHOUSE HOSPITALS.

At the Louth Summer Assizes in Dundalk, the Guardians of the Poor of Dundalk Union appealed against a decree for £4 7s. given by the County Court judge in a case in which Dr. Lavery, the workhouse medical officer, claimed that amount.

The case arose out of the treatment of a military patient in the workhouse for whom it was decided to charge extra, that is, more than the average workhouse hospital weekly cost of maintenance. The Local Government Board objected, but the guardians passed a resolution charging military patients at 10s. 6d. a week maintenance and a guinea a week medical attendance. It appears, as stated by counsel for Dr. Lavery, many patients were brought in under that rule and having deducted the average cost in each case the remainder was handed over to the doctor. In this particular case the guardians refused to do so. Under the Poor Law Relief Act, 1862, the guardians were only empowered to charge the average cost.

The Lord Chief Justice, in giving judgement, said that he had consulted his brother Dodd, who agreed with the decision he was about to give. In his opinion the action of Dr. Lavery must fail. There was no contract between Dr. Lavery and the guardians under which he could recover. The resolution of the guardians (charging more than the weekly average cost of maintenance) in respect of which the action was brought was *ultra vires* and void, and in his opinion the amount should be refunded to the War Office. Dr. Lavery was appointed to attend every patient in the workhouse, and having regard to all the circumstances he would reverse the decree of the Court below. As the case was of importance he was willing to state a case for the opinion of the High Court.

The board of guardians undoubtedly acted *ultra vires*, with or without the sanction of the Local Government Board, when they decided to charge more than the average weekly cost of hospital maintenance, and when they also decided to admit to the workhouse hospital patients other than those for whom they were responsible for their medical relief. The military authorities, and not the board of guardians, are responsible for the medical treatment of their military patients and those of their

dependants who are on the "strength" of the regiment. The only patients who are entitled to be admitted for medical treatment to an Irish workhouse are paupers, poor patients, and members of the Royal Irish Constabulary. The latter are admitted by a special arrangement of long standing. "Poor persons" belong to that class of persons who are too poor to pay for their medical attendance but possess sufficient means to pay the average weekly workhouse hospital cost, which varies from 4s. to 6s. per week throughout Ireland. The admission by the guardians of patients who can afford, and in some cases are willing, to pay for their medical attendance, has become a very grave abuse of the Medical Charities Act in Ireland. It is a hardship on the workhouse doctors to be asked to afford gratuitous medical attendance to those who can well afford to pay for it. It is also a great injustice to private practitioners, who would treat those people for payment if they were not irregularly admitted by the guardians. It is further a hardship on those ratepayers who have not the "necessary influence" or dishonesty to gain admission, like many of their class, to the workhouse hospital and receive free medical treatment as if they were "paupers" or "poor persons," thus defrauding the ratepayers, the workhouse doctors, and those private practitioners who would be their medical attendants if not admitted to the workhouse hospital. The remedy for this workhouse hospital abuse is for the workhouse doctor or any other doctor or ratepayer to report the matter to the Irish Local Government Board, and also to bring the specific cases of abuse before the auditor, who can be compelled to take the necessary action to protect all the interests concerned.

India.

[*FROM OUR SPECIAL CORRESPONDENTS*]

TENURE OF APPOINTMENTS OF HONORARY OFFICERS OF BOMBAY HOSPITALS.

THE Government of Bombay has published the following press notice:

As it appears that considerable misapprehension prevails as to the object and the effect of the orders announced in Government *Press Note*, No. 5,347, dated July 21st, 1913, regarding the tenure of certain appointments, honorary and stipendiary, at the Grant Medical College, and the J. J. and allied hospitals, the Governor in Council is pleased to publish the following reply by the Secretary of Government to a memorandum from the Bombay Medical Union with reference to the tenure of honorary appointments in the teaching hospitals of Bombay.

With regard to the representation in connexion with the terms of appointment of honorary medical officers, and the recommendation that in future these honorary appointments should be made for periods of five and ten years, I am to observe that so far as the posts of honorary assistant surgeon or physician are concerned, the object underlying their creation in 1888 was to secure the continuance of the connexion with the Grant Medical College of the most promising of the students graduating from that institution. It is evident that, having regard to the limitation imposed by circumstances on the number of such honorary officers to whom work can be given in the hospitals, the tenure of their appointments could not be prolonged to the extent recommended by the union without largely divesting the scheme of its main purposes of maintaining a continuous connexion between these institutions and the best men turned out by the college year by year. With regard again to the appointments of honorary surgeons and physicians, I am to observe that the chief object in view in associating practitioners of standing with the work of the hospitals is not, as is assumed in the memorial, an increase in the provision for the instruction of students, which at present is adequately represented by the stipendiary staff of the college, but the extension to members of the independent medical profession of opportunities for study, observation and practice, which they would not otherwise enjoy. On this view of the case, having regard again to the limited number of appointments admissible, it is certainly preferable that these appointments should be offered, in each case for a reasonable period of time, to as large a number of practitioners as possible, rather than that they should be restricted to an extremely small number of specially favoured individuals, as would necessarily be the case if the tenure of each appointment were extended to a period of ten years.

The complaint made, avowedly in the interests of the students, as to the numerical insufficiency and the minor importance of the cases assigned to the honorary medical staff appears to overlook the fact that in the allotment of cases in the hospitals, the primary consideration must be the interests of the patients who are entitled, in all serious cases, to the highest professional skill available. Having regard to that it is unavoidable that the most important cases should fall to the senior member of the regular staff, who are also for the same reason placed in charge of the more advanced students at the college. With reference to the future number of honorary appointments, I am to state that the assumption appearing in the memorial that it represents a reduction from six to three appointments is erroneous. No such reduction has been announced or is in contemplation, the total number of honorary appointments now standing at eight.

In the case of the minor chairs the union recommend that their tenure should be one of ten years in the first instance, extensible by a further period of five years. The reason advanced in support of this recommendation is the apprehension that if the tenure of these posts is only an annual one extensible from year to year, the senior officers of the Indian Medical Service will, from motives of personal jealousy and professional rivalry, deliberately ignore the claims of the best men to retention in those posts, and will recommend their early displacement by men of inferior qualifications, and consequently less potentiality for encroaching on their own practice. With reference to this justification of their recommendations, I am to say that the Governor in Council is surprised that the Bombay Medical Union should have thought fit to make statements which cast an imputation of so grave a nature on the official and professional character of the responsible officers of Government without any attempt to justify them or to supply evidence in their support. His Excellency in Council has no hesitation in dismissing the accusation which these statements imply, and in qualifying as without foundation the apprehension on which they purport to be based.

With regard to the appointment of lecturers and tutors, I am to observe that, so far as the former are concerned, there is no apparent reason why they should hold their posts on terms differing essentially from those applicable to the other teaching appointments in the college. In the case of tutorships, the memorial, when it refers to their purpose as being the maintenance of a higher standard of teaching, indicated a misconception of the nature of the duties attaching to these posts. Those duties are not connected with the higher medical instruction at the college, but consist solely of the individual tuition of students in the elementary methods of examining patients and in case taking. The terms of appointment now prescribed ensure a constant succession of the most promising young graduates to posts in which they are able to gain valuable post-graduate experience, and at the same time hold out to the best men an opportunity of giving proof of their ability, and of qualifying eventually for honorary appointment on the hospital staff.

In conclusion, I am to explain that the principles by which Government have been guided in passing the orders discussed in the memorial are, in the first place, the extension to as wide a circle as possible among the independent medical profession of the benefits of close association with the work, both clinical and tutorial, of the Government hospitals, and, secondly, the retention of the teaching staff for only so long as they are recognized to be the best men available, and no longer. The several recommendations put forward by the Bombay Medical Union appear directly to contravene these principles; their effort would be, on one hand, to restrict very narrowly the scope for association with the work of the hospitals, and, on the other, to impose rigid limits on the tenure of the teaching appointments in the college, resulting in an obligation either to discharge a teacher, whom it might be difficult adequately to replace, or to retain one whose services it might be advantageous to dispense with. Such being the case, His Excellency the Governor in Council is unable to accept the representations contained in the memorial as affording any ground for a reconsideration of the orders already passed.

Correspondence.

THE FUTURE OF THE LISTER INSTITUTE.

SIR,—As one of the few surviving members of the executive committee formed at a meeting of representatives of medicine and science, held at the Mansion House on December 5th, 1889, at the instigation of then Lord Mayor, Sir James Whitehead, I have read with much interest and some concern the contributions under the above heading to recent issues of the JOURNAL. The Mansion House meeting was held with the object of "securing for this country the benefits of Pasteur's treatment of rabies." The executive committee formed for this specific purpose, after careful deliberation, came to the conclusion that this and other allied objects would be most effectually promoted by founding in England a national institute of preventive medicine. Several of its members associated themselves with the Committee for the Prevention of Hydrophobia, whose influence was one of the most potent factors in bringing about by crude, but, as experience proved, scientific methods the extirpation of rabies from this country, and that happy state which justified its establishment, and at the same time the accomplishment of the ultimate object of the Mansion House committee.

The executive committee, however, took a broader view of the situation, and in their letter of appeal to the public

expressed the view that the foundation in this country of an institute in which investigations on the causes and best means of preventing and curing infectious diseases can be carried on, and in which protective material can be prepared in sufficient quantity to supply the national wants had become necessary, and that it was neither fitting nor politic for England to be dependent on foreign laboratories.

The President and Council of the Royal Society considered the subject of the proposed institute, and expressed "their satisfaction that steps are being taken to establish an institution in which researches in bacteriology and into the nature and prevention of infective diseases can be carried on, and the hope that at some future time they may find it within their power to aid such researches by material support." The Council of the British Medical Association also expressed its approval of the idea of a national institute for the study of bacteriology, and agreed "to recommend a grant of £300 towards the expenditure of the current year."

I am not a member of the Lister Institute, nor am I in a position to express an opinion as to whether its record has justified its establishment, if its present organization and management are satisfactory, if these require remodelling, or are capable of being satisfactorily remodelled, but as I was intimately and actively associated with the initiation of the scheme which called it into existence, and took some part in the secretarial duties at a period when an appeal was being made for funds, I hope I may be allowed to express the conviction that any action which would diminish the facilities for independent and unfettered research would be a violation of the principles on which the institute was founded, and a perversion of the intentions of the initiators.—I am, etc.,

JNO. PENBERTHY.
Late Professor of Pathology, Royal Veterinary College.

Newnham, Gloucestershire, August 12th.

"ENCYCLOPAEDIA MEDICA."

SIR,—Since writing to you last in reference to the manner in which Messrs. Green and Sons advertise their *Encyclopaedia Medica* (June 13th, p. 331) a new prospectus, dated July 14th, has been issued by this firm. It professes to contain "A list of contributors to the first edition, with the addition of the names of those who have so far agreed to contribute to the second." It is hard to believe, but it is a fact, that my name is included amongst these, in spite of my previous letters to the medical press on the subject, and in spite of the fact that Messrs. Green had not yet asked for my permission or consent. I have written to them, and their answer begins: "We have your letter, and thought this matter had been adjusted previously, and cannot understand why you should have written to us as you do." The letter then goes on to ask whether I am prepared to revise or to refuse to revise my articles for the new edition, and the final sentence reads, "that every contributor, *so far as we know*" (italics are mine), "is going to revise." This statement does not appear to agree with the statement from the prospectus which I have already quoted.

It will be interesting to know how many of the contributors in this prospectus have actually agreed to revise, or have only agreed in the mind of Messrs. Green.—I am, etc.,

Dublin, August 17th. HENRY JELLETT.

Medical News.

OWING to the necessary curtailment of the number of pages in the weekly issues of the BRITISH MEDICAL JOURNAL, all correspondents are particularly requested to write as succinctly as possible.

THE fourth edition of Sir Alfred Pearce Gould's *Elements of Surgical Diagnosis*, revised by the author, with the assistance of Mr. Eric Pearce Gould, is announced for early publication by Messrs. Cassell and Co.

WITH regard to the inquiry at the instance of the Brighton Insurance Committee on July 1st, as to an application from a drug store for restoration to the list of insurance chemists (as reported in the JOURNAL of July 4th, p. 28), we are informed that the Insurance Commissioners have decided to take no action.

Letters, Notes, and Answers.

☞ *Queries, answers, and communications relating to subjects to which special departments of the* BRITISH MEDICAL JOURNAL *are devoted will be found under their respective headings.*

LETTERS, NOTES, ETC.

A WARNING.

A PHYSICIAN in London writes: On May 30th you inserted a warning against a dusky complexioned man aged about 65, who was obtaining money from medical men. Two weeks ago he succeeded in obtaining a loan of money from me by representing himself to be a Canadian doctor, who was stranded in London owing to the war: an excuse which appeared reasonable but which I am now convinced was false.

WAR AND MOTHERHOOD.

(From a Correspondent.)

OF course the vicar talked about the war, and presently he remarked with pride that a nephew of his, in the Flying Corps, had crossed to Belginm yesterday. "War," I said wisely, "has always been a murderous job, but if there's one corps in which a man can make sure of getting killed, its the Flying Corps." The vicar, looking graver than I expected, rejoined in a low tone, "He was to have been married next month." "Poor chap! Poor girl!" I groaned. "They wanted to get married before he started," continued the vicar dismally, but I said "No, leave the girl free." "Kinder for the girl in the long run," I assented. "But its a delicate problem; and there are thousands of such cases occurring all over Europe at the present moment." "Yes," cried the vicar warmly. "These hasty marriages ought not to be allowed. One night together, then the bride is left pregnant; and soon a widow and a baby have to be supported by the country." "True," I said, "But isn't there another way of looking at it? The men who go to the front are the pick of the nation's manhood." "They are," said the vicar proudly. "And they'll get killed by the thousand," I continued. He nodded impatiently. "Then," I said, "once a war begins, the coming generation will have to be, in the nature of things, begotten by the sickly, the decrepit, and the maimed." "Its only too certain," he groaned. "Well then," I argued, "ought not a far-seing nation to encourage its fighting men to stamp their likeness on their wives before they go to get killed?" "But, Good Heavens," he cried, "the danger to morality! the ultimate cost!" "War always has been a danger to morality," I said, "and it always has been costly. But the danger you refer to might be met by the State endowing the motherhood of only those wives whose children are born within ten months of their husbands leaving home to fight. And the cost, though heavy, would aid not the murdering of useful human beings but the rearing of stalwart human beings who may become useful." "I see," said the vicar with a watery smile: "You would consider it as a productive rather than as a reproductive expenditure."

THE CAUSE OF CANCER.

VICE COTIS writes: Dr. Arthur Todd-White, in the JOURNAL of August 15th, alludes to the possibility that cancer may arise as a result of the excessive ingestion of food preservatives. This suggests a still wider possible source of cancer. We all know that almost the only indisputable point in regard to the causation of cancer is that it can be produced by chronic irritation. Is it not, therefore, well worthy of careful investigation whether or not the deposition in the tissues, or cells themselves, of insoluble sharp crystals of microscopic size produces a chronic irritation resulting in cancer? Such deposition of minute crystals seems very likely to occur in the people and parts of the body specially subject to cancer.

CORRECTIONS.

IN reference to Hoffmann and Kochmann's solution in the JOURNAL of August 8th (p. 302, col. 1, lines 10 and 11 from foot), the proportion of potassium sulphate was incorrectly given as 4 per cent.; it should have been 0.4 per cent.

DR. D. E. ANDERSON desires to correct two errors in the note of his remarks in the brief summary of the proceedings of the Section of Tropical Medicine published on August 10th, page 303. He said that vomiting sickness was known only in Jamaica, and that 16 cases had been reported in 1912. With regard to yaws, he said that both in Jamaica and Trinidad yaws had been reduced since the introduction of salvarsan.

EIGHTY-SECOND ANNUAL MEETING
OF THE
British Medical Association.

Held in Aberdeen on July 29th, 30th, and 31st.

PROCEEDINGS OF SECTIONS.

SECTION OF NAVAL AND MILITARY MEDICINE AND SURGERY.

COMMON AILMENTS IN CAMP: THEIR SIGNIFICANCE AND PREVENTION.

By Cecil Webb-Johnson, M.B., Captain R.A.M.C.(T.F.).

It is a well-known fact that common ailments in camp are responsible for a great wastage of public money and a loss of training for a large percentage of men. At the most, the annual training is only fifteen days, and in many cases, owing to the employers' refusal to allow their employees their full complement of time, it is only possible for them to be in camp for eight days. Owing to the improvement of the Territorial regulations every one of the fifteen days is fully planned to give the best training in the available time. The seriousness of men being off duty for one or more days must be apparent to us all, and if this loss can be either mitigated or prevented the efficiency of the force will be greatly increased.

The efficiency of a fighting force depends, *ceteris paribus*, upon the health of its component parts, and one sick man means not only loss to himself but also to the force in general. He is liable to upset the march if he falls out even for some minor trouble, and he may require the services of several stretcher-bearers to take him home, and thus deprive more serious cases of adequate assistance.

We must remember this: in the Territorial Force we have to deal with men who are during the year engaged in civic life, and who arrive in camp in a condition more or less unfit for strenuous training. For this reason it is all the more important to help and watch them, so that they may be able to do their full training without loss. It is the raw recruits who need the most careful handling and watching, for they are tyros at the art and liable to make mistakes through ignorance, which those with previous experience are wise enough to avoid.

We know that the greatest number of admissions to hospital is amongst men with less than one year's service, and that the lowest is amongst men with eight years' or more experience. Also that the rate of admission into hospital is highest amongst men between 20 and 25, and lowest amongst men between 40 and 50.

This being the case, I believe it is in the interest of the force to pay especial attention to the young recruits, and they should be questioned by their non-commissioned officer as to the state of their health for the first few days of camp life. The recruit is the last man to complain, because he is in the pristine state of enthusiasm, and naturally wishes to appear as strong and capable as his comrades who have had more experience than himself.

The first suggestion I would put forward is that the medical examination should be stricter than it is at present, and that no recruit should be allowed to join the force unless he is likely to be an acquisition to it. When a regiment is below strength there is a great temptation to pass men as fit who, had the numbers been greater, would have been rejected. This is, of course, not so often the fault of the medical officer as of the officer in command, who naturally wishes his regiment to be as near full strength as possible.

We, as officers of His Majesty's Territorial Force, have no politics nor have we any axe to grind, and all we work for is the efficiency of the force, and we must all recognize that it is better to be 10 or 20 per cent. below strength with all desirable men than full strength with 10 per cent. of undesirables. On paper, of course, it looks much better for the regiment to be full strength, but when the time comes for that regiment to be mobilized, it will be found that the undesirables are but a millstone round the neck of the unit in question. "There is always a black spot in our sunshine—it is the shadow of ourselves," and I feel that we, as regimental medical officers, should try our best to do the following:

1. We must insist on examining recruits ourselves, however inconvenient it may prove to be.

Too often recruits are examined by civil medical men in their own district, because the R.A.M.C. officer is not available. This is not a good practice for several reasons, the chief of which is that what may appear to the civilian to be of small importance may, from a military point of view, be most detrimental to a recruit.

A regimental medical officer regularly looking after the troops in camp knows much better than the civilian which points to pay especial attention to. Further, he will have the recruits he passes as fit under his charge at camp, and, if it be discovered later that any mistake has been made in passing a man, he will only have himself to blame, and he alone will be responsible. I have myself seen men in camp who have been passed as sound with varicose veins and with hernias. The subsequent trouble, loss of training and waste of money, are out of all proportion to the time it would have taken to examine a man thoroughly and find out his infirmity in the first place. If the regimental medical officer is not available in his district, in all probability another R.A.M.C. man can be persuaded to do the work.

2. A very thorough examination of the mouth and throat should be made, for a man with bad teeth, enlarged tonsils, or adenoids generally gives trouble when in camp.

A man with a mouthful of bad teeth is practically certain to suffer from toothache, alveolar abscess, or gastric trouble, owing to exposure and change of diet. It is, in my opinion, the duty of the medical officer to reject a man with very bad teeth, unless he guarantees to have them attended to before camp, and it will be doing a service to the nation at large by instilling into his mind the risks he is running of undermining his health by imperfect digestion and absorption of septic matter. I have invariably found that if this be fully explained to the recruit, he can be prevailed upon to go to the hospital and have his mouth put in order.

3. I think a man should be rejected on general grounds, even if he is quite sound, for it is a well-known fact that certain men, although they pass according to the regulations, are not fitted for military service. For example, a man might be quite healthy, but be too fat, or the ratio of height and weight might be quite wrong, or his feet might be badly formed.

I would also have inquiries made by the attesting officer and non-commissioned officer as to the moral character of the recruit, especially with reference to the drink question. Too often one hears at camp of one or two recruits who not only drink heavily themselves, but endeavour to demoralize others in their company or tent.

Of course, we are touching on delicate ground here, but often a medical officer can refuse a man at his medical examination if anything has been found out about him which is likely to do harm to the regiment, before he has been passed as medically fit.

4. I think all recruits should be medically examined *before* going to camp. It may seem superfluous to mention this, but on one occasion I was attached to a regiment and was surprised when asked by the colonel to examine about sixty recruits several days after we had been in camp. The danger of this practice can be recognized, for all cases rejected on medical grounds not only mean a great wastage of public money, but great inconvenience to the regiment. Such a procedure is unfair not only to the men subsequently refused, but also to the regiment and the nation. "He that will have a cake out of the wheat must needs tarry the grinding," and though my suggestions might appear to give more work to the officers, I think subsequent events would prove that their work would be minimized.

In all my remarks it must be fully understood that I am referring not to the regular army, but to the Territorial Force. Having briefly discussed the means of prevention to be taken before camp, we must now see

what can be done during camp, and the following points are worth mentioning:

(*a*) *Cleanliness.*—It is said that "cleanliness is next to godliness," but we know that with some people it is next to impossible.

One cannot be too strict in insisting upon the utmost cleanliness, not only in the person, but in camp generally. The men should be taught to wash themselves regularly, and especially to see that their feet are bathed and thoroughly dried after work is over. It may seem faddy to make a point of washing before eating, but although we are, according to tradition, compelled to consume a peck of dirt in our lifetime, there is no necessity to do so in fifteen days.

There is no doubt that much of the gastric trouble in camp is caused by the men eating with soiled hands and contaminating their food.

Of equal, or of still greater, importance is the thorough cleaning of all cooking utensils, and the kitchens require most careful and constant supervision. No food should on any account be allowed in the tents. The cleanliness of the camp in general, and the tents in particular, both make for the health of the camp. Remember that flies—carriers of disease—flourish in filth. The risks attending exposure and vicissitudes of weather are very small if the men are well clothed and well fed, but these are not enough without cleanliness is added to them.

(*b*) *Removal of Tents.*—Whenever possible, the tents should be moved to fresh ground periodically, the length of time for the original tent ground depending on circumstances, such as the weather, etc. If this is impracticable, all tents should be struck at the end of the first week, so that at least the enclosed ground can have the benefit of the sun and fresh air for a few hours. The tent walls must be looped up for a few hours every day, in spite of the weather.

(*c*) *Clothes and Bedding.*—Proper facilities should be given for hanging up all blankets and beddings, so that they can be sunned and aired. Similar facilities should be given for wet clothes to be dried, not inside, but outside the tents.

(*d*) While on the subject of clothes, I must mention the importance of every man having good serviceable boots and at least two pairs of good thick undarned socks. One of the greatest troubles in camp is blistered feet, and a large percentage of men are rendered unfit for duty for one or more days on this account.

I have already mentioned the importance of there being a compulsory ablution of the feet daily, and if this is not practicable the feet should be thoroughly wiped with a wet towel, and this applies particularly to the toes. In my opinion, unsuitable socks are responsible for more sore feet than any other cause, and it is a pity that there is no fund to supply proper socks for all the men in camp. The County Associations make a grant to men who supply themselves with suitable boots at camp, but ignore the question of socks. Men arrive at camp with one or perhaps two pairs of socks, with crude darnings or holes guaranteed to cause blisters within a week.

It is better to dispense with socks altogether than wear ill-fitting and shrunken ones, and an excellent substitute is an ordinary newspaper wrapped round and moulded to the shape of the foot, for this can be changed daily.

The socks should be greased on the outside with soap, and when they show a tendency to shrink they should be stretched and worn on the opposite feet.

As in my experience the two commonest causes of absence from duty on account of minor ailments are sore feet and gastric troubles, I shall touch lightly upon their treatment. I have already mentioned the importance of suitable boots and socks, compulsory ablution of the feet, etc., and I would now suggest that a foot inspection should always take place a few days after camp has commenced. This is best conducted by the medical officer in conjunction with the officers in command of the various companies. If properly conducted, it takes very little time, and the medical officer can at once tell if any feet require attention. If any blisters are actually present, they should be pricked with an aseptic needle and the serum got rid of. A dressing of some mild antiseptic ointment can then be applied to the blistered parts. In those cases in which no actual blisters are present, but where the skin in parts looks angry and red, an excellent plan is to make the men soak their feet in a bucketful of cold water coloured red with permanganate of potash. Some men complain of excessive sweating of the feet, and in this case they should be bathed in a solution of formalin and water in the proportion of 1 to 800.

A powder of powdered talc 80 parts, starch 15 parts, and boracic or salicylic acid 5 parts, should then be lightly dusted on the feet. If this procedure is adopted, a man will seldom be absent from parade on account of foot soreness. In every case of blistered feet the socks and boots of the men should be inspected.

(*e*) The next commonest minor ailment is gastric trouble. This takes various forms, including: (*a*) Constipation, (*b*) diarrhœa, (*c*) sickness, (*d*) colic. The change of air and food are responsible in a great measure for the constipation which is so common in camp life, and most men who have had previous experience present themselves at medical parade on the second day and ask for an aperient. I would make it a definite rule for inquiry to be made on this point regularly, and especially should this apply to recruits.

Every medical officer must know that cases come to his notice of men being rendered unfit for duty on account of neglect in this respect, and, on being questioned, it will often be found that they will go six or seven days without any action of the bowels. This could all be prevented by making definite inquiries through the non-commissioned officers and seeing that each case was attended to.

Diarrhœa is most commonly caused by previous constipation and invariably means that a man is off duty for one or more days. Other causes are bad teeth and imperfect digestion, damp clothing not being changed, beer drinking, and food which is not good being kept and eaten in the tents. With the diarrhœa are, in a number of cases, vomiting and colic, and they are very difficult to treat properly in camp because there is no proper provision made for special invalid diet. This makes it still more important for us to prevent these troubles by every means in our power, and I think that a careful attention to the bowels during the second or third day in camp will do much to prevent men being off duty from such causes.

GANGRENE IN WAR.

By C. MAX PAGE, M.S., F.R.C.S.,
London.

AT any time, in civil as well as in military practice, the treatment of gangrene calls for close observation and considered judgement, so I venture to think that some remarks on the cases I had the opportunity of seeing and treating in the late Balkan war may prove of practical value.

If the types of gangrene seen under war conditions be classified in accordance with their etiology, they group themselves under the five following headings:

1. Gangrene secondary to the interference with the blood flow through the main vessels of a limb.
2. Traumatic gangrene.
3. Infective gangrene.
4. Gangrene due to vasomotor paralysis.
5. Gangrene secondary to the effect of high explosives.

The occurrence of the disease in young men with healthy circulatory systems is the one feature which is common to all these types, and which differentiates them on the average from gangrene as met with in civil practice. This fact considerably affects the line of treatment and the prognosis.

I will now briefly discuss the clinical phenomena and treatment of these several kinds of gangrene, with special reference to type 4, as this latter form of gangrene has not, it seems, been recorded since the war in the Crimea.

Type 1.

Gangrene of the extremities is occasionally seen as a result of direct slow velocity gunshot injury to the main brachial or femoral vessels; it more often occurs when a bone injury is present as well. High velocity rifle bullets may pass through large vessels and at the time produce few symptoms; subsequently an aneurysmal varix will very likely appear. The symptoms of this latter condition may be evident within a week or so of the injury, and if operation is undertaken at this stage,

probably involving ligature of the artery above and below the sac, gangrene of the affected limb is very likely to occur. Makins[1] states that the only cases of gangrene from aneurysm which came under his notice in the Boer war were secondary to operative interference, and he is very strongly of the opinion that operation should not be undertaken in these cases till two or three months after the injury; operation is at this time simpler, and the secondary circulation has had a chance of becoming properly established. Only one case of traumatic aneurysm of the axillary artery was treated operatively by us in Constantinople. Operation was undertaken nine days after the injury on account of the increased swelling and pain. The circulation in the arm remained good throughout, and the man made an excellent recovery.

In Constantinople I had 4 cases of gangrene secondary to injury of the main vessel, 3 in the arm, and 1 in the leg. Of the cases in the upper extremity, 2 resulted from shrapnel injuries in the subclavian triangle, the apex of the pleura and lung being involved as well as the artery. Both men died shortly after admission, apparently from shock. In the other case, gangrene of the hand followed a comminuted gunshot fracture at the elbow-joint. The gangrene was limited to the hand, but on account of the septic state of the elbow-joint amputation was carried out after admission, when the progress of the gangrene was stationary. The local condition progressed satisfactorily, but unfortunately the man died of acute enteritis a fortnight later.

In general, I think, in this type of gangrene amputation can be carried out near the seat of injury, and as soon as the process is definitely limited. In some instances, if the primary injury has not seriously involved the bone and is not infected, amputation at even a lower level may be safe.

Type 2.

Traumatic gangrene is a term applied to a condition often indistinguishable from infective gangrene. Theoretically it is applied only to those cases in which death of a part results from direct injury, but it is evident that infection will be an important factor in the extent and progress of the condition. The treatment is practically the same as for the infective type.

Type 3.

Acute infection with many organisms may cause some degree of local tissue necrosis. The term "infective gangrene," however, is usually reserved for those cases in which the process is definitely progressive and associated with toxaemia. Under such a classification come phagedaena and the gangrene due to the bacillus of malignant oedema and the *Bacillus acrogenes capsulatus*. Phagedaena or hospital gangrene was of common occurrence in the pre-antiseptic days in both military and civil hospitals, and several types were described by those who had experience in the Franco-Prussian war.[2] Nowadays it is practically not seen except as a complication of soft chancre. Emphysematous gangrene due to the above-mentioned organisms usually occurs in lacerated and grossly infected wounds of the lower extremity. The condition, if well established, extends with astonishing rapidity and produces profound toxaemic symptoms; prompt radical treatment must be undertaken if the patient's life is to be saved. In my experience amputation as far above the apparent level of infection as possible is usually fatal. I have, however, seen two cases—one a man aged 22, the other a boy of 12—survive amputation at the hip-joint for this condition. The alternative is to make free incisions into the affected parts and to dress with hydrogen peroxide or put the limb in a continuous bath. Montprofit states that he saw on the Allies' side during the Balkan war many cases recover after such treatment.[3]

Type 4.

I have assumed in my classification that the cases of symmetrical gangrene which were seen in large numbers among the Turkish troops in the last months of 1912 resulted from a vasomotor disturbance. There was some difference of opinion in regard to the cause responsible for the condition. I will give an account of the gangrene as it appeared in the cases which came under my own observation.

History.—About half the men affected were suffering from enteritis; the distinction between the less acute cholera cases and those of acute dysentery was not at this time always possible. All gave a history of being exposed for long periods on wet ground and of having been on insufficient rations. Many had been in wet trenches for twenty-four hours on end; the temperature in the neighbourhood of Tchatalja (from which most of the cases came) at this time of year was usually about 5° C. above freezing point. The foot and leg gear of those affected varied, but by no means all had been wearing European boots and puttees. The onset of the gangrene was usually painless; in many instances the men dated the existence of the condition from the time of their arrival in hospital, even in cases in which the process was evidently of some standing. Pain was very marked during the period of reaction and was most prominent and difficult to combat in those cases in which no more than the skin was involved.

Type of the Gangrene.—The gangrene was practically always symmetrical and affected the lower extremity in nearly all cases; the fingers were involved occasionally, but, as far as I saw or could learn, never independently of the feet. The extent of the gangrene in the lower extremity varied from mere discoloured blistering over one or two toes to death *en masse* of the leg as high up as the knee. In some men who showed a dusky mottled red appearance of the skin of the feet no actual necrosis occurred, though swelling of the feet and legs persisted in such cases for some weeks. The gangrene was usually dry, but in several of the more extensive instances it became moist, and at S. Stephano Bourdillon saw several deaths from tetanus in this latter class of case. When once the men were in hospital the condition did not tend to advance except in the few instances where emphysematous infection was superadded. Toxaemia was not marked except under the latter circumstances. The urine in the three or four cases examined was normal to the ordinary tests.

Treatment.—In cases where the gangrene was moist and extending, or where signs of tetanus were present, amputation well above the lesion was carried out. The prognosis in this type of the condition was not favourable, as in addition to the profound toxaemia the subjects were usually thoroughly exhausted from exposure and dysentery. When the gangrene was fairly dry the affected parts were powdered with boracic and left exposed to the air or lightly covered with wool; good food and stimulants then assisted the rapid formation of a line of separation. Superficial parts of the toes often separated in fourteen days. When the bone was involved the latter was divided a little above the line of separation. On account of the youth and vigour of the subjects, it was possible to make use of skin flaps right down to the level of separation. In the case of the men affected with enteritis, as might be expected, the course tended to be less favourable, but even in these instances the gangrene, if dry, seldom advanced much after admission of the patients to hospital.

Etiology.—I consider the condition to be strictly comparable to that of frostbite. The arterial circulation of the men affected was rendered extremely poor by the condition of starvation and fatigue; under these circumstances a temperature above freezing was able to produce stasis in the peripheral vessels. No doubt in some instances tight boots and puttees assisted, but, as I have already mentioned, many of the men affected had been wearing the loose native footwear. Dreyer,[4] who reports on 31 cases seen in the German Hospital in Constantinople, takes this view. Depage[5] does not agree with this explanation, and gives as his opinion that the gangrene was due to the pressure of puttees shrinking as they dried. I have already given reasons for showing that this explanation does not satisfactorily account for a large number of cases seen. A further explanation put forward at the time was that the gangrene was due to the troops eating infected rye bread. Against such a possibility was the small quantity of rye bread supplied to the troops and the entire absence of similar symptoms among the local population before the war.

No figures of the mortality of this condition among the Turkish troops are yet available, but certainly many thousands were affected, and the death-rate among those

who were suffering as well from enteric complaints was high. I have not been able to find any record of a similar gangrene among the many accounts of the medical history of the Allies' armies. It is interesting to note that a strictly comparable condition attacked many of the English and French troops in the Crimean war. In English reports and statistics the condition is classified as frostbite, although it appeared quite often in the absence of extreme cold.[6] The number of men invalided on this account was 1,844. The mortality from this cause in the army which served in Bulgaria as well as in the Crimea was 33.3 per cent.; among the troops who only served in the Crimea it was 16.3 per cent. This enormous death-rate was largely due to the complication of enteric diseases and typhus, which were both frequently acquired after the troops were admitted to hospital. The figures relating to sickness incidence will remind you of the deplorable medical conditions under which our troops served in that campaign. For enteric diseases alone, the admissions to hospital amounted in the ex-Bulgarian force to 74.1 per cent. on a strength of 14,959, and in the Crimean army to 86.1 per cent. on a strength of 8,880. Haspel[7] gave an account of the condition from the French point of view which corresponds very closely with the recent experiences in Turkey. He states that amputation nearly always proved fatal and strongly advised conservative treatment.

Type 5.

Extensive gangrene of the extremities has been stated to occur in men after they have recovered from the effects of violent explosives. I have not been able to find any authoritative statement on this subject, and hope that some member of this meeting may have some knowledge of the matter.

The only recent definite communication I can find on the subject of this type of injury is by v. Berdisavljever,[8] reporting from Servia; he says he saw cases of haematuria, haemothorax, and shock as the result of explosions, but he says that in no instance did he see gangrene. Dr. Maclean had under his care in Constantinople a remarkable case of gangrene of all four extremities attributed to this cause.[9]

Such in outline is an account of gangrene as it is met with in war. It will be appreciated that in general it is merely an occasional complication of some other surgical condition, and that it only assumes epidemic importance under rare conditions of service, conditions to which one may hope it will never be the lot of our troops to be again subjected.

SECTION OF OPHTHALMOLOGY.

C. H. USHER, B.A., M.B.Cantab., F.R.C.S.Edin., President.

AN ANALYSIS OF THE RESULTS OF THE NEW SIGHT TESTS OF THE BOARD OF TRADE.

By F. W. EDRIDGE-GREEN, M.D., F.R.C.S.

THE Board of trade has now issued a report on the new sight tests used in the Mercantile Marine. This report covers the period of April 1st to December 31st, 1913. An improved wool test in which the candidate had to match five colours, and a lantern test were used. The cases of colour blindness are divided into those definitely rejected by the local examiners and those referred for a special examination, the local examiner being doubtful. Of the 286 definitely rejected in the local examinations 148 failed in both the lantern and the wool test, and 138 failed in the lantern test only. There was no failure with the wool test which passed the lantern test. Of the 286, 93 appealed, 26 being successful. Of 125 referred cases, 20 were referred on both the lantern and the wools, 101 on the lantern only, 3 on the wools only, and 1 on form vision as well. Of this number there were 30 failures, 3 of these were referred on both the lantern and wool test, 26 on the lantern only, and 1 on form vision as well. Those referred on the wool test alone were passed.

It must be pointed out that the above summary is not given in the report, but is the result of a detailed examination of every case. This is a grave omission considering the importance of the facts which are brought out. It will also be seen that the figures do not agree with the totals given at the end of the report. For instance, the total number of failures in the local colour vision tests is given as 283, but if the number be added up it will be found to be 286. It is particularly surprising that the results of the examinations with the lantern and the wool tests are not tabulated, because they are so important and settle for ever the question of the efficacy of the wool test even in its improved form.

The Departmental Committee wrote with regard to the lantern test and the wool test:

> When the two methods had been in use for a certain number of years, long enough to afford reliable statistical data, the number of cases in which candidates who have failed in one but have passed in the other should be tabulated, and the question of dispensing with one or other could then be considered.

It will be noticed that of the 286 rejected in the local examinations, 148 failed in both the lantern and the wool test, and 138 failed in the lantern test only; there was no failure with the wool test which passed the lantern test. It will be seen, therefore, that, not taking into account the referred cases, over 48 per cent. of the rejected passed the wool test. If we add the referred cases which were rejected—namely, 3 who were referred on the lantern and wools and 26 referred on the lantern only—the percentage of those passing the wool test is still further increased—namely, to over 52 per cent. It will be noticed that those who were referred on the wool test alone were passed. The wool test used was not that of Holmgren, but had added to it two test colours similar to the two principal test colours in my classification test. The figures given for the wool test in the form it is now used do not in any way represent its defectiveness in its original form or even in the form (all three test colours being used in each case) originally adopted by the Board of Trade, after I had stated, in 1889, how very defective the wool test was. In 1909 the Board of Trade added two new test skeins similar to the chief test colours in my classification test, and which I advocated as being the best test colours in 1889 if wools were to be used. Let us therefore compare the percentage of rejections before and after the introduction of these two test colours. The following table gives the number of candidates examined in colour vision and the percentage finally failed in colour vision for different years since the introduction of the wool test.

	Number of Candidates Examined in Colour Vision.	Percentage Finally Failed in Colour Vision.		Number of Candidates Examined in Colour Vision.	Percentage Finally Failed in Colour Vision.
1894-5	*6,680	1.38	1905 ...	5,839	0.80
1896 ...	5,017	1.02	1906 ...	6,410	0.75
1897 ...	5,943	0.66	1907 ...	6,564	1.10
1898 ...	4,080	0.81	1908 ...	6,288	0.70
1899 ...	4,621	0.87	1909 ...	‡5,146 † 882	1.07 1.81
1900 ...	4,300	0.72	1910 ...	7,393	1.51
1901 ...	4,878	0.92	1911 ...	7,192	1.89
1902 ...	4,600	0.74	1912 ...	7,326	2.22
1903 ...	4,622	0.45	1913 ...	§2,068 ‖5,799	3.43 4.9
1904 ...	6,292	0.94			

* September 1st to December 31st. † January to October.
‡ November and December. § January 1st to March 31st.
‖ April 1st to December 31st.

Now, it will be noticed that the percentage of 4.9 is much higher than any previous year. For the ten years extending from 1897 to 1906 inclusive the percentage of rejections never reached 1 per cent., and for 1903 was 0.45 per cent.; therefore for 1913 the rejections are

ten times the number of those in 1903. It is evident, therefore, that either a considerable number have been rejected who should not have been rejected or that in former years a considerable number have been passed who are a danger to the public.

I cannot give details of the examination on appeal, but I entirely disagree with the standard of classification suggested by the Departmental Committee. I have examined many cases which have been rejected by the Board of Trade, and some of these cases I certainly should not have rejected. The examiners on appeal were all strong advocates of the wool test, and Mr. J. H. Parsons, a member of the Departmental Committee, stated in his new book, published after the report, that the wool test was "sufficiently good," and that names should not be used in a test for colour blindness, and did not even mention the lantern test. It is incomprehensible to me how a man can work at a subject and miss such a very simple fact as that certain colour-blind persons can pass the wool test, seeing that over 50 per cent. of dangerous cases can pass this test even in its improved form, and that the fact has been continually and persistently pointed out as it has been by me for the last twenty-five years, and is recognized by the overwhelming majority. Such, however, is scientific method with certain men in this country, and I commend this fact to those who are really interested in the progress of knowledge and in removing the obstacles in the path of the pioneer. It is obvious, however, that advocates of the wool test are not the right persons to fix a standard with the lantern test. The lantern employed is not mine (the official test of the navy), but is similar to one of my discarded models, but not so efficient, as there is no means of altering the luminosity of the lights, and only two, instead of a series of apertures, are used. As I predicted last year, a considerable number of normal-sighted persons are rejected by it; 93 (the summary of the report states 94) out of 286 appealed—that is to say, about one-third of the number. Of this number 26 were successful and 67 unsuccessful (the summary of the report states 68)—that is to say, apart from referred cases, the very large percentage of 27.9 were found to be rejected wrongly. It is probable that a similar percentage would be found if the other two-thirds were examined. This shows how very unfair this lantern test is to the mercantile marine. It should also be noted that two cases passed by the examiners locally for form vision were, on appealing against rejection for colour vision, rejected for form vision, one even on the old standard.

The report of the Departmental Committee contains many misstatements of fact, probably none worse than the following: "The evidence has also established that there are a number of cases, which have been described as 'border-line cases,' in which considerable difficulty has been experienced in determining whether the defects in the vision of the candidate will or will not interfere with his efficient watch keeping. These border-line cases represent much less than 1 per cent. of the candidates examined, but they must include cases of real hardship as in the interests of safety it is impossible to give the benefit of any doubt to the candidate."

Now, the great difficulty in this question for the mercantile marine is where to draw the line; it is not a matter of a fraction of 1 per cent., but the border line region is very large; 25 per cent. of men show definite defects of colour perception, in fact the whole hundred could be graded according to their colour perception, some being very superior to others in distinguishing lights. Now, in the large majority of this 25 per cent. the defect is slight, but they are obviously not up to the standard of the other 75 per cent. What is wanted is that the Admiralty should fix a standard of distance at which it is necessary to recognize lights with and without conditions of fog. If some thousands of persons were tested with actual signal lights with the aid of neutral glasses at the required distances, those rejected could then be submitted to other tests in the laboratory, the efficiency of which would then be determined. It is particularly important that all the bad cases should be rejected, and not that some bad cases should be passed and that slight cases should be rejected. Dr. T. Harrison Butler records a case of a man who passed the Board of Trade lantern but failed with my lantern with a red light, not being able to see it when it was dimmed.

DISCUSSION.

Mr. J. HERBERT PARSONS (London) spoke at length on the Board of Trade tests and upheld them.

Mr. DEVEREUX MARSHALL (London) commented very adversely on the Board of Trade tests and thought that the results obtained were very bad as recorded in the statements published by that body. He upheld the conclusion which Dr. Edridge-Green had made in his paper.

Professor H. GIFFORD (Omaha) strongly advocated the use of the lantern test; he thought it infinitely superior to that of the wools.

Major W. E. MCKECHNIE, I.M.S., said that if the lantern were sufficient in all cases as a practical test it seemed unnecessary to have a wool test, as in practice individuals were required to distinguish lights and not things of the nature of wools. The suggestion of Dr. Edridge-Green—that a standard of normal colour vision should be determined—was of great practical importance. What was practically required was to pass all who could distinguish and see signal lights at all times and to reject when failure to do so might mean danger, and to disqualify no others. To be able to do this—that is, to set up a standard—some thousands of individuals ought to be examined under practical conditions of service in all weathers at sea. Those who were fit for sea service would also be fit for land service. If a public body like the Admiralty would take up this question they could, by testing a sufficient number of persons, determine a mean standard of normal colour vision and the amount of departure from the mean which would constitute the limit beyond which rejection must take place. Having thus determined the range of colour perception within which perfect safety lay, it would be a simple matter to define by a test like that of Dr. Edridge-Green's lantern which candidates should be passed and which rejected. Unless this practical standard could be determined, tests would be apt to be too rigorous or too lax.

A CASE OF LATE INFECTION FOLLOWING ELLIOT'S OPERATION.

By A. HILL GRIFFITH, M.D.,

Lecturer on Ophthalmology, University of Manchester; Ophthalmic Surgeon, Royal Infirmary; Surgeon, Royal Eye Hospital.

I PERFORMED my first trephine for primary glaucoma on January 31st, 1911, and from my hospital statistics I find I have done in all 125 for primary glaucoma, besides a good many for secondary glaucoma and for other diseases.

I am well pleased with the results, and regard the operation as much more satisfactory than iridectomy in chronic glaucoma.

S. E., male, aged 55, came under my care at the Royal Eye Hospital on March 25th, 1912, for chronic glaucoma in both eyes. The vision had been failing very gradually for five years, more seriously for the last five months, with coloured rings around the gas lights.

State on Examination.—The conditions were practically similar in both eyes: Dilatation of the venous trunks around the cornea, anterior chamber shallow, pupil medium wide, cupping of the disc with spontaneous pulsation of the arteries; V. = $\frac{6}{18}$ and with correction of the presbyopia, No. 1 Jaeger slowly. Charts of the field of vision showed the typical contraction of the nasal side.

Operation.—The tension was decidedly increased. Both eyes were operated upon within a short time of each other by upward trephining by Elliot's method, a small iridectomy including the pupillary margin being done, and the conjunctival flap was sutured. The patient was discharged in a month. Both eyes made perfect recovery and kept well for close on two years.

Progress and Result.—On March 11th of this year he presented himself with purulent irido-cyclitis of the *left* eye. No light perception. T − 3, exudation in the pupil, injection of the entire conjunctiva, oedema of the lids, discoloration and inflammation of the iris; the pillars of the coloboma were free and well retracted. The eyeball was removed three days later. I should have mentioned that the patient on being questioned told me that the eye had been affected four days. The other eye is still quite satisfactory in every way. The naked eye preparation of one half the globe which I present to you shows purulent cyclitis, the exudation covering the entire free surface of the ciliary body and posterior surface of the lens.

REMARKS.

Dr. L. Paul, in the May number of the *Klin. Monatsblatter f. Augenheilkunde*, records a case like the above, and says that his is the twenty-eighth case so far recorded. My colleague at the Eye Hospital, Dr. J. Gray Clegg, tells me he has quite recently had a case eighteen months after operation: this with my own brings the total to 30.

This number 30 must, of course, constitute a very small proportion of the total number of cases operated upon, for many thousands have been done. My own experience of 1 in 125 gives a percentage of 0.75. On the other hand, I do not for a moment imagine that all the bad after-results have been published. I must confess that my confidence in the operation has been badly shaken, and I feel it my duty to publish this unfortunate case, and hope to elicit the experience of the gentlemen present as to any unpublished cases, with suggestions for rendering the operation safer.

DISCUSSION.

Dr. H. GIFFORD (Omaha, U.S.A.) said he too had been unfortunate enough to have a case of late infection after a faultless trephining, and it led to entire loss of sight. With the history of cataract operation in mind one ought not to be surprised at these late infections. Doubtless they would remember the cases of late infection reported by Wagenmann years ago: in these, after a cataract operation, the wound healed with a cystoid scar. Such cases were practically in the same position as that of a glaucoma patient, after a successful trephining. Unfortunate as such results were, they constituted no valid ground for rejecting trephining, since, as Axenfeld had pointed out last year, many cases of chronic glaucoma could not be saved from blindness by anything except a fistulizing operation. In still another way a successful trephining was on a parallel with a cataract operation, in respect of liability to sympathetic ophthalmia. Last autumn the speaker had ventured to predict that before long cases of sympathetic ophthalmia following trephining would be reported. Since then he had heard of two such cases—one in the practice of Dr. Spalding of Portland, Maine; one in that of Dr. McReynolds of Dallas, Texas, and it was perfectly certain that more would follow. But this also was no reason for rejecting trephining. That operation had come to stay, and the important thing was to determine what could be done to minimize the danger of such accidents. Every patient with a conjunctival bleb connecting with the interior of the eye should daily use a solution of zinc ½ grain to the ounce or something similar. If he could not be brought to do this he ought at least to carry a prescription for such a solution with instructions to use it promptly on the slightest sign of conjunctival irritation; also to use hot applications if there were any pain, until an ophthalmic surgeon could be consulted. The infection was exogenous and the danger in direct proportion to the prominence of the bleb. A case reported by Kuhnt illustrated this most clearly.

Mr. DEVEREUX MARSHALL (London) said that he considered no operation safe which caused a cystoid scar, although the risk of such might be immeasurably less than the destruction caused by the disease for which it was performed. He detailed a case in which a lady was operated upon for chronic glaucoma in both eyes in 1887, with good results, but with cystoid scars. A conjunctival catarrh developed a year later, and one eye was entirely lost from an infection of irido-cyclitis. He was not surprised to find that occasionally such results followed trephining.

Dr. MONTAGU HARSTON (Hong Kong) said he considered it important always to transilluminate the patient previous to any trephining operation in order to exclude as far as possible any latent sinus infection. He agreed with Mr. Parsons that the flap should be much larger than Dr. Hill Griffith had demonstrated in his drawing; furthermore, it was of extreme importance that dissection under the flap should, as Elliot laid down, be central only, and that the peripherally-situated subconjunctival tissue should remain undisturbed, in order to minimize as much as possible the danger of late infection.

Dr. A. J. BALLANTYNE asked whether in Dr. Griffith's case the trephine hole were covered by a prominent, thin-walled bleb. If so, it was probable that the operation did not strictly follow Elliot's technique, in which the trephine hole did not lie beneath a delicate film of conjunctiva, but was covered by a layer of corneo-scleral tissue isolated by "splitting" of the cornea. It was very probable that cases presenting a prominent thin-walled cystic scar were those which were most liable to late infection.

Mr. HERBERT PARSONS (London) said he was surprised that late infection did not occur more frequently. He thought that a large flap was essential, and also that the trephine wound should be made well forward in the cornea, as Colonel Elliot insisted.

Dr. CASEY A. WOOD (Chicago) said he had seen two cases of infection, and they commenced at the margin of the flap. One occurred three weeks after the operation and one six months afterwards.

Dr. JAMES A. WILSON (Glasgow) thought that the conjunctival flap should be cut as thick as possible. He felt sure that a very thin conjunctival flap over the trephine wound was by no means as great a protection to the eye as a thick one.

Dr. MAITLAND RAMSAY (Glasgow) thought that the ends of the flap should not be cut down to the corneal margin.

Dr. HILL GRIFFITH, in reply, said that the risk of late infection must be considered as an inherent defect of Elliot's operation, and when infection took place it was through the conjunctiva covering the bleb and not through the edges of the conjunctival flap. He entirely rejected Mr. Parsons's suggestion that any slight difference between his own and Elliot's technique could possibly account for the unfortunate result; he agreed with Marshall that it was the presence of the cystoid cicatrix that gave rise to an ever-present danger.

THE CAUSES OF BLINDNESS IN ELEVEN HUNDRED CHILDREN;

WITH SPECIAL REFERENCE TO THE INFLUENCE OF VENEREAL DISEASE.

By N. BISHOP HARMAN, M.A., M.B.Cantab., F.R.C.S.Eng.,
Ophthalmic Surgeon to the West London Hospital, and to the Belgrave Hospital for Children.

FOR the past ten years I have had oversight of a number of London blind schools. All the children admitted to these schools are examined, the state of their eyes and of their bodies is recorded; the cause of the blindness is ascertained, by clinical evidence, by inquiry from the parents or guardians of the child, or by additional inquiry directed to the hospital authority under whose care the child had been at any time. Most of these children have been examined very many times in the course of several years.

The total number of blind and partially blind children brought into this inquiry is 1,100. The causes responsible for their state of blindness may be placed in three groups:

I. Injury or destruction of the cornea consequent on surface inflammations.
II. Inflammation within the eyeball or optic nerve.
III. Congenital defects of the eyes.

GROUP I.

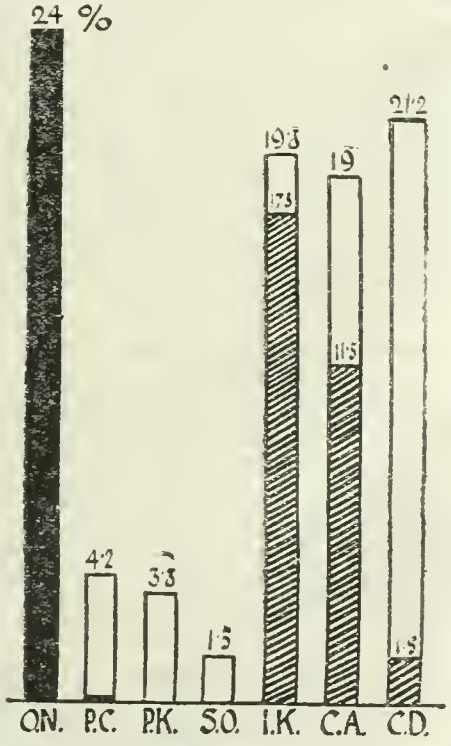
Surface Inflammations.

In the first group, injury or destruction of the cornea consequent on surface inflammations, ophthalmia neonatorum is responsible for by far the greater number of cases of blindness, and in particular for the cases of total blindness. The group contains 351 children, and the causes of the blindness are as follows:

(*a*) Ophthalmia neonatorum ...	266	= 24	per cent.
(*b*) Purulent conjunctivitis of later years	47	= 4.2	,,
(*c*) Phlyctenular keratitis ...	38	= 3.4	,,
	351	= 31.9	,,

The percentages are for the grand total.

(*a*) The diagnosis of those cases marked "ophthalmia neonatorum," so far as the examination of the child at the time of school age is concerned, must rest upon the character of the eye damage, the associated symptoms, and the history of the case as obtained from the parents or other responsible party. There are certain definite characters associated with purulent conjunctivitis occurring within a few days of the birth of the child, and most important amongst these is the occurrence of nystagmus—that is, a constant jerky oscillation of the eyes. This symptom is practically constant as a sequel of gross inflammation occurring within the first few days of life, but it does not occur, with the rarest exceptions, in children who have suffered from as severe a type of inflammation, even to the production of blindness, when the date of the onset of the inflammation is some months or years after birth.



O.N., Ophthalmia neonatorum; P.C., purulent conjunctivitis in later years; P.K., phlyctenular keratitis; S.O., sympathetic ophthalmitis; I.K., interstitial keratitis and iritis; C.A., choroiditis and optic atrophy; C.D., congenital defects.

Gonorrhoeal origin. Syphilitic origin.

(*b*) The cases of purulent conjunctivitis occurring in later months or years of child life were due to a great variety of causes.

Causes unknown—that is, date of origin known, but actual cause not ascertainable ...	14
Eczema and streptococcal infections ...	4
Scarlet fever	5
Measles	10
German measles	1
Meningitis	1
Diphtheria	2
Small-pox	4
Erysipelas	1
Chicken-pox	1
Pneumonia	2
Gonorrhoeal (contracted from vaginal discharge or pus from the eye of an affected baby) ...	2
Total	47

The two last cases are of importance, for they demonstrate the danger of the presence of babies suffering from ophthalmia neonatorum to other members of the community. One is a girl whose motherliness was exercised towards an affected baby; she caught the disease, the cornea ulcerated, and she is blind for life, whilst the baby died. The other is one of a family of three girls; the youngest, a baby, had ophthalmia neonatorum; the whole family contracted the disease, and besides vaginitis. The eyes of one were damaged sufficiently to necessitate her being educated in a blind school.

(*c*) Amongst the cases of phlyctenular keratitis there was no case of suspected venereal inheritance.

Group II.

Blindness due to Inflammation within the Eyeball or Optic Nerve.

This group contains a great variety of cases—inflammations of the cornea, of the iris, of the choroid, and of the optic nerve: but it is sufficient for the purpose of these statistics to place them in two categories, according as the inflammation affected (*a*) the anterior half of the eye or (*b*) the posterior half of the eye. The distinction is arbitrary but convenient.

(*a*) Those affecting the front half of the eye total 217, or 19.8 per cent.; by far the greater number are due to interstitial keratitis; there are a few only of iritis. Syphilis accounts for 17.8 per cent. The figures are as follows:

Interstitial keratitis due to inherited syphilis ...	190
Interstitial keratitis, evidence of syphilis uncertain	14
Interstitial keratitis due to tubercle, etc. ...	7
Iritis due to inherited syphilis	6

In examining my records of the cases tabled above, I have classified all the confirmatory evidences upon which the diagnosis of the cause of the condition was made. These are many, and some of them are so definitely characteristic that there can be no manner of doubt of the certainty of the diagnosis. In most of the cases there were several confirmatory signs, but in every one of these groups in which the diagnosis of inherited syphilis was made there was at least one of these confirmatory signs present.

Confirmatory signs and their frequency in the 190 cases of interstitial keratitis due to inherited syphilis:

Hutchinsonian teeth (including a few "Moon's teeth")	129
Characteristic physiognomy	73
Iritis	77
Choroiditis (disseminated; in many cases there can be no examination of the fundus oculi owing to the opaque cornea)	30
Bad family history	72
Scars at the angles of the mouth	36
Evidence of bone or joint disease	16
Ulceration of the nose or palate	9
Deafness	43

There were 13 cases of interstitial keratitis in which there were no confirmatory signs of an inherited syphilis. On the evidence of experience they would be fairly assigned to this cause, but in the absence of definite confirmation they are not included as syphilitic. It may be noted that some were seen before the Wassermann reaction was discovered; others could not be got to attend hospital for the purpose of making the test.

(*b*) Of those inflammations affecting the posterior half of the eye by far the greater number were due to a form of choroiditis known as "disseminated." This cannot be said to be diagnostic of syphilis, for other conditions are capable of causing the same or very similar conditions, but all evidence goes to prove that these cases are overwhelmingly syphilitic in origin. With the choroiditis there is always more or less atrophy of the retina and of the optic nerve, so that vision is gravely reduced. Closely associated with these cases are many cases of total optic atrophy.

This group includes 222 cases, or 20.5 per cent. Of these, 126, or 56.7 per cent., were definitely syphilitic. This group of cases may be considered in three subgroups: (I) A subgroup of mentally defective, nearly all syphilitics. (II) A subgroup all of whom were syphilitic. (III) A subgroup in which the cause of the condition was indeterminate.

I. Subgroup of cases with mental defect either during or after school years:

Became insane ...	26	...	Syphilitic	...	22
Mentally deficient ...	24	...	,,	...	18
Microcephalic idiots ...	4	...	,,	...	2
Epileptic	10	...	,,	...	9
	64	...	,,	...	51

II. Subgroup of children with disseminated choroiditis or optic atrophy of inherited syphilitic origin (74 cases):

Disseminated choroiditis	59
Optic atrophy	44
Hutchinsonian teeth	38
Physiognomy marked	12
Bad family history	41
Bone or joint disease	8
Deaf	2

III. Subgroup of children with disseminated choroiditis or optic atrophy of which the cause was assigned to other effects than syphilis, or of which the cause was indeterminate (84 cases).

Optic atrophy, cause unknown	29
Optic atrophy with disseminated choroiditis, cause unknown	15
Optic atrophy, post-febrile (5 cases):	
Measles	1
Diphtheria	1
Influenza	1
?	2
Optic atrophy:	
Accidental head injury	3
Hydrocephalus	9
Meningitis	10
Cerebro-spinal meningitis	5
Optic atrophy, familial	7
Choroiditis, familial	3
	84

Here follow a small group of cases of blindness due to causes which fall more or less into this main second group:

Buphthalmia (17 cases):	
No syphilis	10
With honeycombed teeth	2
With Hutchinsonian teeth	5
Sympathetic ophthalmitis, no syphilis	16
Macular defects (23 cases):	
Colobomata	6
Deficiency	8
Day blindness	6
Congenital nystagmus	3

There were some indications of a syphilitic inheritance in two of the macular cases.

Retinitis pigmentosa (21 cases):	
Sporadic cases	11
Familial cases	8
Sole child cases	2

There were indications of syphilis in one case.

GROUP III.

Blindness due to Congenital Defects.

This group includes 233 cases, or 21.2 per cent.; only 16, or 1.45 per cent., were known to be of syphilitic association.

(*a*) Albinism:

Familial cases	10
Sporadic cases	15
Sporadic cases due to syphilis (one illegitimate)	2
	25

(*b*) Defects of the crystalline lenses:

Microphthalmia and cataract	12	Syphilitis	1
Microphthalmia and cataract (hereditary)	5	,,	0
Microcephalic and cataract	6	,,	1
Posterior polar cataract	19	,,	4
Congenital cataract, varied types	51	,,	6
Lamellar cataract (post-natal)	30	,,	1
Dislocated lenses	19	,,	1
	142		14

(*c*) Varied defects of the globes and the accessory organs of vision:

Aniridia	6
Colobomata of iris	10
Microphthalmia	17
Congenital anophthalmia	3
Glioma retinae	3
Defective muscles	2
Defective muscles and face	1
Extreme hypermetropia	3
Oxycephaly	9
	53

No signs of syphilis found.

(*d*) Complicated myopia producing blindness or partial blindness occurred in 13 cases. There were no signs of syphilis found.

General Table of Causes of Blindness.

Cause of Blindness.	No. of Cases.	Gonorrhoea.	Syphilis Certain.	Syphilis Probable.

Totals	1,100	263	343	31
Percentages	100	24.35	31.2	2.8

Percentage of venereal disease in causation of blindness	55.55
Probable same cause	2.8
Total per cent.	58.35

Ophthalmia Neonatorum and Syphilis as Causes of Blindness.

I have examined the tabulated figures of the children attending the blind schools on three occasions—the present and two previous occasions. It will be of interest to compare the returns. On the first occasion the total coming into the count was 255 children; these were examined up to and including 1904. On the second occasion the total coming into the count, which include the previous 255 children, was 363; these were examined up to and including 1906. The third count is that given in the foregoing statements; the children now number 1,100, and they represent all seen up to and including 1913.

Year of Investigation.	Total seen.	Ophthalmia Neonatorum.	Congenital Syphilis.
1904[1]	255	94 = 36.86 %	48 = 18.82 %
1906[2]	363	132 = 36.36 %	64 = 17.60 %
1913	1,100	268 = 24.35 %	343 = 31.2 %

The figures show that there has been a definite diminution of the incidence of cases of blindness caused by ophthalmia neonatorum, and it is reasonable to credit this diminution to the great efforts that have been made to prevent the disease during the past few years. The diminution is really greater than it appears by this method of tabulation, for the cases seen and accounted for in the first two counts are included within the last return.

The apparent increase of the incidence of the cases of congenital syphilis is in part due to the diminution of the cases of ophthalmia, and in part to the use of finer methods of diagnosis—cases that formerly were tabled amongst those of "uncertain origin" are now definitely accounted for.

It is certain that the number of cases of blindness due to ophthalmia is diminishing both actually and relatively to the causes of blindness. But there is not sufficient evidence to state certainly that the apparent increase of the syphilitic cases is due to any other cause than the diminution of one large class of case of blindness and to the better means of diagnosis.

The sum total of this examination of these blind children is the finding that more than one-half of them owe their miserable state of blindness to venereal disease of their parents.

THE FACTOR OF HEREDITY IN MYOPIA.

By James Alexander Wilson, M.D.,
Assistant Surgeon, Ophthalmic Institution, Glasgow.

It is admitted that myopia is frequently hereditary, but the general opinion is that near-work—reading, writing and sewing—is the more important factor in its production, and the chief evidence for this opinion is the striking increase of myopia that occurs during school years.

It is becoming more and more recognized that the laws of heredity are definite and fixed and that the potency of the germ-plasm in genetics is discrediting the influence of environment. Already quite a number of human diseases and malformations are known to conform to Mendelian laws, some descending as dominants, some as recessives, and further, there are some which exhibit the peculiarity of sex-limitation.

Is there anything in the incidence of myopia that suggests the operation of well-known laws of heredity? The collecting of material for such an investigation is a big and at times seems a hopeless task, for so many people are ignorant not only of the character of the eyesight of their parents and immediate ancestors, but also of the meaning of the term "short-sight." Nevertheless we frequently have opportunities of examining two and sometimes three generations, and often we have no difficulty in accepting testimony regarding those who are dead or beyond our reach.

The following table gives some details of 1,500 consecutive cases, and on these my observations are based:

Table I.

Age Groups.	No. of Cases.	Females.	Males.	Average Amount of Myopia.	Percentage of Females.
Years.				Dioptres.	
8 and under	90	54	36	4·5	60
9–12... ...	227	135	92	3.7	59
13–15... ...	172	102	70	4.2	59
16–20... ...	215	140	75	4.9	65
21–30... ...	318	218	100	5.6	68
31–40... ...	224	163	61	5.9	72
Over 40 ...	254	180	74	6.4	70
Totals ...	1,500	992	508		

These cases are ophthalmologically selected, and may not represent the relative distribution of these conditions in the general population, but intrinsic evidence may be found bearing on the question of heredity.

Sex.

In my table there are 992 females and only 508 males—that is, there are nearly two females to one male. It may be said, and as a quite legitimate criticism, that women have more opportunity than men to visit the hospital, and that [illegible] accounts for the greater number of females. School statistics show that females are more liable to myopia than males. Among the school children on my list the percentage of females is 59. At the age of puberty the percentage rises, and it increases from this onwards.

Late development of myopia is acknowledged, but there is no evidence of the frequency of its occurrence. Ten per cent. of my cases say their defective vision came on between the ages of 16 and 35 years, and these people are principally clerks, typists, compositors, domestic servants, tradesmen, and miners. Two-thirds of them are females. All these people have not deceived themselves as to the time of onset. Late development, then, probably accounts for some of the greater prevalence of females among my cases. In some, one eye is more myopic than the other, and the failure of the better eye may have made the person conscious of the defect. Many of these people have relations who are myopic, and I infer that the manifestations of heredity are not confined to school years.

Heredity.

I have classed a patient as having hereditary myopia when I have examined and discovered myopia in a parent, a brother, or a sister, or if I have seen the glasses worn by one of these and found them to be glasses for short-sight. I have also accepted the following statements as evidence of myopia in a parent or relative: (1) That a parent or relative could see to read, write, or sew without glasses at or over 60 years of age; (2) habitually passed friends in the street without being able to recognize them, but yet had good near vision; (3) that glasses were removed for reading; or (4) that when reading the paper was held close to the face. This method of classification gives the following results:

Grandparents myopic	... 54	
Mothers myopic	... 369	
Fathers myopic	... 254	
		— 677
Brothers or sisters myopic	... 164	
Uncles or aunts myopic	... 31	
Cousins myopic	... 9	
		— 204

In 204 cases the evidence of heredity is collateral and the transmitting parent is not disclosed, nevertheless the mother obviously plays the larger part in the transmission of myopia.

Myopia was transmitted—	
From father to son in	... 79 cases.
From father to daughter in ...	... 149 ,,
From mother to son in	... 111 ,,
From mother to daughter in ...	... 231 ,,

These figures do not include all the myopic members of the various families, for probably both sons and daughters have been omitted, but, taken as they stand, then the fathers transmitted myopia to two daughters for one son, and the mothers also transmitted myopia to two daughters for one son.

There is evidence of heredity in 58 per cent.; keratitis is classed as the cause of the myopia in 12 per cent.; cases in which evidence of heredity is unobtainable, 30 per cent.

Arranged according to the amount of myopia:

Low myopia—*i.e.*, up to 3 D. ...	Females 425; males 243
Medium myopia—*i.e.*, 4 to 6 D. ...	Females 249; males 113
High myopia—*i.e.*, 7 to 12 D. ...	Females 217; males 112
Very high myopia—*i.e.*, over 12 D. ...	Females 101; males 40

The following figures indicate the percentages of the cases in these sections that present evidence of heredity; cases due to keratitis are, of course, excluded:

Low myopia	... 65 per cent.
Medium myopia	... 66 ,,
High myopia	... 67 ,,
Very high myopia	... 67 ,,

Table II.

Occupations.	No.	Per Cent.	Average Amount of Myopia.	Hereditary. Per Cent.
			Dioptres.	
School children	491	33.0	4.0	65
Housewives and domestic servants	445	30.0	6.5	63
Shop and factory workers, etc. ...	262	17.5	5.5	63
Clerks, typists, etc.	222	14.5	3.8	60
Labourers and miners	61	4.0	7.0	60
Unknown	19	1.0	—	—

These various degrees of myopia and these various occupations show practically the same evidence of heredity, and from this there follows a suggestion of unity in the subject and of similarity in etiology.

Tscherning's[1] statistics are well known. They were obtained from the examination of 7,523 Danish conscripts, and among these he discovered 627 myopes—that is, 8 per cent. He classed the conscripts as educated and uneducated. In the educated class he had 2,336 persons, and among these he found 420 myopes, or 17 per cent. In the uneducated class he had 5,187, and among these he found 207 myopes, or 4 per cent. The myopia in the educated class was mainly of low degree, and in the uneducated

class was mainly of high degree. These figures may or may not apply to present conditions and may or may not apply to this country; but the inference is that near work is the cause of low myopia and determines its presence or absence.

The following correlation table shows the relation between the amounts of myopia in parents—fathers or mothers—and the amounts in their offspring—sons or daughters. The horizontal line of numbers indicates the amount of myopia in the parents and the vertical that in the offspring. If there were exact correlation in the amounts of myopia, then the entries would begin at 1 and cross the table diagonally to the lower right-hand corner. All entries above this diagonal line indicate higher degrees of myopia in the parents and all below higher degrees in the offspring. The table shows the amounts of myopia in 176 parents and 176 sons and daughters. The ages of the offspring vary from 5 to 30 years, but the majority are under 15 years.

TABLE III.

Fathers or Mothers.

Sons or Daughters.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	18	20	D.

2	7	4	4	5			3	1	1	1				1					27
3	8	2	3	1		1	2	1		1	1	1		2			1		24
4	2	2	4	4	1		1		1			2				1			18
5	1	3	1		1	1				1								1	9
6	1	2	1			1	1			2							1		9
7	2			1			1		1								1		6
8	1			2				1				1				1			6
9					1	1			2										4
10	1								1					1					3
11	1																		1
12	2					1		1			1	2			1				8
13															1				1
14	1								1										2
15																		1	1
16	3											2		1					5
18																			
20									1						2				3
D.	45	24	19	14	4	8	8	8	9	5	2	12	1	6	4	2	3	2	176

This table demonstrates the fact that when myopia is clearly hereditary, then it exists in all degrees—high and low—but that low degrees are more frequently hereditary than high.

High myopia makes its appearance before school work begins, and therefore must be due to heredity; but what has become of the more common variety of hereditary myopia in Tscherning's uneducated class? It may be said that when the myopia is high the intensity of heredity has been great, and that when the myopia is low the impulse of heredity has been less, and that near work or other suitable environment is necessary for the production of this variety, or to enable hereditary tendencies to become manifest. In the absence of this near work, or environment, the factor may lie dormant, skip a generation, or be only partially or fitfully expressed.

This may be the explanation of Tscherning's statistics; but I doubt if any such uneven distribution of myopia could be found in our country to-day. What would his results have been if he had also examined 7,000 young women? Probably in his uneducated class the results would have shown some approximation to the normal distribution. Near-sighted people are adapted for near-sighted pursuits, and moreover they often have a selective predilection in this direction.

This table is interesting in another way. If it is admitted that the myopia in the parents is also hereditary—and acquired characteristics are not supposed to be transmitted—then this table by itself indicates that 23 per cent. of my cases are hereditary.

Is there evidence that myopia of low degree is caused by near work, apart altogether from hereditary predisposition? It is difficult to exclude from the parentage the possibility of hereditary transmission. In my cases the percentage of near workers is relatively small, and the average amount of myopia is relatively low. This low degree of myopia seems to harmonize with the results that Tscherning obtained in his educated class. Many of the near workers on my list believed their occupation was the cause of their defective vision; but 60 per cent. of them gave evidence of heredity, and of those in whom I did not find any evidence of heredity more than one-half admitted that they had defective vision at the age of 16 years. How is it that all people who have to use their eyes much for near work do not become myopic? Is it not simply because of the presence or absence of the factor of heredity? If near work, apart from heredity, is a cause of low myopia, it can only apply to a small percentage of my cases, and in these cases I would prefer to consider it the suitable environment that enables hereditary tendencies to become manifest. Professor Pearson concludes his analysis of the school, or "hot-bed," theory thus[2]:

> Cohn's statistics seem to indicate that the moderate association they exhibit between school environment and degree of myopia is solely a secondary result of a primary relation between age and degree of myopia.

There are among my cases eight families in which both parents are myopic. The following table gives the details:

TABLE IV.

Number of Families.	Number in Families.	Affected.		Not Affected.	
		Females.	Males.	Females.	Males.
8	41	17	10	6	8
		27		14	

Among the unaffected there are one baby, one boy of 3, one girl of 7, and two girls of 10 years of age. Granting that two of these become affected during adolescence, then the percentage affected would be 70.

Here are examples of the pedigrees. Black indicates myopia.

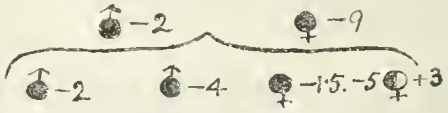

Fig. 1

The numbers indicate the amount of myopia. It will be observed that the youngest member of the family has 5 D. of myopia in the right eye and 3 D. of hypermetropia in the left.

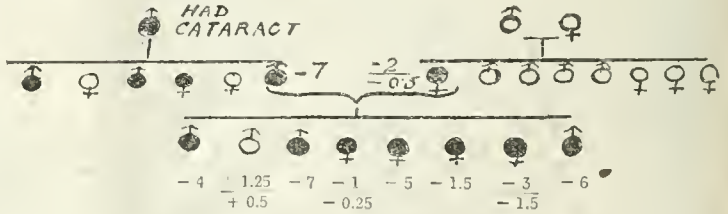

Fig. 2.

The numbers indicate the spectacles worn. The second son is hypermetropic, and so in both these families there is a slight reversion to the other extreme.

The following table gives the details of families where one parent only is myopic. Children under 7 years have been excluded. I obtained these pedigrees while I was collecting the last 500 cases.

TABLE V.

Parents Affected.	Number.	Number in Families.	Number Affected.		Number Not Affected.	
			Females.	Males.	Females.	Males.
Mothers ...	71	295	81	46	82	86
Fathers ...	34	150	44	28	32	46
Totals ...	105	445	125	74	114	132
			199		246	

Percentage affected, 44.

The following table gives the details where neither parent is myopic:

TABLE VI.

Number of Families.	Number in Families.	Affected.		Not Affected.	
		Females.	Males.	Females.	Males.
91	426	63	45	153	160
		113		313	

Percentage affected, 26.

There is evidence in some of these families given in Table VI that a grandparent was myopic, and in others that an uncle or aunt was myopic. In most of these families only 1 member is myopic, in some 2, in two 3, and in one 4 members are myopic.

Here are the details of this last family:

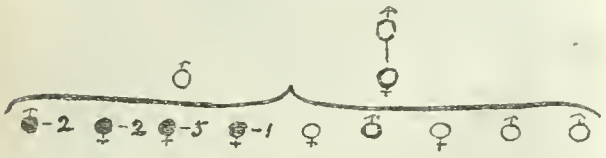

Fig. 3.

I have examined all those people with the exception of some of the younger children, and these have passed the visual tests in the school. These cases are undoubtedly hereditary, though no evidence of heredity is obtainable in the parentage. Myopia may skip one, perhaps two generations. Hereditary myopia may be found in children whose father and mother are emmetropic or normal.

Mr. Worth has reported[3] several families in which the males alone were affected and where the myopia was transmitted by unaffected females, but these he thinks are pathological curiosities.

Does the transmission of myopia conform to Mendelian laws? One of the peculiarities of a character that descends as a Mendelian recessive is that where both parents are affected all the offspring exhibit the characteristic. It is not so in myopia, and therefore we must conclude that it does not descend as a Mendelian recessive. A Mendelian dominant descends from an affected person to an affected person. Again, it is not so in myopia, for it is often transmitted by a person who is unaffected, and thus one is forced to the conclusion that the transmission of myopia does not conform to Mendelian laws. A person may have one eye hypermetropic and the other myopic. This does not suggest Mendelian segregation, for under this system the manifestations must be either present or absent—that is, there is no blending.

It is a fact that myopia is more prevalent in some nations than others, thus there is more among the adult population in Germany than there is with us. Sormani[4] found the greatest number of myopes in Italy among recruits drawn from the southern and sea coast provinces, that is, from districts where there is plenty of open landscape and seascape and abundance of light.

These variations are without doubt racial in character. If in adult populations such as are here instanced myopia is unduly prevalent, then it is only reasonable to expect a similar prevalence among the children and that this should manifest itself in a progressive manner during the years of growth and development, that is, during school years. During these years hypermetropia lessens and myopia increases, in short, the eyeball enlarges along with the other organs and features.

When both parents are myopic then myopia is very prevalent among the offspring; it is less so when only one parent is myopic, and still less so when neither parent is affected. There is irregularity of incidence in individual families, but this is to be expected, as one or both parents may carry unexpressed the hereditary tendency to myopia, or one parent may be hypermetropic. When taken collectively this irregularity disappears.

I have also, though to a less extent, investigated the incidence in cases of hypermetropia, and the pedigrees I have collected harmonize with those of myopia. In one outstanding case of a family of five children three of the children have very high degrees of hypermetropia, yet both parents have full vision and emmetropic refraction. There are other cases where both parents are hypermetropic, and the majority, but not all, of the children are similarly affected. Hypermetropia is the congenital condition, or the starting-point, and the line that subsequently divides hypermetropia from myopia is arbitrary. Perhaps these variations should be considered together, and the question would then be the size of the eyeball, a quantitative character that would probably come under what biometricians call the law of ancestral heredity, or "average ancestral resemblance." "Thus[5] the mean amount of correlation between (1) the two parents and the offspring, (2) the four grandparents and the offspring, (3) the eight great-grandparents and the offspring, is believed to diminish in a geometrical series which is the same for all organisms and for all characters." Pearson regards the actual amounts of these correlations as expressed by the figures 0.6244, 0.1988, 0.0630.

My percentages do not quite agree with these figures, but they show approximation to them. This system seems to offer the best explanation of my results. The appearance of hypermetropia in families where both parents are myopic is an example of ancestral contribution.

Seven per cent. of my cases have cataract in various forms, but the commonest is punctate peripheral opacities, a variety that seems peculiar to myopia, and that is found in quite young people. In only three cases did I observe drop-like areas behind the anterior capsule of the lens.

There seems to be an affinity between myopia and cataract; but I am not yet satisfied that there is any order or system in the association, still it is an association that to some extent differentiates myopia from hypermetropia, and that requires consideration in any endeavour to understand the etiology and pathology of myopia as an entity apart from hypermetropia. I believe I can account for 70 per cent. of my cases, and the remaining 30 per cent. show no features that differentiate them from the others. The extensive changes that are often found in the fundus—changes that are peculiar to myopia—are related only to the age of the patient and the degree of myopia.

Among school children the sexes are found to be disproportionately affected, and this disproportion increases at and beyond the age of puberty, giving in my cases a ratio of two females to one male—a ratio that suggests sex-limitation. The incidence of myopia bears a direct relationship to the amount in the parentage, or extraction, and there is order in the transmission. There is similar evidence of heredity in high degrees and in low degrees of myopia and in the various occupations. There is no special association with any particular occupation, and all these innate characteristics indicate that the etiology of myopia is independent of environment.

THE CHOICE OF A CATARACT OPERATION.

By ERNEST E. MADDOX, M.D., F.R.C.S.Edin.

MR. ERNEST E. MADDOX, in a paper which will be published in full in the *Ophthalmic Review*, indicated a belief that to vary the character of the operation performed so as to meet the precise needs of the individual in question was preferable to practising the same operation on all

patients alike. A surgeon who varied his procedures must be guided in his choice by five considerations, first coming that of safety. The safest procedure was to perform a preliminary iridectomy, and extract the cataract at a second operation. The only disadvantage was that the iridectomy cicatrix sometimes baulked the subsequent carving of a good conjunctival flap. Such difficulty, however, could be overcome by making the iridectomy incision in a different way. The next safest procedure—that of combining the iridectomy and extraction into one operation—was suitable to cases in which the patient's age or calling made the extra loss of time entailed by a second operation a really serious disadvantage. Simple extraction, or removal of the cataract without an iridectomy, was an excellent operation in respect of vision, accommodation, appearance, and lessened probability of occurrence of impaction of the capsule, but was much less safe than the other procedures mentioned. The indications for it were a large cornea, a full anterior chamber, a ripe lens, a "live" iris, a healthy conjunctival sac, and a patient who was quiet and not too old, and free from a tendency to sneeze, cough, vomit, or suffer from acute flatulence. In regard to judgement of visual results, the vision recorded by Snellen's test types after correction of the refraction was not the only good criterion; a very important factor was the patient's ability to see sufficiently well to walk about without glasses. Simple extraction afforded this ability and also the full ordinary field of vision, which in these days of swift vehicles was more valuable than acute definition. The tendency to post-operative astigmatism was also less with this operation, which gave the best results in regard to appearance. The benefit of simple extraction should be afforded to cases which ideally met the stated indications for this procedure: in all others a preliminary iridectomy should be considered; if neither simple extraction nor a preliminary iridectomy operation seemed suitable to the case the combined operation should be performed. Intracapsular procedures should be reserved for cases in which the cataract was immature, and in which ideal facilities for its performance presented themselves. It could not at present be recommended for general adoption. Colonel Henry Smith had done more for it than any one else, but it was still waiting for some finishing touch, or some further flash of genius, to place it beyond the danger line and adapt it to the white races, among whom, owing to the fact that cataracts developed much later in life and other causes, intracapsular extraction was less safe than among Indians.

DISCUSSION.

Major W. E. McKechnie, I.M.S., after discussing a variety of considerations, concluded that the ideal operation was one which would secure complete removal of the lens, but leave other parts normal. This ideal could not yet be attained with certainty. The procedure that came nearest to it was Smith's intracapsular operation, which was at present the operation of choice in Northern India, and there had given very good results. It required more skill than any other, since inaccuracy of technique was less permissible, and it required a larger incision. The chief difficulty was not escape of vitreous, but the toilet of the wound after delivery of the lens. The easiest cases in which to do the intracapsular operation were those of immature cataract in orbits containing little fat, and with loose lids and sunken eyes where the lens was not very big. Largeness of the lens was indicated by a shallow anterior chamber. When the conditions indicated were present this operation was often very easy.

Dr. Casey Wood (Chicago) said there ought to be a distinct understanding as to the particular form of the disease in view when the choice of an operation was discussed. When a cataract occurred as the result of slow, almost physiological, sclerosis of the lens mass and the cataract was mature, and the lens and capsule were easily separable and the eye itself was healthy, and the patient above 60 years of age, almost any cataract operation was likely to be followed by satisfactory results. The difficulties arose when cataracts were immature but sufficiently marked to prevent the patient following his usual occupation and in those which occurred in patients under 60. The latter cases usually occurred in otherwise unhealthy eyes. In both these two latter classes of case the patients should be kept in hospital for a week's rigid preliminary and local systematic examination and treatment, and if there were no contraindications large doses of salicylates or iodides should be given two or three days before and after extraction by the first of the procedures mentioned by Mr. Maddox.

Dr. Angus MacGillivray (Dundee) expressed his preference for a conjunctival bridge operation that he had recently described in the *Edinburgh Medical Journal*.

Dr. Montagu Harston (Hong Kong) said that in dealing with Chinese patients he preferred the intracapsular method, but regarded cases in which he found hypertension as unsuitable for this operation. He regarded undertension in the same light. The tonometric readings which he always took before an operation should be within normal limits.

Mr. J. Herbert Parsons (London) said that in many cases in which the iris did not spring back satisfactorily after simple extraction the danger of prolapse could be completely eliminated by making a small peripheral buttonhole in the iris.

Dr. R. A. Reeve (Toronto) said he had performed a good many operations without iridectomy, and being satisfied with his ordinary methods had not tried the Smith operation.

Dr. Hill Griffith considered the combined operation the safest and best.

Mr. T. H. Bickerton (Liverpool), after a reference to early discussion on the same subject, said that there was much to be said for both methods was evident from the fact that some of the distinguished advocates of the simple method became its most confirmed opponents, and vice versa. But as to-day even the advocates of simple extraction admitted that iridectomy was advisable in certain cases, and as it was not possible always to recognize these "certain" cases before operation, the speaker, in order to ensure the greatest safety in all cases, remained an advocate for the performance of iridectomy, and, whenever possible, of preliminary iridectomy.

Mr. Devereux Marshall (London) said he preferred the simple operation, and if the iris did not go back easily he cut it off, but this he seldom did before the lens was removed. He always made a practice of opening the capsule with the knife as he passed across the anterior chamber.

Dr. H. Gifford (Omaha, U.S.A.) said that with the Indian peasant a one-stage operation was so much a necessity that it was legitimate to take greater risks, but in Europe and America it was comparatively easy to keep track of patients and get them to submit to secondary operations if these proved necessary. The assumption was unwarranted that after the performance of the Homer-Smith preliminary capsulotomy for immature cataracts the entire lens could easily be expressed within from six to twenty-four hours and the danger of secondary glaucoma be averted by careful attention.

In response to an appeal for funds to provide a central supply of radium for Glasgow and the West of Scotland subscriptions to the amount of over £7,300 have been intimated. In addition the Bellahouston trustees have made a grant to the committee of £500 per annum for three years to secure the expense of custody and administration, and give a proper trial for the scheme. Arrangements have been made for the purchase of 600 mg. of radium, which, it is considered, will be ample to meet present requirements. The university authorities have placed a room in the university at the disposal of the committee, and it is now being fitted up as a radiometric laboratory under the supervision of Professor Frederick Soddy, F.R.S. Arrangements are also in progress with the medical institutions in the city for the treatment of patients with radium.

ENGLISH PELLAGRA IN EARLY CHILDHOOD.

BY

CHARLES R. BOX, M.D.,

PHYSICIAN TO ST. THOMAS'S HOSPITAL AND THE LONDON FEVER HOSPITAL.

On December 24th, 1913, a child suspected of being a pellagrin was sent to see me at St. Thomas's Hospital by Dr. C. Stewart Wink from Halstead, Essex.

History.

The parents are strong and healthy; there are no other children, and there have been no miscarriages. The patient, S. S., is a little girl, who was born at Farsley, Yorks, on July 19th, 1909. She was suckled for one year. In March, 1911, the child then being 1 year and 8 months old, a rash with butterfly distribution appeared on her face and lasted until September. At first the eruption was like sunburn or erysipelas; later it

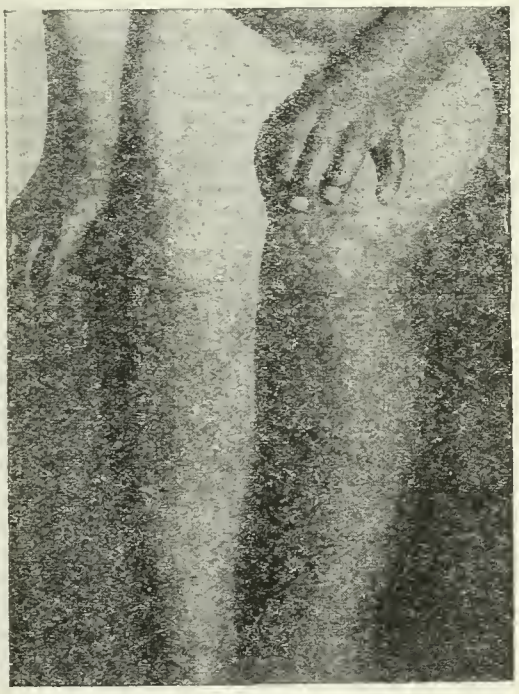
faded, and the skin peeled. The next spring the rash reappeared and ran a similar course. In February, 1913, the parents removed to Halstead in Essex, taking the child with them. The "erysipelas" appeared again, but was a week or two later in its onset. When the rash is present there may be a slight soreness of the perineum and some scalding on micturition, but the soreness is insignificant and does not last so long as the rash on the face. The child has never suffered with digestive or bowel disturbance, and maize flour has never formed part of her dietary, which appeared suitable for her age. There have been no convulsions or fainting attacks.

When I first saw the patient she was 4½ years old. The parents gave the following additional particulars:

She can walk but not run properly, and cannot get up from the floor without hold or struggle. In her bed she is uneasy, constantly tossing about and waking many times in the night with a whining cry. She cannot pick up objects without trembling, and is incontinent as regards her urine. Her disposition is irritable. She is a very weary child all the summer.

The month was December, and the typical eruption was not present, although the skin of the nose was somewhat roughened, and there was a moderately fine tremor of the hands and arms. I had an opportunity of seeing the child again in May this year. The rash had made its fourth appearance, and was very striking. A diffuse dermatitis implicated the flush area of the face, the tip of the nose, and the margins of the mouth. The dorsal aspects of the hands and of the lower thirds of the forearms showed the pellagrous gauntlets, the palmar aspects escaping with the exception of the radial side of the wrists. The legs also were implicated in a peculiar and characteristic fashion, the lower thirds of the thighs, the knees, and the upper parts of the legs being discoloured over an area which was bounded by the lower margin of the frock above and the upper ends of the socks below. The rash everywhere was of a dark brown or sepia colour, and the skin a little roughened.

The child was admitted to St. Thomas's Hospital for further examination and treatment. She was plump, but her weight was just under 24 lb., or nearly a stone less than the average. She was described by the house-physician as looking very well and "sunburnt," the skin of the affected parts being characterized as "tanned." All her movements were tremulous, and a definite, rather coarse tremor implicated the hands and arms, and also on occasions her head; the gait, too, was unsteady, but she could stand erect with the eyes closed. All the reflexes, both deep and superficial, were present and normal. No anaesthesia or muscular wasting could be detected. The ocular fundi were normal, and nystagmus was not noticeable. Although involuntary jerky movements of



the limbs were noted before she was admitted, these were not seen whilst she was in the ward. Physical examination showed nothing amiss with the thoracic or abdominal viscera. The urine contained neither albumin nor sugar. The pulse rate was always slightly accelerated and the temperature rose each day to between 99° and 100° F. The mouth was not sore and the bowels but slightly relaxed. The child was quite intelligent. In a week or two the rash was imperceptible but the tremor persisted. The medical treatment adopted was an intravenous injection of 0.06 gram neo-salvarsan. I have heard that the rash reappeared on her return home.

The interest of the case lies in its indigenous nature, the absence of maize as an article of diet, the early age, twenty months, at which the disease appeared, and the striking way in which the dermatitis involved the uncovered parts about the knees as well as the usual exposed areas on the hands and face. The pronounced tremor with occasional small jerky movements of the limbs is a characteristic nervous manifestation of pellagra.

EIGHT cases of plague and the same number of deaths were recorded in Hong Kong during the week ended August 22nd.

TWO UNUSUAL CASES OF MASTOIDITIS IN CHILDREN.

BY WILLIAM WILSON, B.Sc., M.D.,
HONORARY ASSISTANT SURGEON, ST. JOHN'S EAR HOSPITAL, MANCHESTER

IT is, of course, not unusual for the mastoid region to show signs of suppuration before the tympanic membrane perforates. In the following case, however, there was no bulging and no attempt at perforation of the membrane, which, to the naked eye, was apparently normal:

CASE I.—*Primary Mastoiditis?*

I was called to see a child, aged 2 years, who had been suddenly attacked by mastoid pain, with slight oedema above and behind the auricle. The tympanic membrane was practically normal. Temperature and pulse were slightly raised, but the general condition was good. There were no infected adenoids, but slight reddening of the pharyngeal mucosa was noticed. Owing to the absence of marked constitutional signs and the possibility of the condition being non-suppurative, palliative treatment was adopted.

Three days later, however, without any change for the worse in the general state, fluctuation was obvious above and behind the auricle.

Operation.—The usual incision was made and a subperiosteal abscess was found communicating with the antrum through a fistula in the outer antral wall; the superficial cells extending through the squamosa, above the antrum, were entirely full of pus. The middle ear was, of course, left intact.

Healing was rapid and uneventful. The tympanic membrane throughout was normal.

In every way this case suggested a case of primary mastoiditis. That the superficial air cells of the squamosa should to a great extent be infiltrated with pus, without any signs or symptoms of middle-ear suppuration, is rather unusual. Absence of pain in the ear itself was a noticeable feature throughout. Other members of the family had just recovered from "influenza." There was no preliminary stage of middle-ear inflammation before the mastoid cells were attacked.

CASE II.—*Primary Extradural Abscess?*

A child, aged 8 years, presenting slight mastoid oedema of one side, but no severe constitutional symptoms except slight pyrexia, was sent to me by a doctor who had only the same day been consulted. The child was recovering from a mild attack of whooping-cough. There was some thin watery yellow pus in the external meatus, but on cleansing and packing this did not recur in quantity. No evidence of any perforation of the membrana tympani could be obtained by inspection, by suction, or by the use of hydrogen peroxide after cleansing. The whole external meatus was, however, sodden. No indications of intra-cerebral involvement could be obtained.

Operation.—The usual mastoid incision was made. There was marked congestion of superficial tissues, but no pus in the antrum or middle ear. The mucosa of the antrum was a little oedematous. The lateral sinus was exposed and found to be pulsating. Part of the bridge was removed, but no pus could be obtained from the middle ear. On account of these negative findings, it was decided to open up the posterior fossa. This was done through the posterior antral wall. After removing bone which was apparently healthy, the pus-searcher suddenly perforated what seemed to be the tense wall of an abscess in the posterior fossa. Immediately the operation wound was flooded by the spurting up of about two ounces of thick white pus under pressure. The opening was then sufficiently enlarged to pack the cavity with iodoform gauze, but no attempt was made at any other treatment owing to the copious haemorrhage from the vascular granulations lining the cavity. The mastoid wound was sutured, leaving a space sufficient for the packing of this abscess cavity backwards through its narrow neck. The antrum itself was not packed.

Recovery was rapid, only a small amount of pus being found on the packing gauze, the remainder of the wound healing up cleanly. Hearing was perfect one month afterwards.

Neither before nor after operation was any evidence discovered of perforation of the membrana tympani, nor of pus in the antrum. The only pus ever seen, with the exception of that in the posterior fossa, was in the external meatus before operation, and this never recurred.

During the operation no fluid could be syringed either way through the membrane, nor at any time was there any reaction to hydrogen peroxide in the meatus. The pus present in the meatus on admission was quite different in appearance from that in the posterior fossa. The former was yellowish, then watery; the latter was thick and milky white.

There are two possible explanations: (1) Either the perforation in the tympanic membrane was so small or was so situated that it could not be demonstrated by the methods employed; or (2) the whole tract from external meatus and tympanic membrane to the dura mater was simultaneously affected by an acute infection (probably pneumococcal, from the whooping-cough); this spread by the lymphatics around veins to the posterior fossa, and was there cut off from the surface by lymphangitis occurring in the bony channel.

The pus in the external ear was probably an accumulation from a mixed infection through atmospheric exposure; it is to be remarked in this connexion that there had been no treatment of the ear by syringing. The conditions found and the rapid and complete return to the normal with such simple treatment support the second explanation.

INTRAPERITONEAL RUPTURE OF THE BLADDER.

BY NORMAN FLOWER, M.A., M.B., B.CH.OXON.,
ASSISTANT SURGEON, YEOVIL HOSPITAL.

STATISTICS show that intraperitoneal rupture of the bladder is more common in men than in women, and nearly 90 per cent. of recorded cases occurred in adult males.

The operation for the relief of intraperitoneal rupture necessarily has a high mortality. Dambrin and Papin put it at 43.5 per cent. in 78 cases, but early operative interference and improvements in technique have in recent years reduced it to 20.5 per cent.

Death is due to peritonitis, shock, or haemorrhage. The earlier the operation the better the prognosis. Of 13 cases observed by Zuckerkandl, operated upon in the first twelve hours, 8 recovered, but in 21 cases after twelve hours there were only 6 recoveries.

The case here recorded presents several features of interest. First, the age and type of the subject, together with the associated difficulties to be contended with. Secondly, the operation, which, in itself unorthodox, was performed full twenty-four hours after the accident. Thirdly, it demonstrates the ease with which a rupture of the viscus may be produced in an individual subject to alcoholic excess, a condition which predisposes alike to the neglect of micturition, over-distension of the bladder, and relaxation of the abdominal muscles, whose protective influence is thereby lost.

On May 5th, 1914, I was asked to see a man, nearly 70 years of age, of pronounced alcoholic tendencies, with arteriosclerosis and emphysema and weighing 19 st. The story was that at 9 p.m. the previous night he was returning home when he tripped over a stone and fell upon his face. In the early hours of the morning he was seized with intense pain in the abdomen, and an urgent desire to pass urine, but repeated attempts to void any were ineffectual.

At 5 a.m. he was seen by his medical attendant; a soft rubber catheter was passed and four or five ounces of blood-stained urine drawn off. Two hours later it was passed again and a similar quantity of perfectly clear urine obtained.

He was transferred in the sitting position by motor to a nursing home, and the operation was performed at 9 p.m., that is, precisely twenty-four hours after the accident. I have mentioned that the patient weighed 19 st., and the picture which he presented upon the operating table filled me with misgivings. The diagnosis was that of rupture of the bladder, and, in view of the fact that the patient was so bad a subject, I decided merely to drain the abdomen thoroughly to relieve the fast spreading peritonitis and tie in a catheter rather than delay by trying to find and suture the collapsed bladder. The abdomen was opened and two very large tubes introduced, one to the left flank, whither the urine was tracking, and one down to the bladder. For some hours both tubes drained well, but latterly all the urine came from the pelvic one, and next to nothing from the catheter.

The patient's general condition improved so much that it was decided to look for the bladder and repair the damage. This was done on the fourth day after the first operation. It was by no means easy, even by the suprapubic route, to effect an entrance into the collapsed and, by this time, retracted bladder in so adipose an individual. When once this was accomplished, I was very agreeably surprised to find that the lower end of the pelvic tube had found its way through the small tear at the fundus of the bladder into its interior, thereby affording the most complete drainage possible. This tube was gently withdrawn from the abdominal wound above, and the edges of the tear seized and sutured in the ordinary way. The bladder was temporarily drained by a small suprapubic tube and a Hamilton-Irving's box. In the abdominal wound a short tube was left for forty-eight hours. There was a good deal of sloughing of skin and fat around the tubes, and, as the result of infiltration with urine of the pre-vesical areolar tissue, a

left-sided scrotal abscess and a good deal of oedema of both scrotum and penis developed. These were incised under local anaesthesia. The patient left the nursing home on June 16th, and I have since heard that his progress is satisfactory.

The signs of intraperitoneal laceration of the bladder are in nearly all cases immediately manifested, but here, as in rare instances, the patient passed a few hours after the accident in comparative freedom from urgent symptoms. The explanation of this, of course, lies in the fact that he was probably too anaesthetically intoxicated to be conscious of his condition.

In the treatment of intraperitoneal rupture, the adequate drainage of the peritoneum is obviously of prime importance, but the orthodox method of combining this with the second stage of the operation—namely, the discovery and accurate suture of the laceration—would have occupied time, the expenditure of which, in such a subject, would have been only to court disaster. Even so, during the shorter operation, the continuous administration of oxygen throughout the latter period of the anaesthesia, became imperative.

Yet again it may be urged that at the second operation the suprapubic wound might have been completely closed and a catheter tied in, or catheterization every six hours resorted to. It was found, however, after the preliminary operation, that the patient was particularly intolerant of the presence of the instrument. There was, in addition, some prostatic enlargement, and the bladder itself, friable with fatty infiltration of its walls, demanded very free drainage for the conservation of the intraperitoneal closure. With due regard to the varied complications, I am still inclined to the view that, on the whole, the plan of procedure ultimately adopted was the best.

A SIMPLE METHOD FOR DETERMINING THE AMOUNT OF GLUCOSE IN DIABETIC URINE AND OTHER LIQUIDS.

BY

A. F. DIMMOCK, M.D.,

HARROGATE.

THERE are many methods now in use for estimating the sugar in urine, and many others have been suggested from time to time. The ordinary method by Fehling's solution seems one of the best, but requires apparatus and needs a good deal of experience and skill to arrive at accurate results. The fermentation test is extremely accurate, but it takes a long time to obtain results. An objection to the picric acid test recommended by the late Sir G. Johnson is the fact that creatinin produces a colouring similar to the glucose. The following simple method can easily be used without much apparatus, and gives a quick result:

The urine is diluted twenty times, that is, 10 c.cm. of urine is measured and poured into a 200 c.cm. flask; this is made up to the 200 c.cm. mark, and the whole well shaken. A solution of potassium carbonate (K_2CO_3) 2 oz. to 6 oz. of distilled water, is filtered and made up to 8 oz. To 20 c.cm. of the diluted urine 10 c.cm. of the potassium carbonate solution is added in a small flask, and this is boiled carefully for three minutes, and when cool made up to a definite amount, say 50 or 100 c.cm., with distilled water. In order to estimate the amount of sugar present, a solution of pure glucose is prepared, 1 gram in 200 c.cm. of distilled water; 20 c.cm. of this and 10 c.cm. of the potassium carbonate solution are boiled together in a small flask for three minutes, and when cool made up to 50 c.cm. or 100 c.cm. The two solutions are then compared by holding the glass tubes over a piece of white paper at an angle of 45 degrees. By pouring the liquid from the known solution into a measure glass until the tints of both are alike, and observing the amount of the known glucose solution used, the percentage can be readily determined; for example, if 27 c.cm. of the pure glucose solution were required for the solution, then, multiplying by two, we obtain 5.4 as the percentage of glucose in the urine.

I am quite aware that it is a little troublesome to prepare two solutions, and attempts will be made to use some other method of comparison. Coloured glass seems to offer the best solution of the difficulty. Experiments have been made with various iron solutions (ferric acetate and ferric and ammonium citrate), but none have come up to expectations.

Allen says in his *Chemistry of Urine* that, using normal liquor potassae *B.P.*, when equal parts of this and urine are boiled in a flask or test tube, the test does not indicate with certainty the presence of a small amount—say less than 2 per cent.—of glucose. Albumin should be removed by acetic acid and heat. The colouring matters in urine do not seem to have any effect, but these could easily be removed by lead acetate or subacetate, taking care not to use excess, filtering or allowing to stand; any slight excess of lead is easily soluble in the potassium carbonate solution. The colouring matter of rhubarb and senna becomes reddish-brown with alkali before heating, and samples containing catechol (pyrocatechin) acquire a brown colour on exposure to air.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A MODE OF RETRO-CATHETERISM.

SOME months ago a stockbroker's clerk came to me suffering from retention of urine. All the usual plans failed to relieve him; even that useful expedient of passing an endoscopic tube to the stricture, so as to widen out its face and thus find the aperture. I then used the following method, which I had thought out years ago:

The apparatus required consisted of a long, narrow, fully-curved trocar and cannula, scarcely 6 mm. in thickness, with a round and smooth proximal end, and a filiform 18 in. long, to pass through the cannula. After aspirating the bladder suprapubically by the trocar and cannula and filling the organ with boric acid solution, I reversed the trocar, so that its round blunt end protruded from the distal end of the cannula. This end was then depressed on the trigone; then lowering the hand whilst pushing gently, the instrument slid easily into and beyond the internal meatus. The trocar was withdrawn for the second time and the filiform substituted; aided by pulling the penis forward and upward the filiform passed out through the external meatus. Had it failed to do so, at worst it would have reached the posterior surface of the stricture, and any attempt to deal with the membranous urethra from the perineum would, on account of its presence, be more exact.

After twenty-four hours urethrotomy became easy; the urine in the interval trickled freely alongside the filiform as it always does. Thus a cure was established on cheap terms. I might have used and was prepared to use a larger trocar and cannula, but that would have entailed more risk.

I think the perineal mutilation one often sees is avoidable. If a Wheelhouse operation does not immediately succeed, it is better to open the membranous urethra behind the stricture or to do retro-catheterism; even better perhaps would it be to push a very fine trocar and cannula through the stricture, the direction being aided by the finger tip, a filiform being then passed through the cannula. In any case the puncture would be harmless.

The great secret in a Wheelhouse operation is not to obliterate the little pouch left at the front of the stricture until the orifice is found; if obliterated the chief landmark is gone.

London, E.C. JAMES MACMUNN.

OCCLUSION OF COLON IN A NEWBORN CHILD.

THE following case was of interest in that it showed an occlusion not only of the upper part of the rectum but of the whole colon. I attended a confinement in a primipara aged 28, which, though slow, was otherwise normal, on April 25th, 1913. The pregnancy was also normal, and the baby, a female, looked well nourished and healthy. The next day the child began to vomit at intervals, then the abdomen began to show signs of distension. Urine was passed, but the bowels had not moved. Examination of the anus showed that the sphincter was normal, also the rectum for 2½ in. to 3 in., then it narrowed and became completely occluded. The vomiting became more frequent; there were evidences of pain such as crying and pulling up of the legs.

Post-mortem examination showed that the ileum was distended in its lower two-thirds to within 3 in. of the ileo-caecal valve, where it narrowed considerably. The caecum including the appendix was small but otherwise healthy and patent, but about 1 in. beyond the ileo-caecal

junction the colon narrowed to a white cord-like rudiment which continued to the rectum, where again it presented the appearances above stated. The meso-colon, etc., looked normal. The lower part of the ileum and the whole of the colon was removed down to the rectum and laid open. The colon was with difficulty opened along its free border. The wall was thin, and coated internally by a white hard material resembling inspissated mucus, which was very adherent. The whole rudimentary colon was not thicker than a medium-sized probe. The ileum entered the colon obliquely from below upward, then seemed to dip downward on the inner surface of the caecum, making the lower lip of the opening overlap the upper. The mouth of the opening (that is, the ileo-caecal valve) was transverse, and had thus by its overlapping caused an obstruction which had persisted through fetal life, and caused the death of the child three days after birth.

Rebielus.

CHOYCE'S "SURGERY."

THE third volume of CHOYCE'S *System of Surgery*[1] completes the work. We may say at once that the high level of excellence exhibited in the first two volumes is well maintained and places this book in the front rank of general surgical works of the encyclopaedic order. Plainly, the object of the editor has been to present more than a good textbook. There are many such published in this country, but there is room also for a bigger effort, for a great collection of treatises by men specially fitted for the task.

The contributors to this volume are of the same standing as those of the other volumes, and the various chapters are written in the same lucid, full style. Mr. Rock Carling writes on the cardio-vascular system and on surgical affections of muscles, tendons, and fasciae. The lymphatic system is in the hands of Mr. J. F. Dobson; the lungs and pleura are considered by Mr. H. Morriston Davies. Mr. Sherren writes the chapter on nerves, and the section on the surgery of the central nervous system is by Mr. Wilfred Trotter. Mr. Choyce contributes the sections on diseases of bones and diseases and injuries of the joints—no mean share of original work. Fractures are in the able hands of Mr. Albert J. Walton. We make no attempt to criticize where we find the quality of the work so good. If there is any inequality at all, it is in the number and aptness of the illustrations. Authors differ on the point. On the whole, we think that of late surgical books have suffered from over-illustration; strict supervision should be exercised and pictures introduced only when words fail, or to save words, or to demonstrate a more or less rare condition. Several of the coloured plates in this book would have been quite as convincing in black and white, and some photographs of specimens in jars are very unsatisfactory. Mr. Walton's skiagraphs, though not all now published for the first time, form a well chosen representative collection. Many will feel disposed to regard the last named author's definition of a compound fracture as incomplete in so far as it does not clearly bring out that a compound fracture is one which communicates with the external air through the soft tissues. His teaching that in this class of fractures a plate may occasionally be used is contrary to the experience of many surgeons, including J. B. Murphy. We are glad to find Mr. R. P. Rowlands calling special attention to the "terrible variety of flat-foot due to the talipes valgus that is too often left after Pott's fracture." The frequency with which this deformity is met with in medico-legal practice, and the difficulty the examiner finds in suppressing his own opinion of the work of the man in charge of the case, are equally well known.

We unreservedly congratulate Mr. Choyce and Professor Beattie on the completion of this work, which is a monument to their industry, and we believe will prove a powerful indication of the strength of British surgery of the present day.

THE HOUSING QUESTION.

IN the lecture[2] delivered under the provisions of the Warburton Trust in Manchester in November last, Mr. B. SEEBOHM ROWNTREE discussed how far it was possible to provide satisfactory houses for the working classes at rents which they can afford to pay. He asserted that the permanent causes of the shortage of such houses were that a house takes a century to consume, that land values are comparatively speaking inflexible, and that the working man can only afford a cheap house. He expressed the opinion that to solve the problem of housing a survey of existing conditions must first be made, and that as rapidly as possible there must be an expansion of the minimum wage policy already adopted in connexion with mines, confectionery, tailoring, shirtmaking, chainmaking, and other industries. Measures for the decasualization of labour must be pressed forward. Town planning must be made compulsory and all towns provided with adequate transit facilities, and improved powers must be obtained for the acquisition of land. Money must be more freely lent to public utility societies and the burden of rates on small houses lessened. It must be made a statutory duty of all towns to see that their inhabitants are satisfactorily housed, and anticipating the proposals of the Chancellor of the Exchequer, Mr. Rowntree considered that any grant in aid of rates from national funds should be made conditional upon the proper fulfilment of their statutory duties by local authorities. Professor PIGOU in his lecture delivered in January last considered the housing problem as one aspect of the general problem of poverty. He expressed the opinion that a great part of the squalor and discomfort of certain houses of the poor was not the result of inability to pay a reasonable rent, but flowed from the low character and want of training of those that inhabited them. Advice and help to poor persons in the art of keeping their houses in a good state—like instruction in the art of cooking, the condemnation of uninhabitable houses, and the condemnation of diseased meat—might accomplish no small amount of good. There would still, however, be many persons who, abandoned to their own unaided efforts, could not afford to purchase that quantity and quality of housing accommodation which the general judgement of the country declared to be a necessary minimum. When discussing the policy of subsidies in aid of the housing of the poor, Professor Pigou admitted that it was open to serious practical objections, though he was not convinced that these were incapable of being overcome, and considered that carefully drawn schemes of State assistance towards the housing of the poor ought not to be condemned out of hand upon grounds of principle.

[2] *Lectures on Housing.* By B. S. Rowntree and A. C. Pigou. The Warburton Lectures for 1914. Manchester: The University Press; London: Sherratt and Hughes. 1914. (Post 8vo, pp. 70. 1s. 9d.)

OLD-ESTABLISHED CHARITIES.

THE twenty-third edition of the *Annual Charities Register and Digest*,[3] by Mr. C. S. LOCH, falls into three parts: an introduction, a series of essays on various special branches of philanthropic work, and a register of all institutions and societies having head quarters in London and undertaking work of a charitable order on behalf of residents therein. There is also a comprehensive list of chapter headings and subheadings, and a very full index. The register of philanthropic enterprises divides them primarily into those whose benefits are open to all and those whose operations are confined to certain areas. They are then classified according to the particular class of work they undertake, ordinary schools which contain a charitable element and institutions such as reformatories and prisoners' aid institutions not being overlooked. The information given in respect of all of them is fuller on the whole than that to be found in any other allied publication. The essays are by various authors, each of whom is a more or less well-known specialist on the subject discussed by him. Sir Edward Brabrook, for instance, deals with friendly

[3] *The Annual Charities Register and Digest.* 23rd edition. By C. S. Loch. London: Longmans, Green, and Co. 1914. (Demy 8vo, pp. 1144. 5s. net.)

societies; Dr. H. Rayner with lunatics, idiots, and imbeciles; and Mr. Loch himself supplies an excellent review of the occurrences of 1913. Speaking of national insurance work, he indicates that the greatness of the number of organizations helping to administer the Act is not generally appreciated. The National Union for Insurance, for instance, is a combination of 600 societies, while the General Federation of Trade Unions comprises 175 unions, yet these organizations count as only two on the official list of approved societies. In regard to the free choice of doctor, "which was one of the great attractions of the Act when explained on the political platform," it has, he suggested, been so watered down in practice that even a change from one doctor to another when both are on the panel can be effected only with difficulty. One result has been that many insured persons have preferred to pay for a doctor themselves, and he says:

It is difficult to feel that legislation which results in an arrangement so thoroughly and completely inequitable for insured persons, who have in this way to pay twice over—once to the doctor who does the work, and again to the doctor who does not do it—can be permanently satisfactory.

In regard to Poor Law administration, he remarks that its most disagreeable feature is that both its pecuniary cost and its moral burdensomeness remain essentially unaffected by the enormous development which has taken place in other forms of State philanthropy. The total number of paupers of all classes has hardly been affected by the introduction of old age pensions, the reduction in cost has been quite insignificant, and there are indications that even the trifling declines that have taken place are likely to be quite temporary.

Many other forms of relief, such as free meals to children and assistance to the unemployed, have also been granted tolerably freely for some years without in any way reducing the burden of pauperism; further, even the unexampled trade prosperity, which the country has now been enjoying for a series of years, has had no very considerable effect on the returns of pauperism, and it is alarming to consider what the public burden will amount to when the period of trade depression arrives, which is evidently on its way.

All the essays are of interest, but the part of the volume which really renders it unique is the section modestly entitled, "an introduction." In effect this is an encyclopaedia of information regarding the whole official and voluntary machinery for the prevention of poverty and ill health, and for the relief and amendment of the social, moral, and physical evils arising therefrom. Each part of the volume is remarkably alike in the comprehensiveness of its character, the logical arrangement of its contents, and the succinctness with which each paragraph is written.

NOTES ON BOOKS.

Dr. M. Langeron's *Précis de Microscopie*[4] is an excellent treatise on a rather heterogeneous group of subjects which have but two factors in common; they relate to medicine and require the use of the microscope. It will be useful to the beginner for the exact account of the theory of all branches of microscopy, for it enables him to obtain in a short time sufficient information about the different forms of objective and eyepiece, the different methods of illumination, the theory of staining and of fixation, and of polarization and ultra-microscopy. The exposition is characterized by the lucidity which it is so usual to find in French textbooks. The descriptions of technique are well selected, and are evidently the work of a man who has had to teach students. Sources of error are always mentioned in order that they may be avoided, and the *rationale* of the different procedures is clearly kept in mind. In addition to these very necessary features in a book intended for students there are innumerable practical hints which may be of use to the most experienced. In these days of highly differentiated microscopical technique it is good to find a teacher who emphasizes the fact that the real essential to useful work is the observant eye. Several times we find him emphasizing the fact that most of the great advances have been made by means of unstained preparations, even to the discovery of the spirochaete of syphilis by Schaudinn. The first part of the book deals with the optical part of the subject, the second with general methods of examination, preparation, and staining, whilst the third is devoted to the special technique required for protozoology, helminthology, entomology, histology, clinical medicine, and finally botany, which includes a chapter on bacteriology. The chapter on bacteriology is very short, and deals only with the fundamental points, but so far as it goes it is excellent.

The last number of the *Royal London Ophthalmic Hospital Reports* is largely devoted to the question of inheritance in retinitis pigmentosa, a paper by C. H. Usher on this subject occupying over 100 pages. The first article in the volume is by the late Mr. Nettleship on the progress of cases of retinitis pigmentosa sine pigmento and upon retinitis punctata albiscens, and his portrait forms a frontispiece. Mr. R. A. Greeves contributes a paper upon new growths of the lacrymal gland, and Mr. J. H. Parsons writes upon the visual determination of two points and gives a review of recent work upon the influence of illumination on visual acuity. Mr. A. C. Hudson has a short article upon the surgical treatment of corneal ulcers, followed by one upon serous detachment of the choroid and the ciliary body following perforations of the globe. His instructions for dividing anterior synechiae with a Graefe knife are clear and the method itself is practical and probably in many cases superior to those in which Ziegler's or Lang's knives are employed. The operation was modified by Lang from Abadie.

It is perhaps inevitable that an occasional omission should occur in a volume of such size and scope as the *Directory of Women Teachers for 1914*,[5] but such omissions are few and far between and the contents, as a whole, show every sign of careful editing. The book, indeed, is an achievement upon which the compilers have reason to congratulate themselves. The *Directory* is something more than a mere list of names and qualifications: it is also a guide to those interested in the secondary and higher education of girls, and contains information concerning secondary schools, universities, training colleges, schools of music, art, agriculture, domestic science and other similar institutions. It should, therefore, be of real service not only to parents but also to girls hesitating over the choice of a career. The book is well bound and printed, and the arrangement of its contents leaves nothing to be desired.

BRITISH SPAS.

BUXTON.

The closing of the Continental spas is already having an effect at Buxton, and numbers of visitors who have hitherto been sceptical are realizing that Buxton can offer them, in greater comfort and at less expense, the counterpart of almost every Continental treatment. The Marienbad Moorbäder, the Plombières treatment for colitis, etc., the Bad Ems installation of nasal and throat sprays, the Schwalbach chalybeate baths, the Nauheim treatment for heart troubles, are a few of the eighty-eight different treatments administered by skilled attendants at the baths.

Buxton, at an elevation of 1,000 to 1,200 ft. above the sea, is the highest town in the country, and the air is remarkably dry and bracing. Of the healthiness of the town and the excellence of the sanitary arrangements, no better evidence need be given than the death-rate, 8.1 per 1,000—among the lowest in the country. The surrounding scenery of the Peak District, the golf, tennis, croquet, and the excellent music, illuminated concerts, theatres, etc., amply supply the relaxation of mind necessary for the well-being of the patient.

HARROGATE.

In Harrogate there are no signs of war preparations, and the motto of the town for the moment is "Business as usual." Provisions are back at their old prices, and flour is actually cheaper than it was before war was declared. The hotels and hydros are offering their customary advantages, and the season is now at its height. The varied treatments at the baths continue as usual, and the extra accommodation added to the cure establishments ensures the utmost comfort to patients and visitors. Walks and drives in the beautiful scenery, with bracing moorland air, concerts, and entertainments, render Harrogate a most attractive resort. Thousands of people, whose holidays were postponed because of the outbreak of war, have still to make up their minds where to go, and among them and among the hundreds who have hurried home from Continental spas there must be many who would be well advised to continue their cure at Harrogate.

CLINICAL CONGRESS OF SURGEONS OF NORTH AMERICA.

(*Continued from page 305.*)

DEMONSTRATION OF SKIN DISEASES.

ON July 30th, Dr. J. H. SEQUEIRA demonstrated at the London Hospital a series of cases, which included three of lupus vulgaris that had remained cured since their treatment by Finsen light in 1903, and three of rodent ulcer which had been cured by *x*-ray treatment at dates ranging back to eleven years.

Skiagraphy of the Mastoid Region.

At the meeting of the division for surgical specialities DR. LOGAN TURNER (Edinburgh) read a paper illustrated with a series of lantern slides on the application of skiagraphy to the mastoid region and its use in the detection of disease. He divided the region into the upper and lower mastoid. The two mastoid regions were not always symmetrical. In 300 craniums examined the mastoids were found to be symmetrical in 247, or 82 per cent., and asymmetrical in 53, or 17 cent. approximately. The mastoid bones were of two types, sclerotic or diploic and pneumatic. In the sclerotic or diploic type of mastoid there was the danger of suppurative disease of the ear resulting in chronic suppuration of the middle ear or infection of the labyrinth. In the pneumatic type acute suppurative otitis could be more easily relieved and arrested. Skiagraphy in diagnosis was of little or no value in chronic middle-ear suppuration.

The paper was discussed by Mr. SIDNEY SCOTT (London), who pleaded for stereoscopic skiagrams. These were now possible by means of stereoscopic skiagraphy, and enabled the observer to understand better what existed within the mastoid region.

SEPTIC INVASION OF LATERAL SINUSES.

Mr. HUGH E. JONES (Liverpool) read a paper on the considerations which determine the extent of an operation in septic invasion of the lateral sinus. He did not commence an operation with the fixed idea that the venous channel must be obliterated, its lumen exposed, and, as far as possible, its walls excised from the torcular Herophili to the junction of the jugular vein with the innominate; nor did he say to himself, "All that is necessary is to plug up the sinus for an inch or two after removing the clot." The conditions found, he said, were so varied that the maximum operation might in one case be as futile as the minimum, in another the minor operation as successful as would have been the major, while in a third the maximum operation would appear to give the best, if not the only, chance of recovery. For that reason also it seemed to him that collected statistics were particularly baffling, and of little value as a general guide to the extent of the operation required in an individual case.

Modes of Infection.

Passing to the common mode of infection, he said that in the majority of cases there was a regular progression of events; that progress was interrupted at various stations for a shorter or longer period, according to the anatomical features, the virulence of the infection, and the resisting power of the patient. A peri-sinus abscess might exist for a considerable period before the wall of the sinus succumbed, or might even discharge itself through the fistula formed in the posterior wall of the mastoid without having invaded the sinus. When the sinus wall was penetrated and a clot formed, the process might be arrested at the jugular foramen in one direction and at the entrance of the superior petrosal sinus in the other, a firm clot with a small central abscess being the result. Tracing the progress backwards, when the clot reached the horizontal sinus there was nothing to prevent it from extending to the torcular Herophili, or small fragments from being carried by the backwash into the torcular, and once there the progress of the infection to the other great sinuses was easy. The question of extension to opposite sinuses had not, he considered, received the attention it deserved in the literature. While the sigmoid sinus was firmly clotted extension downwards was less likely to happen than in a backward direction; at one end there was the narrow jugular foramen occasionally crossed by fibrous septa with the curved recess beyond it into which the end of the clot would first be carried. At the other end there was a wide unobstructed sinus; he concluded, therefore, that extension downwards, if it took place at all, did so before the sigmoid clot was fully formed, or after disintegration had set in, or when a half-formed or breaking up clot was disturbed by operation or sudden movements of the head and neck. There were thus five stations at which the natural progress of infection might be temporarily arrested, namely, at the sinus wall, at the superior petrosal sinus, at the entrance into the bulb, at the exit from the bulb, and finally at the junction of the facial vein. It was for the surgeon to determine what stage had been reached at the time of the operation. Extension along the petrosal sinuses to the cavernous sinus was a comparatively rare occurrence. The much discussed anatomical variation whereby one lateral sinus was made to do nearly all the work of two claimed some consideration. The occurrence of a rudimentary sinus on one side was admittedly rare; Linser put it at 3 per cent., and there was no doubt that by the time the necessity for ligation of the internal jugular vein arose, especially in sinus thrombosis, compensatory collateral circulation had been to some extent established. The first necessity in treatment was a complete diagnosis before or during the early stages of the operation so that all that had to be done might be done at the time without recourse to a second operation.

Operative Procedures.

Dr. Hugh Jones also described the operative procedures that he prefers. In every case of temporal bone disease with symptoms suggesting the presence of a peri-sinus abscess or the onset of pyaemia, the sigmoid sinus should be exposed with the least possible disturbance to its walls until healthy wall was seen and the blood in the part was judged to be fluid and the lumen controllable. This might involve removing bone up to or even over the torcular Herophili and down to within reach of the jugular foramen. If no disease was apparent except the extradural abscess and so-called "healthy" granulations springing from the sinus wall, and only one rigor had been observed, it was advisable to wait. If the pyaemia was established, but not severe, and there was a limited occluding clot in the sigmoid, compression should be applied above and below the clot, the clot removed, the outer wall excised between the compresses, and the cavity packed with gauze. If the sinus was obviously diseased, but its contents were partly fluid and the systemic symptoms marked, the internal jugular vein should be exposed in the neck. Even if the sinus was not obviously diseased, and the blood was fluid, with severe pyaemia or symptoms of bulb-thrombosis, the internal jugular vein should be exposed and both sinus and vein occluded, the intervening part being drained and, if necessary, plugged. If the sinus was clotted and the lower limit of diseased wall or clot could not be reached, the vein should be exposed in the neck. This was merely the application of the principle of exposing healthy wall beyond both ends of the clot, without undertaking the much longer and generally unnecessary operation of exposing the bulb. The internal jugular vein at the entry of the common facial vein having been laid bare, several courses should be considered. If the vein was of normal size, looking healthy, and blood was flowing freely through it, it was best to compress temporarily and remove the clot from the sinus down to the jugular foramen; if there was a free flow of blood into the sinus, the sinus should be plugged after draining, and the neck wound should either be closed or Voss' provisional ligatures put in, according to the severity and duration of the systemic symptoms. If the vein was collapsed above the facial, but healthy and full of blood below, it should be tied in two places and divided above the facial, bringing the upper end into the wound and endeavouring to clear out the clot from the bulb by gentle irrigation. The same procedure could be adopted if the upper vein was clotted, but the clot did not reach to the facial vein, and the lower vein was healthy. It was easier in these circumstances to clear the bulb than when the vein was collapsed. When the clot extended beyond the facial junction it was better to tie and divide the internal jugular as low down as possible in the neck. Having dissected up the

vein and tied off the tributaries, including the facial, he excised the greater part and brought the upper end into the wound. There was always a temptation to leave the vein unopened the first day for fear of severe haemorrhage, but the risk of extension of sepsis from the upper vein was too great, and drainage from sinus to vein should be established at once.

The paper was discussed by Mr. Hunter Tod (London), who commented on the small percentage of cases of septic invasion of the lateral sinus which were recognized in the first instance as aural in origin.

Cleft Palate.

At the meeting of the division of surgical specialities a discussion took place on the surgery of cleft palate.

Dr. George V. I. Brown of Milwaukee, whilst in favour of delaying the operation until the age of 18 months, did not contest the advantage of an earlier operation when conditions were favourable.

Dr. Joseph Eastman of Indianapolis spoke of the factors of safety in cleft-palate surgery. Among them was local anaesthesia, which, in addition to other advantages, lessened the amount of blood swallowed. The latter often caused pyrexia. It was obvious that surgeons who operated in the second or third year would have a lower mortality than those who operated earlier. At the same time it would be difficult to say how large a percentage of those not operated upon early perished from disturbances of nutrition before the third year.

Dr. Truman W. Brophy of Chicago advocated operation by the compression method, and in early infancy, before the sixth month.

Sir Arbuthnot Lane said it was formerly taught and universally believed by surgeons that the age of 4 years was the right time to operate for cleft palate. That did not fit in with his views of the mechanical development of the face; he therefore operated at one day old, and at once put into commission all the factors that were in abeyance.

The papers were further discussed by Mr. James Berry and Mr. Percy Legg of London. The former stated his grounds for being opposed to the views of Sir Arbuthnot Lane. The latter was mainly in agreement with Mr. Berry. He did not regard the operation as a life-saving one. It should be performed before the time arrived for speech, namely, within the first year. No operation he considered to be of any service unless the child was taught to speak afterwards.

Ophthalmology.

On Friday night papers on ophthalmology were read and discussed.

Lieutenant-Colonel R. H. Elliot, I.M.S. (Madras), in a paper on the sclero-corneal trephining operation for glaucoma, said that the impaction of iris within the trephine hole ought to be carefully avoided.

The paper was discussed by Mr. Treacher Collins (London), who said that from the first eyes he examined he assumed that entanglement of the iris was an essential part of establishing a filtration scar; but after examining Colonel Elliot's cases he found that his assumption was incorrect.

Mr. F. Richardson Cross of Bristol, in a paper on operative procedure for strabismus, said he was not in favour of an operation until after a course of glasses had been tried. Before 5 years of age he advised the correction of any errors of refraction by glasses, after that age glasses were of no avail.

The paper was discussed by Mr. Bishop Harman of London, who said that squint, from the parent's point of view, was a deformity only, but from the godfatherly point of view of the ophthalmic surgeon it was a matter of vision. The eye should be attended to at once. Simple measures had a marked effect. For instance, a bandage on the good eye for a month might do wonders, might alter the squint, and even shift it to the other eye.

Radiation in Cancer.

Dr. C. Jeff Miller (New Orleans), on July 30th, gave a short outline of his impressions of Professor Krönig's work at the Freiburg clinic. Many cases of cancer had been treated by *x* rays with good results. The treatment had been carried out in cases of deep-seated carcinoma, both early and inoperable, and had been shown to cause disappearance of the growth. He had been much impressed by what he had seen, but was not absolutely convinced.

Treatment of Uterine Cancer.

Dr. James F. Percy (Galesburg, Illinois), in the course of a paper on the treatment of inoperable carcinoma of the uterus by the application of heat, said that carcinoma cells were killed by a temperature of 130° F., whilst normal tissues could stand 135° F. to 140° F. He showed lantern slides illustrating his various instruments. The amount of heat used was controlled by the hand of the operator passed into the pelvis through the opened abdomen. Cancer cells could be destroyed by the same elements that destroyed normal cells, and something was wanted which would only kill the cancer cells; *x* rays were limited in their application. Heat had been used for a long time, but in the wrong way. Tumours had been arrested in animals by raising the temperature of the body to 104–105° F. All methods of treating carcinoma derived from a laboratory had proved useless, unless they were attended by the production of pyrexia, when the growth might degenerate. The temperature of the whole human body could not be raised to a sufficient degree without danger to life. Local heat had been tried by means of hot air, hot water, fulguration, etc., and results had improved when these methods had been combined with operation. An electric heating iron was the easiest and best way of applying heat; it could be raised to any temperature and accurately regulated. A low degree of heat was used, and the temperature of the whole mass raised until the surgeon, wearing a medium thickness rubber glove, was unable to retain his grip on the growth with any comfort; this temperature was then maintained for from ten to fifteen minutes. Charring of the tissues should not occur, the iron not being sufficiently hot either to scorch cotton-wool or to cause a smell of burning tissues. Cancer was destroyed at about 112° F. to 131° F., and the fundamental idea was not cauterization but the raising of the whole mass of growth to a temperature at which cancer cells died. After the main mass had been treated by this means, *x* rays, etc., might be used for the other deposits. A large growth should not be treated at one sitting, but two or even three applications should be made. The treatment did not encourage metastasis, and the results were good. There was, however, a decided tendency to late secondary haemorrhage, and it might be that preliminary ligature of the internal iliac arteries was a necessary precaution. He was convinced that if all cases of cancer of the uterus were submitted to this treatment many patients would be relieved and many actually cured.

Dr. Thomas Wilson (Birmingham) said that the operative treatment of cancer of the uterus was that which had so far stood the test of time. It had made slow but sure progress. Early methods cured about 2 per cent. of cases; the introduction of vaginal hysterectomy raised this to 4 to 10 per cent. Wertheim's operation had still further increased the percentage of cases, and in Great Britain was becoming the routine method of procedure. It was the only way by which infected glands could be excised, and Wertheim had published 14 cases of uterine cancer with infection of the glands at the time of operation which had shown no recurrence of disease after a lapse of five years. The final results obtained in Great Britain were slightly inferior to those of the best Continental clinics but they were steadily improving. The total number of operable cases had doubled in the last ten years, and the number of cases remaining cured after five or more years should now be about 25 per cent.

In the discussion on these papers, Dr. Joseph C. Bloodgood (Baltimore) expressed the opinion that surgeons had hitherto been overwhelmed by their technique, and that attention should be concentrated on the diagnosis of the beginnings of cancer. In the very first stages operation was simple, and results would be infinitely better than at present. The general public ought to be educated to the early recognition of cancer, and in this connexion he expressed the opinion that cancer never began in a healthy spot.

INTESTINAL STASIS.

Sir BERKELEY MOYNIHAN, in introducing a discussion on this subject, said that it was stated that certain bands, webs, membranes, or veils were to be found along the intestine, that these led to stasis, and that the auto-intoxication from this was the cause of certain diseases and exaggerated others. There was no dispute as to the existence of these bands, but with the exception of those at the hepatic and splenic flexures of the colon he thought they were of congenital origin, and could be demonstrated in the fetus and had been described for a very long time. The appearances of the intestine in these cases did not suggest obstruction, and the trouble was probably due to an inability of the intestine to empty itself. He described the appearances and symptoms of a person suffering from a marked degree of stasis, and said that he thought that in this type surgical interference was indicated. With regard to cases of tubercle and rheumatoid arthritis, he had seen cases undoubtedly wonderfully improved after operation for intestinal stasis, but it was not proved that the improvement had been the direct result of this procedure, and it might be due to other causes.

Sir BERTRAND DAWSON said that mechanical effects could not be the only cause of intestinal stasis, and he thought that there was an infective element in addition. There might first of all be a congenital or acquired habit of constipation and subsequent mild infection from the teeth or naso-pharynx. The condition then went from bad to worse until it reached a stage in which, though the constipation might be cured by drugs or enemata, the symptoms of intestinal stasis remained, because the large intestine itself had become a source of evil. He agreed that the colon should be removed, and thought that the fact that a patient showed a relapse after ileo-sigmoidostomy whenever the colon refilled, proved that the symptoms were not due to ileal stasis, but to derangements in the functions of the colon. He urged a more careful selection of cases for operation. The colon had an important function and these operations were severe, so that the indications for operation should be clear.

Sir ARBUTHNOT LANE said that he had nothing to add to what he had often said before about intestinal stasis. If his theories were true they would stand the test of time; if not they would fail. The more civilized an animal or man became the more static he became also, and if he became the subject of stasis then he was more susceptible to invasions of tubercle or other infections.

THE NEXT CONGRESS.

At the conclusion of the Congress, Dr. RODMAN, President of the American Medical Association, said that all the visitors had been profoundly impressed by the hospitality and kindness received in Great Britain, and that the clinical demonstrations and surgical work had been above expectation. Resolutions confirming these sentiments were carried unanimously.

Dr. GEORGE E. ARMSTRONG announced that Dr. Mayo of Rochester had been chosen President elect of the Congress, and Dr. MAYO returned thanks for the honour.

SECRET REMEDIES.

REPORT OF THE SELECT COMMITTEE.

THE Select Committee on Patent Medicines appointed by the Treasury in May, 1912, has presented its report, which was issued to the press on Wednesday evening, August 26th.

FINDINGS.

The Committee reports that after careful consideration of the evidence (which has been reported in our columns from time to time) it finds as follows:

1. That there is a large and increasing sale in this country of patent and proprietary remedies and appliances and of medicated wines.

2. That these remedies are of a widely differing character, comprising (*a*) genuine scientific preparations; (*b*) unobjectionable remedies for simple ailments; and (*c*) many secret remedies making grossly exaggerated claims of efficacy; causing injury by leading sick persons to delay in securing medical treatment; containing in disguise large proportions of alcohol; sold for improper purposes; professing to cure diseases incurable by medication; or essentially and deliberately fraudulent.

3. That this last-mentioned class (*c*) of remedies contains none which spring from therapeutical or medical knowledge, but that they are put upon the market by ignorant persons, and in many cases by cunning swindlers who exploit for their own profit the apparently invincible credulity of the public.

4. That this constitutes a grave and widespread public evil.

5. That in British Dominions and foreign countries severe legal restrictions exist, and that there is a tendency still further to strengthen the law against these articles.

6. That no Department of State and no public officer is charged with the duty controlling the sale and advertisement of proprietary remedies in this country; that the Home Office and the Local Government Board are virtually powerless in this respect; that the Privy Council Office, though supposed to be specially concerned with the sale of drugs, has no initiative in the matter, and in fact, it fulfils no useful function in this connexion.

7. That the existing law is chaotic and has proved inoperative, and that successful prosecution for fraud in the advertisement and sale of secret remedies is fraught with the greatest difficulty, though the Public Prosecutor has perhaps not sufficiently tested the powers of the existing law in respect to such cases.

8. That consequently the traffic in secret remedies, except as regards scheduled poisons and the grosser forms of impropriety, is practically uncontrolled in this country.

9. That this is an intolerable state of things, and that new legislation to deal with it, rather than merely the amendment of existing laws, is urgently needed in the public interest.

10. That grave injury is caused to the public by the existing large sale of medicated wines.

11. And that while, for reasons already given, it is not desirable to require the exhibition of formula of every secret remedy, nevertheless it is improper that under the protection of the law enormous quantities of alleged remedies should be sold the composition of which is unknown to any person except the manufacturers of them; and that therefore the formulae of all secret remedies should be required to be communicated to a competent officer appointed under the authority of a Minister of State, but that such formulae should not be divulged to any other person except as hereinafter recommended.

RECOMMENDATIONS.

The Committee therefore recommends:

1. That the administration of the law governing the advertisement and sale of patent, secret, and proprietary medicines and appliances be co-ordinated and combined under the authority of one Department of State.

2. That this administration be part of the functions of the Ministry of Public Health when such a Department is created, and that in the meanwhile it be undertaken by the Local Government Board.

3. That a competent officer be appointed to this Department, with the duty of advising the Minister at the head of the Department concerned regarding the enforcement of the law in respect of these remedies.

5. That there be established at the Department concerned a register of manufacturers, proprietors, and importers of patent, secret, and proprietary remedies, and that every such person be required to apply for a certificate of registration and to furnish (*a*) the principal address of the responsible manufacturer or representative in this country, and (*b*) a list of the medicine or medicines proposed to be made or imported.

6. That an exact and complete statement of the ingredients and the proportions of the same of every patent, secret, and proprietary remedy; of the contents other than wine, and the alcoholic strength of every medicated wine, and a full statement of the therapeutic claims made or to be made; and a specimen of every appliance for the cure of ailments other than recognized surgical appliances, be furnished to this Department, such information not to be disclosed except as hereinafter

recommended, the Department to control such statement, at their discretion, by analyses made confidentially by the Government chemist.

7. That a special court or commission be constituted with power to permit or to prohibit in the public interest, or on the ground of non-compliance with the law, the sale and advertisement of any patent, secret, or proprietary remedy or appliance, and that the commission appointed for the purpose be a judicial authority, such as a metropolitan police magistrate sitting with two assessors, one appointed by the Department and the other by some such body as the London Chamber of Commerce.

8. That the President of the Local Government Board (or Minister of Health) have power to institute the necessary proceedings to enforce compliance with the law, the sale, and advertisement of any patent, secret, or proprietary remedy or appliance.

9. That a registration number be assigned to every remedy permitted to be sold, and that every bottle or package of it be required to bear the imprint "R.N. . . ." (with the number), and that no other words referring to the registration be permitted.

10. That in the case of a remedy the sale of which is prohibited, the proprietor or manufacturer be entitled to appeal to the High Court against the prohibition.

11. That the Department be empowered to require the name and proportion of any poisonous or potent drug forming an ingredient of any remedy to be exhibited upon the label.

12. That inspectors be placed at the disposal of the Department to examine advertisements and observe the sale of proprietary remedies and appliances.

13. That an annual fee be payable in respect of every registration number issued.

The Committee makes the following recommendations regarding the amendment of existing laws:

1. That the Stamp Acts be consolidated and amended to remove the numerous existing anomalies and unreasonable exceptions. In this connexion, pure drugs vended entire under a fancy name should no longer be exempt from duty; the distinction between the name of an ailment, and the name of an organ the seat of that ailment, should be abandoned; and the exemption of medicines generating carbonic acid gas should be omitted (see Par. 16). Further, any reference in advertising matter to the Government stamp should be prohibited, and no name of a proprietor or firm should be printed upon the stamp.

2. That the Indecent Advertisements Act be amended on the lines of Lord Braye's Bill.

Your Committee further recommend the following legislative enactments:

1. That every medicated wine and every proprietary remedy containing more alcohol than that required for pharmacological purposes, be required to state upon the label the proportion of alcohol contained in it.

2. That the advertisement and sale (except the sale by a doctor's order) of medicines purporting to cure the following diseases be prohibited:

Cancer,	Diabetes,	Locomotor ataxy,
Consumption,	Paralysis,	Bright's disease,
Lupus,	Fits,	Rupture (without operation
Deafness,	Epilepsy,	or appliance).

3. That all advertisements of remedies for diseases arising from sexual intercourse or referring to sexual weakness be prohibited.

4. That all advertisements likely to suggest that a medicine is an abortifacient be prohibited.

5. That it be a breach of the law to change the composition of a remedy without informing the Department of the proposed change.

6. That fancy names for recognized drugs be subject to regulation.

7. That the period of validity of a name used as a trade mark for a drug be limited, as in the case of patents and copyrights.

8. That it be a breach of the law to give a false trade description of any remedy, and that the following be a definition of a false trade description: "A statement, design, or device regarding any article or preparation, or the drugs or ingredients or substances contained therein, or the curative or therapeutic effect thereof, which is false or misleading in any particular." And that the onus of proof that he had reasonable ground for belief in the truth of any statement by him regarding a remedy, be placed upon the manufacturer or proprietor of such remedy.

9. That it be a breach of the law—

(*a*) To enclose with one remedy printed matter recommending another remedy.

(*b*) To invite sufferers from any ailment to correspond with the vendor of a remedy.

(*c*) To make use of the name of a fictitious person in connexion with a remedy. (But it should be within the power of the Department to permit the exemption of an old-established remedy from this provision.)

(*d*) To make use of fictitious testimonials.

(*e*) To publish a recommendation of a secret remedy by a medical practitioner unless his or her full name, qualifications and address be given.

(*f*) To promise to return money paid if a cure is not effected.

The Committee believes that departmental and legislative action as outlined above will not inflict injustice upon any patent or proprietary medicine or appliance; that it will, alike by its operative and its deterrent effect, afford the public efficient and urgently needed protection against injury and fraud; and that no measures of a smaller scope will secure this result.

Medical News.

Owing to the necessary curtailment of the number of pages in the weekly issues of the British Medical Journal, all correspondents are particularly requested to write as succinctly as possible.

The ambulance of 200 beds which the American Hospital of Paris is now establishing is in need of an administrator and secretary having experience of hospital administration. The person appointed must speak French fluently as well as English. Offers should be addressed to Dr. Jarvis, 81, Boulevard Malesherbes, Paris.

The Seamen's Hospital Society has placed 200 beds at the disposal of the Admiralty in the Dreadnought Hospital at Greenwich. The hospital is close to the river, and patients can be removed from the vessel which brings them direct to the hospital. The number of beds could be increased if necessary. In addition the Society has offered 25 beds at its Albert Dock Hospital.

We are pleased to be able to state that the action against the British Medical Association and certain former members of the medical staff of the Mount Vernon Hospital for Consumption and Diseases of the Chest, which was instituted by the president and trustees of such hospital, has been settled by agreement between the parties.

Medical officers whose duties include school work are invited to attend a meeting of the School Medical Service Group of the Society of Medical Officers of Health to be held at 1, Upper Montague Street, Russell Square, London, W.C., on Saturday, September 5th, at 3 p.m., when a petition asking the Council to constitute a Branch of the Society to be called the "School Medical Officers Branch" will be submitted. The Honorary Secretary is Dr. A. Ashkenny, 38, George Road, Edgbaston, Birmingham.

The Yarrow Convalescent Home at Broadstairs, which was established some years ago and endowed by private benevolence, is intended for children whose parents may be of the professional and educated middle classes, but who are possessed of only limited means. An illustration of the desire of those responsible for the management of the institution to render it as efficient as possible is to be found in the erection last year of a dairy in connexion with the home, in order that the milk supplied to the children might be produced under the best possible conditions. On the occasion of the last celebration of founder's day Mr. A. F. Yarrow gave a very satisfactory account of the results which had followed this new enterprise. A comparison was made of the average gain in weight per child during two periods of ten weeks, one of which was prior to, and the other subsequent to, the date of the provision of the new milk supply; it was found there had been an improved daily increment in weight per child of nearly 30 per cent. That the milk of the home is now produced as it should be is evidenced from the statement made by Mr. Yarrow that it was found to contain on examination at the Lister Institute only 1,200 bacteria per cubic centimetre. The example set at the Yarrow Home might well be followed at other institutions.

British Medical Journal.

SATURDAY, AUGUST 29TH, 1914.

EPIDEMIC RISKS IN WAR.

TYPHOID, CHOLERA, AND DYSENTERY.

THE organization of the general hospitals of the Territorial Force seems everywhere to have been completed according to orders within the period allowed by the scheme of mobilization. At present the provision is very much in excess of the demand, but we understand that the staff of some at least have been warned that they may be asked to admit sick or wounded from the Expeditionary Force. Moreover, it is to be expected that a considerable number of patients suffering from diseases of greater or less severity will reach them in ever-increasing numbers from the Territorial Forces at home. Among these patients there will be, it is to be feared, cases of typhoid fever, and it is clear that the nursing of such cases in the Territorial general hospitals established in schools and other requisitioned buildings not primarily adapted to the purpose will present very serious difficulties.

As Sir William Leishman pointed out in the important letter published last week (page 369), no army in recent wars has escaped typhoid fever. In the South African war there were nearly 58,000 cases, the deaths (8,022) exceeded the total number of men killed in action, and in addition nearly 20,000 were invalided. Such measures as were possible in the circumstances have, it appears, been taken to protect by antityphoid vaccination the members of the Expeditionary Force, who will be very specially exposed to the risk of infection under campaign conditions in France and Belgium, but it would be rash to assume that the Territorial Force embodied and retained in this country will escape exposure to the dangers of typhoid fever in epidemic form, though it will no doubt be far easier to guard their sources of water supply and to attend to latrines and camp sanitation generally. These are among the first duties of the officers of the Royal Army Medical Corps (Territorial), and there are in addition available for consultation the sanitary experts who form the sanitary service of the Territorial army.

The medical officers of the Territorial Force, we are confident, have given most anxious attention to this matter, but it may not be out of place to state again that the benefits of inoculation are so well recognized in the regular forces that, though the treatment is voluntary in the British army, unlike the American in which it is compulsory, 93 per cent. of the British troops in India have been thus protected. The result is seen in the fact that last year the deaths numbered twenty, instead of the three or six hundred that used to occur before. We understand that the Vaccine Department of the Royal Army Medical College (Grosvenor Road, London, S.W.) is prepared, with the assistance of the Lister Institute and Sir Almroth Wright, to supply as much antityphoid vaccine as may be required.

But we have also to bear in mind the risk arising from typhoid carriers. It would be too much to hope that there are not among the men who are embodied in the Territorial Forces at home some—it may be a considerable number—who are passing the typhoid bacillus in a virulent state in the urine or faeces, or both, either continually or at irregular and undetermined intervals. The experience of the concentration camp of the American army during the Cuban war proved conclusively that infection spread in tents or huts and from tent to tent or hut to hut in an apparently capricious way, which could best be accounted for by assuming personal contagion from carriers. This must always be easy under the conditions of camp life.

During the three years 1911, 1912, 1913 there were notified in England and Wales, excluding ports, 30,109 cases of typhoid fever, and during the present year nearly 5,000 cases have been notified. Detailed records of all these are in the possession of medical officers of health, and it would not be a difficult matter to trace a proportion of those men of military age who have been affected, and place the information at the service of the medical officers of the Navy, Army, and Territorial Forces, who would thus be forewarned of possible carriers.

Professor Dreyer and Dr. Ainley Walker, in the letter published this week (p. 408) supporting Sir William Leishman's appeal to the profession, after expressing astonishment that in this day of crisis antityphoid inoculation has not been made compulsory in the military services, go on to direct attention to the risk of the occurrence of cholera and dysentery among the troops, especially those serving abroad. They express the opinion that in the case of both diseases there is evidence that a degree of protection can be conferred by means of suitable vaccines, and in this connexion we may refer to the paper on antidysenteric vaccination by Dr. Broughton-Alcock, published in our columns three weeks ago (August 8th, p. 306), in which he describes a method he considers to be both simple and practical.

Mention may also be made of the possibility of the use of vaccines against sepsis. Wounds produced by shells, whether on sea or land, almost inevitably become septic under the conditions of actual warfare, and a prophylactic inoculation of the wounded at the earliest possible moment might prove of considerable value.

THE GOVERNMENT AND HOUSING.

WITHIN four days of the outbreak of war the Government introduced legislation empowering the Board of Agriculture and Fisheries as regards agricultural districts and the Local Government Board elsewhere to make arrangements with local authorities or with authorized societies for the provision of houses for the working classes. The same measure gave power to the Treasury to lend sums for capital expenditure in this direction to the extent of four millions sterling. A circular letter has now been issued by the Local Government Board to the local authorities concerned drawing attention to the Act, which is entitled Housing (No. 2) Act, 1914. Information is asked for as to districts in which further housing for the working classes is required and in which unemployment exists or is likely to arise which the undertaking of building operations might prevent or mitigate. The local authorities are also asked to submit schemes for the consideration of the central departments. The period for which the loans will be granted will be sixty years as regards buildings and eighty years with respect to land. The rate of interest payable is to be that at which the Government may be able to borrow, and with regard to this it has been urged upon the President of

the Local Government Board by a deputation from the National Housing and Town Planning Council that the rate of interest should not be higher than was current before the war. Mr. Samuel pointed out, however, that no one could possibly forecast what the rates of interest would be for several years after the war. The enormous expenditure now going on would produce a scarcity of capital, and if in addition there was a trade boom the rate of interest would be high as a result of the demand for capital. It is hoped that public utility societies as well as local authorities will take advantage of the facilities offered by the Act, and in this connexion it is satisfactory to learn from Mr. Samuel that the Treasury will grant to these societies nine-tenths of the value of the property as against the two-thirds provided for in the Housing, Town Planning, etc., Act, 1909.

THE LONDON COUNTY COUNCIL AMBULANCES.

The concentration of the public mind on the munitions of war and the ancillary organizations essential to its efficient conduct cannot fail to bring under review the great improvement in ambulance construction and organization which has taken place during the last few years. It was the genius of Larrey, who earned the highest tribute ever passed on a fellow man by Napoleon, that first contrived and elaborated the *ambulances volantes* in the service of the Grande Armée. The term "ambulance" is applied both to the *hôpital ambulant*—a moving hospital, or a projection as it were from the hospital base—and to the vehicle for the conveyance of sick and wounded. The great improvement in speed due to motor power and the greater smoothness of running have made the need for full equipment of the civil ambulance with elaborate apparatus less needful. In military work the motor ambulances have still to be tested, and their relative efficiency compared with horsed ambulances. Meanwhile in civil work the supersession of the hand-stretcher, wheel-litter, and horsed ambulance by the motor machine proceeds apace. In the streets of greater London, as already in the city, these will soon be familiar objects. It is anticipated that the first London County Council motor ambulance will be ready early in October, and the remaining seven will be delivered as they are completed. It has been found necessary to make some rearrangement of the sites and distribution of the six ambulance stations comprised in the tentative scheme approved in March last. The sites of the stations already announced at North End Road, Fulham; Boundary Street, Shoreditch; High Road, Lee; London Road, Southwark; and Brixton Hill are already being prepared by direct employment of labour, and tenders have been invited and accepted for the erection thereon of wood and galvanized iron buildings, and for the installation of electric light and telephonic communication. Four of these sites have been easily found (as we all along suggested might be the case) on land already in the possession of the Council. The proposal to place a station in Devonshire Mews, Harley Street, had to be abandoned, and instead a site has been found in Herbrand Street, Euston Road, on one of the Council's housing sites. The proposal of the General Purposes Committee to appoint an officer at £400 to £500 a year to organize the working of the service broke down, and meanwhile the organization of the service is in the competent hands of Lieutenant Sladen, R.N., the Chief Officer of the Fire Brigade. With the inauguration of this service in the autumn, the Council will have at length put into operation the powers which were conferred upon it by the Metropolitan Ambulances Act, 1909.

NAPOLEON AND HIS MEDICAL OFFICERS.

M. Frédéric Masson, who has taken all knowledge about Napoleon to be his province, has contributed an introduction of much historic interest to the *Journal* of Lagneau, a surgeon of the Old Guard who followed the great emperor in his campaigns in Italy, Prussia, Poland, Spain, Austria, Russia, Germany and Belgium. This journal was not long ago published under the editorship of M. Eugène Tattet.[1] M. Masson says that in the military literature of the wars of the Revolution and the Empire the surgeons and physicians of the army have made a deep mark. Larrey, Percy, and Desgenettes, have left works the study of which is necessary to the understanding of certain campaigns, in particular that of Egypt, where their devotion and their eagerness to learn were particularly manifest. Although there is no certain proof of the fact, M. Masson seems inclined to believe that the medical officers did not accompany their comrades of the fighting ranks into captivity, perhaps because they were looked upon as non-combatants, and on this ground were liberated by the enemy; on the other hand, possibly they were the first exchanged. In 1743 an agreement that the hospitals, the wounded, and the military surgeons should be considered neutrals was concluded between the Duc de Noailles and Lord Stair. In 1759 a similar arrangement was made between the Marquis de Barail, commanding in the Province of Flanders, and General Henry Seymour Conway. This agreement included commissaries and chaplains, as well as doctors, hospital orderlies, and others attached to the service of the sick. The idea was making progress when the Revolution, in the very name of humanitarian principles, brought about the most violent reaction. The Convention decreed the immediate execution of prisoners, whether they were *émigrés* or soldiers of the Coalition, wounded or not wounded. There seems to be no mention of what was done with regard to the hospitals and the surgeons, but there is evidence which points to the fact that if the medical officers were accorded certain privileges it was some time before they came in force. Whenever the people rose, as in Egypt and in Spain, the first thing they always did was to butcher the sick, the wounded, and those who had charge of them. Governments, of course, can scarcely be held responsible for such breaches of common humanity. We are proud to think of the courage shown by doctors in the face of angry mobs. During the revolution of 1830, when a crowd came to attack the Invalides, Larrey, standing alone at the entrance, told them they would have to pass over his dead body before touching the sufferers under his care. In the same revolution Dupuytren met the inquiries of the police seeking for insurgents in the Hôtel-Dieu with the reply that he knew nothing about rebels; he had only wounded men there under his charge. In the campaigns against Austria in 1805 and 1809 much regard was paid on both sides to the medical officers. Napoleon gave gold snuff-boxes to a number of the surgeons attached to the hospitals of Vienna in recognition of their care of the French wounded. Louis Vivant Lagneau was a doctor of medicine at the age of 22, and had made arrangements to take over a practice in Paris when he was caught by the conscription and attached to the hospital at Bruges as surgeon of the third class. The demand for surgeons was so great that, notwithstanding facilities extended to students, almost anybody was accepted to fill the vacancies. We hear of the wounded being dressed by bandsmen, inspectors of forage, and men of all sorts and conditions. At the beginning of the wars of the Revolution numbers of seminarists and young priests were caught by the conscription, or enrolled themselves under the flag as a shelter against the Terror, quickly gained a superficial knowledge of minor surgery and gradually went on to operate. In order to give them a regular title, a general examination was after a time prescribed for all officers employed in the army. The medical officers had to suffer many indignities.

[1] *Journal d'un Chirurgien de la Grande Armée* (L. V., Lagneau), 1805–1815. Paris: Emile-Paul Frères, Editeurs, 1913.

They were subordinated, even on professional questions, to the executive, who claimed the right to punish them for breaches of regulations made solely with the object of keeping down expenses regardless of the welfare of the sick and wounded. This kept many excellent men out of the service. Moreover, army doctors could be dismissed without pension or allowance by the Minister of War as soon as a peace was declared. If war broke out again while they were trying to build up a practice in civil life, they were liable to be recalled suddenly to an existence of hardship and danger. They had little prospect of reward or honours. The number of military physicians and surgeons who received titles under the Empire was infinitesimal. It was more profitable to a man to have treated a member of the Imperial household for a cold than to have risked his life on the field of battle. We find only six barons—Boyer, Desgenettes, Heurteloup, Larrey, Percy, and Yvan, and of these Boyer and Yvan had no war service. This is in striking contrast with the multitude of generals who were made counts, dukes, and princes. There were, indeed, a few chevaliers, but these need not be counted, as the title, such as it was, went with the decoration of the Legion of Honour, or that of the Reunion, an order which was soon abolished by Napoleon himself. The pensions granted after years of active service, even to men who had been severely wounded, were scarcely enough to keep the souls and bodies of the veterans together.

THE CHILDREN'S TUBERCULOSIS SANATORIUM AT HOLT.

IN dealing with tuberculosis of the lung, two main considerations have to be kept in view. The first, and the most important, is to check the disease as soon as it shows itself, and the second, to keep it under effective control when it has become established. Hence it follows that the search for evidence of its presence cannot be begun too early in life, and, putting aside the debated question of subsequent immunity, it becomes of the first importance to counteract its virulence and cut short its initial stages wherever possible. Excellent work has been done in this direction for several years past at Holt in Norfolk, where a sanatorium has been recently established in permanent buildings, after its usefulness in temporary premises had been abundantly proved. Accommodation is provided for forty-three children, and they are further supplied, to use the words of the last report, "with those things which are generally absent in home life." Sufficient and suitable food, cleanliness, fresh air and general hygienic control may be regarded as the chief of "those things." While personal health is being maintained, the educational needs of the children are well supplied by means of open-air school. The value of this department has been recognized by the Board of Education and will be subsidized accordingly. The curative results obtained in the early cases, not acute and with only a small portion of lung involved, show remarkable success. A large proportion of the small patients, discharged as fit for the ordinary round of school life, have been found to remain equally fit for long periods up to the present time. Of those with more pronounced disease, a smaller percentage of success must be admitted, but in many cases the disease has been arrested and has remained so up to the last date of inquiry. Work such as this must appeal to every one who recognizes the value to the community of a steady reduction in the number of persons rendered incapable of usefulness as the result of neglected tuberculosis. The Children's Sanatorium at Holt has proved its value and may fairly ask for a larger measure of public support to enable it to meet the increasing demands which are being made upon it.

THE WAR.

THE VALUE OF ANTITYPHOID VACCINATION.

THE APPEAL BY THE WAR OFFICE TO THE PROFESSION.

WE have received the following letter from the Professor and Lecturer in Pathology in the University of Oxford, supporting the appeal from Colonel Sir W. B. Leishman in the JOURNAL of August 22nd (p. 369):

Sir,—It is to be hoped that the widest possible attention will be drawn to the important letter of Colonel Sir W. B. Leishman in your issue of August 22nd.

His statement that even now in the time of war "antityphoid inoculation remains, unfortunately, on a voluntary basis in our army" is an astonishing admission. It is difficult to believe that such a state of affairs will be permitted to continue once the medical profession and the public are made clearly aware of its existence.

Colonel Leishman quotes figures to show the value of antityphoid inoculation, but the matter is one which requires no discussion at the present time. The facts are indisputable, and they are plain enough to be within the comprehension of every intelligent person. There is no kind of question that inoculation properly carried out is protective against typhoid fever.

There is equally no question that casualties from typhoid fever among unprotected troops may acquire an importance at least as great as that of casualties from wounds. And as Colonel Leishman points out, it is hardly less certain that among the troops which will be collected in large camps at home a similar danger of widespread epidemic typhoid fever will arise.

Surely on this account alone it is high time that the Army Medical Department should be empowered to insist upon compulsory inoculation. That they should in time of war be required to proceed by "persuading officers and men" is well-nigh incomprehensible.

It is also necessary to direct attention to the fact that typhoid fever is not the only epidemic disease, nor the most serious, which an army in the field has reason to fear. Cholera is more severe, and dysentery may prove more intractable. Either of these diseases may well make its appearance in the course of a war which involves the greater part of the Continent of Europe, and in which troops from Russia and from the Balkans will continue to be engaged. In the case of both diseases there is evidence that a degree of protection can be conferred by means of suitable vaccines.

Without entering here into a discussion of the question of dysentery, about which it might be held by some that uncertainty remains, it may be stated with confidence that the necessary inoculations against cholera and typhoid could be carried through on each unit within about a month without occasioning on an average the loss of more than four or five separate days of military training. In the majority of cases each inoculation causes at most a day's slight indisposition, while the diseases themselves would mean in many cases the death of the man, and in very many more his loss as an effective.

It is evident that any considerable loss of effectives from diseases against which protective inoculation is available must be regarded as to a great extent an avoidable and unnecessary loss. Surely, even from purely military considerations, it cannot be permitted

that our relatively slender forces should be subjected to avoidable losses.

Accordingly it appears desirable that the appeal issued by Sir W. B. Leishman should be supported in the strongest possible manner by the profession, and that no effort should be spared to emphasize the necessity of rendering protective inoculation compulsory throughout the army.

The labour involved in carrying out a thorough scheme would certainly be heavy. But there are, besides the Lister Institute, a considerable number of university and hospital institutions in the country capable of giving assistance. These, no doubt, would gladly help, if required, in a task of such importance.

We are, etc.,

G. Dreyer.
E. W. Ainley Walker.

Department of Pathology, University of Oxford, August 25th.

THE ROYAL NAVY.

The arrangements made by the Medical Department of the Royal Navy for dealing with the sick and wounded from the fleet seem to be as complete as the foresight of the Admiralty officials and the good will of the coastwise voluntary hospitals can make them. They are adapted both to meet the emergency of a great general action, and to deal with the needs of individual vessels which may suffer in minor encounters.

The first line is formed by the hospital ships which act in conformity with the rules of the Geneva Convention. Notification has been made to the International Authority that the British Navy has eight hospital ships afloat, of which number five are in home waters, Germany six, and Austria three. The duty of the British hospital ships will be to collect the wounded from any general action and to give them first treatment. The ships have a full complement of medical officers and probationer surgeons (dressers). The hospital ships are based on the large Royal Naval Hospitals, and the wounded from the ships will be conveyed to these great institutions where there is a full staff of medical officers reinforced by the special consultants whose names were published last week.

On the East Coast the chief Royal Naval Hospital is that at Chatham with nearly a thousand beds. South of this is the Royal Marine Infirmary at Deal, which is a large hospital with a full medical and sick-berth staff and nurses. Northward there are the so-called Sick Quarters at Shotley in Harwich Harbour, also a modern hospital with a full complement of surgeons, nurses, and sick-berth staff. In the estuary of the Humber a hospital with 250 beds has been organized by Lady Nunburnholme with the sanction of the Admiralty. In the Firth of Forth the Admiralty has accepted a voluntary base hospital established by H.R.H. Princess Christian under the direction of Mr. Alfred Mosely, C.M.G., as an extension of the Naval Sick Quarters at South Queensferry opposite the naval establishment at Rosyth, a surgical staff drawn from the London Hospital, and orderlies supplied by the St. John Ambulance Association.

To meet the needs of individual ships and of the units of the destroyer flotilla which may become engaged in minor actions, these hospitals will be available if convenient. The wounded from the mine-layer *Königin Luise* were, for instance, landed at Shotley, but, in addition, offers have been made to the Admiralty by all the principal hospitals in East Coast towns to receive sick and wounded, and these have been accepted for specified numbers amounting altogether to a large total. Similar offers have been received and accepted from hospitals in towns on the south and west coasts. As a rule, it will be possible to convey wounded from these minor actions direct from their ship in ambulances to the voluntary hospital of the coast town. These offers will also be available to relieve the Royal Naval Hospitals should there be any sudden press of wounded. Ships afloat, including the hospital ships, are in wireless communication with Admiralty head quarters, and if in doubt as to their port for wounded will receive instructions.

Numerous offers have been received to form naval hospitals in various localities by private or municipal enterprise, but it has been considered advisable to accept only those, such as the hospital at Hull, which fit in with the schemes worked out beforehand.

Should any pressure of sick and wounded occur in the Royal Naval Base Hospitals the aim will be, following the principle recognized by all navies and armies, to transfer convalescents as early as possible to convalescent homes or inland hospitals willing to receive such cases. The Medical Department has a long list of such places, and it is to this purpose that private individuals may most usefully turn their energies, although the offers conditionally accepted would appear to be sufficient to meet any need that can at present be foreseen.

No reference has been made here to the great Royal Naval Hospitals at Haslar (Portsmouth) and Plymouth, to the Royal Hospitals at Portland and Haulbowline (Cork Harbour), nor to the Royal Naval Hospitals at Malta, Gibraltar, Bermuda, the Cape of Good Hope, and Hong Kong.

THE ARMY AND TERRITORIAL FORCES.

Typhoid Prophylaxis.

The laboratory at the Royal Army Medical College, Millbank, habitually keeps up a supply of antityphoid vaccine sufficient to meet all the needs of troops in India or elsewhere, and at the date of mobilization it had enough in store to meet the requirements of all regular troops for many months to come.

If, however, very large numbers of the Territorial troops were simultaneously to make up their minds to submit to inoculation, the manufacturing resources of the college itself might be overtaxed. Consequently arrangements have been made with the Lister Institute and the vaccine-therapy department of St. Mary's Hospital to furnish supplies if required. In any case, therefore, every requisition for a supply of antityphoid vaccine made by a Territorial medical officer would be at once met.

It is hoped that sooner or later the whole of the Territorial Force will have been protected against typhoid by inoculation; to this end the authorities, so soon as mobilization began, issued circulars to all Territorial medical officers attached to units urging the importance of inoculation, and as soon as mobilization was completed and the various units were in occupation of their assigned positions throughout the country, Sir William Leishman began to pay personal visits to each unit for the purpose of interviewing the medical officers concerned and posting them up on the whole subject.

Surgical Work.

The arrangements in regard to operative work seem equally well thought out. Attached to every base-hospital there is at least one R.A.M.C. officer who has specialized in operative surgery, and in addition one or more civil surgeons specially selected on account of their surgical accomplishments.

A considerable number of all civil surgeons sent abroad are Fellows of the Royal College of Surgeons, and many of them hold surgical appointments in civil life.

So far as actual operating is concerned, all requirements have been very fully met, but later on it may be thought proper to make further arrangements of a somewhat different character. On the staffs of the Territorial General Hospitals in this country there are men of the very highest surgical skill and attainments, and if the services of some of them can be spared at home they may possibly be utilized by asking them to volunteer to go abroad for attachment to base hospitals, the idea being not that they should operate but that they should be available as consultants in the treatment of doubtful cases.

Sanitary Work.

With the Territorial Force.

Medical officers attached to Territorial units are the responsible advisers of commanding officers on matters of sanitation both in camp and on the march; that is to say, attention to sanitation is part of their ordinary duties.

Apart from this, there is on the head quarters staff of each Territorial division one special sanitary officer whose duty it is to supervise the sanitation of all units in the command. He visits the units, if need be, consults with

the medical officers in direct charge of them, and issues to these any special instructions that he may think necessary. It is this officer who is directly responsible through the A.D.M.S. and the Divisional Commander for the well-being of all units in each command, so far as these can be affected injuriously by defective sanitation.

Many of these divisional sanitary officers are county medical officers of health or men occupying similar positions. Should at any time large bodies of troops be quartered in centres of population it will be the duty of these divisional sanitary officers to arrange with the local medical officers of health for the districts in which they live—as to any special steps that should be taken. The officers of the *(B)* Division of the Sanitary Service (T.F.)* are not likely to be employed as a class, though some of them may be employed as individual medical officers of health.

Apart from these arrangements there is a sanitary officer with a staff of assistants at every port of embarkation and at every base throughout the country.

Abroad.

The arrangements abroad are of the same general nature, but in addition there is a large body of men controlled by specially qualified and experienced officers of the Royal Army Medical Corps, engaged in looking after the sanitary environment of the troops, wherever they are serving. The whole of the men employed under these officers are specially trained, and in order to secure that their work should be effective they were the very first men sent abroad, the object being that they should make preparations in advance by examining water supplies, etc., etc.

Local Hospital and other Medical Arrangements.

Birmingham.

Great attention has been given to the sanitary requirements of the 1st Southern Territorial General Hospital mobilized in the buildings of the University of Birmingham, and authority has been given to expend a large sum of money on the sanitary fittings and the necessary structural alterations which are nearly complete.

One of the great advantages of the University buildings at Edgbaston is that there is a large kitchen which can cook for about 2,000. The lighting, heating, and ventilation of the buildings are worked by a power station in the grounds.

The plans for converting the University buildings into a hospital were prepared about five years ago, and have been constantly revised since. The men of the R.A.M.C.(T.) came into residence on the first day of mobilization and were quartered in the physics block, which makes excellent barracks. The work of converting the various rooms into wards, offices, store-rooms, theatres, etc., was enormous, as the rooms were filled with heavy tables, while in some there were large pieces of machinery which had to be taken to pieces and removed. This work was done by the R.A.M.C.(T.) men, who worked incessantly and very willingly from early morning until late at night.

Agreements had been made with different firms in the city and neighbourhood some years ago to supply equipment in case of need within seven days and were promptly fulfilled. The whole of the equipment was in the hospital within the week, and was placed in the various wards, stores, etc. It is found that a large lecture theatre makes a most excellent store.

The administrator of the Hospital, Lieutenant-Colonel F. Marsh, F.R.C.S., is to be congratulated on having accomplished the task of mobilizing a general hospital in so short a time. During the process of mobilization the other permanent officers were Major J. E. H. Sawyer, M.D., who acts as Registrar, Captain S. G. Webb, M.D., who undertook the duties of Company Officer to the R.A.M.C.(T.) men numbering 109, and Lieutenant Bennison the Quartermaster. On all these officers fell a great deal of responsibility, and they worked hard. The strength of the R.A.M.C.(T.) men was 46 on mobilization, but in three days enough recruits were enlisted to make the numbers up to 109. The new recruits are a most excellent class of men.

On the eighth day of mobilization the medical officers whose services were available on mobilization reported themselves, and they are all ready to take up their work when the occasion arises. They are chosen chiefly from the consultants of the city, and their duties at the hospital are being so arranged as to interfere as little as possible with their work at the civil hospitals and their private practice. To serve in a military hospital means a great sacrifice of income to most of them.

The Territorial sisters and nurses, with Miss Lloyd as their matron, reported themselves on the same day as the medical officers. They number 91, and they have been chosen chiefly from the hospitals in the neighbourhood. Some, however, have come long distances. Their qualification to serve was a training of three years in a civil hospital of over fifty beds. They have been lodged in the Women's Hostel of the University, which is about 300 yards' distance, and is just large enough for them. These nurses have been in residence ever since, and have found plenty of work to employ them in further arranging the wards, etc., covering splints, and nursing a few Territorial soldiers who have been admitted.

The number of beds provided is 520, but they could be increased to about 800 in the buildings themselves. There are large playing grounds around on which wards under canvas or in huts could be established. Such expansion, however, would of necessity mean a corresponding increase in the personnel of the hospital.

A guild has been in existence for some years in connexion with the hospital, which has provided a large number of useful garments, etc.

Arrangements are being made to carry on the educational work of the various departments of the university, which are being used for military purposes, in other buildings in the city.

Portsmouth.

Portsmouth has become quiet since the departure of the troops. But a few days ago further regiments of khaki-clad men arrived here from no one knew where and left for France in the early grey hours of the morning, secretly and silently.

Three council schools have been transformed into up-to-date hospitals, and are ready for nursing our sick fighting men back to health and strength. The Eye and Ear Hospital is prepared to render war service at the shortest notice, as all the new wards are now in order. Splendid work is being done by the Soldiers' and Sailors' Families Association in relieving the families residing in Portsmouth who need assistance owing to the war, and so render it unnecessary for any of them to be driven to any extreme measure, such as selling up their home. At a meeting of the local executive committee of the National Relief Fund, held on August 22nd, it was stated that the National Relief Fund will be available to assist civilian cases. For the moment grants are only being made for dependants of soldiers and sailors. It is the intention to allocate money to the different districts, so far as possible, with reference to their respective needs. The local relief fund now amounts to £3,700, and from this it is intended to forward £3,000 to the central fund, from whence the local grants will come.

Glasgow Territorial Medical Units.

On the outbreak of war the mobilization of the Territorial medical units in Glasgow was carried out satisfactorily, and after the usual period the field units departed to their pre-arranged war stations. The Lowland Mounted Brigade Field Ambulance mobilized within the buildings of the University, and the 1st and 2nd Field Ambulances at the head quarters at Yorkhill. The 3rd and 4th General Hospitals have taken up their quarters at Stobhill Parish Hospital, which has been fully equipped and staffed in readiness for such service as is required. According to previous arrangement the Parish Council of Glasgow removed the 800 patients from the hospital immediately on being notified, to other institutions belonging to the Council. In the General Hospitals now ready there is accommodation for 1,040 patients, and this can be increased if necessary. The equipment was carried out by the Territorial Force Association, and the Scottish Branch of the Red Cross Society provided all auxiliary assistance, such as garments, comforts, and appliances. The Society has also made arrangements for a service of

* There are two divisions of the Sanitary Service (T.F.): (*A*) Sanitary Companies, of which the Army List shows two only, the 1st and 2nd London, and (*B*) sanitary officers whose services are available should they be required.

motor cars to be available on the requisition of the officers commanding the hospitals. Store room has been provided by the Corporation of Glasgow in St. Andrew's Halls, and special arrangements have been made by the executive of the Society for the due concentration of all voluntary effort.

Cambridge Research Hospital.

The Research Hospital at Cambridge has been offered to the War Office as a fully staffed and equipped hospital for the reception of about twenty wounded officers for a year or such shorter time as may be required. Mr. Otto Beit has undertaken to provide funds for the complete equipment and maintenance of the hospital, and for a full medical, surgical, and nursing staff while used for this purpose. Until required by the War Office the work and research of the hospital will continue as usual. The hospital is fully equipped, and possesses an *x* ray department, operating theatre, and pathological laboratories.

THE BRITISH RED CROSS SOCIETY.

Continental Base at Rouen.

THIS week finds the head quarters of the British Red Cross Society at Devonshire House, Piccadilly, W., very busy dispatching a big unit with supplies to Rouen, which is to be the medical base on the Continent. How the various contingents will subsequently be dispersed depends upon the developments of the situation. Although located in France, it is to be understood that the unit is intended for British wounded.

Information has reached London that the unit sent to Brussels, as already reported, has been allowed to withdraw to Antwerp. Before the German occupation, however, two of the surgeons proceeded to the Belgian front, at the request of the Belgian military authorities. Of their present whereabouts information is not yet to hand.

Rest Station.

Through the generosity of a lady who desires to be anonymous, the Red Cross Society has been able to establish a rest station at Havre. It has been planned so that it can be removed to any other port where the sick are detrained, if the requirements of the War Office dictate this transfer. The rest station is interposed between the ambulance trains bringing the wounded from up country and the ship that will carry them to England. An ample staff, cooks, cooking appliances, and everything necessary have been included in the gift. By means of the rest station, which will adjoin the railway, men brought to the coast can be fed, and receive medical attention; those who are dying can be housed, and those who are too desperately ill to bear any more travelling can be retained. When an interval of many hours occurs between the arrival of the train and the departure of the transport or hospital ship the men can be made comfortable at the rest station.

Southampton.

A large base hospital is being established near Southampton, and steps are being taken to acquire ships to be used partly as hospitals and partly as transports. Several yachts, admirably adapted to the purpose of conveying the sick, especially in shallow waters, have been secured.

Staff.

Large numbers of doctors and surgeons have placed themselves at the disposal of the Society, and their standard of ability is high. None but fully trained nurses are being sent out, and the matron reports that there are now 1,500 on the list.

Auxiliary Home Hospitals.

Many offers of private houses to be used as temporary hospitals have been received by the British Red Cross Society, but the time has not arrived when any definite undertaking to utilize these houses can be given. The offers are being arranged with regard to the counties in which they are situated and their relation to the various military hospitals, these particulars influencing the manner in which the offer might be employed in the future. Offers from public institutions are being placed on a special list, and those fully staffed and equipped have been particularly noted as likely to be useful.

Temporary hospitals to be established by Voluntary Aid Detachments form an integral and important link in the Territorial military organization, but detachments are asked not at present to prepare any actual hospitals, but to have schemes for them ready to open at any moment when required by the military authorities. Their equipment, except in the case of a small supply of drugs and dressings, should not necessarily consist of articles except such as can be obtained from neighbouring houses. No Voluntary Aid Detachment will, it is understood, be utilized except in the district in which it is registered, although the military authorities may ask for volunteers for duty elsewhere from specially selected detachments. The recommendations of the British Red Cross Society are (1) that no hospital should be actually prepared before the mobilization order of that hospital has been received from the military authority, in order that personnel and equipment which may be urgently needed elsewhere shall not be uselessly locked up, (2) that funds should not be prematurely laid out on the preparation of these hospitals which might be more usefully expended in other directions, and (3) that the work of institutions intended for other purposes, such as schools and colleges, must not be interfered with, except on military requisition or in consultation with the educational authorities; Voluntary Aid Detachments have no authority to take over of themselves any public or private building.

RED CROSS WORK IN MONMOUTHSHIRE.

A committee has been appointed by the Lord-Lieutenant of the county, consisting of Dr. Rocyn-Jones and Dr. John Cropper, Medical Officer of Health and Honorary Secretary of the British Red Cross Society respectively, under the chairmanship of Sir H. Mather Jackson, Bart., to co-ordinate the voluntary ambulance service of the county. Besides temporary hospitals in various parts, accommodation for at least 200 convalescents has been offered by Colonel Ed. Carre, Mr. D. A. Thomas and others in private houses, and quite half of these are ready for occupation at short notice. The work of the committee is to co-ordinate and direct these efforts, which are being staffed by Voluntary Aid Detachments of the Red Cross.

The question of the acceptance of the offer of the Royal Gwent Hospital at Newport as an auxiliary base hospital is under consideration, but its close proximity to the Cardiff Infirmary makes it doubtful if the authorities will take it up.

The main work of the Volunteer Ambulance Committee will be the allocation of funds to the various convalescent homes, thus assisting the funds of the local branches of the Red Cross Society and St. John Ambulance Association.

RED CROSS WORK IN SCOTLAND.

The Scottish Branch of the British Red Cross Society has its head quarters at 137, Sauchiehall Street, Glasgow, and the country has been divided into four districts to facilitate work and economize time. The Western District, including the City of Glasgow, has Lieutenant-Colonel D. R. M'Ewan as Commissioner; the Eastern, including the City of Edinburgh, has Mr. David Wallace, C.M.G., in the same position; and there are also the Central Eastern District, including the city of Dundee, and the North-Eastern, including Aberdeen, with Colonel W. Gordon Thomson, V.D., and Colonel J. Scott-Riddell, M.V.O., respectively as Commissioners. There are also committees in every county in Scotland, the four large towns being regarded as counties. According to the Geneva Convention, the Red Cross Society can only provide for sick and wounded, or, in other words, for the soldiers who have ceased to become combatants; it cannot, therefore, supply clothing, food, and comforts for troops in the field, but provision for them will, it is understood, be made by the Regimental and Territorial Force Associations.

A great deal of preparatory work is being done at 2, Frederick Street, Edinburgh, the head quarters of the Scottish Branch of the British Red Cross Society in the East of Scotland, the fruit of which will be evident in due time. The Duchess of Montrose, in a letter published in the *Scotsman*, draws the attention of all persons desirous of furnishing aid to the sick and wounded to the fact that such help should be given entirely through the Scottish

branch of the society, "as the unco-ordinated efforts of individuals only lead to overlapping and waste of energy and material." She goes on to point out that the executive in Scotland contains several eminent members of the medical profession, and has Sir George Beatson as chairman, and that it is working in conjunction with representative Red Cross Committees formed in Edinburgh, Glasgow, and Aberdeen. Arrangements have been made for the provision of ambulance trains, for the co-ordination of all offers of temporary hospitals and convalescent homes, and for the reception and distribution of medical stores, hospital clothing, etc. Money, however, was urgently needed at head quarters, and it had to be borne in mind that a Scottish Hospital might suddenly be required at the seat of war, and were the necessary funds available it could be dispatched without delay.

Among the more recent offers made to the Red Cross Society is that by the Duke of Richmond and Gordon, through the Morayshire branch of the society, of his Scottish seat of Gordon Castle, Fochabers, as a convalescent home for sick and wounded.

Major J. Boyd Jamieson, R.A.M.C. (T.F.), has been appointed Sanitary Officer for Edinburgh and Forth Defences (south side) from August 16th.

MEDICAL ATTENDANCE ON PATIENTS OF PRACTITIONERS ON MILITARY DUTY.

IN the last two issues of the JOURNAL meetings of the profession, most of them called by the Executive Committees of the Divisions of the British Medical Association, were reported at which it was resolved that the members of the profession remaining in the district should take every means—

1. To safeguard the interests of medical men on military duty at home and abroad, and to undertake any medical duties for the sole benefit of the absentees.

2. To co-operate with the authorities in giving gratuitous medical attendance to the necessitous dependants of men called away from their employment on the service of the country.

At a meeting of the South-Eastern Counties Division of the Edinburgh Branch the word "dependant" was defined as including "those actually dependent on the wages of those serving the country, but not necessarily to include other members of their families not dependent on their wages for support."

In most instances—possibly in all, though the fact has not always been stated—either the Executive Committee of the Division or a special committee has been appointed to take steps to carry out the resolutions in co-operation with the municipal authorities and local Distress Committees; for example: Dr. F. E. Wynne informs us that at a meeting of all practitioners in the area of the Wigan Division a subcommittee was appointed to meet the Distress Committee to arrange details as to the supply of drugs and any other administrative matters necessary to carry out the resolution to give medical services gratuitously to all dependants of men engaged on active service. Again, Dr. G. Bertram Muriel informs us that at a meeting of the Whitehaven medical men the following resolution was passed and subsequently signed unanimously, and the Mayor is making the necessary arrangements to carry it out:

> We the undersigned medical practitioners of Whitehaven express to His Worship the Mayor our willingness to undertake free of charge the medical treatment of all such dependants, not already provided for, of men engaged in the service of the empire in the Navy, Army, Reserves, and Territorial Forces called to the colours, as may be recommended by the Mayor's Committee; to give all necessary medical and surgical attendance that may be required in connexion with any emergency hospital, convalescent hospital or sanatorium for sailors or soldiers, wounded or invalided, that may be established under the National Fund inaugurated by His Royal Highness the Prince of Wales; and generally to give professional advice and assistance in regard to any scheme that may be devised by His Worship the Mayor for the alleviation of sickness and distress in the borough consequent upon the war.

We are informed that resolutions similar to or identical with those published in previous issues and indicated above, have been adopted by medical practitioners resident in the areas of the following Divisions and Branches:

Bath.
Bristol.
Portsmouth.
Cambridge and Huntingdon.
Nottingham, which proposes also to co-operate with the Red Cross Society.
Huddersfield.
Shropshire and Mid Wales, which, however, still has under consideration the question of the provision of free medical attendance on the necessitous wives and dependants of men called out.
Wandsworth.
Hull (see SUPPLEMENT, p. 157).
North Riding of Yorkshire (see SUPPLEMENT, p. 157).

As will be seen by reports published in this and previous issues, many Panel Committees have adopted similar resolutions, and have recommended that permanent transfers of patients from the insurance lists of absent practitioners should not be sanctioned during the continuance of the war.

The position with regard to midwifery is rather special. In the first place, it is to be remembered that, though members of approved societies who are in the Navy or Army Reserves or in the Territorials, will, from the moment they are called out, be treated not as employed contributors, but as serving sailors or soldiers, the societies will continue to deal with any claims for maternity benefit exactly as if the members had remained ordinary employed contributors. The men will be making weekly contributions at the reduced rate of 3d. There seems, therefore, no reason why midwifery attendance on the wives of insured men on military duty should, as a rule, be given gratuitously, for it is a legitimate charge on the insurance funds and the position has not been directly affected by the war. Further, it has long been the rule that where one practitioner attends a confinement for another, as pretty often happens, the substitute receives half the fee, and it has been suggested that this custom should apply now.

We have already drawn attention to the generous offer of the pharmacists in a number of localities to forego their dispensing fees in respect of the dependants of men in military employ to whom the medical profession has offered to give gratuitous attendance. The cost of drugs must be defrayed from some source, and the general opinion seems to be that it should be provided out of the National Relief Fund of which the Prince of Wales is Treasurer

The whole undertaking—the gratuitous attendance by the medical profession and the supply of drugs at cost price by the pharmacists—is a big matter which will need careful organization to ensure smooth working and to prevent abuse. As was stated last week, this question has already received attention. The Chairman of Council and Medical Secretary of the British Medical Association, acting in consultation with the President and Parliamentary Secretary of the Pharmaceutical Society, have made suggestions on this head which are now under the consideration of the Cabinet Committee. It is probable that an official announcement may shortly be made.

THE WAR AND THE FUTURE OF THE INSURANCE FUNDS.

AT the last monthly meeting of the Salford Insurance Committee it was stated that very few of the Salford panel practitioners belong to the Army Reserves or Territorials, but that in case any practitioner is called up for active service, the other practitioners on the panel will keep his practice together for him during his absence and arrange that he shall not suffer financially. Attention was called to the fact that owing to the absence on service of a large number of the insured persons there is some danger that the medical and sanatorium benefit funds may suffer by deductions. The medical attendance on the wives and families of the men on service will unavoidably fall to a large extent on the panel practitioners, and the men who went away as the best of lives will in only too many cases return as the worst of lives. This will impose a large amount of extra work on the panel doctors which will in many cases last for years, and the extra drain on

the sickness and disablement benefit funds will be a most serious consideration for approved societies. The following resolution was accordingly carried unanimously, and ordered to be sent to the Commissioners:

> That moneys provided under the National Insurance Acts from contributions paid by and on behalf of Reservists and Territorials during their embodiment ought, after a proper proportion has first been set aside for maternity benefit, to be secured proportionally to the approved societies to which they belong and the Insurance Committees in whose areas they reside, in view of the excessive demands that will later fall on the approved societies for sickness and disablement benefits and upon the panel practitioners and pharmacists for medical and sanatorium benefits.

It will be seen that in many respects this resolution is in accord with the opinions expressed in the leading article in the BRITISH MEDICAL JOURNAL of last week.

WAR RISKS.

AT a special meeting of the Committee of the Medical Sickness Annuity and Life Assurance Society on August 21st, the following resolutions were adopted:

> Any member serving with His Majesty's Forces on active service abroad shall be allowed to retain his membership without extra premium, and shall, on return to the United Kingdom, come into sickness and accident benefit.
>
> Any member serving with His Majesty's Forces while in the United Kingdom shall be held fully covered for sickness and accidents without extra premium.
>
> Any member insured for life assurance serving with His Majesty's Forces either abroad or in the United Kingdom shall not be charged any extra premium, and shall be held fully covered.

NOTES.

DRUG STOCKS AND THE DRUG TRADE.

Duty-Free Alcohol.

IT has been suggested in the press, and in letters we have received, that an explanation of the want of enterprise among manufacturers in Great Britain which has led to the trade in fine chemicals and synthetic products passing so largely into the hands of German firms is to be found in unreasonable restrictions imposed by the Excise and Customs in this country on the use of alcohol for manufacturing purposes. This is not the case, but in place of expressing any opinion of our own on the subject we are glad to be able, by the courtesy of the Editor of the *Pharmaceutical Journal*, to make the following extracts from an article which will appear in the issue of that journal for this week:

"The alcohol difficulty is the least of the obstacles, and we have little doubt that at the present juncture the authorities would not hesitate to grant all reasonable facilities to manufacturers who desire and have the means to perform the patriotic duty of keeping up the supplies of valuable drugs. The idea that the coal-tar colour industry was lost by this country for want of duty-free spirit has become so firmly rooted that it still persists, notwithstanding the definite statement of a Departmental Committee, which made a thorough investigation of the subject, that the assertion was based upon no solid foundation of fact. The Committee made certain recommendations, which were largely adopted, for removing certain disabilities under which British manufacturers did suffer, and the present position may be briefly stated in the words of Mr. Thomas Tyrer, who is one of the best authorities on the subject: "There is nothing to prevent, upon application and proof, the use of spirit for any purpose whatsoever, provided, of course, a suitable denaturant is submitted for approval by the authorities, and there are numerous instances in this country in which such an application has been made and granted." Each case will be considered upon its merits, and there can be no question of any general extension of the use of specially denatured alcohol."

PROPOSED CHOLERA CORPS FOR THE RUSSIAN RED CROSS.

A scheme is on foot to organize a special corps for cholera service with the Russian forces, and the Russian authorities are considering the proposal. The scheme at present contemplates the enrolment of ten medical men and twenty nurses. It is desirable that medical volunteers for this work should have had practical experience of cholera as clinicians or bacteriologists, and that nurses should have had a full hospital training. Applications, in the first instance by letter only, may be sent to the Secretary of the Provisional Committee, 67, Margaret Street, W.

NATIONAL RELIEF FUND.

The Secretaries of the Prince of Wales's National Relief Fund (York House, St. James's Palace, S.W.) state that the Subscription Subcommittee has heard of a good many cases in which use has been made of its name, or of the names of those connected with it, with the object of securing support for appeals which are quite unauthorized. The public are warned that any extravagant or grotesque appeals emanate from persons who have neither the authorization nor the support of this Committee.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

BRISTOL.

OPENING OF A NEW WING AT THE GENERAL HOSPITAL.

THE ceremony of opening the new wing of the General Hospital was performed on July 27th by the President, Mr. George Alfred Wills, who in the course of his address said that the original hospital was founded in 1832 in order to afford medical assistance to the poor in the district around Redcliffe, beginning with only 30 beds. In 1853 the main building was erected, and again in 1891 a wing was opened, making the number of beds up to 200. Additional accommodation being required, a successful appeal was made for £40,000.

Mr. Herbert Baker, the treasurer, having stated that the new buildings were absolutely free from debt both for the actual structure and for the fittings and furniture, Dr. Michell Clarke, the senior physician, expressed the gratification of the staff at the completion of the work—an addition to the number of beds for which there had been an urgent demand. He did not think there would be any less need for institutions like theirs now the Insurance Act was in full working; indeed, the need might be greater, and he hoped that the voluntary system would continue for many years to come. The great advance of medicine during the last few years was largely due, he believed, to the voluntary hospitals, because they attracted the best men and gave facilities for research. He wanted it clearly understood by the patients who came for treatment that no experiments were practised on them, for no procedure was carried out there which would not be done in private practice.

The new building is a plain serviceable structure, made of reinforced concrete without the slightest attempt either to follow the style of the older buildings or to add to the architectural beauties of the city. Money has not been spent on the outside, but nothing has been spared to make the inside as complete as modern requirements demand. The site is a strip of ground on the south side of the old buildings. On the basement floor is a dental department, the entrance being from Commercial Road. This has a porter's room, two large waiting-rooms for men and women, two surgeries, a recovery room, a conservation room, arranged with eight chairs, but capable of holding twelve or more, and a work-room and offices. There are also on this floor a dining-room for sisters and nurses and for laundry maids; and a new laundry. The ground floor contains six private sitting-rooms and bedrooms for resident officers, an officers' smoking-room, a mess-room for men students and one for women students, and also for the matron and assistant matron, a private room for the staff, and a room for the registrar and other offices.

The first floor is devoted to women's medical ward. This is made to hold 25 beds, but will only be used for 22 at present. At the south end is a large sun balcony. There is also a single-bed ward and a two-bed ward, sister's room, ward kitchen, larder, and rooms for storing linen and patients' clothes. The sanitary wing contains the usual equipment. Attached is a clinical laboratory.

The second floor is to be a maternity ward, and is, like the one below, a potential 25-bed unit. It is intended

as now arranged to have 12 beds—10 in the large ward and 2 in a separate ward. It has attached a day-room, and a sun balcony large enough to take all the beds of the ward. The administrative portion of this ward has a room for washing babies, provided with four basins; an operating room; a room where the patients can wash and change upon arrival, and a room for the staff.

The roof of the building is a garden or airing place for the women patients. Each floor is connected with a fire escape reaching from the roof to the ground, and by connecting the top story with the old building 22 new rooms for nurses have been added.

All the floors are of teak and the wall surface is of Keen's cement, which it is intended to finish with enamel. The heating is by low pressure hot water, the circulation being accelerated by means of electrically-driven pumps. In the large wards the warming is supplemented by open fires.

The ventilation is by natural means, including the opening of windows. Extraction shafts are carried up the sides of the building. The operating theatre alone is ventilated by mechanical means—namely, an electric fan to effect an interchange six times in an hour.

A water-softening plant has been provided for the hot water supply, laundry purposes, and boiler feed make-up. It is estimated that its introduction will save something like 50 per cent. in the cost of soap and 35 per cent. in the cost of soda.

A new pathological department has been erected on land behind the museum.

MANCHESTER AND DISTRICT.

Maternity Benefit and the Salford Board of Guardians.

Ever since maternity benefit under the Insurance Act came into operation, the Salford Board of Guardians have found that a considerable number of women who are entitled to the benefit have applied for and had to be granted admission to the union infirmary for their confinements and for several weeks afterwards. On their dismissal they obtained the benefit of 30s., and in some cases £3, and as the guardians had no right to demand any part of this, the women thus obtained at the expense of the ratepayers all they desired in the way of medical attention and board, and made a clear profit of the maternity benefit which was intended really to pay for the expenses incident to confinement. The guardians felt that this was hardly fair to the ratepayers, especially as some of the women in question were unmarried and had been in the infirmary several times before for the same purpose. The guardians accordingly wrote to the Commissioners calling their attention to the matter and asking that they should be empowered to recover part of the cost of maintenance in the infirmary out of the maternity benefit. The Commissioners have now replied to the effect that no payment on account of maternity benefit can be made while the mother is in hospital; that, if the hospital is one that is supported out of public funds, the benefit must be applied in whole or in part for her dependants, if any, and that when she leaves the hospital she is entitled herself to receive the whole or such balance as remains of the benefit. The Commissioners conclude: "The right to this benefit is absolute, and the provisions of the National Insurance Acts do not enable the Commissioners to take action on the lines indicated in the resolution passed by the guardians." There can be no question that the attitude of the Commissioners is legally correct, and much can be urged in favour of the law as it stands when it applies to respectable or unfortunate women. But when it is applied to include unmarried women of bad character, who in many cases time after time thus impose on the ratepayers and afterwards spend the benefit in any way rather than for the purpose for which it was intended, it is impossible to deny that the guardians have some right to complain of the indiscriminate character of the law.

Health of Manchester School Children.

The annual report of the school medical officer for Manchester, Dr. A. Brown Ritchie, shows that during the year 1913 nearly 30,000 children were medically inspected and examined. The tendency towards a gradual increase in the height and weight of the children, which was noted in previous reports, is again recorded, although the standard is still below the anthropometric standard of 1883. Attention is specially drawn to the home circumstances of many of the children. Many of the boys out of school hours are employed as messengers and in street trading, and the deteriorating effect of this is often very noticeable. Bad effects, too, are often noted among the girls, owing to the excessive amount of domestic work which many of them have to do. In the case of the boys the medical officer has frequently had to intervene, but it is evidently difficult to deal with the girls. Dr. Ritchie states that the general standard of cleanliness in the schools has gradually risen; he says "only those having experience of pre-inspection days can at all realize the enormous change."

During the year 1913 there was an extensive epidemic of scarlet fever among the children, the cases reaching the number of 2,252, which was nearly as many as the number recorded in the two previous years together. It was specially noticeable that the schools attended by the Jewish children were most seriously affected, and numerous visits were paid to the Jewish schools, though it is satisfactory to find that there was practically no proof of school infection. The number of cases of diphtheria was 342, which is the greatest on record. On the other hand, the number of cases of measles, though it reached 3,747, was the lowest on record. It was found necessary to lay continuous stress on measles as being one of the most serious diseases which they had to deal with. It was only with difficulty that they were gradually dissipating the old idea that measles is a trivial complaint which every child must have once, and which requires no medical treatment. The teachers were now realizing to a greater extent the rôle of measles as a retarder of intellectual progress. Evidence is accumulating that after an attack a child is not so mentally alert as he was, and combining with this all the other complications to which measles leads, Dr. Ritchie regards it as the great cause of much scholastic inefficiency.

With regard to defective vision, it is largely as a result of previous work of inspection that in the year 1913 the number of fresh cases requiring spectacles was considerably less than the average of the previous four years, though the total number of children wearing spectacles has risen. The problem of dealing with defective teeth still remains a difficulty, and Dr. Ritchie considers that if any visible improvement is to be made, dental clinics will have to be provided. In addition to this, for a very large group of cases the treatment required can only fully be given by providing open-air schools. He recommends, too, that at least six school clinics ought to be established, three to begin with in Hulme, Ancoats, and Gorton. It may be added that the committee has already considered this last recommendation, and has approved plans for a clinic for Hulme. The Chairman of the Committee, Sir T. T. Shann, specially called attention to the decrease in the school attendance which was due to the more efficient medical inspection. The more thorough this inspection became, the more must the school attendance suffer. A few years ago the Board of Education paid grants for children who were unable to attend school owing to illness, and he thought the Board ought to do the same to-day. He was glad that pressure was being brought to bear in this direction by the education authorities.

WALES.

King Edward VII Welsh National Memorial Association.

No more fitting memorial could be found of the late King Edward, who for so many years was the Prince of Wales, than that which has for its object the prevention of a preventable disease in the Principality. Within a very short time the Welsh National Memorial Association, with its thoroughly representative body of governors and council, has raised a sum of £200,000, and has inaugurated a scheme which, when complete, should bring the means of treatment within the reach of all consumptives in Wales. The second annual report of the association, for the year ending March 31st, 1914, states that the counties of Wales, with the sole exception of Pembrokeshire, have

been divided up into 14 areas, each controlled by a district committee conversant with local needs and able to report thereon to the central council. Tuberculosis hospitals, sanatoriums, institutes, and visiting stations, staffed by skilled medical officers with special experience of tuberculosis, are being provided in these areas. The nursing of cases is undertaken by existing nursing organizations. The scheme provides for 549 beds in tuberculosis hospitals, but at present only 87 are available, but 299 beds are provided in various sanatoriums throughout the country. Plans for two large sanatoriums in the north and south of Wales, respectively, have been accepted and sites obtained. The capital expenditure must of course be heavy, and more money is required to bring the whole scheme to fruition. The cost per bed has been carefully estimated, and will probably exceed £200. The report for the past year contains a large amount of statistical and other information which should prove useful to the organizing committees of similar undertakings. Institutes or "visiting stations" have been established within the areas of seventeen county councils or county borough councils, and the work carried on in them corresponds with that of the tuberculosis dispensary as already formulated for many similar bodies in England. In Wales, as in other parts, a certain amount of unreasoning opposition has had to be contended with, but it is gradually being overcome. Thus far the results of sanatorium treatment show an approximate figure of 50 per cent. for complete arrest of disease with disappearance of bacilli from the sputum. Of the cases treated in hospital, presumably limited to advanced cases, a definite improvement is recorded in 66.8 per cent. A relatively smaller number of good results appear to have been obtained in the course of institute treatment, but the reports of domiciliary treatment seem to be encouraging, and although many of the cases were already too far advanced for any real improvement, the success in the earlier cases has justified one of the physicians in commenting favourably upon the possibility of carrying out effective treatment at home.

The Tubercle Bacillus in Streets and Parks.

Perhaps the most important information from the preventive point of view is conveyed in the report of the tuberculosis physician at Swansea, Dr. Frank Clifford, who has made a series of careful observations upon samples of sputum taken from the ground in the streets, parks, and football grounds most frequented by the public, and has found that tubercle bacilli were present in nearly 60 per cent. of such samples. Such a demonstration of the common danger speaks for itself, and once more suggests the reflection that much of the money spent in treatment is thrown away so long as this obvious source for the dissemination of the disease is permitted to go on without legislative restriction.

The Educational Value of Sanatorium Discipline.

Sanatorium treatment, unless it be intelligently appreciated by the patients whom it serves, may sometimes fail to aid recovery. The patient sent to the sanatorium against his will is only too apt to resent exposure to draughts and to imagine "chills." He may also object to limitation of the amount of warm clothing which he has hitherto considered essential to prevent catching cold. Such a patient gets little good from his stay in the institution, and may induce a spirit of discontent amongst others. Hence the importance of informing any intending patient as to the reasons for the routine life of the sanatorium and as to the necessity for strict conformation with hygienic regulations during his course of treatment. With a view to providing this information, Dr. Marcus Paterson, the medical director of the Memorial Association, has drawn up a short and concise pamphlet which every candidate for admission to a sanatorium is required not only to read but to sign before he can be accepted. He has recently supplemented this pamphlet by another entitled *Advice to a Patient who leaves a Sanatorium fit for Work* (Cardiff: Murrell, Richards, and Co., Limited, 1914), which is given to every patient who leaves the sanatorium in fit condition for work. The advice which it contains is couched in the simplest language, conveying in conversational style a strong appeal to the common sense of the individual to utilize the knowledge that he must have acquired, and pointing out all the weak points and dangers that may beset him in his efforts to obtain suitable work and to maintain his recovered health. Exception might perhaps be taken to some of the remarks upon various articles of diet, and allowance must always be made for individual peculiarities of appetite and digestion, but the little pamphlet as a whole may be warmly commended to the notice of all sanatorium managers.

Ireland.

[*FROM OUR SPECIAL CORRESPONDENTS.*]

The Belfast Scheme for Combating Tuberculosis.

The Belfast scheme for combating tuberculosis is now in fair working order. Some years ago the death-rate from consumption was exceedingly high; the numbers of deaths fell, however, from over 1,000 to 811 in 1909, to 825 in 1910, and to 802 in both 1911 and 1912; in 1913 it rose to 844, with 318 from non-pulmonary forms of tuberculosis, so that the question is not one of facing a disease which is naturally declining with gradually improved hygiene. We have gone back during the last year.

The Forster Green Consumptive Hospital has some 60 beds and a dispensary, the Abbey Poor Law Sanatorium had 265 beds, and the Throne Consumptive Hospital 10 beds. Under the new scheme the City Council has taken over the Abbey Sanatorium from the Poor Law guardians and will add 200 beds; an extra dispensary is already provided and working, so that the city will very shortly have 500 beds, two working and well-equipped dispensaries, and a staff of one principal tuberculosis medical officer, two assistant medical officers, and five female visitors. Extensions are in contemplation in the near future; the two dispensaries will be supplemented by two others, and the scheme includes the provision for "a modern central institute, equipped for clinical, electrical, bacteriological, and clerical work;" there is also in contemplation a dental department, an open-air hospital school, and a farm colony, which will be an extension of the Abbey grounds. The important and complicated problem of the relation of the health of the child to consumption in the adult is also awaiting solution, and the department will join in the prevention of the disease in its relation to the health of the child. The population of the city is now estimated at 400,000; the total deaths from all forms of tuberculosis numbered 1,162 last year; the number of insured is over 160,000, and of these 1,200 received sanatorium treatment last year; consequently provision must be made for about 3,000 new cases annually.

The cost is estimated at £45,000 per annum, but by utilizing the provisions of the Insurance Act the cost will not be much more than £16,000 per annum, and a large part of this sum is already paid by the city for the Abbey Sanatorium and for the beds maintained by the Corporation in the Forster Green Hospital. The Government grant for building purposes has already been received; the cost of domiciliary treatment will be met out of a special fund based on the product of 6d. per head of insured persons *plus* an arbitrary amount for the treatment of non-insured; the rate of remuneration will be £1 per head and the balance left over at the end of the year will be divided.

Sir Patrick Dun's Hospital.

The report of the governors of Sir Patrick Dun's Hospital for the past year states that during the year 343 persons suffering from accidents were admitted, 136 fever patients received treatment, and 1,115 general cases were also admitted for treatment. In the extern department 13,920 cases of accident received treatment, 4,702 visits were made to the general dispensary; 1,044 visits were made in respect of diseases peculiar to women, and 2,030 cases were treated for affections of the throat, nose, and ear; 16,876 visits were made to the dispensary for dressing; 3,420 visits were made to the accident room for special dressings. The daily "diets" issued reached the high figure of 31,079, and the average daily number of beds occupied was 85.1. The cost per bed calculated on maintenance of patients was £21 13s. 10d., and the cost per bed calculated on maintenance of the establishment was £46 6s. 3d. The income from all sources, exclusive

of bequests, for the year amounted to £4,700, and the expenditure for the same period, exclusive of building accounts, £6,764.

SIXPENCE A BAG FOR FLIES.

Posters have been issued by Sir Charles Cameron, Medical Officer for Health, Dublin, stating that cases of typhoid fever have recently occurred, which there was good reason to suppose were caused by eating infected cockles, and that it is essential that cockles or mussels should be thoroughly boiled. It is notified that bags to contain dead flies can be obtained at the Sanitary Office, Cork Hill, and that sixpence will be paid for each full bag.

Correspondence.

NERVE CELLS IN THE AORTA AND ANGINA PECTORIS.

SIR,—The leading article in the JOURNAL for July 29th under the above title, which gives a summary of Manoélian's recent paper on the subject,[1] is a useful reminder of the fact, somewhat needed at the moment, that when we have obtained a picture of the cardiovascular movements we are not at the end of a rational interpretation of the clinical phenomena of heart disease. Manoélian's paper contains a number of interesting observations, few of which, however, can be regarded as altogether new. The post-aortic situation of the plexuses he describes is certainly not new, and his anastomoses resembling "motor plates" have, I think, very questionably the significance attributed to the structures he describes.

His most important observations are, perhaps, his detection of ganglion cells in the connective tissue of the "middle coat" of the aorta and the presence of apparently sensory fibres there. This last observation, if confirmed, is the most important and original he makes. For as regards the presence of ganglion cells in the mesarterium, this fact has already been demonstrated by myself in the case of the coronary artery, and this not in the dog, on which animal Manoélian's observations were made, but in a man who was also the subject of a small intra-arterial coronary aneurysm, and suffered much from angina pectoris, in an access of which he died.[2]

As regards angina pectoris itself, the tendency is frequently manifested to express, on some single principle, its nature. The myogenist has very little difficulty in settling the matter by a sweeping generalization affecting some Gaskellian quality of cardiac muscle, contractility for choice. But a more detailed consideration of the phenomena of cardio-aortic pain leaves little doubt that the interpretation of these phenomena is as various as the phenomena themselves, and Manoélian's researches, as you remark, usefully support views concerning an aortic variety of angina which have frequently been advanced by Sir Clifford Allbutt in this country and more recently by Vaquez and others elsewhere. While granting this, however, I altogether take exception to Manoélian's statement, reproduced by yourself, of the absence of proof of pathological states in the coronary arteries capable of accounting for angina pectoris *in some cases*. Indeed, the facts I have already mentioned show that both the anatomical and pathological conditions capable of explaining aortic angina are likewise to be met with in the coronary arteries and explain coronary angina—a circumstance which, surely, was *a priori* to be conjectured.—I am, etc.,

London, W., July 26th. ALEXANDER MORISON.

PATHOLOGICAL LABORATORIES.

SIR,—I wonder how many have noted the incongruity of issuing in the same number of the BRITISH MEDICAL JOURNAL (1) an editorial (page 193) in which health authorities are stated to be concerned mainly with sanitation, and where it is inferred that their officers are persons who know little of clinical matters, and (2) a statement (on page 200) that the City Bacteriologist of Glasgow examined 7,234 specimens for medical practitioners last year. I have often heard the following question asked: "Why this constant effort in the pages of the JOURNAL to circumscribe the sphere of work of public health bodies which are vitally concerned with *everything* which is likely to reduce the prevalence of disease?" These health authorities have efficiently discharged clinical functions for years in their fever hospitals, and are now with marked success undertaking the care of tuberculous cases and of ailing school children. Again, in many places health authorities have already either established bacteriological laboratories, or arranged with universities for bacteriological work to be done. The M.O.H. of a county or county borough is not a head clerk or a sanitary inspector, as certain persons appear to imagine, but the controlling head of all medical work performed by the municipality. Clearly it is better to encourage existing bodies to extend their arrangements for bacteriological and pathological work rather than create an *ad hoc* authority, and thus add yet another body to those already in existence dealing with matters concerning the public health.

Surely what is wanted is the concentration of all matters concerning public health in one body, and so promote efficiency and economy, rather than have several authorities doing the same or similar work, with the resulting extravagance, overlapping, waste of effort, and waste of money.

What is being done in Glasgow under the supervision of the M.O.H. can be done and is being done elsewhere, and, with very little modification, can be made to fulfil every object desired by those who are anxious to limit the scope of work of existing public health officers. The suggestion that such laboratories should be controlled by the Insurance Commissioners is very amusing to one who carefully read the criticisms of such bodies in your pages of twenty months ago.

I could adduce many reasons why nursing facilities also should be provided by arrangement with the councils of counties and county boroughs, but this letter is already sufficiently long.—I am, etc.,

T. W. NAYLOR BARLOW,
Medical Officer of Health, and Honorary Secretary-elect, Society of Medical Officers of Health.

Wallasey, Aug. 10th.

SCHOOL MEDICAL OFFICERS.

SIR,—One still occasionally hears the gibe against school medical officers, who are busy forming themselves into a group for the discussion of their peculiar interests, scientific and sociological—and I dare say it is said of the tuberculosis officers also, who are doing the same thing—that it is only a movement of discontented juniors bent on forcing up their own salaries.

Now there is no doubt an increase of salary has a perennial interest for most of us, but this does not entirely explain the agitation. The fact is, specialized services, like the school medical service, are more and more feeling the need of being self-contained and self-feeding. We shall not in future be able to staff the lower ranks with mere transitional young people on their way to general practice or other departments of the public medical service, for which indeed experience in school work very imperfectly fits them. The ideal of the future must be that of a civil service in which even the lower grades of responsible workers must have a living wage, so that, if they go no higher, their lives will not have been a disastrous failure.—I am, etc.,

Stafford, July 18th. JOHN PRIESTLEY.

DR. JANE WALKER, president of the Association of Registered Medical Women, states that a subcommittee has been formed to collect information as to the different forms of assistance which medical women can give in the contingencies arising from the state of war, to collect data from the whole body of medical women as to possibilities of rendering service, to form a bureau to which requests for help can be sent, and to organize whatever help can be given. It is anticipated that medical women will probably be needed for civilian work rather than for work directly connected with the army. Communications should be addressed to the secretary, 17, Pembroke Square, Kensington, W.

Universities and Colleges.

ACADEMIC POSITION OF STUDENTS ON MILITARY SERVICE.

Immediately after the outbreak of war we suggested that the case of medical students who had volunteered for duty as dressers should receive special consideration from the university and other licensing authorities. The matter has since been considered by some of the universities in respect of their undergraduates generally. The following letter addressed to us by Sir Donald MacAlister, Principal of Glasgow University, seems to express the general attitude assumed by the authorities of the universities which have moved in the matter:

Sir,—May I ask for your kind offices in conveying to undergraduate students, called to active service for their country, the assurance that the University of Glasgow will do what it can to safeguard their academic interests? The authorities whom I have been able to consult agree with me in recommending that to such students every consideration should be extended which the Ordinances will permit. In relation to attendance on courses of instruction, to duration of study, to periods of notice required, and the like, account will be taken of a student's absence on military duty, so as, if possible, to ensure that his graduation shall not be unduly delayed.—I am, Sir, yours very faithfully,

Donald MacAlister,
Principal.

University of Glasgow,
August 19th, 1914.

The Vice-Chancellor of the University of Oxford anticipates that the same course will be followed as during the war in South Africa—that is to say, that the time limit for entering the Honours Schools will be extended, and that, by a separate decree for each individual, other undergraduates will be allowed to count the terms elapsed during their absence as if they had been in residence.

The Senate of the University of Cambridge has decided "to allow terms and leave to 'degrade' (that is, to postpone examination) to all undergraduates prevented from residing by the requirements of military service."

The Vice-Chancellor of the University of London states that he is confident that the Senate will do all in its power to render it easy for members of the university, and especially for cadets of the Officers' Training Corps, to offer their services, and that it will (1) remit fees paid in for examinations which a student is unable to take, and (2) that generally it will take each and every step possible to prevent students who are serving their country from being in any way prejudiced in their university career.

It is proposed to hold a meeting of the Vice-Chancellors of the universities of Liverpool, Manchester, Leeds and Sheffield, before the session begins to consider how far common action can be secured in dealing with the various claims for consideration that may be expected to arise. The Vice-Chancellor of the University of Liverpool, who makes the announcement, states that in due time everything that can be done by the university will be done to safeguard the interests of members of the staff and of students who have offered themselves for national service at home or abroad—"It is our duty to ensure, so far as may be, that one sacrifice shall not involve another."

Sir George Hare Philipson, writing on behalf of the College of Medicine, and Dr. W. H. Hadow on behalf of Armstrong College, state that at the first meeting of the Senate of the University of Durham a special grace will be proposed to safeguard the interests of all undergraduates who have volunteered for training or for active service. The session at both colleges will open at the appointed time. The Vice-Chancellor states that the colleges at Durham have taken similar steps.

The Vice-Chancellor of the University of Wales has undertaken that the university will arrange that, in the case of students who entered the university in 1911, the coming session shall not be reckoned as the last of the four years beyond which honours in the B.A. or B.Sc. degree cannot be obtained, so that they may complete honours schemes in the session 1915-16 under the same conditions under which they would have completed them in the coming session. As pursuance of qualifying courses is essential for initial degrees, a year of absence cannot be reckoned as a year of the qualifying period, but, subject to this proviso, he has no doubt that the university will be anxious to consider cases of disability arising other than the one above provided for, with a view to making special arrangements for their relief.

UNIVERSITY OF GLASGOW.

Special Graduation for Medical Students.

Among the undergraduates who volunteered their services for the war were a number of medical students who had practically concluded their course, and would have come up for examination in October. Arrangements were made for a special examination, and the following passed and received the degree of M.B., Ch.B., on August 15th: Edmund Tytler Burke, John Eglinton Cameron, Thomas Ingram Dunn, James Jackson Finlay, Allan Dumbreck Fraser, M.A., B.Sc., Robert Masson Greig, Fergus Leslie Henderson, Alastair Caulfield Jebb, Douglas Reid King, George M'Cullum, Joseph M'Culloch, *Archibald Munn M'Cutcheon, David Mackie, Percival John Moir, †§Andrew Pickin, John Stuart Prentice, James Vallance, ‡†William Semple Wallace, †Joseph Bannister Williamson, B.Sc.

* Received degrees of M.B., Ch.B., with honours.
† Received degrees of M.B., Ch.B., with commendation.
‡ Passed with distinction in surgery and clinical surgery.
§ Passed with distinction in midwifery.

SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have been approved in the subjects indicated:

Medicine.—*D. Aucutt, *†H. S. Baker, *A. G. Bodman, *P. H. Burton, *†W. E. K. Coles, *L. S. Daly, *C. D. Day, *†J. A. W. Ebden, *†C. de W. Gibb, *R. M. Handfield-Jones, *†G. W. Hassall, *†H. R. Ibbotson, G. L. Lawlor, *A. N. Minns, *T. S. Nelson, *†G. D. Newton, †L. E. Pimm, †R. H. Simpson, †C. R. Smith, †L. H. Terry.

Forensic Medicine.—D. Aucutt, H. S. Baker, A. G. Bodman, P. H. Burton, W. E. K. Coles, L. S. Daly, J. A. W. Ebden, C. de W. Gibb, R. M. Handfield-Jones, A. N. Minns, T. S. Nelson, G. D. Newton, L. E. Pimm, R. H. Simpson, C. R. Smith, L. H. Terry, E. M. Townsend.

Midwifery.—D. Aucutt, H. S. Baker, A. G. Bodman, P. H. Burton, W. E. K. Coles, V. H. M. A. Dangerfield, J. A. W. Ebden, C. de W. Gibb, A. E. Gravelle, R. M. Handfield-Jones, A. N. Minns, T. S. Nelson, H. B. Padwick, L. E. Pimm, R. H. Simpson, F. Simpson, C. R. Smith, L. H. Terry.

Surgery.—*D. Aucutt, *†H. S. Baker, *†A. G. Bodman, †L. B. Clarke, *†W. E. K. Coles, *L. S. Daly, *†J. A. W. Ebden, *†C. de W. Gibb, *†R. M. Handfield-Jones, *†G. W. Maw, †A. N. Minns, †T. S. Nelson, †G. D. Newton, †H. T. Roberts, †M. P. dos Santos, *†R. H. Simpson, *†C. R. Smith, *†L. H. Terry, *†J. A. Watson.

* Section I. † Section II.

The diploma of the Society has been granted to Messrs. H. S. Baker, A. G. Bodman, W. E. K. Coles, V. H. M. A. Dangerfield, L. S. Daly, C. D. Day, J. A. W. Ebden, C. de W. Gibb, R. M. Handfield-Jones, A. N. Minns, T. S. Nelson, R. H. Simpson, C. R. Smith, L. H. Terry, L. B. Clarke, G. W. Maw, H. T. Roberts, M. P. dos Santos, and J. A. Watson.

Obituary.

OLIVER HUMPHREY FOWLER,

CIRENCESTER.

Mr. Fowler, of Cirencester, whose death at the age of 74 took place on August 10th, was for forty years a leading practitioner in the Cotswolds. He was born at Kingsclere, Hants, where his father practised, and received his medical education at St. Bartholomew's Hospital. He obtained the diploma of M.R.C.S.Eng. in 1864, and two years later began work at Cirencester as locumtenent to the late Mr. Edward Cripps. Soon afterwards he joined Mr. Cripps as a partner, and was associated subsequently with his son, Mr. E. C. Cripps. Later on Mr. Fowler became the senior of three partners. He early obtained a leading position in the district, and his success was due in large measure to his untiring industry and powers of physical endurance; he was in the saddle early in the morning and his work was not finished until late in the evening, yet he was always able to turn up everywhere and anywhere to meet a professional engagement or take part in a social gathering, neat and spick and span, full of buoyant, not to say boyish, spirits; with his weather-beaten face and athletic figure, he looked very much an old-fashioned sportsman, but never, we believe, gave any time to field sports. His whole energies were devoted to his profession and to public work. He was surgeon to the Cottage Hospital and to the Cirencester Hospital, which grew out of it, and at the time of his death was an active member of the managing committee. He was one of the founders of the Winsley Sanatorium for consumptives and for long a member of its managing committee.

At Christmas, 1906, Mr. Fowler retired, and at a meeting in Cirencester, presided over by Earl Bathurst, was presented by his patients and friends with an address accompanied by a fine silver cup; in the address the signatories gave expression to their deep gratitude for his constant care, patience, and kindness in their times of sickness. "In matters which have touched us nearly," the address continued, "we have always been able to rely on you as a true friend, as well as a medical adviser; you have inspired us with complete confidence in the soundness of your judgement, as well as in your skill in treatment, and we know that all alike would testify to the faithfulness, honour, and delicacy with which you have discharged your duties."

After his retirement he became a member of the Cirencester Urban District Council, and was its chairman from

1911 until his retirement last year. He was secretary also to the Cirencester Children's Care Committee.

Mr. Fowler was an old member of the British Medical Association and had been president of the Gloucestershire Branch. He worked hard to ensure the success of the Annual Meeting of the Association in Cheltenham in 1901, and both before and after that date was a regular attendant at the annual meetings of the Association and had made a host of friends among the members.

Mr. Fowler was twice married and leaves three sons by his first wife.

The funeral, which took place at Cirencester on August 13th, was attended by a large concourse of friends, including many members of the medical profession.

PROFESSOR RICHARD JOHN ANDERSON, M.A., M.D.

GALWAY.

PROFESSOR ANDERSON died on July 25th at his residence, Beech Hill, Newry, after a short illness, having been at his duties in Galway up to the beginning of April. He was born in Newry on July 29th, 1848. He received his medical education at Queen's College, Belfast, and St. Bartholomew's, London, and also studied in Leipsig, Paris, Heidelberg, and Naples.

As a boy he was remarkable for his scholastic attainments, and afterwards as a student at the Queen's College, Belfast, his career was brilliant. He took the M.A. degree with first class honours and gold medal in 1870, and the M.D. degree with first class honours and gold medal in 1872. In the same year he took the diploma of M.R.C.S.

For a time he entered general practice, having been appointed to the No. 2 Dispensary District, Newry, in 1873, but in 1875 he became demonstrator and lecturer in anatomy and physiology to the Queen's College, Galway, and, after holding that post until 1883, he was appointed to be professor of biology, mineralogy, and geology in the same college, a post he held until his death.

He was examiner in the old Royal University, and afterwards in the National University. He was Honorary President of the Anatomy Section of the International Congress of Medicine in Lisbon in 1906 and of the Physiological Section of the International Congress of Medicine at Budapest, 1909.

He was co-editor of various Continental anatomical and physiological periodicals, and published many papers on scientific subjects in British and Continental journals.

Those who knew him intimately were always charmed to have an opportunity of a social hour with him. Many of his old students and scholars will miss his friendly and useful counsel. By his death Ireland has lost another of her talented sons. R. E. H.

Dr. WM. ALEXANDER, of Liverpool, writes as follows: I was much shocked to hear of the death of my old friend and companion of my college days. Richard John Anderson, even in those early days, was an encyclopaedia of all kinds of scientific knowledge. His bent was to academic pursuits, and not to practical medicine, and the records of his college and of scientific societies show how hard he worked and with how much success.

He rarely failed to attend the annual meetings of the British Medical Association, or of the British Association. The year before last he was my guest at the meeting of the British Medical Association in Liverpool. He had acquired very quaint and lovable ways, and was full of humorous stories, with which he delighted my guests whom he met at my table. The tale of his days is now told, and after a well-spent life he now rests from his labours.

J. D. FARQUHARSON, M.B., C.M.,

NEWCASTLE-UPON-TYNE.

IT is with great regret that we record the death of Dr. James D. Farquharson of Newcastle-upon-Tyne. He was one of the best known practitioners in the city, and his loss will be keenly felt in many spheres of activity.

He was born at Perth in 1858, the son of a contractor, and was educated at Kinnoul, and then at Perth Academy. He started business at an early age in Glasgow, and through his interest in athletics became attached to the *Glasgow Evening News*. In a short time he rose to be sporting editor of this paper and he retained that position during the whole of his undergraduate career. He graduated in 1884 at the University of Glasgow with commendation, and immediately started practice as assistant to the late Dr. Lynn, Newcastle-upon-Tyne, on whose decease, soon after, he succeeded to the practice, which, by his conspicuous ability and urbanity of manner, he rapidly increased. It was only his habits of concentration and power of doing with the minimum of rest that enabled him to carry on for nearly thirty years what was considered one of the best practices in the city.

Dr. Farquharson had many interests. He was for some years a member of the council of the city of his adoption. He did not often take part in debate, but whenever he spoke his remarks showed that he had brought to bear upon the question under discussion careful and intelligent study. To military matters he gave a great deal of time and thought. For over twenty years he was a member of the Newcastle Royal Garrison Artillery, and held the rank of Major, R.A.M.C. (T.F.); within the last two months he received the V.D. He enjoyed great popularity with the officers and men. He was one of the founders of the Pen and Palette Club, and twice president; he was many times president of the Burns Club, an active member of the Glasgow University Club, president of the West End Medical Society, joint secretary of the Northumberland and Durham Medical Society, Fellow of the British Gynaecological Society, Fellow of the Edinburgh Obstetrical Society, and also a member of the executive of the Newcastle Division of the British Medical Association.

In politics he was a Conservative and an ardent tariff reformer. His chief recreations were hunting and fishing. He was a son of the Highlands, and to hear Farquharson at his best was in the evening when, the day's work done, he would regale those present with an account of his fishing experiences in some remote Highland loch. He had all the hospitality of his countrymen and his generosity was unbounded.

For some time his health had caused anxiety to his friends. Three years ago he had general septicaemia, from which he really never recovered. His death at a comparatively early age is sincerely mourned by a wide circle of friends, and the deepest sympathy is extended to his widow, son, and daughter.

The interment took place at Melton Village, near Doncaster.

SURGEON-GENERAL WILLIAM MAXWELL CRAIG, C.B., R.N.

By the death of Surgeon-General William Maxwell Craig the naval service has lost a brilliant officer at the height of his career of usefulness at a time when his great ability as a surgeon and capacity for organization would have been of the greatest value to the nation.

He was born in India in 1859, was educated in Edinburgh, and graduated M.B., C.M. in that university in 1880. After being house-surgeon at the Peterborough Infirmary, he entered the Naval Medical Service, and served as surgeon on the West Coast of Africa, in the Channel Fleet, and on the China station. He was afterwards posted in succession to the Royal Marines at Plymouth, and the Royal Naval Hospital, Plymouth. When the hospital ship *Maine* was taken over by the Admiralty he was the first principal medical officer; under his capable organization this became a most important asset to the fleet during 1901–3. Subsequently he was in charge of the Royal Naval Hospital at Simonstown, Cape Colony, and on his return to England he was in charge of the junior surgical section at the Royal Naval Hospital, Haslar, which appointment he gave up on being promoted to the rank of Deputy Surgeon-General in 1909. In 1910 he was again appointed to Haslar, this time in charge of the senior surgical section. This appointment he held for several years, and at its conclusion he received the thanks of the Lords of the Admiralty. He was promoted to Surgeon-General in May, 1914, and was made a Companion of the Bath on the occasion of the King's birthday last year. He was chosen President of the Naval and Military Section of the British Medical Association meeting held at Aberdeen this year, but much to his regret was by medical advice obliged to throw this up and take the much needed rest necessitated by the strenuous life of the

last few years. His death took place at 6, Glebe Place, Chelsea, on August 6th.

Throughout his life he was always a keen officer, a man of great resource, always willing and able to give advice and help to his subordinates; a steadfast friend and loved by all who knew him, his passing away has left a great gap impossible to fill both among his brother officers and his immediate relations. He leaves one son, who is now a subaltern in the Royal Marine Light Infantry, to carry on the traditions of the family in the service which he loved so well.

The death of Dr. Albert Roberts Pyne, of Toronto, took place on July 6th. Dr. Pyne was Dominion analyst, and a brother of the Hon. Dr. R. A. Pyne, Minister of Education for the province of Ontario. The late Dr. Pyne was 65 years of age; he was born in Waterford, Ireland, and was the son of Dr. Thomas Pyne.

The announcement of the death of Dr. Colin Garner, of Preston, at the early age of 34, will have been received with great regret by those who knew him as a student in Edinburgh as well as by many friends in the district in which he practised. Dr. Garner, who was the son of Dr. J. E. Garner, who was so well known to many members of the Association as an active member of the Representative Body, obtained the diplomas granted by the Conjoint Board in Scotland in 1904, and was afterwards for a time assistant house-surgeon at the Sunderland Infirmary; subsequently he joined his father in practice, and succeeded him last year as medical officer to the No. 1 District of the Preston Union. Some months ago he suffered from scarlet fever, and did not recover sufficiently to resume practice.

The death of Mr. Myers-Ward, one of the lecturers on physiology at King's College, London, occurred recently at Skegness, where he had gone for the summer vacation. Mr. Myers-Ward, who was a Birmingham student, was at one time professor of physiology at Sheffield. In 1902 he was appointed lecturer on physiology to Charing Cross Hospital Medical School. When in 1911 the anatomy and physiology departments of this school were transferred to King's College, he became lecturer on physiology in that college. At Charing Cross he served as a member of the school committee from 1903 onwards, and in 1909 was elected dean. His work in this capacity was carried out under difficult conditions, especially during the "transition period," and was much appreciated by the staff. Mr. Myers-Ward's death will leave a gap not only in his immediate circle but in the teaching world. He was a specialist in practical histology, his technical ability being universally admired. He was an excellent teacher, and had great influence with students. As a friend Mr. Myers-Ward was of the somewhat brusque but absolutely true type. He liked his old students to keep in touch with him, and never failed to help them when opportunities occurred. Many of them feel that whatever manliness they may have is partly due to their association with him.

Lieutenant-Colonel Henry Percival George Elkington, R.A.M.C., died at Shorncliffe on August 5th, aged 50. He was the son of the late Deputy Surgeon-General A. G. Elkington, of the Brigade of Guards, was educated at St. George's, and took the M.R.C.S. and L.S.A. in 1885, and the D.P.H. of the London Colleges in 1894. He entered the army as surgeon on January 30th, 1886; became surgeon-major on January 30th, 1898; and lieutenant-colonel on January 30th, 1906, being placed on the selected list from February 13th, 1913. He served in the Hazara campaign of 1891 on the North-West Frontier of India.

Lieutenant-Colonel Charles Malcolm Moore, Bombay Medical Service, died at Quetta on July 23rd, of an accidental gunshot wound. He was the son of David Moore, Director of the Botanical Garden at Glasnevin, Dublin, and was born on February 4th, 1864, and educated at Trinity College, Dublin, where he took the degrees of B.A., M.B., B.Ch., and B.A.O., in 1888; also the M.D., M.A.O., and D.P.H. in 1889. Entering the I.M.S. as surgeon on March 30th, 1889, he became major on March 30th, 1901, and lieutenant-colonel on March 30th, 1909, and was promoted to the selected list on June 13th, 1913. He served on the North-West Frontier of India in the operations in the Kurrum Valley in August and September, 1897, receiving the medal with two clasps; in the Tirah campaign of 1897-98, in the reconnaissance of the Kharmana defile, and action of November 7th, 1897, and in the operations against the Khani Khel Chamkannis, clasp; also in China in 1900. He had been medical officer of the 106th Hazara Pioneers for the last ten years, since that regiment was raised at Quetta in 1904.

Lieutenant-Colonel Sydney Edward Duncan, R.A.M.C. (retired), was killed by a fall from a three-story window, at Barrow, on August 7th. He was born on August 16th, 1856; educated at University College, London; and took the M.R.C.S. in 1878, and the L.R.C.P.Edinburgh in 1879. He was assistant medical officer to the Western Fever Hospital of the Metropolitan Asylums Board, to the Metropolitan District Asylum at Caterham, and to the London County Asylum at Banstead, so that he was much older than most of his fellow-officers when he entered the army as surgeon on January 31st, 1885. He became surgeon-major on May 1st, 1897, and lieutenant-colonel on January 31st, 1905, retiring on April 20th, 1910. After his retirement he was employed by the War Office as medical officer at Shrewsbury, and had gone to Barrow on the recent mobilization. He served for some time in the South African war during 1900-1, and was present at the actions of Houtnek, Vet River, and Zand River, in the Orange River Colony, and in those at Johannesburg, Pretoria, and Diamond Hill in the Transvaal, receiving the Queen's medal with four clasps, and the King's medal with two clasps.

Public Health
AND
POOR LAW MEDICAL SERVICES.

TEACHING OF HYGIENE.

Mr. Pease, in a reply to Sir Godfrey Baring, stated shortly before the adjournment that hygiene was one of the subjects of the instruction in a public elementary school named in Article 2 of the Code. It was there defined as instruction adapted to the ages and sexes of the scholars in the elementary rules of personal health, particularly in respect of food, drink (including alcohol), clothing, cleanliness, and fresh air. An official syllabus of lessons on temperance had been issued. Some suggestions as to the teaching of hygiene were given in Section XII of the report of the chief medical officer of the Board for 1910. Mr. Pease added that the subject was one in which education authorities and teachers took considerable interest, and there seemed to be no reason for interfering with their discretion.

NOTIFICATION BY PARTNER OF A MEDICAL OFFICER OF HEALTH.

J. F. B. Section 11 of the Infectious Disease (Notification) Act, 1889, provides that where a medical practitioner attending on a patient is himself the medical officer of health of the district he is entitled to the fees for notifying to which he would be entitled if he were not the medical officer of health. A medical officer of health is entitled to a fee of 2s. 6d. for notifying a case which occurs in his private practice. The partner of a medical officer of health should claim the ordinary fees for notifying; his position as partner does not affect him at all. The above remarks apply also to notifications of cases of tuberculosis.

The Board of Agriculture has issued a useful leaflet (to be obtained free on application to the secretary, 4, Whitehall Place, S.W.) containing suggestions for the autumn treatment of land by the holders of allotments and gardens, and for the sowing of turnips, carrots, onions, lettuce, and spinach at the present time.

The Year Book of Radiology for 1915 is announced by Messrs. Longmans and Co. as in preparation, edited by Dr. Robert Knox and Mr. James H. Gardiner, F.C.S. The object of the work is to give an account of the more recent advances in the knowledge of radium, *x* rays, and the allied phenomena, both from the medical and physical points of view. Notices of new books and apparatus, legal information, physical data, hints for the laboratory, and matters connected with practice will be included.

Letters, Notes, and Answers.

QUERIES.

CORN asks for information as to Desoulter's artificial legs, and whether the metal in them is suitable for use at the seaside.

ANSWERS.

KAFFRARIAN. Cryogenine is stated by Crinon (*Revue des Médicaments Nouveaux*, 1908, p. 124) to be metabenzamido-semicarbazide. It is a white crystalline powder, which is only very slightly soluble in water; no information can be found regarding its solubility in alcohol. Various reports recommend it for use in the treatment of the fever of tuberculosis.

TREATMENT OF PRURITUS ANI.

DR. W. F. SOMERVILLE (Glasgow) writes that the local application of high frequency currents as a rule gives speedy and permanent relief. If this method of treatment is not available, an ointment containing 80 grains of calomel, 40 grains of camphor, and 20 grains of quinine to the ounce will probably remove the anal irritation. An evacuation at bedtime and scrupulous cleanliness after stool would assist in obtaining a cure.

OLD CASE BOOKS.

H.—The purchaser of a medical practice is only entitled legally to what is set out in the deed of purchase. This may or may not include old case books, etc. But it is not unusual for the vendor to hand over books connected with the practice that will assist his successor in carrying it on. Old case books dealing with patients in the past who may be dead or have left the neighbourhood, and which may contain confidential matters having no bearing on the future conducting of the practice, should be burnt.

LETTERS, NOTES, ETC.

THE SUPPLY OF LOCUMTENENTS.

MR. PERCIVAL TURNER (London, W.C.) writes to thank the very numerous practitioners who have so generously written and offered their services at reduced fees in this time of stress. He adds, in reply to correspondents, (1) that during the summer months very many practices return to their owners little or no profit; (2) that very few service men in practice will draw £1 a day from panel cheques, especially as in many cases their panels are largely depleted through patients who have joined the army or navy, and that private practice will be also affected owing to the unanimous and generous decision of the profession to attend free of charge patients dependent on men called to active service; (3) that all the old established and recognized agents are only charging fees in proportion to the sums received by the locumtenents.

SPECIAL MARK FOR DOCTORS' CARS.

DR. J. MOORE BENNETT of Ruddington, Notts., suggests that at the present time it would be well that doctors' motor cars should bear some distinguishing mark in order that the public may easily obtain their services in case of accident, and also reliable information as to the nearest place where accommodation can be obtained for men and horses. The Automobile Association and Motor Union informs us that it has passed on to the Home Office information it has received to the effect that in Canada and the United States the cars owned by doctors are distinguished by a square white plate bearing a green cross, which is placed immediately over the number plate.

PITUITRIN IN LABOUR.

MR. REGINALD JOHNSON, B.A., M.B., B.Ch., B.A.O.Dub. (Singapore), writes: I have been reading with interest the letters concerning the use of pituitrin in labour. I began to use pituitrin over eighteen months ago, and have never had any bad results. In the tropics there is a common saying that birth is usually easier and less painful than at home. I cannot say that I have found this so, but I have certainly found pituitrin a great help. In two cases in which I was sure the pains had not started, but I knew the patients to be at full term, I used pituitrin with the idea of starting pains. In one case, a young healthy woman, the result was immediate, as pains began five minutes after an injection of 1 c.cm. into the buttocks. The pains in both cases tended to die away in about one hour, but were renewed on injection of another cubic centimetre of the drug. I had to give in all 10 c.cm. to each case. There was slight blue asphyxia of the babies. I do not advise the injection of pituitrin to produce labour until a great deal more is known about the drug. One effect I have noticed in several babies who have been helped into the world by pituitrin, and that is an unnatural brightness of their eyes and a general look of "wide-awakeness." They have now and again made almost convulsive movements. This condition passed off in each case in a few hours' time. I have never used more than 3 c.cm. I have used pituitrin in a few cases of slight contraction of the pelvis with good results. From what I can see of the drug, it ought not to be thought of in eclampsia or placenta praevia. In eclampsia the raising of the blood pressure is detrimental, and in placenta praevia the condition of the lower uterine segment is enough to prevent use of the drug. In all my cases the patient passed water with great ease within twelve hours of the child's birth. In an ordinary normal case I give pituitrin in the following way: I wait till the os is fully dilated, and if the membranes are unruptured I rupture them. I give 1 c.cm. of pituitrin into the buttocks, and get ready to guard the perineum; there is usually only one long pain, which I ease by using a little chloroform, and then pains become regular and strong. The danger is that with such strong pains the perineum may be torn, and as the head is distending the perineum at the time it is often advisable to administer a little chloroform and to tell the woman not to strain. The placenta in all my cases came away in about five minutes after the child. I have never had a case of *post-partum* haemorrhage out of over sixty cases. One hour after the placenta has come away I give ½ c.cm. of pituitrin subcutaneously, and repeat the dose in two hours. I agree with Dr. P. A. Hendley (JOURNAL, May 16th), when he says that we must not rely on pituitrin alone. My last case was a multipara. It was her third child in thirty-eight months. I saw her when the os was not fully dilated; the membranes had ruptured, but the pains were somewhat feeble and ineffective. At 3.15 a.m. I gave her 1 c.cm. of pituitrin into the buttocks. At 3.30 a.m. the child had been born quite naturally, the placenta following as soon as the cord had been tied and cut. As Dr. Hendley says, "careful selection of cases" is necessary. With the knowledge that the drug produces pains and hastens expulsion of the child, comes the desire to push the drug. Never give more than 4 c.cm. of pituitrin to one case, and give it at intervals of one hour and in doses of 1 c.cm. at a time.

FOOD VALUES AND VITAL PRINCIPLES: A WARNING.

DR. J. GORDON SHARP (Leeds) writes: Much advice is now being given to the laity as to the best and most economical food to buy, and the only point apparently kept in view is the food value. My reason for troubling you is to ask medical men to interest themselves in this subject and to warn the people against all foodstuffs which have been artificially treated by heat, cold, or electricity, for by these means their vital principles (vitamines) may be destroyed or materially impaired. Condensed and dried milks and prepared and concentrated cereals are all to be suspected. There is to-day less fear of the people not getting enough nourishment than there is of them losing the elements of freshness in their food. Especially should we be on our guard in prescribing foodstuffs for the poor, for babies, and for all who must of necessity live on a limited dietary. All who see the condition of the poor and especially of the children who throng our large out-patient departments will realize the importance of this subject.

HILL DIARRHOEA.

A CORRESPONDENT has sent us a specimen of an Indian native remedy for "hill diarrhoea" which, he states, has proved efficacious in the case of a patient who lived in India for over forty years. Microscopical examination of the specimen shows that it consists largely, if not entirely, of the fruit of some plant of the order Umbelliferae, having a fairly strong resemblance to anise. On the other hand, the odour is more like that of cummin. It is not possible to say with certainty from the microscopical appearance that there is no other drug present besides the umbelliferous fruit, but there is no clear evidence of another. No alkaloid has been detected and the powder consists apparently only of the powdered vegetable tissue. It would not be possible to identify it further or to report on its constituents, unless a much larger quantity were available for examination, including at least some of the fruits not in the powdered condition.

THE

British Medical Journal.

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION.

LONDON: SATURDAY, SEPTEMBER 5TH, 1914.

EDUCATIONAL NUMBER, SESSIONS 1914-1915.

THE PROFESSION OF MEDICINE.

THE main object of this issue of the BRITISH MEDICAL JOURNAL is to meet the needs of two classes—those who require information as to the course which must be followed in order to become a legally qualified practitioner of medicine, and those who, having already obtained this position, are doubtful as to what particular path in medicine they should choose as a life career.

In this country the conditions with which those who desire to enter the medical profession must comply are regulated by a statutory body known as the General Medical Council, and a statement of its requirements will be found on page 422. The task of examining candidates as to their fitness to practise medicine is left to the universities and to certain corporations in England, Scotland, and Ireland, but the Council takes steps to ensure that the tests imposed do not fall below a certain standard, and that none of these bodies admit to their examinations persons who have not undergone certain definite courses of instruction at one or other of the many recognized medical schools.

Successful candidates at such examinations eventually receive from the body holding them either degrees—in the case of the universities—or diplomas or licences—in the case of the corporations—entitling them to claim that their names shall be inserted in the *Medical Register* kept by the General Medical Council. The difference in the result is, however, no criterion of the comparative difficulty of the examinations undergone, nor yet of the expenditure in time and money that has been involved by the education necessary to pass them. At one time the holders of diplomas and licences formed the great majority of all medical men, especially in England and Wales, but of recent years universities have greatly multiplied; consequently so many medical men now hold degrees that, save in exceptional circumstances, the wisest course for a medical student is to aim at a degree, though it may be desirable to take also a diploma or licence.

Apart from the degrees and diplomas and licences, on the strength of which the General Medical Council grants admission to the *Register*, most of the bodies in question bestow on candidates who have passed further examinations higher titles, such as "Fellow" and "Doctor of Medicine." It may be said that as a rule they are worth obtaining, though the difficulty of doing so, as also the added professional status they confer, varies considerably. There are also a certain number of diplomas in special branches of work, such as public health and tropical medicine, which are superfluous in the case of the great majority of medical men, but either useful or absolutely necessary in the case of those who wish to specialize in the work covered by them.

The expenditure involved in successfully completing a medical curriculum varies so much that no very precise statement on the subject can well be made. Apart from differences in the charges made by different medical schools for instruction, there are differences also in the fees for examination, as well as in those charged for the actual certificates given to successful students, whether these relate to degrees, licences, or diplomas. Besides this, not all medical students, however industrious, get through their examinations with equal facility, and since in any case their professional education must continue for at least five years—a period exceeded by the vast majority—and since the cost of living in different parts of the kingdom varies considerably, and personal expenditure varies still more, it can only be said that no one should think of entering the profession of medicine who is unprepared to spend on his medical education a sum of about £1,000.

When once a medical graduate, diplomate, or licentiate has obtained the insertion of his name on the *Medical Register* there are many courses open to him; he can aim at becoming a general practitioner, or at entering one of the Government services at home or abroad; or at specializing in public health or asylum work; or in pure science; or in one or other of the many modern subdivisions of medicine and surgery. Most of these different paths in medicine are considered in some detail elsewhere, but a few observations may here be made as to the first and last of them.

A man becomes a general practitioner either by taking a house and waiting for patients to seek his services, or by entering into partnership with some already established practitioner. The successful conduct of a private practice entails, however, the possession of a great deal of knowledge other than that acquired at the medical schools, and consequently no man is likely to be accepted as a partner, or to prove successful as an independent practitioner, unless he has first gained experience in private practice as an assistant. The pay of assistants was at one time very small, but of late years has risen to what is quite a respectable figure, when consideration is paid to the

fact that most assistants are still more or less *in statu pupillari*. Their average pay may be put down as between £150 and £250 a year.

The path of those whose ambitions lie in the direction of becoming consultants or specialists is rugged. Their eventual success will depend not only upon their mental attainments and capacity for hard work, but on their possession of the various qualities which help to win for a man the confidence both of his colleagues and of the general public. Moreover, since it is certain that, however well equipped they may be, they will not for many years make as specialists enough to pay their outgoings, this particular path is open only to those who are in possession of sufficient means to maintain themselves for an indeterminable number of years, or who are able, by acting as coaches or by other means, to make sufficient to defray their expenses.

It is not the purpose of this number to put forward any opinion as to what paths in medicine offer the greatest attractions, whether financial or scientific, nor even as to the attractions of the profession as a whole. Still, this at least ought to be said: the movement represented by the passage three years ago of the National Insurance Act is not yet at an end, and the full effects even of this Act itself cannot be foretold with certainty. Consequently the whole medical profession must be regarded as in a state of mutation. The various straws, however, by which the direction of the wind may to some extent be gauged certainly indicate that the profession of medicine is less than ever one which those can be advised to enter whose financial means are likely to be totally exhausted by the time they have completed their studies. Nor should it be entered by any but those who, besides being endowed with a good deal of altruism and a love of science, are physically strong, free from hereditary and other weaknesses, and likely to prove capable of sustaining a very trying existence.

It is to be remembered, too, that the financial returns of the vast majority of medical men are of a very moderate kind and that the incomes of even the most successful practitioners compare but ill with those obtained by persons of equal eminence in other walks of life.

Finally, it should be noted that a further quality every medical man should possess is a strong sense of *esprit de corps*. Medicine, like the Church, is a profession which the general public—as also public authorities—persistently regards as being of a semi-philanthropic character; furthermore, it is a profession whose aims and requirements are very ill understood by persons who have not undergone a medical education, including in that term not only a certain number of years at a medical school, but also a certain number of years passed in the actual practice of medicine. Consequently the interests of the medical profession, both on its financial and scientific sides, are continually being attacked, sometimes openly, sometimes insidiously. For this reason it is absolutely essential that medical men should band themselves together for the common protection of themselves and the profession that they represent, and to this end join the British Medical Association[1] as soon as they have entered their names on the *Medical Register*. For the objects of this body are to promote the progress of medical science and the interests of the medical profession, and its past history shows that it has well fulfilled them.

[1] The ordinary subscription of members resident within the United Kingdom is £2 2s., but as from January 1st, 1915, those admitted within two years from the date of their registration pay only 25s. until the expiration of four years from such registration. Members resident outside the United Kingdom pay 25s. to the parent Association.

THE GENERAL MEDICAL COUNCIL.

THE General Medical Council is a body which was called into existence by the first Medical Act of 1858. A certain number of its members are elected by the medical profession, and the rest—who form the great majority—are nominated by Government itself and by the universities and such medical corporations of the United Kingdom as have a statutory right to issue diplomas. Its head quarters are at 299, Oxford Street, and it has branch offices at 54, George Street, Edinburgh, and 35, Dawson Street, Dublin. Its duties are to control the medical and dental professions in the interests of the general public, and to that end to maintain a register of legally qualified practitioners. It is admission to this *Register*, and not the possession of a medical degree or diploma, that constitutes a person a legally qualified practitioner. The Council is bound to admit to the *Register* those who hold the degrees or diplomas granted by the bodies represented among its members, but it can prescribe the terms on which those bodies shall grant such diplomas or degrees, and it can erase from the *Register* the name of any medical man or dentist who has been convicted before a court of law of an ordinary crime or of a serious offence against public morality, or who is proved before the Council itself to have been guilty of certain actions which the Council regards as professionally infamous. Its disciplinary powers are strictly limited to legally qualified practitioners, and it has no control whatever over irregular practitioners of any kind.

An account of the regulations that the Council has drawn up in respect of the education of medical students here follows and should be carefully studied. The primarily important things to note about them are that they entail (1) the production of proof of a certain degree of proficiency in subjects of preliminary or general education; (2) application for registration as a medical student either at the head-quarter office in London or at one of the branch offices in Edinburgh and Dublin, although this latter requirement is not invariably enforced.

PRELIMINARY EDUCATION.

The subjects of which proof of efficient knowledge must be produced by applicants for registration as medical students are as follows:

(1) *English:* Grammar; paraphrasing; composition; questions on English history and geography.
(2) *Latin:* Grammar; translation into English from unprescribed Latin books; translation into Latin of a continuous English passage, and of short idiomatic English sentences. In the case of natives of India or other Oriental countries, whose vernacular is other than English, a classical Oriental language may be accepted as equivalent to Latin.
(3) *Mathematics:* Arithmetic; algebra, including easy quadratic equations; geometry, including the subject matter of Euclid, Books i, ii, and iii, and simple deductions.
(4) One of the following subjects:
(*a*) *Greek:* Grammar; translation into English from unprescribed Greek books; translation into Greek of short idiomatic English sentences; or
(*b*) *A modern language:* Grammar; translation into English from unprescribed books; translation of a continuous English passage, and of short idiomatic English sentences.

The Council does not hold an examination itself in these subjects, but expects a candidate to prove his knowledge of them by the production of evidence either that he holds a degree in arts or that he has passed one or other of the tests imposed by various educational bodies which it recognizes for this purpose. Such tests include the matriculations of universities at home and abroad, and the "local examinations" held by the Universities of Oxford and Cambridge, the "leaving" and other examinations held by the Education Departments in Scotland, Ireland, and Wales, as also the examinations of the College of Preceptors and the Educational Institute of Scotland. In regard, however, to nearly all these tests the Council qualifies its acceptance of them by some condition, and these vary so considerably and are so numerous that the leaflet issued by the Council should itself be studied.

REGISTRATION OF MEDICAL STUDENTS.

In addition to showing that he has passed one of these examinations, any person applying for registration as a medical student must (1) produce satisfactory evidence that he has attained the age of 16 years; (2) show that he

has commenced medical study at a university or school of medicine, or at a teaching institution recognized by one of the licensing bodies and approved by the Council. The commencement of professional study will not be reckoned as dating earlier than fifteen days before the date of registration.

Application for registration should be addressed to the Registrar for the division of the United Kingdom in which the applicant is residing—England and Wales, or Scotland, or Ireland. It must be made on a special form, which can be obtained on application at the offices either of the General Medical Council itself or of one of the various licensing bodies and medical schools, and when forwarded it should be accompanied by the certificates as to age and general education.

The regulations with regard to registration apply equally to medical and dental students, with the exception that in the case of the latter pupilage with a registered dental practitioner may be regarded as a commencement of professional study, and that applications for registration should be addressed to the London office only.

Professional Education.

The rule is that it is only from the date which appears against his name in the *Students' Register* that the medical student's career officially begins; thereafter five years must pass before he can present himself for the final examination for any diploma which entitles its lawful possessor to registration as a qualified medical practitioner under the Medical Acts.

There are, however, certain important exceptions to this rule: thus (1) to meet the circumstances brought about by the dates at which sessions of the medical schools commence and end, the close of the fifth year may be reckoned as occurring at the expiration of fifty-seven months from the date of registration. (2) Graduates in arts or science of any university recognized by the General Medical Council, who have spent a year in the study of physics, chemistry, and biology, and have passed an examination in these subjects for the degrees in question, may be held to have completed the first of the requisite five years. (3) The Council will accept as six months of that year six months passed, subsequent to obtaining a certificate in general education, as a student of chemistry, physics, or biology at any teaching institution recognized by a licensing body and approved by itself. In any case, the period of five years must be one of bona fide study, and during its course education in the following subjects must be pursued and examinations passed:

(i) Physics, including the Elementary Mechanics of Solids and Fluids, and the rudiments of Heat, Light, and Electricity.
(ii) Chemistry, including the principles of the science, and the details which bear on the study of medicine.
(iii) Elementary Biology.
(iv) Anatomy.
(v) Physiology.
(vi) Materia Medica and Pharmacy.
(vii) Pathology.
(viii) Pharmacology and Therapeutics.
(ix) Medicine, including Medical Anatomy and Clinical Medicine.
(x) Surgery, including Surgical Anatomy and Clinical Surgery.
(xi) Midwifery, including Diseases peculiar to Women and to newborn Children.
(xii) Theory and Practice of Vaccination.
(xiii) Forensic Medicine.
(xiv) Hygiene.
(xv) Mental Disease.
(xvi) Anaesthetics.

The practical study of Subject (xi) shall not commence until the student has held the offices of Clinical Clerk and Surgical Dresser, and the work done in connexion with it must follow prescribed lines. The Council also expects that study of the Subjects vii to xvi shall extend over not less than twenty-four months subsequent to success at the examination in Subjects iv and v. It also now recommends licensing bodies to require of candidates at their final examinations evidence of instruction in the administration of anaesthetics and in infectious diseases, and of sedulous attention in hospital wards, out-patient departments, and *post-mortem* rooms, as clerks and the like.

Wherever the first of the five years is spent, the next three must be passed at one of the schools of medicine recognized by any of the licensing bodies enumerated in the schedule to the Medical Act of 1858. The final or fifth year the Council recommends should be devoted to clinical work at any public hospital or dispensary at home or abroad which is recognized by any of the licensing bodies.

Special Considerations.

The requirements of the General Medical Council in respect of the education of those who desire to enter the medical profession have now been given in sufficient detail, but before leaving this part of the subject the steps which the aspirant should take may finally be rehearsed in their due order:

(1) Pass an examination in arts;
(2) Enter himself at a medical school or other scientific institution recognized by the Council;
(3) Get himself registered as a medical student;
(4) Study for a minimum of five years certain prescribed subjects;
(5) Meanwhile pass sundry intermediate examinations, and, finally, at the end of the fifth year, one which will entitle him to receive at the hands of a licensing body a legal authority to practise.

The Arts Certificate.—There are, however, other important considerations; thus, it is not a matter of indifference what certificate of proficiency in general education, or arts, the student obtains. The General Medical Council, it is true, will accept any of the large number of tests to which reference has been made, and this, too, is the case with practically all the college corporations in England, Scotland, and Ireland. But all the licensing bodies are not equally accommodating; some of the universities require that their own ordinary matriculation should be passed, others have special matriculation examinations for those wishing to join their medical faculty, and a third and larger number will accept any arts degree and certain matriculation examinations, as well as several other of the tests entered in the Council's list.

The first thing, therefore, the future medical student should, if possible, decide is at what degrees or diplomas he intends to aim, and then find out what arts certificate will be required. If he cannot decide the question in advance, the best course probably would be to matriculate at London University, choosing as two of his optional subjects Latin and one other language, so as to meet the requirements of the General Medical Council with respect to general education. It is a troublesome examination in many respects, but gives a wide choice of subjects, and has the advantage of being accepted as sufficient testimony to general education by a larger number of bodies than is any other analogous examination.

The Minimum Period.—Another point to remember is that the period of five years mentioned is a minimum; a good deal more will almost certainly be required even by the man of good abilities and reasonable industry. Besides these qualities, a student to obtain a registrable qualification in the minimum period of five years, or fifty-seven months, must have a considerable amount of good luck; in other words, he must keep in good health through every term, and never fail at a single examination. Otherwise it is almost inevitable that his career as a student should be prolonged for a greater or smaller number of months beyond the possible minimum. Thus, for instance, a student before presenting himself for any examination has to get what is called "signed up" for the subjects covered by that examination; this means that his teachers have to certify that he has attended the required number of lectures or classes in the subjects in question. If, however, the student happens to be ill during the term when such lectures or classes are taking place, he may miss a sufficient number of them to make it impossible for him to be "signed up." Then, again, should a student fail to satisfy the examiners at some examination, he cannot present himself again for re-examination for at least three months. This fact generally entails further consequences, because, apart from the student's success at the next stage in his career being imperilled by his having to give up some time to restudying the subjects in which he has failed, the Examining Boards in the majority of instances insist upon a definite interval elapsing between a student passing one examination and his presenting himself for that which should follow it. Then, again, many Boards refuse to recognize lectures and classes which have been attended at a date anterior to that at which the student has passed the requisite examination in earlier subjects. Failure at an examination may thus not only mean

deferment of the date of examinations, but deferment of the commencement of the student's study of certain subjects. It is thus exceedingly easy for a student to fail to qualify in five years, and, as a matter of fact, the vast majority of students take very much longer than that period.

Furthermore, in speaking of the minimum period, it is to be remembered that that time is only sufficient to gain a registrable qualification, such as a Bachelorship of Medicine or Surgery or a diploma of one of the Royal Colleges. These are quite sufficient for the purposes of general practice, or for entering the Services, etc., but those who wish to take a higher qualification—for instance, the F.R.C.S.Eng.—must prolong their work for another year or more. So, too, must in some cases they who desire to convert their Bachelorship into an M.D. This may entail further formal examination, but at some universities the M.D. is obtainable on presentation of a thesis when the Bachelor has attained a certain age, and has practised his profession for a certain number of years. However, a student's career proper may be considered, perhaps, to have ended at the time he obtains his first registrable qualification, for while preparing himself for any further tests he can, and usually does, hold some junior appointment which more or less covers his expenses.

The Normal Course.

In conclusion, it may be convenient to sketch the general fashion in which the student will pass his five years or more, but discussion of this need not be prolonged, because once a student has entered at a school, and chosen the degrees or diplomas at which he wishes to aim, the dean of the school will guide his steps in every particular.

Whatever the precise final goal, the path thereto is in all cases identical in broad outline. Practically it is divided into three stages, the conclusion of each being marked by an appropriate examination. In the first stage the student acquires a more or less extensive knowledge of the preliminary sciences — chemistry, physics, and biology; in the second he studies anatomy and physiology; and the third he devotes to the real work of his future life—medicine and surgery and their branches. During each of these stages the student must attend not less than the prescribed number of lectures and classes to ensure getting "signed up" in the subjects of the stage and also do a very considerable amount of practical work. As for the examinations at the end of the stages, these are known by different titles by different examining bodies, but "preliminary science," "intermediate," and "final" are in common use. Some bodies demand that the student should pass in all the subjects of one stage at one time; others allow the candidate to present himself in each of the subjects separately, thus multiplying the actual number of examinations, but limiting their scope. There are also differences in the requirements of the different licensing bodies as to the length of each stage, but practically all demand that the second shall be longer than the first, and the third not shorter than the second. By the length of the allotted stage the candidate may gauge the comparative importance the licensing body attaches to the subjects within the stage and the difficulty of the tests it will impose, and he may feel certain that the time allotted is none too much.

In any case it should be the aim of the student to get through his first two stages as quickly as his abilities and the regulations will allow; and, as a rule, he should have completed the first stage by the end of his first year, and may hope to complete the second stage not later than the end of his third year. He will then have two years in which to prepare for his final examination, and it will prove a very crowded period, for he has to get into it not only medicine, surgery, and midwifery proper, but many other allied subjects, such as pathology and bacteriology, forensic medicine, gynaecology, and therapeutics. In the first of the final two years he may be able to complete his formal lectures, and thus have the fifth year for entirely practical work and private study; during those two years, too, he will take part in the work of his hospital by holding clerkships and dressership in the wards and out-patient department for the periods laid down by the licensing bodies. Then, at length, after perhaps a few weeks of special coaching, he will be ready to present himself for his final examination, which the regulations of most bodies will allow him to divide into two or more parts. The final examination passed in its entirety, he will be able to claim registration as a qualified medical practitioner at the hands of the General Medical Council, and become an independent personage. There is still room for him to continue a student's career if he will, for, apart from the higher qualifications to which reference has been made, it may seem to him worth while to devote time to acquiring greater knowledge of some particular branch of medicine, such as ophthalmology or laryngology, or to undergo the courses of study necessary to obtain a diploma of special proficiency in questions of public health (page 452), or in tropical medicine (page 451). Points such as these, however, the student will be fully capable of deciding for himself when he has reached the stage to which our account has now brought him.

The next matters to be considered, therefore, are the requirements in detail of the different licensing bodies, and what they have to offer in the way of degrees and diplomas.

The English Universities.

THERE are eleven universities in England and Wales, and some account of each of them follows. With one exception they all have fully developed medical faculties. The exception is the University of Wales, whose constituent colleges are those of Aberystwith, Bangor, and Cardiff. It is in a position, however, to grant degrees, and has laid down a six years' curriculum for candidates for the M.B. degree, and it already provides, at the School of Medicine at Cardiff—of which an account will be found at page 444—thorough training in the work of the first three or four years.

UNIVERSITY OF OXFORD.

THE professional degrees conferred by this university are those of Bachelor of Medicine (B.M.), Bachelor of Surgery (B.Ch.), Doctor of Medicine (D.M.), and Master of Surgery (M.Ch.). It also grants a diploma in State Medicine and a diploma in Ophthalmology. On receiving the B.M. the candidate is entitled to registration by the General Medical Council. In favourable circumstances this degree and the B.Ch. may be obtained in six or seven years from matriculation. Before receiving either, however, the candidate must have taken a degree in Arts (B.A.), for which three years' residence within the university is necessary. This, however, does not necessarily mean deferment of professional study for that period; for some of the subjects chosen for the final stage of the arts course may be the same as those in which examinations would in any case have to be passed for the medical degrees.

THE B.A. DEGREE.

A candidate may obtain the B.A. degree in either of the following ways:

(*a*) By passing Responsions (or one of the examinations which are accepted as equivalent), Moderations, a Scripture examination, or, in the event of a candidate objecting, an examination in some substituted book; and the Final Pass School in three subjects, two of which may be the same as two in the preliminary examinations in natural science.[1]

(*b*) By passing Responsions, an additional subject in Responsions, the Scripture examination, some of the preliminary examinations in the Natural Science School,[1] or the Preliminary Examination and the School of Jurisprudence, or the Honour School of Mathematics in the first public examination; and one of the final honour examinations.

Responsions and the additional subject may be passed before a candidate is a member of the university;[2] Moderations and Scripture can be passed in or after the second term; the final pass school may be taken any time after

[1] The four subjects of the medical preliminary examinations are four of the subjects in the natural science preliminary, and can be commenced directly after passing Responsions.

[2] Membership is constituted by matriculation and by becoming a member of a college or hall, or a non-collegiate student.

Moderations; a final honour school may be taken at the end of the third or within the fourth academical year—that is, twelve or sixteen terms respectively; the preliminary examinations of the Natural Science School may be taken as soon as Responsions have been passed.

Professional Degrees.

To obtain the B.M., B.Ch. degrees the candidate must first pass in four of the subjects of the Preliminary Examination of the Natural Science School—namely, physics, chemistry, zoology, and botany.

He then has two further examinations to pass—the First M.B. and the Second M.B. These take place twice a year, the first on the Thursday, the second on the Wednesday, of the eighth week of Michaelmas and Trinity terms. Every candidate at the First M.B. is examined in human anatomy and also in physiology and in organic chemistry, unless he has previously taken a first or second class in the two latter subjects in the Natural Science School. Once he has passed this examination he can, on production of certain certificates, be examined as soon as he pleases in pathology, forensic medicine, and hygiene, materia medica, and pharmacology[1] (subjects of the second examination), but cannot present himself for the remaining subjects—medicine, surgery, and midwifery—until the twenty-fourth term from the date of his matriculation, and not until a period of at least twenty-two months have elapsed from the date of his passing the first examination, and he must take all the three subjects at one and the same time.

D.M. and M.Ch. Degrees.

A Bachelor of Medicine who wishes to proceed to the M.D. must have entered his thirty-ninth term and must present a dissertation for approval by the appointed examiners. If a candidate for the M.Ch., he must have entered his twenty-seventh term and must pass an examination which is held in June.

Teaching.

The several colleges provide their undergraduate members with tutors for all examinations up to the B.A. degree. In addition, the university provides certain courses of instruction, including lectures, demonstrations, and practical work, which cover all the subjects of the Preliminary Examination and First M.B., and in part those of the Final Examination. For the diploma in State Medicine and the diploma in Ophthalmology certain of the courses can be taken in Oxford.

Scholarships.

The several colleges grant scholarships of £80 a year, tenable for four years, in natural science, chemistry, physics, and biology. Exhibitions of varying value are also awarded in these subjects. Particulars can be obtained on application to the college tutors. A Radcliffe Travelling Fellowship of £200 a year, tenable for three years, is conferred annually; candidates must have taken the B.M. degree. A Philip Walker Studentship in Pathology of £200 a year, tenable for two years, is awarded biennially for the encouragement of research in pathology, as also are the Rolleston Memorial Prize, for research in natural science (including pathology), and the C. Theodore Williams Scholarships in Anatomy and Physiology, and in Pathology, of the value of £50 each, tenable for two years.

Fees.

An annual fee of £2 10s. is paid to the university for the first four years, being reduced to £1 when the B.A. has been taken. For the degree the fees are—the B.A., £7 10s.; the B.M. and B.Ch., £14; the D.M., £25; the M.Ch., £12. College fees, varying in amount, are paid for the first four years of membership and in taking degrees. Tuition fees vary from £21 to £30. The minimum annual cost of living during the three university terms may be regarded as not less than £120.

UNIVERSITY OF CAMBRIDGE.

The professional degrees given by this university are those of Bachelor of Medicine (M.B.) and Bachelor of Surgery (B.C.), which entitle the possessor to admission to the *Register* by the General Medical Council, and the higher degrees of Doctor of Medicine and Master of Surgery. It also grants diplomas in State Medicine and Tropical Medicine to persons who are registered medical practitioners, but not necessarily graduates of the university.[2] A candidate for the M.B., B.C. degrees need not possess a degree in arts; it is sufficient if he has passed the *Previous examination* or some other examination accepted by the university as its equivalent.

Professional Examinations.

To obtain the M.B., the candidate must pass three examinations, of which the latter two take place twice a year—in Michaelmas and Easter terms; those who are finally successful receive the B.C. degree without further examination.

First M.B. or Preliminary Examination in Science.—This comprises (1) chemistry, (2) physics, (3) elementary biology. The parts may be taken together or separately. In either case the candidate before admission to examination must have satisfied the requirements in respect of the *Previous examination*, paid the matriculation fee, and entered on his first or some later term of residence. The examination is held three times a year—in October, December, and June.

Second M.B.—This examination, which cannot be passed until the first examination has been completed, comprises Part I, human anatomy and physiology; Part II, elementary pharmacology, including pharmaceutical chemistry and the elements of general pathology. No one may enter Part II unless he has passed Part I. The candidate must be signed up in both subjects and have dissected for six months.

Third M.B.—This is divided into two parts, to neither of which is the candidate admitted until he has passed the examinations previously mentioned. A candidate for the first part, which deals with surgery and midwifery, must be signed up in these subjects and have completed two years of hospital practice.

Before admission to the second part the candidate must have completed five years of medical study and be duly signed up in all subjects. He must also possess certificates showing that he has fulfilled all the recommendations as well as the requirements of the General Medical Council. The examination consists of principles and practice of physic, pathology, and pharmacology.

Act for the M.B.—Before receiving his degree, a candidate who has been successful at the Final M.B. has to write a thesis. This he reads in public on an assigned day, and is then questioned concerning it and other subjects of medicine by the Regius Professor of Medicine. If approved at this test he is then certified as having "kept the Act" satisfactorily, and in due course receives his degree. Medical degrees may be taken in absence, the candidate sending a thesis to the Regius Professor of Physic, which is laid before the Board.

The Higher Degrees.

The M.D. degree may be taken by an M.B. of three years' standing, after keeping a further Act and writing a short extemporary essay, in which he may deal at his choice with either medicine, physiology, pathology, or State medicine. The M.C. degree may be granted to a candidate who has qualified for the B.C. at least three years previously; he is then examined in pathology, surgery, surgical anatomy, and surgical operations, or submits books or writings of his own which constitute original and meritorious contributions to the science and art of surgery.

Fees.

In addition to college fees, tutorial fees, and the expenses of living, the following examination fees are payable: First M.B., £4 4s.; Second M.B., £4 4s.; Third M.B., £9 9s. For schedules referring to the examinations, lists of schools recognized by the university, and other information, application should be made to the University Registrar.

UNIVERSITY OF LONDON.

Under the regulations of the University of London, the degrees obtainable in the Faculty of Medicine are those of Bachelor of Medicine and Surgery, Master of Surgery in two branches, and Doctor of Medicine in six different branches. The university has its own matriculation

[1] A candidate who passed in materia medica and pharmacy under the old regulations in the First Examination before April 14th, 1909, is exempt from the examination in materia medica and pharmacology in the second examination.

[2] See p. 451.

examination, and this is of so peculiar a kind that candidates should secure and carefully study the booklets relating to it.

In no circumstances is a degree granted to any one in less than three years after the date at which he passed the Matriculation Examination or obtained registration in some other way, and unless they are already registered medical practitioners of a certain age and standing, all students must pass not less than five and a half years in professional study subsequent to matriculation. Four and a half of those years must be passed at one or more of the medical institutions or schools at home or abroad recognized by the university for the purpose; and not less than one school of the university itself.

PROFESSIONAL EXAMINATIONS.

M.B., B.S.—There are three examinations, the two last being subdivided. They are held twice a year.

The First Examination covers inorganic chemistry, general biology, and physics, there being two papers, a practical test and a possible viva voce test in each subject. The names of successful candidates are placed in alphabetical order, with a note as to any subject in which a candidate has distinguished himself.

The Second Examination, Part I, cannot be passed within six months of the passing of the First Examination. It covers organic and applied chemistry, the candidate's knowledge being tested as in the earlier examination. It is a pass examination, but a mark of distinction may be won.

Candidates for Part II must have passed the First Examination at least eighteen months previously besides having completed Part I of the Second Examination. The subjects are anatomy, physiology, and pharmacology, the tests being written, oral, and practical. Candidates who fail in one subject may offer themselves for re-examination in that subject alone if the examiners think fit.

No candidate is admitted to the Third M.B., B.S. examination within three academic years from the date of his completing the Second Examination. The subjects are medicine (including therapeutics and mental diseases), pathology, forensic medicine and hygiene, surgery, and midwifery and diseases of women. They may be divided into two groups, one comprising medicine, pathology, forensic medicine and hygiene, and the other surgery and midwifery and diseases of women. Either group may be taken first at the option of the candidate, or the groups may be taken together. Only candidates who show a competent knowledge of all the subjects comprising a group are passed. There is no separate examination held for honours, but in the list of successful candidates the names are divided into an honours list and a pass list, in each of which the names are placed in alphabetical order, and a university medal may be awarded the candidate who has most distinguished himself in the whole examination.

THE HIGHER DEGREES.

M.D.—An examination for the M.D. is held twice yearly—in December and July. Every candidate must have passed the examination for the M.B., B.S., unless he became M.B. before May, 1904. He may present himself for examination in any one of the following branches: (1) Medicine, (2) pathology, (3) mental diseases and psychology, (4) midwifery and diseases of women, (5) State medicine, (6) tropical medicine; and, if he wishes, may pass also in another branch at a subsequent examination.

The period that must elapse between acquiring the M.B. and sitting for the M.D. in any branch varies with the nature of the candidate's previous work between one year and two years, and in all cases evidence must be afforded of special study of the subject chosen, whatever the branch; both written and practical examinations must be passed, though exemptions can be obtained from the former in exceptional circumstances. In each branch the scheme of examination is the same: two papers on its special subject, a paper on an allied subject—for example, medicine in the case of branch (4), pathology in branch (1)—an essay on one of two suggested topics connected with the special subject, and a clinical or other practical test. In any branch of the M.D. Examination a gold medal of the value of £20 may be awarded.

M.S.—The regulations with regard to the Mastership in Surgery are of a corresponding kind, but there are only two branches in which it may be obtained—General Surgery and Dental Surgery.

FEES.

For Matriculation: £2 for each entry. First Examination: £5 for each entry to the whole examination. For re-examination in one subject the fee is £2. Second Examination, Part I: £2 for the first and each subsequent entry. Second Examination, Part II: £8 for each entry to the whole examination. For re-examination in one subject the fee is £4. M.B., B.S. Examination: £10 for each entry to the whole examination, and £5 for examination or re-examination in either group. M.D. and M.S. Examinations: £20 and £10 on re-examination.

UNIVERSITY OF DURHAM.

To its own graduates, who may be of either sex, this university grants the degrees of Bachelor and Doctor of Medicine (M.B. and M.D.) and Bachelor and Master of Surgery (B.S. and M.S.); it also grants special degrees and diplomas in State Medicine, Psychiatry, and Dental Surgery.[1] To become a graduate, however, at the university it is not necessary to pass the major portion of the five years' curriculum within its precincts, or even to commence that period by matriculation. It is sufficient if, before he presents himself for his final examination, the candidate has passed at least one year in study at the University of Durham College of Medicine, including the practice of the Royal Victoria Infirmary in the same city. The earlier examinations may be passed while a student elsewhere, but not less than a year must elapse between the time that the student satisfies the requirements of the university as regards matriculation and his presenting himself for the Final M.B., B.S. Examination.

MATRICULATION.

The university has its own matriculation examination, but accepts the tests of a considerable number of other educational bodies as a full or partial equivalent. A list may be obtained on application.

PROFESSIONAL EXAMINATIONS.

There are four professional examinations for the M.B., B.S. degrees. They are held twice a year—in March and June. The first deals with elementary anatomy and biology, chemistry, and physics; the second with anatomy and physiology; the third with pathology, materia medica and pharmacy, elementary bacteriology, medical jurisprudence, and public health. At the final M.B., B.S., the candidate is examined in medicine and clinical and psychological medicine; surgery and clinical surgery; midwifery and diseases of women and children; clinical and practical gynaecology and therapeutics.

M.D.—A Bachelor of Medicine who wishes to proceed to this higher degree must be of at least two years' standing, and satisfy the university that he knows either Greek or German. He then submits a typewritten essay dealing with original work or observation of his own, and is examined in its subject. If the candidate is not an M.B. of the university, he must be a practitioner of fifteen years' standing and submit to special tests.[2]

B.S.—A candidate for this degree must have passed the examination for the M.B. of the university, and have attended courses on operative surgery and regional anatomy. He must then perform operations on the dead body before the examiners.

M.S.—Candidates for this degree must, like those for the M.D., satisfy the authorities as to their knowledge of Greek or German, and must have been engaged in practice for at least two years subsequent to becoming B.S. Durham. They are submitted to an examination which covers the whole range of surgical knowledge.

FEES.

The following fees are payable: Matriculation or its equivalent, £1 10s.; First, Second, and Third M.B. Examinations, each £5; Final M.B., £10; M.D., B.S., and M.S., £5 for each examination and £6 6s. for each degree. Further information respecting the examinations and

[1] See pp. 452 and 455. [2] See p. 449.

degrees may be obtained from Professor Howden, at the University of Durham College of Medicine, Newcastle-on-Tyne.

VICTORIA UNIVERSITY OF MANCHESTER.

This university grants the four ordinary degrees in medicine and surgery, M.B. and Ch.B. and M.D. and Ch.M.; a diploma and a degree (B.Sc.) in public health: a certificate in factory and in school hygiene; a diploma in psychological medicine; and a degree and diploma in dental surgery. Candidates for degrees must pass the special Matriculation Examination prescribed by the Faculty of Medicine (or some equivalent examination accepted in lieu thereof; see the prospectus of the Joint Matriculation Board), and study at the university itself for at least two years of the five years' curriculum, one such year being subsequent to the passing of the First M.B. Examination. The Matriculation Examination comprises (1) Latin, (2) mathematics, (3) the English language, its literature and history; (4) English history; (5) two subjects at choice, one of which must be a language approved by the Joint Board, the other being elementary mechanics, *or* physics, chemistry, geography, natural history, *or* botany. It is held in July and September.

Professional Examinations.

M.B., Ch.B.—There are four examinations for this degree. They must be passed in proper order, and before admission to them the candidate must be duly certified as having attended in the subjects involved. At all examinations the subjects, or groups of subjects, prescribed can be taken separately or together, as the candidate pleases. The First M.B. is divided into Part 1, inorganic chemistry and physics; Part 2, biology (including animal and vegetable morphology, physiology, and laboratory work); Part 3, elementary organic chemistry and bio-chemistry. The parts may be taken separately or together. At the Second M.B. the candidate is examined in anatomy and physiology; at the Third in pathology, hygiene, and pharmacology and therapeutics (including materia medica and practical pharmacy). The Final Examination includes medicine, systematic and clinical (separate papers being given on mental diseases), and diseases of children, surgery (systematic, clinical, and practical, with a separate paper on ophthalmology), obstetrics and gynaecology, and forensic medicine and toxicology.

M.D.—A candidate for this degree must be an M.B. of at least one year's standing. He has a choice between presenting an original dissertation or undergoing a written (practical and clinical) examination in medicine, and a written and practical examination in pathology, and one other subject to be selected by the candidate.

Ch.M.—A candidate must have held, since becoming Ch.B., and for not less than six months, an appointment in a public institution affording opportunity for the study of practical surgery, and produce certificates of having attended certain courses of study. The examination comprises the general field of surgery, including ophthalmology and bacteriology.

Fees for Examinations.

The following fees are payable: Matriculation, £2; on readmission, £1 10s. Each M.B. examination, £5; on readmission, after failure, £2. M.D., including the conferring of the degree, £10. Ch.M., £5 each for the examination and degree. Application for further information should be addressed to the Dean of the Medical Faculty.

UNIVERSITY OF BIRMINGHAM.

This university confers the ordinary medical and surgical degrees—M.B., Ch.B., M.D., and Ch.M., and also diplomas and degrees in State medicine and dentistry. It has a plan, too, by which, extending his study to six instead of five years, the M.B., Ch.B. candidate may become a Bachelor in Science as well. Of the five years' curriculum, the first four must be spent, as a rule, at the university itself, the fifth being passed at any approved school or schools. Occasionally, however, the Senate will reduce the period of enforced residence to three years and exempt from the First M.B. those who have passed elsewhere an examination considered to be its equivalent.

All students in the Medical Faculty must (1) either matriculate in mathematics, in chemistry or experimental mechanics, in the English language and literature and history, and in Latin, and one other foreign language; or (2) show that they have passed an examination deemed an equivalent elsewhere. Subject to certain provisos, the following are at present thus regarded:

(*a*) The Previous Examination of the University of Cambridge if it includes the "additional subjects." (*b*) Responsions of the University of Oxford, except in mathematics. (*c*) The Matriculation Examination of a recognized university. (*d*) The Higher Certificate of the Oxford and Cambridge Boards. (*e*) The Oxford or Cambridge Senior Local Examination.

Professional Examinations.

The candidate for the M.B., Ch.B. degrees has five examinations to pass. In the second and final examinations the candidate must pass in all the prescribed subjects or undergo the whole examination again.

First M.B.—This deals with chemistry, physics, and elementary biology; it may be passed before the student commences residence at the university, provided the regulations as to matriculation have been met.

Second M.B.—This deals with anatomy and physiology, and the student must pass in both simultaneously.

Third M.B.—This deals with general pathology and bacteriology, materia medica, and practical pharmacy.

Fourth M.B.—This takes place at the end of the fourth year, the subjects being forensic medicine, toxicology, public health, therapeutics and special pathology.

Final M.B.—This comprises medicine, surgery, midwifery and diseases of women, ophthalmology, and mental diseases. The candidate, in addition to more ordinary certificates, must be prepared with a certificate of having acted as a *post-mortem* clerk for three months, and received special instruction in anaesthetics and clinical instruction in diseases peculiar to women, asylum ward work, and ophthalmology. In respect to the latter he must show that he has learnt refraction work. He also has to present to the examiners reports drawn up by himself on six gynaecological cases, and certificates drawn up by himself regarding four actual cases of lunacy, and notes respecting two others.

M.D.—An ordinary candidate for this degree must be an M.B., Ch.B. of not less than one year's standing. He presents an original thesis for approval, and then passes a general examination in the principles and practice of medicine. From the latter the Board of Examiners may exempt a candidate whose thesis is of exceptional merit. The regulations respecting the Ch.M. are of the same general character. Subject to certain requirements as regards special research or other post-graduate study, graduates of other universities may obtain the M.D. and Ch.M. in the same way as the holders of the Birmingham M.B., Ch.B.

Fees.

The fee for matriculation is £2, and that for each of the first four professional examinations the same amount: M.B., Ch.B. degree fee, £8; M.D. and Ch.M. examination, £10 each. For further particulars application should be made to the Dean of the Medical Faculty.

UNIVERSITY OF LEEDS.

The degrees granted in the Medical Faculty of this university are Bachelor of Medicine, Bachelor of Surgery (M.B. and Ch.B.), and Bachelor of Dental Surgery (B.Ch.D.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), and Master of Dental Surgery (M.Ch.D.). It also gives diplomas in public health, psychology, and in dental surgery.

Candidates for the M.B. must have attended courses of instruction approved by the university for not less than five years, two at least of such years having been passed in the university subsequently to the date of passing the first examination. They must also have matriculated by satisfying the examiners in (1) English (language or literature); (2) English history; (3) mathematics; (4) Latin; (5) two of the following, one of which must be a language; (*a*) Greek, (*b*) French, (*c*) German, (*d*) some other modern language approved by the Board, (*e*) either mechanics or physics, (*f*) chemistry, (*g*) geography, (*h*) natural history. Exemption from the examination may be granted to applicants holding certificates of having

passed examinations of a standard deemed by the Matriculation Board to be at least equal to the Board's examination.

PROFESSIONAL EXAMINATIONS.

The examinations for the M.B., Ch.B. number three. The first deals with (1) physics and chemistry, (2) biology. In each subject laboratory work is included, but the two parts can be taken separately. For neither can the candidate present himself until after matriculation, and at least two or three terms' approved work in the respective subjects indicated.

Second M.B.—This may be taken in two parts, (*a*) anatomy and physiology, including practical work; (*b*) materia medica and pharmacy, including actual compounding of drugs. The candidate's certificates must show, among other things, that he has dissected during at least five terms.

Final M.B.—This may be divided into three parts. The first part, pathology and bacteriology, may be taken at the end of the tenth term; the second part, forensic medicine and public health, and the third part, medicine, surgery, and obstetrics, cannot be taken before the end of the fifth year; and before being admitted to the examination in its subjects the candidate, in addition to ordinary certificates, must produce proof that he has done both intern and extern maternity work, and received clinical instruction in gynaecology, and in eye, skin, or laryngeal diseases, and in the administration of anaesthetics. This division covers all branches of surgery, medicine (including mental diseases and diseases of children), and obstetrics and gynaecology. Passages for translation from French and German are included in the papers on medicine. First and second class honours may be obtained in this division.

M.D.—A candidate for this degree must be an M.B., B.Ch. of at least one year's standing. He presents a dissertation embodying the results of personal observation or original research, and, if this is approved, passes an examination which consists in the writing of an extemporary essay, and answering questions on the history of medicine and the subject of his dissertation.

Ch.M.—The candidate for this degree must have been admitted to the M.B., Ch.B. not less than a year previously, and during that time must have held for at least six months a surgical appointment in a public institution affording full opportunity for the study of practical surgery. In addition, he must have attended certain special courses, including one on ophthalmology and one on bacteriology; he is then examined in the subject of surgery in all its branches.

FEES.

The matriculation fee is £2, and on readmission £1 10s. For each of the other examinations £5, and £2 on readmission. On conferment of the degree of Ch.M. £5 is payable, the same remark applying to the M.D. degree.

UNIVERSITY OF LIVERPOOL.

THIS university, besides granting degrees in medicine (M.B. and M.D.) and in surgery (Ch.B. and Ch.M.), gives a degree in dental surgery (B.D.S.), a degree in hygiene (M.H.), and degrees in Veterinary Science (B.V.Sc., and M.V.Sc.). Diplomas are awarded in dental surgery (L.D.S.), tropical medicine (D.T.M.), public health (D.P.H.), ophthalmic surgery (D.Ch.O.), veterinary science (D.V.H.), and in several single subjects.

MATRICULATION.

The Matriculation Examination is governed by the Joint Matriculation Board, 24, Dover Street, Manchester, which accepts under certain conditions the tests of several other bodies as its equivalent. These *include* the Matriculation of London University, the Senior Local Examination of Oxford and Cambridge, the Higher Certificate of the Joint Oxford and Cambridge Board, Responsions of the University of Oxford, the Previous Examination of the University of Cambridge, the Leaving Certificate of the Scottish Education Department, and the Senior Certificate of the Central Welsh Board. Of the five years' curriculum, not less than two must be passed in the university itself, one such year being subsequent to the date of passing the First M.B. Examination.

PROFESSIONAL EXAMINATIONS.

Candidates for the M.B., Ch.B. degrees have three examinations to pass, the first including (1) chemistry, inorganic, organic, and physical; (2) biology, including zoology and botany; (3) physics. Section 2 may be taken alone or in conjunction with Sections 1 and 3.

Second M.B.—This test covers (1) anatomy and physiology, including physiological chemistry and histology, and (2) materia medica, pharmacy, and pharmacology; these two sections may be taken separately.

Final M.B.—This examination deals with six subjects, which may be taken altogether or divided into three parts: (1) Pathology, morbid anatomy, and bacteriology; (2) therapeutics, forensic medicine, toxicology, and public health; (3) obstetrics and diseases of women, surgery, including ophthalmology, medicine, including mental diseases and diseases of children.

M.D. and Ch.M.—Candidates for these degrees must have received the M.B. and Ch.B. at least a year previously. The M.D. candidate submits for approval a dissertation covering original work, the M.Ch. candidate undergoing an examination in all subjects of surgery, including ophthalmology. Other information concerning the diplomas of this university and its medical school will be found on page 451.

UNIVERSITY OF SHEFFIELD.

THE degrees of this university (M.B., Ch.B., and M.D. and Ch.M.) and the diploma in public health are open to candidates of either sex. Candidates for a degree must have matriculated in the university or have passed such other examination as may be recognized for this purpose.

PROFESSIONAL EXAMINATIONS.

A candidate for the degrees of M.B., Ch.B. must produce certificates that he will have attained the age of 21 years on the day of graduation; that he has pursued the courses of study required by the university regulations during a period of not less than five years subsequently to the date of his matriculation, three of such years at least having been passed in the university, one at least being subsequent to the passing of the first examination. He or she has eventually to pass the following examinations in due order:

First Examination.—The subjects are chemistry, physics, and biology. The intermediate examination in science—chemistry, physics, and biology—will, on payment of the required additional fee, be accepted instead of this examination. Candidates on presenting themselves for this examination are required to furnish certificates of having attended for not less than one year approved courses of instruction, after matriculation, in (i) chemistry, inorganic and organic; (ii) physics; (iii) biology.

Second Examination.—The subjects are anatomy and physiology. The candidate must have completed the third winter session of professional study, must have passed the First Examination, and must have attended (1) lectures on anatomy, and dissections during five terms; (2) lectures on physiology during four terms, practical, experimental, and chemical physiology during four terms, and histology during one term.

Third Examination.—The subjects are pathology and pharmacology. Candidates must have completed the fourth year of medical study and completed the requisite courses in these subjects, including *post-mortem* clerkship for three months.

Final Examination.—The subjects are medicine (including forensic medicine, public health, mental diseases, and diseases of children), surgery, obstetrics, and gynaecology. Candidates must satisfy the examiners in all subjects at the same examination. Candidates must have completed the fifth year of study.

M.D.—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, must present a thesis embodying observations in some subject approved by the Professor of Medicine, and must pass an examination in the principles and practice of medicine.

Ch.M.—Candidates for the degree of Master of Surgery must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, and must, since taking the degrees of M.B., Ch.B., have held for not less than six

months a surgical appointment in a public hospital or other public institution affording full opportunity for the study of practical surgery. The subjects of examination are systematic, clinical, and operative surgery, surgical anatomy, surgical pathology, and bacteriology.

Other information concerning this university will be found in the section devoted to Provincial Medical Schools.

UNIVERSITY OF BRISTOL.

THE university grants the following degrees: In medicine and surgery, M.B. and Ch.B., M.D., Ch.M. (the M.D. may be taken in State Medicine); in dental surgery, B.D.S., M.D.S. Diplomas in public health (D.P.H.) and dental surgery (L.D.S.) are also granted. Candidates for degrees must pass the Matriculation Examination (or some equivalent examination accepted in lieu thereof; see the Regulations for Matriculation), and study at the university itself for at least three years of the five and a half years' curriculum, two such years being subsequent to the passing of the Second M.B. Examination. The Matriculation Examination comprises (1) Latin, (2) mathematics, (3) English grammar and composition, (4, 5) two subjects at choice, one of which must be a foreign language. It is held in July and September.

PROFESSIONAL EXAMINATIONS.

M.B., Ch.B.—There are three examinations for this degree. They must be passed in proper order, and before admission to them the candidate must be duly certified as having attended in the subjects involved. The First M.B. comprises chemistry, physics, botany, and zoology. The Second M.B. comprises organic chemistry, elementary anatomy (Part I), advanced anatomy, physiology (Part II). The two groups may be taken separately or together. The Final Examination includes materia medica and pharmacy, pharmacology and therapeutics, general pathology, morbid anatomy and bacteriology (Part I), special pathology, forensic medicine, toxicology and public health, obstetrics (including diseases of women), surgery (systematic, clinical, practical, and operative), medicine (systematic, clinical, and practical), including mental diseases (Part II). The two groups may be taken separately or together. At the option of the candidate forensic medicine and toxicology may be taken either with Group I or Group II. First or second class honours may be obtained by a candidate whose work is deemed of sufficient merit, but cannot be awarded to one who has recorded against him a failure at any examination after the First M.B.

M.D.—A candidate for this degree must be an M.B. and Ch.B. of at least two years' standing. He has a choice between presenting an original dissertation, undergoing a general examination in medicine (including medical anatomy, medical pathology and bacteriology, systematic and clinical medicine), or passing an examination in State medicine.

Ch.M.—A candidate must have attended, since becoming M.B., Ch.B., and for not less than two years, a public institution affording opportunity for the study of practical surgery, and produce certificates to that effect; the candidate shall be required to pass a general examination in surgery (including surgical anatomy, surgical pathology and bacteriology, operative and clinical surgery), and to present a dissertation in some department of surgery. He must be of two years' standing as an M.B., Ch.B.

Applications for other information should be addressed to the Dean of the Medical Faculty.

UNIVERSITY OF WALES.

THE statutes of the University of Wales provide for a Faculty of Medicine and for the granting by it of the following degrees: Bachelor in Medicine (M.B.), Bachelor in Surgery (B.Ch.), Master in Surgery (M.Ch.), and Doctor in Medicine (M.D.).

A candidate for the M.B., Ch.B. cannot be admitted to examination until the completion of not less than six academic years subsequent to matriculation in the university, and of these years at least three must have been passed as a student in one of the constituent colleges of the university. He must also hold an Arts or Science degree of the University of Wales, or of some other university approved for this purpose. Some of the courses of study pursued for a B.Sc. or B.A. degree may be counted as part of the courses required for the degrees in the Medical Faculty.

The courses for the M.B., Ch.B. are divided into two sections, of which the first include the preliminary subjects—physics, chemistry, botany, zoology; and the ancillary subjects—organic chemistry, human anatomy, and physiology. Study of the preliminary subjects must extend over at least one academic year, study of the ancillary subjects must extend over at least two academic years, and, excepting organic chemistry, cannot be commenced until all the preliminary courses have been completed; hence the first section of the course must occupy not less than three years. The second section includes courses in pathology, bacteriology, pharmacology, medicine, surgery, and obstetrics, and cannot be commenced until the examinations relating to the preliminary and ancillary courses have been passed. Examinations in the earlier subjects are held at the end of each academi year, and in the subjects of the second section each July.

English Medical Corporations.

THERE are three medical corporations in England—the Royal College of Physicians, the Royal College of Surgeons, and the Society of Apothecaries of London. The first two combine for certain purposes to form what is known as the "Conjoint Board." Details concerning this body, its component colleges, and the third licensing body here follow.

THE CONJOINT BOARD.

THIS body deals with the qualifications of all candidates for the Licence of the Royal College of Physicians of London and for the Membership of the Royal College of Surgeons of England. It prescribes for them certain periods of study, and recommends those who satisfy it for the licence and diploma of Membership respectively. The successful candidate is then entitled to admission to the *Medical Register* as an M.R.C.S.Eng., L.R.C.P.Lond. It performs the same task in connexion with diplomas in State medicine and tropical diseases jointly issued by the two colleges in question. It obliges all candidates to pass one of a large number of examinations which it considers satisfactory tests of general education, and thereafter to pass five years in professional study at a recognized medical school, allowing, however, six months to be spent at any institution which may be recognized by the Board as giving efficient education in chemistry and physics. A list of such institutions, as also of the tests accepted in regard to general education, can be obtained from the Secretary of the Board at Examination Hall, Queen Square, Bloomsbury, W.C.

PROFESSIONAL EXAMINATIONS.

There are three examinations for the Conjoint diploma, or M.R.C.S., L.R.C.P., which are commonly known as First Conjoint, Second Conjoint, and Final.

First Conjoint.—This examination is in four parts: (1) Chemistry, (2) physics, (3) elementary biology, (4) practical pharmacy.

A candidate must present himself for examination in Parts I and II together until he has reached the required standard to pass in both, or in one of these parts, but he will not be allowed to pass in one part unless he obtains at the same time half the number of marks required to pass in the other part. A candidate may take Parts III and IV separately, or he may present himself for the whole examination at one time.

Before admission to either part the candidate must show that he has undergone certain courses of theoretical and practical instruction, but these courses need not be completed within one year, nor need they run concurrently, and they may be commenced or attended before the candidate passes the required preliminary examination in general education. A candidate referred in any part or parts will not be admitted to re-examination for three months. If referred in chemistry, physics, or biology he must produce evidence of further instruction. Those who are already graduates in medicine, or who have passed an

examination in the same subjects before a university board for a degree in medicine, may obtain exemption from re-examination in those subjects at this examination.

Second Conjoint.—This examination deals with anatomy and physiology, and both subjects must be passed at the same time. A candidate must have attended at a recognized medical school lectures on anatomy, physiology, and a course of practical physiology and histology, and have dissected for twelve months during the ordinary sessions. The study of anatomy and physiology before passing in two of the first three parts of the first examination is not recognized. If rejected, a candidate, before being admitted to re-examination, must continue his studies at a recognized medical school for not less than three months.

Final Conjoint.—This examination consists of three parts: Part I, medicine, including medical anatomy, pathology, practical pharmacy,[1] therapeutics, forensic medicine, and public health; Part II, surgery, including pathology, surgical anatomy, and the use of surgical appliances; Part III, midwifery and gynaecology. The examination may be passed at one time or in each part separately. Evidence of attendance at courses of instruction in the subjects of the three parts must be produced, and also of having conducted twenty labours. A candidate will be admissible to Parts I, II, and III of the Third or Final Examination at the expiration of two years (twenty-four months) from the date of passing the Second Examination, and on production of the required certificates of study, provided that the examination is not completed before the expiration of five years (five winter and five summer sessions) from the date of passing the Preliminary Examination. A rejected candidate must produce evidence of further instruction during three months.

NOTE.—A person holding a Colonial, Indian, or foreign qualification which entitles him to practise in the country where such qualification has been obtained is, after a course of study and examination equivalent to these required by the Regulations of the two Royal Colleges, admissible to the Second and Third or Final Examinations without any interval. Members of an English, Scottish, or Irish university are under certain conditions eligible for admission to the Third or Final Examination two years after passing at their university the subjects included in the First and Second Examinations of the Board.

A Doctor or Bachelor of Medicine or Surgery of an Indian, Colonial, or foreign university recognized for the purpose, who shall have passed at his university in the subjects of the First and Second Examinations will be eligible for admission to the Third or Final Examinations two years after passing in the said subjects.

FEES.

First examination, £10 10s. Re-examinations, Parts I and II, £3 3s.; Parts III and IV, each £2 2s. Second examination, £10 10s. Re-examination, £6 6s. Third examination, £21. Re-examination, Part I, medicine, £5 5s.; practical pharmacy, £2 2s. Part II, surgery, £5 5s. Part III, midwifery and diseases of women, £3 3s. Members of an English, Scottish, or Irish university, £5 5s. For the diplomas, £36 15s.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THIS College has three grades—its Licentiates, its Members, and its Fellows. The Licence is only issued through the Conjoint Board, as already stated, unless the candidate commenced professional studies before October, 1884. Its Membership is only granted to those who have passed the final examinations for the Licence; or those who are registered practitioners and graduates of a recognized university; in any case they must be persons over 25 years of age, who do not practise in partnership, dispense medicines, or engage in trade. Candidates are examined in pathology and the practice of physic, partly in writing and partly viva voce. Those under 40 are also examined in Latin, and either Greek, French, or German. The examination fee is £6 6s., the Membership fee being £42, or the difference between that sum and what the candidate has already paid if a Licentiate. The body of Fellows is maintained by election from among the Members.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THIS College has two grades—Members and Fellows. The Members are admitted as stated in the section dealing with the Conjoint Board. The Fellowship is granted after examination to persons at least 25 years of age who have been engaged in professional studies for six years. There are two examinations—the first in anatomy and physiology, which may be passed after the third winter session; the second, chiefly directed to surgery, which may be passed after six years of professional study. Candidates must pass the Final Examination of the Examining Board in England and be admitted Members of the College before admission to the Second Examination for the Fellowship, except in the case of graduates in medicine and surgery of not less than four years' standing of universities recognized by the College for the purpose, who are required to attend for one year the surgical practice of a general hospital recognized by the College after obtaining their degrees. The College also issues a diploma in dentistry.[1]

Fees.—At first examination: £5 5s. At second examination: £12 12s. Diploma fee: Members, £3 3s.; non-members, £13 13s.

SOCIETY OF APOTHECARIES OF LONDON.

THIS body confers a registrable diploma in medicine, surgery, and midwifery, now known as the L.M.S.S.A., on those successful at the following examinations:

Primary Examination.—This is divided into two parts, of which Part I includes elementary biology, chemistry, chemical physics, practical chemistry, pharmacy. Part II includes anatomy, physiology, and histology, and cannot be passed before the completion of twelve months' practical anatomy, with demonstrations. The subjects cannot be taken separately, except in the event of the candidate having previously passed in one. Candidates will be excused any or all the subjects of the primary examination on producing evidence that they have passed equivalent examinations before an examining body recognized by the Society. Candidates referred in anatomy will be required to produce evidence of further work in the dissecting room before being admitted to re-examination.

Final Examination.—This is divided into two sections, the first of which is subdivided into three parts. Part I includes the principles and practice of surgery, surgical pathology, operative manipulation, surgical anatomy, instruments and appliances. Part II includes: (*a*) The principles and practice of medicine (including therapeutics, pharmacology, and prescriptions), pathology, and morbid histology; (*b*) forensic medicine, hygiene, theory and practice of vaccination, and mental diseases. Part III includes midwifery, gynaecology, and diseases of newborn children, obstetric instruments and appliances. A candidate for any part of Section 1 must have passed not less than three winter sessions and two summer sessions at one or more of the medical schools recognized by the Society. Section 2 consists of clinical surgery and clinical medicine and medical anatomy, and a candidate before appearing at it must have completed five years of medical study.

FEES.

Primary examinations, £5 5s.; final, £15 15s. Further information may be obtained from the Secretary, Court of Examiners, Apothecaries' Hall, Blackfriars, E.C.

The Scottish Universities.

THERE are in Scotland four universities, each of them possessing a faculty of medicine, and having the right to confer degrees which admit the holder to the *Medical Register*. In essential points the regulations in their medical faculties for undergraduates are on all-fours with one another, so that an account can be given of all of them together.

The universities in question are those of Edinburgh, Glasgow, Aberdeen, and St. Andrews, and in point of standing and repute it is not easy to differentiate between them. What provision each of the cities in which these universities are situated makes for the education of medical students will be found in the section on Medical Schools in Scotland; here it need merely be said that

[1] Candidates who have previously passed in practical pharmacy will not be re-examined in that subject at the Third Examination.

[1] See p. 455.

degrees in medicine from Scotland as a whole have always enjoyed an excellent repute.

The degrees granted in medicine and surgery to candidates of either sex are four in number—Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.). The two former are not separably obtainable one from the other. Besides these degrees a diploma in tropical medicine and hygiene is obtainable from the University of Edinburgh, as also a diploma in psychiatry. As for public health, registrable degrees in this subject are granted both by the University of Edinburgh and that of Glasgow, while diplomas in public health may be obtained from the universities of St. Andrews and Aberdeen. Information as to these will be found in the appropriate sections dealing respectively with preventive medicine and tropical medicine.

Matriculation.

There is a special matriculation examination for medical students, the subjects being English, Latin, elementary mathematics, and either Greek or French or German. Candidates are required to pass in all these subjects either at one or at not more than two examinations, but they can present themselves as often as they please. A large number of corresponding tests held by other bodies are accepted as the equivalent of this examination.

Professional Education.

The regulations comply in all respects with the requirements and recommendations of the General Medical Council, and in addition necessitate definite study for stated periods of diseases of children, of the larynx, ear and nose, of the skin, of ophthalmology, and of mental diseases. In respect of the various courses certificates must be obtained showing that the student has not only attended the courses regularly, but has duly performed the work of the class. Out of the necessary five years of medical study, not less than two must be spent at the university whose degrees the student hopes to obtain, and the balance at any place officially recognized for such purpose. In each academic year there are two sessions—one lasting from the beginning of October to the middle of March, and the other from the middle of April to the end of June.

Professional Examinations.

The distinctive feature of the Scottish curriculum is that, though nominally there are only four examinations, each of these may be, and habitually is, split up by the student into sections. Hence, a student may complete some stage of his career during the course of nearly every session. Thus, by the end of the first winter session the student may get rid of physics and chemistry. At the end of the first summer session he can finish with botany and zoology, and with anatomy and physiology at the end of the second. Practical materia medica may be taken at any period of examination after the necessary course of instruction has been attended. Pathology and materia medica he will pass at the end of the third year, and so on, until the final examination in midwifery, surgery and medicine, and the corresponding clinical subjects at the end of the fifth year of study. At each examination the candidate may pass "with distinction," and a record is kept of the merit displayed, so that, when the time comes for the candidate to graduate, one who has done well throughout can be declared as graduating with first or second class honours. A further point in the system is that the student's own teachers commonly take some part in his examination.

Of the four examinations, the first deals with physics, botany, zoology, and chemistry; the second with anatomy and physiology; the third with materia medica and pathology; the fourth with medicine and surgery (clinical and systematic), midwifery, forensic medicine, and public health, and clinical gynaecology. The first three examinations are held three times a year; the final twice a year.

Exemption from the first professional examination can be obtained by candidates who have passed a degree examination in its subjects at any recognized university. When a candidate presents himself for an examination in several of its parts, but is not successful in all of them, he is credited at the next examination with those subjects in which he has previously been approved.

The Higher Degrees.

It is open to those who are already M.B., Ch.B. to proceed either to the M.D. or the Ch.M. A candidate for the former must have been engaged for not less than one year at work in the medical wards of a hospital or in scientific research in a recognized laboratory or in the Naval or Military Medical Services, or have been at least two years in general practice, and he must be 24 years of age. He has to write a thesis on any subject not exclusively surgical, and is examined in clinical medicine and in some one or other of its special departments. The regulations for candidates for the Ch.M. are of a corresponding character, a period of surgical work in a hospital or elsewhere being substituted for medical work, and his thesis being on a surgical rather than a medical subject. He is examined in surgical anatomy, clinical surgery, operative surgery, and in some of the special departments of surgery.

Fees.

It is estimated that the class examination and other fees for the M.B., Ch.B. come altogether to £150, the separate fees included in this calculation being as follows:

	£	s.	d.
Preliminary Examination	0	10	6
First Professional	6	6	0
Second Professional	5	5	0
Third Professional	4	4	0
Finals	7	7	0

Re-entry in any subject in which the candidate has failed entails a fresh payment of £1 1s. Candidates for the M.D. and Ch.M. pay £15 15s., and on re-entry £5 5s.

More detailed information with regard to the University of Edinburgh can be obtained from the *Medical Programme*, price 2d., which is published by Mr. Thin, 55, South Bridge, Edinburgh, or on application to the Dean of the Faculty of Medicine. Similar information about Glasgow should be sought from the Assistant Clerk, Matriculation Office, Glasgow. With regard to Aberdeen, application may be made to the Secretary of the Medical Faculty, Marischal College. In respect of St. Andrews, information can be obtained either from the Secretary of the University or, alternatively, the Secretary of the United College, St. Andrews, or the Secretary of University College, Dundee, these being the two constituent colleges of the University of St. Andrews.

Finally, it should be mentioned that, in connexion with all the Scottish universities, including St. Andrews, there are valuable bursaries and scholarships, some information as to which will be found in the article on Medical Schools.

The Scottish Corporations.

There are three medical corporations in Scotland—the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Their licences can be separately obtained only by persons who are already in possession of a recognized qualification—in surgery in the case of the College of Physicians, and in medicine in the case of the College of Surgeons and the Faculty of Physicians and Surgeons of Glasgow. All others must submit to the examinations held by the Conjoint Board which the three corporations have combined to form. Details concerning this Board and its component colleges follow. The conditions on which their higher qualifications are granted will be found set forth separately in connexion with each corporation.

THE CONJOINT BOARD IN SCOTLAND.

This body has charge of all questions connected with candidates for the Conjoint Licences of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Those finally approved by it are entitled to registration and to the initials denoting the Licences of the three bodies concerned — namely, L.R.C.P.Edin., L.R.C.S.Edin., and L.R.F.P.S.Glasg. The Board requires all candidates to comply with the regulations of the General Medical

Council as set forth on page 422. It has an arts examination of its own, but is prepared to accept in its place any of the other educational tests approved by the General Medical Council.

Professional Curriculum.

Subsequent to registration as a medical student, the candidate must pass not less than five years in medical study, each comprising a winter and a summer session. The Board does not exact that candidates shall pursue their study at any particular place, and is prepared to accept certificates of having attended the necessary courses from any recognized medical school.

Its examinations are four in number, each of them being held six times every year—four times in Edinburgh and twice in Glasgow; and it is open to candidates to present themselves for examination at either place. The first examination deals with physics, chemistry, and elementary biology: the second with anatomy and physiology, including histology; the third with pathology and materia medica, including pharmacy; and the final with (1) medicine, including therapeutics, medical anatomy, and clinical medicine; (2) surgery, including surgical anatomy, clinical surgery, and diseases and injuries of the eyes; (3) midwifery and diseases of women and of newborn children; (4) medical jurisprudence and hygiene. Candidates may also be examined on diseases of children, diseases of the ear and throat, insanity, vaccination, etc.

These examinations must be passed in due order, and before admission to any of them the candidate must supply certificates showing that he has completed the due periods of study of their subjects. He can present himself in any single subject of the first three examinations. As regards the final examination, a candidate can present himself in medical jurisprudence and hygiene at any time after completion of the third examination and of his study of these subjects; but in medicine, surgery, and midwifery he cannot present himself until the completion of five years' study, and he must take them all simultaneously. A candidate who takes up several subjects of an examination or the whole of the subjects at one time but fails in some of them, is credited at the next examination with those subjects in which he has been approved.

Part or entire exemption from the three first examinations may be granted to those who have already passed before other bodies examinations deemed by the Board as equivalent to its own; but all candidates for the conjoint licence must sit for the final examination, and at no examination can a candidate present himself within three months of his rejection by some other licensing body.

Fees.

It is estimated that the total cost of lectures and fees for the conjoint licence is about £152. The separate examination fees are as follows: First, Second, and Third Professional, £5 each; Final, £15. On re-entry for any of the first three examinations £3, and on re-entry for the Final, £5. If the re-entry is only in one or two subjects, the fees are smaller.

Information concerning this Board should be sought either from Mr. D. L. Eadie, 50, George Square, Edinburgh, or from Mr. Walter Hurst, Faculty Hall, 242, St. Vincent Street, Glasgow.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

This College has two grades—its Licence and its Fellowship. Licentiates may be of either sex, but for the Fellowship women are not eligible. As an original qualification the Licence is only granted after fulfilment of the regulations of the Conjoint Board, but as an additional qualification can be obtained by those already possessed of a registrable qualification in medicine. In this case the candidate has to pass a written, oral, and clinical examination in surgery and surgical anatomy, and may be asked to operate on the dead body. The fee is £15 15s., of which £10 10s. is returned to unsuccessful candidates. On due cause being shown, a special examination may be granted, the fee being £20, of which £10 is returned to a candidate if he is not approved.

Candidates for the Fellowship must be not less than 25 years of age, and have been in practice subsequent to registration for at least two years, and must hold either a surgical degree from a university recognized for that purpose by the College, or an approved diploma obtained as the result of an examination which includes surgery as well as medicine. Candidates are examined in surgery, including clinical and operative surgery, surgical anatomy, and one other subject which they may choose from among the following: Ophthalmology, laryngology, including aural and nasal surgery, dental surgery, advanced midwifery with obstetric surgery, gynaecology, surgical pathology and operative surgery, and advanced anatomy. The examination is written, oral, and clinical or practical. A candidate who desires to be examined must give one month's notice, his application for admission being supported by two Fellows of the College, one of whom must be resident in Edinburgh, or, in default, by testimonials obtained specially for the purpose.

Licentiates of the College pay £35, and others £45. For further information application should be made to the Clerk of the College, Mr. D. L. Eadie, 50, George Square, Edinburgh.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

This College has three grades—Licentiateship, Membership, and Fellowship; to the latter women are not admissible. The regulations applying to candidates for the Licentiateship have already been generally indicated. If desirous of receiving it apart from those of the other two corporations, they must be holders of a surgical qualification recognized by the College, and must pass an examination corresponding to the medical part of the Final Examination of the Conjoint Board, and conditioned in the same way, and also an examination in materia medica. The fee for examination is 15 guineas, a special examination being obtainable on due cause being shown, and on payment of 5 guineas extra. Ordinary examinations take place monthly on the first Wednesday, except in September and October. A candidate for the Membership must be either a Licentiate of a Royal College of Physicians or a graduate in medicine of a British or Irish university, and in either case not less than 24 years of age. He is examined in medicine and therapeutics, and in one further subject at his choice. This may be either (*a*) one of the departments of medicine specially professed; (*b*) psychology; (*c*) general pathology and morbid anatomy; (*d*) medical jurisprudence; (*e*) public health; (*f*) midwifery; (*g*) gynaecology; (*h*) diseases of children; or (*i*) tropical medicine. Licentiates of the College pay £21, others £36 15s. The examination is held quarterly, and application for admission to it must be made a month previous to its date. For the Fellowship, the candidate must have been a member of the College for at least three years, and, if accepted, pays fees amounting altogether to a little less than £65. Any further details required can be obtained on application to the Secretary of the College.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

This body possesses two classes Licentiates and Fellows. The regulations applying to the former correspond with those respecting candidates for the Licence of the Royal College of Surgeons of Edinburgh. Candidates for the single Licence are examined in surgery (including clinical surgery and surgical anatomy). The fee is £15 15s., and examinations are held quarterly. Candidates for the Fellowship must be qualified medical men of not less than two years' standing and 24 years of age. Candidates approved at this examination are then eligible for election as Fellows. The Faculty can also elect two Fellows annually without previously submitting them to examination, provided they "have highly distinguished themselves in medical science or practice." They must be of not less than ten years' standing and 40 years of age. Further information can be obtained from Mr. A. Duncan, B.A., LL.D., Faculty Hall, St. Vincent Street, Glasgow.

The Irish Universities.

THERE are three universities in Ireland, and each of them has a medical faculty. These are the University of Dublin, usually known as Trinity College, Dublin, the Queen's University of Belfast, and the National University of Ireland. The two former teach students, examine them, and grant or withhold degrees accordingly; while the third is by way of being an academic body only, inasmuch as its practical work is divided up among three constituent colleges, situated, one at Cork, another at Galway, and the third in Dublin. The regulations of all these universities in respect of medical degrees are given in the following sections; while specific information as to the arrangements for the education of medical students made at each of them will be found in the section relating to Irish Medical Schools.

UNIVERSITY OF DUBLIN.

THIS university, better known, perhaps, as Trinity College, Dublin, grants two degrees in medicine (M.B. and M.D.), two in surgery (B.Ch. and M.Ch.), two in midwifery (B.A.O. and M.A.O.), and diplomas in the same subjects and in public health. It also confers two degrees in dentistry. Its degrees it grants only to those who, besides having passed the Professional Examination, have graduated in arts.

PROFESSIONAL EXAMINATIONS.

A candidate for the Final Examination for the M.B., B.Ch., and B.A.O. degrees must be a matriculated student of at least five years' standing, and though he need not have taken his degree in arts before admission to the Professional Examination, he cannot take his medical degrees until he has been admitted a B.A. At least three years of the five years' medical curriculum must be pursued at the School of Physic of the university. The examinations which students must pass are the Preliminary Scientific, the Intermediate Medical, and the Final, and of course before admission to any of them he must be duly signed up as regards study in the subjects involved.

Preliminary Scientific.—This covers (*a*) chemistry and physics, (*b*) botany and zoology; the two divisions may be taken together or at different times.

Intermediate Medical.—This is divided into two parts: (*a*) Anatomy, physiology, and histology; (*b*) applied anatomy and applied physiology. The two parts may be taken separately, but in each part all subjects must be passed at one time.

Final Examination.—Part I: Hygiene and medical jurisprudence, pathology, materia medica, and therapeutics. *Part II:* (*a*) Midwifery, gynaecology (clinical, paper, and viva voce); (*b*) medicine, clinical medicine, and mental diseases; (*c*) surgery in all branches, including clinical ophthalmology. The three sections of Part II may be taken separately or together. In either case the full curriculum must have been completed, nor can the final subject be taken until at least the end of the fifth year.

M.D.—The candidate must have passed all the qualifying examinations in medicine, surgery, and midwifery, and have taken, or have been qualified to take, the degree of B.A. three years previously. He must read a thesis before the Regius Professor of Physic.

M.Ch.—The candidate must be a B.Ch. of not less than three years' standing, and have been engaged in practice for two years. Graduates of ten years' standing may be given a special examination.

M.A.O.—The candidate must have passed the qualifying examination in medicine, surgery, and midwifery. The examination is specially directed to obstetrics and practical gynaecology.

For the university diplomas mentioned the candidate must have completed two years in arts and five in medical studies. The examination and courses required are the same as for the degrees.

FEES.

Matriculation, 5s.: M.B., B.Ch., B.A.O., £17; M.D., £13; M.Ch., £11; M.A.O., £5; L.M., L.Ch., L.A.O., £11. Further information may be obtained from the Registrar of the School of Physic, Trinity College, Dublin.

QUEEN'S UNIVERSITY, BELFAST.

THE degrees granted by the Medical Faculty of this university are as follows: Bachelor of Medicine (M.B.), Bachelor of Surgery (B.Ch.), Bachelor of Obstetrics (B.A.O.), Doctor of Medicine (M.D.), Master of Surgery (M.Ch.), Master of Obstetrics (M.A.O.). The university also confers a diploma in public health. The first three degrees mentioned serve as a qualification for admission to the *Medical Register*, and are not granted separately. In addition to matriculating and passing his professional examinations, a candidate for these degrees must have passed three of the regulation five years as a student at the Belfast School of Medicine.

PROFESSIONAL EXAMINATIONS.

The examinations for the M.B., B.Ch., B.A.O. are four in number. The first deals with: (1) Inorganic, organic, and practical chemistry, (2) experimental and practical physics, (3) botany and practical botany, (4) zoology and practical zoology. It is divided into two parts, of which botany and zoology form one. The Second Examination covers anatomy and physiology, and may be taken at the end of the second year of the student's career. The Third Examination includes: (1) Pathology, (2) materia medica, pharmacology and therapeutics, (3) medical jurisprudence, and (4) hygiene. To be valid a certificate in regard to the study of the subjects of this examination must show that the work has been done subject to passing the First Examination.

The Final Examination includes: (1) Medicine, (2) surgery, (3) midwifery, (4) ophthalmology, and otology. The student may pass in all subjects at once at the end of his fifth year, or he may divide the examination into two parts—namely, (1) systematic, (2) clinical, practical, and oral. The first part may be taken at the end of the fourth year, but for the second part the candidate may not present himself until the end of his fifth year. No certificate in regard to study of the subjects of this examination will be valid unless the work was done subsequent to passage in all the subjects of the Second Examination.

THE HIGHER DEGREES.

Candidates for the degree of Doctor of Medicine must be graduates in medicine of at least three years' standing, unless they hold also a degree of the university in arts or science. In that case a standing of two academic years will suffice. Moreover, candidates must be able to show that the interval has been passed in the pursuit of such courses of study or practical work as may be prescribed. The degree may be conferred either (*a*) after a formal examination, or (*b*) in recognition of the merits of a thesis or of some piece of original study or research carried out by the candidate, followed by an oral or other examination in its subject. When an ordinary examination is imposed it will include (1) a written paper on the principles and practice of medicine, (2) a commentary on a selected clinical case, (3) a clinical and viva voce examination, and (4) a written paper and clinical or practical and viva voce examination of a subject chosen from the following list: (1) Human anatomy, including embryology, (2) physiology, (3) pathology, (4) pharmacology and therapeutics, (5) sanitary science and public health, (6) forensic medicine and toxicology, (7) mental diseases. The regulations for the degrees of M.Ch. and M.A.O. are of the same general nature.

NATIONAL UNIVERSITY OF IRELAND.

THE National University of Ireland carries on most of its educational work through three constituent colleges—one in Dublin, one in Cork, and one in Galway. Each of these provides a full medical curriculum, and all candidates for the medical degrees of the university must pass three of their five years of study at one or other of them. These years do not count except after matriculation or recognition as a student of the Medical Faculty obtained in some other fashion. The candidates at each constituent college are examined thereat by the university, and a common standard of education is secured by all courses of instruction and the regulations concerning them having to be approved by the Senate, after considering report thereon from the Board of Studies of the University. In

addition to the ordinary degrees in medicine and surgery, the university grants those of Bachelor and Master of Obstetrics, Bachelor and Master of Science in Public Health, and Bachelor and Master in Dental Surgery, as well as diplomas in Public Health and in Mental Diseases.

Professional Examinations.

There are four examinations. The first, which should be passed at the end of the first year, includes Part A (chemistry and physics) and Part B (botany and zoology), which parts candidates may take separately or together. At the end of the second year they should pass in anatomy and physiology; and at the end of the fourth year in pathology, materia medica and therapeutics, hygiene and public health, forensic medicine, and toxicology. The final examination is divided into three parts, each of which may be taken separately—namely, (*a*) Medicine, including mental diseases; (*b*) surgery, including ophthalmology and otology; (*c*) midwifery and gynaecology.

The higher degrees are obtainable either by examination or on presentation of an approved work, but in each case not less than three years must have elapsed since the candidate acquired the corresponding degree of Bachelor. Further information as to the constituent colleges will be found in the section relating to Irish Medical Schools.

The Irish Corporations.

There are three licensing bodies other than the Medical Faculties of Universities, and, just as in London, there are two Royal Colleges of Physicians and Surgeons and an Apothecaries' Hall. The similarity is still more complete, for in Ireland also the two colleges have formed a Conjoint Board, as in London, which is responsible for the recommendation of candidates to the two bodies for their respective licences. The Apothecaries' Hall gives its Licence separately.

THE CONJOINT BOARD IN IRELAND.

This body requires of candidates the passage either of its own preliminary examination in the subjects of general education or proof that the candidate has passed one of the tests accepted by the General Medical Council.

Professional Examinations.

There are four professional examinations, the first of which cannot be passed earlier than the end of the first winter session, nor the fourth before the conclusion of full five years of medical study, and before being admitted to any of them the candidate must show that he has studied the different subjects in practice and theory for the requisite periods, certificates to this effect being accepted from the authorities of most of the recognized medical schools at home and abroad. The first and second examinations deal respectively with (*a*) chemistry and physics, and (*b*) biology; and (*a*) anatomy, and (*b*) physiology and histology. All parts of these examinations, as also of the following one, which deals with (*a*) pathology, (*b*) materia medica, pharmacy, and therapeutics, (*c*) public health and forensic medicine, may be taken separately.

Final Examination.—This is divided into three divisions, which cannot be completed until at least four years have passed in medical studies other than those for the first examination, and five years, at least, since the beginning of the curriculum. The divisions are (*a*) medicine, including fevers, mental diseases, and diseases of children; (*b*) surgery, including ophthalmic and operative surgery; (*c*) midwifery, including diseases of women and newborn children, and the theory and practice of vaccination. Candidates are recommended to present themselves in all the subjects of the Final Examination at one time, but a candidate at or after the end of the fourth year may present himself in any one of the divisions (*a*), (*b*), or (*c*), provided he has completed his curriculum as far as concerns the division in which he presents himself.

Fees.—Preliminary Examination, £2 2s.; re-examination, £1 1s. First Professional Examination, £15 15s.; Second, £10 10s.; Third, £9 9s.; Final, £6 6s.; re-examination fee is £2 2s. for each division.

Further information can be obtained from Mr. Alfred Miller, Secretary of the Committee of Management, Royal College of Surgeons, 123, St. Stephen's Green, Dublin.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

Those whose names already appear on the *Medical Register* can obtain the separate Licence in Medicine of this College, and its Licence in Midwifery. In either case an examination has to be passed in the subjects indicated, questions on midwifery, hygiene, and jurisprudence being included in the examination for the Licence in Medicine. For the Licence in Midwifery practitioners of over five years' standing are exempted from examination by printed questions. The other grades of the College are Members and Fellows. The former are admitted after an examination which is open to all university graduates in medicine and Licentiates in medicine of Royal Colleges of Physicians, and deals with the general subjects of medicine. Fellows are selected, by vote, from among the Members.

Fees.—For the Licence in Medicine, 15 guineas; for the Licence in Midwifery, 5 guineas; or 16 guineas for both if they are taken within an interval of a month. Special examinations cost in each case 5 guineas extra. For the Membership, 20 guineas to a Licentiate of the College; 35 guineas to others; a special examination costing 10 guineas extra. The Fellowship £35, in addition to stamp duty, £25. Information as to special examinations and other points can be obtained from the Registrar, the Royal College of Physicians, Kildare Street, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

This body, besides granting a Licence in Surgery, admits those possessed of registrable surgical qualifications to its Fellowship under certain conditions. Its Licence is usually granted conjointly with that of the College of Physicians, but it is given separately to holders of a registrable qualification in medicine, provided that the College is satisfied that adequate courses of study have been pursued, and provided its own professional examination is passed. This examination is held on its behalf by the Conjoint Board, and is identical with the ordinary surgical portion of the examinations imposed by that body.

The Fellowship.—Candidates for the Fellowship must pass two examinations, of which the first is in anatomy (including dissections), physiology, and histology; and the second in surgery (including surgical anatomy) and pathology. Both examinations are partly written, partly practical, and partly viva voce; while the final examination includes the performance of operations. All subjects of either examination must be passed at one time, and to neither can a candidate be admitted who has been rejected in any of its subjects by any other licensing body within three months. Candidates are not admitted to the Primary Examination except on evidence that they have already passed an examination in anatomy, physiology, and histology, held by some university or other body whose degrees or licences entitle the holder to admission to the *Register;* if, however, the candidate is a person whose name is on the Colonial or foreign medical *Register*, at the discretion of the Council. Candidates for the Final Examination must be over 25 years of age, produce a certificate of general good conduct signed by two or more Fellows of the College, and, if successful, must make a declaration before admission to the effect that they do not conduct dispensing practices, and will not do so as long as they are Fellows.

Fees.—Candidates for the Licence pay 5 guineas for examination, which sum, if they pass, is counted as part of the fee payable on admission to the Licence, this being 25 guineas. Candidates for the Fellowship pay 5 guineas for each examination, the total of 10 guineas being reckoned as part of the fee payable on admission to the Fellowship. That fee is 25 guineas in the case of those who are already Licentiates, and 40 guineas in the case of others.

APOTHECARIES' HALL OF IRELAND.

A diploma is granted by this Hall which entitles the holder to be registered as a practitioner of medicine, surgery, and midwifery, and confers also the privileges of an apothecary.

Two periods of dissection, each not less than six months, must be included, and twenty-seven months of hospital attendance, or its equivalent. Three professional examinations have to be passed; they are held quarterly. The Primary Examination deals with biology, physics, and chemistry, practical and theoretical; the Intermediate Examination is in practical anatomy and physiology, and histology and materia medica. A candidate who has passed tests in any of the subjects of these examinations before another licensing body is exempt from further examination in such subjects. The Final Examination deals with, Part I, pathology and medical jurisprudence and hygiene; Part II, medicine, surgery, midwifery, and pharmacy. The Hall's own examination in all these subjects must be passed. Women candidates are eligible.

Fees.—Primary Examination, £5 5s.; Intermediate Examination, £10 10s.; Final Examination, £15 15s.; Final alone, when the others have been passed elsewhere, £21. Application for other information should be made to the Registrar, 40, Mary Street, Dublin.

MEDICAL SCHOOLS AND COLLEGES.

LONDON.

APART from post-graduate and other special schools, the medical schools of London number as many as fourteen, including in the count two institutions which provide education only in the preliminary and intermediate subjects, under the title of "university centres."

Little guidance can be given in these columns as to choice of one school rather than another, for such choice must depend largely on personal factors. In a general way, however, it may be said that while to the student of to-day it may, perhaps, be almost a matter of indifference to what school he belongs, there is often in after-life a certain advantage in having been an alumnus at one of the more celebrated schools. On the other hand, at the smaller schools more opportunities, perhaps, present themselves to the average man for obtaining student appointments, and especially the coveted posts of house-physician and house-surgeon.

Information as to the fees at the different schools, and the scholarships, prizes, and junior appointments which they offer, will be found in the following pages, and should be carefully studied by those who have no personal reason for preferring one to the other. The courses which they provide are fundamentally the same, and in all of them the arrangements made are such as to meet the requirements of students of every class—of those who are aiming at the diplomas of the Conjoint Board or the Apothecaries' Society not less than of those who have London or other university degrees in view. At all, too, as has been said, special facilities are offered to men who have commenced their professional education at the older universities, Oxford and Cambridge. Apart from these facts, the only point to which attention can usefully be directed is that on personal inquiry and investigation reason may perhaps be found for regarding the teaching accommodation and general arrangements for students at some schools as superior to those at others.

ST. BARTHOLOMEW'S.

THIS institution fills one side of Smithfield and Giltspur Street, sharing with the Post Office buildings a large island of ground separated practically from all other buildings; it is on the edge of the City, and easily reached from all parts of London. The hospital contains 750 beds. Extensive new buildings, opened in July, 1907, occupy part of the ground acquired from the old Bluecoat School, and these materially enhance the attractions of the hospital as a place of medical study. The medical school buildings, including the library and the chemical, physical, biological, and physiological laboratories, and anatomical department have now at their side a very large building, which includes club rooms for the Students' Union, a writing room, luncheon and dining halls, new quarters for the resident staff, and an out-patient department and accommodation for special departments of such large size as to be unsurpassed by any hospital in the kingdom. During the year 1909 a second block of new buildings was completed. These form the pathological department, and include, in addition to a new and extensive *post-mortem* room, large and well-equipped laboratories for clinical pathology, pathological histology, bacteriology, and chemical pathology, altogether forming the most complete pathological department in the country. Within the precincts of the hospital also there is a residential college for a large number of students. The Students' Union owns, moreover, grounds of some 10 acres in extent for recreative purposes at Winchmore Hill, which is easily accessible from the hospital.

Special classes are held for students preparing for the Preliminary Scientific and other examinations for the M.B., M.D. of the Universities of London, Oxford, and Cambridge, and for the higher surgical degrees at the same universities, including the M.Ch.Oxon., M.C.Cantab., M.S.Lond., and F.R.C.S.Eng. Special laboratory instruction for the D.P.H. of Cambridge, Oxford, Durham, and London is also given.

Appointments.—Clinical clerks to the physicians and to the physician-accoucheur, and dressers to the surgeons and in the casualty department, are chosen from the students; clerks and dressers are also selected from the students to attend in the out-patient rooms, in the special departments (Ophthalmic, Orthopaedic, Gynaecological, Laryngological, Aural, Dermatological, Electrical, and Dental), and in the *post-mortem* room. Chief assistants and clinical assistants are selected from qualified men appointed yearly to help in the general medical, surgical, and in the special departments. Ten house-physicians and ten house-surgeons are appointed annually. During their first six months of office they act as "Junior" house-physicians and house-surgeons, and receive a salary of £25 a year. During their second six months they become "Senior" house-physicians and house-surgeons, and are provided with rooms by the hospital authorities, and receive a salary of £80 a year. A resident midwifery assistant, an ophthalmic house-surgeon, and a house-surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Two assistant anaesthetists are appointed annually, and receive salaries of £120 and £100 a year respectively. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year.

Scholarships.—Five entrance scholarships are annually awarded after an examination held in September. The subjects of examination and conditions of eligibility for these scholarships are: (1) Two scholarships, value £75 each, in not fewer than two nor more than three of the following subjects—Chemistry, Physics, Botany, Zoology, Physiology, and Anatomy, limited to students under 25 years of age who have not entered on the medical or surgical practice of any London medical school. (2) One scholarship, value £150, in not fewer than three of the following subjects—Chemistry, Physics, Botany, Zoology, and Physiology, limited to students under 21 years of age who have not entered on the medical or surgical practice of any London medical school. (3) The entrance scholarship in Arts, of the value of £100, will be given in Latin and Mathematics, with one other language—Greek, French, or German. (4) The Jeaffreson Exhibition in Mathematics, Latin, and one other language—Greek, French, or German—and of the value of £50. The value of the scholarships and prizes is over £1,000 annually.

Further information and a handbook can be obtained on application to the Dean of the Medical School, St. Bartholomew's Hospital.

CHARING CROSS.

THIS school, with its hospital, is situated in the very centre of London, and courses of instruction are specially designed to meet the requirements for the University of London degrees, the diplomas of the Royal Colleges, and the final studies of other universities. The hospital, with its convalescent home at Limpsfield, contains 200 beds. Over 2,000 cases pass through its wards each year, and some 24,000 out-patients and casualties are treated. There are special departments for all classes of work.

The school has an arrangement whereby its students can carry out their work in the primary and intermediate portions of their studies in the laboratories of the University of London (King's College), which are situated within a few minutes' walk of the hospital. This enables its students to get the best university education from a large professional and teaching staff in their earlier

studies, while still allowing them to take advantage of their own school for social and collegiate purposes.

A large laboratory, capable of accommodating up to 100 students, is available for general pathological work, demonstrations, and research, and systematic demonstrations covering the whole range of pathology are arranged daily throughout each session between 10 a.m. and 5 p.m. Good departments are also available for other final subjects of bacteriology, chemical pathology, materia medica, toxicology, public health, and operative surgery, and also for research work by post-graduates. Some of these serve King's College as its "University Laboratories of Public Health and Bacteriology."

The museum contains over 4,000 specimens, and has received a notable collection of over 700 gynaecological specimens, "The Cuthbert Lockyer Collection," from one of the members of its hospital and school staff.

The library contains the latest editions of the usual textbooks and the chief medical periodicals. The Students' Club Union includes reading and smoking rooms, cloak-room, refreshment room, and adds greatly to the social comfort of the students.

Appointments.—Demonstratorships and assistant demonstratorships are open to students of the school. Medical, surgical, and obstetric registrars to the hospital are appointed annually. Six house-physicians, six house-surgeons, and two resident obstetric officers are appointed each year after competitive examination. They are provided with board and residence in the hospital. Clinical clerks and dressers are appointed in the general and special departments of the hospital, and every student holds in turn the post of pathological assistant and assists at the autopsies, and on the completion of his clinical appointments takes up the duty for three months of pathological clerk in the clinical laboratory. Special facilities are offered for students and post-graduates desiring to take up particular classes or work in the wards and special departments of the hospital for longer or shorter periods.

Fees.—Sessional payments of 17 guineas for the winter session and 8 guineas for the summer session for London University and other university students, and 15 guineas and 7 guineas respectively for Conjoint Board students, with an entrance fee of 10 guineas; or a total composition fee for five and a half years' tuition of 120 guineas in the case of London University students, and of 110 guineas for five years' tuition for the Conjoint Board students. The above fees are inclusive, with the exception of vaccination, dispensing, and fever hospital attendance, which have to be taken outside the school.

All information desired may be had of the Dean (Dr. William Hunter), the Medical School, Charing Cross Hospital, London, W.C.

ST. GEORGE'S.

THIS school is at Hyde Park Corner, and is carried on in connexion with St. George's Hospital, an institution having a service of 436 beds, of which 100 are at the convalescent hospital founded by Atkinson Morley at Wimbledon. It provides for the instruction of its students in the preliminary and intermediate subjects of the curriculum at the teaching centres of London University established at King's College and University College. The school at Hyde Park Corner is devoted entirely to the teaching of clinical subjects, great attention being paid by the members of the staff to individual teaching. A number of special courses are given, in which the requirements of university and all other examinations receive careful attention.

The St. George's Hospital Club consists of an amalgamation club, with smoking and luncheon rooms on the hospital premises, and other students' clubs, with an athletic ground at Wimbledon. Students have the advantage of a well-filled library of medical and scientific books. A register of accredited apartments, and a list of medical men and others willing to receive St. George's men as boarders, may be seen on application to the Dean.

Appointments. — Dresserships to the surgeons and clinical clerkships to the physicians are open without fee to all students of the hospital. There is a large number of resident appointments, which may be held for six, twelve, or eighteen months, and are open without fee to every perpetual student of the hospital, and are made strictly in accordance with the merits of the candidates. Besides this, after the student has held a house appointment, the following are, among others, open to him: Medical registrarship at £200 per annum; surgical registrarship at £200 per annum; curatorship of the museum at £200 per annum; assistant curatorship of the museum at £100 per annum; obstetric assistantship, resident, at £50 per annum; the post of resident anaesthetist at £100 per annum; the post of senior anaesthetist at £50 per annum; the posts (2) of junior anaesthetists, each at £30 per annum.

Scholarships.—Two university entrance scholarships in anatomy and physiology (70 guineas and £50) are awarded at the commencement of each winter session. The William Brown Exhibition of the value of £100 per annum (tenable for two years) is awarded by examination to a perpetual pupil of the hospital every second year. The William Brown Exhibition of £40 (tenable for three years) is awarded by examination to a perpetual pupil of the hospital every third year. Other prizes to the value of £200 are awarded annually to the students of the hospital.

Fees.—First year (preliminary science or first conjoint) £26 5s., or £21, according to course. Second and third years, £63 in two equal instalments. For the course of clinical study, in the fourth and subsequent years, entrance fee, £10 10s.; annual composition fee, £31 10s. No entrance fee is payable by St. George's students who have studied at King's and University Colleges.

Further information may be obtained from the Dean of the Medical School.

GUY'S.

THE hospital contains 617 beds in constant occupation; an additional 50 beds have been opened on the medical side of the hospital. Thirty-three beds are set apart for diseases of the eye, and 40 for the most urgent and interesting medical cases, which form the subjects of the weekly clinical lectures. There is a special ward of 32 beds for the reception of cases of diseases of women and for cases of difficult labour. Beds are also allotted to the throat and ear departments, to the orthopaedic department, and to the department for the treatment of diseases of the genito-urinary system.

The medical college fronts the east gate of the hospital, providing accommodation for 60 resident students. This contains a dining-hall, reading rooms, a library of general literature, and a gymnasium for the use of the residents and of the members of the Clubs Union. The athletic ground at Honor Oak Park is reached from the hospital in twenty minutes. The Gordon Museum of Pathology, the Wills Library, the newly-built Departments of Chemistry, Physics, Pathology, and Pharmacology, and the school buildings in general, afford unrivalled opportunities for a liberal education and for research. Special classes are held for the First and Second Examinations for Medical Degrees of the University of London and for the first F.R.C.S.Eng. Special teaching is provided to meet the requirements of the universities of London, Oxford, and Cambridge in general pathology and pharmacology.

Appointments.—All appointments are given to students without extra payment, and according to the merits of the candidates, as determined by a committee of the medical staff. Sixteen out-patient officers, 8 house-physicians, 20 assistant house-surgeons, 8 house-surgeons, 2 ophthalmic house-surgeons, and 9 resident obstetric assistants are appointed annually. The house-physicians and house-surgeons, obstetric residents, and ophthalmic house-surgeons hold office for six months each, and receive free board and lodging in the college. Every student is provided with rooms and commons in the hospital during the period of his "take in" as dresser. In addition to the clerkships and dresserships in the medical and surgical wards, students are appointed to the posts of clinical assistant, dresser, or clerk in the special departments of ophthalmology, laryngology, gynaecology, diseases of children, diseases of the nervous system, dermatology, otology, electricity, anaesthetics, and dentistry. More than 150 additional appointments have been added to the list of those annually open to students of the hospital, the majority of them being in the special departments.

Scholarships, Prizes, etc.—The following entrance scholarships are awarded annually in the month of September: A Junior Scholarships in Arts, Classics, Mathematics, and Modern Languages, and Science, of the value of £120, £100, and £50,

open to candidates under 21 years of age. B. Senior or University Scholarships of the value of £75 and £35, open to candidates under 25 years of age, who have completed their study of Anatomy and Physiology. Subjects, any two of the following: Anatomy, Physiology, Pharmacology, General Pathology, Organic Chemistry, Biology, and Physics. Junior prizes for general proficiency, £20, £15, £10; Hilton prize for Dissection, £5; Michael Harris prize for Anatomy, £10; Sands-Cox Scholarship for Physiology, £15 for three years; Wooldridge Memorial prize for Physiology, £10; Beaney prize for Pathology, £34: Treasurer's gold medal in Medicine, Treasurer's gold medal in Surgery, and the Golding-Bird gold medal and scholarship for Bacteriology (£20) are awarded annually after competitive examination. The Gull Studentship in Pathology and the Beaney Scholarship in Materia Medica, of the annual value of £150 and £31 10s. respectively, are awarded without examination to enable research to be carried on in these subjects. An Arthur Durham Travelling Scholarship of £100 is awarded triennially. The Douglas Research Studentship in Pathology, value £300 per annum, is awarded without examination.

Fees.—An annual composition fee is paid by all students until a registrable qualification is obtained. Further information may be obtained from the Dean of the Medical School.

King's College Hospital.

The medical school carried on in connexion with this institution, at Denmark Hill, deals, as do the sister institutions at Westminster and University College Hospitals, with the advanced or final subjects of the medical curriculum. The arrangements for education in these subjects are very complete. The new and up-to-date hospital contains 286 beds, which number will ere long be increased. When complete there will be over 600 beds. There are special departments for diseases of women and children, nervous diseases, ophthalmology, otology, laryngology, dermatology, dental surgery, etc.; pathological and vaccine departments are also included.

Appointments.—Sixteen resident medical and surgical officers are appointed yearly, as well as dressers and clerks in the wards, out-patient departments, *post-mortem* room, and special departments. Each of the special departments has several clinical assistants, and there are six registrars, most of whom receive salaries. There is also a Union Club, which combines athletics, music, and other societies connected with the school, and provides also a common room.

Fees.—The composition fee is 70 guineas if paid in one sum, or 72 guineas in two instalments, one of 40 guineas at entrance and the other of 32 guineas at the commencement of the second year.

The prospectus of the school can be obtained on application to its Secretary, Mr. Clifton Kelway, King's College Hospital, Denmark Hill, S.E.

The London.

This hospital (which contains 922 beds) and its medical college and dental school are in the Mile End Road, Whitechapel. All the departments are modern, and adapted for the teaching of all subjects in the curriculum. Special classes for the first and second M.B.Lond., the primary and final Fellowships, and other examinations are held. Those for the final and primary F.R.C.S. commence early in September. A residential hostel on hospital ground has been opened for the convenience of students who wish to live near the wards and casualty departments. The college athletic club is at Highams Park, and is open to all members of the Clubs Union.

Appointments.—The salaried appointments open to students are those of medical registrars (3), surgical registrars (3), obstetric registrar, registrars in the ear, nose, and throat department (2), medical, surgical, and obstetric tutors; senior dressers to out-patients; clinical assistants in the medical, surgical, ophthalmic, aural, light and skin, orthopaedic, and electrical departments. There are 2 resident accoucheurs, 6 resident house-physicians, and 8 resident house-surgeons, 7 receiving-room officers, 2 emergency officers, 1 assistant director of Pathological Institute, and 3 pathological assistants, also paid and unpaid clinical assistants in the various special departments. In addition there are numerous assistantships, clerkships, and dresserships in the various departments.

Scholarships and Prizes.—The following is a list of scholarships and prizes: At Entrance: Price Scholarship in Science, £100; in Anatomy and Physiology, £52 10s.; Entrance Scholarship in Science, £50; Epsom Scholarship, £126; Buxton Scholarship in Arts, £31 10s. After Entrance: Anatomy and Physiology Scholarship, £25; Letheby Prizes, £25; Prizes in Clinical Medicine, Surgery, and Obstetrics, £20 each; Duckworth Nelson Prize, £10; Hutchinson Prize, £40: Sutton Prize, £20; Sir Andrew Clark Prize, £26; Anderson Prizes, £9; Dressers' Prizes, £40; Practical Anatomy Prizes, £10; Douro Hoare Prize, £5; Wynne Baxter Prize, £5 5s.; Harold Fink Prize in Dental Surgery, £5 5s.; Prize in Dental Microscopy, £5; Frank Farmer Prize, £5 5s. The London Hospital Medical College and the Eliza Ann Alston Medical Research Funds amount to over £21,000.

Fees.—Full course, entrance fee, 15 or 20 guineas, according to examinations passed; annual fee 30 guineas. Full information may be obtained from the Dean at the London Hospital Medical College, Mile End, E.

St. Mary's.

This school and its hospital are situated in Praed Street, in the neighbourhood of the residential districts of Paddington, Bayswater, and North Kensington, and is thus especially convenient to students who wish to reside in the immediate vicinity. A register of approved lodgings is kept in the office of the Medical School.

The athletic ground at Park Royal, Acton, is easily accessible from the Medical School. It is seven acres in area, and provides ample accommodation for the various athletic clubs; the pavilion is large and well equipped.

The hospital contains 305 beds, of which 31 are devoted to treatment by therapeutic inoculation.

The Medical School provides complete courses in the preliminary and intermediate subjects of the curriculum which are recognized by the University of London as approved courses for internal students. Students may join in October, January, or April.

The departments of biology, chemistry, anatomy, physiology, and pathology are under the direction of full-time lecturers, and special courses are provided twice yearly for the Primary F.R.C.S. In addition special tuition is provided for the Intermediate and Final Examinations of the universities of Oxford, Cambridge, and London, and for the Final F.R.C.S.

All clinical appointments in the hospital are free to students of the school, the term of office in each case being of four months' duration, and the resident medical officers are chosen by competitive examination. Six house-physicians, six house-surgeons, four obstetric officers, and two resident medical officers to the inoculation wards are appointed each year, and receive board and residence in the hospital. A large number of salaried appointments are open annually to qualified students, including those of medical registrar, surgical registrar, casualty physician, casualty house-surgeon, resident assistant anaesthetist, assistant curator, together with several demonstratorships. In the inoculation department there are nine assistantships, the salaries of which amount to £1,600 per annum.

Scholarships.—There are Entrance Scholarships in Natural Science. One of £100, one of £50, one of £25, and two University Scholarships of £52 10s. awarded annually by competitive examination in September.

Fees.—The composition fee for students is £140 if paid in one sum, or £145 if paid in four instalments. University students who have completed their examinations in anatomy and physiology are admitted on payment of a composition fee of 65 guineas (£68 5s.) paid in one sum, or 70 guineas (£73 10s.) if paid in two annual instalments. Separate courses of lectures, laboratory work, or hospital practice may be taken.

The School Calendar and full information can be obtained from the Secretary, St. Mary's Hospital Medical School, Paddington, W.

The Middlesex.

The school and hospital are in Mortimer Street, W., close to Oxford Circus, Goodge Street, and Portland Road stations. There is a residential college for a limited number of students overlooking the hospital garden, a gymnasium within the precincts of the hospital, and an athletic ground within easy distance at Park Royal. The hospital contains 440 beds, including a wing containing

90 beds for patients suffering from cancer, and special cancer investigation laboratories, which offer unrivalled opportunities for the study of this disease, both in its clinical and pathological aspects. In connexion with the investigation laboratories there are several valuable scholarships awarded.

There are special wards for maternity and gynaecological cases, and for diseases of children and of the skin and eye.

The Bland-Sutton Institute of Pathology is under the charge of a director, who has a staff of assistants. The institute, which includes a pathological and anatomical museum, a lecture theatre, large pathological and public health laboratories, and smaller rooms for original investigation, will be opened in October. Bacteriological, chemical, and microscopical examinations of material from the wards, operating theatres, and out-patient departments are carried out in the laboratories. Senior students are eligible for clerkships in the laboratories of the institute, and every facility is given for original investigation.

In the electro-therapeutical department special attention is given to the treatment of lupus and cancer by the *x* ray, and opportunities are afforded to students wishing to become acquainted with the use of the apparatus employed in this method of treatment.

Appointments.—Twenty-two resident appointments are open annually for competition among students of the hospital. The officers reside and board in the residential college free of expense. Two Casualty medical and two Casualty surgical officers, and two resident officers to the special departments, are appointed annually. Eight house-surgeons are appointed every year at intervals of two months, after examination; six house-physicians are also appointed annually at similar intervals. An Obstetric and Gynaecological house-surgeon is appointed every six months. In the Out-patient departments the appointments are: clerk and dresser to the physicians and surgeons to out-patients; clerk in the departments for diseases of the skin and nervous diseases; dresser to the department for diseases of women, to the ophthalmic surgeon, to the throat and ear department, and to the dental surgeon. Extern midwifery clerks and *post-mortem* clerks are also appointed. The appointments are so arranged that every student may, during his course, hold all the out-patient and in-patient clerkships and dresserships. Students must have held an out-patient clerkship and dresserships before being eligible to hold in-patient clerkships or dresserships. No student can be appointed to any of these offices until he has passed the second examination of the Examining Board in England or its equivalent. Non-resident qualified clinical assistants are appointed in the Medical, Surgical, Skin, Neurological, Ophthalmic, Throat and Ear, Odontological, Children's, and Electro-therapeutical Out-patient departments.

Scholarships.—Three Entrance Scholarships, value £100, £50, and £25 respectively, are open to students commencing their medical studies in April or October, 1914. An annual Entrance Scholarship, of the value of £50, is open to students of the universities of Oxford and Cambridge who have completed the curriculum for, or passed the examinations in, anatomy and physiology. The examination for these scholarships will take place on September 21st, 22nd, and 23rd. Application for admission must be made on or before September 12th. Students joining the school in the previous April are eligible. The Freer Lucas Scholarship, value £126, is annually awarded on the nomination of the head master to a pupil of Epsom College who has passed the first examination for medical degrees (Preliminary Scientific Examination). There is also a scholarship, value £50, awarded annually to students from New Zealand. In addition to the Entrance Scholarships, there are a number of other valuable scholarships, prizes, and exhibitions open to students of the hospital, including the Broderip Scholarships, value £60 and £40; Lyell Gold Medal and Scholarship, value £55 5s.; Freeman Scholarship, value £30; John Murray Gold Medal and Scholarship, value £25; Hetley Clinical Prize, value £25; Leopold Hudson Prize, value 11 guineas; and the Second Year's Exhibition, value 10 guineas.

Fees.—The composition fee for students taking the London University degree is 145 guineas, or by five equal annual instalments of £32 11s. For those who have passed the first examination for medical degrees the fee is 120 guineas, or by four equal annual instalments of £34 2s. 6d. Students taking the Conjoint Board diploma pay 135 guineas, or by five equal annual instalments of £30 9s. Students who have passed the First Professional Examination pay 115 guineas, or by four equal annual instalments of £32 16s. 3d. For members of universities and others who have completed their anatomical and physiological studies the fee is 70 guineas, or by three equal annual instalments of £26 5s.

Further information may be obtained on application to the Dean.

ST. THOMAS'S.

THIS school, and the hospital in connexion with which it works, is situated in Lambeth, the joint buildings on the Thames facing the Houses of Parliament, and forming one of the well-known architectural features of London.

The school buildings are separated from the hospital by a quadrangle on which there are cricket practice nets for the use of the students, and comprise numerous theatres, laboratories, and classrooms well adapted for the modern teaching of large bodies of students in the subjects of the medical curriculum. A splendid library and reading room and a complete museum are open to all students from 9 a.m. to 5 p.m.; Saturdays, 2 p.m. The club premises contain a dining room and smoking and reading room supplied with daily and illustrated weekly papers, and a gymnasium. Good meals are obtainable at a moderate tariff. The Terrace affords facilities for exercise and recreation. A cloak-room with lockers, and a lavatory with bath rooms, are in the main school building. Students are thus able to spend the whole day at the school. The sports ground of more than nine acres in extent is at Chiswick. It can be reached in forty minutes from the hospital; it is admirably adapted for football, cricket, lawn tennis, and athletic sports.

The hospital contains 604 beds, and in addition to the ordinary provisions of a great hospital has connected with its out-patient department physicians' and surgeons' rooms provided with ample sitting accommodation, so that large numbers of students are enabled to follow closely the practice and teaching of the out-patient staff. There is a full complement of special departments, and connected with the hospital a special tuberculosis department gives opportunity for instruction of students. There is a clinical theatre, centrally situated, so as to facilitate the illustration of lectures by patients from the wards and out-patient room; it is arranged also for lantern demonstrations. The maternity ward, containing 20 beds, gives students full facilities for maternity training, under supervision, within the precincts of the hospital. This obviates any necessity for seeking instruction elsewhere, and fully prepares the student for the extern maternity practice of the hospital district. The revised regulations of the examining bodies can thus be fully complied with.

Appointments.—All hospital appointments are open to students without charge. A resident assistant physician and a resident assistant surgeon are appointed annually at a salary of £150 each, with board and lodging. Two hospital registrars, at an annual salary of £150 each, are appointed yearly. The tenure of these offices may be renewed for a term not exceeding two years. Eight resident casualty officers and anaesthetists are appointed every six months. An obstetric tutor and registrar is appointed each year at an annual salary of £50. Four house-physicians, four house-surgeons, two obstetric house-physicians, two ophthalmic house-surgeons, and eight clinical assistants in the special departments are appointed every three months, and hold office for six months if recommended for re-election. Two research assistants (bacteriological and chemical) at salaries of £200 per annum each. Clinical clerkships and dresserships to the in-patient and out-patient departments are available to the number of 400 each year.

Scholarships.—There are five entrance scholarships offered: Two in Arts, giving one year's free tuition; one of £150 and one of £60, in Chemistry, Physics, and Biology, for students who have not received instruction in Anatomy or Physiology; one of £50 in any two of the following subjects: Anatomy, Physiology, or Chemistry, for students who have completed their examinations in Anatomy and Physiology, for a medical degree in any of the universities of the United Kingdom, and have not entered as students in any London medical school Numerous scholarships, prizes, and medals are open for competition throughout the whole career of a student, including a Fellowship of £100 given by the Salters' Company for research in Pharmacology, and the Louis Jenner Research Scholarship of the annual value of £60 for Pathological research.

Fees.—The entrance fee for second year's students is 20 guineas; for third year's students 10 guineas. The annual composition fee is 30 guineas. For Preliminary Science students the fee is 15 guineas. The fees cover all tutorial classes given by the school teachers, and there are no extra charges made for materials required in practical courses. Special courses of instruction are given for various examinations, and a register of lodgings is kept at the school. A list of medical practitioners, clergymen, and others who receive students is also available. Further information may be obtained from the Secretary of the School, St. Thomas's Hospital, Albert Embankment, S.E.

University College Hospital.

The school, which forms part of the Corporation of University College Hospital, is in immediate proximity to the hospital in University Street and opposite University College. It comprises departments of medicine and clinical medicine, surgery and clinical surgery, midwifery and gynaecology, pathology including morbid anatomy, clinical pathology and bacteriology, cardiography, forensic medicine, mental physiology and mental diseases, dental surgery, practical pharmacy, and other departments for the study of special diseases, such as those of the eye, skin, ear, and throat, and for instruction in anaesthetics, electro-therapeutics, and radiography.

The school thus provides the final course of study for the degrees of the universities of London, Oxford, Cambridge, and Durham, and for the diplomas of the Royal Colleges of Physicians and Surgeons, and the Licence of the Society of Apothecaries. Special bacteriological classes are also held in preparation for the various diplomas of public health. Each department is also equipped for more advanced work, and provides facilities for research.

A student may enter the medical school at the commencement of his career, in which case he will pursue his preliminary and intermediate studies at the University of London, University College, and his final studies in the school. He may also enter the school for the final studies after having completed his preliminary and intermediate studies at any recognized university or school.

Scholarships.—The following scholarships and prizes are open to competition: Two Entrance Exhibitions of 80 guineas each, awarded after a competitive examination in anatomy and physiology; Graham Scholarship in pathology of a sum not exceeding £200 per annum; the Atkinson Morley Scholarship of £45 a year for three years, awarded after examination in the theory and practice of surgery; the Atchison Scholarship of £55 a year for two years for general proficiency in medical studies; Magrath Clinical Scholarship, value about £100; the Filliter Exhibition in pathology of £30; Graham Gold Medal for research work; four Fellowes Medals in clinical medicine; Liston Medals in clinical surgery; the Bruce Medal in pathology and surgery; two Tuke Medals in pathology, and the Erichsen Prize for practical surgery.

Appointments.—All the appointments at the hospital are reserved for students of the school, the dresserships and clerkships being open, of course, to those who have still to qualify. The qualified appointments, in addition to a number of posts as house-physicians and house-surgeons and obstetric assistants, include the appointments of resident medical officer, surgical registrar, obstetric registrar, casualty medical officers, casualty surgical officers, assistant in ear, nose, and throat department, assistant in ophthalmic department, registrar in anaesthetic department, and deputy anaesthetists.

Fees.—The fee for the full course of final studies at the school is 80 guineas if paid in one sum, or 82 guineas if paid in two instalments.

Westminster.

This school, with its hospital, situated in Broad Sanctuary, opposite Westminster Abbey, provides for the education of its students in the preliminary and intermediate subjects of the University of London at King's College. The rest of the work is done in the school buildings near the hospital, which contains upwards of 200 beds, and affords most ample facilities for instruction in all branches of medicine and surgery.

Appointments.—A medical and surgical registrar are appointed annually, each with a salary of £50. Two house-physicians, three house-surgeons, one assistant house-physician, one assistant house-surgeon, and a resident obstetric assistant are appointed after examination, and are provided with rooms and commons, except the assistant house-physician and the assistant house-surgeon, who are provided with commons only. The assistant house-physician after three months' service becomes house-physician for a further period of six months, and the assistant house-surgeon, after two months' service, becomes house-surgeon for a further period of six months. Clinical assistants to the assistant physicians and assistant surgeons, and to the officers in charge of special departments, are appointed from among qualified students. Every student must perform the duties of out-patient dresser for four months, and afterwards hold the office of in-patient dresser for four months. He is also required to serve two terms of four months each as medical clinical clerk to in-patient physician and one term as gynaecological clinical clerk. Two Pathological clerks are appointed every four months to assist in the *post-mortem* room. No student is eligible as an in-patient dresser or clinical clerk until he has passed the Second Examination of the Conjoint Board, or an equivalent examination. Clerks and dressers in the special departments of hospital practice are periodically appointed. So far as vacancies permit, students of other hospitals are admitted to in-patients' dresserships or clerkships.

Scholarships.—The following scholarships are offered for competition during the year 1914-15. In the summer session two natural science scholarships, £60 and £30, and one in Arts, £60 (and again in July, 1915). In the winter session two scholarships in anatomy and physiology, £50 each. In the spring two scholarships in anatomy and physiology, £50 each.

Fees.—The annual composition fee is 25 guineas, and an entrance fee of 15 guineas is payable by every student, including scholars. Under certain conditions 10 guineas of the entrance fee is returnable on qualification. Special terms are given to the sons of medical men. These fees include subscriptions for membership of the Clubs Union.

Further information can be obtained on application to the Dean at the Westminster Hospital Medical School, Caxton Street, Westminster, S.W.

London (Royal Free Hospital) School of Medicine for Women.

This school is carried on at 8, Hunter Street, Brunswick Square, in connexion with the Royal Free Hospital, and it is, like all the other London schools which have so far been mentioned, one of the constituent schools of the Medical Faculty of London University. The new school buildings, among the best of their kind, were completed in 1900 at a cost, with equipment, of over £35,000. The laboratories are large and well lighted, and are fully equipped for the first and second medical examination courses of the University of London. A large library and common room are provided for the use of the students, and sets of chambers to accommodate sixteen students.

The hospital has 165 beds, all of which are available for clinical instruction. A new block is in course of construction, containing a Maternity Department, with a lying-in ward of 8 beds, new and enlarged students' quarters, a new Out-Patients' Department, with special operating theatre, and departments for massage, electrical and *x*-ray work, dentistry and casualty. There are also separate departments for gynaecology and obstetrics, and diseases of the eye, ear, and skin. Instruction is given in anaesthetics, bacteriology, etc., in addition to the ordinary clinical lectures and demonstrations and tutorial classes. Students attend the practice of one of the fever hospitals of the Metropolitan Asylums Board, and receive special instruction in lunacy at Bethlem Hospital; they are also admitted to the practice of a number of special hospitals.

The work of the school includes preparation for the M.B., B.S.Lond., the diplomas of the Royal Colleges of England and of the Conjoint Boards of Scotland and Ireland, and the Society of Apothecaries, London; also for the greater part of the course required by the University of Durham and the other universities of England which admit women to their degrees, and the University of Glasgow; also for the medical school and general hospital course for dental students.

Appointments.—Qualified students of the school can obtain appointments as house-physician and house-surgeon, obstetric assistants, surgical and medical registrars,

anaesthetists, medical electrician, radiographer, curators of the school and hospital museums, and clinical assistants and demonstrators in various subjects.

Scholarships.—The Isabel Thorne Entrance Scholarship value £30, the St. Dunstan's Medical Exhibition value £60 a year for three years, extendible to five years, and the Mabel Sharman-Crawford Scholarship value £20 a year for four years, are offered for competition in each year. The Bostock Scholarship, value £60 a year for two or four years, is awarded by the Reid Trustees on the result of an examination held in May by the University of London. The holder of the scholarship must enter the London School of Medicine for Women. The Agnes Guthrie Bursary for Dental Students, value £60, is awarded each year. The John Byron Bursary of £20 a year for two years, the Helen Prideaux Prize of £40, the Mabel Webb Research Scholarship of £30 for two years, the Fanny Butler Scholarship of £14 10s. a year for four years, together with many other scholarships and prizes, are offered on sundry conditions. Various missionary societies also offer scholarships on certain conditions, and assist ladies who wish to go to India and other countries as medical missionaries.

Fees.—University of London and diplomas of Royal Colleges of England course for the first medical examination, £25; course for second and third, £135; course after the second medical examination, £90. Composition fee for course of study for other qualifications, £140. Further information can be obtained from the Secretary.

King's College.

SINCE the incorporation of King's College in the University of London, the instruction given to medical students is carried out there in the classes of the Faculty of Science (Medical Division), and deals only with the subjects of the preliminary and intermediate parts of the curriculum. King's College Hospital (which see) is now a separate institution, and the studies for the final examinations only are carried out there.

A special class for the Matriculation Examination is also held.

There is a large athletic ground at Wormwood Scrubbs, managed by the Students' Union Society.

Scholarships.—The entrance scholarships are: 1. Two to four Warneford Scholarships, each £25 for four years; subjects—mathematics, classics, divinity. 2. One Sambrooke Exhibition of £25 for two years, open; subjects of examination—mathematics, elementary physics, inorganic chemistry, botany, and biology. The holders of the preceding awards must proceed to King's College Hospital. 3. Rabbeth Scholarship, value £20, in July, for the best student of the first year. 4. Second year's scholarship, value £20, for the best student of the second year.

Fees.—Information as to fees can be obtained from the Dean of the Medical Division of the Faculty of Science at the College.

Information as to scholarships and subjects of examinations can be obtained from the Secretary of the College.

University College.

THIS institution, one of the principal component parts of the University of London, possesses a Faculty of Medical Sciences whose work covers all the subjects included in the group commonly known as the preliminary medical sciences—namely, physics, chemistry, botany, and zoology; and also the intermediate medical sciences—namely, anatomy, physiology, and pharmacology. The Department of Hygiene and Public Health prepares for the diplomas in public health of the Royal Colleges and of the various universities. Research work is undertaken in all the above-named departments, as well as in pathological chemistry, the work of which is entirely post-graduate. It undertakes the education of students in all the subjects mentioned, leaving them free to complete their education in the strictly professional subjects—medicine, surgery, and the like—at any one of the recognized schools of advanced medical studies. The work is somewhat differently arranged, accordingly as whether the student has in view the degrees of the University of London or the diplomas of the Royal Colleges. In either case the whole work to be done is divided into courses devised to meet the requirements of different examinations, and students can join the College for any of them. The general arrangements for the benefit of students include membership of the Union Society, with its gymnasium and athletic ground. There is also a collegiate residence for about forty students at Ealing.

Scholarships.—The scholarships and exhibitions obtainable include the Bucknill Scholarship, value 135 guineas, in chemistry, physics, botany, and zoology (the successful student must complete his work at University College Hospital Medical School), and two entrance exhibitions on the same subject, each of the value of 55 guineas.

Fees.—The fees for the courses covering the work of the First Examination for medical degrees of the University of London, and in both parts of the Second Examination, amount to 84 guineas. The fees for the courses covering the corresponding examinations held by the Conjoint Board in England come together to 79 guineas. These fees may be divided into payments for the different courses which it may be desired to take out, but do not cover tuition for more than a stated period.

A handbook specially relating to this faculty may be obtained on application to the Provost of University College.

Cooke's School.

THIS school is prepared to admit to its supplementary work all who may wish to join the same, but in regard to its curriculum work it does not receive more than half a dozen students in the course of the year; these have special advantages, both as regards anatomy and physiology. The fees, we are informed, are but slightly in excess of current charges. The operations of surgery are performed on the dead body.

The school, which is open all the year round, possesses a good collection of anatomical models, physiological and chemical apparatus, and gentlemen preparing for the higher examinations (F.R.C.S.Eng., M.B.Cambridge, Oxford, London, etc.) receive special instruction in the more difficult subjects. Other information may be obtained from the Secretary on the school premises, Handel Street, W.C.

THE PROVINCES.

THERE are in England and Wales, not counting London, ten medical schools, each, with one exception, supplying instruction in the full medical curriculum. Accounts of them here follow, these being placed more or less roughly in the order of their foundation. In several cases there is appended information concerning other hospitals than those directly connected with the school in question; such hospitals, officially and unofficially, play a part in the education which the students of the school receive, and in any case serve as places of additional or post-graduate study.

Oxford and Cambridge.

BOTH at Oxford and Cambridge there are medical schools which furnish unsurpassed opportunities for obtaining a good knowledge of the preliminary sciences and of anatomy, physiology, and pathology. The laboratories are excellently equipped, and the teaching staffs most distinguished. Both schools provide a full medical curriculum, and there is no essential reason why the student should not complete his career at either of them, but this is not commonly done. The local hospitals are comparatively small, so the authorities encourage the students, so soon as they have completed the earlier examinations, to join some London school, and thus spend the time of their preparation for the final examination in a city where the opportunities for gaining clinical knowledge are greater and more varied.

University of Durham College of Medicine.

THIS, the Medical School of the Faculty of Medicine of the University of Durham, is in the neighbouring city, Newcastle-on-Tyne. Its classes and lectures are arranged to meet the requirements of the university in all the degrees which the latter grants, and also those of the other examining bodies. The students do their work in the preliminary sciences at Armstrong College, also part of the university, and their clinical work in the new *Royal Victoria Infirmary*, an institution with over 400 beds and special accommodation for the benefit of students. In a new wing of the school itself there are the departments of bacteriology and physiology. There are also in this wing a gymnasium and a set of rooms for the use of the Students' Union.

Appointments.—Assistant demonstrators of anatomy and prosectors for the professor of anatomy, assistant

physiologists, pathological assistants, assistants to the dental surgeon, and assistants in the eye department, throat and ear department, and department for skin diseases, are elected annually. Four times in the year clinical clerks and dressers are appointed for three months.

Scholarships.—A University of Durham Scholarship, value £100, for proficiency in arts, open annually at the beginning of the winter session to intending students. The Pear Scholarship, value £150, for proficiency in arts (when vacant). The Dickinson Memorial Scholarship, interest of £400, with a gold medal, for medicine, surgery, midwifery, and pathology, open to perpetual students in their fifth year. The Tulloch Scholarship, interest of £400 annually, for anatomy, physiology, and chemistry, for students at the end of their second year. The Charlton Memorial Scholarship, interest of £700 annually, open to full students entered for the class of medicine, at the end of their fourth or fifth winter. The Gibb Scholarship, interest of £500 annually, for pathology, at the end of summer session. Gibson Prize, interest of £225, for midwifery. Outterson Wood Prize, interest of £250, for psychological medicine. The Goyder Memorial Scholarship, proceeds of £325; subjects: Clinical medicine and clinical surgery. Luke Armstrong Memorial Scholarship, proceeds of £680, for best essay in some subject in comparative pathology. The Stephen Scott Scholarship in Surgery, interest on £1,000 annually. The Heath Scholarship in Surgery, interest on £4,000, awarded every other year. First award in 1896.

Fees.—The composition fee for lectures at the college is 72 guineas. Composition fee for hospital practice 35 guineas, *plus* £2 2s. yearly for three years payable to Committee of Royal Victoria Infirmary. Other information should be sought from the Secretary of the School at Newcastle.

Other Hospitals.—The Hospital for Sick Children and the Infirmary for Diseases of the Eye throw open their various departments to students.

Birmingham.

The school in this city is carried on by the Medical Faculty of the University of Birmingham, its students having an adequate number of good laboratories, class-rooms, and other necessaries devoted to their use by the university. The clinical work is done at the General and Queen's Hospitals, which are amalgamated for this purpose. Together they have upwards of 500 beds for medical, surgical, and special cases, and with an array of special departments of all kinds, including one for lying-in women. Clinical instruction is given in the wards and out-patient and special departments daily, and formal clinical lectures delivered weekly throughout the winter and summer sessions. Special tutorial classes are also held alike for the degrees of Birmingham and some other universities and for the diplomas of Corporations.

Appointments.—The large number of appointments open to past or other students include the following:—At the General Hospital: 1 resident medical officer, salary £100 a year; 1 resident surgical officer, salary £100 a year; 1 resident pathologist, salary £50 a year; 2 non-resident casualty assistant physicians, salary £50 a year; 3 non-resident surgical casualty officers, salary £50 a year; 2 non-resident anaesthetists, salary £50 a year; 4 house-surgeons, office tenable for nine months, £50 a year; 1 house-surgeon to the gynaecological and 1 to the ophthalmic and aural departments, each tenable for six months, £50 a year; 3 house-physicians, post tenable for six months, £50 a year; 1 resident medical officer at the Jaffray Branch Hospital, salary £150 a year; 1 resident assistant at the Jaffray Branch Hospital, tenable for three months. At the Queen's Hospital: 3 house-physicians and 3 house-surgeons (post vacant in January and April); 1 obstetric and ophthalmic house-surgeon (post vacant in April and October). These appointments are tenable for six months. Salaries at the rate of £50 per annum, with board, lodging, and washing. One resident dresser, tenable for three months; candidates must previously have attended their lectures, etc., and need not be qualified. At the Maternity Hospital: 1 house-surgeon, salary £50 a year. At the City Workhouse and Workhouse Infirmary: 5 resident medical officers. At the Birmingham General and Branch Dispensaries: 12 resident surgeons. At the Birmingham Lunatic Asylums: 5 assistant medical officers. At the City Fever Hospitals: 3 assistant medical officers. At the Children's Hospital: 1 resident surgical officer, 1 resident medical officer. At the Birmingham and Midland Eye Hospital: 4 resident surgeons. At the Orthopaedic and Spinal Hospital: 2 clinical assistants (non-resident). At the Ear and Throat Hospital: 1 house-surgeon, £70 a year; 4 clinical assistants (non-resident). There are also 4 non-resident Poor Law appointments in the gift of the Board of Guardians.

Scholarships.—There are numerous money and other awards for students of sufficient merit, among them being the following: The Walter Myers Travelling Studentship of £150; the Sands-Cox Scholarship of £42 (an entrance scholarship in the Faculty of Medicine, awarded on matriculation marks); four Queen's Scholarships of £10 10s. each, awarded annually at the second, third, fourth, and final university examinations respectively; one or more Sydenham Scholarships, allotted on entrance to students who are the sons of deceased medical men. The Ingleby Scholarship of £10 for proficiency in midwifery and diseases of women. There is also an entrance scholarship of £37 10s. for students proceeding to a degree in dental surgery. University Clinical Board Prizes are awarded annually as follows: Senior Medical Prize, Gold Medal; Senior Surgical Prize, Gold Medal; Midwifery Prize, Gold Medal; Junior Medical Prize, Silver Medal; Junior Surgical Prize, Silver Medal.

Fees.—The composition fee is £85. This covers all the work required for the degrees of Birmingham and some other universities, and for the ordinary qualifications of licensing corporations, but not the additional courses required for the Fellowship of the Royal College of Surgeons of England, the diploma and degrees of the university in State medicine and some other special work. Other information should be sought from the Dean of the Medical Faculty.

Manchester.

The staff of the Medical School in this city constitutes the Medical Faculty of the Victoria University, all the arrangements for the instruction of students, both in their earlier and their later studies, being of an elaborate nature. The clinical work of the undergraduates is done chiefly in connexion with the Royal Infirmary, an institution which itself contains about 592 beds, and has associated with it a large convalescent home and the Royal Lunatic Asylum at Cheadle. Instruction in practical gynaecology and midwifery is given at the Royal Infirmary and the St. Mary's Hospitals.

Appointments.—The following are among the appointments open to past and present students of this school in connexion with its arrangements for clinical tuition: A surgical registrar, at £75 per annum; a pathological registrar, at £100 per annum; a medical registrar, at £75 per annum; a surgical tutor, at £30 per annum; a director of the clinical laboratory, at £250 per annum, and 1 assistant director, at £75; 3 assistant medical officers and 3 assistant surgical officers, each at £35 per annum; 1 assistant surgical officer, Aural department, at £35 per annum; 5 anaesthetists, at £50 per annum each; 1 medical officer for radiography and electricity, £100 per annum; 1 medical officer for home patients, one year, £150 per annum; 1 resident medical officer, one year, £150 per annum; ditto, at Cheadle, one year, £150 per annum; 1 resident surgical officer, one year, £150 per annum; 2 resident medical officers for Central Branch, £100 per annum; 1 accident room house-surgeon, six months, £100 per annum; 1 assistant medical officer at the Convalescent Hospital at Cheadle, appointed every six months, at a salary of £80 per annum; 8 senior and 8 junior house-surgeons and 10 house-physicians, appointed during the year for a term of six months. Resident officers are appointed to the Gynaecological, the Eye, and the Ear and Throat departments every six months. Four or more clinical clerks are attached to each physician and assistant physician, and 4 or more dressers to each surgeon and assistant surgeon, to the Gynaecological surgeon and assistant Gynaecological surgeon, to the Ophthalmic surgeon, and to the surgeon for the Ear and Throat department, and 4 or more clerks to the Pathologist, 2 clerks to the Director of the Clinical Laboratory, and a number of clerks, not exceeding 6, are appointed to assist the medical officer for home patients. Accident-room dressers are appointed every three months, 3 senior dressers and 12 or more junior dressers.

Entrance and other Scholarships.—The following are among the scholarships obtainable by students of the school: Rogers and Seaton Scholarships in Arts (in alternate years), £40 per

annum, tenable for two years. Two Dalton (entrance) Scholarships in Mathematics, tenable for two years, value £40, one being awarded annually, except in such years as a Cartwright Scholarship is awarded. Cartwright Scholarship, £35 per annum, tenable for three years. Three Hulme Scholarships, tenable for three years, of £35, one being awarded annually for proficiency in subjects of general education. Two James Gaskill Scholarships of £35, tenable for two years, one being awarded annually for proficiency in the branches of Mechanics and Chemistry. A Dora Muir Scholarship, £30 per annum, tenable for three years, and open to the competition of women students only. This is awarded triennially; next competition in May, 1917. Sir J. P. Kay-Shuttleworth Scholarship, £30 per annum, tenable for three years, open to the competition of scholars from Sedbergh School, Giggleswick School, and Burnley Grammar School. Subjects: Mathematics, Chemistry, and Mechanics. Dreschfeld Memorial Scholarship, value £30, tenable for one year and awarded triennally on the results of the Entrance Examination. A Theodores Modern Languages Exhibition, £20, awarded annually. Two Dauntesey Medical Scholarships, value £45 and £35, tenable for one year, for candidates who have not commenced the second year of study leading to a medical qualification. Subjects: Zoology, Botany, and Chemistry. Two Entrance Scholarships in Medicine, value £100, awarded annually for proficiency in Arts or Science respectively. Two Research Fellowships in Public Health of £50 each, awarded annually. Tom Jones Exhibition in Anatomy: £25, offered annually. Robert Platt Physiological Exhibitions: Two, about £15 each, offered annually. A Robert Platt Physiological Scholarship of £50, tenable for two years. A Robert Platt Zoological and Botanical Scholarship, £50. A Leech Fellowship of £100 for original research after graduation. A Graduate Scholarship in Medicine: One of £25, tenable for one year, awarded annually for proficiency shown at Final M.B. Examination. The Tom Jones Memorial Surgical Scholarship: Value £100, tenable for one year, awarded usually triennially; next award in September, 1916. The Turner Medical Scholarship: Value £20, awarded annually for proficiency in certain subjects of the Final M.B., Ch.B. Examination. The John Henry Agnew Scholarship of £30, awarded annually for proficiency in the Diseases of Children. The Bradley Memorial Scholarship in Clinical Surgery of £20. The Ashby Memorial Scholarship, tenable for one year (£100), for research in the Diseases of Children; offered biennially; next award, 1916. Sidney Renshaw Exhibition in Physiology: One, offered annually.

Fees.—The composition fee for the university courses in medicine is 70 guineas, payable in three instalments of 30, 20, and 20 guineas, but this sum does not include the fee to cover the work required for the First M.B. Examination. This is £25, payable in one sum. A prospectus and further information about the school and scholarships may be obtained on application to the Registrar.

Clinical Work.—The Royal Eye Hospital, the Manchester Northern Hospital for Women and Children, the well-known Hospital for Children at Pendlebury, and St. Mary's Hospital for Diseases of Women and Children all make arrangements for the instruction of students.

LIVERPOOL.

THE Medical School of this city is part of the university, and, owing to the enlightened liberality of several men of wealth, is exceptionally well provided with special laboratories, as well as with ordinary spacious and well-equipped classrooms and laboratories for the instruction of students proceeding to medical degrees and diplomas in special and ordinary subjects. All the laboratories and other rooms are situated close to one another and intercommunicate, together forming large blocks of buildings. The work of students throughout all stages of their career is arranged upon very satisfactory lines, and the teaching hospitals, of which an account is given below, have amalgamated to form the clinical school of the university.

Appointments.—The nature of the appointments open to past and other students at this school will be gathered from the account which follows of the hospitals forming its clinical department.

Scholarships.—The awards made each year to successful students total over £1,000. They include the following: Two Holt Fellowships, one in Pathology, the other in Physiology; a Robert Gee Fellowship in Anatomy; an Alexander Fellowship for Research in Pathology; a Johnston Colonial Fellowship in Pathology, Bacteriology, and Bio-Chemistry; a John W. Garrett International Fellowship in Physiology, Pathology, and Bio-Chemistry; an Ethel Boyce Fellowship in Gynaecology and Pathology, and a Thelwall Thomas Fellowship in Surgical Pathology, all of the value of £100; a University Scholarship of £25, awarded on the results of the Second M.B. Examinations; a Scholarship in Mechanical Dentistry of £20; two Lyon Jones Scholarships, of the annual value of £21 each for two years, one for the junior and the other for senior students; the Derby Exhibition of £15; the Clinical School Exhibition of £15; the Torr Gold Medal in Anatomy; the George Holt Medal in Physiology; the Kanthack Medal in Pathology; the Robert Gee Prize of £5 5s. in Children's Diseases; two Robert Gee Entrance Scholarships, each of the value of £25 per annum for two years; Orthodontia Prizes, Senior £3 3s., Junior £1 1s.; Dental Operating Prizes, Senior £4 4s., Junior £2 2s.; Ash's Prize in Dental Surgery, value £2 2s.; and other Entrance Scholarships.

Fees.—Information as to the fees paid for the courses of instruction provided by the schools should be sought from the Dean of the Medical Faculty.

The Clinical School.

As many as 9 hospitals have combined to form the clinical school of the university, these being: The Royal Infirmary, the David Lewis Northern Hospital, the Royal Southern Hospital, the Stanley Hospital, the Infirmary for Children, the Hospital for Women, the Eye and Ear Infirmary, St. Paul's Eye Hospital, and St. George's Hospital for Diseases of the Skin. Between them they provide over 1,200 beds.

LEEDS.

THE School of Medicine—which is open to both male and female students—in this city forms the teaching centre of the Medical Faculty of the University of Leeds, and is situated in immediate proximity to the General Infirmary, where students sufficiently advanced receive their clinical instruction. The buildings were opened in 1894, and contain excellent dissecting rooms, several well-arranged laboratories for physiology, pathology, and bacteriology, three lecture theatres, and several similar class rooms. In addition there are a library and reading room and two museums, one being devoted to pathology and the other to anatomy. The comfort of the students is secured by common rooms and refectory in which they can take meals. It is estimated by the authorities that the approximate cost of medical education to a student in this university is £195, *plus*, of course, the expenses of living during the five years covered by the curriculum. The General Infirmary has over 420 beds in constant use, and includes gynaecological and ophthalmic wards and a large out-patient department. The Ida and Robert Arthington Semi-convalescent Hospitals, Cookridge, attached to the infirmary, has over 80 beds. The West Riding Lunatic Asylum at Wakefield is also open for the study of mental diseases. Students can, in addition, attend the practice of the Leeds Public Dispensary (where the practical instruction in dental subjects is also given), the City Fever Hospitals (100 beds), the Hospital for Women and Children, and the Leeds Maternity Hospital.

Appointments.—One senior anaesthetist, £50; 7 assistants, £25 each; medical and surgical tutor, at £125 each per annum; 1 resident medical and 1 surgical officer, each at £150 per annum; 1 casualty officer, at £125 per annum; 1 resident ophthalmic officer, at £100 per annum; 1 resident aural officer, at £100 per annum; 1 resident obstetric officer, at £50 (attached to the gynaecological ward and an extensive external maternity department); 1 ophthalmic house-surgeon, at £50 per annum; 3 house-physicians, each holding office for six months, and 4 house-surgeons, holding office for six months. Surgical dressers are appointed every six months; physicians' clerks, ophthalmic and aural dressers, gynaecological ward clerks, gynaecological out-patient clerks, maternity clerks, assistant physicians' clerks, dermatological clerks, and assistant surgeons' dressers, dressers in the casualty room, *post-mortem* clerks, and laboratory assistants every three months. A clinical pathologist (£300 per annum), together with an assistant clinical pathologist (£150), has charge of the pathological laboratory. A resident medical officer (honorarium, £30) is also appointed every six months for the Ida Semi-convalescent Hospital. Appointments are also open to students at the Leeds Public Dispensary (1 senior and 4 junior resident medical officers, with salaries commencing at £80), at the Hospital for Women (2 house-surgeons, at £50 per annum, and 2 anaesthetists, £20), and at the West Riding Asylums.

Scholarships.—The university awards annually a scholarship on the results of the July Matriculation Examination in the form of a free admission to the lectures and classes given in the university, which are covered by the composition fee. The

infirmary also awards a scholarship on the results of the first examination, of the value of 40 guineas, in the form of a free admission to the clinical teaching of the infirmary.

Fees.—The fee for a complete course for the First M.B. is £27; the composition fee for the course for the second and third examinations is £73 2s. 6d. (for students who have passed the second examination, £48 16s. 6d.), and for the clinical work at the infirmary, £42.

Further information can be obtained from the Academic and Clinical Subdeans, School of Medicine, Leeds.

SHEFFIELD.

In this city the Medical School is one of the departments of the university, being conducted and controlled by its Medical Faculty, and occupying practically the entire north wing of the quadrangle of the university buildings overlooking Weston Park. The laboratories and lecture rooms connected with the subjects of the first and second examinations — namely, chemistry, physics, biology, anatomy, and physiology—are, both as regards structural arrangements and scientific equipment, on the most modern and complete lines. No expense has been spared in the matter of apparatus for teaching or research work, and the facilities for practical study in these subjects are as excellent as all the other arrangements of the school.

For students of pathology and bacteriology there are laboratories replete with everything necessary for the most advanced work, and a large pathological museum, which is open daily. In addition, there is a museum devoted to materia medica specimens, and a large library and reading room. There are a number of recreation, athletic, and other societies, all under the management of an annually elected students' representative council, and large and comfortable common rooms both for men and women students. In the university buildings there is a refectory open to all students of the school, and a university journal, *Floreamus*, edited by a joint committee of the staff and students, is published each term. The ordinary clinical work of the school is done at the Royal Infirmary and Royal Hospital, which have amalgamated for the purpose of clinical instruction, and provide 517 beds for the treatment of medical, surgical, and special cases, including diseases of the eye.

In addition, the Royal Infirmary has special departments for the treatment of diseases of the skin and ear, with beds assigned to them; whilst at the Royal Hospital there are special out-patient departments for diseases of the throat, ear, skin, orthopaedics, and mental diseases. The medical and surgical staffs attend daily, and give clinical instruction in the wards and out-patient rooms. Clinical lectures in medicine and surgery are given weekly. Instruction in the practical administration of anaesthetics is given at either institution by the anaesthetists, and the *post-mortem* examinations at both institutions are in charge of the Professor of Pathology, and afford ample material for study of this subject. Students also have the advantage of being able to attend the practice of the Jessop Hospital for Diseases of Women, while special courses on fever are given at the City Fever Hospital, and on mental diseases at the South Yorkshire Asylum.

Appointments.—The following appointments are open to all students who have passed their examinations in anatomy and physiology: (1) Casualty dresserships, (2) surgical dresserships, (3) medical clerkships, (4) pathological clerkships, (5) ophthalmic clerkships, (6) clerk to the skin department, etc. Except in the case of casualty dressers, these appointments are made for three months, commencing on the first day of October, January, April, and July. The casualty dresserships last two months, beginning on the first of any month. All students are required to hold them, and to have attended the tutorial classes for casualty dressers, before being eligible for any other of the above appointments.

Scholarships.—Entrance Medical Scholarship, value from £122 to £130, open to both sexes. A Special Medical Scholarship, value £100, open to women only, is awarded on the result of the Joint Board Matriculation Examination. Open to any woman candidate over 16 and under 25 who has not previously registered as a medical student. Two Town Trustees' Scholarships, each of the value of £50, tenable for three years, for boys or girls under the age of 19 years who have been educated in a Sheffield secondary school for a period not less than two years immediately preceding the examination. Four Town Trustees' Scholarships, value £50, for boys or girls under 19 years of age, educated in any school in Sheffield, secondary or otherwise. Town Trustees' Fellowship, value £75, tenable for one year. Mechanics' Institute Fellowship, value £50 (with remission of fees), tenable for one year, and renewable for a second year. The Frederick Clifford Scholarship, value about £50, tenable for two years. Kaye Scholarship, for proficiency in anatomy and physiology, value £22 10s. Gold and bronze medals are also awarded for proficiency in various subjects.

Fees.—The composition fee of £80, payable in three instalments, covers attendance on all the courses of lectures and practical classes, except pharmacy, required for a degree course in the university, or for the ordinary qualifications in medicine and surgery of the Examining Boards. It does not include hospital practice, the fee for which is £49 17s. 6d., payable in three instalments.

BRISTOL.

THE school is carried on by the Faculty of Medicine of the university, and provides full instruction for all its degrees and diplomas. The allied hospitals (Bristol Royal Infirmary and Bristol General Hospital) have between them 470 beds and extensive out-patient departments, special clinics for diseases of women and children, and those of the eye, throat, and ear, in addition to arrangements for dental work and large outdoor maternity departments. At each of these institutions there are well-arranged pathological departments, comprising large pathological museums, *post-mortem* rooms, and laboratories for morbid anatomy. There are also laboratories for work in clinical pathology, bacteriology, and cytology, in which special instruction is given in these subjects. Departments are provided and well equipped for *x*-ray work, both for diagnosis and treatment, the various forms of electrical treatment, including high-frequency currents, electric baths, Finsen light treatment, and massage.

The students of the school have also the advantage of attending the practice of the Royal Hospital for Sick Children and Women, containing 108 beds, and that of the Bristol Eye Hospital, with 40 beds. The total number of beds available for clinical instruction is therefore upwards of 600. Excellent facilities are thus afforded to students for obtaining a wide and thorough acquaintance with all branches of medical and surgical work. Each student has the opportunity of personally studying a large number of cases and acquiring practical skill in diagnosis and treatment. All classes are open to women.

Appointments.—(1) Undergraduate: Clinical clerkships, dresserships, also ophthalmic, obstetric, and pathological clerkships, are tenable at the Bristol Royal Infirmary and the Bristol General Hospital. In these institutions the dressers reside in rotation free of charge. (2) Post-graduate: —At the Bristol Royal Infirmary: Two house-surgeons, £100 each per annum; 2 house-physicians, £100; resident obstetric and ophthalmic house-surgeon, £75; throat, nose, and ear house-surgeon, £75; casualty officer, £50; dental house-surgeon, £100. All these appointments are made for twelve months, except that of casualty officer, which is for six months. From the resident officers a senior resident officer is appointed at an additional salary of £30. At the Bristol General Hospital: Senior house-surgeon, £150 per annum; casualty house-surgeon, £100 per annum, if another resident appointment has been previously held; two house-physicians, £80 per annum; house-surgeon, £80 per annum; dental house-surgeon, £200 per annum. All these appointments are for six months, except that of senior house-surgeon, which is for three years, and that of dental house-surgeon, which is for two years.

Scholarships.—The following are among the scholarships and other awards open to students of the school: Two Martin Memorial Pathological Scholarships, of £10 each; the Tibbits Memorial Prize, value 9 guineas, for proficiency in practical surgery; the Committee's Gold and Silver Medals for fifth-year students for general proficiency; the Augustin Prichard Prize, value 7 guineas, for proficiency in anatomy; the Henry Clark Prize, value 11 guineas, for general proficiency; the Crosby Leonard Prize, value 7 guineas, for proficiency in surgery; the Suple Surgical Prize, a gold medal and 7 guineas; the Suple Medical Prize, a gold medal and 7 guineas; the Henry Marshall Prize, value £12, for dressers; the H. M. Clarke Scholarship, value £15, for proficiency in surgery; the Sanders Scholarship, value £22 10s., for general proficiency.

Fees.—The fee for all the courses required for the medical curriculum, including hospital practice, is 135 guineas.

Cardiff.

The school in this city is carried on by the University College of South Wales and Monmouthshire, and devotes itself at present principally to training students during the first three or four years of the medical curriculum, all classes being open to women students. The courses of instruction given are recognized by all licensing bodies in Great Britain, and after passing the tests corresponding to the first three years of the curriculum, the student can complete his course, for whatever degree he is aiming at, in London or elsewhere. Besides this, there is an arrangement with the Managing Committee of the infirmary by which students at the school can take advantage of the opportunities for acquiring experience afforded in the wards of this large, well-ordered hospital. Hence many students, especially from Wales and Monmouthshire, find it convenient to avail themselves of the advantages of being able to pursue the earlier part of their medical curriculum near home. They can also obtain instruction in vaccination and in the administration of anaesthetics, and with a little additional work can qualify for the B.Sc. degree of the University of Wales. This degree includes the subjects which comprise the first three years of a medical student's curriculum, and it (or the B.A.) is a compulsory degree for those students who propose to sit for the M.B., Ch.B. of the University of Wales. There is also a department of public health, in which all the work for diplomas in State medicine, whether for the University of Wales or other Examining Boards, can be done. A Chair of Pathology and Bacteriology has been established, and before long there will be facilities for the study of the subjects of the fourth year of the medical curriculum.

Post-graduate vacation courses are carried on in association with the Cardiff Infirmary.

Scholarships.—There is a considerable number of scholarships connected with the college, and open to students of the School of Medicine, information as to which can be obtained on application.

Fees.—The composition fee for the three years' courses required for students proceeding to the M.B.Lond. is £63; that for the two years' courses for students proceeding to a diploma of the licensing corporations being £41 10s. The composition fee for D.P.H. classes is £30. Further information may be obtained on application to the Dean of the Faculty of Medicine.

SCOTLAND.

As will be gathered from the following paragraphs, the facilities for acquiring a medical education in Scotland are very ample, whether the student be proceeding to a university degree or to a diploma. To the descriptions of its different medical centres is in some cases added an account of hospitals which either play an official part in the education given to students as yet unqualified or offer valuable opportunities for post-graduation work.

Aberdeen.

The school is conducted by the Faculty of Medicine. This comprises twelve chairs, from which instruction is given in all the main branches of medical science—namely, botany, zoology, physics, chemistry, anatomy, physiology, materia medica, pathology, forensic medicine, surgery, medicine, and midwifery. Special opportunities for practical instruction are afforded in the laboratories and museums attached to these departments.

Clinical instruction is obtained in the Royal Infirmary (accommodating 230 patients), the Royal Lunatic Asylum (700 patients), the Sick Children's Hospital (85 patients), the City Fever Hospital (250 patients), the General Dispensary, Maternity, and Vaccine Institution (10,000 out-patients annually), and the Ophthalmic Institution (1,600 patients annually). Courses of practical instruction are given in diseases of children at the Sick Children's Hospital; in fevers at the City Fever Hospital; in insanity at the Royal Asylum; in diseases of ear, nose, and throat at the Infirmary and Dispensary; in diseases of the eye at the Infirmary and Eye Institution; in diseases of the skin at the Royal Infirmary.

Bursaries.—Scholarships and Fellowships, to the number of fifty and of the annual value of £1,180, may be held by students of medicine in this university. They range from £8 to £100 per annum, and are tenable in most cases for two or three years.

Fees.—The fee for each university course is, as a general rule, £4 4s.; and for a second attendance, £3 3s. An inclusive fee of 90 guineas is now payable, covering the necessary instruction within the university. Matriculation fee, both sessions, £1 1s.; summer session alone, 10s. 6d. Royal Infirmary, perpetual fee, £10; or, first year, £5 10s.; second year, £5. The winter session begins on October 15th.

Edinburgh.

There are three Schools of Medicine: the School of the University, the School of Medicine of the Royal Colleges, Edinburgh, and the Edinburgh School of Medicine for Women.

The University School.—This school, in addition to other resources of the university, has the following means of affording practical instruction: Royal Botanic Garden, Herbarium, and Museum; Zoological Laboratory and Museum of Science and Art; Physical Laboratory; Chemical Laboratories; Dissecting Room, Bone Room, and Anatomical Museum; Physiological Laboratory; Medical Jurisprudence Laboratories; John Usher Institute of Public Health; Materia Medica Museum and Laboratory; *Post-mortem* Department of the Royal Infirmary and University Pathological and Bacteriological Laboratory; Tutorial Classes of Practice of Physic, of Clinical Medicine, and Clinical Surgery, Surgery, and Midwifery; and the practice of the hospital mentioned on the following page.

Fees.—The sessional fee for zoology, botany, chemistry, anatomy lectures, physiology, pathology, materia medica, medical jurisprudence, surgery, medicine, midwifery and gynaecology, clinical surgery (winter), clinical medicine (winter), is £4 4s. each. Second course £3 3s. Third free. A perpetual ticket taken at the beginning of the first year is £6 6s. Physics, practical chemistry, advanced practical physiology, practical pathology, practical anatomy (winter), operative surgery, obstetric operations, practical materia medica, including pharmacy, pathological bacteriology, experimental pharmacology, vertebrate morphology and comparative embryology, are £3 3s. Clinical surgery, £2 2s. per term. Clinical medicine, first term, £3 13s. 6d.; subsequent terms, £2 2s. No perpetual ticket in these subjects. Practical botany (besides garden fee of 5s.), elementary practical zoology, practical physiology (experimental), practical physiology (histological), practical botany (advanced), practical zoology (advanced), practical anatomy (summer), anthropology, anatomy demonstrations, diseases of children, diseases of the eye, diseases of the larynx, ear, and nose, diseases of tropical climates, clinical instruction on diseases of the skin, regional anatomy, physiological chemistry, invertebrate zoology, organic chemistry, mental diseases, £2 2s. Applied anatomy (medical and surgical), £1 1s. Vaccination, £1 1s.

Scholarships.—There is a very large number of funds for the assistance of students by means of bursaries, scholarships, exhibitions, and money awards from the beginning to the end of their undergraduate career. In addition there are funds which help those who have taken a first degree in medicine and surgery to continue at work as research students. The value of these awards, and the conditions attaching to them, are so varied that those interested should consult the prospectus of the school itself. No other university is in a better, even if in as good, a position to smooth the financial path of earnest students.

The School of Medicine of the Royal Colleges.—This school is composed of lecturers licensed by the Royal College of Physicians and the Royal College of Surgeons, and also recognized by the university through their *licentia docendi*: for the sake of convenience they lecture in separate buildings near to the Royal Infirmary, but form a single corporate body governed by a board consisting of five members elected by the Royal College of Physicians, of five members elected by the Royal College of Surgeons, and of five members elected by the lecturers in the school. This board, with the assistance of the standing committees of the school, supervises the whole management, and especially the maintenance of the efficiency and discipline of the school. The different buildings at present utilized for the purposes of lecturing

are the following: (1) Surgeons' Hall, Nicolson Street: (2) New School, Bristo Street; (3) Nicolson Square; (4) Marshall Street; and other places. The teaching is similar to that of the Scottish universities, and the students receive similar certificates at the close of each session. The courses on the special subjects not included in the curriculum of the Examining Boards are also conducted by teachers specially qualified in each branch, and have for the last quarter of a century formed a special feature of the school. The fees payable for class and other instruction, and including the sums payable on admission to the examination of the Conjoint Board for the triple qualification, amount to about £115. The Calendar, giving full information regarding classes and fees, can be obtained gratis on application to the Dean of the School, 11, Bristo Place, Edinburgh.

THE EDINBURGH SCHOOL OF MEDICINE FOR WOMEN.—The Edinburgh School of Medicine for Women provides all the classes required for a complete curriculum. The classes qualify for the university degree in medicine, for the diploma of the Royal Colleges, and for the triple qualification. The lecturers of the school are specially recognized by the Court of Edinburgh University for the education of women who propose taking the degree in medicine of the University of Edinburgh. Most of the classes are held in Surgeons' Hall. The office of the school and a sitting-room and other conveniences are provided in the same building for the use of the women students. The clinical instruction of the students is conducted in the wards of the Royal Infirmary specially set apart for the purpose, in the Royal Hospital for Sick Children, in the City Hospital for Infectious Diseases, at Bangour Asylum, and at the various public dispensaries. The fees and the regulations as to the course of study are the same as for pupils at the School for Male Students. Further particulars are obtainable from the Secretary of the School, Surgeons' Hall, Edinburgh.

Clinical Work.

A large number of institutions take part in the clinical instruction of students attending the Edinburgh schools, the more important of them being the Edinburgh Royal Infirmary; the Royal Victoria Hospital for Consumption; the Royal Edinburgh Hospital for Sick Children; the Edinburgh Eye, Ear, and Throat Infirmary; the Edinburgh Royal Maternity and Simpson Memorial Hospital; the Edinburgh City Hospital for Infectious Diseases at Colinton Mains; the Royal Mental Hospital, Morningside; and the District Asylum at Bangour Village. Taken together these institutions furnish some 3,000 beds.

GLASGOW.

THERE are five medical schools in this city: the two schools of the university, one of which (Queen Margaret College) is for women students; St. Mungo's College (the school of the Royal Infirmary), Anderson's College, and the Western Medical School.

THE UNIVERSITY SCHOOL FOR MEN.—The whole course of study required for graduation at the University of Glasgow can be passed here. Besides provision for lectures there is practical and clinical work at the hospitals, and practical courses are conducted in the laboratories of the following departments: Surgery, Pathology, Public Health, Pharmacy, Physiology, Anatomy, Chemistry, Zoology, Physics, and Botany; the Botanic Garden and the Hunterian Museum are also open to students. New buildings and equipments have been provided for botany, for practical anatomy, for operative surgery, as well as for pathology; the very large additions made a few years ago to the Chemical Laboratory rendered it one of the most extensive in Scotland. The classrooms and laboratories for the departments of Physiology, Materia Medica, and Medical Jurisprudence and Public Health are also of recent erection, and are elaborately equipped. The university, in short, has made great and successful efforts to extend and improve the accommodation of the medical departments, to strengthen the teaching staff, and to encourage post-graduate and research work. Three very extensive general hospitals in the city afford exceptional opportunities for clinical instruction—namely, the Western Infirmary (600 beds), near the university, and attended by the bulk of the men students; the Royal Infirmary (600 beds); and the Victoria Infirmary (260 beds); while the Royal Asylum (460 beds), the Royal Hospital for Sick Children (74 beds), the Maternity Hospital (34 beds), the Glasgow Eye Infirmary (100 beds), the fever hospitals at Belvidere (680 beds), and Ruchill (540 beds), and other institutions afford facilities for the practical study of special branches.

Bursaries.—Bursaries confined to the Medical Faculty amount in annual value to about £1,000, while bursaries in any Faculty, amounting to about the same annual sum, may be held by students of medicine, a number of both sets being open to women. Several valuable scholarships may be held by medical students who have graduated in Arts. Some of the bursaries are described below.

Fees.—The matriculation fee for each year is £1 1s. In most cases the fee for each university class is £4 4s., but in some cases it is £3 3s. For hospital attendance students pay an entrance fee of £10 10s. at the Western Infirmary, with an additional fee of £3 3s. for each winter and £2 2s. for each summer clinical course; at the Royal Infirmary the fees are somewhat similar. The university fee for the four professional examinations is £23 2s. (£6 6s. for each of the first and second examinations, and £5 5s. for each of the third and fourth). For the whole curriculum the fees for matriculation, class attendance, hospital attendance, and professional examinations amount to £150.

For further information apply to the Registrar, Glasgow University.

Bursaries.—The following bursaries are open to undergraduates of both sexes: The Gibson Bursary, annual value £56, tenable for four years. This is open to medical students who are preparing for service as medical missionaries in connexion with the Church of Scotland, and will be awarded to the eligible candidate who has gained the highest number of marks in the First Professional Examination. One Logan Bursary, annual value £16, tenable for four years; appointment by the Senate. The Mackintosh Mental Science Bursary in medicine, of the value of £31, is awarded annually to the student (of either sex) attending the class of insanity who stands first in an examination in that subject, the bursar to continue the practical study of the subject to the satisfaction of the Faculty of Medicine. The Gardiner Bursary, annual value £14, tenable for two years, will be awarded after the autumn professional examination to the candidate who has passed in physiology at the Second Professional Examination, and whose aggregate of marks in that subject and in chemistry and physics of the First Professional Examination is the highest. The following are tenable in any faculty: Two Pratt Bursaries (each £20 and tenable for four years); and two Taylor Bursaries (each £10, tenable for four years). Andrew and Bethia Stewart Bursaries (50 each, tenable for three years); candidates must have taken the M.A. degree of Glasgow. There is a special examination. Nine Glasgow Highland Society's Bursaries, for students of Highland descent, of the annual value of £25, and tenable for five years; two vacant each year. The Carnegie Trust for the Universities of Scotland is empowered to pay the whole or part of the university ordinary class fees of students of Scottish birth or extraction, under conditions given in the *University Calendar*. The Dobbie Smith Gold Medal is awarded for the best essay on a prescribed subject within the science of botany. The Brunton Memorial Prize of £10 is awarded annually to the most distinguished graduate in medicine of the year. The University Commissioners issued an ordinance to make regulations for the admission of women to certain bursaries, scholarships, and fellowships. Scholarships and fellowships are offered by the Carnegie Trust in science and medicine for post-graduate study. There are also four McCunn Medical Research Scholarships (£100 for one year) for graduates in medicine of the Scottish universities.

QUEEN MARGARET COLLEGE.—In this, the Women's Medical School of the University of Glasgow, the courses of study, degrees, regulations, fees, etc., are the same as for men. Women students have their own buildings, with classrooms, reading room, library, etc. They are taught in some classes apart from male students, in others together with them, but in either case have all the rights and privileges of university students. Their clinical studies are taken in the Royal Infirmary, where wards containing 400 beds are available for their use, and in its dispensary; also in the Royal Hospital for Sick Children, the Glasgow Ear Hospital, the Royal Asylum, Gartnavel; the Ophthalmic Institution, the City of Glasgow Fever Hospitals, Belvidere and Ruchill, and the Glasgow Royal Maternity and Women's Hospital.

Scholarship.—The Arthur Scholarship, annual value £20, tenable for three years. Open to competition by medical students of first year at the First Professional Examination in October each year. This scholarship is the gift of Mrs. Arthur, of Barshaw, and is restricted to women medical students.

Board for Students.—A house of residence for women students, Queen Margaret Hall, is situated near the college. The cost of board and residence is from 17s. 6d. to 25s. 6d.

per week, according to accommodation. Full information can be obtained from the Mistress, Queen Margaret College, or from the Warden, Queen Margaret Hall, Bute Gardens, Glasgow.

St. Mungo's College.—This is the Medical School of the Royal Infirmary, which is the largest in Glasgow. The infirmary is situated in Cathedral Square, Castle Street, and has car communication with every part of the city. St. Mungo's College is in the infirmary grounds.

The infirmary has (including the ophthalmic department) over 660 beds, the average number occupied in 1913 being over 600. There are special beds and wards for diseases of women, of the throat, nose, and ear, venereal diseases, burns, and septic cases. In the out-patient department the attendances in 1913 numbered over 180,000. In addition to the large medical and surgical departments, there are departments for special diseases—namely, diseases of women, of the throat and nose, of the ear, of the eye, of the skin, and of the teeth. There is also a fully equipped electrical pavilion, and year by year the latest and most approved apparatus for diagnosis and treatment are added.

Appointments.—Five house-physicians and ten house-surgeons, who must be fully qualified, are appointed every six months, and board in the hospital free of charge. Clerks and dressers are appointed by the physicians and surgeons. As a large number of cases of acute diseases and accidents of a varied character are received, these appointments are very valuable.

Fees.—The average class fee is £2 2s. The fees for all the lectures, practical classes, and hospital attendance necessary for candidates for the diplomas of the English or Scottish Colleges of Physicians and Surgeons amount to about £70. The classes are open to male and female students.

The Anderson College of Medicine.—This school provides education in all subjects of the curriculum both for medical and dental students. The school buildings are situated in Dumbarton Road, immediately to the west of the entrance of the Western Infirmary, within two minutes' walk of that institution and four minutes' walk of the university. The hospital practice and clinical lectures are provided in the Western or Royal Infirmary; pathology in the Western or Royal Infirmary; vaccination and dispensary practice in the Western or Royal Infirmary Dispensary. These classes are recognized by all the licensing corporations in the United Kingdom, and also by the Universities of London, Durham, Glasgow, and Edinburgh (the latter two under certain conditions which are stated in the school Calendar). The courses (lectures and laboratory) in public health are also recognized by the Scottish Licensing Board, Queen's University of Belfast, the Irish Colleges, and the University of Cambridge.

Fees.—The fees for the lectures and practical work required by ordinary students range between 1 and 5 guineas a session. In the Public Health Department the fee for a six months' course is £12 12s. The Carnegie Trust pays the fees of students at Anderson's College on conditions regarding which particulars may be obtained from the Secretary, Carnegie Trust Offices, Edinburgh.

A Calendar will be sent on receipt of a post-card by the Secretary to the Medical Faculty, the Anderson College of Medicine, Glasgow W., who will forward any further information which may be desired.

Glasgow Western Medical School.—This school, which is situated in University Avenue, faces the principal entrance to the university, and is not far from the Western Infirmary. The subjects in which it affords instruction by means of lectures and demonstrations are anatomy, medicine, surgery, ophthalmology, dermatology, midwifery, gynaecology, and diseases of the ear, the throat, and the nose. Some of the classes qualify for the medical degrees of the university, and also for the diplomas of the Scottish Conjoint Board. The fee for most of the subjects is £2 2s. There is no matriculation fee. Further particulars relating to the school can be obtained from its Secretary, Mr. J. N. Morton, 58, Bath Street, Glasgow.

Clinical Work.

The opportunities for obtaining clinical instruction and experience are ample, the following institutions all making arrangements for the benefit of ordinary and post-graduate students: The Royal Infirmary, the Glasgow Western Infirmary, the Glasgow Eye Infirmary, the Royal Hospital for Sick Children, and the Glasgow Hospital for Diseases of the Ear, Nose, and Throat.

St. Andrews and Dundee.

The medical departments in these two teaching centres cater specially for students proceeding to the degrees of the University of St. Andrews, but admit other students as well. In the former city the United College provides education in all subjects of the first two years. In Dundee, University College provides for the needs of students from the beginning to the end of the five years' curriculum. Its buildings are modern, and contain laboratories and work-rooms for anatomy, physiology, materia medica, pathology, ophthalmology, public health, medicine, surgery, and gynaecology. The clinical work of the school is facilitated by various institutions. The class fees are 4 guineas for systematic classes, and 3 guineas for practical classes. The hospital ticket is £1 1s. for three months, £3 3s. a year, or perpetual £10 in one sum or £10 10s. in instalments. Added up, the fees for the curriculum amount to about 100 guineas. In connexion with both institutions there are bursaries and scholarships of considerable value, which are awarded after competitive examination. Information as to these can be obtained from the Secretary of the University of St. Andrews. Information regarding the clinical facilities may be obtained from Professor Kynoch, Dean of the Medical Faculty, Medical School, Dundee.

Clinical Work.

Good opportunities for clinical work are afforded by the Dundee Royal Infirmary, the instruction given thereat being recognized for purposes of graduation by all the Scottish universities, the University of London, the University of Cambridge, the Royal University of Ireland, and by the Royal Colleges of England and Scotland.

IRELAND.

There is a choice of six schools for those prosecuting their medical studies in Ireland, and for clinical instruction the choice is equally satisfactory and varied, though the hospitals themselves are comparatively small. Some account of the schools follows:

Dublin.

The School of Physic.

This school is in Trinity College, Dublin, and is carried on under the joint auspices of the University of Dublin and of the Royal College of Physicians in Ireland; the King's professors of institutes of medicine, practice of medicine, materia medica, and midwifery being appointed by the latter. Clinical instruction is given at Sir Patrick Dun's Hospital, and some twelve other metropolitan hospitals and asylums are recognized by the Board. A three weeks' post-graduate course is given each autumn, and covers all departments of medicine and surgery. Information concerning the post-graduate course can be obtained from Dr. Alfred Parsons, 27, Lower Fitzwilliam Street.

The Schools of Surgery.

These are schools carried on in Dublin under the supervision and control of the Council of the Royal College of Surgeons. They are formed of the college's own school, combined with two famous old medical schools—Carmichael and Ledwich; they are attached to the college by charter. The buildings contain spacious dissecting rooms, one set apart for lady students, and special pathological, bacteriological, public health, chemical, and pharmaceutical laboratories. Advantage can be taken of the lectures and instruction afforded by students otherwise unconnected with the college.

Prizes.—Among the prizes annually awarded are: The Barker Anatomical Prize (£26 5s.); the Carmichael Scholarship (£15); the Mayne Scholarship (£8); the Gold Medal in Surgery, and the Stoney Memorial Gold Medal in Anatomy; class prizes of £2 and £1, accompanied by silver medals, will also be given in each subject.

The next session begins October 15th. A prospectus can be obtained post free on application to Mr. Alfred Miller, Registrar, Royal College of Surgeons, Dublin.

University College.

This is one of the constituent colleges of the National University of Ireland, and at present conducts its work at buildings on St. Stephen's Green, at those formerly occupied by the Cecilia Street School of Medicine, and at the University Buildings in Earlsfort Terrace. Its permanent home is not yet ready. It possesses a good library, and the arrangements for the teaching of medical students from beginning to end of the curriculum are adequate. The teaching staff is numerous, and through it the college is connected with many of the hospitals of the city. Students, however, are allowed to pursue their studies at any of the hospitals recognized for the purpose by the university.

Clinical Work.

There are numerous well-arranged hospitals in and around the city, and almost all of these are recognized for teaching purposes by the Conjoint Board of Ireland, the University of Dublin, the National University of Ireland, and by like bodies elsewhere in the United Kingdom. Among them are the Mater Misericordiae Hospital, with 345 beds; Dr. Steevens's Hospital at Kingsbridge, with 200; Meath Hospital and County Dublin Infirmary, with 160; Mercer's Hospital, close to Trinity College, with 120; the Royal City of Dublin Hospital, with 124; the Adelaide Hospital, with 140; the Royal Victoria Eye and Ear Hospital, with 100 beds; Sir Patrick Dun's, which has a direct connexion with the School of Physic, and the combined institutions formed by the Hardwicke Fever Hospital, the Richmond Surgical Hospital, and the Whitworth Medical Hospital, with an aggregate of 230 beds. As for that known as the Rotunda Hospital, this practically consists of two distinct hospitals, and is believed to be the largest combined maternity and gynaecological hospital in the United Kingdom. It receives nearly 3,000 patients every year, and apart from ordinary out-patient work of a gynaecological order annually attends approximately 2,000 women at their own homes during their confinement. It possesses residential quarters for students, and, taken as a whole, offers exceptional opportunities for study both to ordinary students and to post-graduates of any nationality.

BELFAST.

The Medical School is part of the Faculty of Medicine of Queen's University, Belfast, and provides a complete medical curriculum for all purposes. The laboratories in connexion with the departments of biology, chemistry, physiology, pathology, anatomy, physics, and materia medica are all excellent, and there is a Students' Union which gives students the advantage of dining rooms, reading rooms, a library, and various recreation rooms. Women are eligible as students. Clinical instruction is given at the Royal Victoria Hospital, which was rebuilt a few years ago and has 300 beds, and the Mater Infirmorum Hospital, which has 150 beds. Other hospitals open to the students of the university are: The Maternity Hospital, the Ulster Hospital for Women and Children, the Hospital for Sick Children, the Ophthalmic Hospital, the Benn Ulster Eye, Ear, and Throat Hospital, the Union Infirmary and Fever Hospital, the Fever Hospital, Purdysburn, the District Lunatic Asylum, the Samaritan Hospital, Forster Green Hospital for Diseases of the Chest, and the Belfast Hospital for Skin Diseases.

Scholarships.—(1) 12 are assigned as Entrance Scholarships in the Faculties of Arts, Science, and Medicine, tenable for one year; (2) 16 Professional Scholarships, value from £15 to £40 each; (3) 1 Hutchinson Stewart Scholarship, £12, in mental diseases; (4) 1 Mackay Wilson Travelling Scholarship, £100, awarded triennially; (5) Isabella Tod Memorial Scholarship, tenable for three years, awarded triennially to a woman student; (6) numerous sessional prizes. There is also a post-graduate research fund open to all graduates of not more than three years' standing. Gold medals are awarded at the M.D. examination.

Fees.—The cost of the curriculum intended for students proceeding to the degrees of the Queen's University of Belfast is, approximately, £105. This includes examination fees and a perpetual ticket for attendance at the Royal Victoria Hospital or the Mater Infirmorum Hospital, but not fees for the special hospitals. The course for the Conjoint Board costs about the same amount. A pamphlet containing full information can be obtained on application to the Secretary, Queen's University, Belfast.

UNIVERSITY COLLEGE, CORK.

This institution, formerly known as Queen's College, Cork, is one of the constituent colleges of the new National University. It holds examinations for all the faculties of that university, in addition to continuing the work which it has hitherto performed—namely, that of providing education adapted to the needs of medical students at all stages of their career. Its first aim is to fit students for the degrees of the new university, but students proceeding for the examinations of the Conjoint Boards of England, Scotland, or Ireland, the Society of Apothecaries of London, or the Apothecaries' Hall of Ireland, or London University, can arrange the courses of lectures which they attend, and the order in which they attend them, to meet the requirements of those bodies. Certificates of attendance at the college courses are also accepted by the University of Cambridge. Clinical instruction is given at the North and South Infirmaries (each 100 beds) and at the Cork Union Hospital (1,200 beds). Students can also attend the Mercy Hospital (60 beds), the County and City of Cork Lying-in Hospital, the Maternity, the Hospital for Diseases of Women and Children, the Fever Hospital, the Ophthalmic and Aural Hospital, and the Eglington Lunatic Asylum. The session extends from October to June inclusive. The college contains laboratories in the departments of biology, chemistry, physiology, pathology, and materia medica and pharmacy, and there are a botanic garden and plant-houses in the grounds.

Scholarships.—Over £4,000 is available annually for scholarships in the college. Particulars as to each of them can be obtained on application to the Registrar.

Fees.—The fees for the lectures and hospital attendances required by the National University of Ireland course, including examination fees, come to about £120. Further information can be found in the college regulations, or obtained on application to the Registrar.

UNIVERSITY COLLEGE, GALWAY.

This institution is one of the constituent colleges of the National University of Ireland, and includes Faculties of Arts, Science, Law, Engineering, and Medicine. Candidates for degrees in medicine must reside for three years. For the remaining two years certificates from any recognized medical school are accepted. The college buildings are well lighted and well ventilated, and contain dissecting rooms, an anatomical theatre, and laboratories for the study of physiology, chemistry, physics, and other departments of medical science. For pathology and chemistry new laboratories are in process of construction. It has good grounds surrounding it, and there are many arrangements, such as a library and an athletic union, for the benefit of those belonging to the Medical Faculty, as well as for students in other departments of the college. The clinical teaching, which is recognized as qualifying not only for the degrees of the National University, but for those of London University and the diplomas of the various colleges in the three kingdoms, is carried on at the Galway County Hospital, the Galway Union Hospital, and the Galway Fever Hospital. The former is a general hospital, and at the two latter students have ample opportunities of studying zymotic and chronic diseases. The Union Hospital has a special ward for diseases of children. The college entrance scholarships number thirteen, and range in value from £30 to £25 each. They are open to all students, including those of the Faculty of Medicine. For students in their second, third, and fourth years, two scholarships are in each year reserved for those belonging to the Faculty of Medicine. Further information can be obtained on application to the Registrar.

CLINICAL HOSPITALS IN ENGLAND.

THERE are a great many hospitals in the United Kingdom which, though not connected with any medical school, open their doors either to those who have yet to become qualified, to those who are doing post-graduation work, or to both. The facilities they offer for gaining practical clinical experience are very great, and should not be overlooked. Their honorary staffs commonly make a point of giving what instruction opportunity offers, and at those which are situated in the larger towns there are often appointments as clinical assistants to be obtained. In addition, they all have to offer, at shorter or longer

intervals, appointments in the way of resident medical officerships, house-physicianships, and house-surgeoncies. These are usually paid offices, which may be held for periods varying from six months to a year. Some of those situated in the great medical centres in the provinces, and in Scotland and Ireland, have already been mentioned in speaking of the medical schools in these localities, but it should be added that there are many other provincial hospitals where admirable work is done and at which much valuable experience can be gained both by senior and junior students, and by those already admitted to the *Medical Register*. Cases in point are the Royal Infirmary, Bradford; the Royal Sussex County Hospital, Brighton; the Royal United Hospital, Bath; the Kent and Canterbury Hospital; Derbyshire Royal Infirmary; the Royal Albert Hospital and Eye Infirmary, Devonport; the Royal Devon and Exeter Hospital; the West of England Eye Infirmary, Exeter; the Gloucestershire Royal Infirmary and Eye Institution; the Royal Infirmary, Leicester; the County Hospital, Lincoln; the General Hospital, Northampton; the Norfolk and Norwich Hospital; the General Hospital, Nottingham; the Royal Portsmouth Hospital; the Royal South Hants and Southampton Hospital; the Staffordshire General Infirmary, Stafford; the North Staffordshire Infirmary at Hartshill; the Royal Hants County Hospital, Winchester; the Wolverhampton and Staffordshire General Hospital, and the County Hospital, York. As for hospitals in the metropolis, so many of these play the part of clinical schools that it is worth while to classify them.

General Hospitals.—These include the Dreadnought Hospital at Greenwich, and its annexe at the Albert Dock, which form the head quarters of the London School of Clinical Medicine and the London School of Tropical Medicine; the West London Hospital and the Prince of Wales's General Hospital, Tottenham, both of these being described in the article on post-graduate work; the Great Northern Central Hospital, Holloway Road, an institution containing 185 beds; and the Temperance Hospital in Hampstead Road.

Children's Hospitals.—There are at least five of these, the leader among them being the Hospital for Sick Children, Great Ormond Street, which has 240 beds. There are also the East London Hospital for Children, Shadwell, with 124 cots; the Queen's Hospital for Children, Bethnal Green, with 134; the Belgrave Hospital for Children, which has a considerable out-patient department, but in-patient accommodation for only 40 children; the Paddington Green Children's Hospital, an institution of about the same size; the Evelina Hospital for Sick Children, Southwark Bridge Road, with 76 beds; and the Victoria Hospital for Children, Chelsea, with 104.

Hospitals for Women.—These include Queen Charlotte's, which specializes in the teaching of midwifery; the Samaritan Hospital for Women, Marylebone Road; the Hospital for Women, Soho Square; the Chelsea Hospital for Women, Fulham Road; and the New Hospital for Women in Euston Road, the latter being in the nature of a general hospital so far as concerns the class of case treated.

Eye Hospitals.—The largest of these is the Moorfields Eye Hospital, City Road, with 138 beds and a very large out-patient department; others are the Royal Westminster Ophthalmic Hospital, near Charing Cross, the Royal Eye Hospital, Southwark, each with about 40 beds; and the Central London Ophthalmic Hospital, Judd Street, W.C., with 28.

Fever Hospitals.—The Metropolitan Asylums Board has under its control a good many institutions for the treatment of the more serious zymotic disorders, and makes special arrangements for the instruction of students in this subject, and grants certificates at the end of the courses. Detailed information should be sought from the Clerk to the Board, Victoria Embankment.

Chest Hospitals.—The largest of these is the Brompton Hospital for Consumption, which has 333 beds and a large sanatorium at Frimley. There is also the City of London Hospital for Diseases of the Chest, Victoria Park, with 175 beds, and the Royal Hospital for Diseases of the Chest, City Road, which during the past eighteen months has reorganized its various departments with the object of better fitting itself to act as a tuberculosis school. Further afield is the Mount Vernon Hospital, Northwood, which has an out-patient department in Fitzroy Square, W.

Nose, Throat, and Ear Hospitals.—The institutions which confine their work to disorders of the throat, nose, and ear all make special arrangements for the benefit of senior and post-graduate students. They are the Metropolitan Ear, Nose, and Throat Hospital, Fitzroy Square; the Royal Ear Hospital, Dean Street; the Central London Throat and Ear Hospital, Gray's Inn Road; and the Hospital for Diseases of the Throat, Golden Square—the latter, which possesses 75 beds, being the largest of the four institutions.

Miscellaneous Special Hospitals.—Among these are the Bethlem Royal Hospital, Southwark, which confines its work to the treatment of mental diseases; St. Peter's Hospital for Stone and Urinary Diseases, Henrietta Street, Covent Garden; St. Mark's Hospital, City Road, which devotes itself to the treatment of diseases of the rectum, including cancer and fistula; St. John's Hospital for Diseases of the Skin, in Leicester Square; the Hospital for Diseases of the Skin, Stamford Street, Blackfriars; and the National Hospital for the Paralysed and Epileptic, Queen Square, W.C., an institution possessing 200 beds and a worldwide reputation.

Detailed information as to the teaching arrangements of all these institutions may be obtained on application to their secretaries.

MEDICAL EDUCATION OF WOMEN.

WOMEN are admitted to the medical examinations of the following qualifying bodies: All the universities of Great Britain, with the exception of Oxford and Cambridge; the Royal College of Physicians, London, and the Royal College of Surgeons, England; the Society of Apothecaries of London; the Conjoint Colleges of Scotland and of Ireland.

The regulations of each differ considerably, so that it is necessary for a student to decide, before beginning her course, which degree or diploma she will aim at obtaining. The ordinary regulations of the General Medical Council (see page 422) must be observed, and women can pursue their education either at certain schools only open to women, or at ordinary schools where they do their work more or less in common with men students.

The schools which admit women only are the London (Royal Free Hospital) School of Medicine for Women, which is one of the constituent schools of the Medical Faculty of the University of London; the Edinburgh School of Medicine for Women (see page 445), and Queen Margaret College, Glasgow (see page 445). Women are also admitted to the schools of medicine conducted in connexion with the Universities of Dublin, Dundee, Durham, Liverpool, Manchester, Birmingham, Leeds, Sheffield, Bristol, and Aberdeen; St. Mungo's College, Glasgow, the Schools of Surgery of the Royal College of Surgeons in Ireland and of the National University of Ireland in Dublin, Cork, and Galway. Women can also attend classes for the first three years of the medical curriculum at University College, Cardiff.

Year by year the openings for women who adopt a medical career have increased, and the field open to their energies is now wide. Women hold many appointments as resident medical officers in hospitals for women and children all over the country, and are eligible for appointments in some general hospitals, and in a large number of sanatoriums, infirmaries, fever hospitals, and asylums. Many medical women are also engaged in public health and school inspection work.

As regards the London School of Medicine for Women, particulars will be found at p. 439 in the article on London Medical Schools.

DEGREES FOR PRACTITIONERS.

AT one time it was almost the universal custom for medical students educated in London not to seek a university degree, and as that custom still prevails to a considerable extent, a very large proportion of medical men in actual practice in England possess diplomas to practise but not degrees in medicine. This is a fact which they sometimes find reason to regret, and to such practitioners the following

paragraphs may be of interest. It should be noted that the M.D. degree of the University of Brussels is not registrable when it has been obtained subsequently to June, 1886, but this fact does not lessen its value to those who see any utility in possessing a degree as well as a registrable diploma.

University of London.

Registered medical practitioners who have passed the First Examination for medical degrees and the Second Examination for medical degrees, Part I, may proceed to the Second Examination for medical degrees, Part II, and M.B., B.S. Examinations without observing the intervals prescribed by the regulations on producing certificates that they have gone through the required course of study at a school of the university; subject to the proviso that no degree of the university can in any circumstances be granted by examination to any one in less than three years after passing the Matriculation Examination or after admission by the university of the candidate's right to exemption therefrom.

University of Durham.

The degree of M.D. is granted by the University of Durham to registered practitioners of not less than fifteen years' standing, who have been qualified and in practice for that period, upon the following conditions without residence: The candidate must be 40 years of age, and must produce a certificate of moral character from three registered medical practitioners. Should he not have passed previously to the professional examination in virtue of which his name was placed on the *Register* an examination in arts, he is examined in classics and mathematics; if otherwise, he is required to translate into English passages from any one of the following Latin authors: Caesar. *De Bello Gallico* (first three books), Virgil, *Æuid* (first three books), or Celsus (first three books).

Professional Examination.—The candidate must pass an examination in the following subjects: (i) Principles and practice of medicine, including psychological medicine, hygiene, and therapeutics; (ii) principles and practice of surgery; (iii) midwifery and diseases of women and children; (iv) pathology, medical and surgical; (v) anatomy, medical and surgical; (vi) medical jurisprudence and toxicology. The examination is conducted by means of printed papers, clinically and viva voce, at the College of Medicine, Northumberland Road, Newcastle, and in the Royal Victoria Infirmary, Newcastle. The classical portion of the examination may be taken separately from the professional on payment of a portion (£10 10s.) of the full fee.

Foreign and Colonial Practitioners.—Natives of India or the British Colonies are placed on the same footing as natives of Great Britain. Natives of India must produce evidence from an Indian university that they have passed within one year an examination in Latin.

Fees.—The inclusive fee is 50 guineas; if a candidate fail to pass, 20 guineas are retained, but if he present himself again, 40 guineas only are required.

Dates, etc.—The examinations are held twice a year, towards the end of March and of June. Notice, accompanied by the fee and certificates, must be sent to Professor Howden, Secretary of the University of Durham College of Medicine, Newcastle on-Tyne, at least twenty-eight days before the commencement of the examination.

University of Brussels.

This university grants its M.D. to such foreign candidates as are already duly qualified in medicine and surgery in their own countries, provided they pass the three examinations imposed. These must be passed in due order, but if desired may be passed without any formal interlude, the time covered in the latter case being ten or twelve days. They are viva voce examinations, the language used being French. There is, however, an official interpreter present, whose services are at the disposition of candidates; besides this, the examiners commonly speak the English language. At their desire candidates may also undergo written tests on payment of an extra fee of £1 for each test, but such written examination does not exempt them from the viva voce examination. There are now over six hundred medical men holding this degree in England and the colonies.

Examinations.—Of the three examinations, the first Doctorate covers general medicine, materia medica and pharmacology, general surgery, and the theory of midwifery. The second covers general therapeutics, pathology and morbid anatomy (including microscopy), special and general therapeutics, the special branches of surgery, and mental diseases. The third covers public health, medical jurisprudence, clinical medicine, and surgery, operative surgery (including the performance of some of the commoner operations on the dead subject), ophthalmology, midwifery (including obstetric operations on a model), regional anatomy (with dissection), and bacteriology. The examinations commence on the first Tuesday in November, December, March, and May, and the second Tuesday in June.

Fees.—The fees aggregate to £22; they are paid in advance, but those for any examinations to which a candidate has not been admitted are returned to him. A rejected candidate may be examined three months later on repayment of the examination fee, provided his second appearance takes place in the course of the same academic year; otherwise the matriculation fee (£8 12s.) must be paid again. Any fee paid includes the right to attend any lectures delivered in connexion with the subjects of the examination to which it relates. Other information can be obtained either from the Secretary of the University, 14, Rue des Sols, Brussels, or from Dr. Arthur Haydon, Honorary Secretary of the Brussels Medical Graduates' Association, 11, Welbeck Street, Cavendish Square.

POST-GRADUATION STUDY.

THE value, and in some circumstances even the necessity, of post-graduation study is now so generally recognized that there is no occasion to dilate upon it here. The need for some means of acquiring direct knowledge of the technique of the new branches which are constantly springing up is indeed so generally felt among otherwise experienced practitioners, that several institutions designed solely for their benefit have been at work now for some years. Of these institutions some account follows. Beyond this it need merely be said that in most medical centres it is now exceptional for one or more courses for qualified men not to be held once or more often during the year; that most of the institutions mentioned in the section on Clinical Hospitals make special arrangements for the benefit of qualified men desirous of studying work of the kind undertaken within their wards; and that valuable adjuncts to post-graduation study exist in the shape of the Library of the British Medical Association—one specially rich in recent works—of the libraries of the several universities, and in those of the Royal College of Surgeons of England and of the Royal Colleges of Physicians in London and in Edinburgh.

London Medical Graduates' College and Polyclinic.

This institution, familiarly known as the Polyclinic, opened its doors some fourteen years ago, its work being arranged on quite original lines. The soundness of these became very early apparent, and large numbers of practitioners now attend the classes and avail themselves of the various forms of instruction which the college offers.

The work is carried on in a building in central London which is well arranged and readily accessible from all quarters. It stands at the corner of Chenies and Ridgmount Streets, its postal address being 22, Chenies Street, W.C. This latter street runs at right angles to Tottenham Court Road, crossing Gower Street. The ground floor of the college is given up to the classrooms, which are furnished with various appliances for clinical instruction. When occasion requires, the partitions between adjacent rooms can be removed, and a lecture room of fine proportions thus provided. On the first floor is a library, a reading room, and the consultation theatre, and on the upper floor is found an excellent laboratory for bacteriology and clinical pathology, each table being provided with its own set of reagents and test tubes and its Bunsen burner. Besides these rooms there is in the basement an important annexe in the shape of a dark room, so arranged that twelve patients can be examined simultaneously, but

separately from each other, with the ophthalmoscope, laryngoscope, or other instruments of precision. An adjoining room is fitted with appliances for instruction in ophthalmic cases, such as type tests, working models of eyes, stereoscopes, lenses, etc.

The most characteristic feature of the school is the system of consultations and clinical demonstrations. These take place every afternoon at four o'clock, and patients attend them either at the invitation of the management, or they may be brought by practitioners who are members of the school. Besides the excellent opportunities for teaching which these consultations afford, they provide occasion for discussing difficulties and studying exceptional forms of disease by the most recent methods of diagnosis. Notes are taken of the cases, and are supplemented on occasion by photographs or other portraits of the rarer morbid conditions.

On Mondays, Tuesdays, Wednesdays, and Thursdays of each session, at 5.15 p.m., formal lectures are delivered on medicine, surgery, and their branches, while at the same hour on Fridays the resident pathologist gives an occasional pathological demonstration.

An annual payment of 1 guinea admits to the consultations and lectures, and secures the use of the reading room, museum, and library; subscribers also receive the *Polyclinic Journal*, which is published every month.

Of practical classes there are four sessions in the year, each lasting six weeks, while a vacation course extending over three weeks takes place in August.

These classes include all special subjects, including abdominal surgery, clinical examination of gastric contents, cardiology, cystoscopy, massage, medical hydrology, and sigmoidoscopy.

Provision is also made for those who are reading for the higher qualifications, special tutorial classes being conducted for this purpose. Full particulars of all the work done may be obtained on application to the Medical Superintendent, 22 Chenies Street, W.C.

West London Post-Graduate College.

The work of this institution is carried on at the West London Hospital, the first in London to devote its clinical material solely to the instruction of qualified medical men. The college started in 1895, and the present building was opened in 1901; it is provided with lecture, reading, writing, and class rooms, and accommodation of all sorts for the convenience of post-graduate students. In the last five years the yearly entry has averaged over 220.

As for ward work, the students accompany the senior staff on their visits to the wards at 2.30 p.m. daily, and also go round with the resident medical officers in the morning. Out-patient work begins at 2.15 p.m. This department is large, and affords ample facilities for post-graduates to see and examine patients. There are the usual special departments dealing with diseases of the eye, ear, throat, nose, skin, orthopaedics, *x*-ray work, electro-therapeutics, gynaecology, and mental diseases of children. Post-graduates are appointed to act as clinical assistants for three or six months. There is no charge to members of the college. Practical classes are held in medicine, general practical surgery, gastro-intestinal surgery, surface anatomy, and blood and urine analysis, cystoscopy, venereal disease, tropical diseases, retinoscopy, ophthalmic operative surgery, when material is available, and in operative surgery. The size of the classes is limited so as to ensure that each student shall have full opportunities of gaining experience in methods of examination and treatment.

Operations take place at 2 p.m. daily, the surgeons often availing themselves of the assistance of the post-graduates, and in any case making arrangements so that they can readily see what is going on. The anaesthetists give instruction in the administration of different anaesthetics, including spinal analgesia, on the operating days, students being allowed to administer them under supervision, while special classes are held in each session.

The pathological laboratory is in charge of a pathologist who attends every day. In bacteriology and microscopy special instruction is given on three mornings a week, the students working at other times under the general guidance of the pathologist.

Demonstrations are given every day in the morning by the assistant physicians, assistant surgeons, and by the medical and surgical registrars in practical medicine and surgery. Lectures of a practical kind are given daily (except Saturday and Sunday) at 5 p.m.

The arrangements of the college may be said to be equally suited to those who are preparing themselves for examination for the higher degrees and diplomas, to the needs of officers in the different services on study leave, who attend in large numbers, and to those medical men in ordinary practice who desire to get themselves up to date in general medicine and surgery, or to make a special study of some particular branch of work. The college, it may be noted, is in a residential quarter, and there are plenty of good lodgings in its neighbourhood.

The fees are as follows: Hospital practice, including all ordinary demonstrations and lectures, £1 1s. for one week, £3 3s. for one month, £4 4s. for six weeks, £6 6s. for three months, £10 10s. for six months, £15 15s. for one year, and £30 for a life ticket. Every year in August there is a special vacation class lasting four weeks, for which the fee is £3 3s. Three months' instruction in the administration of anaesthetics costs £3 3s. Subscriptions for any course can be taken out from any date. The certificates of the school are recognized by the Admiralty, the War Office, the Colonial Office, the India Office, and the University of London (for higher degrees).

A prospectus concerning the school can be obtained on application to the Dean.

London School of Clinical Medicine (Post-Graduate) Dreadnought Hospital, Greenwich, S.E.

The school buildings, lecture rooms, operative surgery, classrooms, pathological laboratories, museum, library, etc., are in the Seamen's Hospital at Greenwich. The whole hospital of 250 beds, with its out-patient departments, is open to students from 10 a.m. till 5 p.m.

Medical, surgical, and special department in-patient clinics are held every afternoon except Saturday by the senior members of the staff, whilst out-patients are demonstrated daily in the forenoon in the medical, surgical, and special departments by the assistant physicians and assistant surgeons. Operations are performed daily both in the in-patient and out-patient theatres. A series of lectures are delivered each session in the afternoon by specially invited lecturers. Emeritus lecturers, members of the staff of the Dreadnought Hospital, and by members of the staff of the hospitals affiliated to the school. Practical classes are arranged each session in the following subjects: The practice of medicine, diseases of the nervous system, medical diseases of women, medical diseases of children, diseases of the skin, practice of surgery, operative surgery, diseases of the eye; diseases of throat, nose, and ear; surgical diseases of women, midwifery and gynaecology, surgical diseases of children, pathology, clinical pathology, bacteriology, surgical and medical pathology, hygiene and public health; the administration of anaesthetics, radiography, mental diseases.

Two sessions of five months (October–February) and four months (April–July) are held in each year. The session's work is arranged so as to enable individual students to join the demonstrations, etc., at any time during the session.

Affiliated to the London School of Clinical Medicine for the purposes of extension of the variety of clinical material and teaching are the Royal Waterloo Hospital for Children and Women, the Miller General Hospital, Greenwich, and the Bethlem Royal Hospital for Mental Diseases. These hospitals are directly linked to the Dreadnought both by rail and by tram. The supply of material affords exceptional facilities for practical instruction in operative surgery and in pathology. There is also a wide field for the study of venereal diseases, on which special clinics are given, and there is a department with open-air wards for the treatment of tuberculosis. Every variety of disease may be studied in the wards and out-patient rooms of the Dreadnought Hospital and at the affiliated hospitals. The certificates of the school are recognized by the University of London (for the higher degree), the Admiralty and the War Office, the India Office, and the Colonial Office.

Appointments.—There are a medical superintendent, surgical and medical registrars, two house-physicians, and

two house-surgeons at the Dreadnought Hospital, Greenwich. The pay of these officers varies from £50 to £150.

Prospectuses, lists of special lectures, and other particulars can be obtained on application to the Dean at the School.

North-East London Post-Graduate College.

The head quarters of this post-graduate school are situated at the Prince of Wales's General Hospital, which is in the midst of what is now a densely-populated neighbourhood containing about a quarter of a million inhabitants. It contains 125 beds, and its precise situation is South Tottenham, N., where it is within a few minutes' walk of South Tottenham Station on the Midland Railway, Seven Sisters Station on the Great Eastern Railway, and Tottenham Hale on the Great Eastern main line. It is also readily accessible from Finsbury Park and Hackney by electric tram passing the hospital door, and by corresponding means may be reached easily from Dalston, Edmonton, Hackney, and other parts of North London.

The college is recognized by the Admiralty and the India Office for the purposes of study leave, and by the University of London as a place for advanced study for the M.D. and M.S. degrees; the course of practical teaching of bacteriology is approved by the University of Cambridge for its D.P.H. diploma, and there are ample arrangements for the convenience of men who are thus working, or who are general practitioners desirous of getting themselves into touch with modern methods. There is provided for their use a reading and writing room, and they can obtain afternoon tea and receive telephonic messages; similarly there is a reference and lending library for their benefit, and a museum and pathological laboratory in which they can work. The hospital as a whole certainly affords excellent facilities to qualified medical practitioners who wish to take part for a time in the work of an active general hospital, or to obtain special instruction in the several branches of medicine and surgery, since it is open to them to study diseases of the eye, ear, throat, nose, skin, fevers, children's diseases, psychological medicine, dental surgery, radiography, and the application of electricity in disease, and the administration of anaesthetics. Throughout the sessions into which the year's work is divided, clinics, lectures, and demonstrations are given by members of the teaching staff in the lecture room, in the wards, in the various out-patient departments, and in certain affiliated institutions. Operations are performed every afternoon of the week except Saturday. Special classes are arranged in modern methods of the investigation and treatment of diseases of the lungs and heart, gynaecology, diseases of children; diseases of the throat, nose, and ear; diagnosis of diseases of the nervous system, ophthalmoscopy and refraction, diseases of the skin, abdominal surgery, surgical anatomy, surgery of the urogenital tract, radiography, anaesthetics, bacteriology, clinical pathology, vaccine therapy, pathological chemistry, and medical electricity. In all these classes the numbers are carefully limited, so as to give every member full opportunity for work.

As for fees, these are as follows: One guinea for a three months' course of study in any one department, which may be begun at any time; a fee of 3 guineas admits to the whole practice of the hospital for a similar term (one month, 2 guineas), and a perpetual ticket for the practice of the hospital may be obtained on payment of a fee of 10 guineas. Clinical assistants are appointed in the various departments. A certificate, signed by the staff, may be obtained at the end of three months' hospital attendance.

Additional information about the college and its work can be obtained on application to the Dean of the Post-Graduate College, at the hospital, or at 142, Harley Street, London, W.

TROPICAL MEDICINE.

There are Schools of Tropical Medicine in London and Liverpool, and several examining bodies have instituted diplomas or degrees in the subject. The Colonial Office now expects all nominees for the Colonial Medical Service to pass through one or other of the two schools mentioned before their appointments are confirmed, and commercial firms engaged in tropical enterprise commonly demand from medical applicants for employment corresponding evidence of special knowledge. Information with regard to these schools and diplomas and degrees follows.

Diplomas and Degrees.

London University.—Tropical medicine is one of the six branches in which the M.D. degree may be obtained, the regulations relating to the curriculum and examination corresponding to those applying to the other branches.

London Conjoint Board.—This body grants a diploma in tropical medicine to candidates after an examination usually held in the months of April and July. Ordinary candidates must present evidence of having attended, subsequently to obtaining a registrable qualification in medicine, surgery, and midwifery, (1) practical instruction in bacteriology, parasitology, medical zoology, and haematology, in a laboratory recognized for this purpose during not less than six months; (2) instruction in hygiene applicable to tropical countries; (3) the clinical practice of a hospital recognized for the study of tropical diseases during not less than six months. These conditions may be modified in the case of candidates who have had practical experience in tropical countries deemed likely to have furnished them with the same kind of training. The fee for admission to the examination is £9 9s.

University of Edinburgh.—This university grants a diploma in tropical medicine and hygiene after an examination which is usually held twice a year. It is open to those who are graduates of the university in medicine and surgery, and to registered practitioners who have had experience of tropical diseases in a tropical country, who may be approved by the Senatus on the recommendation of the Faculty of Medicine. In addition to this the candidates must show that they have attended approved courses of instruction in practical bacteriology (including the pathogenic micro-organisms of tropical diseases), in diseases of tropical climates (including the zoological characters and life-history of disease-carrying insects), in tropical hygiene, and in clinical study of tropical diseases. They must possess, too, certificates of efficiency in the conduct of *post-mortem* examinations. The examination is in the four subjects indicated, the fee for each part being £1 1s.

University of Liverpool.—A diploma in tropical medicine is given by this university to students who have been through the courses provided by the Liverpool School of Tropical Medicine, and have passed the examination held twice yearly by the university examiners. The examination lasts three days, and consists (1) of three papers dealing with tropical medicine, tropical pathology, and tropical sanitation and entomology respectively; (2) of a clinical examination; and (3) of an oral examination. The results are declared as soon as possible afterwards. Further information can be obtained from the Dean of the Faculty of Medicine, University of Liverpool.

University of Cambridge.—This university grants a diploma in tropical medicine and hygiene to any person whose name has been on the *Medical Register* for not less than a year, provided that he passes the examination of the university in this subject. Previous to admission to the examination he must produce approved evidence that he has studied pathology (including parasitology and bacteriology in relation to tropical diseases), clinical medicine, and surgery, at a hospital for tropical diseases, and hygiene and methods of sanitation applicable to tropical climates.

The examination deals with the following subjects:

1. The methods of pathological and bacteriological investigation. The examination of the blood. The characters, diagnosis, and life-history of animal and vegetable parasites. The examination, chemical and microscopic, of poisonous or contaminated foods and waters.

2. The origin, pathology, propagation, distribution, prevention, symptoms, diagnosis, and treatment of the epidemic, endemic, and other diseases of tropical climates, including malaria; blackwater fever; trypanosomiasis; relapsing fever; dengue; yellow fever; plague; tetanus; beri-beri; dysentery and hepatic abscess, cholera, enteric fever, Malta fever, and specific diarrhoeal affections of the tropics; diseases due to cestode and other worms; filariasis; bilharzial disease; specific

boils, sores, and other cutaneous affections; mycetoma; ophthalmic affections of the tropics; affections caused by poisonous plants and animals, and by poisoned weapons; sunstroke.

3. The general effects on health in the tropics of seasons and climate, soil, water, and food. Personal hygiene, acclimatization. Principles of general hygiene, with special reference to food supplies and water supplies, sites, dwellings, drainage, and the disposal of refuse. The sanitation of native quarters, camps, plantations, factories, hospitals, asylums, gaols, pilgrim and coolie ships. Principles and methods of disinfection.

Examinations are held in January and August each year, and last four days. The fee for the examination and diploma is 9 guineas on admission or readmission. Application for further information should be made to Dr. G. S. Graham-Smith, Pathological Laboratory, Cambridge.

Schools.

London School of Tropical Medicine.—This school is under the auspices of the Seamen's Hospital Society. Its buildings, laboratories, museum, library, etc., are within the grounds of the Branch Hospital, Royal Victoria and Albert Dock (Station, Connaught Road, Great Eastern Railway), and excellent opportunities are afforded to students and others who may be desirous of studying diseases incidental to tropical climates before entering the services or going abroad. In the hospitals of the society are to be found cases of tropical disease such as may be met with in actual practice in the tropics. There are three courses in the year, each lasting three months, beginning October 1st, January 15th, and May 1st respectively. The course is so arranged as to equip men for the Cambridge and English Conjoint Board diplomas in tropical medicine. Advanced classes in entomology, protozoology, and helminthology are held each term by the respective teachers in those subjects, and for the accommodation of students taking these advanced courses new and commodious laboratories have been provided. The laboratories, museum, and library are open all day, and clinical instruction is given daily in the wards of the hospitals. Certificates are granted after examination to those who complete a full course. Resident chambers are available for students. All qualified medical practitioners and students in the final year of their studies and qualified veterinary surgeons may attend the course. Women graduates are received as students. The Stanley Memorial Grant of about £55, and the Wandsworth Scholarship of about £300, for research work, are awarded annually. A prospectus and other information can be obtained on application to the Secretary, Seamen's Hospital, Greenwich.

Liverpool School of Tropical Medicine.—This school is affiliated with the University of Liverpool and the Royal Southern Hospital of Liverpool. Two full courses of instruction are given every year, commencing on January 6th and September 15th, lasting for the term of about thirteen weeks, and followed by the examination for the diploma of tropical medicine given by the University of Liverpool. Each course consists:

(1) Of a systematic series of lectures on tropical medicine and sanitation delivered by the Professor of Tropical Medicine at the university; (2) of systematic lectures and demonstrations on tropical pathology, parasitology, and bacteriology by the Professor of Parasitology and the Lecturer on Parasitology at the university; (3) of similar instruction on medical entomology by the Professor of Medical Entomology and the Lecturer on Entomology at the university; and (4) of clinical lectures and demonstrations delivered at the Royal Southern Hospital by the physicians in charge of the tropical ward or the professor.

The instruction given occupies six hours a day for five days a week during the term. Teaching under headings (2) and (3) above is delivered in the laboratory of the school at the university, which contains accommodation for thirty students, with all necessary appurtenances, including a well-equipped museum, a class library, and access to the general departmental library. Teaching under heading (4) is given in the tropical ward and the attached clinical laboratories of the Royal Southern Hospital on two or three afternoons a week.

In addition to the full courses, an advanced course of practical instruction in tropical pathology and medical entomology, lasting one month, is given every year in June; it is of such a kind as to be very useful to medical men returning from the tropics on short leave. A special course of instruction in entomology, etc., is also given three times a year to officers of the East and West African Colonial Services.

Students of the school who do not care to undertake the examination held by the university at the end of each term for its diplomas in tropical medicine are given a certificate for attendance if the latter has been satisfactory.

It is proposed to institute at an early date a course of instruction in tropical sanitation. Full particulars will be issued as soon as possible.

For research students there is excellent accommodation at the laboratories of the school in the university, and also in the research laboratories of the school at Runcorn, 16 miles distant from the city.

Since it was instituted the school has dispatched to the tropics thirty scientific expeditions, many of the workers having been taken from among its students. The work done by them has been published in twenty-one special memoirs, with many plates and figures, besides textbooks and numerous articles in the scientific press.

Fees.—The fee for the full course of instruction is £13 13s., with an extra charge of 10s. 6d. for the use of a microscope if required. The fee for the Diploma Examination is £5 5s., and that for the Advanced Course is £4 4s. Further information about the school may be obtained on application to the Secretary, 10B, Exchange Buildings, Liverpool.

PSYCHOLOGICAL MEDICINE.

The study of mental diseases has long been a necessary part of the ordinary medical curriculum, and mental psychology is one of the branches of medicine which candidates for the M.D. degree of the University of London can take up. In addition diplomas in psychiatry can be obtained from the universities of Edinburgh, Leeds, and Cambridge. The Medico-Psychological Association of Great Britain and Ireland also grants certificates of proficiency after examination and encourage study of psychology and connected subjects by the offer of prizes for competition.

Those who take up psychological medicine as a career work as medical officers either of private mental hospitals, or of county or other public institutions of the same order. In all cases they are resident officers, those in the lower ranks always receiving board and lodging in addition to their salary. As a whole they fall into three ranks—junior assistant medical officers, senior assistant medical officers, and medical superintendents. The salaries of those belonging to the junior rank have hitherto been in the neighbourhood of £150 a year, and those of senior assistants about £300 a year, but have recently shown some tendency to rise. Medical superintendents, whose pay commonly ranges between £500 and £1,500 a year, are always provided with a house in the grounds of their asylum, and usually draw allowances in the way of vegetables, coal, and light; at some asylums the same rule applies to senior assistant medical officers.

Many asylums are now provided with pathological departments, and this fact, coupled with increasing knowledge of the physical causes of mental disease, has made asylum work more scientifically interesting than formerly. Nevertheless, asylum work as a career is by no means growing in favour, and is unlikely to do so until all the public asylums throughout the country have been linked up in such fashion that their officers can be regarded as members of one common service. At present it is quite possible for a man who does excellent work to remain in the lower rank all his life, and this fact, coupled with the desirability of minimizing as far as possible other existing drawbacks to asylum life, has recently led to the starting of a movement for reform; and in this the British Medical Association is co-operating.

PUBLIC HEALTH SERVICES.

The Public Health Service, to use the term in a strict sense, consists of medical officers of health appointed by local public health authorities and holding office under varying conditions of tenure. In addition, there are county medical officers appointed by the county councils. The latter are not, strictly speaking, public health authorities; the duties of their medical officers are somewhat similar to those of other medical officers of health, but include

few executive functions. In many of the county boroughs and counties, assistant medical officers of health or assistant county medical officers are appointed, and such appointments may afford stepping stones for promotion to higher offices. The service is, however, not unified throughout the country, and there is no regular system of promotion; appointments are to be obtained only by application to some particular local authority which has advertised a vacancy.

Also ungraded are two other services which have been brought into existence by recent legislation, and whose members are charged with duties which bring them into more or less direct relation with public health authorities or county councils and their officers. The members of the one are called school medical officers, and those of the other tuberculosis officers. Appointments as school medical officer are made by education authorities, while appointments as tuberculosis officer are made in fulfilment of the duties imposed directly on the county councils and the county borough councils, and indirectly on the Insurance Committees by the scheme for the treatment and prevention of tuberculosis which was worked out by the Local Government Board for England in consultation with the Insurance Commissioners.

The Local Government Board for England, it may be noted, employs a staff of medical inspectors in connexion with the performance of its duty as the controlling department of the Government in matters of public health, and the same is true of the corresponding boards in Scotland and Ireland. The medical men forming these staffs are, however, appointed to their position directly by the head of the Local Government Board in each country, and the posts are not open to public competition.

Medical Officers of Health.

The office of medical officer of health in a county borough—a designation which now includes nearly all the larger towns—is in practice a permanent appointment so long as the incumbent desires to retain it, and is the same by law in administrative counties and metropolitan boroughs. The position of a medical officer of health to an urban or a rural district, or to a combination of districts which have joined together to obtain the services of a whole-time medical officer of health, is much less satisfactory, for his appointment is terminable at the will of the public health authority served by him. This fact tends to militate against the efficiency of the service, and consequently the British Medical Association, in co-operation with some other bodies, has long been endeavouring to induce Parliament to establish security of tenure of office and superannuation for medical officers of health. In view of statements recently made by the Government, security of tenure, at any rate, seems likely soon to be granted. A medical officer of health to a district or combination of districts having 50,000 inhabitants must hold a diploma in public health. The first step which must be taken by any medical man who desires to follow the career of medical officer of health must be therefore to obtain such a diploma.

School Medical Officers.

School medical officers are appointed by local education authorities under schemes of medical inspection of school children which must be approved by the Board of Education. Primarily their duty is to detect among the children attending the public elementary schools any physical or mental defect which may retard the education of such children, and to inform their parents of its existence. But practically their duties vary considerably in different areas. This is because most approved schemes of inspection include systems of work which aim at facilitating the task of parents in obtaining for their children the necessary treatment, at checking the results of the latter, and at keeping each defective child under skilled observation both at home and at school until it has passed altogether out of the hands of education authorities. The general object of all schemes alike is to make the inspection imposed by law of benefit not merely to the individual child, but to the community at large, by preventing conditions which lead to the existence of a large proportion of inefficient citizens among the adult population. In short, the work is so far related to that of a medical officer of health that in most areas the senior school medical officer fills both appointments, his work, when necessary, being supplemented by that of whole- or part-time assistants. Whole-time assistants are commonly paid salaries ranging between £250 and £300 a year, the chief attraction of the posts being that they may lead on to appointment as medical officer of health of some large area where the combined salary of medical officer of health and school medical officer will represent a fair income. In view of this consideration, if for no other reason, it is desirable for a prospective whole-time school medical officer to obtain a diploma in public health.

Tuberculosis Officers.

The prescribed duties of tuberculosis officers are to act as advisers to Insurance Committees in connexion with the operation of the sanatorium clauses of the National Insurance Act and to take charge of the work of the tuberculosis dispensary, which is the main unit of the Departmental Committee's scheme. A tuberculosis officer is a whole-time officer; he should have special training in tuberculosis work, and be of suitable age and attainments to command general confidence. At present the number of appointments is small, and the salary generally attached to them is in the neighbourhood of £500 a year.

Diplomas in Public Health.

Most of the universities and licensing corporations now grant diplomas in public health to candidates who pass the examinations imposed by them. Since all such tests must conform to the requirements of the General Medical Council there is considerable similarity in their nature, though they differ not a little in their reputed difficulty. All of them aim at excluding any candidate who does not appear to have a thorough knowledge of his work in theory and in practice, for the regulations of the General Medical Council demand that the granting of a diploma in Sanitary Science, State Medicine, or Public Health shall be proof of the "possession of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health." The tests, in short, are supposed to constitute an honour and not a mere pass examination. As regards the special tuition required, it is now easy to obtain this in practically every centre of medical education, and at almost every medical school of any importance. It is desirable to note in this connexion that the chemical and bacteriological examinations for many of the health diplomas are so practical, and the time allowed so short, that unless a candidate—even though familiar with the duties of M.O.H.—has a considerable amount of the manipulative dexterity only to be acquired by ample work in a laboratory, he would not be likely to satisfy the examiners.

The regulations of the General Medical Council require that every candidate (subsequent to obtaining a registrable qualification in medicine and surgery) shall have passed through a stated curriculum in the subjects of sanitary science. This must last not less than nine calendar months, and include four months' study in a laboratory in which chemistry, bacteriology, and the pathology of diseases of animals transmissible to man are taught, six months' practice study of the duties involved by public health administration, and attendance at least twice weekly for three months on the practice of a hospital for infectious diseases, at which instruction is given in methods of administration. These rules do not apply to practitioners registered or entitled to be registered before January 1st, 1890, while that regarding six months' practical study of public health administration is waived in the case of a candidate who has himself been in charge of a sanitary district with a population of not less than 15,000 for a period of not less than three years. The study in question must be passed under the personal supervision of a medical officer possessing certain definite facilities for affording it, these being carefully described in the regulations. The period may be reduced to three months in the case of a candidate who has undergone a corresponding period of study in the public health department of a recognized medical school, or who has been resident medical officer at a hospital for infectious diseases with accommodation for 100 patients for not less than three months. The laboratory study must include at least 240 hours' work, not more than half being devoted to practical chemistry. The examinations imposed by the diploma-granting bodies

must extend over not less than four days, one at least being devoted to practical work in the laboratory, and one to practical examination in, and reporting on, subjects within the duties of a medical officer of health, including those of a school medical officer.

The steps which examining bodies take to ascertain the candidate's fitness for a diploma are in all cases much the same, though the order in which the subjects are taken is not always identical. Practically all of them divide the examination subjects into two parts, which are usually taken by candidates at more or less widely separate dates. Many of the bodies also have an age clause not allowing the candidate to complete the examinations until he is two or three years older than the average newly-qualified man. The general rule is to place in the First Examination such subjects as chemistry and physics (in relation to the air, water, food), ventilation, the sanitation of houses, principles of architecture, of sanitary engineering, geology in relation to the same, bacteriology in all its relations, and the pathology of human and epizootic diseases. Two or more papers are devoted to such subjects, this being followed by a corresponding number of practical examinations in the laboratory, at one of which the candidates will have to complete an analysis of a specimen of water, discover the impurity in some specimens of air, identify the adulteration in some food specimens, and the like. The other laboratory examination will probably be given up to the preparation of bacteriological specimens, the identification of cultures and parasites, and other tests of practical knowledge of bacteriology; as a rule, a viva voce on the work done follows. In the second part are commonly included two or more papers dealing with sanitary law, epidemiology, vital statistics, the management of hospitals, and all other general questions which affect the public health. The practical examination in this part commonly consists in drawing up a report on the sanitary construction and condition of some actual building or habitation, the whole being followed, perhaps, by a clinical examination in a fever hospital, and nearly always by a viva voce test in which the candidate is called upon to explain the use of apparatus shown him, express an opinion of specimens of food, and answer offhand queries as to the established practice concerning various points of sanitary administration, including school work. As has been stated, however, there are variations among the examining bodies which, though possibly not great in themselves, may be quite enough materially to increase or diminish the difficulty of passing examinations which many Boards seriously endeavour to make a proof of really high proficiency. Every candidate, therefore, should, when he has settled what diploma or degree in State medicine he wishes to obtain, seek the schedule relating to it from the authority concerned. A certain number of the universities grant degrees in the subject as well as diplomas, but only the latter constitute a legal qualification in State medicine.

THE PUBLIC SERVICES.

THE ROYAL NAVY, THE ARMY, AND THE INDIAN MEDICAL SERVICE.

THE medical departments of the Royal Navy, of the Army, and of the Indian Government employ between them some three thousand medical men and fill vacancies in the ranks of the services thus formed by offering commissions for competition once or more often each year. All candidates must be between the ages of 21 and 28 years, and besides possessing registrable qualifications to practise medicine and surgery in Great Britain and Ireland, must be adjudged by the Medical Boards appointed for the purpose to be physically fit for service before permission is accorded them to compete at the entrance examinations. Special attention is given to a candidate's power of vision; a moderate degree of myopia is not considered a disqualification, provided that it can be corrected by glasses so as to secure adequate vision for the performance of operations, and that no organic disease of the eye exists. Testimony has also to be furnished, or is sought by the authority concerned, with regard to the candidate's moral and general character, and the Secretary of State in each service reserves the right to refuse permission to compete to any candidate he pleases.

In the case of a candidate for the Indian Medical Service, the certificates submitted must include one showing that he has studied in an ophthalmic department for not less than three months, the work including refraction, and candidates for the other two services who have qualified in the Officers' Training Corps, or who have been employed in active service, receive an allowance of marks. In all three services the prospect of a medical officer attaining to the highest administrative grades depends to a large extent on the regulations with regard to compulsory retirement at the age of 55 (if below a certain grade at that age), so there is a distinct advantage in entering them at the earliest possible age.

In peace and apart from climatic conditions the lives of officers in these three services are of a less trying nature than those of civilian practitioners, and in the Royal Army Medical Corps, and still more in the Indian Medical Service, the opportunities for professional work of the highest kind are exceptionally great. In regard to emoluments, the pay in no rank is high, but in all it is sufficiently good to make the possession of private means not absolutely necessary. Furthermore, officers in all three services enjoy considerable social advantages, and are relieved to some extent from the ordinary cares of married existence by a system of allowances for widows and orphans. They are also, if they live, able to retire from work at a comparatively early age on pensions representing a larger capital than that which an average general practitioner is able to accumulate as the result of his professional labours. An officer in the Indian Medical Service, for instance, can retire after seventeen years' service on £300 a year, and after thirty on £700 a year with large additions should he have been employed in certain positions. In the other two services twenty years is the lowest pensionable length of service (the minimum is £365 a year, the maximum £1,125); but from either of them an officer whose record is good can retire while still under 30 years of age with a gratuity of £1,000. In the Indian Medical Service, after working for three years in a military capacity officers are allowed as a rule to transfer, if they please, to the civil department. Therein they do work not essentially dissimilar from that performed by civilian practitioners in other warm climates, but retain their military titles and are promoted from one grade to another as their service lengthens. It should be added that during the last few years competition for admission to the Navy has been very slight, while that for admission to the Indian Medical Service has greatly fallen. The reason is that the attractions of both services set forth above are to some extent counterbalanced by removable causes of discontent among their members. The nature of these can be learned from recent issues of the BRITISH MEDICAL JOURNAL.

Candidates for all three services have to fill in printed forms before the question of permitting them to compete is considered, and copies of these, together with detailed information as to what each service has to offer, can be obtained on application to the Director-General of the Royal Navy, the Secretary of the War Office, and the Military Secretary of the India Office, respectively.

PRISON MEDICAL SERVICE.

CANDIDATES for the medical staff are approved by the Secretary of State for the Home Office on the recommendation of the Prison Commissioners. The Chairman of the Board is Sir Evelyn Ruggles-Brise, K.C.B. Application for employment may be made to the Board on a special form, which can be obtained from the Secretary, Prison Commission, Home Office, London, S.W.

In the smaller prisons the medical officer is usually a local practitioner, but in the larger the members of the medical staff are required to give their whole time to the service.

In the case of those required to give their whole time to the service the appointment in the first instance is to the post of deputy medical officer, and from the seniors of this rank the medical officers are selected as vacancies occur. The deputy medical officers are paid £225 yearly, rising to £400, with unfurnished quarters. The whole-time

medical officers are paid £450, rising to £550, with unfurnished quarters. There are twenty deputy medical officers and ten whole-time and forty-six part-time medical officers. The number of vacancies is never large.

APPOINTMENTS UNDER THE COLONIAL OFFICE.

MEDICAL appointments are from time to time filled up by the Colonial Office in various Crown and other Colonies, and vacancies in the West African Medical Staff are of fairly frequent occurrence. As a rule officers are required on appointment to undergo a three months' course of instruction at the London or Liverpool School of Tropical Medicine, and to obtain a certificate of proficiency before taking up their appointment. In addition to the ordinary medical appointments, vacancies also occasionally occur for which specialists are required—for example, to take charge of a lunatic asylum.

The nominal value of the appointments varies very considerably; but, as a general rule, it will be found on close examination that the rates of pay correspond in real value pretty closely when questions of climate, opportunities for private practice, the cost of living, and the actual work demanded are taken into consideration. The posts to which the lower salaries are attached commonly involve work which can be regarded as merely an adjunct to ordinary private practice, while high pay means either few opportunities for practice, an undesirable climate, or work of a special character demanding high administrative ability. Taken as a whole, all these appointments may be put down as offering their occupant the opportunity of gaining his livelihood, and possibly saving a little money, in a fashion which will test his abilities to the full. Pamphlets relating to the various appointments in its gift are published by the Colonial Office, and copies can be obtained on application by letter to the Assistant Private Secretary, the Colonial Office, Downing Street, S.W.

It may be added that, apart from the Government appointments mentioned, a large number of men find employment as medical officers of mining and other companies carrying on their operations in various parts of the tropics. Much caution should be exercised in accepting these appointments, and those to whom they are offered would find it worth while to read what was said on the subject in our issues for May 25th, 1912, and August 24th, 1912.

MEDICAL MISSIONARIES.

To medical men suitably endowed the mission field seems to offer increasing opportunities for interesting work. We find that at the beginning of this year over 450 medical practitioners holding British degrees or diplomas were employed in different parts of the world by missionary societies; and the latter seem to stand in constant need of men and women to fill vacancies as they occur, and also to enable them to take advantage of fresh openings. It is not usually expected, or indeed considered desirable, that a medical missionary should take a position such as would otherwise be occupied by an ordained clergyman or minister, but it is essential that he should be willing to take his share of definite missionary work in any hospital in which he may be placed and that he should be adequately prepared for this purpose. As for scientific and other qualifications for the work, a medical missionary, apart from being physically capable of sustaining what may prove to be a trying life, should be a thoroughly well trained physician and surgeon. It is very desirable that he should have held a residential appointment at a general hospital and have a good knowledge more particularly of practical surgery, tropical medicine, and the treatment of eye diseases. Working as many missionaries do in isolated parts of the world, they have very large professional responsibilities thrown upon them, and should be persons endowed with much natural resource, capable of devising occasionally their own appliances and of being independent of other assistance than that which they themselves can bring into existence. There are, of course, many medical mission hospitals which are excellently equipped, but the workers even in these have to be less dependent on thoroughly trained assistants and on an unfailing supply of instruments all handed to them at precisely the right moment, than need those who do corresponding work in the hospitals of thoroughly civilized countries. It would seem at first sight as if professional work performed in the circumstances indicated must be full of disappointments and entirely unattractive, but this is much less true than might be supposed. For one thing, the natives of most countries in which medical missionaries work are notably satisfactory as surgical patients. It should be added that, apart from ordinary professional work, it is not uncommon nowadays, at all events in China, for medical missionaries to be called upon to take a part in the professional training of native practitioners. It may be noted, in conclusion, that there exist societies whose purpose it is to assist intending medical missionaries in professional preparation, and that a certain number of scholarships have been established for the benefit of the latter. Societies from whom useful information can be obtained are the London Medical Missionary Association, 49, Highbury New Park, N.W.; the Edinburgh Medical Missionary Association, 56, George Square, Edinburgh; and the Society for Promoting Christian Knowledge, Northumberland Avenue, S.W.

MEDICAL PRACTICE IN BRITISH COLONIES AND FOREIGN COUNTRIES.

MEDICAL Acts have now been passed in almost all places forming part of the British Empire beyond the seas, and registers of duly qualified practitioners are consequently maintained. To these registers medical men educated in the United Kingdom are always admissible merely on payment of a fee, provided they produce evidence that they are of good repute and eligible for registration in the United Kingdom. The only exception to this statement that need be made relates to the Dominion of Canada. Until eighteen months ago each of its provinces acted in medical connexions as an independent State, but last year a Medical Act which established a State examination and a common register for the whole country came partly into operation. It could not come into complete operation until each province had amended its existing Medical Act so as to come into line with the new Act. This step is understood to have now been taken by all of them; but it is not clear how far the reciprocity with the United Kingdom previously accorded by all but Ontario and the three Western provinces has been affected. Consequently, any medical man proposing to practise in Canada should first communicate with the Registrar of the Medical Council of Canada, 180, Cooper Street, Ottawa, stating what degrees or diplomas he holds and the length of the curriculum he has undergone, and asking for information as to the precise steps he must take in order to obtain admission to the Dominion Register.

Italy, Egypt, and the Principality of Monaco are the only foreign States which accord a right to practise in virtue of British degrees and diplomas, though the authorities in Spain occasionally issue a temporary permit in favour of British practitioners, and those of Holland and Greece sometimes exempt British practitioners from portions of the examinations imposed on ordinary candidates for registration. In all other Continental countries a British medical man desiring to exercise his profession therein must pass practically the same examinations as those imposed on natives of the country. The same observation applies to all foreign States in the South American continent, while each of the United States of North America has its own laws and regulations; some of them admit any holder of a degree or diploma to their Register, but the majority require a candidate for registration to submit to an examination.

Dental Surgery.

THE profession of dentistry in this country is on the same footing as that of medicine; that is to say, only those who have complied with certain stipulations laid down by the General Medical Council have a legal right to practise dental surgery. This, unfortunately, by no means implies

that the practice of dentistry is confined to legally qualified practitioners, for the Dental Acts offer even less protection to dental surgeons than do the Medical Acts to doctors. An ordinary medical man is within his legal rights if he practises dental surgery, but since owing to his lack of the necessary technical training he could not do so with success, dental surgery is in effect legally practised solely by men of two classes—those who hold a qualification both in dental surgery and in medicine and those who hold a qualification in dental surgery alone or have otherwise obtained admission to the *Dentists Register*. The early stages of the education of dental and medical students cover the same subjects, and it is possible to combine the two educations so as to obtain qualification both in medicine and in dental surgery without any very great extension of the time which would be necessary to become a registered medical man alone.

In any case a prospective dental surgeon must obtain registration as a dental student (see p. 422) and thereafter pursue a curriculum which lasts a minimum of four years. His education does not necessarily become differentiated from that of an ordinary medical student until he has passed an examination in the subjects covered by the First Professional Examination held by the various degree or diploma granting bodies—namely, elementary chemistry, biology, physiology and anatomy. As a rule, however, the student who is seeking the L.D.S. only at once enters upon the two years' course of study of mechanical dentistry,[1] which he can take under a registered dental practitioner, or, better still, at a recognized dental hospital and school. During this period he should also study chemistry and physics, and, if possible, pass the examination in these subjects, so that when he has completed his two years' study of mechanical dentistry he can proceed with the First Professional Examination.

During the last two years, which must be spent at a medical school and hospital, concurrently with attendance at the dental hospital, in addition to studying anatomy and physiology, surgery and pathology, he will include in his work the more specific subjects—namely: Dental anatomy and physiology, dental histology, dental surgery and pathology, and practical dental surgery, for all of which he must be "signed up" by the authorities of the dental and medical schools before entrance to the Final Examination for the Licence.

Recognized dental schools are numerous; in London there are those connected with the Royal Dental Hospital, Leicester Square; the National Dental Hospital, Great Portland Street; Guy's Hospital and the London Hospital. In the provinces and Scotland and Ireland there are those connected with the universities of Sheffield, Manchester, Liverpool, Leeds, Bristol, Durham and Birmingham, and the Devon and Exeter Dental Hospital; the Edinburgh Incorporated Dental Hospital; the Glasgow Incorporated Dental Hospital; the Royal Infirmary, Glasgow; and the Dental Hospital of Ireland, Dublin. As for qualifications in dental surgery, these are almost equally numerous; licences in dental surgery being granted by the Royal Colleges of Surgeons of England, Edinburgh and Ireland; the Royal Faculty of Physicians and Surgeons of Glasgow, and all the universities that have been mentioned. A majority of provincial universities also grant degrees in dental surgery, and this subject is one of the branches of surgery in which a Bachelor of Surgery of the University of London can proceed to the Mastership (see page 425). There are considerable variations in the order in which different licensing bodies require various subjects to be taken up, and every prospective dental student should consequently study not only the regulations of the General Medical Council, but also those of the body whose licence or degree he hopes to obtain.

[1] A student's two years' training in mechanical dentistry may be undergone at any time, but it does not count as part of his four years' curriculum unless he has previously been registered as a dental student. Some examining bodies demand three years' training in mechanical dentistry.

THE WINTER SESSION IN THE MEDICAL SCHOOLS.

INFORMATION received from the deans of the various medical schools shows that by the middle of October the work of the winter session of the medical schools will be in full progress throughout the United Kingdom, despite the difficulties created in some localities by the existence of the war. The London schools as a whole are adhering to their customary date—namely, October 1st—while, as a rule, in the provinces and in Scotland and in Ireland work will begin—likewise in accordance with established precedent—on dates varying between five and fourteen days later.

At St. Bartholomew's Hospital the commencement of term will be marked as usual by a gathering of old students at dinner in the Great Hall on October 1st, Dr. W. S. A. Griffith being in the chair. At St. George's there will be a distribution of prizes on October 1st, followed by an address from Mr. A. E. Shipley, F.R.S., Master of Christ's College, Cambridge, on the subject of zoology and medicine; while on the evening of the same day an old students' dinner will take place at Prince's Restaurant, with the Right Hon. Sir Gerard Lowther, G.C.M.G., C.B., in the chair. There will also be a distribution of prizes at St. Mary's Hospital, an address being delivered by Sir Philip Magnus, M.P. for the University of London; but no dinner will be held this year. At the London School of Medicine for Women an inaugural address will be delivered by Dr. Frances Ivens. At King's College Hospital work will begin on October 1st without ceremony, but on the following day past and present students are to meet at the Waldorf Hotel for dinner, and it is hoped that Sir Arthur Sloggett, Director-General of the Army Medical Department, will find time to take the chair. At the Middlesex Hospital the opening of term will be marked by a distribution of prizes by H.S.H. Prince Alexander of Teck, and an address will be delivered by Dr. C. Hubert Bond, Emeritus Lecturer in Psychiatry. In the evening Sir John Bland-Sutton is to take the chair at a dinner at the Trocadero. At the other metropolitan schools work will likewise begin on October 1st, but without any formal ceremony, though at the London Hospital a dinner has been arranged for October 6th, when Dr. C. A. Mercier will preside over a gathering of past and present students at the Savoy Hotel.

At Aberdeen the commencement of term on October 15th will be marked by the induction of two new professors—Professor Frederick Soddy to the chair of chemistry, and Professor Theodore Shannan to that of pathology. At the medical school of the University of Leeds work will commence on October 1st, an address being delivered by Professor Arthur Keith, F.R.S., and a dinner being held in the evening. The medical school of the University of Durham and the School of Physic of Trinity College, Dublin, are others which this year will follow the metropolitan custom and commence work on October 1st. At Manchester work will be inaugurated on October 8th by an address from Professor E. S. Reynolds, on the industrial diseases of Greater Manchester, and at Liverpool work will begin on October 8th, and on the following day Sir Victor Horsley is to deliver the William Mitchell Banks lecture.

We mentioned last week that the Senate of the University of Leeds had resolved that no member of the university should be placed at a disadvantage in academic studies or status owing to his absence on active service or on other approved duty in connexion with national defence, and may now add that a corresponding resolution is everywhere in view.

EIGHTY-SECOND ANNUAL MEETING
OF THE
British Medical Association.

Held in Aberdeen on July 29th, 30th, and 31st.

PROCEEDINGS OF SECTIONS.

SECTION OF SURGERY.

J. SCOTT RIDDELL, M.V.O., M.B., C.M., President.

DISCUSSION ON THE ETIOLOGY AND TREATMENT OF CARCINOMA OF THE TONGUE.

OPENING PAPER.

By WALTER G. SPENCER, M.S.,
Surgeon to the Westminster Hospital.

(*Synopsis.*)

I SHALL best respond to the honour conferred upon me in the invitation to open this discussion by a brief statement particularly relating to the recognition of cancer of the tongue in its earliest stages by the aid of the microscope.

It has been the hope of those who have paid special attention to cancer, like the late Sir Henry Butlin, that by removing the conditions which were destined to become cancerous, or, what practically comes to the same thing, cancer in its earliest stages, a safe cure without deformity might be ensured. This would offer an escape from the vicious circle of severe and deforming operations, so often followed by recurrence because done too late. Owing, however, to the introduction of fresh methods of treating inflammatory conditions by salvarsan, or exposure to *x* rays or radium, there are now further causes of delay.

It is a fact of first importance that an inflammatory condition exists on the tongue for a time before carcinoma actually commences. Such lesions are well known under the names of chronic superficial glossitis, leucoplakia, papilloma, wart, chronic ulcer, fissure, or irritable scar.

As to the lesions due to syphilis, the Wassermann reaction is an important aid to diagnosis, and the administration of salvarsan aids in clearing off the earlier manifestations, and will prevent many cases from going on to cancer. But salvarsan has no influence on old syphilitic lesions, and certainly none when an epithelial new growth is about to begin. The position remains the same as before the use of salvarsan. Within a fortnight after its administration there should be an absolute improvement leading to the disappearance of the glossitis, or recourse must be had to surgery.

Faced by a smoker's patch which does not disappear with the cessation of smoking, the view must be adopted that such a patch is really a cancerous lesion, however long the development of the epithelioma may be postponed.

A dental ulcer may within a few weeks become the seat of cancer. A section through such an ulcer five weeks after its production showed evidences of the commencement. In two further cases in which the precise time from the production of the ulcer to the date of the operation could be fixed, the duration was ten weeks; in one, after the removal of half the tongue, the floor of the mouth, and the lymphatic glands in the submaxillary region, the disease reappeared in the posterior triangle of the neck of the same side; in the second case, after a similar operation, there occurred a deep infiltration by carcinoma in the region of the hyoid bone on both sides.

The importance of oral sepsis as an aggravation of carcinoma is obvious; the distinct thesis that oral sepsis *per se* is a cause of cancer is another matter. The term "oral sepsis" lacks definition. Patients complain of irritability and pain in the tongue, of a wandering rash, or of swollen and tender papillae, or of recurring attacks of herpes, and excluding cases caused by syphilis, gout, or smoking, the cause may well lie in some pyorrhoea about the lower incisor teeth. But then the noteworthy point is the absence of a definite and persistent lesion such as gives rise to cancer. In the absence of such, fear of the onset of cancer is baseless.

The earlier stages of cancer as seen under the microscope present a proliferation and keratinization of the active cells of the epidermis within the limits of the epithelium, even the formation of cell nests, before there is any extension into the underlying subepithelial connective tissue. At first in this latter tissue there is no change at all; later an infiltration by small round cells takes place.

The specimens exhibited may be distinguished into those—

(1) In which the change is wholly in the epidermis.

(2) With the foregoing there is an infiltration of small round cells in the subepithelial connective tissue.

(3) Further, a commencing downgrowth of the epithelial columns, but not so far as to invade the muscular substance of the tongue.

(4) Simultaneously with the last there is seen in the lymphatic sinuses of the lymph glands which correspond to the particular area affected a collection of small round cells in the lymphatic sinuses of these glands.

Of these small round cells the great majority are of inflammatory origin, but it is necessary to assume that among them are some cells derived from the epithelium, which can develop epithelioma, although at the moment none can be recognized as actually epitheliomatous. This statement applies both to the small round cells in the subepithelial tissue and in the sinuses of the lymphatic glands. The term "precancerous" is too indefinite; it is necessary to include the zone of small cell infiltration as part of the cancer. I am allowed to quote the authority of Dr. E. Bashford and Dr. James A. Murray, from their experiments on the transmission of squamous celled carcinoma in the mouse, that the small cell zone should be included as part of the cancer. By contrast, lesions were exhibited with no tendency to cancer, such as lingua plicata, hypertrophied papillae, and melanoglossia or black tongue. Sections show no subepithelial small cell infiltration.

The author has followed Butlin in removing all persistent lesions, a procedure free from risk; no deformity results if the patch is small and single.

The best way of recognizing that an epithelioma has begun, and its extent, is to have a microscopic section made immediately whilst the surgeon waits. This avoids the very real objection that the patient may refuse to undergo a second operation until too late. Guided by such an immediate section, the surgeon must then remove sufficient to include all the small cell infiltration, and if an epitheliomatous downgrowth into a subepithelial tissue is found, he must then proceed to remove the contents of the corresponding anterior triangle. In doing this, if the mylohyoid muscle and hypoglossal nerve are not injured, the patient will recover good articulation, and, as the wound does not communicate with the mouth, it may be expected to heal by the first intention.

The histories of cases quoted prove that this is a reliable procedure so long as the epithelioma has not extended beyond the subepithelial connective tissue, because the epitheliomatous infection has as yet passed through the lymphatics to the corresponding glands without being arrested in the course of the lymphatics. If it fails, the reason is that there has been such a widespread invasion from the first that even the most extensive operation would be useless, as instanced by cases which were quoted. When epithelioma has invaded the muscular substance of the tongue and also the lymphatic glands, it is then that an excision *en masse* or *en bloc* becomes necessary. There is then a risk of death after the operation, and deformity follows, varying with the extent of the operation. In the less malignant cases there is a prolongation of life, but, the three years' limit passed, there is still no certainty that late recurrence may not supervene. In the more virulent cases life is prolonged for a year or so; the most painful feature in this class of case is the suffering endured after recurrence has set in. A few cases of limited recurrence are benefited by secondary operations, as in the cases quoted.

As for palliative treatment, the greatest amount of relief is obtained by reducing the septic decomposition of the ulcerating surface by painting on several times a day some efficient non-irritating antiseptic, such as mercury bicyanide, 1 in 1,000. Other proposed methods of palliative

treatment seem contraindicated—the division of the lingual nerve, because it is useless; the application of *x* rays, because the glands develop the more rapidly; the insertion of radium, because of the greatly increased pain; diathermy, because, whilst effectually disinfecting the surface for the time, a general anaesthetic is required, and so it can be used only exceptionally as compared with the continuous use of an antiseptic; the injection of adrenalin, because it causes sloughing.

In illustration of this paper the author exhibited a series of microscopic sections and photographs to which were attached histories from some typical cases. After the discussion these were placed on view in the Pathological Museum.]

DISCUSSION.

Before the formal discussion was begun, Professor J. KAY JAMIESON (Leeds) and Mr. J. F. DOBSON (Leeds) gave an elaborate demonstration relating to the distribution of the lymphatic vessels and glands of the tongue, and based thereon certain conclusions. Among these were: that Crile's block dissection was the only adequate operation for removal of glands; that the bilateral gland operation was indicated in growths of the tip and fraenum, of the dorsal surface, of the lateral border, if at all advanced towards the mid-line, and of the back of the tongue; and that unilateral gland operation was permissible only in early growths of the lateral border. The glands were invaded as a result of permeation of the smaller lymphatic vessels in the substance of the tongue followed by passage of emboli along the larger vessels to the glands. The large vessels themselves were not permeated. It was not, therefore, necessary to remove the large lymphatic trunks, and also not practicable, seeing the course that these vessels ran. Lenthal Cheatle's work had shown that a much more radical removal of the primary growth was advisable than had previously been generally believed. It did not prove that the larger trunks were permeated or need be removed. Therefore, though in early cases, particularly of growth in the lateral border, an intrabuccal operation would suffice, if care were taken to cut the tongue off close to the hyoid bone, it was clear that in the later cases only an extrabuccal operation would do. As for dividing the entire procedure into stages, a unilateral Crile and intrabuccal excision of half the tongue might be performed at one sitting in early lateral border growths; but, if the patient were in poor condition, the Crile should be performed ten days after the intrabuccal excision. In more advanced growths and in all growths of tip, fraenum, or back of tongue, a Syme, or modified Syme (for tip), should first be performed, both submaxillary sets of glands and the submental glands being removed at the same time, and a double Crile should be performed ten to sixteen days later, the jugular vein being left on one side. Alternatively the procedure might spread over three sittings, the tongue being first removed by Syme's method, and a Crile operation performed on either side at two subsequent sittings.

Mr. CHARLES P. CHILDE (Portsmouth) pointed out that inasmuch as cancer was frequently grafted on old syphilitic tongues, apparent improvement under iodides was only too likely to occur and to lead to a disastrous waste of time. In a doubtful case the time required to obtain a competent microscopic report was the only legitimate delay. His invariable practice was to ligature the lingual artery previous to excision of the tongue, as this greatly facilitated the intrabuccal procedure, and also, by obviating complication of obstruction of breathing from blood, rendered preliminary laryngotomy or tracheotomy, with all their disadvantages, unnecessary. Before tying the lingual he always performed a Crile gland dissection if the disease were unilateral, and removal of only half the tongue and the glands on one side alone seemed necessary. He tied the facial artery when he had turned the submaxillary gland out of its bed, cut through the hyoglossus close to the hyoid bone, and then, exposing the lingual artery, cut it between two ligatures. Formerly he used to do less than this, and found the disease almost invariably recurred. Consequently, complete dissection should be the rule. It was not difficult, and could usually be completed in three-quarters of an hour. The tongue part of the operation should be done if possible immediately after the gland dissection, because if postponed for a fortnight it was possible that in the interval cancer cells might be carried to the neck and there form the starting-point of a recurrence. If in the first place it was decided—owing to fear that the patient would not stand the whole operation—to divide it into two sittings, there was an additional reason for beginning with the gland dissection; if the tongue were removed first the patient might refuse the subsequent dissection in the neck, not recognizing any inconvenience or danger at that spot, whereas if the gland dissection were completed he would not afterwards refuse removal of the disease in the mouth. This had actually occurred to the speaker some years ago. After removal of the tongue the patient refused the neck dissection and got a recurrence there within a few months. When it was considered necessary to remove the whole tongue and perform a neck dissection on both sides, the operation must be divided into two stages, as it was too severe an operation for one sitting, and the procedure otherwise modified. The speaker never removed both internal jugular veins; he commenced by the usual block dissection on the worse side and ligatured the lingual on that side. He also endeavoured at this sitting to remove the tongue, and if he thought this possible ligatured the lingual on the other side, this occupying about ten minutes. At the end of a fortnight or three weeks he dissected the anterior and submaxillary triangles of the remaining side of the neck, but did not include in it removal of the internal jugular vein. In cases involving the fraenum and the floor of the mouth, necessitating division of the lower jaw to remove the disease effectually, the operation had frequently to be performed in three stages—dissection of the neck on one side with ligature of the lingual, followed a fortnight later by dissection of the other side of the neck, and when this later wound was healed, division of the lower jaw in the mid-line and excision of the primary disease. It was too dangerous to have the mouth communicating with an extensive fresh wound in the neck, such as the gland dissection involved. Men suffering from intraoral carcinoma were generally advanced in years and frequently broken in health, and it was often a nice point to decide how much they would stand. The speaker always went for a very thorough removal, if possible, as it was really better, not for statistics, but for the patient to die after the operation than to have an early recurrence and endure the miseries of his disease all over again within a few months.

Mr. MCADAM ECCLES (London) said that it was an interesting fact that only one patch on a tongue might become carcinomatous, the rest remaining free from malignancy. There were two places widely distant from the tongue where similar conditions seemed to exist—namely, the mucous membrane of the bladder and the skin of the digits in *x*-ray damage. It was not uncommon to find attached to the bladder mucous membrane more than one patch of papilloma. One of these patches might show infiltration of the mucous membrane with epithelial cells, and that it had become malignant. Why of numerous patches did one become malignant? Again, the patches of thickened epithelium—"warty excrescences"—all too frequently seen on the digits of the early workers with *x* rays, might be quite numerous and yet only one patch become epitheliomatous. Until the cause of carcinoma was discovered, operation in early cases offered by far the best prospect of cure. In early cases of carcinoma of the tongue the speaker believed the free removal of glands was perhaps the most important part of the whole operative measures. He was accustomed to deal with the glands first, as in this way the removal of these structures was assured, the patient not objecting to the intrabuccal operation later, usually within a fortnight. In dealing with the tongue itself the extent of the operation must go beyond the small round-celled infiltration upon which Mr. Spencer had laid so much stress.

Mr. HEY GROVES (Bristol) referred to the very great advantages of division of the lower jaw as the preliminary of all extensive operations for the removal of the tongue.

The point which prevented many from doing this was the fact that non-union or necrosis of the jaw often resulted from it when done in the ordinary way by a linear division of the symphysis. If, instead of this, the jaw were divided by a > shaped saw-cut, with the two portions of the > bevelled in opposite directions, then the union of the bone after wire suture invariably took place simply and certainly. After division of the jaw there was a freedom of access to the intrinsic muscles of the tongue right down to the hyoid bone, with complete vascular control, which was attained by no other means. In the matter of anaesthesia, the intratracheal method presented overwhelming advantages. Not only did it prevent blood and septic material from entering the air passages, but it gave a quiet anaesthesia which was almost free from post-operative shock. But in order to introduce an intratracheal catheter in bad cases, where the tongue was much fixed, it was necessary to use indirect laryngoscopy, as the rigidity of the floor of the mouth would often prevent the larynx being pulled forward into line with the mouth in the way demanded by the direct laryngoscopy.

Dr. T. K. DALZIEL (Glasgow) called attention to the presence of a lymphatic gland lying close to the mastoid process often adherent to the base of the skull. He had frequently observed that even after most thorough operations for malignant disease in the mouth and pharynx recurrence took place in that gland, and his practice now was to ensure its removal with the others more obviously involved. He dissented from the view that there was special danger in doing the double-sided operation. He saw no particular benefit in intratracheal anaesthesia; he performed tracheotomy so that he was able to deal with the floor of the mouth thoroughly in the after-treatment by packing the operation area with gauze.

Professor CAIRD (Edinburgh) believed that the diagnosis of lingual carcinoma was easy, and that, moreover, no morbid tissue was more readily recognized under the microscope. All the so-called "precancerous conditions" he had encountered had either already become malignant or remained simple, and yielded to simple treatment under observation. He had not found that syphilis played the rôle so frequently attributed to it as a factor. He now generally employed novocain as a local anaesthetic, and with it it was possible to carry out most complete intra-buccal operations without pain or difficulty. In every case he removed the entire half, or both halves, of the tongue at the first sitting, as by so doing the septic original focus was got rid of, and there could be no further propagation by the lymphatic channels from that source. No gag was required, and Whitehead's or Syme's method was selected according to the requirements of the case. After ten days, under general or with local anaesthesia, all the lymphatic structures, along with the submaxillary and a portion of the parotid glands, and such veins as were in too suspicious proximity, were removed in one sheet from the submaxillary region to the sterno-clavicular articulation. The identification of the lymphatic structures was easier at the second sitting, from the inflammatory reaction which followed on the primary removal of the tongue. At the second sitting it was well to open into the mouth, thus dealing with any remains of the hyoglossus and lymphatic elements about the mylohyoid muscle. The mortality of such operations was remarkably low, but unfortunately the ultimate prognosis was very uncertain, the most promising cases turning out badly, and vice versa. Recurrence was frequent, but rarely took place in the mouth or vicinity of the hyoid bone; it rather favoured the lower post-auricular area. He only removed the lymphatics on both sides of the neck when very definite indications for this course were present.

Mr. LUCAS (Birmingham) found that in about one-half of his cases of tongue cancer syphilis had pre-existed. Most of the patients had been smokers, and nearly all suffered from arterio-sclerosis. In regard to operative technique, he favoured splitting the jaw. He employed Crile's method of anaesthesia by a double nasal tube, and placed a plug of gauze in the back of the mouth.

Mr. SPENCER, in reply, pointed out that Sampson Handley's permeation theory did not hold good in the early stages of cancer of the tongue, but only in the later stages. In his experience, cancer of the tongue did follow syphilis. General statistics were against the operation of dividing the lower jaw, on account of sinus formation and recurrence in the jaw.

A METHOD OF OPENING THE ABDOMEN FOR APPENDICECTOMY.

By GEORGE H. EDINGTON, M.D., D.Sc., F.R.F.P.S.,
Surgeon, Western Infirmary; and Lecturer in Clinical Surgery, University of Glasgow.

IN the performance of laparotomy the surgeon aims at an incision giving good access to the viscus on which he wishes to operate, and leaving a scar so situated and supported as to reduce to a minimum the probability of post-operative hernia. The method which I shall now briefly describe, and which I have employed for appendicectomy many times during the past year, seems to me satisfactorily to realize both these aims.

The principles underlying the method are: (1) Division of the posterior sheath of the rectus transversely, in the direction of the aponeurotic fibres, and (2) preservation of the muscle itself to form a support to the scar. And, while I claim no originality for the principles, the details of the technique which I follow have been elaborated by myself, and I make no apology for communicating them.

It was while perusing Mr. Maylard's interesting work on *Practice and Problem in Abdominal Surgery*[1] that my attention first was directed to the importance of dividing transversely the posterior sheath of the rectus. The idea of preserving the rectus muscle to act subsequently as a support to the scar in the posterior sheath was derived from Messrs. Battle and Corner's description of their operation;[2] and more recently from Dr. Gwilym Davies's paper in the *Annals of Surgery*.[3]

The method of operation consists in exposing the rectus muscle, loosening it in its sheath, retracting towards the middle line, and transverse division of the posterior sheath and peritoneum. After the appendix has been removed, and the posterior sheath and peritoneum sutured, the rectus is allowed to fall back into its normal position, and the anterior sheath and superficial wound closed.

Incision.—An incision through the skin and superficial fascia, and exposing the aponeurosis, is made transversely from the middle line outwards to a fingerbreadth inside the iliac crest, and at the level of one fingerbreadth above the anterior superior spine. This level is chosen because, while it gives good access to the base of the appendix, it avoids in the majority of individuals the subumbilical tendinous intersection in the rectus, and lies below the nerve (eleventh or twelfth dorsal),[4] which pierces the outer edge of the sheath in this neighbourhood to supply the muscle. It is desirable to avoid the intersection because the intimate connexion between that structure and the anterior sheath would require extensive division before the muscle could be mobilized. The desirability of avoiding the nerve is obvious.

Opening the Sheath.—A transverse incision, about half an inch in length, is then made in the aponeurosis over the rectus. This incision is made about one inch outside the linea alba, and is then prolonged by blunt-pointed scissors outwards to the linea semilunaris. Frequently a small arterial twig on the anterior surface of the muscle is divided at the inner end of the incision, and requires ligation.

As the outer half of the rectus is exposed, the aponeurotic sheath is seen to separate into two layers. The superficial layer is the aponeurosis of the external oblique muscle, and as it is divided obliquely to the direction of its fibres it gapes somewhat and usually gives a clear view of the deeper layer.

Separation of the Muscle.—The rectus is separated from the edges of the opening in the anterior sheath and also from the linea semilunaris by the closed scissors; the index finger is introduced under the edge of the muscle and separates it from the posterior sheath until the deep epigastric vessels come into view. The muscle thus loosened is retracted by hooks towards the middle line, the lower lip of the anterior sheath incision is hooked

downwards, and the transversely coursing fibres of the posterior sheath are thus exposed.

Opening the Posterior Sheath.—The posterior sheath and along with it the peritoneum is opened in the direction of the fibres transversely or slightly upwards and inwards. Should, as occasionally happens, an intercostal nerve enter the sheath at the level of the field of operation, it is easily separated from the posterior sheath and held clear while the latter is being incised. The upper and lower lips of the opening are caught in toothed forceps and retracted, and the caecum immediately comes into view, is brought out of the wound, and the appendix removed.

Closure of Wound.—Peritoneum and posterior sheath are closed by a continuous catgut suture, beginning at the inner end of the opening. The muscle is then let go and the anterior sheath similarly closed. To obliterate the subcutaneous space three or four silkworm-gut sutures are passed through skin and subcutaneous tissue and anterior sheath. They are not tied till the skin edges have been approximated by a continuous suture of silkworm-gut. By this means drainage of the subcutaneous space by a drainage tube is rendered unnecessary.

Enlarging Opening (if necessary).—It may be found necessary during the operation to enlarge the opening in the peritoneum—for example, if the appendix be retro-colic, in retro-caecal abscess, etc. If so, the enlargement is made *outwards* into the internal oblique and transversalis muscles and in the direction of their fibres, enlarging at the same time the opening in the external oblique aponeurosis. In such an event, when sewing the wound the suture of the posterior sheath is continued outwards to close the aperture in the muscles.

Drainage.—Should drainage of peritoneum be considered necessary—and I may here say that I am employing drainage less and less—the drainage tube or gauze is brought out through the aperture in the internal oblique and transversalis muscles.

After-treatment.—The patient is kept in bed for a fortnight, sitting up in bed about the eleventh or twelfth day. If drainage has been necessary, he is not allowed up till the drainage track has closed.

Results.—I have employed the method in close on 100 cases, and where there has been primary closure of the incision the results, as regards absence of hernial protrusion, have been absolutely satisfactory.

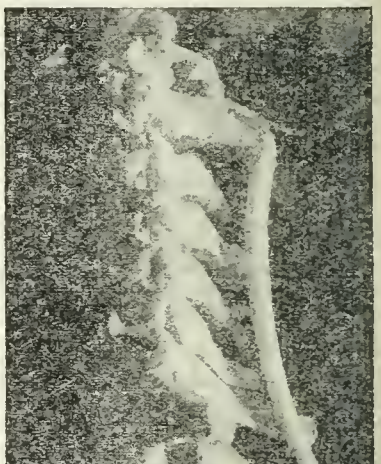
POTT'S DISEASE IN CERVICAL REGION, WITH METHODS OF BONY SPLINTING.

By ALEXANDER DON, M.A., M.B.Aberd., F.R.C.S.Edin.,

Examiner in Surgery, University of Aberdeen.

EXPERIENCE of the older methods of treating caries of the cervical spine by splints, rest in bed, etc., has been so unsatisfactory and so prolonged that one feels justified in bringing forward any method which will help to shorten the period of recovery from such a trying disease. Bony splinting in other regions of the spine is fairly well known. Hibb's method, by fracturing the base of the spine above and turning it down to unite with the body of the vertebra below, is useful and satisfactory mainly in the dorsal region. Albee's method of splitting the spinous processes and grafting a piece of bone from the tibia into the V thus formed is equally satisfactory in both the dorsal and lumbar regions. But if one looks at the spines of the vertebrae in the cervical region it is seen that one is limited to the very stumpy spine of the second, shaped like a house-roof, and to the rather prominent seventh spine. Between these the spines could neither be split nor turned down, and even the second and seventh could with difficulty be made use of for either of the two methods mentioned. The anatomy of the spinal axis requires only passing notice. The muscles and fascia are so interlaced and so firmly fixed between the transverse and the spinous processes that it is impossible for any abscess arising from disease of the bodies to get round into the region of the spines, so that you have a clear area for operative work behind the lateral processes. Of course, these lateral and spinous processes themselves do sometimes get affected by tubercle, as do all joints and cancellous bony tissue, but in the cervical region the disease is nearly always in the bodies of the vertebrae below the second.

The spine is normally fixed at two points—the bodies in front and the articulations laterally, and if either of these becomes diseased, the muscles and ligaments behind and around the spinal axis have to conserve rigidity to prevent pain. But the muscles soon get tired, during rest, get relaxed, and further damage and pain is the result of movement. Another point of fixation must be sought for when either the bodies or joints are affected, and in disease of the bodies below the second, the seventh and second spines are available. The method I employ is to expose the spines from below the seventh to above the second spine by an ordinary central incision, clear well of periosteum the seventh and under-side of second spines, and then to pack the space with gauze to arrest haemorrhage. A piece of rib long enough to stretch from the tip of the seventh spine to well over the second is quickly excised subperiosteally from a most convenient part of the chest wall next the operator. A hole is drilled in the wider (generally anterior) end of this piece, big enough to fit easily over the seventh spine, which has been cleared of periosteum to receive it. When the piece is adjusted over the seventh spine, with the convexity forwards, it is then easy to mark and cut across at the point which will just fit into the groove below the second spine. A small hole for a suture is drilled in the upper end of the piece of rib, and through this a stitch of silver wire or catgut is put and a curved round needle threaded to one end of it. With the needle it is quite easy to get a good grip of the interspinous ligaments and tendons between the second and first vertebrae or base of skull and thus to fix the upper end of the splint. Much does not depend on this suture, for the muscles and fascia when sutured together over the splint in closing the wound are sufficient to hold it in good position till healing takes place. This bony cervical spine (see figure) shows the splint in position better than any explanation that I can give. Should the second spine not be available owing to the disease being in the first or second vertebrae, a length of rib is taken sufficient to be jammed against the base of the skull and fixed there as before.



I shall give brief notes of a case so treated.

The patient, a boy of 14, a mill worker, was under my care in the Royal Infirmary, Dundee, in March, 1912, and at that time had some tuberculous glands removed from his neck. A year later he came under the care of one of my colleagues with a retropharyngeal abscess which was opened through the mouth. The note on admission to my colleague's ward says: "The patient sits up in bed evidently distressed. Salivation profuse. Breathing laboured—a long inspiration and a short expiration. There is no swelling in the neck, but a soft swelling, visible and palpable, projects into the pharynx from the posterior pharyngeal wall."

His condition after the operation was critical for some time, but the abscess cavity soon closed, though he complained of great pain in the neck. Three months later he was transferred to my ward with the following complaint: "Pain in occipital region, increased when head is moved. When asked to sit up in bed, does so very slowly, supporting head at the back with both hands. If asked to turn his head to the side, right or left, he turns his whole body with it. Nothing visible on posterior wall of pharynx."

A radiogram revealed, rather indistinctly, some thinning and erosion by disease of the third and fourth vertebral bodies, and I decided to fix the spine by the method I have described. This was done on May 17th, 1913, and he was put to bed with his head and neck between sandbags. The wound healed

per primam, but later some redness from pressure showed over the seventh spine. A pad of wool soon corrected this. On June 7th, after sitting up for a short time, he complained of a little pain in the neck, and a jurymast splint was adjusted, but he could only wear it for an hour, when it had to be removed, and he was again placed on his back with sandbags. By June 24th he was able to sit up with no complaint of pain, and on July 3rd he was out walking in the hospital grounds. Since then he has kept well, and though I think it would be advantageous to keep a patient after such an operation continually on his back for at least two months, we were forced to allow this boy up or to strap him down in bed, as after he had no pain he would persist in sitting up whenever the nurses' backs were turned.

COMBINED SECTIONS OF MEDICINE, DISEASES OF CHILDREN, AND ELECTRO-THERAPEUTICS AND RADIOLOGY.

DISCUSSION ON THE DIAGNOSIS OF CHRONIC PULMONARY TUBERCULOSIS IN INFANCY AND CHILDHOOD.

OPENING PAPERS.

I.—D. B. LEES, M.D.Cantab., F.R.C.P.Lond.,
Consulting Physician to St. Mary's Hospital and to the Hospital for Sick Children, Great Ormond Street.

AFTER pointing out that children exhibit the same susceptibility towards tuberculosis as they do towards rheumatism and zymotic disorders, and that the clinical picture of pulmonary tuberculosis in children differs from that in adults just as is the case in rheumatism, Dr. Lees indicated that it was his intention to endeavour to show that, quite independently of any assistance from bacteriology or radiology, it was not only possible, but even easy, to establish a diagnosis of chronic pulmonary tuberculosis in children by inspection, palpation, percussion and auscultation, provided these were carefully and methodically used.

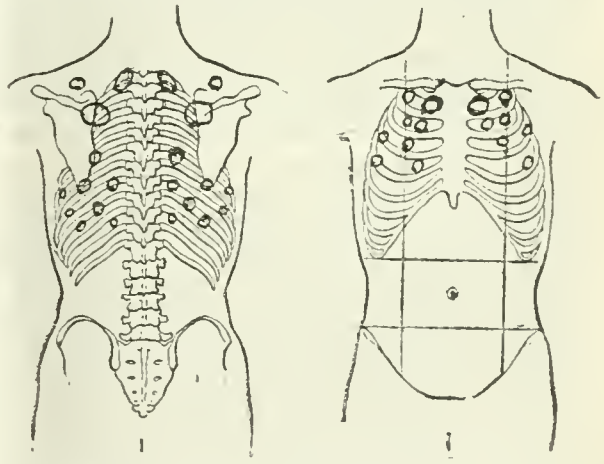
Continuing, he said: I lay stress on the words "carefully and methodically used," because I am convinced that failure in diagnosis by means of percussion and auscultation is due to a defective method and to insufficient care in conducting the examination. It is essential to successful percussion of the chest that all the patient's muscles shall be relaxed, and also that an adequate counter-resistance shall be provided for even the gentlest percussion-stroke. Both are impossible for the front of the chest while the patient is standing or setting erect; it is essential that he shall be lying on a comfortable couch with his muscles relaxed. Little or no progress will be made in this matter until this fact is generally recognized, and the recumbent position adopted for every case. For the examination of the back of the chest, the sitting (slightly stooping) posture, with the hands on the anterior aspect of the opposite shoulders, the elbows near to each other, and the muscles voluntarily relaxed, allows sufficient relaxation of the dorsal muscles and sufficient counter-resistance to the percussion-stroke.

The regular employment of this method will soon convince any physician that very definite dull areas in certain characteristic regions of the chest wall can frequently be detected in cases of suspected tuberculosis in which auscultation reveals hardly any crepitant or catarrhal sounds, any prolongation of expiration, or any wavy inspiration. In fact, there may be an entire absence of morbid sounds, and the only auscultatory evidence may be a defect of air entry over the dull areas, in cases where the percussion evidence is undoubted and even marked. If in such cases there is no cough, no sputum, and no obvious pyrexia, it is no wonder that the physician who relies almost wholly on auscultation reports that he "can detect no evidence of pulmonary tuberculosis." And yet the percussion evidence may be absolutely decisive, and the local defect of air entry quite characteristic.

The annexed diagrams show the distribution of the dull percussion areas in incipient and early pulmonary tuberculosis in adults and adolescents. This distribution is invariable, occurring regularly in case after case, whether bacilli are present in the sputum or absent, and whether or not there is any sputum at all. The distribution is nearly symmetrical in the two lungs, but presents certain invariable differences, evidently due to the fact that the right lung has three lobes, while the left has only two. The largest of these dull areas are always in the upper parts of the lungs, in positions corresponding to those indicated twenty years ago by Sir James Kingston Fowler, from pathological observation, as the earliest sites of origin of pulmonary tuberculosis.

This distribution of dull areas is quite different from the irregularly distributed areas of pulmonary collapse or atelectasis, and also from the usual localization of a pneumococcal or influenzal bronchopneumonia, and also from the usual position of pulmonary infarcts. It has been present in every case of early pulmonary tuberculosis which I have examined during the last few years. Almost invariably the whole series of typical spots can be detected in both lungs, though they are usually larger on one side than on the other. Only very rarely, and in the very earliest stage of an infectious, they may be present in the apex or apices of one lung only.

All the dull areas shown in this diagram are pulmonary areas. Occasionally, even in adults, and especially in those who have suffered from spasmodic dyspnoea described as "asthma," it is possible to detect on the posterior aspect of the chest an area of dullness, which is



caused by enlargement of the bronchial glands, especially of those situated at the root of the right lung. This area is found close to the spine at the third dorsal level—a position which is definitely below the dull areas of the upper apices and internal to the dull areas of the lower apices. If this glandular area is small it may exist on the right side only; if larger, it may usually be detected (but much smaller) on the left side also.

The real existence of these dull pulmonary and glandular areas is readily confirmed by an *x*-ray examination. In every one of six cases of incipient pulmonary tuberculosis in which I had detected their presence, my colleague, Dr. Harrison Orton, without knowing my results beforehand, confirmed them by examination by screen and photograph. The last of the six was specially interesting, because Dr. Orton's verdict, based on the screen examination, appeared to contradict my previous result by percussion, but when he took the photograph he found that it confirmed the facts revealed by percussion.

The precise investigation of these typical dull areas of pulmonary tuberculosis is important for prognosis as well as for diagnosis. The exact size of the six large apical areas—two in the upper part of the upper lobe in each lung and one in the upper part of each lower lobe—ought to be carefully measured and recorded once a month in every case of pulmonary tuberculosis. The measure may easily be made with sufficient clinical accuracy, in finger-breadths and fractions of a fingerbreadth, during the routine examination of the patient and without his knowledge. The fingerbreadth is a standard invariable for the same observer, and it is always available. The comparison of such monthly records, taken in conjunction with a monthly record of gain or loss of weight and a

consideration of the improvement or deterioration of symptoms and of auscultatory evidence, gives unerring information as to the progress of the case, and a decided diminution in the size of the dull areas affords good grounds for a hopeful prognosis, even when the other conditions show little improvement.

The records of size of the dull areas may conveniently be preserved in the form of a simple diagram, in which the upper part shows the front view of the chest and indicates the size of these areas in the inner and outer parts of the first and second intercostal spaces, while the lower part shows the back view of the chest and indicates the size of the areas in the inner and outer parts of the suprascapular fossa on each side, and also that of the lower lobe dull area on each side at the extremity of the scapular spine.

Brief notes of the auscultatory signs should be added on the right of the diagram, and on the left the date of the record and the patient's weight. Examples of the usefulness of these diagrams are given in my published Bradshaw Lecture.

All that I have said thus far about the typical dull areas of pulmonary tuberculosis has related to adults and adolescents. But our debate to-day is concerned only with infancy and childhood. In this early period of life the clinical picture produced by a tuberculous infection has special features which differentiate it from the clinical picture produced by a similar infection in adults. Probably in consequence of the more active lymphatic circulation in young children, it is certainly true that in them a tuberculous infection of the finest bronchial tubes and alveoli is less likely than in adults to develop into a disease limited to these localities, and is much more likely than in adults to spread along the peribronchial lymphatics to the pulmonary, bronchial, and tracheal lymphatic glands. This is much more prone to happen on the right side than on the left.

The reason for this remarkable predominance of the right side is not clear. It is true that a more marked infection of the right lung than of the left by incipient pulmonary tuberculosis is about twice as frequent as a more marked infection of the left lung than of the right. But this does not seem wholly to explain the very special proclivity to implication of the bronchial glands on the right side. Possibly the explanation may be found in the anatomical relations of the pulmonary lymphatics. When the tuberculous infection is specially virulent or the child's power of resistance is unusually feeble, the affected glands become much swollen and press upon the adjoining structures, especially upon the root of the lung and upon the right pneumogastric nerve and posterior pulmonary plexus. The compression and irritation of the vagus may bring about a spasmodic dyspnoea which is fairly described as "asthma," or a spasmodic contraction of the adductors of the vocal cords causing symptoms described as "croup." The effects of pressure on the root of the lung are even more serious, especially when a gland softens and ruptures into a bronchial tube, causing a rapid tuberculization of the middle or lower lobe of the lung with bronchopneumonic consolidation and frequently an outbreak of acute miliary tuberculosis of the lungs. Or a localized empyema may be produced, which may cause the greatest difficulty in diagnosis. In one such case, in a girl of about 11 years old, under my care at the Hospital for Sick Children, my colleague, Mr. Stansfield Collier, succeeded in opening a small empyema situated in the interlobar fissure of the right side, and evacuated a small amount of caseous pus, with the result that the child recovered her health.

The peribronchial tuberculous fibroses and the swollen bronchial glands which are almost invariably present to a greater or less extent in children affected by chronic pulmonary tuberculosis form a very striking picture on *x*-ray examination. But in order to secure a correct interpretation of what is thus revealed to us, it is necessary in the first place to remember that no sound conclusions can be based on a screen examination without the aid of a photograph. I have already mentioned a case in which a screen examination by so highly skilled an expert as Dr. Harrison Orton led to a conclusion which was reversed by a photograph taken on the same day. Even with regard to a photograph the highest technical skill is required if mistaken conclusions are to be avoided. All the apparatus must be of the best, and the exposure must be extremely short, for a longer exposure makes the finest details obscure. And when a first-rate negative has been obtained the greatest care is needed for its correct interpretation. For in such a photograph the effects of morbid changes in different transverse vertical planes are all thrown on one plane and almost inextricably mixed. Not only so, but the mixed result will vary according to the angle which the sensitive plate makes with the chest wall at the time the photograph is taken—an angle which will be different in well developed and in ill developed chests. Thus, the fine "mottling" caused by incipient pulmonary tuberculosis at one of the areas already described may be projected on an entirely different area, and it may require the greatest care to disentangle them. Yet it is the fine "mottling" which should be searched for if we are to draw right conclusions as to the origin and progress of the morbid process. The thickenings around the bronchi which cause radiating lines and the gross changes at the roots of the lungs are far less important for a true understanding of the real course of the morbid process. In a large number of cases in which these root areas and radiating lines are the most prominent objects in a photograph, and the only definite results (except for defective lighting up of the apical regions and lessened movement of the diaphragm) that can be seen by the fluorescent screen, they may be really of very little present importance. We may compare them to the extinct volcanoes which are so conspicuous, and so inactive, on the surface of the moon. For fibroid and calcareous changes may be quite quiescent, as Dr. Jordan has shown by taking *x*-ray photographs of the roots of lungs passed as "healthy" in the *post-mortem* room.

It is the fine "mottling" which is all-important in the diagnosis of early pulmonary tuberculosis, and this is lost on the fluorescent screen and obtained with difficulty in a photograph, and even when obtained liable to be misplaced and therefore misinterpreted.

A careful percussion, however, will detect these small areas of an incipient pulmonary tuberculosis when even the best *x*-ray photograph shows little or nothing definite, and it will give their true localization with complete accuracy. A careful percussion will also easily demonstrate the existence of large (sometimes very large) typical areas in cases where there are few or no morbid sounds audible, and in which the *x*-ray findings are so obvious that the radiologist is led to the belief that the disease is spreading backwards from the glands along the bronchi to the lung tissue. The large typical areas seem to disprove this theory.

A second cause of the distortion of the clinical picture of chronic pulmonary tuberculosis in infants and young children is their special susceptibility to mixed infections. Children are much more liable than adults to bronchopneumonia—pneumococcal, streptococcal, diphtherial, or due to the microbes of measles or of whooping-cough. It is a commonplace of experience that what appeared at first to be a simple bronchitis or bronchopneumonia has often been followed by manifest tuberculosis, and that measles and whooping-cough owe a great part of their fatality to a tuberculous infection which is either introduced along with the microbes of these diseases, or aroused from latency in a child already tuberculous. Fortunately for diagnosis, the dull areas so freely scattered over the lungs in the various infections above mentioned affect chiefly the lower halves of the lungs. A predominant localization at the six typical areas at the four apices is probably proof of the tuberculous nature of a supposed simple bronchopneumonia.

A careful clinical examination of the thorax in children, and even in infants, who are suffering from what is thought to be merely a catarrh or an ordinary bronchitis very frequently reveals the typical distribution of small dull areas at the apices and other parts of the lungs, exactly as found in tuberculous adults and as shown in the diagram. It is a clinical confirmation of the results obtained by the cutaneous reaction to tuberculin, which demonstrates the existence of a tuberculous infection in many cases in which the fact is not obvious without careful percussion. It explains the greater frequency of infection of the thoracic glands as compared with the mesenteric, and confirms the fact, clearly proved by *post-*

mortem examination, that fatal tuberculosis in children originates far more frequently in the lungs than in the intestines.

The existence of mixed infections makes the diagnosis by percussion more difficult, especially as regards the lower half of the lung, but I believe that the discovery of the six typical dull areas at the four apices is sufficient ground for asserting either that the fresh infection by pneumococci, streptococci, or the microbes of diphtheria, of measles, or of whooping-cough, is accompanied by a tuberculous infection, or that the fresh infection has attacked a child who is already tuberculous.

In each of three *x*-ray negatives taken by Dr. Ironside Bruce from children in whom I had detected what appeared to me to be characteristic percussion evidence of past or present pulmonary tuberculosis, additional dull areas close to the spine at the third dorsal level seemed to indicate enlarged bronchial glands. The *x*-ray report in each case stated that there was increased opacity in both lungs, often most marked towards the root, and in each case "small rounded opacities arranged in groups" were present, which are, at all events, very suggestive of tuberculosis. In one of these three cases the cutaneous reaction to tuberculin gave a positive result; the child died in hospital, but no autopsy was obtained. The other two cases recovered sufficiently to leave the hospital; in one of these the cutaneous reaction to tuberculin gave a negative result; in the other it was not tested.

It appears to me, therefore, that careful and accurate percussion is of primary importance in the diagnosis of early pulmonary tuberculosis, both in the child and in the adult, and that it is capable of detecting the disease at a much earlier period than is possible by any other method of investigation. It is a method which does not require any expensive or complicated apparatus, which is independent of the laboratory and its products, and which calls only for care and accuracy on the part of the doctor. When the general practitioner of medicine realizes what is possible for him in diagnosis by careful percussion and auscultation, and determines his treatment in accordance with the knowledge which he may thus easily acquire, the final extinction of the disease known as pulmonary phthisis will have become a possibility.

[Dr. Lees then concluded by relating four recent cases. The first demonstrated the importance of percussion evidence, and of deficient entry of air, in a case in which absolutely no morbid sounds could be heard on auscultation. The second illustrated the production of asthma in a young child by enlarged tuberculous bronchial glands. The third was complicated by spinal caries. The fourth demonstrated the possibility and the importance of detecting the very earliest indications of tuberculosis of lung and bronchial gland, when one lung only might be implicated. All four cases were treated by the method of continuous antiseptic inhalation described by the author in his Bradshaw Lecture, and all had made a good recovery.]

II.—Clive Riviere, M.D.Lond., F.R.C.P.Lond.,
Physician, East London Hospital for Children, Shadwell; Physician for Out-patients, City of London Hospital for Diseases of the Chest.

Chronic pulmonary tuberculosis is nothing more than a "curiosity" in infancy. The susceptibility of the young tubercle-free human is so great that tuberculosis nearly always runs an acute or subacute course during the first three or four years of life. After this period chronic forms of tuberculosis begin to appear, and become more and more frequent as age advances.

It is a peculiarity of "primary" as opposed to "super" infection with the tubercle bacillus that the lymphatic glands draining the point of entry bear the brunt of the first onset. In consequence of this, and partly also on account of the activity of lymphatic structures in early life, tuberculosis in childhood is essentially a tuberculosis of glands in the first instance. The point of entry is little in evidence, or in some cases disappears, and the diseased glands form, from the clinical standpoint, a primary focus from which tuberculosis may spread elsewhere.

Thus in the pulmonary area, in the child, the first stage clinically is disease of the tracheo-bronchial glands, and this is nearly always associated with more or less secondary spread into the lung itself, forming what is termed "hilus tuberculosis." Such secondary lung infiltration is not necessarily accompanied by any symptoms or signs indicative of its presence: it is only when it reaches a notable extent that it claims separate recognition. In most cases the terms "tuberculosis of tracheo-bronchial glands" and "hilus tuberculosis" may be used synonymously.

This tuberculosis of tracheo-bronchial glands, giving rise to symptoms and to characteristic physical signs, is so much commoner in children than is apical phthisis that we cannot afford to omit it from our discussion to-day. It is very apt to be confused with phthisis, but must be clearly separated from it on account of its different course, different prognosis, and the different treatment it requires. It represents, in all probability, the material out of which adult phthisis is manufactured, but it generally runs a very chronic and uneventful course during childhood, often with but little or even no effect on the general health. Indeed, it is in the school rather than in the hospital that these cases are common, and it is, perhaps, for this reason that the earliest signs of thoracic gland disease have been hitherto but little sought for or recognized. Its treatment is that of a localized tuberculosis, and thus differs widely from that required in an autotoxic disease, such as phthisis.

Apical phthisis is but rarely seen below the age of 7 years, and does not become at all common till near the time of puberty. Its course is familiar to all, and I need only here remark that, certain broncho-pneumonic cases apart, phthisis is of far more favourable prognosis in children than in adults.

We have, then, two separate conditions before us for diagnosis, and I hope that subsequent speakers will make it quite clear to which of these conditions their remarks are directed.

Tuberculosis of Tracheo-Bronchial Glands.

I propose to ask members under this heading to tell us those signs they have found most useful in its diagnosis, my own contribution being confined to a certain sign which, I think, merits the attention of this meeting. There is nothing new or startling in the mention of dullness in the interscapular region as a sign of enlarged chest glands. Ever since Leblond described this sign in 1824—that is, two years before the introduction by Piorry of mediate percussion—the textbooks have nearly all mentioned interscapular dullness as a sign of tuberculosis of chest glands. But the earlier observations, including those of Leblond, were made on cases of advanced disease confirmed by *post-mortem* examination, and there is little doubt that the impairment they recorded was generally that of lung infiltration secondary to the glandular disease. Since then interscapular impairment has been accepted without much comment as a sign of enlarged chest-glands, and is invariably described as occurring on either side of the spine, or in some cases on both. Only a few German authorities—Henoch, Biedert and Litting, Heubner, and some others—denied on theoretical grounds that interscapular impairment could arise from enlargement of these gland groups.

So much for the earlier observations, restricted, for the most part, to demonstration of the physical signs of advanced disease. Two notable additions to our clinical armamentarium now enable us to discover disease at a far earlier stage. Of these the first is the widespread recognition of gentle percussion, and the second is the introduction of the Roentgen rays into medicine. For it was not till the final appeal to the skiagram could be made that the significance of the physical signs in really early cases could receive confirmation.

The point I claim to put before you to-day as something new is the fact, hitherto unrecorded, that interscapular impairment as an early sign of tuberculosis of tracheo-bronchial glands occurs on the right side only.

For a long time, though impressed with the fact that I failed to meet with left-sided impairment in these cases, I was content to attribute the fact to the well-recognized tendency of the glands round the right root to suffer earlier and more extensively than those of the left. This, however, soon seemed insufficient explanation of a sign invariably right-sided in the large number of cases I had examined. Moreover, the anomaly arose that with strictly right-sided signs *x* rays usually discovered diseased

glands on both sides of the chest. It seemed clear that some striking anatomical difference between the two sides was involved, and, without going into further detail here, I may say that evidence is collecting to point to pressure on the right pulmonary artery where it passes in front of the bifurcation-glands as the causation of these right-sided signs. The bifurcation-glands are those most commonly tuberculous of all the thoracic group; they show the most extreme changes, and hence are probably the first to suffer. Batten found them affected in 67 of 83 cases, the root glands on the right side coming next in frequency, and being affected among 59 of these cases. Hence a sign which depends on enlargement of the bifurcation-glands, if subsequent research confirms this, must be of considerable value in the diagnosis of tuberculous disease in the chest. As a matter of fact, the sign to be here described is quite commonly elicited, though it is not invariably present, where enlarged glands have been discovered by other methods. Among a batch of seven school children in whom Dr. C. G. L. Reade had found *x*-ray shadows indicative of root disease, four showed this area of right interscapular impairment, and there was present in these no other sign on which a diagnosis of enlarged thoracic glands could have been made. One of the remaining three appeared to be a case of bronchiectasis, so that this sign was present in two-thirds of this small group detected by *x*-ray examination.

I will now proceed to describe this sign so as to elicit the experience of others on this point, and to bring it to the attention of those who have not yet found it.

The Normal.—Normally there exists an area of slight impairment to gentle percussion on each side of the spine between the first and fifth dorsal vertebrae, extending out about one inch from the middle line. This area is not difficult to map out in thin children, but becomes more difficult in adults, especially in those with thick dorsal musculature.

The Right-sided Dullness of Gland Disease.—It is an increase in size and in dullness of this area on the right side which constitutes the sign I desire to bring to your notice. The normal impairment becomes more marked, being often sufficient to be termed "dullness," and extends out two or three inches from the middle line. The area extends downwards to the sixth, seventh, or even the eighth vertebral spine, while its outer limit, mapped by percussion from without inwards, forms a well-defined curved line, though the note outside it is sometimes not so good as that over corresponding parts of the opposite lung. It is interesting and important that this clear outer limit can be shown to undergo a distinct respiratory fluctuation during deep breathing. There is also present in nearly all cases slight impairment at the apex of the lung, both front and back, with some diminution of the area of apical resonance as described by Kroenig. It is

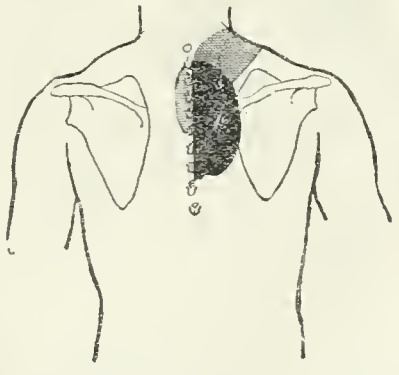


Fig. 1.—Areas of impairment in tuberculosis of tracheo-bronchial glands.

this apical impairment that leads most of these cases, when found, to receive the diagnosis of phthisis in children. I have had many such sent to me at my chest hospital from surrounding schools with this diagnosis, proving that the signs are sufficiently coarse to be discoverable in a noisy school clinic, and that a need has thus arisen for emphasizing their true significance. The distinction is, indeed, of the highest importance; a lung infiltration on the one hand, a condition of serious import; on the other hand, a mere change of air content, in all probability due to interference with certain "lines of communication."

It may, perhaps, be as well at this place to emphasize the points in which the signs differ from those of apical phthisis in children. It seems very natural, at first sight, that the clinician, especially if he places what I should like to call a proper reliance on percussion, should regard

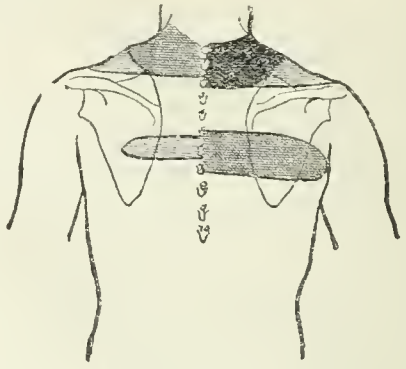

Fig. 2.—Areas of impairment in phthisis.

the apical and interscapular impairment in these cases as evidence of lung involvement at the top of the upper and lower lobes respectively on the right side. There are, however, on further examination, certain well-marked differences between these signs and those of true phthisis.

Tuberculosis of Tracheo-Bronchial Glands.	*Phthisis.*
In gland disease the apical impairment is less marked than that in the interscapular region; it may be appreciable behind only, and tends to vary in its amount at different examinations.	In phthisis, on the other hand, it is the apical impairment which is the most marked and fixed, the lower lobe being secondarily involved, and there may be, as confirmatory evidence, some slight impairment or contraction of Kroenig's area of resonance at the left apex also.
The interscapular dullness in gland disease spreads out from the middle line, and has a well-defined outer border if percussion is made from without inwards.	In cases of phthisis, however, an area of the shape and size referred to is never present apart from glandular disease. Instead there is found an area of impairment no less characteristic in position and outline, but with no resemblance to that produced by glandular enlargement. (See diagram.) On auscultation, moreover, in phthisis sooner or later râles appear at the apex, and at a later stage they may be found also over the apex of the lower lobe.
In glandular enlargement râles practically never appear over the area of apical impairment, and are even uncommon over the interscapular area. It is only where cases progress to considerable lung disease—and this is uncommon—that râles appear over the back at all. More often if râles are heard anywhere in these cases, it is in the region of the nipple and below this in front. Indeed, the striking point about these cases of glandular enlargement is how slight altogether are the auscultatory findings—either no change in the breath sounds, or, not uncommonly, an accentuated conduction from the larger tubes about the apex.	

Phthisis.

The diagnosis of phthisis in children is but little removed from its diagnosis in adults. It is not, in my experience, any more difficult, unless perhaps in the smaller chance of a confirmatory sputum examination. The different physical conditions of the child's chest do, however, make some difference in the reliability to be placed on various signs. Thus, conduction of sounds is more striking, both of tubular breath sounds from the bronchi to the surface, and also of abnormal sounds, such as râles, from one part of the chest to another. For this reason blowing breath sounds, especially on the right side, are to

be interpreted with caution. It is a striking comment that where the diagnosis of phthisis is wrongly made, it is nearly always at the right apex. I would warn, also, against any but the very lightest percussion audible over the lungs of a child; anything more than this will elicit a higher note at the right apex, and if allowance has to be made for this, comparison of the two sides becomes a farce. To really gentle percussion the lung apices are strictly equal, and the slightest shade of difference, if in the same respiratory phase, may be interpreted as an undoubted abnormality.

I have no doubt myself that the most valuable of all the physical signs of phthisis are those obtainable by gentle percussion. They are, particularly in the child, the earliest, and they are the least open to fallacy. Impairment at an apex means, pleurisy apart, nothing more than a diminution in the air content of the lung tissue at this point, and may, consequently, be as likely due to collapse of some causation as to the deposition of tubercle. But the appearance of a second area of impairment of characteristic outline over the lower lobe behind makes tubercle extremely probable, and a third area at the opposite apex is practically pathognomonic. (See diagram.) These confirmatory areas are present at a quite early stage, nearly always by the time suspicious symptoms have brought the patient to the physician. I am far from denying the value of auscultation—all signs should be taken together in the diagnosis of phthisis—but gentle percussion patiently practised will give, in my opinion, an assurance which can be derived from no other source. The man who relies too greatly on auscultation will be repeatedly scored off by the skiagrapher, and, in my opinion, he will deserve it. Cases of phthisis are to be found where considerable areas of impairment correspond with advanced deep-seated disease revealed by *x* rays, but where no râles or other added sounds are present, and where the stethoscope alone could hardly have achieved more than a doubtful diagnosis.

The profession in this country is, in my opinion, greatly indebted to Dr. Lees for his insistence on the value of percussion and of topographical percussion in the diagnosis of phthisis. I have myself become fully convinced of the reality of the areas he has described; he has himself pointed out elsewhere that the mere presence of these areas is no evidence of active disease, and that, once present, they may persist for the remainder of the individual's life. It is, perhaps, only to be expected, therefore, in view of the ubiquity of tubercle infection, that the areas described by Dr. Lees should be discoverable in a very large number of healthy people. In my own experience they have been present in every chest examined with this point in view, and I should not, therefore, myself regard their mere presence as any evidence of clinical disease. Whether they are absent in the strictly tubercle-free is a point of very great interest, but one which I have myself had no opportunity yet of deciding. I think there is no doubt, however, that these areas enlarge in cases of active disease, and it would seem, therefore, possible that a diagnosis of phthisis could be made by their careful measurement, though I should myself consider it a difficult and laborious means of arriving at this result. Practical experience has taught me to place reliance on the larger areas of impairment, two on each side, already brought to your notice in my diagram, and I would recommend these to your consideration as a sheet-anchor in the diagnosis of pulmonary tubercle.

III.—W. IRONSIDE BRUCE, M.D.Aberd.,

Physician, *X*-ray and Electrical Departments, Charing Cross Hospital; Honorary Radiographer, Hospital for Sick Children, Great Ormond Street.

THOSE familiar with *x*-ray examination of the thorax cannot fail to recognize that this method of investigating the lung in pulmonary tuberculosis of childhood is of the utmost value. Fortunately, the lung is very easily penetrated by the radiation from the *x*-ray tube on account of the large amount of air such tissues contain, and in consequence the slightest infiltration of the bronchi or substance of this organ by some opaque material, fluid or fibrotic in nature, produces alterations in the normal appearance of these structures which are easily recognizable. Tuberculous infiltration of the lung is associated with blocking up of the alveoli by catarrhal products and the formation of fibrous tissue, and since fluid and fibrous tissue are much less permeable to the *x*-ray radiation than normal lung, shadows must result when a photographic exposure is made, the distribution and shape of such shadows, as might be expected, being characteristic.

Diversity of opinion as to the exact appearance of tuberculous lung may be explained by variation in the technique employed. The chest may be examined first by the fluorescent screen, and secondly, by using the photographic plate, that is by skiagram. The screen is useful in viewing the movement of the diaphragms and heart, but the amount of detail available is very small.

Fine detail is absolutely necessary for the recognition of tuberculous infiltration of lung, and this can only be obtained by employing the photographic method. In order that efficient skiagrams may be secured, it is essential that the exposure be made without movement of the lung. When dealing with an adult all that is necessary is to instruct the patient to expand the chest fully and hold the breath, but with children it is a difficult matter to ensure the absence of movement of the diaphragm during the exposure, despite the fact that very short exposures are now possible. Improved instrumentation will, no doubt, abolish this difficulty, but in the meantime useful results may be obtained by getting the child to practise holding the breath before the examination. In this connexion it is well to remember that instantaneous exposure, as now made, is only possible with the use of an intensifying screen or screens—a procedure which is followed by considerable graining of the plate and loss of detail sufficient to make such skiagrams of little use for the purpose under consideration.

Should it be found that the diaphragm has moved during the exposure, the result cannot be relied upon, for detail is lost in the most surprising manner, and a well-marked infiltration may be unrecognizable. In very young children occasionally the involvement of one lung results in inhibition of the movements of the diaphragm, and thus good detail is available.

With regard to the appearance of tuberculous lung in *x*-ray examination: The *screen* shows that there is some limitation of the movement of the diaphragm on the affected side; increased opacity, most noticeable on comparing the lungs in this respect on inspiration, and general elongation of the cardiac opacity. The *skiagram* shows increased opacity of the affected lung, which is to some extent striated in arrangement, but is also made up of small rounded opacities arranged in groups.

There appears to be considerable difference of opinion as to the value of these signs individually. Thus, limitation of movement of the diaphragm may result from any inflammatory lesion of the lung or any such condition in the immediate vicinity of the diaphragm, either in the thorax or abdomen. The increased opacity of the lung on inspiration may be caused by the limitation of the movement of the diaphragm alone, or may be due to inflammatory lesions other than tuberculous. The elongation of the cardiac opacity, though indicating a tuberculous type of thorax, does not prove tubercle to be present.

The striated opacity noticeable in skiagrams may result from old inflammatory lesions, and may therefore be seen, and is certainly seen, in healthy subjects. The rounded opacities arranged in groups constitute an appearance which may be relied upon, except that it is difficult to distinguish active from inactive, simple catarrhal from tuberculous infiltration. For the recognition of tuberculosis of the lung all these signs should therefore be employed, and no single one of them be placed in the position of first importance.

In chronic tuberculous diseases of the lungs the typical appearances just described may undergo alterations, for when infiltration is dense the smaller rounded opacities may overlap and larger patches result, or it is possible that an area of the lung affected may become more or less uniformly opaque, though there always remains some degree of irregularity. When lung tissue has been destroyed and cavity formation has occurred, this process produces areas of great translucency, usually rounded in shape, and not unusually surrounded by more densely infiltrated lung tissue, which results in prominence of the translucent areas and sharpness of their margins.

Fibrosis of the lung, when extensive, results in displacement of the viscera towards the affected side, so that the contracted lung becomes uniformly opaque, recognition of

the condition underlying the fibrosis being then dependent on typical appearances observed in part of the affected lung, or on the opposite side.

Pleural effusion, when present in quantity, produces total obliteration of all detail, and obscures the outline of the diaphragm and heart, the opacity thus produced being evenly distributed. The amount of fluid present may be estimated by examination in the erect posture, when its upper limit can be made out, or by noting the amount of displacement of viscera when the cavity is completely filled.

When pneumothorax occurs, the diaphragm on the affected side is immobile, and remains in the position of full inspiration, the collapsed lung being usually visible as a dense mass lying in the region of the root. Should a fluid effusion be associated with air in the pleural cavity, the condition of affairs is most beautifully demonstrated, for in the erect posture the upper limit of the opaque fluid is represented by a sharp horizontal line, the direction of this line being maintained notwithstanding alterations in the position of the subject. On shaking the patient the splashing movements of the fluid can be plainly seen with the screen. From an *x*-ray point of view chronic tuberculous disease may be confused with certain other diseases of the lung. Lobar pneumonia results in increased opacity of the affected lung, but this increase in opacity is uniform, lobar distribution often being indicated. When a small fluid effusion is present, in tuberculous disease of the lung, the evenly distributed opacity caused by the fluid may be confusing, but examination in the erect posture and lying down will demonstrate movements of the fluid, and so serve to indicate the correct diagnosis. Should the fluid be localized, movement will not take place on change of posture, but fortunately under these circumstances the imprisoned fluid presents a sharp outline which is unmistakable.

Catarrhal pneumonia presents an appearance on *x*-ray examination which may be very difficult to distinguish from that of tuberculous disease. Rounded opacities somewhat similar to those of a dense tuberculous infiltration are to be seen, but they are larger and usually more widely distributed. Pleural effusion is usually distinguishable, as already mentioned, by its movement on alteration of the position of the patient, but when occurring in conjunction with tuberculous disease all detail may be obliterated, a diagnosis being impossible unless the fluid is removed, or a typical lesion is present in the opposite lung.

The demonstration of bronchiectasis by *x* rays is most disappointing, for all that may be observed is a small amount of fibrous tissue formation represented by opacity striated in arrangement; should fluid remain in the cavities, large irregularly shaped opaque patches result.

The appearance of an abscess of the lung is quite unlike that of tuberculous disease, for the former presents a localized area of opacity, which is not uniform and is most irregular in outline.

Hydatid cyst occurring in the lung produces a sharply-outlined shadow, roughly spherical in shape and of uniform opacity, its appearance being quite unmistakable.

DISCUSSION.

Dr. FRANK EVE (Hull) thought that the only fruitful way to study pulmonary tuberculosis in children was to begin by separating cases into groups. The cases in one of these, which was very small, closely resembled pulmonary tuberculosis of the adult, the physical signs being easily recognizable by the time the cases came to the hospital. The other, a much larger group, was formed of cases of glandular tuberculosis of the hilus; the cases generally occurred in children who were much less ill, and in whom the physical signs were very variable, transitory, and unconvincing. These children did very well on the hospital balcony, and seldom seemed to die of the disease. When they did so (as in a recent case he had had of suffocation following ulceration into the trachea) the lung might not be obviously tuberculous. Hence in many cases, if not in all, it was bewildering and incorrect to think or speak of these cases as pulmonary tuberculosis at all; they should be considered as tuberculosis of glands which happened to be near the lung. In these glandular cases the prognosis was quite good, and the treatment that of tuberculous glands.

Dr. CHARLES MCNEIL (Edinburgh) suggested that the statement made by Dr. Riviere, to the effect that nearly every child showed on light percussion areas of dullness at one or both apices, and that these areas were significant of apical tuberculosis, active or latent, involved the conclusion that tuberculous infection was practically universal. That might be true in some European localities, but neither from *post-mortem* statistics nor from tuberculin tests was there forthcoming the evidence of such widespread tuberculous infection in Great Britain. The presence of numerous small enlarged glands above both clavicles had been adopted in some places as a clinical stigma of apical tuberculosis in children. But an investigation for the presence of these glands in some 300 children showed them to be present in over 90 per cent.

Dr. D. LAWSON (Banchory, N.B.) welcomed the statement that *x* rays in themselves should not be relied upon for diagnosis, for he had long held the view that *x* rays and physical diagnosis were not competitive, but that the one method was the complement of the other. Evidence of the presence of enlarged hilus glands did not necessarily indicate tuberculosis. He recalled one case which he followed to the *post-mortem* room, and which turned out to be one of endothelioma starting in the pleura.

Dr. FREDERICK LANGMEAD (London) confessed to being much impressed by the difficulty of diagnosing tuberculosis in small children, and thought that others experienced it likewise, for there was great discrepancy between the results of the bacteriological tests and the findings by the ordinary methods of physical examination. Positive tuberculin tests had been obtained in a very large proportion of school children of all ages, and even as great a percentage as 80 or more of children over 10 years of age had reacted positively in Vienna and other Continental centres. Now, if one accepted a positive reaction as evidence of past or present tuberculosis, it was clear that the great majority of cases were undiagnosable by ordinary physical methods, for in the routine examination of school children only a few per thousand were detected. With a few exceptions, all medical inspectors of school children were agreed as to the small percentage of clinically diagnosable cases. If the tuberculin tests were considered fallacious this argument fell to the ground, but *post-mortem* evidence was in their favour, and bore out the contention that a very large proportion of children either had or had had tuberculosis. In many of these cases the thoracic glands and roots of the lung were the parts affected, and presumably areas of dullness and opacity to *x* rays would be present, according to the views of the openers of the discussion, but it was scarcely possible to treat the majority of school children as though active tuberculosis were present until it had been proved to be latent. He did not wish to minimize the value of *x* rays as a means of diagnosis, for he had often obtained great help from their use. In certain cases in which his colleagues and himself had been unable to come to a definite conclusion, a skiagram had proved that tuberculosis was present without a shadow of doubt. The most serious limitation to the value of percussion, and in most instances to skiagraphy also, was the impossibility of deciding by such means whether the tuberculous focus was active or not. That was the all-important question, on the answer to which hung the need for treatment or notification. It was the practical problem which had to be faced more often than any other in connexion with this disease in children. To come to a decision, repeated examination was necessary in the earliest cases, and observation of the patient's symptoms, such as weight, temperature, cough, etc., was essential. By percussion or by skiagraphy, alone or combined, no decision could be reached as to whether a child needed treatment.

Dr. E. E. PREST (New Cumnock) agreed with Dr. Langmead that the point of importance was the activity or otherwise of the disease. They had heard from Dr. Eve that the proportion of children suffering from pulmonary tuberculosis was not large, but that such cases, in distinction from those of glandular tuberculosis of the hilus, were immediately recognizable. There must, however, be certain intermediate stages between a case which was at once recognizable and a case which was doubtful. In Ayrshire

he got a considerable number of children with definite physical signs in the lungs, and was accustomed to inquire very carefully into their history in order to discover whether there were night sweating, inability to eat food, constant tiredness, and lessened weight, because, if these existed, the case must be treated. It was safer, for some of them at least, to rely far more on symptoms—although this might be heterodox—than on physical signs, the full meaning of which many of them were unable to appreciate.

Dr. D. BARTY KING (London) said that some years ago, while examining a number of London school children, he thoroughly tested for true phthisis, with the result that out of 1,500 examinations only about 4 per 1,000 children revealed this condition on ordinary clinical examination. The presence of glands in the neck was sometimes put down as a sign of pulmonary tuberculosis, but was quite fallacious. It was quite a frequent occurrence to have, as he had had the previous week, a case which had been treated for six months as one of pulmonary tuberculosis, with marked dullness at both apices, and to find, on taking the case into the observation wards, that nothing of this nature was discoverable in the lung at all, and that the *x*-ray report and the cutaneous tuberculin test were negative. In one case recently brought to his notice the *x*-ray report stated that there was peribronchial mottling, and inferred definite pulmonary tuberculosis of the left lower lobe of the lung. Clinically, from the posterior aspect, there were a few crepitations. The patient died of another affection, and at the necropsy he took care to section the lung from the roots towards the periphery, finding thickened bronchi, but no trace whatever of tuberculosis. On staining for tubercle there was no trace. He would suggest that skiagraphers should report, in the first place, exactly what they saw, and on the other side, quite separately, what interpretation they placed on it.

Dr. F. J. SMITH (President of the Section of Medicine), after summing up the discussion, said he preferred to trust more to a patient's feelings than to any physical signs for his view as to taking therapeutic measures. Bronchopneumonia slew as many children as tubercle, though in a different manner.

Dr. D. B. LEES, in reply, desired to say (1) that the dull areas, though found very frequently, were not universal, even in children. In many cases, both in adults and in children, none of the dull areas characteristic of pulmonary tuberculosis could be detected; (2) the frequency with which these dull areas were found in children was roughly approximate to the results obtained by the tuberculin test. If percussion were perfectly carried out, the parallelism between clinical, experimental, and pathological results would become very much closer than it had been in the past; (3) as had been brought to their notice already, and as he himself had emphasized elsewhere, the discovery of these dull areas did not prove an active condition. One judged partly by auscultatory signs and partly by symptoms, but in all doubtful cases it was best to advise a short course of treatment by rest and antiseptic inhalation for two or three weeks. If at the end of that course the dull areas had distinctly diminished in size, there was good reason for believing that there was a certain amount of activity about them. The younger the patient in whom such dull areas were detected, the greater was the probability that they indicated active disease. An incipient pulmonary tuberculosis was often insidious in onset, and might slowly extend, with very little auscultatory evidence, and with few or no general symptoms. (4) Several speakers had expressed very definitely a belief that the two conditions of "apical phthisis" and what had been called "hilus tuberculosis" were different in nature. One saw a similar difference in cases of tuberculosis in adults. In children the difference was more marked; there was greater tendency to spread, and less tendency to break down. They were different types of the same disease, pulmonary tuberculosis. (5) Until physicians would undertake to improve their percussion they would not make progress in this matter, and this failure in accurate diagnosis might easily cause disaster in the practice of those who were treating cases by means of tuberculin.

Dr. CLIVE RIVIERE, in his reply, pointed out that what he and his colleagues in opening the discussion had endeavoured to do was to draw attention to points in diagnosis which they considered the most helpful; they were quite alive to other points. The speaker, for instance, fully recognized the distinction between tuberculous infection and tuberculous disease, and they agreed with Dr. F. J. Smith and Dr. Prest on the importance of considering symptoms, and disagreed with Dr. McNeil as to the value of cutaneous tuberculin tests, since these could only discover tuberculous infection. The fact that they were discussing chronic disease practically excluded infants, and the cutaneous tuberculin tests were not of much value after infancy was past. He agreed with Dr. Eve that cases of tuberculous chest glands hardly merited the title of "pulmonary tuberculosis," although the lung was often slightly involved. The speaker had introduced them into the discussion because they gave definite lung signs, and because these signs were commonly mistaken for those of true lung infiltration. Both *post-mortem* experience and skiagrams upheld the view of a spread of tuberculosis outwards from the glands against the lymph stream; the work of Ghon, quoted by Dr. Barty King, dealt only with primary lung infection in infants, and not with the later stage in older children.

Dr. IRONSIDE BRUCE, in reply to a question, said that as to the diaphragmatic excursion in children, the distinction between the right and left diaphragm was less considerable than in adults. The right was a little higher in children, but not in such a marked degree as in cases occurring later in life. In children it was not possible to distinguish between a serous and a purulent fluid. Dr. Langmead had stated that by *x*-ray examinations active and inactive conditions could not be distinguished, but this was not invariably true. Of some cases it was possible to say that they were active, and of others that they were inactive, although, of course, many cases were indistinguishable. He had purposely omitted any mention of striations extending from the root, as they were seen in perfectly healthy children, so he did not rely upon them; but he did rely upon opacities which were arranged in groups, for they seemed to represent catarrhal infiltration of the lung.

ON SOME CONDITIONS SIMULATING CHRONIC APPENDICITIS.*

BY JOHN MORLEY, M.B., CH.M., F.R.C.S.,
SURGEON TO ANCOATS HOSPITAL, MANCHESTER; LECTURER IN CLINICAL ANATOMY, UNIVERSITY OF MANCHESTER, ETC.

THE undoubted fact that in past years many unnecessary operations for appendicitis have been performed where the appendix was not the cause of the symptoms should challenge us to a far more critical attitude of mind. It is particularly in that variety of chronic appendicitis characterized by chronic pain and tenderness in the right iliac fossa, without any history of acute attacks, that mistakes occur, and only those other causes of similar symptoms that lie in the immediate neighbourhood of the appendix are here considered. Lane and his followers hold that symptoms simulating chronic appendicitis may be caused by a kink of the lower ileum produced by a peritoneal band occasionally present on the left or inferior aspect of the ileum some three inches from the caecum, which tethers down the gut near the pelvic brim. Lane's view of the origin of this band—that it was acquired as the result of a tendency to enteroptosis—has been quite disproved, as has the peritonitic theory, though inflammatory bands may occur in the same situation. The band is congenital in origin and a relic of the descent of the testis or ovary. There is no evidence that the band had caused any intestinal stasis in my own cases, either from radiographic findings, clinical histories, or appearances at operation, and it is argued that, apart from the very rare accident of inflammatory contraction of the band, it probably never gives rise to trouble, so that the many ingenious operations devised for dealing with it are the outcome of misdirected enthusiasm.

*Abstract of a paper read before the annual meeting of the Lancashire and Cheshire Branch of the British Medical Association.

Jackson's pericolic membrane, on the other hand, may give rise to symptoms simulating chronic appendicitis. This occasional membrane is a congenital abnormality, and takes origin from the primitive right lateral process of the great omentum. When only a limited band persists as a relic of the membrane, constriction of the ascending colon may result, though often the symptoms resembling chronic appendicitis are due to an associated abnormal mobility of the proximal colon.

In the condition of mobile proximal colon, which is a reversion to the primitive pronograde arrangement, the patient is predisposed from birth to constipation and the various ills resulting from it. Symptoms resembling chronic appendicitis may result, or actual inflammation of the appendix, but in either case the right surgical procedure is not a simple appendicectomy, but fixation of the colon back into the right loin.

The commonest cause of an erroneous diagnosis of chronic appendicitis is right tubo-ovarian disease, often of gonorrhoeal or septic origin. In such cases a spasmodic contraction of the right psoas muscle sometimes occurs on palpation, which may be mistaken for an abscess or a neoplasm.

Many cases of chronic pain in the right iliac fossa cannot, with our present knowledge, be diagnosed with precision before operation. All that can be said is that they need exploration. In exploring, the incision should be adequate for an inspection of all the possible sources of the mischief, and such source when found should be dealt with by appropriate measures. The practice of a blind appendicectomy in such cases through a 2 in. gridiron incision is unscientific, and often disastrous to the patient's prospects of a cure.

AN UNUSUAL CASE OF APPENDICITIS.

BY

E. W. M. HUBERT PHILLIPS, M.A., M.B., B.S.Oxon.,

SURGEON TO MISS TALBOT'S HOSPITAL, MARGAM, GLAMORGANSHIRE.

A COLLIER was suddenly seized with abdominal pain of such severity as to necessitate the administration of chloroform by his medical attendant, Dr. Cooper of Kenfig Hill, Glamorgan. On the following day I was sent for in consultation and advised removal to Miss Talbot's Hospital at Port Talbot. The patient complained of sharp continuous pain situated under the heart and in the upper part of the abdomen, of obstinate constipation, and of vomiting of clear green fluid. In 1887 he had a similar pain which lasted five days; it came on after a fall from a tree. On five occasions since then he had suffered from the same pain, of greater or less severity, the attacks lasting five or six days.

His face was pale and typically Hippocratic and covered with beads of perspiration. The tongue was clean, the pulse was 78, and the temperature 96.8° F. The abdomen was not distended. The respiratory movements were good, but better on the right side than on the left. Superficial and deep epigastric tenderness were present, and there was a zone of hyperaesthesia in the left hypochondrium. There was deep tenderness on pressure over the left kidney region posteriorly. The whole of the left side was tympanitic. The liver dullness was normal. The apex of the left lung showed some apical retraction, Krönig's sign being present, and there was some impairment of breath sounds. There was a slight systolic murmur at the apex of the heart, conducted out to the axilla. The urine was normal. There was slight leucocytosis. Loewi's adrenalin mydriasis test was applied with a view to determine the possible presence of pancreatitis. The result was negative. There was nothing definitely indicative of perforation of a peptic ulcer. Repeated enemas were unavailing.

The patient was seen by my partner, Dr. J. H. Davies, and it was decided to wait twelve hours before proceeding to laparotomy in view of the patient's history. The patient appeared to improve slightly, but in about eight hours he suddenly became much worse; the temperature fell to 96°; the pulse went up to 102, and became very thin. He was now evidently moribund. Operation was out of the question, and in a few hours the patient died, evidently of shock.

Post-mortem Examination.

The caecum and ascending colon were enormously distended and hyperaemic. This part of the gut was freely movable, and had a large mesentery. It lay looped between the hepatic and splenic flexures, below the transverse colon and great omentum, and suspended on the left to the cardiac end of a dilated stomach, by the tip, middle, and mesentery of a long recurved appendix.

The appendix, when unravelled, was 9½ in. long, was full of hard concretions, and was gangrenous at its tip. The tip was densely adherent to the greater curvature of the stomach on the left side, and by fine adhesions to the spleen. The right iliac fossa was occupied by coils of small intestine.

There was a small calcareous old focus of phthisis at the apex of the left lung. There was some thickening of the mitral valve.

A CASE OF RUPTURE OF THE KIDNEY FROM SLIGHT TRAUMA.

BY J. LEE ATKINSON, M.R.C.S., L.R.C.P.,

VICTORIA, AUSTRALIA.

RUPTURE of the kidney is a comparatively rare result of trauma, and more particularly so when the actual kidney tissue itself is lacerated. Keen quotes Küster's statistics of injuries under his observation in the clinics of Berlin and Basle, and these show only 10 cases in 7,741 injuries, or a little over 1 in 1,000.[1] Israels, with a large experience of renal surgery, had only 1 operative case.[2]

But in practically all cases met with either in actual practice or in the records, the condition has always been caused by a severe accident, such as falling from a height, crushing between buffers of a train, or by the wheel of a heavy cart passing over the abdomen. In view of these facts the following case is of interest, as the injury was caused by an accident of the most trivial nature, and the subsequent history also contains points of interest.

R. A., a girl of 14, above the average height and well made in proportion, had never had a previous illness of any consequence. At 9 p.m. on August 28th, 1913, she ran along the verandah of the house after a dog. Between the two corner posts of the verandah some light wire netting had been fixed to a height of 2 ft. and fastened on each side to the post by a light staple. The floor of the verandah was 11 in. from the ground, and immediately beneath it at that point was a large flower bed which the day previously had been dug over, and in consequence was in a soft condition. The end of the verandah was only 15 ft. from the door, and so she could not have gained much momentum in the short distance. She ran into the netting, having forgotten it was there, and it caught her in the middle, gave way, and she fell on to the flower bed. She immediately complained of intense abdominal pain with nausea, and was carried into the house. A quarter of an hour later she wanted to micturate, and passed a quantity of bright arterial blood. Dr. Parker of Kingston was sent for and he telephoned for me.

I saw the girl at 1 a.m., and she was lying in bed in a condition of profound shock. The abdomen was rigid, and she complained of great pain, not confined to any particular region. Another marked feature was thirst. The temperature was 97° F.; the pulse 124, thin and thready. The face was pallid and the facies Hippocratica well marked. The right flank was dull on percussion, but the liver dullness was hard to make out; it was diminished in area. She had passed blood by the urethra three times since the accident—about a pint in all. Owing to the fact that the parents were away from home, operation was delayed until their return at 10 a.m. on the following day.

Operation.

A median subumbilical exploratory incision was first made, and immediately the peritoneum was opened about a pint of blood-stained serum gushed out, together with a large quantity of faecal-smelling gas. With sponges the abdominal cavity was dried as far as possible and the bladder examined. There was no sign of any injury to that organ, but it was of bluish colour, due to the blood it contained.

The ascending colon was pushed towards the middle line and was congested and dilated at the caecal end. About midway between the caecum and the splenic flexure there was a kink, formed by the lower end having a long mesocolon allowing a partial volvulus. Just above this kink, and about on the level of the junction of the lower and middle third of the kidney, was a transverse tear, about an inch long, into the lumen of the gut. On replacing the lower end of the colon in its normal position and fixing it there by shortening stitches in the mesentery, a quantity of flatus escaped from the rent in the bowel wall and the whole of the ascending colon collapsed.

The tear in the wall was repaired with Lembert sutures, which were themselves oversewn again. There was no trace of faeces on the peritoneum or of any material whatever from the colon.

The left kidney was normal, but the whole of the right kidney pouch was occupied by a large fluctuating tumour.

Then the abdominal incision was closed, and in view of an after-event it is worth while noting that the layers were all sewn up separately, the inner ones with Van Horn's gut No. 1, and the skin with medium silkworm gut.

The patient was turned on to her left side and a pillow placed under her side. After a hurried cleansing of the skin and painting it with iodine the kidney was exposed through the loin. As soon as the deep fascia was opened a lot of dark blood and clot escaped. The kidney was felt to be lacerated, with the laceration extending right through the kidney substance; but as the upper pole was much more badly injured than the lower, it was decided to remove that portion and put deep sutures in the remaining portion in the hope of saving half the kidney. This was done, and having cleaned out as much blood and clot as possible, the wound was closed, leaving a large cigarette drain reaching down to, but not touching, the remains of the kidney.

The patient was then returned to bed, but as she was in a very low condition continuous rectal salines containing adrenalin were administered. She rallied well and was feeling comparatively comfortable by evening. She only vomited once.

Next day (August 30th) she felt comfortable. The temperature varied from 99° to 101.4°, pulse from 116 to 134, respirations 24 to 32. There was a good deal of blood-stained discharge from the tube; this had diminished on August 31st, but the temperature rose to 103°. The bowels were opened three times.

On September 1st the patient complained of slight headache and nausea; the temperature rose to 105°, the respirations to 42, and the pulse to 140. A vaccine of *Bacillus coli* was administered in a dose of five million. She began to cough towards evening. The bowels were opened twice during the day. During the night she was delirious at times, but at 6 a.m. on September 2nd she had a profuse sweat and the delirium ceased. By midday the temperature was down to 101.6°. The cough grew more troublesome, and it was found that the right base was dull with diminished voice sounds. From the way in which this condition afterwards cleared up it seems probable that the lung was also crushed at the base, although the sputum never contained any blood. No rib was broken at the time of the accident.

On September 4th the condition was much the same, but the temperature dropped still further to 99.8° at 6 p.m. The abdomen was supple, and there was no abdominal pain. The bowels acted once daily. She slept fairly well at night. There was very little discharge on the dressing that day.

On September 7th at 6 a.m. the temperature had dropped to 99°, but when the dressing was changed there was a decided smell of ammonia. Otherwise the condition was much improved and the cough almost gone. She was on a light diet and ate food well. When the wound was dressed on September 8th there was a fair quantity of urine on the dressing although the tube had been shortened on the previous day, and on September 9th a renal fistula was well established. The temperature during the day reached 103°; the bowels were opened once; the diet was reduced.

On September 10th the patient felt very well. The only discomfort was irritation of the wound in the loin, due to the urine. The abdominal wound having healed by first intention, and union being apparently good, the stitches were removed and the binder replaced. The temperature still varied from 100° to 102.2°. She slept well and had no pain. As the bowels did not open on September 11th the nurse gave an enema at 7 p.m. The bowels acted without effort, but an hour later she awoke from a light sleep and called the nurse, and said that "her inside had fallen out"; the nurse raised the clothes, and saw coils of intestine protruding from the lower edge of the binder. I arrived at 10 p.m., and found that the abdominal wound had given way along its whole length, and the edges appeared smooth, as if varnished. I returned the bowels to the abdominal cavity, and sewed up with through-and-through stitches. When I removed these stitches ten days later perfect union had occurred, and there was no sign of early ventral hernia nor any division of the muscles.

For the next week she steadily improved, but on September 16th developed oedema of the legs affecting the right leg more than the left. The wound in the loin looked very unhealthy, large sloughs having formed along the track of the fistula, which was discharging urine and pus freely. The temperature also became remittent in type, although the patient herself was feeling very well.

On September 17th I removed her to the hospital, and on the following day reopened the wound in the loin. I found the remnant of the kidney in a very unhealthy state and decided that the best course to pursue was to remove it. Accordingly I tied off the vessels and ureter and removed the organ. Then swabbing out the cavity I sewed up the wound and left a small drain in.

For the next few mornings the cavity was syringed out with hydrogen peroxide solution and the temperature came down, gradually reaching normal on September 25th. By that time all the discharge had ceased and the wound was looking healthy. The oedema of the legs continued, but was now confined to the right leg, was slight and did not seem to be increased by exertion.

She eventually returned home on October 14th, after an uneventful convalescence, and when last seen she was in the best of health and had put on 9 lb. in weight in the previous month.

The points of interest in the case are the trivial accident causing such disastrous results, and the spontaneous opening of the abdominal wound thirty-six hours after removal of the stitches on the tenth day. It is curious, considering the contamination of the peritoneum on the skin and dressings and binder, to say little of the friction of its surface by the dry dressings, that no infection resulted, but I have since heard of a similar case in a Melbourne general hospital after a hysterectomy, when the wound reopened on the day following removal of the stitches, just subsequent to the administration of an enema. In that case also no ill effects occurred.

As if to prove the irony of things, on the day that this patient left the hospital I admitted a child aged 1 year and 10 months, who had been kicked at close quarters by a big Clydesdale mare. The print of the hoof covered its abdomen, but the only injury received was a fracture of the right femur.

THE TREATMENT OF ACUTE GONORRHOEA IN MEN.

BY J. G. HAYES, F.R.C.P. AND S. IREL.,
LATE CLINICAL ASSISTANT AND HOUSE-SURGEON, ALL SAINTS' HOSPITAL FOR GENITO-URINARY DISEASES, LONDON.

I FEEL convinced that, with very few exceptions, it takes on an average from two to three months to cure gonorrhoea. The general treatment consists of dieting, resting, and the taking of certain drugs. Butchers' meat, alcohol of any kind, strong tea or coffee, condiments and spices should be prohibited; milk and milk puddings, fish, chicken, eggs, vegetables, weak tea, water, and mineral waters may be permitted. Plenty of bland fluid is advisable, though in some cases of acute posterior urethritis lessening the fluid intake seems to lessen the urgency and frequency of micturition, and so gives a little more physiological rest to the inflamed membrane. If the patient can remain in bed for a week or two, well and good, but that is usually out of the question: consequently, it is advisable to instruct him to take no unnecessary exercise, to retire to bed early, and to avoid all sexual excitements.

It is best to start at once with urinary antiseptics, such as urotropin and cystopurin, for they tend to minimize the severity of the disease and shorten the acute stages; they may be continued for some weeks. When the anterior urethra only is affected, some alkaline diuretic may be given; and when the posterior urethra is involved, some of the balsams, though often their effect on the digestive system prohibits the latter, and they are by no means necessary.

In considering local treatment we may divide the urethra into (1) the anterior or movable urethra, and (2) the posterior or fixed.

The anterior urethra extends from the meatus to the bulb, is ensheathed in the corpus spongiosum, and is about 5 in. long. Its mucous lining is studded with many openings, larger (lacunae of Morgagni) and smaller (glands of Littre). Further back, opening into the bulbous portion, are the two ducts of Cowper's glands. The chief complication of anterior urethritis is stricture.

The posterior urethra, which embraces the membranous and prostatic portions, is about 2 in. long. It is usually involved about the second week of the disease, and as the ducts from the prostatic gland and the common ejaculatory ducts open into it, it is the source of the more serious local and systemic complications. Attempts to treat posterior urethritis by ordinary anterior injections are futile. Even when the anterior urethra only is diseased we are dealing with a delicate mucous membrane, and strong injections are to be deprecated.

In local treatment support of the parts is the first indication, and should be carried out by a support that will lift both scrotum and penis up against the abdominal wall. The meatus should be protected by aseptic wool, and sponged over with some antiseptic solution whenever

the opportunity arises, to prevent contamination of clothing.

Of the injection or irrigation methods recommended, Janet's appears to be the best. There are special irrigators made for this treatment with two-way nozzles by means of which the anterior urethra only may be lavaged or through-and-through irrigation carried out; the process is very simple and the results exceedingly satisfactory.

In the early stages, where the anterior urethra is affected, anterior irrigations of potassium permanganate (1 in 6,000 solution) will be found beneficial. It is best to use low pressure and only irrigate about the first three inches of the urethra, using a pint of solution at a time; it is well to do this twice daily. Should there be much pain or swelling of the penis, irrigations may be withheld until it subsides.

As soon as symptoms of posterior urethritis, indicated by urgency and frequency of micturition, are observed, through-and-through irrigation should be commenced, beginning with 1 in 10,000 solution potassium permanganate, very gradually increased from day to day till about 1 in 3,000 can be tolerated; the best temperature for the solution is between 95° and 100° F. At the end of a week or ten days the urine, which had previously been cloudy with pus, begins to clear, and small shreds or flakes may be seen floating in it; at this stage irrigations may be reduced to one a day. Complications such as prostatitis and epididymitis may arise, but they are so modified in extent that they are readily amenable to treatment.

When all acute symptoms have abated, it is well to make a rule of passing a Kollman's anterior dilator once a week, and stretching it very gradually and gently up till it meets with resistance; in any case it should not be stretched beyond 37 as indicated on the dial. This method serves the double purpose of expressing any secretions that may have got lodged in the glands of Littre or the lacunae of Morgagni, and at the same time acts as an excellent precaution against stricture.

Each dilatation should be followed by a through-and-through irrigation with a solution of potassium permanganate (1 in 6,000). At this period the prostate, seminal vesicles, and Cowper's glands should be examined, and, if necessary, massaged.

Through the courtesy of the senior surgeon of All Saints' Hospital I have had the opportunity of studying a great number of acute and chronic cases of gonorrhoea, and, regarding the treatment, the above are the conclusions I have drawn. The vaccines I have found more useful in the chronic complications than in the acute stages of gonorrhoea.

MEDICAL, SURGICAL, OBSTETRICAL.

ANTITYPHOID INOCULATION.

A Speedy Method of Inoculating.

In the preventive inoculation of the troops with typhoid and other vaccines the following method may be of service where time is limited. By such a method I have been enabled to inject carefully graduated doses of vaccines and serums (½ c.cm. and 1 c.cm. doses) into mice at the rate of 60 to 80 an hour; even when an occasional, animal has complicated matters by a temporary escape.

The vaccine, contained preferably in a 20 c.cm. bottle, is poured into a cold sterile watch-glass or Petrie dish and sucked up into a cold sterile all-glass 20 c.cm. syringe, graduated into ½ c.cms. This is done more rapidly without attaching a needle. Some twenty to forty sterile needles boiled in water to which a little soda has been added should be available, as also a pair of sterilized dressing forceps for picking out the needles. In the case of 1 c.cm. doses as many as twenty inoculations can be made from one syringeful by merely throwing off a needle after each inoculation and affixing another. The men being lined up, an assistant (unqualified), slightly in advance of the operator, prepares the skin with 2 per cent. iodine, and another assistant behind the operator repeats the iodine application so as to seal the puncture with iodine after the inoculation. The chief precaution to be observed is to keep the needle pointing downwards to prevent the weight of the piston drawing into the syringe the tissue fluid from the last man inoculated. A fairly long needle will also prevent this reflux, as also the gradual removal of the needle towards the end of the inoculation.

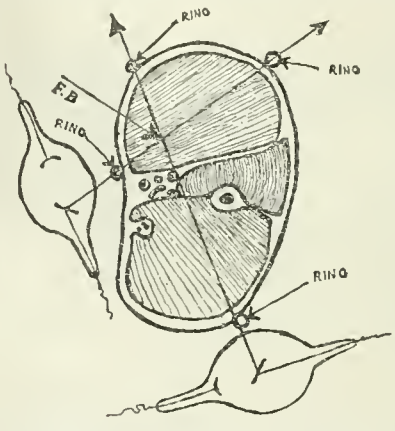
If such precautions are observed the procedure is as safe as any other, and with men as the subjects instead of mice, should enable any one to perform at least eighty inoculations an hour. Those accustomed to inoculation on the large scale will no doubt have their own methods, but I put the suggestion forward chiefly to Territorial R.A.M.C. officers who may not previously have been called upon in this way.

ARNOLD RENSHAW, M.B., B.S.
The University, Manchester.

LOCALIZATION OF FOREIGN BODIES.

THE following is a simple, and, as far as I am concerned, original, method of localizing an embedded foreign body by means of the *x*-ray tube and fluorescent screen.

The part should first be so thoroughly cleansed that little will be needed immediately before the surgical exploration. The couch and under surface of the screen should be covered with sterilized material. A rubber band of suitable size is then made to encircle the limb at the level of the foreign body. This band carries on it four small metal rings or pieces of bent wire, which can be moved along it, but not too easily. Two observations are then made with the rays, and the rings moved with forceps till they cover the foreign body above and below in two widely different planes. If they have been carefully placed and the limb properly rotated, the body will be found at the intersection of the two lines joining the opposite rings; and it can be approached from whatever direction best suits the anatomy of the part.



I have not tried the method in many cases, since experience is rather limited here, but think I ought not to keep it to myself any longer; I desire rather to throw it out as a suggestion to others, with a good hope that it may be found practical.

W. REGINALD WILSON, M.A., M.B., B.C.Cantab.,
Honorary Surgeon, Doncaster Royal Infirmary.

GALYL IN SYPHILIS.
